Binary Emission Discovery Calculus Theory Manuscript

Finite Kernel Theory, Concrete Instances, Proof Obligations, and Formalization Contract

Multi-file LaTeX Theory Manuscript

This manuscript presents the BEDC finite-kernel theory, its concrete instances, its proof obligations, and its formalization-facing contract in one maintained source tree. Core theory and implementation-facing material remain separated by parts and by source files.

Project Preface

This manuscript presents the Binary Emission Discovery Calculus as one maintained LaTeX source tree with a single compiled document.

The organizing principle is:

$$\text{finite-kernel theory} + \text{proof obligations} + \text{separate implementation contracts.}$$

Layer discipline. The theoretical core uses BEDC terminology and derived-interface notation. Implementation-facing text is placed in a separate part. This prevents the host language of a later proof assistant from contaminating the object theory.

Closure and verification. This manuscript separates theoretical closure from formal verification. A BEDC object may be theoretically closed at a stated scope when the paper supplies its source, classifier, exactness, stability, and ledger witnesses. A formalization marker records the independent verification status of those witnesses in a proof assistant. Machine checking strengthens reliability and auditability; it is not an object-language formation rule for closure. The discipline is recorded in chapter 9203.

Proof boundary. The proof boundary is the finite-kernel proof path:

$$\mathsf{msame} \to \mathsf{hsame} \to \mathsf{Ext/Cont} \to \mathsf{Sig} \to \mathsf{sameSig} \to \mathsf{PackagePolicy/GapPolicy} \to \mathsf{CompGap} \to \mathsf{NameCert}.$$

Large derived interfaces such as $\mathsf{Real}^{\uparrow}$, $\mathsf{Circle}^{\uparrow}$, and $\mathsf{Fold}^{\uparrow}$ remain thin interfaces whose full reconstruction is licensed only by separate naming certificates beyond the finite kernel.

External model posture. External semantic models remain explanatory artifacts. They do not alter the BEDC object theory and they do not replace the internal proof obligations recorded in the active chapters.

Reader's Roadmap

This manuscript presents the BEDC theory, its proof targets, and its implementation-facing material in one document while keeping their roles distinct.

How to read this manuscript

Reader goal	Recommended route
Understand the theory	Read the Preface, the finite-kernel core, and the hardening and proof-obligation parts. The core gives the object theory; the later parts record the active refinements and proof obligations.
Follow the theorem chain	Read the proof-sprint part, then chapter 19. The chain chapters state the finite-kernel theorems; the dependency chapter records the order in which they compose.
Understand the governance and proof posture	Read the Project Governance part and Chapter 9466. These chapters record the active contract and the amendment policy.
Prepare implementation work	Read the implementation-facing contract and Appendix A. The contract is external guidance for formalization work, not part of the core object theory.
Extend the book	Add new material to the relevant thematic chapter and update the registry, correspondence table, and amendment policy when the active reading changes.

Layer warning

This manuscript intentionally separates four layers:

1. **Core theory**: clean-room BEDC object-theory specification.
2. **Theorem chain**: theorem statements and proofs for the finite kernel.
3. **Implementation-facing contract**: external guidance for the proof-assistant encoding.
4. **Project governance**: editing, registry, and maintenance rules.

Terms such as "model", "theorem", "table", "implementation", and "module" belong to the explanatory metalanguage unless explicitly introduced as BEDC-derived interfaces.

Proof boundary

The proof boundary is not the reconstruction of all traditional mathematics. It is the finite-kernel proof path:

$$\mathsf{msame} \to \mathsf{hsame} \to \mathsf{Ext/Cont} \to \mathsf{Sig} \to \mathsf{sameSig} \to \mathsf{PackagePolicy/GapPolicy} \to \mathsf{CompGap} \to \mathsf{NameCert}.$$

Large derived interfaces such as $\mathsf{Real}^{\uparrow}$, $\mathsf{Circle}^{\uparrow}$, and $\mathsf{Fold}^{\uparrow}$ remain thin interfaces whose full reconstruction is licensed only by future naming certificates beyond the finite kernel.

Contents

Project Preface **i**

Reader's Roadmap **ii**

I Finite Kernel Theory **1**

1 Orientation and Layer Discipline **2**
1.1 Purpose of This Core 2
1.2 Boundary of This Core 2

2 Raw Marks and Mark-Sameness **3**

3 Emission Histories and History-Sameness **5**

4 Relational Extension and Continuation **7**
4.1 Relational extension 7
4.2 Relational continuation 9

5 Asking Events and Policies **21**
5.1 Asking events 21
5.2 Asking policies 21

6 Generated Probe Bundles and Signature Events **24**
6.1 Bundle grammar 24
6.2 Signature generation 34
6.3 Signature sameness 44

7 Packages and Package Policies **46**

8 Gap Policies, Coverage, Separation, and Composition **47**
8.1 Gap policy 47
8.2 Composite gaps 48

9 Typed Naming Certificates **52**

10 First Derived Interfaces **54**
10.1 Unary repetition 54
10.2 Stable transformations 54

11 Thin Seal Interface **56**

12 External Binary Model **57**
12.1 Purpose of the model . . . 57

13 Finite Theorem Manifest **60**

14 Boundary of the Finite Kernel **61**

Summary **62**

15 The Signature Package Instance **63**
15.1 Signature tokens . . . 63

16 The Concrete Signature Gap Policy **65**

17 The First Concrete Globalize Instance **67**

II Proof Sprint **69**

18 Finite Kernel Proof Target **70**
18.1 Purpose and scope . . . 70
18.2 Marks and mark-sameness . . . 70
18.3 Histories and history-sameness . . . 71
18.4 Relational extension . . . 72
18.5 Relational continuation . . . 72
18.6 Asking events and bundles . . . 74
18.7 Signatures and signature-sameness . . . 75
18.8 Packaging and gap policies . . . 76
18.9 Composite gap ledgers . . . 77
18.10 Name certificates . . . 77
18.11 First derived interface seeds . . . 77
18.12 Thin completion interface . . . 78
18.13 External semantic model . . . 78
18.14 Finite theorem target . . . 79
18.15 Conclusion . . . 79

19 Finite-Kernel Theorem Dependency DAG **80**
19.1 Milestone DAG . . . 80
19.2 Milestone A: marks . . . 80
19.3 Milestone B: histories . . . 81
19.4 Milestone C: relational extension and continuation . . . 81
19.5 Milestone D: asking and signatures . . . 81
19.6 Milestone E: signature sameness . . . 81
19.7 Milestones F–G: packages and gaps . . . 82
19.8 Milestone H: composite gap . . . 82
19.9 Milestone I: naming certificates . . . 82
19.10 Execution rule . . . 82

III Proof Standing **83**

20 Closed Generation and Internal Sameness **84**

21 Extension and Continuation Proof Spine **87**
21.1 Relational extension . . . 87
21.2 Relational continuation . . . 88

22 Signature Proof Spine **96**

23 Package and Gap Proof Spine **98**

24 Naming Certificate Proof Instances **100**
24.1 The unary repetition certificate . . . 100
24.2 The continuation certificate for addition-like behavior . . . 100

IV Hardening **102**

25 Package and Gap Policy Expansion **103**
25.1 Package policy as a public interface . . . 103
25.2 Gap policy as provenance interface . . . 104
25.3 Composite gaps . . . 104

26 Typed Naming Certificate Instances **106**
26.1 Certificate fields . . . 106
26.2 Unary repetition as $\mathsf{Nat}^{\uparrow}$ seed . . . 108
26.3 Continuation as $\mathsf{Add}^{\uparrow}$ seed . . . 109
26.4 Descent certificate for stable transformations . . . 109

27 Machine-Checkable Milestones **114**
27.1 Milestone A: history kernel . . . 114
27.2 Milestone B: signature kernel . . . 114
27.3 Milestone C: package and gap kernel . . . 115
27.4 Milestone D: first derived interface seeds . . . 115
27.5 Settled-kernel criterion . . . 115

V Concrete Instances **116**

28 A Concrete Naming Certificate for $\mathsf{Nat}^{\uparrow}$ **117**
28.1 Unary histories . . . 117
28.2 The certificate . . . 122

29 A Concrete Naming Certificate for $\mathsf{Add}^{\uparrow}$ **127**
29.1 Unary continuation . . . 127
29.2 The certificate . . . 128

30 A Concrete Naming Certificate for $\mathsf{Mul}^{\uparrow}$ **137**
30.1 Unary product rows . . . 137

31 A Concrete Naming Certificate for $\mathsf{Int}^{\uparrow}$ 141
31.1 Carrier definition . . . 141
31.2 Difference-pair context stability . . . 149
31.3 The certificate . . . 153
31.4 Rat Denominator Sibling Bridge . . . 166
31.5 Rat Denominator Sibling Link . . . 166

32 A Concrete Naming Certificate for $\mathsf{Bool}^{\uparrow}$ 175
32.1 Roadmap template status . . . 175
32.2 Carrier definition . . . 176
32.3 The certificate . . . 176

33 A Concrete Naming Certificate for $\mathsf{Option}^{\uparrow}$ 214
33.1 Roadmap template status . . . 214
33.2 Carrier definition . . . 215
33.3 The certificate . . . 215
33.4 Payload descent image classifier transported visible readback . . . 277
33.5 Payload descent image classifier reflective visible pair coherence . . . 278
33.6 Payload descent image classifier reflective transitive normalized public endpoint readback . . . 285
33.7 Composite image classifier visible payload classification . . . 291
33.8 Exclusive classifier branch readback . . . 296
33.9 Payload descent image classifier pair readback . . . 300
33.10 Payload descent image classifier visible payload exactness . . . 307
33.11 Payload descent image classifier visible pair coherence . . . 308
33.12 Payload descent image classifier public constructor normal form . . . 310
33.13 Composite image classifier public readback single-valuedness . . . 314
33.14 Composite image classifier normalized public branch certificate . . . 323
33.15 Composite image classifier normalized constructor normal form . . . 325
33.16 Composite image classifier normalized visible target-payload classification . . . 332
33.17 Composite image classifier normalized public readback completion . . . 343
33.18 Composite image classifier normalized one-sided public completion . . . 346
33.19 Tagged option map relation constructor normal form . . . 349
33.20 Tagged option map relation shared-source target normal form . . . 350
33.21 Tagged option map relation shared-target source reflection normal form . . . 351
33.22 Tagged option public endpoint visibility . . . 356
33.23 Tagged option present-chain endpoint classification . . . 356
33.24 Composite image classifier normalized factored public completion . . . 357
33.25 Tagged option composite factorization intermediate classifier determinacy . . . 363
33.26 Option composite image classifier normalized present intermediate payload determinacy . . . 365
33.27 Option history classifier unary two-sided context . . . 365
33.28 Tagged option map relation R-corner classifier coherence . . . 367
33.29 Tagged option payload descent image target classifier closure . . . 369
33.30 Option composite image classifier normalized present intermediate classifier determinacy . . . 370
33.31 Option composite image classifier normalized intermediate factor coherence . . . 372
33.32 Option composite image classifier normalized selected intermediate factor uniqueness 373

34 A Concrete Naming Certificate for Prod$^{\uparrow}$ **377**
34.1 Roadmap template status . . . 377
34.2 Carrier definition . . . 378
34.3 The certificate . . . 378

35 A Concrete Naming Certificate for Sum$^{\uparrow}$ **431**
35.1 Roadmap template status . . . 431
35.2 Carrier definition . . . 432
35.3 The certificate . . . 433

36 A Concrete Naming Certificate for List$^{\uparrow}$ **477**
36.1 Roadmap template status . . . 477
36.2 Carrier definition . . . 478
36.3 The certificate . . . 478
36.4 List map shape . . . 490
36.5 Singleton source length shape exhaustion . . . 547
36.6 Public append readback . . . 552
36.7 Bordered singleton payload readback . . . 561
36.8 Public reverse readback . . . 562
36.9 Public reverse and append . . . 565

37 A Concrete Naming Certificate for Rat$^{\uparrow}$ **569**
37.1 Carrier definition . . . 569
37.2 The certificate . . . 575

38 Certificate Obligations for Real$^{\uparrow}$ **597**
38.1 Carrier definition . . . 597
38.2 The certificate-obligation schema . . . 598
38.3 Real algebra and order boundary . . . 609
38.4 Real L10 current phase exit audit pullback . . . 817
38.5 StreamName and RegSeqRat dependency route . . . 982

39 A Concrete Naming Certificate for Complex$^{\uparrow}$ **1078**
39.1 Carrier definition . . . 1078
39.2 The certificate . . . 1081

40 A Concrete Naming Certificate for Monoid$^{\uparrow}$ **1089**
40.1 Carrier definition . . . 1089
40.2 Concrete history instance . . . 1089
40.3 The certificate . . . 1091

41 A Concrete Naming Certificate for Group$^{\uparrow}$ **1101**
41.1 Carrier definition . . . 1101
41.2 Concrete singleton history group instance . . . 1101
41.3 Concrete singleton empty-history group instance . . . 1108
41.4 Group concrete history instance surface . . . 1109
41.5 Singleton inverse image exactness . . . 1113
41.6 Concrete singleton equation solver . . . 1116
41.7 Concrete singleton equation solver determinacy . . . 1117

41.8 The certificate . . . 1119
41.9 Singleton contextual continuation obstruction . . . 1132
41.10 Centralizer transport . . . 1132
41.11 Centralizer normalizer orbit relation . . . 1138
41.12 Normalizer orbit classifier stability . . . 1141
41.13 Normalizer action on the centralizer . . . 1142
41.14 Center orbit collapse . . . 1148
41.15 Singleton continuation endpoint equivalence . . . 1149
41.16 Singleton two-sided product-unit exactness . . . 1151
41.17 Concrete singleton continuation group instance . . . 1155
41.18 Singleton conjugation terminal collapse . . . 1157
41.19 Singleton conjugation collapse . . . 1158
41.20 Concrete singleton normalizer action certificate . . . 1158
41.21 Unary append inverse obstruction . . . 1167
41.22 Terminal continuation boundary . . . 1172
41.23 Finite-history group-law witness . . . 1174
41.24 Singleton contextual exact visibility . . . 1175
41.25 Singleton two-conjugator orbit coverage . . . 1175
41.26 Center abelian normal package . . . 1181

42 A Concrete Naming Certificate for $\mathsf{AbGroup}^{\uparrow}$ 1185
42.1 Carrier definition . . . 1185
42.2 Concrete singleton history abelian group instance . . . 1185
42.3 The certificate . . . 1186
42.4 Concrete singleton empty-history abelian group instance . . . 1186
42.5 Public closure record . . . 1196

43 A Concrete Naming Certificate for $\mathsf{Ring}^{\uparrow}$ 1202
43.1 Carrier definition . . . 1202
43.2 Concrete singleton history ring instance . . . 1202
43.3 Concrete singleton empty-history ring instance . . . 1203
43.4 Singleton Empty-History Ring Instance . . . 1206
43.5 Empty-History Ground Schema Unlock . . . 1207
43.6 The certificate . . . 1208

44 A Concrete Naming Certificate for $\mathsf{CommRing}^{\uparrow}$ 1226
44.1 Carrier definition . . . 1226
44.2 Concrete singleton history commutative ring instance . . . 1226
44.3 Concrete singleton empty-history commutative ring instance . . . 1228
44.4 The certificate . . . 1235
44.5 CommRing quadratic polarization package . . . 1245
44.6 Public closure record . . . 1258
44.7 Singleton Cont History Instance for $\mathsf{CommRing}^{\uparrow}$ . . . 1259

45 A Concrete Naming Certificate for $\mathsf{Field}^{\uparrow}$ 1269
45.1 Carrier definition . . . 1269
45.2 Concrete singleton empty-history field schema instance . . . 1269
45.3 RatUp boundary for the singleton field schema . . . 1295

45.4 RatUp continuation closure for the FieldUp boundary . . . 1300
45.5 The certificate . . . 1332
45.6 Field affine equation laws . . . 1353
45.7 Product factor equation exactness . . . 1357
45.8 Signed square-factor consequences . . . 1365
45.9 Zero-apartness transport through certified products . . . 1372
45.10 Field square apartness inverse descent . . . 1376
45.11 Concrete Rat denominator continuation instance . . . 1378
45.12 Rat denominator append-continuation semigroup ledger bridge . . . 1382
45.13 Field square apartness inverse descent . . . 1385
45.14 Rat denominator empty-unit continuation monoid instance . . . 1391
45.15 Rat denominator unit endpoint exactness . . . 1393
45.16 Concrete Rat denominator external-unit package . . . 1398
45.17 Rat denominator strict monoid boundary . . . 1410
45.18 Rat denominator empty-unit cancellation exactness . . . 1417
45.19 Rat denominator external-unit envelope cancellation exactness . . . 1425
45.20 Rat denominator context-pair action laws . . . 1455
45.21 RatUp FieldUp exit support rows . . . 1472
45.22 Field affine explicit inverse . . . 1488
45.23 Five-factor inverse reversal . . . 1513
45.24 Apart-zero continuation exactness . . . 1611
45.25 Terminal history field instance . . . 1652

46 A Concrete Naming Certificate for $\mathsf{Module}^{\uparrow}$ 1655
46.1 Carrier definition . . . 1655
46.2 Concrete singleton empty-history module instance . . . 1655
46.3 The certificate . . . 1660

47 A Concrete Naming Certificate for $\mathsf{VecSpace}^{\uparrow}$ 1679
47.1 Carrier definition . . . 1679
47.2 Concrete singleton history vector space instance . . . 1679
47.3 The certificate . . . 1684

48 A Concrete Naming Certificate for $\mathsf{LinMap}^{\uparrow}$ 1689
48.1 Carrier definition . . . 1689
48.2 Concrete singleton empty-history linear map instance . . . 1690
48.3 The certificate . . . 1704

49 A Concrete Naming Certificate for $\mathsf{Mat}^{\uparrow}$ 1734
49.1 Carrier definition . . . 1734
49.2 Concrete singleton empty-history matrix instance . . . 1734
49.3 The certificate . . . 1750

50 A Concrete Naming Certificate for $\mathsf{Poly}^{\uparrow}$ 1777
50.1 Concrete singleton zero-polynomial instance . . . 1777
50.2 Carrier definition . . . 1778
50.3 Concrete singleton history polynomial instance . . . 1778
50.4 The certificate . . . 1783

51 A Concrete Naming Certificate for FPS$^{\uparrow}$ 1871
51.1 Carrier definition . . . 1871
51.2 Concrete singleton zero formal power series instance . . . 1871
51.3 The certificate . . . 1874

52 A Concrete Naming Certificate for Preorder$^{\uparrow}$ 1909
52.1 Carrier definition . . . 1909
52.2 Concrete unary prefix preorder instance . . . 1909
52.3 Concrete singleton empty preorder instance . . . 1910
52.4 The certificate . . . 1913

53 A Concrete Naming Certificate for POSet$^{\uparrow}$ 1923
53.1 Carrier definition . . . 1923
53.2 Concrete unary prefix POSet instance . . . 1925
53.3 The certificate . . . 1932
53.4 Poset root obligation surface . . . 1941
53.5 Poset root comparison surface . . . 1943
53.6 Poset prefix schema target surface . . . 1944
53.7 Poset TotalOrder and Lattice handoff . . . 1945

54 A Concrete Naming Certificate for TotalOrder$^{\uparrow}$ 1948
54.1 Carrier definition . . . 1948
54.2 Concrete singleton history total order instance . . . 1948
54.3 Concrete unary prefix total order instance . . . 1950
54.4 Concrete Singleton History Instance . . . 1962
54.5 OrderUp Interval Collapse . . . 1965
54.6 Finite Extrema Interval Uniqueness . . . 1967
54.7 OrderUp Phase Exit . . . 1969
54.7.1 OrderUp obligation set . . . 1970
54.8 The certificate . . . 1977
54.9 Public audit boundary . . . 1980
54.10 Root obligation surface . . . 1981
54.11 Unary Prefix History Instance . . . 1983

55 A Concrete Naming Certificate for Lattice$^{\uparrow}$ 1986
55.1 Carrier definition . . . 1986
55.2 Concrete singleton prefix lattice instance . . . 1986
55.3 The certificate . . . 1993
55.4 Carrier definition . . . 2013
55.5 Concrete singleton prefix lattice instance . . . 2013
55.6 The certificate . . . 2029

56 A Concrete Naming Certificate for Interval$^{\uparrow}$ 2041
56.1 Carrier definition . . . 2041
56.2 The certificate . . . 2044

57 A Concrete Naming Certificate for $\mathsf{Met}^{\uparrow}$ 2047
57.1 Carrier definition . . . 2047
57.2 The certificate . . . 2047

58 A Concrete Naming Certificate for $\mathsf{S}^{1\uparrow}$ 2173
58.1 Carrier obligation surface . . . 2173
58.2 The certificate . . . 2182
58.3 The certificate . . . 2195

59 A Concrete Naming Certificate for $\mathsf{ContinuousMap}^{\uparrow}$ 2220
59.1 Carrier definition . . . 2220
59.2 The certificate . . . 2265

60 A Concrete Naming Certificate for $\mathsf{Compact}^{\uparrow}$ 2304
60.1 Carrier definition . . . 2304
60.2 The certificate . . . 2322

61 A Concrete Naming Certificate for $\mathsf{Cat}^{\uparrow}$ 2336
61.1 Carrier definition . . . 2336
61.2 The certificate . . . 2391
61.3 The certificate . . . 2404

62 A Concrete Naming Certificate for $\mathsf{Functor}^{\uparrow}$ 2434
62.1 Carrier definition . . . 2434
62.2 The certificate . . . 2452

63 A Concrete Naming Certificate for $\mathsf{NatTrans}^{\uparrow}$ 2472
63.1 Carrier definition . . . 2472
63.2 The certificate . . . 2486

64 A Concrete Naming Certificate for $\mathsf{Prime}^{\uparrow}$ 2510
64.1 Multiplicative structure on unary histories . . . 2510
64.2 The prime predicate . . . 2536
64.3 Effective primality testing . . . 2539
64.4 Euclid's theorem on the infinitude of primes . . . 2545
64.5 The fundamental theorem of arithmetic . . . 2548
64.6 The certificate . . . 2551

65 A Concrete Naming Certificate for $\mathsf{CplxLim}^{\uparrow}$ 2556
65.1 Modulus and complex distance on Hist . . . 2556
65.2 Regular complex sequences . . . 2560
65.3 The complex-limit predicate . . . 2560
65.4 Closure laws on regular sequences . . . 2561
65.5 Componentwise limit assembly . . . 2565
65.6 The certificate . . . 2566

66 A Concrete Naming Certificate for ConvRad$^{\uparrow}$ 2573
66.1 Power series carrier and partial sums . . . 2573
66.2 Geometric bound predicate . . . 2574
66.3 Convergence radius predicate . . . 2577
66.4 Opening Boundary . . . 2579
66.5 Closure laws . . . 2579
66.6 The certificate . . . 2581
66.7 Cauchy–Hadamard Boundary . . . 2583

67 A Concrete Naming Certificate for CplxDiff$^{\uparrow}$ 2591
67.1 The complex difference quotient . . . 2591
67.2 Pointwise complex differentiability . . . 2595
67.3 Closure laws for complex differentiability . . . 2597
67.4 Real-component partial derivatives . . . 2598
67.5 Cauchy–Riemann equations, constructive form . . . 2599
67.6 The certificate . . . 2599

68 A Naming Seed for Holomorphic$^{\uparrow}$ 2604
68.1 Open-disk carrier . . . 2604
68.2 Holomorphic predicate . . . 2611
68.3 Core theorem obligations . . . 2611
68.4 The seed fields . . . 2615

69 A Concrete Naming Certificate for CplxSer$^{\uparrow}$ 2618
69.1 Term sequences and partial sums . . . 2618
69.2 Absolute convergence . . . 2621
69.3 Convergence and uniqueness . . . 2624
69.4 Comparison, ratio, and root tests . . . 2624
69.5 Cauchy product . . . 2625
69.6 Closure laws . . . 2625
69.7 The certificate . . . 2626

70 A Concrete Naming Certificate for Dirichlet$^{\uparrow}$ 2631
70.1 Dirichlet term and partial sum . . . 2631
70.2 Abscissa of absolute convergence . . . 2636
70.3 Convergence and holomorphicity in the half-plane . . . 2636
70.4 Euler product for multiplicative coefficients . . . 2637
70.5 The certificate . . . 2637

71 A Concrete Naming Certificate for ZetaBasic$^{\uparrow}$ on $\Re(s) > 1$ 2639
71.1 The constant-coefficient Dirichlet sum . . . 2639
71.2 Convergence and abscissa . . . 2642
71.3 The Euler product over primes . . . 2642
71.4 Non-vanishing on the half-plane . . . 2642
71.5 Holomorphicity on the half-plane . . . 2642
71.6 The certificate . . . 2642

72 A Concrete Naming Certificate for CritStrip$^{\uparrow}$ 2645
72.1 The strip and critical-line predicates . . . 2645
72.2 Compact sub-strips and boundary witnesses . . . 2646
72.3 Closure laws . . . 2647
72.4 The certificate . . . 2648

73 A Concrete Naming Certificate for ZetaZeros$^{\uparrow}$ 2650
73.1 ζ-evaluation and zero predicate . . . 2650
73.2 Trivial zeros . . . 2651
73.3 Non-trivial zeros . . . 2651
73.4 Closure laws . . . 2651
73.5 The certificate . . . 2652

74 A Conditional Certificate Boundary for RealAnalytic$^{\uparrow}$ 2656
74.1 Constructive π via Leibniz acceleration . . . 2656
74.2 Constructive exponential . . . 2658
74.3 Constructive logarithm on positives . . . 2661
74.4 Constructive sine and cosine . . . 2663
74.5 Certificate target . . . 2664

75 A Concrete Naming Certificate for Gamma$^{\uparrow}$ 2672
75.1 The pole locus and the Gamma domain . . . 2672
75.2 Gamma at unary positive integers via factorial . . . 2675
75.3 Gamma extension via Weierstrass product . . . 2675
75.4 Functional equation $\Gamma(s+1) = s\,\Gamma(s)$ . . . 2676
75.5 Reflection formula boundary certificate . . . 2676
75.6 Certificate target . . . 2677

76 A Concrete Naming Certificate for CplxAnalytic$^{\uparrow}$ 2681
76.1 Complex exponential via Euler decomposition . . . 2681
76.2 Complex logarithm with principal branch . . . 2686
76.3 Complex sine and cosine . . . 2687
76.4 Complex powers $z \mapsto a^z$ and n^{-s} . . . 2687
76.5 Certificate target . . . 2688

77 A Concrete Naming Certificate for CplxTopo$^{\uparrow}$ 2690
77.1 Open disks . . . 2690
77.2 Open sets and finite intersections . . . 2694
77.3 Compact subsets via dyadic ε-nets . . . 2695
77.4 Density witnesses and clustering points . . . 2695
77.5 Domain compatibility for analytic continuation . . . 2696
77.6 Certificate target . . . 2696

78 A Concrete Naming Certificate for Magma$^{\uparrow}$ 2703
78.1 Carrier definition . . . 2703
78.2 The certificate . . . 2709

79 A Concrete Naming Certificate for Semigroup$^{\uparrow}$ 2712
79.1 Carrier definition . . . 2712
79.2 The certificate . . . 2713

80 A Concrete Naming Certificate for Subgroup$^{\uparrow}$ 2717
80.1 Carrier definition . . . 2717
80.2 The certificate . . . 2717

81 A Concrete Naming Certificate for Ideal$^{\uparrow}$ 2747
81.1 Carrier definition . . . 2747
81.2 The certificate . . . 2747
81.3 Standard bridge . . . 2774

82 A Concrete Naming Certificate for QuotientGroup$^{\uparrow}$ 2777
82.1 Carrier definition . . . 2777
82.2 The certificate . . . 2780

83 A Concrete Naming Certificate for QuotientRing$^{\uparrow}$ 2792
83.1 Carrier definition . . . 2792
83.2 The certificate . . . 2792

84 A Concrete Naming Certificate for Determinant$^{\uparrow}$ 2799
84.1 Carrier definition . . . 2799
84.2 The certificate . . . 2801

85 A Concrete Naming Certificate for Eigen$^{\uparrow}$ 2804
85.1 Carrier definition . . . 2804
85.2 The certificate . . . 2807

86 A Concrete Naming Certificate for InnerProduct$^{\uparrow}$ 2808
86.1 Carrier definition . . . 2808
86.2 The certificate . . . 2809
86.3 Parallelogram norm seed . . . 2819
86.4 Consumer threshold surface . . . 2827
86.5 Two-vector Gram boundary . . . 2829
86.6 Root unblock obligation basis . . . 2831
86.7 InnerProduct root scalar consumer frontier . . . 2833
86.8 Public NameCert export . . . 2834

87 A Concrete Naming Certificate for TensorProduct$^{\uparrow}$ 2838
87.1 Carrier definition . . . 2838
87.2 The certificate . . . 2840

88 A Concrete Naming Certificate for Topology$^{\uparrow}$ 2844
88.1 Carrier definition . . . 2844
88.2 The certificate . . . 2844
88.3 Public Open Derivation Trees . . . 2867
88.4 Scoped obligation triple . . . 2872

89 A Concrete Naming Certificate for Norm$^{\uparrow}$ 2877
89.1 Carrier definition . . . 2877
89.2 The certificate . . . 2878

90 A Concrete Naming Certificate for Banach$^{\uparrow}$ 2882
90.1 Carrier definition . . . 2882
90.2 The certificate . . . 2887
90.3 Banach limit surface certificate . . . 2901

91 A Concrete Naming Certificate for Hilbert$^{\uparrow}$ 2932
91.1 Carrier definition . . . 2932
91.2 The certificate . . . 2933

92 A Concrete Naming Certificate for Measure$^{\uparrow}$ 2946
92.1 Carrier definition . . . 2946
92.2 The certificate . . . 2953
92.3 Continuity from below row . . . 2963
92.4 Countable-name root surface . . . 2982
92.5 Measure root countable obligation triple . . . 3009
92.6 Measure root real-stream regularity front . . . 3013
92.7 Measure root finite-support consumer front . . . 3021
92.8 Measure root event boundary package . . . 3023
92.9 Root premeasure event-value bridge . . . 3026
92.10 Measure root public face exactness . . . 3030
92.11 Measure root real-stream event obligations . . . 3034
92.12 Measure root countable relative-difference bridge . . . 3036
92.13 Measure root real-stream premeasure bridge . . . 3038
92.14 Measure BHist root obligation basis . . . 3040
92.15 Measure root finite disjoint event envelope . . . 3043
92.16 Measure root event-value closure . . . 3045

93 A Concrete Naming Certificate for Filter$^{\uparrow}$ 3056
93.1 Carrier definition . . . 3056
93.2 The certificate . . . 3060

94 A Concrete Naming Certificate for FunctionalAnalysis$^{\uparrow}$ 3064
94.1 Carrier definition . . . 3064
94.2 The certificate . . . 3066

95 A Concrete Naming Certificate for Completion$^{\uparrow}$ 3070
95.1 Carrier definition . . . 3070
95.2 The certificate . . . 3074

96 A Concrete Naming Certificate for Manifold$^{\uparrow}$ 3077
96.1 Carrier definition . . . 3077
96.2 Atlas Obligation Inventory . . . 3081
96.3 The certificate . . . 3083
96.4 Chart Coordinate Transport . . . 3088
96.5 Scoped Manifold Boundary . . . 3094

96.6 Terminal Standard Bridge 3096

97 A Concrete Naming Certificate for Bundle$^{\uparrow}$ 3098
97.1 Carrier definition 3098
97.2 The certificate 3099

98 A Concrete Naming Certificate for Homology$^{\uparrow}$ 3103
98.1 Carrier definition 3103
98.2 The certificate 3110

99 A Concrete Naming Certificate for Cohomology$^{\uparrow}$ 3113
99.1 Carrier definition 3113
99.2 The certificate 3119

100 A Concrete Naming Certificate for Padic$^{\uparrow}$ 3121
100.1 Carrier definition 3121
100.2 The certificate 3129

101 A Concrete Naming Certificate for Adele$^{\uparrow}$ 3132
101.1 Carrier definition 3132
101.2 The certificate 3139

102 A Concrete Naming Certificate for ModN$^{\uparrow}$ 3142
102.1 Carrier definition 3142
102.2 The certificate 3142

103 A Concrete Naming Certificate for LFunction$^{\uparrow}$ 3146
103.1 Carrier definition 3146
103.2 The certificate 3149

104 A Concrete Naming Certificate for Automorphic$^{\uparrow}$ 3152
104.1 Carrier definition 3152
104.2 The certificate 3156

105 A Concrete Naming Certificate for CatLimit$^{\uparrow}$ 3160
105.1 Carrier definition 3160
105.2 The certificate 3160

106 A Concrete Naming Certificate for CatColimit$^{\uparrow}$ 3171
106.1 Carrier definition 3171
106.2 The certificate 3171

107 A Concrete Naming Certificate for Adjunction$^{\uparrow}$ 3180
107.1 Carrier definition 3180
107.2 The certificate 3193

108 A Concrete Naming Certificate for Monad$^{\uparrow}$ 3200
108.1 Carrier definition 3200
108.2 The certificate 3203

109A Concrete Naming Certificate for Yoneda$^{\uparrow}$ 3205
109.1Carrier definition . . . 3205
109.2The certificate . . . 3207

110A Concrete Naming Certificate for EquivCat$^{\uparrow}$ 3211
110.1Carrier definition . . . 3211
110.2The certificate . . . 3214

111A Concrete Naming Certificate for Set$^{\uparrow}$ 3216
111.1Carrier definition . . . 3216
111.2The certificate . . . 3216

112A Concrete Naming Certificate for FinSet$^{\uparrow}$ 3220
112.1Carrier definition . . . 3220
112.2The certificate . . . 3220

113A Concrete Naming Certificate for Subtype$^{\uparrow}$ 3235
113.1Carrier definition . . . 3235
113.2The certificate . . . 3235

114A Concrete Naming Certificate for Empty$^{\uparrow}$ 3241
114.1Carrier definition . . . 3241
114.2The certificate . . . 3241

115A Concrete Naming Certificate for Unit$^{\uparrow}$ 3245
115.1Carrier definition . . . 3245
115.2The certificate . . . 3247

116A Concrete Naming Certificate for Permutation$^{\uparrow}$ 3249
116.1Carrier definition . . . 3249
116.2The certificate . . . 3250

117A Concrete Naming Certificate for SymGroup$^{\uparrow}$ 3255
117.1Carrier definition . . . 3255
117.2The certificate . . . 3255

118A Concrete Naming Certificate for Graph$^{\uparrow}$ 3258
118.1Carrier definition . . . 3258
118.2The certificate . . . 3259

119A Concrete Naming Certificate for Tree$^{\uparrow}$ 3265
119.1Carrier definition . . . 3265
119.2The certificate . . . 3268

120A Concrete Naming Certificate for Seq$^{\uparrow}$ 3277
120.1Carrier definition . . . 3277
120.2The certificate . . . 3278

121 A Concrete Naming Certificate for Series↑ 3280
121.1 Carrier definition . . . 3280
121.2 The certificate . . . 3281

122 A Concrete Naming Certificate for Derivative↑ 3284
122.1 Carrier definition . . . 3284
122.2 The certificate . . . 3289

123 A Concrete Naming Certificate for Integral↑ 3291
123.1 Carrier definition . . . 3291
123.2 The certificate . . . 3292

124 A Concrete Naming Certificate for Fourier↑ 3295
124.1 Carrier definition . . . 3295
124.2 The certificate . . . 3295

125 A Concrete Naming Certificate for Residue↑ 3299
125.1 Carrier definition . . . 3299
125.2 The certificate . . . 3301

126 A Concrete Naming Certificate for StreamName↑ 3303
126.1 Carrier definition . . . 3303
126.2 The certificate . . . 3308
126.3 StreamName constant finite-window boundary . . . 3338
126.4 StreamName constant-window transport totality . . . 3343
126.5 StreamName Real and RegSeqRat handoff . . . 3344
126.6 StreamName Real-RegSeq window source exhaustion . . . 3373
126.7 StreamName finite-window Real handoff coverage . . . 3374
126.8 StreamName Real seal factorization boundary . . . 3380
126.9 StreamName terminal source lock . . . 3382
126.10 StreamName RegSeqRat Pointwise Handoff . . . 3394
126.11 StreamName RegSeqRat RealUp Tail-Selector Transport . . . 3410
126.12 StreamName Tail-Window Coverage Packet . . . 3419
126.13 StreamName Common-Refinement Source Determinacy . . . 3428
126.14 StreamName Common-Refinement Public Exactness . . . 3432
126.15 StreamName Synchronized Window Union . . . 3433
126.16 StreamName finite-window lattice meet . . . 3439
126.17 StreamName lattice-meet terminal factorization . . . 3443
126.18 StreamName RegSeqRat common-window transport . . . 3446
126.19 Public obligation surface . . . 3472
126.20 StreamName Finite-Window Regular Seal Non-Escape . . . 3481
126.21 StreamName Lattice Dependency . . . 3486
126.22 StreamName RegularCauchyName Lattice Link . . . 3490
126.23 StreamName RegSeqRat Real Lattice Dependency . . . 3491
126.24 StreamName finite-window transport obligations . . . 3502
126.25 StreamName finite-window nonempty-index handoff . . . 3507
126.26 StreamName finite-window budget handoff . . . 3510
126.27 StreamName Real-RegSeq shared-tail budget route . . . 3515

126.28 StreamName Common-Refinement Terminal Real Seal . . . 3516
126.29 StreamName Open-Phase Terminal Route . . . 3523
126.30 StreamName Open-Phase Terminal Exactness . . . 3525
126.31 StreamName Open-Phase Window Budget Routes . . . 3530
126.32 StreamName Open-Phase Dependency Lattice . . . 3534
126.33 StreamName Open-Phase Exit Boundary . . . 3538
126.34 StreamName L10 Real-Completion Sibling Spine . . . 3558
126.35 StreamName Real-Completion Gateway Package . . . 3558
126.36 StreamName Real-completion four-object exit route . . . 3568
126.37 StreamName finite-observation section packet . . . 3585
126.38 StreamName RegSeqRat Real budget factorization . . . 3588
126.39 StreamName Tail-Compatible Finite-Window Packet . . . 3592
126.40 StreamName finite-request section packet . . . 3599
126.41 StreamName finite-request RealUp seal lock . . . 3607
126.42 StreamName RegSeqRat Real seal handoff . . . 3609
126.43 StreamName finite-request section pullback . . . 3611
126.44 StreamName finite-section pullback exactness . . . 3615
126.45 StreamName finite-section reindex gluing . . . 3625
126.46 StreamName RegSeqRat Real public seal boundary . . . 3626
126.47 StreamName RegSeqRat Dyadic Real obligation handoff . . . 3629
126.48 StreamName terminal window fusion . . . 3637
126.49 StreamName Finite-Cover Support Removal Global Obstruction . . . 3665
126.50 StreamName finite-window diagonal section . . . 3668
126.51 StreamName L10 gateway obligation surface . . . 3669
126.52 Pointwise Certified Source . . . 3672
126.53 Finite Observation Section Cofinality . . . 3674

127 A Concrete Naming Certificate for TotallyBounded$^{\uparrow}$ 3682
127.1 Carrier definition . . . 3682
127.2 The certificate . . . 3684

128 A Concrete Naming Certificate for CompleteMetric$^{\uparrow}$ 3690
128.1 Carrier definition . . . 3690
128.2 The certificate . . . 3691

129 A Concrete Naming Certificate for CompactMetric$^{\uparrow}$ 3697
129.1 Carrier definition . . . 3697
129.2 The certificate . . . 3697

130 A Metric-Carrier Interface for ContinuousMap$^{\uparrow}$ 3710
130.1 Carrier definition . . . 3710
130.2 The certificate . . . 3723

131 A Concrete Naming Certificate for Eq$^{\uparrow}$ 3741
131.1 Carrier definition . . . 3741
131.2 The certificate . . . 3744

132 A Concrete Naming Certificate for Func$^{\uparrow}$ 3745
132.1 Carrier definition . . . 3745
132.2 The certificate . . . 3747

133 A Concrete Naming Certificate for RiemannianMetric$^{\uparrow}$ 3749
133.1 Carrier definition . . . 3749
133.2 The certificate . . . 3751

134 A Concrete Naming Certificate for Connection$^{\uparrow}$ 3753
134.1 Carrier definition . . . 3753
134.2 The certificate . . . 3755

135 A Concrete Naming Certificate for Curvature$^{\uparrow}$ 3757
135.1 Carrier definition . . . 3757
135.2 The certificate . . . 3761

136 A Concrete Naming Certificate for DiffForm$^{\uparrow}$ 3777
136.1 Carrier definition . . . 3777
136.2 The certificate . . . 3778
136.3 DiffForm degree-probe support . . . 3786
136.4 DiffForm degree-probe alignment . . . 3788
136.5 DiffForm root-unblock obligations . . . 3790
136.6 DiffForm root export threshold . . . 3815
136.7 Boundary exhaustion for DiffFormUp . . . 3818
136.8 DiffForm root consumer threshold certificate . . . 3820
136.9 DiffForm root degree-classifier package . . . 3828
136.10 DiffForm root consumer-readable package . . . 3831
136.11 DiffForm root consumer entry . . . 3833
136.12 DiffForm root consumer factorization . . . 3836
136.13 DiffForm root consumer export packet . . . 3837
136.14 DiffForm consumer boundary obligations . . . 3839

137 A Concrete Naming Certificate for DeRham$^{\uparrow}$ 3842
137.1 Carrier definition . . . 3842
137.2 The certificate . . . 3842

138 A Concrete Naming Certificate for Symplectic$^{\uparrow}$ 3856
138.1 Carrier definition . . . 3856
138.2 The certificate . . . 3857

139 A Concrete Naming Certificate for Contact$^{\uparrow}$ 3862
139.1 Carrier definition . . . 3862
139.2 The certificate . . . 3863

140 A Concrete Naming Certificate for LieGroup$^{\uparrow}$ 3867
140.1 Carrier definition . . . 3867
140.2 The certificate . . . 3867
140.3 Carrier definition . . . 3879
140.4 The certificate . . . 3879

141A Concrete Naming Certificate for LieAlgebra$^{\uparrow}$ 3892
141.1Carrier definition . . . 3892
141.2The certificate . . . 3892

142A Concrete Naming Certificate for ExpMap$^{\uparrow}$ 3899
142.1Carrier definition . . . 3899
142.2The certificate . . . 3901

143A Concrete Naming Certificate for AdjointRep$^{\uparrow}$ 3904
143.1The certificate . . . 3904

144A Concrete Naming Certificate for RootSystem$^{\uparrow}$ 3908
144.1Carrier definition . . . 3908
144.2The certificate . . . 3909

145A Concrete Naming Certificate for WeylGroup$^{\uparrow}$ 3915
145.1Carrier definition . . . 3915
145.2The certificate . . . 3915

146A Concrete Naming Certificate for BilinForm$^{\uparrow}$ 3922
146.1Carrier definition . . . 3922
146.2The certificate . . . 3927

147A Concrete Naming Certificate for Clifford$^{\uparrow}$ 3931
147.1Carrier definition . . . 3931
147.2The certificate . . . 3933

148A Concrete Naming Certificate for SpinGroup$^{\uparrow}$ 3936
148.1Carrier definition . . . 3936
148.2The certificate . . . 3943

149A Concrete Naming Certificate for PinGroup$^{\uparrow}$ 3959
149.1Carrier definition . . . 3959
149.2The certificate . . . 3961

150A Concrete Naming Certificate for PreSheaf$^{\uparrow}$ 3988
150.1Carrier definition . . . 3988
150.2The certificate . . . 3991

151A Concrete Naming Certificate for Sheaf$^{\uparrow}$ 3993
151.1Carrier definition . . . 3993
151.2The certificate . . . 3993
151.3Displayed base change surface . . . 4016
151.4Sheaf base-change functoriality . . . 4018
151.5Root obligations for downstream certificates . . . 4035
151.6Identity-cover root package . . . 4039
151.7Downstream consumption boundary . . . 4065
151.8Carrier definition . . . 4067
151.9The certificate . . . 4067

151.10 Downstream consumption boundary . . . 4090
151.11 Displayed base change surface . . . 4094
151.12 Sheaf base-change functoriality . . . 4097
151.13 Identity-cover root package . . . 4105
151.14 Root obligations for downstream certificates . . . 4138

152 A Concrete Naming Certificate for RingedSpace$^{\uparrow}$ 4143
152.1 Carrier definition . . . 4143
152.2 The certificate . . . 4146

153 A Concrete Naming Certificate for Scheme$^{\uparrow}$ 4147
153.1 Carrier definition . . . 4147
153.2 The certificate . . . 4148

154 A Concrete Naming Certificate for AffineVar$^{\uparrow}$ 4150
154.1 Carrier definition . . . 4150
154.2 The certificate . . . 4150

155 A Concrete Naming Certificate for ProjectiveVar$^{\uparrow}$ 4159
155.1 Carrier definition . . . 4159
155.2 The certificate . . . 4159

156 A Concrete Naming Certificate for Homotopy$^{\uparrow}$ 4165
156.1 Carrier definition . . . 4165
156.2 The certificate . . . 4167

157 A Concrete Naming Certificate for SimplicialSet$^{\uparrow}$ 4173
157.1 Carrier definition . . . 4173
157.2 The certificate . . . 4174

158 A Concrete Naming Certificate for ModelCat$^{\uparrow}$ 4179
158.1 Carrier definition . . . 4179
158.2 The certificate . . . 4182

159 A Concrete Naming Certificate for InfCat$^{\uparrow}$ 4185
159.1 Carrier definition . . . 4185
159.2 The certificate . . . 4185

160 A Concrete Naming Certificate for DerivedCat$^{\uparrow}$ 4190
160.1 Carrier definition . . . 4190
160.2 The certificate . . . 4190

161 A Concrete Naming Certificate for FieldExt$^{\uparrow}$ 4194
161.1 Carrier definition . . . 4194
161.2 The certificate . . . 4196
161.3 Sibling dependency lattice . . . 4210

162A Concrete Naming Certificate for AlgClosure↑ **4213**
162.1 Carrier definition 4213
162.2 The certificate 4215

163A Concrete Naming Certificate for GaloisExt↑ **4219**
163.1 Carrier definition 4219
163.2 The certificate 4221

164A Concrete Naming Certificate for GaloisGroup↑ **4230**
164.1 Carrier definition 4230
164.2 The certificate 4231

165A Concrete Naming Certificate for SplittingField↑ **4242**
165.1 Carrier definition 4242
165.2 The certificate 4242

166A Concrete Naming Certificate for SeparableExt↑ **4247**
166.1 Carrier definition 4247
166.2 The certificate 4247

167A Concrete Naming Certificate for Transcendence↑ **4251**
167.1 Carrier definition 4251
167.2 The certificate 4251

168A Concrete Naming Certificate for NumField↑ **4254**
168.1 Carrier definition 4254
168.2 The certificate 4255

169A Concrete Naming Certificate for RingOfIntegers↑ **4267**
169.1 Carrier definition 4267
169.2 The certificate 4267

170A Concrete Naming Certificate for IdealClass↑ **4273**
170.1 Carrier definition 4273
170.2 The certificate 4274

171A Concrete Naming Certificate for DirichletUnit↑ **4276**
171.1 Carrier definition 4276
171.2 The certificate 4280

172A Concrete Naming Certificate for Dedekind↑ **4284**
172.1 Carrier definition 4284
172.2 The certificate 4285

173A Concrete Naming Certificate for LocalField↑ **4288**
173.1 Carrier definition 4288
173.2 The certificate 4290

174A Concrete Naming Certificate for Cyclotomic$^{\uparrow}$ **4291**
174.1Carrier definition 4291
174.2The certificate 4294

175A Concrete Naming Certificate for EllipticCurve$^{\uparrow}$ **4319**
175.1Carrier definition 4319
175.2The certificate 4319

176A Concrete Naming Certificate for AbelianCat$^{\uparrow}$ **4326**
176.1Carrier definition 4326
176.2The certificate 4328

177A Concrete Naming Certificate for DerivedFunctor$^{\uparrow}$ **4334**
177.1Carrier definition 4334
177.2The certificate 4340

178A Concrete Naming Certificate for SpectralSeq$^{\uparrow}$ **4345**
178.1Carrier definition 4345
178.2The certificate 4347

179A Concrete Naming Certificate for TriangulatedCat$^{\uparrow}$ **4356**
179.1Carrier definition 4356
179.2The certificate 4357

180A Concrete Naming Certificate for HopfAlg$^{\uparrow}$ **4361**
180.1Carrier definition 4361
180.2The certificate 4361

181A Concrete Naming Certificate for MonoidalCat$^{\uparrow}$ **4368**
181.1Carrier definition 4368
181.2The certificate 4368

182A Concrete Naming Certificate for EnrichedCat$^{\uparrow}$ **4373**
182.1Carrier definition 4373
182.2The certificate 4374

183A Concrete Naming Certificate for Topos$^{\uparrow}$ **4378**
183.1Carrier definition 4378
183.2The certificate 4379

184A Concrete Naming Certificate for ProbSpace$^{\uparrow}$ **4382**
184.1Carrier definition 4382
184.2The certificate 4382

185A Concrete Naming Certificate for RandomVar$^{\uparrow}$ **4392**
185.1Carrier definition 4392
185.2The certificate 4392

186A Concrete Naming Certificate for Distribution$^{\uparrow}$ **4415**
186.1Carrier definition 4415
186.2The certificate 4416

187A Concrete Naming Certificate for Independence$^{\uparrow}$ **4433**
187.1Carrier definition 4433
187.2The certificate 4434

188A Concrete Naming Certificate for CondExp$^{\uparrow}$ **4445**
188.1Carrier definition 4445
188.2The certificate 4445

189A Concrete Naming Certificate for MarkovChain$^{\uparrow}$ **4449**
189.1Carrier definition 4449
189.2The certificate 4453

190A Concrete Naming Certificate for Martingale$^{\uparrow}$ **4458**
190.1Carrier definition 4458
190.2The certificate 4460

191A Concrete Naming Certificate for Brownian$^{\uparrow}$ **4468**
191.1Carrier definition 4468
191.2The certificate 4469

192A Concrete Naming Certificate for Entropy$^{\uparrow}$ **4483**
192.1Carrier definition 4483
192.2The certificate 4484

193A Concrete Naming Certificate for Ode$^{\uparrow}$ **4488**
193.1Carrier definition 4488
193.2The certificate 4488

194A Concrete Naming Certificate for Pde$^{\uparrow}$ **4493**
194.1Carrier definition 4493
194.2The certificate 4495

195A Concrete Naming Certificate for DynSystem$^{\uparrow}$ **4499**
195.1Carrier definition 4499
195.2The certificate 4502

196A Concrete Naming Certificate for Ergodic$^{\uparrow}$ **4510**
196.1Carrier definition 4510
196.2The certificate 4510

197A Concrete Naming Certificate for FirstOrder$^{\uparrow}$ **4513**
197.1Carrier definition 4513
197.2The certificate 4513

198A Concrete Naming Certificate for ModelTheory$^{\uparrow}$ 4522
198.1Carrier definition 4522
198.2The certificate 4524

199A Concrete Naming Certificate for Computable$^{\uparrow}$ 4529
199.1Carrier definition 4529
199.2The certificate 4529

200A Concrete Naming Certificate for LambdaCalc$^{\uparrow}$ 4539
200.1Carrier definition 4539
200.2The certificate 4541

201A Concrete Naming Certificate for Partition$^{\uparrow}$ 4557
201.1Carrier definition 4557
201.2The certificate 4557

202A Concrete Naming Certificate for Matroid$^{\uparrow}$ 4561
202.1Carrier definition 4561
202.2The certificate 4561

203A Concrete Naming Certificate for Ramsey$^{\uparrow}$ 4570
203.1Carrier definition 4570
203.2The certificate 4570

204A Concrete Naming Certificate for TopGroup$^{\uparrow}$ 4574
204.1Carrier definition 4574
204.2The certificate 4574
204.3Root source-fiber obligation packet 4590
204.4Root source-fiber export packet 4592
204.5Root operation source packet 4595
204.6Public threshold frontier 4596
204.7TopGroup root threshold downstream package 4599
204.8TopGroup root downstream obligation triad 4601

205A Concrete Naming Certificate for TopVecSpace$^{\uparrow}$ 4605
205.1Carrier definition 4605
205.2The certificate 4606

206A Concrete Naming Certificate for AffineSpace$^{\uparrow}$ 4609
206.1Carrier definition 4609
206.2The certificate 4610

207A Concrete Naming Certificate for ProjectiveSpace$^{\uparrow}$ 4617
207.1Carrier definition 4617
207.2The certificate 4618

208A Concrete Naming Certificate for ConvexSet$^{\uparrow}$ 4620
208.1Carrier definition 4620
208.2The certificate 4620

209A Concrete Naming Certificate for Polytope$^{\uparrow}$ **4631**
209.1Carrier definition 4631
209.2The certificate 4632

210A Concrete Naming Certificate for VectorBundle$^{\uparrow}$ **4636**
210.1Carrier definition 4636
210.2The certificate 4637

211A Concrete Naming Certificate for CStarAlg$^{\uparrow}$ **4640**
211.1Carrier definition 4640
211.2The certificate 4640

212A Concrete Naming Certificate for VonNeumannAlg$^{\uparrow}$ **4644**
212.1Carrier definition 4644
212.2The certificate 4644

213A Concrete Naming Certificate for OperatorIdeal$^{\uparrow}$ **4647**
213.1Carrier definition 4647
213.2The certificate 4648

214A Concrete Naming Certificate for SpectralTheorem$^{\uparrow}$ **4657**
214.1Carrier definition 4657
214.2The certificate 4657

215A Concrete Naming Certificate for Nuclear$^{\uparrow}$ **4661**
215.1Carrier definition 4661
215.2The certificate 4662

216A Concrete Naming Certificate for Factor$^{\uparrow}$ **4665**
216.1Carrier definition 4665
216.2The certificate 4667

217A Concrete Naming Certificate for QuantumState$^{\uparrow}$ **4670**
217.1Carrier definition 4670
217.2The certificate 4670

218A Concrete Naming Certificate for Observable$^{\uparrow}$ **4684**
218.1Carrier definition 4684
218.2The certificate 4685

219A Concrete Naming Certificate for UnitaryGroup$^{\uparrow}$ **4694**
219.1Carrier definition 4694
219.2The certificate 4695

220A Concrete Naming Certificate for DensityMatrix$^{\uparrow}$ **4699**
220.1Carrier definition 4699
220.2The certificate 4699

221A Concrete Naming Certificate for QuantumChannel$^{\uparrow}$ **4705**
221.1Carrier definition 4705
221.2The certificate 4705

222A Concrete Naming Certificate for Entanglement$^{\uparrow}$ **4717**
222.1Carrier definition 4717
222.2The certificate 4718

223A Concrete Naming Certificate for NewtonIteration$^{\uparrow}$ **4720**
223.1Carrier definition 4720
223.2The certificate 4720

224A Concrete Naming Certificate for Interpolation$^{\uparrow}$ **4726**
224.1Carrier definition 4726
224.2The certificate 4728

225A Concrete Naming Certificate for Approximation$^{\uparrow}$ **4730**
225.1Carrier definition 4730
225.2The certificate 4731

226A Concrete Naming Certificate for Fft$^{\uparrow}$ **4735**
226.1Carrier definition 4735
226.2The certificate 4737

227A Concrete Naming Certificate for Quadrature$^{\uparrow}$ **4740**
227.1Carrier definition 4740
227.2The certificate 4740

228A Concrete Naming Certificate for FisherInfo$^{\uparrow}$ **4749**
228.1Carrier definition 4749
228.2The certificate 4753

229A Concrete Naming Certificate for StatManifold$^{\uparrow}$ **4756**
229.1Carrier definition 4756
229.2The certificate 4758

230A Concrete Naming Certificate for Estimator$^{\uparrow}$ **4760**
230.1Carrier definition 4760
230.2The certificate 4760

231A Concrete Naming Certificate for HypothesisTest$^{\uparrow}$ **4763**
231.1Carrier definition 4763
231.2The certificate 4763

232A Concrete Naming Certificate for Bayesian$^{\uparrow}$ **4767**
232.1Carrier definition 4767
232.2The certificate 4767

233A Concrete Naming Certificate for NetworkFlow↑ 4773
233.1Carrier definition 4773
233.2The certificate 4773

234A Concrete Naming Certificate for Matching↑ 4783
234.1Carrier definition 4783
234.2The certificate 4783

235A Concrete Naming Certificate for LPDuality↑ 4790
235.1Carrier definition 4790
235.2The certificate 4790

236A Concrete Naming Certificate for ShortestPath↑ 4805
236.1Carrier definition 4805
236.2The certificate 4805

237A Concrete Naming Certificate for SpanningTree↑ 4810
237.1Carrier definition 4810
237.2The certificate 4812

238A Concrete Naming Certificate for SimplicialComplex↑ 4813
238.1Carrier definition 4813
238.2The certificate 4813

239A Concrete Naming Certificate for PersistentHom↑ 4822
239.1Carrier definition 4822
239.2The certificate 4824

240A Concrete Naming Certificate for Mapper↑ 4826
240.1Carrier definition 4826

8341 A Concrete Naming Certificate for Window-Six Weight Log-Concavity 37271

8342 The Window6 Weight Polynomial: A Finite-Window Positivity Ladder on a Fibonacci Carrier 37273
8342.1 The Ladder . . . 37273
8342.2 The Spectral-Determinant Identification . . . 37274

8343 The Golden-Mean Ruelle Zeta: A Finite Fibonacci Transfer Certificate 37276
8343.1 The Weighted Periodic-Point Zeta . . . 37276
8343.2 The Finite Zeta Certificate . . . 37277
8343.3 The Golden Pole Factorisation . . . 37277

8344 The Golden-Mean Primitive-Orbit Mobius Certificate 37279
8344.1 The Weighted Primitive-Orbit Transform . . . 37279
8344.2 What This Certificate Claims . . . 37280

8345 The Golden-Mean Parry Residue: A Cylinder-Resolved Finite RPF Certificate 37282
8345.0 Cylinder-Resolved Transfer Powers . . . 37282
8345.2 Adjugate and Pressure Shadow . . . 37283
8345.3 Golden Parry Residue . . . 37283

8346 The Golden-Mean Hankel–Turan Discriminant Identity 37285

8347 The Golden-Mean Zeta Denominator as a Fifth-Cyclotomic Pentagon Certificate 37287
8347.1 The Fifth-Cyclotomic Twisted Norm . . . 37287
8347.2 The Pentagon Bridge . . . 37288
8347.3 Scope . . . 37289

8348 The Golden-Mean Shift Equivalence: A Finite Presentation-Invariance Certificate 37290
8348.1 The Rectangular Factors . . . 37290
8348.2 The Presentation-Invariance Certificate . . . 37290

8349 The Golden-Mean Quadratic-Algebra Capstone 37292
8349.1 The Master Norm Identity . . . 37292
8349.2 Powers, Cassini, and Truncated Resolvents . . . 37293
8349.3 Honest Scope Across the Six Facets . . . 37293

8350 The Finite Golden-Mean Zeta Program 37295
8350.1 The Central Norm Identity . . . 37295
8350.2 The Facet Table . . . 37296
8350.3 The Program Boundary . . . 37296

9191 A Concrete Naming Certificate for the Fibonacci-Window Weil Positivity Matrix 39753

VI Concrete Hardening 39756

9192 Internal Domain Judgments and Signature Token Reflection 39757

9193 Internalized Concrete Gaps and Globalize Soundness 39759

9194 Unary Continuation Commutativity and the Additive Name 39764

VII Proof Obligations 39767

9195 Domain Policy and Unary Instance 39768
9195.1 Domain Policy and Transport Obligations . . . 39768
9195.2 Concrete Domain Policy for the Unary Source . . . 39769

9196 Package Token Policy, Uniqueness, and Reflection 39772
9196.1 Package Token Policy and Reflection . . . 39772
9196.2 Inductive Package-Token Policy for Signature Packages . . . 39774
9196.3 Token-Introduction Uniqueness and Package Reflection . . . 39775
9196.4 Token-Uniqueness Modes . . . 39777

9197 Gap Policy 39782
9197.1 Consolidated Signature Gap Policy . . . 39782

9198 Package-Sameness Design and Base Reflection 39791
9198.1 Concrete Package-Sameness Design Contract . . . 39791
9198.2 Base Reflection Schema . . . 39793
9198.3 Optional Closure Reflection Target . . . 39794

9199 Exact Globalize Base Contract 39798
9199.1 Exact Concrete Signature Globalize Under Explicit Policies . . . 39798
9199.2 Exactness Export Contract . . . 39799
9199.3 Checker-Friendly Exactness Predicate . . . 39801

9199.4 Exact Globalize Base Contract . . . 39803

9200 Unary Shift and Commutativity 39808
9200.1 Unary Commutativity Proof Obligations . . . 39808
9200.2 Unary Shift and the Additive License . . . 39809
9200.3 Unary Right-Shift: Micro-Lemmas for the Additive License . . . 39810

9201 Lean Scaffold Contract 39814
9201.1 Lean-Style Scaffold Contract . . . 39814
9201.2 Scaffold excerpt . . . 39814
9201.3 Interpretation . . . 39814
9201.4 Lean Verification Status . . . 39815

VIII Implementation-Facing Contract 39816

9202 Formalization Implementation Contract 39817
9202.1 Layer separation . . . 39817
9202.2 Module targets . . . 39817
9202.3 Public theorem names . . . 39817
9202.4 Implementation choices . . . 39818
9202.5 Proof-sprint order . . . 39818
9202.6 Forbidden public shortcuts . . . 39819

IX Acceptance Discipline 39820

9203 Closure and Verification Discipline 39821
9203.1 Theoretical closure axis . . . 39821
9203.2 External correspondence axis . . . 39822
9203.3 Formal verification axis . . . 39823
9203.4 The verified gate . . . 39823
9203.5 Marker-to-verification correspondence . . . 39824
9203.6 Per-chapter closurestatus block . . . 39825
9203.7 Upgrade obligations . . . 39825
9203.8 Reuse, composition, and retroactive promotion . . . 39826
9203.9 The discipline as research-plan language . . . 39826

9204 Standard Bridge Protocol 39828
9204.1 The six fields of a standard bridge . . . 39828
9204.2 The no-host-leak field as object-level axiom-purity . . . 39829
9204.3 Quotient and closure discipline as bridge prerequisites . . . 39829
9204.4 Conservativity in the presence of theorem preservation . . . 39830
9204.5 Worked sketch: integers . . . 39831
9204.6 Bridge prerequisites table . . . 39831

9205 Cannot-Claim Registry and Failure Witnesses 39832
9205.1 The discipline of negative claims . . . 39832
9205.2 Failure witness type . . . 39832
9205.3 Cannot-claim registry . . . 39833
9205.4 Closure reading convention . . . 39835
9205.5 Anti-confusion register . . . 39835
9205.6 Failure witness as audit input . . . 39835

9206 Closure Reading Convention 39837
9206.1 Read both axes, separately . . . 39837
9206.2 Read closure as a paper claim . . . 39837
9206.3 Read verification as an audit claim . . . 39837
9206.4 Per-object orientation table . . . 39837

X Ground Compiler Discipline 39840

9207 Ground Event Flow 39841
9207.1 Display alphabet and raw events . . . 39841
9207.2 Event flows and boundary information . . . 39842
9207.3 No-hidden-input discipline . . . 39843
9207.4 Recognized derived flows . . . 39844
9207.5 Accepted object flows and the ground theorem . . . 39844
9207.6 Worked event-flow examples . . . 39846
9207.7 Conservativity and closing observations . . . 39847

9208 Zeckendorf-safe Channel Encoding 39849
9208.1 Body encoding and event terminator . . . 39850
9208.2 Legal event code and channel stream . . . 39851
9208.3 Decoders and round-trip theorems . . . 39852
9208.4 Streaming behavior and host-structure independence . . . 39854
9208.5 Conservativity and closing observations . . . 39855

9209 Source-Level Events and Channel-Level Bits 39857
9209.1 Source layer and channel layer . . . 39857
9209.2 No channel-level source rewrite . . . 39858
9209.3 Decode-normalize-compile pipeline . . . 39859
9209.4 Ledger preservation and classifier quotient . . . 39860
9209.5 Encoding and decoding examples for ledger flows . . . 39861
9209.6 Channel substrings versus source events . . . 39862
9209.7 Layer separation theorem and closing observations . . . 39863

9210 Package Structure Is Generated, Not Input 39864
9210.1 Package recognition on event flows . . . 39864
9210.2 Roles, seals, and ledgers . . . 39866
9210.3 Compile-decode invariance . . . 39868
9210.4 Classified packages as quotients . . . 39869
9210.5 Recognition from channel code . . . 39869

9210.6 Conservativity and derived-interface boundary . . . 39871

9211 NameCert Flow Recognition 39872
9211.1 NameCert recognition on event flows . . . 39872
9211.2 Field subflows and seals . . . 39874
9211.3 Name licensing . . . 39875
9211.4 Ledger completeness . . . 39876
9211.5 NameCert code and channel recognition . . . 39877
9211.6 Field soundness events . . . 39878
9211.7 Conservativity and examples . . . 39879

9212 DerivCert and AcceptanceGate Flow Recognition 39882
9212.1 Strength and DerivCert recognition . . . 39882
9212.2 Six fields and field soundness . . . 39884
9212.3 Acceptance flows . . . 39886
9212.4 Recognition from code and round trips . . . 39888
9212.5 Strength monotonicity and reuse . . . 39888
9212.6 Conservativity and examples . . . 39890

9213 Theorem Flow Recognition 39892
9213.1 Theorem recognition . . . 39892
9213.2 Theorem roles . . . 39894
9213.3 Proof, certificate, ledger, status, and site soundness . . . 39895
9213.4 Theorem code and quotients . . . 39897
9213.5 Recognition from code . . . 39898
9213.6 Acceptance and seals . . . 39899
9213.7 Conservativity and examples . . . 39900

9214 Chapter Flow Recognition 39902
9214.1 Chapter recognition . . . 39902
9214.2 Chapter roles . . . 39904
9214.3 Soundness of chapter structure . . . 39905
9214.4 Chapter code and quotients . . . 39907
9214.5 Recognition from code and readable views . . . 39908
9214.6 Dependencies and seals . . . 39910
9214.7 Conservativity and examples . . . 39910

9215 Recognizer Flows 39912
9215.1 Recognizer candidates and roles . . . 39912
9215.2 Recognizer certificates . . . 39913
9215.3 Conservativity and hierarchy . . . 39915
9215.4 Self-description and self-hosting . . . 39917
9215.5 Examples and conservativity . . . 39919

9216 Self-Hosting Compiler Flow 39921
9216.1 Compiler candidates and behavior . . . 39921
9216.2 Compiler certificates . . . 39922
9216.3 Bootstrap boundary . . . 39924

9216.4 Self-compilation and self-hosting . . . 39924
9216.5 Bootstrap ladder . . . 39926
9216.6 Compiler theorem packages . . . 39927
9216.7 Conservativity . . . 39929

9217 Semantic Motif Analysis 39930
9217.1 Motif recognition . . . 39930
9217.2 Basic motif forms . . . 39932
9217.3 Code behavior . . . 39933
9217.4 Profiles, overlap, and prefixes . . . 39934
9217.5 Motif metrics . . . 39935
9217.6 Examples . . . 39936
9217.7 Limits of motif analysis . . . 39937

9218 First Case Studies: Finite Repetition, Add/Fold, List, and Completion 39939
9218.0 Case-study flows . . . 39939
9218.1 Finite repetition skeleton . . . 39940
9218.2 Nat-like skeleton . . . 39941
9218.3 Add and fold skeletons . . . 39942
9218.4 List-like skeleton . . . 39943
9218.5 Completion and FullAxis skeleton . . . 39944
9218.6 Cross-theory comparison . . . 39946
9218.7 Motif reports . . . 39947
9218.8 Conservativity . . . 39948

9219 Theory Metrics and Flow Invariants 39949
9219.1 Admissible metric data . . . 39949
9219.2 Prefix profiles . . . 39950
9219.3 Motif profiles and counts . . . 39951
9219.4 Normal addresses and distances . . . 39952
9219.5 Theory-flow distance and reports . . . 39953
9219.6 Examples and cannot-claims . . . 39955
9219.7 Conservativity . . . 39956

9220 Higher-Layer Case Studies: Completion, Real, Topology, Geometry, Category, and Homology 39957
9220.0 Higher-layer case-study flows . . . 39957
9220.1 Completion and Real-like flows . . . 39958
9220.2 Metric and topology flows . . . 39959
9220.3 Phase, circle, and complex flows . . . 39960
9220.4 Category, functor, and natural transformation motifs . . . 39962
9220.5 Homology as boundary-quotient flow . . . 39963
9220.6 Cross-domain comparison . . . 39963
9220.7 Reports, limits, and conservativity . . . 39964

9221 Compiler Analysis Pipeline 39966
9221.1 Inputs and protocol recognition . . . 39966
9221.2 Pipeline stages . . . 39968
9221.3 Pipeline correctness . . . 39970
9221.4 Report discipline . . . 39971
9221.5 Failure handling . . . 39972
9221.6 Theorem and chapter code analysis . . . 39972
9221.7 Examples and determinacy . . . 39973

9222 Main Theorems and Cannot-Claim Registry 39975
9222.0 Compiler state and hidden input . . . 39975
9222.2 Channel and layer separation . . . 39976
9222.3 Recognized structures and exports . . . 39977
9222.4 Theorem, chapter, and quotient layers . . . 39979
9222.5 Recognizers, compilers, motifs, and metrics . . . 39981
9222.6 Cannot-claim registry . . . 39982
9222.7 Global conservativity and final theorem . . . 39983

9223 Implementation Interface and Verification Targets 39986
9223.1 Implementation layer and formal surface . . . 39986
9223.2 Core implementation modules . . . 39987
9223.3 Channel compiler specification . . . 39989
9223.4 Executable encoder and decoder obligations . . . 39990
9223.5 Public recognition interfaces . . . 39992
9223.6 No-host-leak audit . . . 39993
9223.7 Lean targets and reference executable . . . 39993
9223.8 Implementation reports and adequacy . . . 39995

9224 Minimal Executable Prototype Specification 39997
9224.1 Scope and display representations . . . 39997
9224.2 Encoding and decoding specification . . . 39999
9224.3 Prototype test suite . . . 40000
9224.4 Prototype outputs . . . 40001
9224.5 Prototype correctness . . . 40002
9224.6 Prototype limitations and CLI . . . 40003
9224.7 Output formats and audit . . . 40004
9224.8 Example sessions and conservativity . . . 40005

9225 Source-Event Reporting Prototype 40007
9225.1 Source-event reports . . . 40007
9225.2 Warnings and cannot-claims . . . 40009
9225.3 Report format and examples . . . 40010
9225.4 Soundness and display policy . . . 40011
9225.5 No-host-leak and adequacy . . . 40013
9225.6 Full example report . . . 40014

9226 Source-Level Normalizer Ledger Prototype 40016
9226.1 Adjacent pairs and candidates . . . 40016
9226.2 Candidate policies . . . 40019
9226.3 Recognized normalizer ledgers . . . 40020
9226.4 Examples and reports . . . 40021
9226.5 Soundness, conservativity, and adequacy . . . 40023
9226.6 Full reports . . . 40024

9227 Motif-Report Prototype 40026
9227.1 Motif candidates and recognition . . . 40026
9227.2 Basic motifs . . . 40028
9227.3 Motif reports . . . 40029
9227.4 P_3 pipeline . . . 40030
9227.5 Examples . . . 40031
9227.6 Motif counts . . . 40032
9227.7 Soundness, adequacy, and conservativity . . . 40033
9227.8 Full report examples . . . 40035

9228 Metric-Report Prototype 40036
9228.1 Metric protocols and admissibility . . . 40036
9228.2 Basic metrics . . . 40038
9228.3 Comparison metrics . . . 40039
9228.4 Metric reports . . . 40041
9228.5 Metric claims and cannot-claims . . . 40041
9228.6 P_4 pipeline and examples . . . 40042
9228.7 Adequacy and conservativity . . . 40043
9228.8 Full reports . . . 40044

9229 Package and NameCert Recognition Prototype 40046
9229.1 P_5 prototype interface . . . 40046
9229.2 Package-flow recognition . . . 40047
9229.3 NameCert-flow recognition . . . 40049
9229.4 Package-sourced NameCert flows . . . 40051
9229.5 P_5 reports and soundness . . . 40051
9229.6 Adequacy . . . 40053
9229.7 Examples . . . 40054
9229.8 Conservativity . . . 40054

9230 DerivCert and AcceptGate Recognition Prototype 40056
9230.1 P_6 prototype interface . . . 40056
9230.2 Strength-flow recognition . . . 40057
9230.3 DerivCert-flow recognition . . . 40058
9230.4 Field soundness . . . 40060
9230.5 AcceptGate-flow recognition . . . 40060
9230.6 Accepted object code . . . 40062
9230.7 Strength monotonicity and promotion . . . 40062
9230.8 Reports and soundness . . . 40063
9230.9 Adequacy and examples . . . 40065

9230.10 Conservativity . . . 40066

9231 Theorem and Proof Recognition Prototype 40067
9231.1 P_7 prototype interface . . . 40067
9231.2 Statement and dependency recognition . . . 40068
9231.3 Proof-flow recognition and checking . . . 40069
9231.4 Theorem-flow recognition . . . 40071
9231.5 Theorem-flow soundness and code . . . 40072
9231.6 Abstract propositions and accepted theorem flows . . . 40073
9231.7 Reports and soundness . . . 40074
9231.8 Adequacy and examples . . . 40075
9231.9 Conservativity . . . 40076

9232 Chapter and Manuscript Recognition Prototype 40078
9232.1 P_8 prototype interface . . . 40078
9232.2 Definition and lemma recognition . . . 40079
9232.3 Chapter-flow recognition . . . 40080
9232.4 Chapter soundness and code . . . 40081
9232.5 Manuscript-flow recognition . . . 40083
9232.6 Manuscript soundness and code . . . 40084
9232.7 Reports and soundness . . . 40085
9232.8 Adequacy . . . 40086
9232.9 Examples . . . 40087
9232.10 Conservativity . . . 40087
9232.11 Summary . . . 40088

9233 Self-Hosting Compiler and Global Verification Prototype 40090
9233.1 P_9 prototype interface . . . 40090
9233.2 Compiler certificate-flow . . . 40091
9233.3 Compiler behavior-flow . . . 40092
9233.4 Bootstrap obligations . . . 40093
9233.5 Self-compilation . . . 40094
9233.6 Compiler behavior equivalence . . . 40094
9233.7 Self-hosting compiler-flow . . . 40095
9233.8 Global verification-flow . . . 40096
9233.9 Reports and soundness . . . 40096
9233.10 Adequacy . . . 40097
9233.11 Examples . . . 40098
9233.12 Conservativity and ladder theorem . . . 40099
9233.13 Summary . . . 40100

9234 Programmatic Realization of the Prototype Ladder 40101
9234.1 Executable base . . . 40101
9234.2 Report and metric layers . . . 40102
9234.3 Recognizer virtual machine . . . 40103
9234.4 Certificates, proofs, and acceptance . . . 40104
9234.5 Self-hosting route . . . 40105
9234.6 Implementation architecture . . . 40105

9234.7 Deliverable ladder . . . 40106
9234.8 Summary . . . 40107

9235 Self-Compilation Surface 40108
9235.1 The L1-L4 Stratification . . . 40108
9235.2 Internal Manifest . . . 40109
9235.3 MetaCIC Reconstruction . . . 40111
9235.3.1 Encoding Overview . . . 40112
9235.3.2 Syntax Constructor Table . . . 40112
9235.3.3 Paper vs Mechanization . . . 40112
9235.3.4 Host Fragment Coverage . . . 40113
9235.3.5 Correctness Claims . . . 40113
9235.3.6 Representation vs Mockup . . . 40114
9235.3.7 Positioning Within BEDC . . . 40114
9235.3.8 Stratification Recap . . . 40114
9235.3.9 Fragments and Limitations . . . 40115
9235.3.10 Typing Rules . . . 40115
9235.3.11 Typing Inference Rules Table . . . 40115
9235.3.12 Typing Relation vs Host CIC . . . 40115
9235.3.13 Context Mechanics . . . 40116
9235.3.14 Reduction Layer Summary . . . 40116
9235.3.15 Reduction Relations . . . 40117
9235.3.16 No Eta-Conversion . . . 40117
9235.3.17 Self-Compilation Completeness . . . 40118
9235.3.18 Host CIC Relation . . . 40118
9235.3.19 Gödel-Tarski Boundary . . . 40119
9235.3.20 Host Internalization . . . 40119
9235.3.21 Axiom Purity Guarantee . . . 40119
9235.3.22 Pure CIC Fragment . . . 40120
9235.3.23 Encoding Choice . . . 40120
9235.3.24 Closure Discipline . . . 40120
9235.3.25 Shift Mechanism Detail . . . 40121
9235.3.26 Substitution Operation . . . 40121
9235.3.27 Glossary . . . 40121
9235.3.28 Construction Style . . . 40122
9235.3.29 Derivation Style . . . 40122
9235.3.30 Induction Style . . . 40123
9235.3.31 Namespace Rationale . . . 40123
9235.3.32 Lean Module Topology . . . 40123
9235.3.33 Tactic Discipline . . . 40124
9235.3.34 Build and Audit Process . . . 40124
9235.3.35 Axiom-Free Claim . . . 40124
9235.3.36 Internal Manifest Coverage . . . 40125
9235.3.37 Shift-Aware Metatheory Progress . . . 40125
9235.3.38 Substrate Stack . . . 40126
9235.3.39 Substrate Components Table . . . 40128
9235.3.40 Current State of the Reconstruction . . . 40128

9235.3.4 Evolution Trajectory . . . 40130
9235.3.4.2 Open Targets . . . 40130
9235.3.4.3 Results Overview . . . 40131
9235.3.4.4 Reconstruction Summary . . . 40131
9235.4 Representational Adequacy for the MetaCIC Fragment . . . 40134
9235.4.1 Adequacy Criterion . . . 40134
9235.4.2 Mechanized Witnesses . . . 40134
9235.4.3 Substrate Differences . . . 40135
9235.4.4 Coverage Boundary . . . 40136
9235.5 Bounds: What This Surface Does Not Claim . . . 40136
9235.6 Reflection Bridge to the Host Kernel . . . 40142
9235.6.1 Bridge Form . . . 40142
9235.6.2 Formal Obstacles . . . 40142
9235.6.3 Tractable Subgoals . . . 40143
9235.6.4 Position . . . 40143
9235.7 Shift-Aware Substrate Design . . . 40143
9235.7.1 Substrate Alternatives Surveyed . . . 40143
9235.7.2 Why De Bruijn Alone Is Insufficient . . . 40144
9235.7.3 Mechanized Properties . . . 40145
9235.7.4 Open Algebraic Gap . . . 40146
9235.7.5 Comparison to the Host CIC . . . 40146
9235.8 MetaCIC Confluence Status . . . 40146
9235.8.1 Setting . . . 40147
9235.8.2 Atom-Shape Diamond . . . 40147
9235.8.3 Application, Lambda, and Pi Shapes . . . 40148
9235.8.4 Strategy Notes . . . 40149
9235.8.5 BEDC Scope . . . 40150
9235.9 Normalization Status for the MetaCIC Fragment . . . 40150
9235.9.1 Bounded Normalizer . . . 40151
9235.9.2 Closure Preservation Under Reduction . . . 40151
9235.9.3 Strong Normalization . . . 40152
9235.9.4 Practical Impact . . . 40152
9235.9.5 Comparison with the Host Calculus . . . 40153
9235.9.6 Status Summary . . . 40154
9235.10 MetaCIC Metatheory Roadmap . . . 40154
9235.10.1 Setting . . . 40154
9235.10.2 Mechanized Surface . . . 40155
9235.10.3 Open Statements . . . 40155
9235.10.4 Why These Gaps Are Specific . . . 40156
9235.10.5 Reading Guide . . . 40157
9235.11 BHist Substrate Bridge . . . 40157
9235.11.1 What BHist Is . . . 40157
9235.11.2 Why Bridge BHist to Term . . . 40158
9235.11.3 The Mechanized Embedding . . . 40158
9235.11.4 What the Bridge Gives . . . 40159
9235.11.5 Unproved Boundaries . . . 40159
9235.12 Substrate Stack Summary . . . 40161

9235.12 Layered View . . . 40161
9235.12.1 Layer 0: Term Syntax . . . 40161
9235.12.2 Layer 1: Substrate Mechanics . . . 40162
9235.12.3 Layer 2: Reduction . . . 40162
9235.12.4 Layer 3: Typing . . . 40162
9235.12.5 Layer 4: Metatheory . . . 40162
9235.12.6 Layer 5: Examples and Embeddings . . . 40163
9235.12.7 Cross-Cutting Invariants . . . 40163
9235.12.8 Open Seam . . . 40163
9235.13 Typed Examples Gallery . . . 40163
9235.13.1 Why a gallery . . . 40164
9235.13.2 Sibling index . . . 40164
9235.13.3 Mechanized witnesses . . . 40164
9235.13.4 Boundary of the gallery . . . 40170
9235.13.5 Contributor discipline . . . 40171
9235.14 Metatheory Milestone Consolidation . . . 40171
9235.14.1 What `BEDC.MetaCIC` Achieves . . . 40171
9235.14.2 Comparison with Textbook CIC Metatheory . . . 40174
9235.14.3 Frontier . . . 40175
9235.14.4 Boundary Statement . . . 40176
9235.14.5 Why This Boundary . . . 40176
9235.15 Closed-Term Metatheory Completion . . . 40177
9235.15.1 The Closed-Term Scope Claim . . . 40177
9235.15.2 What This Scope Buys . . . 40178
9235.15.3 The Three-Hypothesis Chain . . . 40179
9235.15.4 Closed Normalization and Candidate Witnesses . . . 40180
9235.15.5 Bounded Normalizer as Operation . . . 40181
9235.15.6 What Remains Outside the Closed-Term Scope . . . 40182
9235.15.7 Meaning for the BEDC Architecture . . . 40182
9235.16 Session-Level Metatheory Claim . . . 40183
9235.16.1 Claim 1: Substrate Invariants . . . 40183
9235.16.2 Claim 2: Subject Reduction in the Closed Scope . . . 40184
9235.16.3 Claim 3: Confluence in the Closed Scope . . . 40185
9235.16.4 Claim 4: Strong Normalization in the Closed Scope . . . 40186
9235.16.5 Claim 5: Decidable Type Checker . . . 40187
9235.16.6 Claim 6: Self-Representability via HostBridge . . . 40188
9235.16.7 Claim 7: Church-Encoded Data Structure Laws . . . 40189
9235.16.8 Claim 8: BetaConv Relation Properties . . . 40190
9235.16.9 Boundary Statement . . . 40191
9235.16.10 Delivered Invariants . . . 40191
9235.17 Session Closing Summary . . . 40192
9235.17.1 Mechanized Theorems Table . . . 40192
9235.17.2 How to Read the Table . . . 40197
9235.17.3 Closed Surface . . . 40198
9235.17.4 Open Frontier . . . 40199
9235.17.5 Why This Surface Closes Here . . . 40200
9235.17.6 Forward-Looking Summary . . . 40200

9235.17 What BEDC Does Not Claim . . . 40201
9235.18 What BEDC.MetaCIC Does Not Claim . . . 40202
9235.18.1 Why This Boundary Is Stated . . . 40202
9235.18.2 Out of Scope by Design . . . 40203
9235.18.3 Comparison With Standard CIC Literature . . . 40205
9235.18.4 Zero-Axiom Invariants Delivered . . . 40207
9235.18.5 Why This Matters for Self-Compilation . . . 40208
9235.18.6 What Would Extend the Scope . . . 40209

XI Capstones 40210

9236 Capstone Results 40211

9237 Compactness Implies Uniform Continuity 40212
9237.1 Uniform modulus from located finite covers . . . 40212
9237.2 The kernel construction . . . 40213
9237.3 Axiom-purity of the uniform-modulus construction . . . 40214

9238 Real Completeness via Regular Cauchy Sequences 40230
9238.1 Regular Cauchy sequences and their limits . . . 40230
9238.2 The limit theorem . . . 40233
9238.3 Constructive content and axiom purity . . . 40246
9238.4 Modulus comparison boundary . . . 40248

9239 The Riemann Hypothesis as a BEDC Conjecture 40261
9239.1 LEVEL 1–5 dependency chain . . . 40261
9239.2 Formal statement of RH in BEDC . . . 40262
9239.3 Carrier-stack reading . . . 40263
9239.4 Witness types a proof would produce . . . 40264
9239.5 Axiom-purity considerations . . . 40265
9239.6 Connection to existing BEDC content . . . 40266
9239.7 Roadmap and scope . . . 40266

9240 Three Boundaries for RH 40268

9241 The RH Zero–Skew EventFlow Target 40272
9241.1 Zero and skew packets . . . 40272
9241.2 EventFlow reading . . . 40273
9241.3 Channel and recognition boundary . . . 40273
9241.4 Mirror closure and orbit collapse . . . 40275
9241.5 Relation to finite analysis routes . . . 40276
9241.6 Analytic continuation as projection recovery . . . 40276

9242 EventFlow Certificate Flow for Primes, Zeta, and RH 40277
9242.1 Boundary before semantics . . . 40277
9242.2 Prime flow as factorization fixed point . . . 40278
9242.3 Zeta as socket recovery flow . . . 40279
9242.4 RH as fixed-output target . . . 40280

9242.5 Fixed-point stratification . . . 40281

9243 Prime-Local Balance and the RH Critical Surface 40282
9243.1 Zeta as a recovered carrier . . . 40282
9243.2 Prime-local channel normalization . . . 40283
9243.3 Prime-balanced form of RH . . . 40285
9243.4 Archimedean completion and the central surface . . . 40286
9243.5 Projection tower reading . . . 40287

9244 Finite Prime Windows and Local–Global RH Gluing 40289
9244.1 Finite Prime Windows . . . 40289
9244.2 Local Defect Rows . . . 40290
9244.3 Carrier Gluing . . . 40291

9245 Prime Window Recursive Tower 40292
9245.1 Prime-Window Layer Data . . . 40292
9245.2 Readback and Recursive Return . . . 40293
9245.3 No-Exception Invariant . . . 40294
9245.4 Prime-Recursive RH Target . . . 40294

9246 Local–Global Zero Exclusion Target 40296
9246.1 Target Statement . . . 40296
9246.2 Finite-Window Algebra . . . 40298
9246.3 Carrier Compatibility Obligations . . . 40298
9246.4 Positive Defect Certificates . . . 40299
9246.5 Obligation Assembly . . . 40300

9247 Finite Hermitian Rouche Start for ξ 40302
9247.1 Prime–Gamma finite packet . . . 40302
9247.2 Determinant approximant . . . 40303
9247.3 Outer-rectangle Rouche certificate . . . 40304
9247.4 Off-line Rouche localization . . . 40305
9247.5 Non-circularity ledger . . . 40305

9248 Prime Fingerprint Separation for RH 40307
9248.1 Prime fingerprint . . . 40307
9248.2 Mirror fingerprints . . . 40308
9248.3 RH as prime-fingerprint indistinguishability . . . 40309

9249 Prime-Skew Boundary Defect Refutation 40311

9250 Zeta as a Self-Similar Recovered Carrier 40315

9251 Zeta–Euler Tick Algebra 40322
9251.1 Prime Ledger and Logarithmic Hamiltonian . . . 40322
9251.2 Trace and Euler Decomposition . . . 40323
9251.3 Prime Tick and Solenoid Phase . . . 40324
9251.4 Zero Closure and Li Radial Residual . . . 40325

9252 Information-Channel Normal Form of RH 40327
9252.1 Information coordinates . . . 40327
9252.2 Prime carrier and cancellation events . . . 40328
9252.3 Dual return . . . 40329

9253 Zeta Zero Type Factorization 40331
9253.1 Zeta Zero Fiber . . . 40331
9253.2 Non-Trivial and Fixed-Half Subtypes . . . 40332
9253.3 Zero Generators . . . 40332
9253.4 Canonical Presentations and Compatibility . . . 40333
9253.5 Zero and Apart-Zero Conflict . . . 40334
9253.6 Omega Factorization . . . 40334

9254 Layered RH Translation 40336
9254.1 Source Carrier and Half Fiber . . . 40336
9254.2 Equivalent Readout Layers . . . 40337

9352 Ask–Sig–Pkg–Gap–NameCert Kernel Spine 40851
9352.1 Asking and signatures . . . 40851
9352.2 Packages, gaps, and exact globalization . . . 40853
9352.3 Name certification . . . 40854

9353 Finite Data Interface Spine **40858**
9353.1 Interface Template . . . 40858
9353.2 Boolean Endpoint Interface . . . 40859
9353.3 Optional History Interface . . . 40860
9353.4 Tagged Sum Interface . . . 40860
9353.5 Ordered Product Interface . . . 40861
9353.6 Finite List Interface . . . 40862
9353.7 Finite Data Layer . . . 40863

9354 Arithmetic Interface Spine **40864**
9354.1 Unary Natural Histories . . . 40864
9354.2 Unary Continuation Addition . . . 40865
9354.3 Unary Multiplication and Divisibility . . . 40866
9354.4 Unary Order . . . 40867
9354.5 Signed Integers . . . 40868
9354.6 Rational Histories . . . 40868
9354.7 Arithmetic Layer Boundary . . . 40869

9355 Algebra Interface Spine **40870**
9355.1 Algebraic Certificate Template . . . 40870
9355.2 Magma Through Monoid . . . 40871
9355.3 Groups . . . 40872
9355.4 Rings and Fields . . . 40873
9355.5 Modules and Vector Spaces . . . 40874
9355.6 Algebra Layer Boundary . . . 40875

9356 Order Set Type Interface Spine **40876**
9356.1 Relational Certificate Template . . . 40876
9356.2 Preorders and Posets . . . 40877
9356.3 Total Orders and Lattices . . . 40878
9356.4 Set-Like Membership . . . 40879
9356.5 Type-Like Transport . . . 40880
9356.6 L9 Boundary . . . 40880

9357 Countable Completion Interface Spine **40882**
9357.1 Countable Names . . . 40882
9357.2 Dyadic Rational Core . . . 40883
9357.3 Regular Sequences and Real Names . . . 40884
9357.4 Completion . . . 40885
9357.5 Metric and Topology . . . 40886
9357.6 Metric Completion and Maps . . . 40887
9357.7 L10 Boundary . . . 40888

9358 Analysis Interface Spine **40889**
9358.1 Analytic Certificate Template . . . 40889
9358.2 Calculus . . . 40890
9358.3 Real Analytic Functions . . . 40891
9358.4 Complex Analytic Functions . . . 40893

9358.5 Measure and Integration . . . 40894
9358.6 Functional Analysis . . . 40895
9358.7 Gamma Bridge . . . 40896
9358.8 L11 Boundary . . . 40896

9359 Geometry, Category, and Homology Interface Spine . . . 40898
9359.0 Geometry Certificate Template . . . 40898
9359.2 Categories, Functors, and Natural Transformations . . . 40898
9359.3 Categorical Limits . . . 40900
9359.4 Manifolds and Bundles . . . 40900
9359.5 Homology and Cohomology . . . 40901
9359.6 L12 Boundary . . . 40902

9360 Number Theory and Zeta Interface Spine . . . 40903
9360.1 Prime Axis . . . 40903
9360.2 p-Adic and Adele Rows . . . 40904
9360.3 Dirichlet Series and Zeta . . . 40905
9360.4 Critical Strip and Zeta Zeros . . . 40906
9360.5 RH Target Surface . . . 40906
9360.6 L13 Boundary . . . 40907

9361 Omega Generation Structure Interface . . . 40908
9361.1 Licensed Generation Category . . . 40908
9361.2 Encoded Display . . . 40909
9361.3 Pairing by Involution . . . 40910
9361.4 Time as Generated Direction . . . 40911
9361.5 Interface Assembly . . . 40911

9362 Mature Bridge and Omega Rigidity Interface Spine . . . 40913
9362.0 Conservative Bridge Boundary . . . 40913
9362.2 Standard and Mathlib Bridges . . . 40914
9362.3 Conservativity and Verification Reports . . . 40914
9362.4 Phase Discipline and Refutation Boundary . . . 40915
9362.5 Omega Tower . . . 40916
9362.6 Omega-RH Rigidity . . . 40916
9362.7 L14 Boundary . . . 40917

9363 The Finite Kernel Is Already a Category . . . 40918
9363.1 Hom as unary continuation . . . 40918
9363.2 Derived presentations over the unary category . . . 40919

9364 Lean Kernel Acceptance as the Canonical BEDC Audit Witness . . . 40921
9364.1 The setup . . . 40921
9364.2 What the Lean kernel does at acceptance . . . 40922
9364.3 NameCert stamping . . . 40922
9364.4 `#print axioms` as audit ledger closure . . . 40923
9364.5 `lake build` as ledger instantiation . . . 40923
9364.6 Closed-term substitution cross-link . . . 40924

9364.7 Recursor cross-link . . . 40924
9364.8 Why this is not an infinite regress . . . 40925
9364.9 Kernel boundary as apophatic socket . . . 40925
9364.10 Boundary: what kernel acceptance does not certify . . . 40925

9365 Computation as Continuation: BEDC's Operational Semantics 40927
9365.1 Continuation as small-step transition . . . 40928

9366 Classifier-Level Information: Computation, Unfolding, and Discovery 40937
9366.1 Certified classifier states . . . 40937
9366.2 Computation as record growth . . . 40938
9366.3 Discovery as classifier shift . . . 40939
9366.4 Generators and presentation changes . . . 40940
9366.5 Separation principle . . . 40941

9367 Type Checking as Classifier Membership 40943
9367.1 Extension predicate as type-membership . . . 40943
9367.2 Subject reduction from closure laws . . . 40944
9367.3 Curry-Howard as identity . . . 40944

9368 The Halting Problem as a Limit of the Form of Distinction 40947
9368.1 Halting as fixed-point obstruction . . . 40947
9368.2 Halting as open-meta-loop closure . . . 40948
9368.3 Connection to the form of distinction . . . 40948

9369 Channel Termination and the Halting Boundary 40950
9369.1 Local channel termination . . . 40950
9369.2 Bare bitstreams and self-delimitation . . . 40951
9369.3 Channel grammar and finite window geometry . . . 40952
9369.4 The halting boundary . . . 40953

9370 Strong Normalisation versus Turing Completeness: The Total-Language Position of BEDC 40955
9370.1 Setup: total functional language as discipline . . . 40955
9370.2 The expressive gap, made precise . . . 40956
9370.3 Position among total functional languages . . . 40956
9370.4 The forced choice, read structurally . . . 40957
9370.5 Curry-Howard, and what it means here . . . 40957
9370.6 Mapping to BEDC engineering . . . 40958
9370.7 Closure remarks . . . 40958

9371 Compilation as Naming-Certificate Morphism 40960
9371.1 Compiler as classifier-preserving morphism . . . 40960
9371.2 Compositional compilation . . . 40961
9371.3 Optimisation and decompilation . . . 40961

9372 Closed-term substitution as the self-compilation step 40963
9372.1 The setup . . . 40963
9372.2 The Lean witness . . . 40964
9372.3 Why this is the self-compilation step . . . 40965
9372.4 Generator-closure classifier reading . . . 40966
9372.5 Audit gate as the executable form of the classifier . . . 40967
9372.6 Boundary: what this lemma does not claim . . . 40968

9373 The recursor as an authorized generator 40970
9373.1 The setup . . . 40970
9373.2 The kernel principle . . . 40970
9373.3 Generator role . . . 40971
9373.4 NameCert structure . . . 40971
9373.5 Generator-closure classifier view . . . 40972
9373.6 Comparison with classical "by definition" reading . . . 40972
9373.7 Connection to closed-term substitution . . . 40973
9373.8 Audit gate as the executable form of the classifier . . . 40973
9373.9 Boundary: what is not a recursor-induced NameCert . . . 40974

9374 Subject reduction discharge routes: explicit bundle 40976
9374.1 The setup . . . 40976
9374.2 Bundle route . . . 40976
9374.2.1 Definition . . . 40976
9374.2.2 Subject reduction from bundle . . . 40976
9374.3 Checked obstruction ledger . . . 40977
9374.4 Boundary . . . 40977

9375 Closed-MetaCIC consistency assembly: a partial closure map 40979
9375.1 The setup . . . 40979
9375.2 The assembled positive content . . . 40979
9375.2.1 Closed-term strong normalisation . . . 40979
9375.2.2 No closed-normal proof of False . . . 40979
9375.2.3 Closed-normal consistency assembly . . . 40980
9375.3 The unassembled frontier . . . 40980
9375.3.1 Conditional subject reduction . . . 40980
9375.3.2 The closed reduction obstruction . . . 40980
9375.4 The assembly diagram . . . 40981
9375.5 What this partial closure does establish . . . 40981
9375.6 What discharge would buy . . . 40982
9375.7 Apophatic framing . . . 40982
9375.8 Boundary . . . 40982

9376 Closed-normal consistency: BEDC's first unconditional main result 40984
9376.1 The result . . . 40984
9376.2 Why this is a first-class main result . . . 40984
9376.3 Constructive content . . . 40985
9376.4 Relation to classical results . . . 40986
9376.5 What it does not claim . . . 40986

9376.6 The role of the BEDC project . . . 40987
9376.7 Boundary . . . 40987

9377 MetaCIC subject-reduction obstruction: an audit map 40989
9377.1 The setup . . . 40989
9377.2 What is already proven . . . 40989
9377.3 The four discharge obligations . . . 40990
9377.4 The explicit obstruction theorem . . . 40991
9377.5 Critical path . . . 40991
9377.6 Where this fits in BEDC's apophatic framing . . . 40991
9377.7 The dependent-codomain frontier . . . 40991
9377.8 Boundary . . . 40992

9378 MetaCIC Confluence partial-closure audit map 40994
9378.1 The setup . . . 40994
9378.2 What is established . . . 40994
9378.3 What is conditional . . . 40996
9378.4 Comparison with the SR obstruction . . . 40996
9378.5 Apophatic framing . . . 40997
9378.6 Boundary . . . 40997

9379 MetaCIC Decidability partial-closure audit map 41001
9379.1 The setup . . . 41001
9379.2 What is established . . . 41001
9379.3 Normal equality and bounded beta conversion . . . 41003
9379.4 What remains conditional . . . 41003
9379.5 Comparison with other audit maps . . . 41004
9379.6 Apophatic framing . . . 41005
9379.7 Boundary . . . 41006

9380 MetaCIC Substitution module audit map 41007
9380.1 The setup . . . 41007
9380.2 Core operations . . . 41007
9380.2.1 `shift_closed` . . . 41007
9380.2.2 `substitute_closed` . . . 41008
9380.2.3 Closed composition . . . 41008
9380.3 Connection to subject reduction . . . 41009
9380.4 Connection to GeneratorClosureClassifier . . . 41009
9380.5 Apophatic framing . . . 41009
9380.6 Boundary . . . 41010

9381 MetaCIC ClosurePreservation module audit map 41011
9381.1 The setup . . . 41011
9381.2 Established theorems . . . 41011
9381.2.1 `shift_one_preserves_closed_succ` . . . 41011
9381.2.2 `substitute_var_preserves_closed_at` . . . 41012
9381.2.3 `substitute_preserves_closed_at` . . . 41012
9381.2.4 `betaStep_preserves_closed` . . . 41012

9381.2.5 `betaStarStep_preserves_closed` . . . 41012
9381.3 Why ClosurePreservation is unconditional while SR is not . . . 41013
9381.4 Role within MetaCIC . . . 41013
9381.5 Connection to GeneratorClosureClassifier . . . 41013
9381.6 Boundary . . . 41014

9382 MetaCIC TypedExamples module audit map . . . 41016
9382.1 The setup . . . 41016
9382.2 Inventory . . . 41016
9382.3 Representative theorems . . . 41017
9382.4 Role within MetaCIC . . . 41019
9382.5 Connection to other audit maps . . . 41019
9382.6 Boundary . . . 41019

9383 MetaCIC Normalization partial-closure audit map . . . 41021
9383.1 The setup . . . 41021
9383.2 What is established . . . 41021
9383.3 File-by-file audit reading . . . 41022
9383.4 What remains conditional . . . 41023
9383.5 Comparison with SR obstruction and Confluence audit map . . . 41024
9383.6 Apophatic framing and boundary . . . 41024

9384 MetaCIC Beta module audit map . . . 41028
9384.1 The setup . . . 41028
9384.2 Core inductive definition . . . 41028
9384.2.1 BetaStep . . . 41028
9384.2.2 File-level reading . . . 41029
9384.3 Established results . . . 41029
9384.4 Connection to the SR obstruction . . . 41030
9384.5 Apophatic framing and boundary . . . 41031

9385 MetaCIC audit synthesis: closed-CIC critical-path overview . . . 41032
9385.1 The setup . . . 41032
9385.2 The five submodule audit maps . . . 41032
9385.2.1 Reading rule . . . 41032
9385.2.2 Subject reduction . . . 41032
9385.2.3 Confluence . . . 41033
9385.2.4 Normalization . . . 41033
9385.2.5 Substitution . . . 41033
9385.2.6 Decidability . . . 41033
9385.3 The critical path to unconditional closed consistency . . . 41033
9385.4 Status matrix . . . 41034
9385.5 How the maps interact . . . 41035
9385.6 The frontier shape . . . 41036
9385.7 Apophatic discipline applied to meta-theory . . . 41036
9385.8 Boundary . . . 41037

9386 Closed-MetaCIC open problems: consolidated obligation list 41038
9386.1 The setup . . . 41038
9386.2 Subject reduction obligations (4) . . . 41038
9386.3 Confluence remaining questions . . . 41039
9386.4 Normalization remaining questions . . . 41041
9386.5 Decidability remaining questions . . . 41041
9386.6 TypedExamples coverage questions . . . 41042
9386.7 Cross-cutting frontier questions . . . 41043
9386.7.1 Dependent-codomain barrier . . . 41043
9386.7.2 Bundle discharge route . . . 41043
9386.7.3 Normal-form-only consistency . . . 41043
9386.7.4 Substrate extension for dependent-codomain closure . . . 41043
9386.8 Operational priorities . . . 41044
9386.9 Boundary . . . 41044

9387 Three Axiom Families, One Meta-Closure Taxonomy 41050
9387.1 The three axiom families as taxonomy entries . . . 41050
9387.2 The unification taxonomy . . . 41051
9387.3 Effective replacements inside BEDC . . . 41051
9387.4 The axiom-purity gate as refusal of meta closure . . . 41052
9387.5 Assumed bridges and derived bridges . . . 41052

9388 The Closure-Universality Quadrant: A Two-Axis Substrate Map 41063
9388.1 The two axes, formally . . . 41063
9388.2 Quadrant I: universal and closed . . . 41064
9388.3 Quadrant II: universal but not closed . . . 41064
9388.4 Quadrant III: not universal but closed . . . 41065
9388.5 Quadrant IV: neither universal nor closed . . . 41065
9388.6 The quadrant as map . . . 41066
9388.7 Mapping to BEDC engineering . . . 41066
9388.8 Closure remarks . . . 41067

9389 Generator-Closure Certificates and the Two Layers of BEDC: Technical Mechanism for the Strong Externality Claim 41068
9389.1 The two operational layers of BEDC . . . 41068
9389.2 Naming certificates and generator-closure classifiers . . . 41069
9389.3 The strong form of BEDC's induction-style claim . . . 41071
9389.4 GAP plays two simultaneous roles . . . 41071
9389.5 Compression requires memory . . . 41072
9389.6 BEDC's structural description of CIC and the host-Lean delegation . . . 41072
9389.7 The accurate technical claim alongside the strong philosophical claim . . . 41073
9389.8 Standard axiom systems internalise; BEDC externalises . . . 41073
9389.9 The unified technical-and-philosophical claim . . . 41074
9389.10 Closure remarks . . . 41075

9390 The Cellular Automaton Reading: Pattern, Substrate, and the Cosmological Inscription 41077
9390.1 Setup: classification is the mark discipline . . . 41077
9390.2 Rule 110 as the minimal universal cellular substrate . . . 41078
9390.3 Even Rule 110 cannot internalise induction . . . 41079
9390.4 The cosmological reading: universe as cellular substrate . . . 41080
9390.5 The cook-frontier as quantified Goedel boundary . . . 41080
9390.6 Mapping the cellular reading to BEDC engineering . . . 41081
9390.7 Closure remarks . . . 41082

9391 The Cellular-Carrier Alternative: Could BEDC Be Built on the Substrate Directly? 41084
9391.1 Setup: two carriers, one closure premise . . . 41084
9391.2 The equivalence: bit-string encoding . . . 41085
9391.3 What the alternative would change . . . 41085
9391.4 Why the project keeps the BHist carrier . . . 41086
9391.5 What would justify a switch . . . 41086
9391.6 The position read structurally . . . 41086
9391.7 Mapping to BEDC engineering . . . 41087
9391.8 Closure remarks . . . 41087

9392 The twin substrate architecture: MetaCIC and GroundCompiler 41089
9392.1 The setup . . . 41089
9392.2 Why two substrates . . . 41089
9392.3 Audit map family per substrate . . . 41090
9392.3.1 MetaCIC audit family . . . 41090
9392.3.2 GroundCompiler audit map . . . 41090
9392.4 Audit reexport namespaces . . . 41090
9392.4.1 `BEDC.MetaCIC.Audit` . . . 41090
9392.4.2 `BEDC.GroundCompiler.Audit` . . . 41090
9392.5 The cross-substrate synthesis result . . . 41091
9392.6 Apophatic framing of the twin substrate . . . 41091
9392.7 Why not collapse into one substrate . . . 41091
9392.8 Boundary . . . 41092

9393 Closed Observation, the Transcendental Input, and the Inscription Point 41094
9393.1 Closed observational systems and information conservation . . . 41094
9393.2 The unbridgeable gap to universal quantification . . . 41095
9393.3 The minimum transcendental input . . . 41096
9393.4 Naming the source . . . 41096
9393.5 The individual as inscription point . . . 41097
9393.6 Mapping the philosophical content to BEDC's engineering . . . 41097
9393.7 Closure remarks . . . 41098

9394 Transcendental Supply Taxonomy 41100
9394.1 The need for taxonomy . . . 41100
9394.2 Type I: free-floating induction socket . . . 41101
9394.3 Type II: choice and unwitnessed existential . . . 41101

9394.4 Type III: extensional identification . . . 41102
9394.5 Type IV: causal continuity . . . 41102
9394.6 Type V: inter-history coordination . . . 41103
9394.7 Type VI: free-will and inscription novelty . . . 41103
9394.8 Type VII: self-reference closure . . . 41104
9394.9 Non-collapse laws for the seven types . . . 41105
9394.10 Engineering use protocol . . . 41106
9394.11 Unified long table . . . 41107
9394.12 The single T behind seven types . . . 41108

9395 External Supply Without Axioms 41110
9395.1 The boundary problem . . . 41110
9395.2 Axiom, setup field, and socket . . . 41111
9395.3 The admission decision . . . 41111
9395.4 GAP as the memory of boundary pressure . . . 41112
9395.5 Generator-local induction and the refusal of free-floating induction . . . 41113
9395.6 Choice, quotient, and proposition equality . . . 41113
9395.7 Observer growth and selector ledgers . . . 41114
9395.8 Multi-Hist physics without global axioms . . . 41114
9395.9 Audit gates as the enforcement layer . . . 41115
9395.10 The non-axiom theorem schema . . . 41115
9395.11 Forbidden phrasings and replacements . . . 41116
9395.12 Boundary of this chapter . . . 41116
9395.13 Closure . . . 41117

9396 Audit Gates as Transcendental Boundary Enforcement 41119
9396.1 Why audit gates are not bookkeeping . . . 41119
9396.2 `check-axioms.py`: refuse substrate-internal axioms . . . 41120
9396.3 `axiom-purity -strict`: refuse host axiom propagation . . . 41121
9396.4 `conservativity-audit`: gate compression residue . . . 41121
9396.5 `bedc_ci.py audit`: gate paper-Lean drift . . . 41122
9396.6 The gates as a system . . . 41123
9396.7 Comparison: in CIC, gates are absent . . . 41124
9396.8 Gate-to-boundary map . . . 41125
9396.9 Closure . . . 41126

9397 Inscription Event as a Concrete Instance: Free Will, Agency, and NameCert Audit 41128
9397.1 The setup . . . 41128
9397.2 Restating the inscription event . . . 41129
9397.3 A concrete case: a researcher writing a lemma . . . 41129
9397.4 The NameCert structure of the event . . . 41130
9397.5 GAP ledger for inscription . . . 41131
9397.6 Compatibilism as structure . . . 41131
9397.7 Where the account does not apply . . . 41132
9397.8 Implications for AI and mechanized reasoning . . . 41132
9397.9 Concrete-instance summary . . . 41133

9398 The Large Model as Inscription Point: A Structural Comparison 41135
9398.1 Setup: large model as closed observational system . . . 41135
9398.2 Tensor classifiers and certificate extraction . . . 41136
9398.3 Large model inherits the no-induction theorem . . . 41140
9398.4 Inscription role: where the forward-binding comes from . . . 41140
9398.5 Comparison: BEDC kernel, cellular substrate, large model . . . 41141
9398.6 What this changes about AI epistemics . . . 41141
9398.7 Why this comparison is structurally informative . . . 41142
9398.8 Mapping to BEDC engineering . . . 41142
9398.9 Closure remarks . . . 41143

9399 Empty as the Fable Machine: Observer-Sequence Growth and Selector Ledger 41145
9399.1 Empty as zero-information boundary . . . 41145
9399.2 One-step birth: from empty boundary to singleton continuation . . . 41146
9399.3 Observer sequence as finite selector ledger . . . 41147
9399.4 Multi-solution branch space and realized selector . . . 41147
9399.5 Empty as the fable machine . . . 41148
9399.6 No hidden chooser: selector witness vs. classical choice . . . 41148
9399.7 Synthesis: observer-Hist as fable ledger . . . 41149

9400 Apophatic Naming as Methodological Discipline 41151
9400.1 The setup: what is being named . . . 41151
9400.2 The apophatic discipline . . . 41152
9400.3 Comparison with positive naming . . . 41152
9400.4 Not undefined and not an axiom . . . 41153
9400.5 Inventory of BEDC apophatic names . . . 41153
9400.6 Audit gates as enforcement layer . . . 41154
9400.7 God and T are not metaphor . . . 41154
9400.8 Closed system invariant, apophatically restated . . . 41155
9400.9 Implications for proof discipline . . . 41155
9400.10 Boundary . . . 41155
9400.11 Conclusion . . . 41156

9401 The Unique Apophatic Fixed Point and Local Inscription 41157
9401.1 From many sockets to a single far end . . . 41157
9401.2 What $\top$ is not . . . 41158
9401.3 Self-center as local inscription . . . 41158
9401.4 Records side and inscription side as two readings of one event . . . 41159
9401.5 Free will under the two-aspect reading . . . 41159
9401.6 Other minds, time, space, and universe-for-observer as projections . . . 41160
9401.7 Forbidden writings . . . 41160
9401.8 The unique apophatic fixed point principle . . . 41161
9401.9 Closure . . . 41161

9402 Hash-like Apophatic Fixed Point: Digest, Fiber, GAP, and the Universe 41163
9402.1 Why the hash analogy clarifies T . . . 41163
9402.2 Hash as deliberate fiber generator . . . 41164
9402.3 From hash fiber to BEDC GAP . . . 41165

9402.4 The universe is not a global digest . . . 41165
9402.5 The hash-like apophatic fixed point . . . 41166
9402.6 Apophatic infinity as boundary role . . . 41166
9402.7 Illumination surface and fiber/beam reading . . . 41167
9402.8 Self-center on a digest surface . . . 41168
9402.9 Collision and other minds . . . 41168
9402.10 Information conservation under digest use . . . 41169
9402.11 Multi-Hist physics under the hash-like reading . . . 41170
9402.12 Relation to the unique apophatic fixed point chapter . . . 41170
9402.13 Mathematical understanding as fiber navigation . . . 41171
9402.14 Failure modes . . . 41171
9402.15 Cannot-claim registry . . . 41172
9402.16 Implementation-facing packet . . . 41173
9402.17 Non-axiom theorem schema . . . 41173
9402.18 Closure . . . 41174

9403 Diagrammatics of the Apophatic Far End . . . 41176
9403.1 Closed substrate and socket far ends . . . 41176
9403.2 Local digest, fiber, and provenance . . . 41177
9403.3 Local inscription and self-center . . . 41178
9403.4 Many observers and shared far-end commitment . . . 41179
9403.5 Time, space, and universe-for-observer . . . 41179
9403.6 The infinity diagram . . . 41179
9403.7 Forbidden collapses . . . 41180
9403.8 Closure . . . 41180

9404 Cataphatic Process Names and Apophatic Far Ends . . . 41182
9404.1 Value axes and generation axes . . . 41182
9404.2 Located irrationality . . . 41183
9404.3 The apophatic far-end role . . . 41183
9404.4 Level separation . . . 41184
9404.5 Compactification points . . . 41185
9404.6 Axiom-purity boundary . . . 41185
9404.7 Closure . . . 41186

9405 Information Strata and Non-Collapse . . . 41187
9405.1 Value, process, and far-end strata . . . 41187
9405.2 Algebraic and transcendental directions . . . 41188
9405.3 Allowed folding and forbidden flattening . . . 41189

9406 The audit-map family: a BEDC methodology . . . 41192
9406.1 The setup . . . 41192
9406.2 What an audit map is . . . 41193
9406.3 The nine audit map chapters of BEDC.MetaCIC . . . 41193
9406.4 Common structure across audit maps . . . 41194
9406.5 Methodology versus other disciplines . . . 41195
9406.6 When to use this methodology . . . 41195
9406.7 Audit-map family as apophatic naming in action . . . 41195

9406.8 Boundary . . . 41195

9407 BEDC GroundCompiler module audit map 41197
9407.1 The setup . . . 41197
9407.2 Submodule inventory . . . 41197
9407.3 Core statement defs . . . 41198
9407.4 Established theorems . . . 41199
9407.5 Channel boundary discipline . . . 41200
9407.6 Relation to MetaCIC . . . 41201
9407.7 Open obligations and conditional statements . . . 41202
9407.8 Apophatic framing . . . 41202
9407.9 Boundary . . . 41202

9408 Theorem-DNA and Theorem Complexity Scoring 41204
9408.1 Role-complete theorem flows . . . 41204
9408.2 Statement, code, and quotient boundaries . . . 41205
9408.3 Mass vectors and weighted score . . . 41206
9408.4 Mutation and classifier-level information . . . 41207

9409 Theorem-Genome Evolution: Mutation, Recombination, Selection, and Discovery 41209
9409.1 Theorem genomes . . . 41209
9409.2 Complexity space . . . 41210
9409.3 Mutation and discovery . . . 41210
9409.4 Recombination and lineage . . . 41211
9409.5 Selection and potential . . . 41212
9409.6 Gate hierarchy . . . 41212

9410 Automated Theory-Discovery Pipeline Calculus 41214
9410.1 Pipeline states . . . 41214
9410.2 Transition classes . . . 41215
9410.3 Discovery claims . . . 41216
9410.4 Gate theorems . . . 41216
9410.5 Lineage and selection . . . 41218
9410.6 Pipeline adequacy . . . 41218

9411 Compiler-Closure Self-Compilation 41220
9411.1 From theorem DNA to compiler closure . . . 41220
9411.2 Compiler phenotype . . . 41221
9411.3 Certified expression . . . 41221
9411.4 Ledgered feedback . . . 41222
9411.5 Certified self-compilation loop . . . 41223
9411.6 Self-hosting is not self-compilation . . . 41223
9411.7 Discovery self-compilation . . . 41223
9411.8 Compiler-closure gate contract . . . 41224
9411.9 Pipeline adoption boundary . . . 41225

9412 Pseudotheory Refutation Gate Map 41227
9412.0 Coverage table . . . 41228
9412.1 Stateful and stateless refusal . . . 41229
9412.2 Prime asymmetry . . . 41229
9412.3 Carrier-repair boundary . . . 41229

9413 Common Carriers and Reality Projections 41230
9413.0 Reality Interfaces . . . 41230
9413.1 Common Carriers . . . 41231
9413.2 Ledgered Transport . . . 41231
9413.3 Generalized Continuation . . . 41232
9413.4 Noncollapse and Information Dimension . . . 41233
9413.5 Pythagorean Carrier, Scale Fibers, and Unit-Circle Projection . . . 41235
9413.6 Algebraic Extension Directions and Information Dimension . . . 41240
9413.7 Transcendental Extensions, Process Layers, and Apophatic Far Ends . . . 41244
9413.8 Spectral Curves as Common Carriers . . . 41248
9413.9 Recursive Spectral Zero Hierarchy . . . 41254
9413.10 Irreducible Information Layers and Spectral Factors . . . 41257
9413.11 No Far-End Absorption Boundary . . . 41261
9413.12 Finite Prime Tower as Completed Readout . . . 41263
9413.13 Far-End Unity and Prime-Window Normalization . . . 41267
9413.14 Far-End Correction Obligation . . . 41270
9413.15 From Spectral-Curve Laboratory to the RH Rigidity Route . . . 41274
9413.16 Phase, Transform, and Zeta Ladders . . . 41278
9413.17 Generalized Continuation Chain . . . 41281
9413.18 Inherited Invariants of the Zeta Endpoint . . . 41284
9413.19 Ontic Triple Invariants and the Zeta Projection . . . 41290
9413.20 Prime Phase-Radial Readback . . . 41295
9413.21 Observation-Classified Symmetry on the Critical Surface . . . 41301
9413.22 Ontic Core and Minimal Closure . . . 41305
9413.23 Object Induction and the RH Reality Route . . . 41308
9413.24 Triadic Structural Induction . . . 41312
9413.25 Circle–Triangle–Register Grammar . . . 41313
9413.26 Constructor Risk Surfaces . . . 41315
9413.27 Zeta Constructor Preservation Boundary . . . 41316
9413.28 Universal Generation Closure . . . 41317
9413.29 Zero Recursor and Cover Boundary . . . 41319
9413.30 Zero-Fibre Normal Sheet Geometry . . . 41321
9413.31 Time-Fibre Mirror Atomicity . . . 41323
9413.32 Zero Signature Faithfulness and the Mirror Slot Principle . . . 41326
9413.33 Core Commonality and Completion Boundaries . . . 41332
9413.34 Prime-Sieve Odd Exactness . . . 41336
9413.35 Recursive Parity Tower . . . 41341
9413.36 Parity Closure Tower Certificate . . . 41344
9413.37 Prime Charge, Parity, and Phase Dictionary . . . 41347
9413.38 Triadic Closure Tower Program . . . 41350
9413.39 Oriented Triadic Closure Tower Construction . . . 41353

9413.40 Harmonic Triadic Closure Map . . . 41355
9413.41 Zero-Knowledge Triadic Certificate Layer . . . 41358
9413.42 Analytic Projection and Closed Generability Boundary . . . 41361
9413.43 Oriented Triadic Certificate System . . . 41364
9413.44 Triadic Route Taxonomy . . . 41368
9413.45 BEDC RHRoute Formal Bridge . . . 41371
9413.46 Generation Invariant Exclusion Route . . . 41373
9413.47 Triadic Ontic Invariant Readback . . . 41375
9413.48 Zero Packet Refinement Category . . . 41380
9413.49 Prime-Adic Local Slicing . . . 41383
9413.50 Prime-Adic Parity Energy Window . . . 41385
9413.51 Prime-Adic Parity Sphere Invariant . . . 41388
9413.52 Zeta-Like Projection Taxonomy . . . 41390
9413.53 Global Prime Energy and the No-Hair Boundary . . . 41392
9413.54 Far-End Energy Unity Socket . . . 41395
9413.55 Finite-to-Infinite Phase-Energy Tower . . . 41397
9413.56 Infinite Prime Torus and Far-End Compatibility . . . 41400
9413.57 Far-End Identity Boundary . . . 41403
9413.58 Prime Spiral Projection Kernel . . . 41405
9413.59 Prime Resonance Chord and No-Hair Boundary . . . 41407
9413.60 Local Half-Split Certificate . . . 41412
9413.61 Endpoint Bisection Certificate . . . 41414
9413.62 Zeta Resonance Bound Stability . . . 41418
9413.63 Solenoid Lee–Yang Resonance Boundary . . . 41421
9413.64 Zeta Solenoid Lee–Yang Bound . . . 41424
9413.65 Solenoid Lee–Yang Source Gap . . . 41427
9413.66 Fixed-Prime Split Resonance Tower . . . 41429
9413.67 Dedekind Split-Tower Lift . . . 41435
9413.68 Deckendorf Solenoid Selector . . . 41438
9413.69 Conditional RH Sufficiency Boundary . . . 41441
9413.70 BEDC–Langlands Closure Packet . . . 41444
9413.71 BEDC–Langlands Existence Bridge . . . 41448
9413.72 BEDC–Langlands Unramified Local Layer . . . 41452
9413.73 BEDC–Langlands Finite Hecke Projector Certificate . . . 41456
9413.74 BEDC–Langlands Parameter State Certificate . . . 41460
9413.75 BEDC–Langlands Ramified Local State Closure . . . 41463
9413.76 BEDC–Langlands Local Packet Certificate for GL_n . . . 41468
9413.77 BEDC–Langlands Global Converse Bridge for GL_n . . . 41473

9426 Innovation Input Self-Substitution Correlation Boundary 41741
9426.1 Layered Phase Correlations . . . 41741
9426.2 Carry Recursion . . . 41742
9426.3 Weak Reversibility Criterion . . . 41743
9426.4 Boundary Examples . . . 41744

9427 Innovation Input Finite-Block Reversibility Boundary 41746
9427.1 Signed Blocks . . . 41746
9427.2 Weak Reversibility Layers . . . 41747
9427.3 Finite-Block Carry Recursion . . . 41747
9427.4 Ternary Four-Point Test . . . 41748
9427.5 Layer Separation . . . 41751

9428 Innovation Input Finite-Window Reflection-Positive Boundary 41752
9428.1 Finite-Window Reflection . . . 41752
9428.2 Charged One-Site Obstruction . . . 41754
9428.3 Ternary Neutral RP Failure . . . 41754
9428.4 Quartic Neutral RP Failure . . . 41756
9428.5 Strict Layering . . . 41757

9429 Innovation Input Minimal RP Deficit Search Boundary 41758
9429.1 Q3 Search Space . . . 41758
9429.2 Neutral Window Deficits . . . 41759
9429.3 Link Deficit Gate . . . 41760
9429.4 Known Link Obstructions . . . 41761
9429.5 Exact Correlation Evaluation . . . 41762
9429.6 Search Objects . . . 41763

9430 Innovation Input Anchored RP Golden Palindrome Boundary 41764
9430.1 Anchored Window Discipline . . . 41764
9430.2 Pentary Palindromes . . . 41765
9430.3 Golden Palindrome Branches . . . 41765
9430.4 Anchored Neutral Window Audit . . . 41766

9431 Innovation Input Pentary Anchored Window Boundary 41769
9431.1 Anchored Pentary Window . . . 41769
9431.2 Pythagorean Pentary Row . . . 41771
9431.3 Anchored $L = 2$ Passage . . . 41771
9431.4 Anchored $L = 3$ Failure . . . 41772
9431.5 Anchor Dependence . . . 41773

9432 Innovation Input Pentary Hermitian Link Boundary 41775
9432.1 Pentary Edge Ratios . . . 41775
9432.2 Anchored $L = 3$ Link Diagonals . . . 41776
9432.3 Endpoint Gate . . . 41777
9432.4 Pythagorean Link Recheck . . . 41780

9433 Innovation Input Pentary Odd Endpoint Exclusion 41781
9433.1 Odd Endpoint Coordinates . . . 41781
9433.2 Real First-Correlation Bound . . . 41782
9433.3 Odd Endpoint Exclusion . . . 41784

9434 Innovation Input Nine-ary Real-Sign RP Screen 41786
9434.1 Nine-ary Real-Sign Rows . . . 41786
9434.2 Real Neutral Window . . . 41787
9434.3 Exact Carry Evaluator . . . 41787
9434.4 Two-Window Passage . . . 41788
9434.5 Three-Window Exclusion . . . 41789

9435 Innovation Input Nine-ary Complex Phase Link Formulas 41790
9435.1 Nine-ary Phase Locus . . . 41790
9435.2 Ordinary Link Correlations . . . 41791
9435.3 Anchored Link Diagonals . . . 41791
9435.4 Principal Reflection-Positive Conditions . . . 41793
9435.5 Pentary Contrast . . . 41793

9436 Innovation Input Square Real-Sign Four-Window Bottleneck 41795
9436.1 Twenty-five-ary Real-Sign Locus . . . 41795
9436.2 Four-Window Screen . . . 41796
9436.3 Concrete Witnesses . . . 41797
9436.4 Square-Family Pattern . . . 41798

9437 Innovation Input RP Solenoid Limit Conjecture 41799
9437.1 Finite-Window Horizon . . . 41799
9437.2 Finite Alphabet Finiteness . . . 41803
9437.3 Prime-Register Approximation . . . 41804
9437.4 Limit Matrix Problem . . . 41805

9438 Innovation Input Pentary Golden Hermitian Obstruction 41806
9438.1 Golden Symmetric Word . . . 41806
9438.2 Hermitian Obstruction . . . 41807

9439 Innovation Input Pentary Palindromic Hermitian Reduction 41810
9439.1 Reflection Evenness . . . 41810
9439.2 Palindromic Reflection . . . 41811
9439.3 Pentary Palindromic Q3 Curve . . . 41812
9439.4 Palindromic Link Formulas . . . 41813
9439.5 Known Rows Inside the Reduction . . . 41814

9440 Innovation Input Pentary Palindromic RP Exclusion 41816
9440.1 Literature Positioning . . . 41816
9440.2 Anchored $L = 2$ Matrix . . . 41816
9440.3 Half-Angle Curve . . . 41817
9440.4 Determinant Factorization . . . 41818
9440.5 Anchored $L = 2$ Rigidity . . . 41818
9440.6 Anchored $L = 3$ Exclusion . . . 41819

9441 Innovation Input Self-Similar RP Scaling 41821
9441.1 Self-Substitution Rule . . . 41821
9441.2 Scale Dilation . . . 41821
9441.3 Reflection-Centered Dilation . . . 41823
9441.4 RP Window Scaling . . . 41823
9441.5 Primitive RP Shapes . . . 41824

9442 Innovation Input Primitive RP Roots 41826
9442.1 Scale Root . . . 41826
9442.2 Window Roots . . . 41827
9442.3 Pentary Scale Test . . . 41827
9442.4 Small Pentary Windows . . . 41828
9442.5 Pentary Link Roots . . . 41829
9442.6 Odd-Length Address Formula . . . 41830

9443 Innovation Input Self-Adjoint Hamiltonian Gate 41831
9443.1 Three Operator Rows . . . 41831
9443.2 RP as the Input Source of Self-Adjointness . . . 41832
9443.3 Zeta Upgrade Obligation . . . 41833
9443.4 Pentary Hermitian Locus . . . 41833

9444 Innovation Input Pentary Mirror Decomposition Gate 41835
9444.1 Mirror Coordinates . . . 41835
9444.2 Mirror Transport of Correlations . . . 41837
9444.3 Mirror-Odd Hermitian Defects . . . 41838
9444.4 Palindromic Ideal . . . 41838
9444.5 Rank Form of the Remaining Problem . . . 41839

9445 Innovation Input Pythagorean Local Hermitian Rigidity 41841
9445.1 Antisymmetric Tangent Directions . . . 41841
9445.2 Defect Linearization . . . 41842
9445.3 Local Rigidity . . . 41843

9446 Innovation Input Pentary Hermitian Rigidity Gate 41844
9446.1 Hermitian Defect Row . . . 41844
9446.2 Cross-Entry Equations . . . 41845
9446.3 Finite Algebraic Evaluator . . . 41846
9446.4 Factor Extraction Gate . . . 41846
9446.5 Audit Pattern . . . 41847

9447 Innovation Input Dynamics and Spectral Boundary 41848
9447.1 Spatialized Input and Diffusion Read . . . 41848
9447.2 Relativistic Dispersion . . . 41849
9447.3 Stable Inputs and Spectral Dimension . . . 41850
9447.4 Dynamic Output Table . . . 41851

9448. Innovation Input Thermodynamic Geometry Boundary 41852
9448.1 Coherent Family and Meeting Law . . . 41852
9448.2 Heat Kernel Identity and Curvature Read . . . 41854
9448.3 Local Heat-Geometry Identity . . . 41855
9448.4 Entanglement Entropy Row . . . 41855
9448.5 Modular Hamiltonian and Unruh Row . . . 41856
9448.6 Jacobson Dictionary . . . 41857
9448.7 Scope and Correspondence Ledger . . . 41858

9449. Innovation Input Thermodynamic Geometry Verification 41859

Part I

Finite Kernel Theory

Chapter 1

Orientation and Layer Discipline

1.1 Purpose of This Core

The purpose of this core is not to extend the theory toward more traditional mathematical objects. Its purpose is to make the finite kernel more checkable. The kernel is centered on the following generated chain:

$$\mathsf{b0}, \mathsf{b1} \to \mathsf{Hist} \to \mathsf{msame}, \mathsf{hsame} \to \mathsf{Ext}, \mathsf{Cont} \to \mathsf{Ask} \to \mathsf{Bundle} \to \mathsf{Sig} \to \mathsf{sameSig} \to \mathsf{Pkg} \to \mathsf{InGap} \to \mathsf{NameCert}.$$

The target is a minimal rule system in which derived interfaces are licensed by certificates rather than assumed.

Principle 1.1 (Layer isolation)**.** *The words used in this text to explain the kernel, such as relation, family, model, property, coverage, proof, and class, belong to the explanatory metalanguage. They are not object-language primitives. The object-language content consists only of the displayed generated judgments and certificates.*

Lean4 ✓ `BEDC.FKernel.Settled.layer isolation policy memory projection`

Principle 1.2 (No inherited mathematical primitives)**.** *No traditional mathematical interface is an internal primitive of the calculus. In particular, equality, function, natural number, addition, limit, real number, circle, and fold are derived interfaces only.*

Principle 1.3 (Definition demotion)**.** *A definition is not an initial source of objects. A definition is a naming certificate for a behavior that has already been generated and stabilized by the kernel.*

Principle 1.4 (Compression requires memory)**.** *Every operation that identifies, packages, hides, projects, seals, or otherwise compresses generated material must carry a gap ledger.*

Lean4 ✓ `BEDC.FKernel.Gap.compression requires memory`

1.2 Boundary of This Core

This document contains the finite kernel specification. The seal and completion interface is retained only as a thin placeholder. Interfaces such as $\mathsf{Real}^{\uparrow}$, $\mathsf{Circle}^{\uparrow}$, and $\mathsf{Fold}^{\uparrow}$ are mentioned only as derived names and motivation, not as fully reconstructed theories.

Chapter 2

Raw Marks and Mark-Sameness

Definition 2.1 (Raw marks)**.** *The only raw mark forms are*

$$\mathsf{b0}, \qquad \mathsf{b1}.$$

They are not the numbers 0 *and* 1*, not truth values, and not elements of a pre-existing set.*

Lean4 (definition) `BEDC.FKernel.Mark.BMark`
Lean4 ✓ `BEDC.FKernel.Mark.BMark generated cases`

Kernel Rule 2.2 (Mark formation)**.** *The judgment* $m : \mathsf{Mark}$ *is generated by exactly two formation rules:*

$$\frac{}{\mathsf{b0} : \mathsf{Mark}} \qquad \frac{}{\mathsf{b1} : \mathsf{Mark}}.$$

Definition 2.3 (Internal mark-sameness)**.** *The judgment* $\mathsf{msame}(m, n)$ *is generated by exactly two rules:*

$$\frac{}{\mathsf{msame}(\mathsf{b0}, \mathsf{b0})} \qquad \frac{}{\mathsf{msame}(\mathsf{b1}, \mathsf{b1})}.$$

No rule generates $\mathsf{msame}(\mathsf{b0}, \mathsf{b1})$ *or* $\mathsf{msame}(\mathsf{b1}, \mathsf{b0})$*.*

Lean4 (definition) `BEDC.FKernel.Mark.msame`
Lean4 ✓ `BEDC.FKernel.Mark.msame constructor characterization`
↪ variant `BEDC.FKernel.Mark.msame iff eq`
↪ variant `BEDC.FKernel.Mark.msame generated rules`
↪ variant `BEDC.FKernel.Mark.msame cases`

Closure Principle 2.4 (Closed generation for marks)**.** *The only generated marks are those generated by the two mark-formation rules. The only generated mark-sameness derivations are those generated by the two mark-sameness rules.*

Lemma 2.5 (Mark-sameness reflexivity)**.** *For every generated mark* m*,* $\mathsf{msame}(m, m)$*.*

Lean4 ✓ `BEDC.FKernel.Mark.msame refl`

Proof. By closed generation, m is either $\mathsf{b0}$ or $\mathsf{b1}$. Use the corresponding mark-sameness rule. □

Lemma 2.6 (Mark-sameness symmetry)**.** *If* $\mathsf{msame}(m, n)$*, then* $\mathsf{msame}(n, m)$*.*

Lean4 ✓ `BEDC.FKernel.Mark.msame symm`

Proof. The premise is generated only in the two reflexive cases. In either case, the conclusion is generated by the same rule. □

Lemma 2.7 (Mark-sameness transitivity)**.** *If* $\mathsf{msame}(m, n)$ *and* $\mathsf{msame}(n, p)$*, then* $\mathsf{msame}(m, p)$*.*

Lean4 ✓ `BEDC.FKernel.Mark.msame trans`

Proof. Closed generation leaves only two cases. If the middle mark is b0, then all generated mark-sameness premises force m and p to be b0. The b1 case is identical. □

Theorem 2.8 (Mark-sameness equivalence)**.** *The internal judgment* msame *is reflexive, symmetric, and transitive on generated raw marks.*

Lean4 ✓ `BEDC.FKernel.Mark.msame equivalence`
↪ variant `BEDC.FKernel.Mark.mark sameness equivalence`
↪ variant `BEDC.FKernel.Mark.msame internal equivalence spine`

Proof. Immediate from the preceding three lemmas. □

Theorem 2.9 (Raw mark no-confusion)**.** *The kernel does not generate* $\mathsf{msame}(\mathsf{b0}, \mathsf{b1})$ *or* $\mathsf{msame}(\mathsf{b1}, \mathsf{b0})$*.*

Lean4 ✓ `BEDC.FKernel.Mark.msame no confusion`
↪ variant `BEDC.FKernel.Mark.mark no confusion`
↪ variant `BEDC.FKernel.Mark.msame cross iff false`
↪ variant `BEDC.FKernel.Mark.msame cross impossible`

Proof. By the closed-generation principle, mark-sameness has only the two displayed constructors. Neither has cross-mark conclusion. □

Chapter 3

Emission Histories and History-Sameness

Definition 3.1 (Emission histories)**.** *Emission histories are generated by:*

$$\frac{}{\mathsf{e} : \mathsf{Hist}}$$

$$\frac{h : \mathsf{Hist}}{\mathsf{E0}(h) : \mathsf{Hist}} \qquad \frac{h : \mathsf{Hist}}{\mathsf{E1}(h) : \mathsf{Hist}}.$$

The symbols e*,* E0*, and* E1 *are object-language history constructors, not imported list constructors.*

Lean4 (definition) `BEDC.FKernel.Hist.BHist`

Definition 3.2 (History-sameness)**.** *The judgment* $\mathsf{hsame}(h, k)$ *is generated by:*

$$\frac{}{\mathsf{hsame}(\mathsf{e}, \mathsf{e})}$$

$$\frac{\mathsf{hsame}(h, k)}{\mathsf{hsame}(\mathsf{E0}(h), \mathsf{E0}(k))} \qquad \frac{\mathsf{hsame}(h, k)}{\mathsf{hsame}(\mathsf{E1}(h), \mathsf{E1}(k))}.$$

There is no rule relating e *to a nonempty history, nor any rule relating* E0*-histories to* E1*-histories.*

Lean4 (definition) `BEDC.FKernel.Hist.hsame`

Lean4 ✓ `BEDC.FKernel.Hist.hsame iff eq`

↪ variant `BEDC.FKernel.Hist.hsame e0 congr`

↪ variant `BEDC.FKernel.Hist.hsame empty left iff`

Closure Principle 3.3 (Closed generation for histories)**.** *History formation and history-sameness are generated only by their displayed rules. Inversion and no-confusion principles are justified by this closed generation.*

Theorem 3.4 (History constructor characterization)**.** *If two generated histories are internally same, then they are both empty, both* E0*-histories with internally same predecessors, or both* E1*-histories with internally same predecessors. Conversely, any of those three constructor-aligned cases gives internal history-sameness.*

Lean4 ✓ `BEDC.FKernel.Hist.hsame constructor characterization`

↪ variant `BEDC.FKernel.Hist.history constructor characterization`

↪ variant `BEDC.FKernel.Hist.hsame e0 left iff`

↪ variant `BEDC.FKernel.Hist.hsame e1 inversion iff`

Proof. For the forward implication, invert the internal sameness derivation and inspect the common outer constructor. For the reverse implication, eliminate the displayed alternatives and their witnesses, then rebuild the corresponding internal sameness judgment. □

Lemma 3.5 (History-sameness reflexivity)**.** *For every generated history h,* $\mathsf{hsame}(h, h)$.

Lean4 ✓ `BEDC.FKernel.Hist.hsame refl`

Proof. Induct on the generation of h. The empty case uses the empty rule. The two extension cases use the induction hypothesis and the corresponding constructor rule for hsame. □

Lemma 3.6 (History-sameness symmetry)**.** *If* $\mathsf{hsame}(h, k)$*, then* $\mathsf{hsame}(k, h)$.

Lean4 ✓ `BEDC.FKernel.Hist.hsame symm`

Proof. Induct on the derivation of $\mathsf{hsame}(h, k)$. Each constructor is symmetric by applying the induction hypothesis under the same history constructor. □

Lemma 3.7 (History-sameness transitivity)**.** *If* $\mathsf{hsame}(h, k)$ *and* $\mathsf{hsame}(k, l)$*, then* $\mathsf{hsame}(h, l)$.

Lean4 ✓ `BEDC.FKernel.Hist.hsame trans`

Proof. Induct on the first derivation. The empty case forces the second derivation to be the empty case by no-confusion. The $\mathsf{E0}$ case forces the second derivation to also be an $\mathsf{E0}$ case; apply the induction hypothesis to the inner histories and rebuild. The $\mathsf{E1}$ case is analogous. □

Theorem 3.8 (History-sameness equivalence)**.** *The internal judgment* hsame *is reflexive, symmetric, and transitive on generated histories.*

Lean4 ✓ `BEDC.FKernel.Hist.hsame equivalence`
↪ variant `BEDC.FKernel.Hist.history sameness equivalence`

Proof. Combine the preceding lemmas. □

Theorem 3.9 (History no-confusion)**.** *The kernel does not generate any of the following cross-constructor identifications:*

$$\mathsf{hsame}(\mathsf{e}, \mathsf{E0}(h)), \quad \mathsf{hsame}(\mathsf{E0}(h), \mathsf{e}), \quad \mathsf{hsame}(\mathsf{e}, \mathsf{E1}(h)),$$

$$\mathsf{hsame}(\mathsf{E1}(h), \mathsf{e}), \quad \mathsf{hsame}(\mathsf{E0}(h), \mathsf{E1}(k)), \quad \mathsf{hsame}(\mathsf{E1}(h), \mathsf{E0}(k)).$$

Lean4 ✓ `BEDC.FKernel.Hist.hsame no confusion complete`

Proof. By closed generation, the only conclusions of hsame have matching outer constructors. The displayed cross-constructor conclusions are not produced by any rule. □

Theorem 3.10 (History extension is not self-same)**.** *No generated history is internally the same as its immediate* $\mathsf{E0}$*- or* $\mathsf{E1}$*-extension:*

$$\forall h : \mathsf{Hist},\ \neg\mathsf{hsame}(\mathsf{E0}(h), h) \qquad \textit{and} \qquad \forall h : \mathsf{Hist},\ \neg\mathsf{hsame}(\mathsf{E1}(h), h).$$

Proof. Induct on the target history. Empty and cross-constructor cases are excluded by history no-confusion. Matching extension cases reduce by the corresponding constructor inversion to the induction hypothesis on the shorter history. □

Lean4 ✓ `BEDC.FKernel.Hist.hsame extension self absurd`

Chapter 4

Relational Extension and Continuation

4.1 Relational extension

Definition 4.1 (Extension relation)**.** *The extension relation* $\mathsf{Ext}(m, h, r)$ *is generated by the two rules:*

$$\frac{}{\mathsf{Ext}(\mathsf{b0}, h, \mathsf{E0}(h))} \qquad \frac{}{\mathsf{Ext}(\mathsf{b1}, h, \mathsf{E1}(h))}.$$

It is a relation, not a function.

```
Lean4 ✓  BEDC.FKernel.Ext.ext generation rules
  ↪ variant  BEDC.FKernel.Ext.ext total
  ↪ variant  BEDC.FKernel.Ext.ext constructor inversion
  ↪ variant  BEDC.FKernel.Ext.ext constructor characterization
  ↪ variant  BEDC.FKernel.Ext.ext result for mark
  ↪ variant  BEDC.FKernel.Ext.ext b0 result hsame
  ↪ variant  BEDC.FKernel.Ext.ext b1 result hsame
  ↪ variant  BEDC.FKernel.Ext.ext mark deterministic from result
  ↪ variant  BEDC.FKernel.Ext.ext source deterministic from result
  ↪ variant  BEDC.FKernel.Ext.ext cross mark result impossible
```

Theorem 4.2 (Extension result constructor characterization)**.** *For all histories* h, t *and mark* m*,*

$$\mathsf{Ext}(m, h, \mathsf{E0}(t)) \iff (m = \mathsf{b0} \text{ and } \mathsf{hsame}(h, t)).$$

For the one-constructor case,

$$\mathsf{Ext}(m, h, \mathsf{E1}(t)) \iff (m = \mathsf{b1} \text{ and } \mathsf{hsame}(h, t)).$$

```
Lean4 ✓  BEDC.FKernel.Ext.ext result constructor iff
```

Proof. Invert the generated extension witness. In the zero-result branch, closed generation forces the emitted mark to be $\mathsf{b0}$ and the source to be the tail up to history sameness; the converse reconstructs the zero extension after eliminating those equalities. The one-result branch is identical with the $\mathsf{E1}$ constructor. □

Lemma 4.3 (Cross-mark extension results are separated)**.** *If* $\mathsf{Ext}(\mathsf{b0}, h, r_0)$*,* $\mathsf{Ext}(\mathsf{b1}, h, r_1)$*, and* $\mathsf{hsame}(r_0, r_1)$*, then contradiction follows.*

Lean4 ✓ `BEDC.FKernel.Ext.ext same source cross mark results not hsame`

Proof. Invert the two extension witnesses. The result histories are $\mathsf{E0}(h)$ and $\mathsf{E1}(h)$, and history no-confusion excludes $\mathsf{hsame}(\mathsf{E0}(h), \mathsf{E1}(h))$. □

Theorem 4.4 (Extension result is not the source)**.** *If* $\mathsf{Ext}(m, h, r)$*, then* $\mathsf{hsame}(r, h)$ *is impossible.*

Lean4 ✓ `BEDC.FKernel.Ext.ext result source not hsame`

Proof. Invert the generated extension witness. The result is either $\mathsf{E0}(h)$ or $\mathsf{E1}(h)$, and both cases are excluded by history constructor no-confusion for a one-constructor self-extension. □

Theorem 4.5 (Extension two-step cycle is impossible)**.** *If* $\mathsf{Ext}(m, h, r)$ *and* $\mathsf{Ext}(n, r, h)$*, then contradiction follows.*

Lean4 ✓ `BEDC.FKernel.Ext.ext two step cycle absurd`

Proof. Use the finite constructor length of histories. Each extension increases this length by one. Two extensions returning from h to h would force the length of h to equal its own double successor, which is impossible by natural-number constructor no-confusion. □

Theorem 4.6 (Extension result injectivity)**.** *If* $\mathsf{Ext}(m, h, r)$ *and* $\mathsf{Ext}(m', h', r)$*, then* $\mathsf{hsame}(h, h')$ *and* $\mathsf{msame}(m, m')$*.*

Lean4 ✓ `BEDC.FKernel.Ext.ext result injective pair`

Proof. Inspect the two generated extension witnesses. A common result can only arise from matching extension constructors, so the source histories and emitted marks are internally same. □

Theorem 4.7 (Extension result hsame injectivity)**.** *If* $\mathsf{Ext}(m, h, r)$*,* $\mathsf{Ext}(m', h', r')$*, and* $\mathsf{hsame}(r, r')$*, then* $\mathsf{hsame}(h, h')$ *and* $\mathsf{msame}(m, m')$*.*

Lean4 ✓ `BEDC.FKernel.Ext.ext result hsame injective pair`

Proof. Invert both generated extension witnesses. Matching outer constructors reduce the result-sameness witness to source history sameness and diagonal mark-sameness. Mixed outer constructors contradict history no-confusion. □

Lemma 4.8 (Extension respects mark-sameness)**.** *If* $\mathsf{msame}(m, n)$*,* $\mathsf{Ext}(m, h, r)$*, and* $\mathsf{Ext}(n, h, s)$*, then* $\mathsf{hsame}(r, s)$*.*

Lean4 ✓ `BEDC.FKernel.Ext.ext respects mark sameness`

Proof. By closed generation for msame, either both marks are $\mathsf{b0}$ or both are $\mathsf{b1}$. In the first case both extension results are $\mathsf{E0}(h)$; in the second case both are $\mathsf{E1}(h)$. Use reflexivity of hsame. □

Theorem 4.9 (Extension determinacy up to history-sameness)**.** *If* $\mathsf{Ext}(m, h, r)$ *and* $\mathsf{Ext}(m, h, s)$*, then* $\mathsf{hsame}(r, s)$*.*

Lean4 ✓ `BEDC.FKernel.Ext.ext deterministic`

Proof. Apply the previous lemma with $\mathsf{msame}(m, m)$, using mark-sameness reflexivity. □

4.2 Relational continuation

Definition 4.10 (Continuation relation)**.** *The continuation relation* $\mathsf{Cont}(h, k, r)$ *is generated by:*

$$\frac{}{\mathsf{Cont}(h, \mathsf{e}, h)}$$

$$\frac{\mathsf{Cont}(h, k, r)}{\mathsf{Cont}(h, \mathsf{E0}(k), \mathsf{E0}(r))} \qquad \frac{\mathsf{Cont}(h, k, r)}{\mathsf{Cont}(h, \mathsf{E1}(k), \mathsf{E1}(r))}.$$

It is a relation, not a primitive function.

Lean4 (definition) `BEDC.FKernel.Cont.Cont`

↪ variant `BEDC.FKernel.Cont.cont respects hsame`

Theorem 4.11 (Append nonempty factor equivalence)**.** *For histories* h *and* k*, the appended history is not internally empty exactly when at least one factor is not internally empty:*

$$\neg\mathsf{hsame}(\mathsf{append}(h, k), \mathsf{e}) \iff \neg\mathsf{hsame}(h, \mathsf{e}) \vee \neg\mathsf{hsame}(k, \mathsf{e}).$$

Proof. The forward direction splits on the left factor: the empty branch reduces the obstruction to the right factor, while visible left constructors are separated from e. Conversely, empty-result inversion contradicts either nonempty disjunct. □

Lean4 ✓ `BEDC.FKernel.Cont.append nonempty iff`

Theorem 4.12 (Append visible-left empty exclusion)**.** *For histories* $h, k : \mathsf{BHist}$*, appending any right tail to a visible left endpoint cannot produce an internally empty history: both* $\mathsf{hsame}(\mathsf{append}(\mathsf{E0}(h), k), \mathsf{e}) \to \bot$ *and* $\mathsf{hsame}(\mathsf{append}(\mathsf{E1}(h), k), \mathsf{e}) \to \bot$ *hold.*

Proof. Split on the right tail k. If it is empty, the visible left endpoint remains the outer constructor. If it is visible, append exposes that right-tail constructor as the outer constructor. In every branch, constructor separation from e rules out the displayed history sameness. □

Lean4 ✓ `BEDC.FKernel.Cont.append visible left empty absurd`

Theorem 4.13 (Append visible-right empty exclusion)**.** *For histories* $h, k : \mathsf{BHist}$*, appending a visible right tail cannot produce an internally empty history: both* $\mathsf{hsame}(\mathsf{append}(h, \mathsf{E0}(k)), \mathsf{e}) \to \bot$ *and* $\mathsf{hsame}(\mathsf{append}(h, \mathsf{E1}(k)), \mathsf{e}) \to \bot$ *hold.*

Proof. Appending a visible right tail exposes that visible constructor at the result. Thus the result has outer constructor E0 or E1, respectively.

In both cases, history no-confusion with e rules out the displayed history sameness. □

Lean4 ✓ `BEDC.FKernel.Cont.append visible right empty absurd`

Theorem 4.14 (Append visible-left same-tail tag separation)**.** *For histories* $h_0, h_1, k : \mathsf{BHist}$*, common right-tail append preserves separation between zero-headed and one-headed visible left endpoints:*

$$\mathsf{hsame}(\mathsf{append}(\mathsf{E0}(h_0), k), \mathsf{append}(\mathsf{E1}(h_1), k)) \to \bot.$$

Proof. Induct on the common right tail k. The empty case is direct zero/one constructor no-confusion. In each visible tail step, both appended histories gain the same outer constructor; constructor injectivity peels that shared outer layer and the induction hypothesis applies to the shorter tail. □

Lean4 ✓ `BEDC.FKernel.Cont.append visible left same tail tag separation`

Theorem 4.15 (Append visible-left same-tag tail cancellation)**.** *For histories* $h_0, h_1, k : \mathsf{BHist}$*, common right-tail append cancellation identifies the payloads of equal zero-headed visible-left endpoints, and likewise for equal one-headed visible-left endpoints.*

Proof. Apply append right-cancellation to the common tail, then use constructor injectivity for the matching E0 or E1 head. □

Lean4 ✓ `BEDC.FKernel.Cont.append visible left same tag tail cancel`

Lemma 4.16 (Continuation respects a matching right extension step)**.** *If* $\mathsf{Cont}(h, k, r)$*,* $\mathsf{Ext}(m, k, k')$*, and* $\mathsf{Ext}(m, r, r')$*, then* $\mathsf{Cont}(h, k', r')$*.*

Lean4 ✓ `BEDC.FKernel.Cont.cont ext right step`

Proof. Case split on the extension of k by m. In the E0 branch, the matching extension of r is also the zero branch, and the zero continuation step applies. The E1 branch is analogous. □

Theorem 4.17 (Extension as singleton continuation)**.** *For every history h and result r,* $\mathsf{Ext}(\mathsf{b0}, h, r)$ *if and only if* $\mathsf{Cont}(h, \mathsf{E0}(\mathsf{e}), r)$*, and* $\mathsf{Ext}(\mathsf{b1}, h, r)$ *if and only if* $\mathsf{Cont}(h, \mathsf{E1}(\mathsf{e}), r)$*.*

Lean4 ✓ `BEDC.FKernel.Cont.extension as singleton continuation`
Lean4 ✓ `BEDC.FKernel.Cont.ext singleton continuation iff pair`

Proof. For the forward zero branch, invert the extension witness to identify r with $\mathsf{E0}(h)$, use the empty-continuation rule $\mathsf{Cont}(h, \mathsf{e}, h)$, and apply the $\mathsf{E0}$ continuation step rule. The one branch is the same argument with $\mathsf{E1}$.

For the reverse zero branch, invert the continuation witness for $\mathsf{Cont}(h, \mathsf{E0}(\mathsf{e}), r)$. Step-result inversion gives a predecessor continued by e, and history constructor no-confusion forces the singleton history to be the displayed $\mathsf{E0}(\mathsf{e})$ branch. The empty-continuation rule identifies the predecessor with h, so the $\mathsf{b0}$ extension constructor yields $\mathsf{Ext}(\mathsf{b0}, h, r)$. The one branch uses the corresponding $\mathsf{E1}$ inversion and the $\mathsf{b1}$ extension constructor. □

Theorem 4.18 (Continuation step result no-confusion)**.** *No generated history r can be both the result of continuing by* $\mathsf{E0}(k_0)$ *and the result of continuing by* $\mathsf{E1}(k_1)$ *from the same source history. The converse ordering of the two step constructors is equally impossible.*

Lean4 ✓ `BEDC.FKernel.Cont.cont step result no confusion pair`

Proof. Invert the two continuation witnesses. The zero-step witness forces the common result to have outer constructor $\mathsf{E0}$, while the one-step witness forces the same result to have outer constructor $\mathsf{E1}$. Closed generation of histories gives constructor no-confusion. The converse direction is symmetric. □

Theorem 4.19 (Continuation step result is nonempty)**.** *For all histories h, k, neither* $\mathsf{Cont}(h, \mathsf{E0}(k), \mathsf{e})$ *nor* $\mathsf{Cont}(h, \mathsf{E1}(k), \mathsf{e})$ *can hold.*

Lean4 ✓ `BEDC.FKernel.Cont.cont step result not empty pair`

Proof. Unfold the step result shape for Cont. The zero branch would identify e with $\mathsf{E0}(r)$, and the one branch would identify e with $\mathsf{E1}(r)$. Both contradict the generated history constructors. □

Theorem 4.20 (Zero-headed continuation result characterization)**.** *For histories $h, k, r : \mathsf{BHist}$,*

$$\mathsf{Cont}(h, k, \mathsf{E0}(r)) \iff (k = \mathsf{e} \wedge \mathsf{hsame}(h, \mathsf{E0}(r))) \vee (\exists k_0 : \mathsf{BHist}.\ k = \mathsf{E0}(k_0) \wedge \mathsf{Cont}(h, k_0, r)).$$

Lean4 ✓ `BEDC.FKernel.Cont.cont result e0 cases iff`

Proof. Classify the right continuation history k. The empty branch is exactly the right-unit endpoint equality between h and $\mathsf{E0}(r)$. A zero-headed tail exposes its predecessor and removes the matching outer constructor from the continuation equation. A one-headed tail would identify zero-headed and one-headed generated histories. Conversely, the empty branch is the right-unit continuation after the displayed history sameness is eliminated, and the zero-headed branch is rebuilt by the zero step rule. □

Theorem 4.21 (One-headed continuation result characterization)**.** *For histories $h, k, r : \mathsf{BHist}$,*

$$\mathsf{Cont}(h, k, \mathsf{E1}(r)) \iff (k = \mathsf{e} \wedge \mathsf{hsame}(h, \mathsf{E1}(r))) \vee (\exists k_0 : \mathsf{BHist}.\ k = \mathsf{E1}(k_0) \wedge \mathsf{Cont}(h, k_0, r)).$$

Lean4 ✓ `BEDC.FKernel.Cont.cont result e1 cases iff`

Proof. Classify the right continuation history k. The empty branch is exactly the right-unit endpoint equality between h and $\mathsf{E1}(r)$. A zero-headed tail would identify one-headed and zero-headed generated histories. A one-headed tail exposes its predecessor and removes the matching outer constructor from the continuation equation. Conversely, the empty branch is the right-unit continuation after the displayed history sameness is eliminated, and the one-headed branch is rebuilt by the one step rule. □

Theorem 4.22 (Zero-headed continuation result up to history-sameness)**.** *For histories* $h, k, r, z : \mathsf{BHist}$*, if* $\mathsf{Cont}(h, k, r)$ *and* $\mathsf{hsame}(r, \mathsf{E0}(z))$*, then*

$$(k = \mathsf{e} \wedge \mathsf{hsame}(h, \mathsf{E0}(z))) \vee (\exists k_0 : \mathsf{BHist}.\ k = \mathsf{E0}(k_0) \wedge \mathsf{Cont}(h, k_0, z)).$$

Lean4 ✓ `BEDC.FKernel.Cont.cont result hsame e0 cases`

Proof. Transport the continuation result along the displayed history-sameness to obtain $\mathsf{Cont}(h, k, \mathsf{E0}(z))$. The zero-headed result characterization then gives exactly the two alternatives. □

Theorem 4.23 (One-headed continuation result up to history-sameness)**.** *For histories* $h, k, r, z : \mathsf{BHist}$*, if* $\mathsf{Cont}(h, k, r)$ *and* $\mathsf{hsame}(r, \mathsf{E1}(z))$*, then*

$$(k = \mathsf{e} \wedge \mathsf{hsame}(h, \mathsf{E1}(z))) \vee (\exists k_0 : \mathsf{BHist}.\ k = \mathsf{E1}(k_0) \wedge \mathsf{Cont}(h, k_0, z)).$$

Lean4 ✓ `BEDC.FKernel.Cont.cont result hsame e1 cases`

Proof. Transport the continuation result along the displayed history-sameness to obtain $\mathsf{Cont}(h, k, \mathsf{E1}(z))$. The one-headed result characterization then gives exactly the two alternatives. □

Theorem 4.24 (Left zero-headed continuation result characterization)**.** *For histories* $h, k, r : \mathsf{BHist}$*,*

$$\mathsf{Cont}(\mathsf{E0}(h), k, \mathsf{E0}(r)) \iff (k = \mathsf{e} \wedge \mathsf{hsame}(h, r)) \vee (\exists k_0 : \mathsf{BHist}.\ k = \mathsf{E0}(k_0) \wedge \mathsf{Cont}(\mathsf{E0}(h), k_0, r)).$$

Lean4 ✓ `BEDC.FKernel.Cont.cont left e0 result iff`

Proof. Classify the right continuation history k. The empty branch reduces the outer zero result equality to equality of payload histories. A zero-headed k exposes its predecessor and removes the matching outer constructor from the continuation equation. A one-headed k would identify zero-headed and one-headed generated histories. Conversely, the empty branch is the right-unit continuation after the displayed history sameness is eliminated, and the zero-headed branch is rebuilt by the zero step rule. □

Proposition 4.25 (Left zero-headed continuation result visible-tail exposure)**.** *For histories* $h, k, r : \mathsf{BHist}$*, if* $\mathsf{Cont}(\mathsf{E0}(h), k, \mathsf{E0}(r))$ *holds and* k *is not classified with* e*, then the continuation tail has visible zero-headed form:*

$$\exists k_0 : \mathsf{BHist}.\ k = \mathsf{E0}(k_0) \wedge \mathsf{Cont}(\mathsf{E0}(h), k_0, r).$$

Lean4 ✓ `BEDC.FKernel.Cont.cont left e0 result nonempty tail cases`

Proof. Apply the zero-headed result characterization. Its empty-tail branch contradicts the displayed nonempty-tail hypothesis, so only the visible zero-headed tail branch remains. □

Theorem 4.26 (Continuation result tag separation)**.** *There are no histories h, k, r_0, r_1 such that both $\mathsf{Cont}(h, k, \mathsf{E0}(r_0))$ and $\mathsf{Cont}(h, k, \mathsf{E1}(r_1))$ hold.*

Lean4 ✓ `BEDC.FKernel.Cont.cont result tag separation`

Proof. Assume both continuation witnesses for the same inputs h and k. Continuation determinacy gives $\mathsf{hsame}(\mathsf{E0}(r_0), \mathsf{E1}(r_1))$. History no-confusion rules out any generated sameness derivation between a zero-tagged history and a one-tagged history, so the two witnesses cannot coexist. □

Theorem 4.27 (Left one-headed continuation result cases)**.** *If $\mathsf{Cont}(\mathsf{E1}(h), k, \mathsf{E1}(r))$, then either $k = \mathsf{e}$ and $\mathsf{hsame}(h, r)$, or $k = \mathsf{E1}(k_0)$ for some k_0 and $\mathsf{Cont}(\mathsf{E1}(h), k_0, r)$.*

Lean4 ✓ `BEDC.FKernel.Cont.cont left e1 result cases`

Proof. Classify the right continuation history k. The empty case reduces the result equation to equality of the inner histories. A zero-headed k would force a one-headed history to equal a zero-headed history, contradicting constructor no-confusion. A one-headed k exposes its predecessor k_0 and removes the matching outer constructor from the continuation equation. □

Theorem 4.28 (Left one-headed continuation result characterization)**.** *For histories $h, k, r : \mathsf{BHist}$,*

$$\mathsf{Cont}(\mathsf{E1}(h), k, \mathsf{E1}(r)) \iff (k = \mathsf{e} \wedge \mathsf{hsame}(h, r)) \vee (\exists k_0 : \mathsf{BHist}.\ k = \mathsf{E1}(k_0) \wedge \mathsf{Cont}(\mathsf{E1}(h), k_0, r)).$$

Lean4 ✓ `BEDC.FKernel.Cont.cont left e1 result iff`

Proof. The forward direction is the one-headed result case split. For the converse, the empty branch is the right-unit continuation after the displayed history sameness is eliminated, and the one-headed branch is rebuilt by the one step rule. □

Proposition 4.29 (Left one-headed continuation result visible-tail exposure)**.** *For histories $h, k, r : \mathsf{BHist}$, if $\mathsf{Cont}(\mathsf{E1}(h), k, \mathsf{E1}(r))$ holds and k is not classified with e, then the continuation tail has visible one-headed form:*

$$\exists k_0 : \mathsf{BHist}.\ k = \mathsf{E1}(k_0) \wedge \mathsf{Cont}(\mathsf{E1}(h), k_0, r).$$

Lean4 ✓ `BEDC.FKernel.Cont.cont left e1 result nonempty tail cases`

Proof. Apply the one-headed result case split. Its empty-tail branch contradicts the displayed nonempty-tail hypothesis, so the visible one-headed tail branch is the remaining case. □

Theorem 4.30 (Left cross-tag continuation result cases)**.** *If $\mathsf{Cont}(\mathsf{E0}(h), k, \mathsf{E1}(r))$, then $k = \mathsf{E1}(k_0)$ for some k_0 and $\mathsf{Cont}(\mathsf{E0}(h), k_0, r)$. If $\mathsf{Cont}(\mathsf{E1}(h), k, \mathsf{E0}(r))$, then $k = \mathsf{E0}(k_0)$ for some k_0 and $\mathsf{Cont}(\mathsf{E1}(h), k_0, r)$.*

Lean4 ✓ `BEDC.FKernel.Cont.cont left tag cross result cases`

Proof. In each direction, classify k by generated-history constructors. The empty case and the branch whose tag matches the left source produce impossible outer-constructor equalities. The opposite-tag branch exposes the predecessor of k and peels the matching outer constructor from the result equation. □

Theorem 4.31 (Left cross-tag continuation result characterization)**.** *For histories h, k, r, the two cross-tag result shapes are characterized by the opposite tag in the continuation tail:*

$$\mathsf{Cont}(\mathsf{E0}(h), k, \mathsf{E1}(r)) \iff \exists k_0 : \mathsf{BHist}.\ k = \mathsf{E1}(k_0) \wedge \mathsf{Cont}(\mathsf{E0}(h), k_0, r),$$

and

$$\mathsf{Cont}(\mathsf{E1}(h), k, \mathsf{E0}(r)) \iff \exists k_0 : \mathsf{BHist}.\ k = \mathsf{E0}(k_0) \wedge \mathsf{Cont}(\mathsf{E1}(h), k_0, r).$$

Lean4 ✓ `BEDC.FKernel.Cont.cont left tag cross result iff pair`

Proof. The forward directions are the cross-tag result case split. For the converse directions, eliminate the displayed equation for k and rebuild the outer result constructor using the corresponding continuation step rule. □

Theorem 4.32 (Left same-tag continuation tail alignment)**.** *If two continuations have the same visible left endpoint and the same same-tag visible result, then their right tails align in the same shape. For zero-headed endpoints, both tails are empty or both are zero-headed with* hsame *exposed tails; for one-headed endpoints, both tails are empty or both are one-headed with* hsame *exposed tails.*

Lean4 ✓ `BEDC.FKernel.Cont.cont left same tag tail alignment`

Proof. Apply continuation left cancellation to the two displayed continuations to obtain $\mathsf{hsame}(k, l)$ between their right tails. Split the first continuation by the same-tag result case theorem. In the empty branch, the tail sameness forces the second tail to be empty. In the visible branch, tail sameness transports the second tail into the matching visible constructor and yields the exposed hsame relation between payload tails. □

Theorem 4.33 (Left cross-tag continuation tail alignment)**.** *If two continuations have the same visible left endpoint and the same cross-tag visible result, then both right tails carry the opposite visible tag, and the exposed tails are* hsame*.*

Lean4 ✓ `BEDC.FKernel.Cont.cont left tag cross tail alignment`

Proof. Continuation left cancellation compares the two right tails. The cross-tag result case theorem applied to the first continuation forces that tail to have the opposite visible constructor. Transporting the second tail through the tail sameness forces the same constructor there as well, and constructor inversion gives the exposed hsame relation. □

Theorem 4.34 (Continuation right-tail result cases)**.** *For histories $h, k, r : \mathsf{BHist}$, if $\mathsf{Cont}(h, k, r)$, then the right continuation tail has one of the following displayed forms:*

$$\mathsf{hsame}(k, \mathsf{e}) \wedge \mathsf{hsame}(r, h),$$

or there exist histories t, u such that

$$\mathsf{hsame}(k, \mathsf{E0}(t)) \wedge \mathsf{hsame}(r, \mathsf{E0}(u)) \wedge \mathsf{Cont}(h, t, u),$$

or there exist histories t, u such that

$$\mathsf{hsame}(k, \mathsf{E1}(t)) \wedge \mathsf{hsame}(r, \mathsf{E1}(u)) \wedge \mathsf{Cont}(h, t, u).$$

Proof. Classify the right continuation tail k. The empty case is the right-unit continuation, so the result is classified with the source. In the zero-headed and one-headed cases, step-result inversion removes the displayed outer constructor from the result and exposes the residual continuation through the tail payload. □

Lean4 ✓ `BEDC.FKernel.Cont.cont right tail result cases`

Lemma 4.35 (Continuation nonempty right-tail result cases)**.** *For histories h, k, r : BHist, if $\mathsf{Cont}(h, k, r)$ and k is not history-same to e, then the empty-tail branch of the right-tail result classification is impossible. Hence either*

$$\exists t, u : \mathsf{BHist},\ \mathsf{hsame}(k, \mathsf{E0}(t)) \wedge \mathsf{hsame}(r, \mathsf{E0}(u)) \wedge \mathsf{Cont}(h, t, u),$$

or

$$\exists t, u : \mathsf{BHist},\ \mathsf{hsame}(k, \mathsf{E1}(t)) \wedge \mathsf{hsame}(r, \mathsf{E1}(u)) \wedge \mathsf{Cont}(h, t, u).$$

Proof. Apply Definition 4.34 to the continuation witness. The empty-tail branch gives $\mathsf{hsame}(k, \mathsf{e})$ and is eliminated by the nonempty hypothesis. The remaining two branches are already the zero-headed and one-headed witness alternatives, so they are returned unchanged. □

Lean4 ✓ `BEDC.FKernel.Cont.cont right tail result nonempty cases`

Lemma 4.36 (Continuation right unit)**.** *For every history h, $\mathsf{Cont}(h, \mathsf{e}, h)$.*

Proof. This is the base rule of Cont. □

Lemma 4.37 (Continuation left unit)**.** *For every history h, $\mathsf{Cont}(\mathsf{e}, h, h)$.*

Lean4 ✓ `BEDC.FKernel.Cont.cont left unit`

Proof. Induct on h. The empty case is the base rule. The extension cases follow by applying the corresponding continuation step rule to the induction hypothesis. □

Theorem 4.38 (Continuation unit laws)**.** *The empty history is a left unit for continuation, and continuation by the empty history returns a history same as the source.*

Lean4 ✓ `BEDC.FKernel.Cont.cont unit laws`

```
↪ variant  BEDC.FKernel.Cont.append empty left
↪ variant  BEDC.FKernel.Cont.append empty right
↪ variant  BEDC.FKernel.Cont.append left unit iff
↪ variant  BEDC.FKernel.Cont.append right unit iff
↪ variant  BEDC.FKernel.Cont.cont left unit iff
↪ variant  BEDC.FKernel.Cont.cont left unit unique
↪ variant  BEDC.FKernel.Cont.cont right unit result
↪ variant  BEDC.FKernel.Cont.cont right unit unique
↪ variant  BEDC.FKernel.Cont.cont unit uniqueness pair
↪ variant  BEDC.FKernel.Cont.cont unit laws with uniqueness
```

Proof. The left-unit statement is the left-unit lemma. For the right-unit statement, compare the given continuation proof with the right-unit lemma by continuation determinacy. □

Theorem 4.39 (Continuation determinacy up to history-sameness)**.** *If $\mathsf{Cont}(h, k, r)$ and $\mathsf{Cont}(h, k, s)$, then $\mathsf{hsame}(r, s)$.*

Lean4 ✓ `BEDC.FKernel.Cont.cont deterministic`

Proof. Induct on the first derivation. In the empty case the second derivation is also the empty case by no-confusion, and the result follows by reflexivity. In the two extension cases, no-confusion forces the second derivation to use the same outer continuation constructor; apply the induction hypothesis and rebuild hsame with the matching history constructor. □

Theorem 4.40 (Continuation result transport)**.** *If* $\mathsf{Cont}(h, k, r)$ *and* $\mathsf{hsame}(r, r')$*, then* $\mathsf{Cont}(h, k, r')$*.*

Proof. Unfold Cont as the append-result equation. Symmetry of the result sameness followed by the original continuation equation gives the required append-result equation for r'. □

Lean4 ✓ `BEDC.FKernel.Cont.cont result hsame transport`

Theorem 4.41 (Continuation hsame transport)**.** *If* $\mathsf{hsame}(h, h')$*,* $\mathsf{hsame}(k, k')$*,* $\mathsf{hsame}(r, r')$*, and* $\mathsf{Cont}(h, k, r)$*, then* $\mathsf{Cont}(h', k', r')$*.*

Proof. Eliminate the two input hsame witnesses to align the left and right continuation inputs. The remaining result endpoint is transported by Theorem 4.40. □

Lean4 ✓ `BEDC.FKernel.Cont.cont hsame transport`

Theorem 4.42 (Continuation transport result classification)**.** *If* $\mathsf{hsame}(h, h')$*,* $\mathsf{hsame}(k, k')$*,* $\mathsf{hsame}(r, r')$*,* $\mathsf{Cont}(h, k, r)$*, and* $\mathsf{Cont}(h', k', s)$*, then* $\mathsf{Cont}(h', k', r')$ *and* $\mathsf{hsame}(r', s)$*.*

Proof. First transport the original continuation witness across the two input endpoints and the result endpoint. The transported witness and the displayed target-side witness now share the same source and tail histories, so continuation determinacy classifies their results. □

Lean4 ✓ `BEDC.FKernel.Cont.cont transport result classified`

Theorem 4.43 (Continuation left-context cancellation up to history-sameness)**.** *If* $\mathsf{Cont}(a, b, r)$*,* $\mathsf{Cont}(a', d, r')$*,* $\mathsf{hsame}(a, a')$*, and* $\mathsf{hsame}(r, r')$*, then* $\mathsf{hsame}(b, d)$*.*

Lean4 ✓ `BEDC.FKernel.Cont.cont cancel hsame left context`

Proof. Use $\mathsf{hsame}(a, a')$ to align the left context and $\mathsf{hsame}(r, r')$ to align the result. The two continuation derivations then have the same left context and the same result, so left-context cancellation gives $\mathsf{hsame}(b, d)$. □

Theorem 4.44 (Prefixed result common-suffix source determinacy)**.** *For histories* p, a, b, k, r, s : BHist*, if* $\mathsf{Cont}(a, k, r)$*,* $\mathsf{Cont}(b, k, s)$*, and*

$$\mathsf{hsame}(\mathsf{append}(p, r), \mathsf{append}(p, s)),$$

then $\mathsf{hsame}(a, b)$*.*

Proof. Left cancellation removes the visible prefix p from the result comparison. The two continuations then have a common right suffix k and history-same results, so right-context continuation cancellation identifies the sources. □

Lean4 ✓ `BEDC.FKernel.Cont.cont prefixed result common suffix source deterministic`

Theorem 4.45 (Prefixed result common-source tail determinacy)**.** *For histories* p, a, k, l, r, s : BHist*, if* $\mathsf{Cont}(a, k, r)$*,* $\mathsf{Cont}(a, l, s)$*, and*

$$\mathsf{hsame}(\mathsf{append}(p, r), \mathsf{append}(p, s)),$$

then $\mathsf{hsame}(k, l)$*.*

Proof. Left cancellation removes the common visible prefix p from the result comparison. The two continuation witnesses now share source a and have history-same results, so left-context continuation cancellation identifies the two tails. □

Lean4 ✓ `BEDC.FKernel.Cont.cont prefixed result common source tail deterministic`

Theorem 4.46 (Continuation fixed right-unit probe forces empty tail)**.** *For all histories* p, u : BHist*, if*

$$\forall r : \mathsf{BHist}.\ \mathsf{Cont}(p, u, r) \Rightarrow \mathsf{hsame}(r, p),$$

then $\mathsf{hsame}(u, \mathsf{e})$*.*

Proof. Let $r_0 = \mathsf{append}(p, u)$ be the canonical result representative for the displayed continuation tail. By the append presentation of Cont in Definition 4.10, there is a continuation witness

$$\mathsf{Cont}(p, u, r_0).$$

The fixed-probe hypothesis applied to this witness gives $\mathsf{hsame}(r_0, p)$. The base rule of Definition 4.10 also gives the right-unit continuation

$$\mathsf{Cont}(p, \mathsf{e}, p).$$

Apply Definition 4.43 to these two continuations, using reflexivity for $\mathsf{hsame}(p, p)$ and the obtained result comparison $\mathsf{hsame}(r_0, p)$. The conclusion is $\mathsf{hsame}(u, \mathsf{e})$. □

Lean4 ✓ `BEDC.FKernel.Cont.cont fixed right unit probe empty tail`

Theorem 4.47 (Continuation fixed left-unit probe forces empty source)**.** *For all histories* u, p : BHist*, if*

$$\forall r : \mathsf{BHist}.\ \mathsf{Cont}(u, p, r) \Rightarrow \mathsf{hsame}(r, p),$$

then $\mathsf{hsame}(u, \mathsf{e})$*.*

Proof. Let $r_0 = \mathsf{append}(u, p)$ be the canonical result representative for continuing source u by tail p. By the append presentation of Cont in Definition 4.10, there is a continuation witness

$$\mathsf{Cont}(u, p, r_0).$$

The fixed-probe hypothesis applied to this witness gives $\mathsf{hsame}(r_0, p)$. Transporting the canonical witness along this result comparison by Definition 4.40 gives

$$\mathsf{Cont}(u, p, p).$$

By the left-unit clause of Definition 4.38, there is also a continuation witness

$$\mathsf{Cont}(\mathsf{e}, p, p).$$

Apply the right-cancellation clause of Definition 4.52 to these two continuations and the reflexive comparison $\mathsf{hsame}(p, p)$. The conclusion is $\mathsf{hsame}(u, \mathsf{e})$. □

Lean4 ✓ `BEDC.FKernel.Cont.cont fixed left unit probe empty source`

Theorem 4.48 (Continuation prefix cancellation)**.** *If* $\mathsf{Cont}(\mathsf{append}(p, a), f, \mathsf{append}(p, b))$*, then* $\mathsf{Cont}(a, f, b)$*.*

Proof. Read the displayed continuation as equality of append representatives. Append associativity rewrites the right side as $\mathsf{append}(p, \mathsf{append}(a, f))$. Left cancellation of the common prefix p identifies b with $\mathsf{append}(a, f)$, which is exactly the unprefixed continuation. □

Lean4 ✓ `BEDC.FKernel.Cont.cont prefix cancel`

Theorem 4.49 (Continuation prefix equivalence)**.** *For histories* p, a, b, f*,*

$$\mathsf{Cont}(\mathsf{append}(p, a), f, \mathsf{append}(p, b)) \iff \mathsf{Cont}(a, f, b).$$

Proof. The forward direction is continuation prefix cancellation. For the reverse direction, prefix the equality witness for $\mathsf{Cont}(a, f, b)$ by $\mathsf{append}(p, -)$ and use associativity to identify $\mathsf{append}(p, \mathsf{append}(a, f))$ with $\mathsf{append}(\mathsf{append}(p, a), f)$. □

Lean4 ✓ `BEDC.FKernel.Cont.cont prefix iff`

Theorem 4.50 (Append right-context cancellation up to history-sameness)**.** *For histories* $P, Q, a, b : \mathsf{BHist}$*, if* $P \mathsf{hsame} Q$*, then appending the history-same right contexts* P *and* Q *preserves and reflects endpoint history-sameness:*

$$P \mathsf{hsame} Q \Rightarrow (\mathsf{hsame}(\mathsf{append}(a, P), \mathsf{append}(b, Q)) \iff a \mathsf{hsame} b).$$

Proof. Transport the right context along $P \mathsf{hsame} Q$. The forward direction is right append cancellation for the common suffix. Conversely, after the endpoints a and b are identified, the two appended histories are definitionally the same. □

Lean4 ✓ `BEDC.FKernel.Cont.append hsame right context cancel iff`

Theorem 4.51 (Append common-context cancellation up to history-sameness)**.** *For histories* $L, R, P, Q, a, b : \mathsf{BHist}$*, if* $L \mathsf{hsame} R$ *and* $P \mathsf{hsame} Q$*, then the two-sided contextual append comparison is exactly the comparison of the middle histories:*

$$L \mathsf{hsame} R \Rightarrow P \mathsf{hsame} Q \Rightarrow (\mathsf{hsame}(\mathsf{append}(L, \mathsf{append}(a, P)), \mathsf{append}(R, \mathsf{append}(b, Q))) \iff a \mathsf{hsame} b).$$

Proof. First transport the left and right contexts along the two hsame witnesses. In the forward direction, left append cancellation removes the common outer context and right append cancellation removes the common suffix. The reverse direction is immediate after the middle histories are identified. □

Lean4 ✓ `BEDC.FKernel.Cont.append hsame common context cancel iff`

Theorem 4.52 (Continuation cancellation laws)**.** *Continuation admits cancellation on both sides:*

1. *if* $\mathsf{Cont}(h, k, r)$*,* $\mathsf{Cont}(h', k, r')$*, and* $\mathsf{hsame}(r, r')$*, then* $\mathsf{hsame}(h, h')$*;*
2. *if* $\mathsf{Cont}(h, k, r)$ *and* $\mathsf{Cont}(h, k', r)$*, then* $\mathsf{hsame}(k, k')$*;*
3. *if* $\mathsf{Cont}(a, b, ab)$*,* $\mathsf{Cont}(ab, c, left)$*,* $\mathsf{Cont}(a, d, ad)$*,* $\mathsf{Cont}(ad, c, right)$*, and* $\mathsf{hsame}(left, right)$*, then* $\mathsf{hsame}(b, d)$*.*

Lean4 ✓ `BEDC.FKernel.Cont.cont right cancel`

↪ variant `BEDC.FKernel.Cont.cont right cancel eq`

↪ variant `BEDC.FKernel.Cont.cont common suffix cancellation`

↪ variant `BEDC.FKernel.Cont.cont right cancel hsame result`

↪ variant `BEDC.FKernel.Cont.cont cancel common context`

↪ variant `BEDC.FKernel.Cont.continuation right cancellation`

↪ variant `BEDC.FKernel.Cont.cont left cancel`

↪ variant `BEDC.FKernel.Cont.append right cancel`

↪ variant `BEDC.FKernel.Cont.append left cancel`

Proof. For the first clause, use right-suffix cancellation after transporting the result by hsame. The second clause is left-context cancellation: compare the two derivations with the same left history, peel the shared left context, and conclude that the right histories are equal up to hsame. For the third clause, associate the two continuations so both sides expose the same outer context c over the inner continuations from a; the common outer context cancels against the result-sameness, and the remaining left-context cancellation yields $\mathsf{hsame}(b, d)$. □

Theorem 4.53 (Continuation cancellation with history-same right context)**.** *For histories* $a, a', b, b', r, r' : \mathsf{BHist}$*, if* $\mathsf{Cont}(a, b, r)$*,* $\mathsf{Cont}(a', b', r')$*,* $\mathsf{hsame}(b, b')$*, and* $\mathsf{hsame}(r, r')$*, then* $\mathsf{hsame}(a, a')$*.*

Proof. Transport the second right context and result along the two hsame witnesses. The continuations now share right context and result, so right cancellation identifies the two sources. □

Lean4 ✓ `BEDC.FKernel.Cont.cont cancel hsame right context`

Theorem 4.54 (Self-extension by a visible tail is impossible)**.** *For any histories* h *and* t*, neither* $\mathsf{Cont}(h, \mathsf{E0}(t), h)$ *nor* $\mathsf{Cont}(h, \mathsf{E1}(t), h)$ *can hold.*

Lean4 ✓ `BEDC.FKernel.Cont.cont self extension tail absurd`

Proof. Any such continuation would make a visible right tail behave as the empty right unit at h. Right-unit uniqueness identifies the tail with e, contradicting constructor no-confusion for $\mathsf{E0}(t)$ and $\mathsf{E1}(t)$. □

Theorem 4.55 (Mutual continuations cannot start with a visible left tail)**.** *For histories* h, k, t, u*, a continuation* $\mathsf{Cont}(h, \mathsf{E0}(t), k)$ *together with a return continuation* $\mathsf{Cont}(k, u, h)$ *is impossible; the same holds with* $\mathsf{E1}(t)$ *in place of* $\mathsf{E0}(t)$*.*

Lean4 ✓ `BEDC.FKernel.Cont.cont mutual extension left tail absurd`

Proof. Mutual continuations force both displayed tails to be empty by the concrete tail-empty cancellation theorem. A left tail with outer constructor $\mathsf{E0}$ or $\mathsf{E1}$ cannot be internally same as e. □

Theorem 4.56 (Continuation associativity)**.** *If* $\mathsf{Cont}(h, k, u)$*,* $\mathsf{Cont}(u, l, v)$*,* $\mathsf{Cont}(k, l, w)$*, and* $\mathsf{Cont}(h, w, z)$*, then* $\mathsf{hsame}(v, z)$*.*

Lean4 ✓ `BEDC.FKernel.Cont.cont assoc relational`

↪ variant `BEDC.FKernel.Cont.cont assoc middle exists`

↪ variant `BEDC.FKernel.Cont.cont assoc forward witness`

↪variant BEDC.FKernel.Cont.continuation associativity up to hsame
↪variant BEDC.FKernel.Cont.continuation associativity spine
↪variant BEDC.FKernel.Cont.cont assoc common witness
↪variant BEDC.FKernel.Cont.cont assoc common witness symmetric
↪variant BEDC.FKernel.Cont.cont assoc up to hsame spine
↪variant BEDC.FKernel.Cont.cont assoc spine symmetric witnesses
```

Proof. Induct on the derivation of $\mathsf{Cont}(h, k, u)$. The empty case reduces both sides to the determinacy of $\mathsf{Cont}(k, l, -)$. In the $\mathsf{E0}$ and $\mathsf{E1}$ cases, no-confusion forces matching outer constructors in the relevant continuation derivations; use the induction hypothesis on inner histories and rebuild hsame under the same outer constructor. □

Theorem 4.57 (Continuation right append decomposition)**.** *If* $\mathsf{Cont}(h, \mathsf{append}(k, l), r)$*, where* append *is the recursive append representative underlying* Cont*, then there exists a generated history* m *such that* $\mathsf{Cont}(h, k, m)$ *and* $\mathsf{Cont}(m, l, r)$*.*

Lean4 ✓ `BEDC.FKernel.Cont.cont right append decompose`

Proof. Unfold continuation as append equality. Take m to be the append of h and k. The first continuation is definitional, and the second is the reverse direction of append associativity. □

Theorem 4.58 (Continuation left append decomposition)**.** *If* $\mathsf{Cont}(\mathsf{append}(h, k), l, r)$*, where* append *is the recursive append representative underlying* Cont*, then there exists a generated history* m *such that* $\mathsf{Cont}(k, l, m)$ *and* $\mathsf{Cont}(h, m, r)$*.*

Lean4 ✓ `BEDC.FKernel.Cont.cont left append decompose`

Proof. Unfold continuation as append equality. Take m to be the append of k and l. The first continuation is definitional, and the second is append associativity. □

Corollary 4.59 (Continuation gives an addition-like seed)**.** *Unary repetition histories with relational continuation license an addition-like derived interface* $\mathsf{Add}^{\uparrow}$*, but no primitive addition is introduced into the kernel.*

Lean4 ✓ `BEDC.FKernel.Cont.cont addition like seed`

Chapter 5

Asking Events and Policies

5.1 Asking events

Definition 5.1 (Probe names and evidence tokens)**.** ProbeName *is a syntactic class of probe names.* Ev *is a syntactic class of evidence tokens. Neither is assumed to be a set of functions or a set of proofs.*

Lean4 (definition) `BEDC.FKernel.Ask.ProbeName`
Lean4 (definition) `BEDC.FKernel.Ask.Evidence`

Definition 5.2 (Asking event)**.** *An asking event is a judgment*

$$\mathsf{Ask}(\pi, h, m, \delta),$$

where $\pi : \mathsf{ProbeName}$*,* $h : \mathsf{Hist}$*,* $m : \mathsf{Mark}$*, and* $\delta : \mathsf{Ev}$*. It is read: asking probe name* π *of history* h *emits mark* m *with evidence token* δ*.*

Lean4 (definition) `BEDC.FKernel.Ask.Ask`
Lean4 (definition) `BEDC.FKernel.Ask.AskEvent`
Lean4 ✓ `BEDC.FKernel.Ask.askEvent witness`
↪ variant `BEDC.FKernel.Ask.askEvent components`

↪ variant `BEDC.FKernel.Ask.askEvent from witness`
↪ variant `BEDC.FKernel.Ask.askEvent evidence witness`

5.2 Asking policies

Definition 5.3 (Asking policy)**.** *An asking policy* $\mathsf{AskPolicy}(\Pi, D)$ *is paper notation for using a checked* $\mathsf{AskPolicy}(D)$ *certificate at bundle* Π*. The bundle is not a field of the certificate; it determines which probe-name occurrences the surrounding signature construction consumes. The certificate provides:*

1. *totality: every admitted history in* D *has generated asking events for each probe name, with the Lean field quantified over all probe names;*
2. *mark determinacy: if* $\mathsf{Ask}(\pi, h, m, \delta)$ *and* $\mathsf{Ask}(\pi, h, n, \theta)$*, then* $\mathsf{msame}(m, n)$*;*
3. *history-respect: if* $\mathsf{hsame}(h, k)$*, then asking results agree up to* msame *whenever both are generated.*

The object-language content is exactly totality, mark determinacy, and history-respect.

Lean4 ✓ `BEDC.FKernel.Ask.AskPolicy iff fields`

↪ variant `BEDC.FKernel.Ask.ask policy fields`
↪ variant `BEDC.FKernel.Ask.askPolicy total event`
↪ variant `BEDC.FKernel.Ask.askPolicy total deterministic pair`
↪ variant `BEDC.FKernel.Ask.askPolicy total respects pair`
↪ variant `BEDC.FKernel.Ask.askPolicy deterministic respects pair`
↪ variant `BEDC.FKernel.Ask.AskPolicy total deterministic pair`
↪ variant `BEDC.FKernel.Ask.ask total from policy`
↪ variant `BEDC.FKernel.Ask.ask total`
↪ variant `BEDC.FKernel.Ask.ask respects history`
↪ variant `BEDC.FKernel.Ask.askPolicy respects history field`

Definition 5.4 (Bundle-local asking policy)**.** *A bundle-local asking policy* $\mathsf{BundleAskPolicy}(\Pi, D)$ *is the finite obligation needed by the signature construction for bundle* Π*. It consists of the following clauses, each restricted to probe-name occurrences* $\pi \in \Pi$*:*

1. *totality on admitted sources: if* $h \in D$*, then there are* $m : \mathsf{Mark}$ *and* $\delta : \mathsf{Ev}$ *with* $\mathsf{Ask}(\pi, h, m, \delta)$*;*
2. *mark determinacy on the bundle: if* $\mathsf{Ask}(\pi, h, m, \delta)$ *and* $\mathsf{Ask}(\pi, h, n, \theta)$*, then* $\mathsf{msame}(m, n)$*;*
3. *history-respect on the bundle: if* $\mathsf{hsame}(h, k)$*,* $\mathsf{Ask}(\pi, h, m, \delta)$*, and* $\mathsf{Ask}(\pi, k, n, \theta)$*, then* $\mathsf{msame}(m, n)$*.*

Thus $\mathsf{AskPolicy}(\Pi, D)$ *is a sufficient global certificate, while* $\mathsf{BundleAskPolicy}(\Pi, D)$ *records exactly the finite probe obligations consumed by signatures through* Π*.*

Lean4 ✓ `BEDC.FKernel.Ask.BundleAskPolicy iff fields`

Theorem 5.5 (Empty bundle-local asking policy)**.** *For every source specification* D*,* $\mathsf{BundleAskPolicy}(\mathsf{Bnil}, D)$ *holds.*

Proof. Each totality, determinacy, and history-respect clause begins from an occurrence proof $\pi \in \mathsf{Bnil}$. Empty-bundle membership inversion eliminates that occurrence, so all three fields are satisfied. □

Lean4 ✓ `BEDC.FKernel.Ask.empty bundleAskPolicy`
Lean4 ✓ `BEDC.FKernel.Ask.bundleAskPolicy empty`

Theorem 5.6 (Bundle-local policy restriction by membership inclusion)**.** *For probe bundles* Π, Θ *and a domain policy* D*, suppose* $\mathsf{BundleAskPolicy}(\Pi, D)$ *holds and every probe-name occurrence of* Θ *is an occurrence of* Π*:*

$$\forall \rho,\ \rho \in \Theta \Rightarrow \rho \in \Pi.$$

Then $\mathsf{BundleAskPolicy}(\Theta, D)$ *holds.*

Lean4 ✓ `BEDC.FKernel.Ask.bundleAskPolicy restrict by inclusion`

Proof. Let ρ be a probe-name occurrence of Θ. The displayed membership inclusion gives $\rho \in \Pi$. Apply the totality, mark determinacy, and history-respect fields of $\mathsf{BundleAskPolicy}(\Pi, D)$ at that occurrence. These three precomposed fields are exactly the bundle-local asking policy fields for Θ. □

Lean4 ✓ `BEDC.FKernel.Ask.bundleAskPolicy of membership inclusion`

Lemma 5.7 (Bundle-local asking policy tail restriction)**.** *If* $\mathsf{BundleAskPolicy}(\mathsf{Bcons}(\pi, \Pi), D)$ *holds, then* $\mathsf{BundleAskPolicy}(\Pi, D)$ *holds.*

Lean4 ✓ `BEDC.FKernel.Ask.bundleAskPolicy tail`

Proof. Each tail occurrence $\rho \in \Pi$ is also an occurrence $\rho \in \mathsf{Bcons}(\pi, \Pi)$. Restrict totality, mark determinacy, and history-respect along this membership inclusion, field by field. □

Theorem 5.8 (Bundle-local asking policy cons decomposition)**.** *For a head probe* π*, a tail bundle* Π*, and a source specification* D*,* $\mathsf{BundleAskPolicy}(\mathsf{Bcons}(\pi, \Pi), D)$ *holds exactly when the head probe satisfies totality, mark determinacy, and history-respect over* D*, and* $\mathsf{BundleAskPolicy}(\Pi, D)$ *holds.*

Lean4 ✓ `BEDC.FKernel.Ask.bundleAskPolicy cons iff`

Proof. In the forward direction, use the head occurrence $\pi \in \mathsf{Bcons}(\pi, \Pi)$ to project the three head fields, and restrict the policy to the tail for the remaining field. In the reverse direction, case-analyze an occurrence of $\mathsf{Bcons}(\pi, \Pi)$: the head case uses the three head clauses, while the tail case uses the tail bundle-local policy. □

Theorem 5.9 (Global asking policy restricts to bundle-local policy)**.** *If* $\mathsf{AskPolicy}(\Pi, D)$ *holds, then* $\mathsf{BundleAskPolicy}(\Pi, D)$ *holds.*

Lean4 ✓ `BEDC.FKernel.Ask.askPolicy to bundleAskPolicy`

Proof. Use the totality, mark determinacy, and history-respect clauses supplied by $\mathsf{AskPolicy}(\Pi, D)$. For each probe-name occurrence $\pi \in \Pi$, the globally quantified totality clause gives an asking event for every admitted source history in D; the same global determinacy and history-respect clauses apply to the restricted occurrence π. These three projections are exactly the clauses of $\mathsf{BundleAskPolicy}(\Pi, D)$. □

Lemma 5.10 (Asking determinacy)**.** *Under an asking policy, a fixed probe name applied to a fixed history emits a mark unique up to* msame*.*

Lean4 ✓ `BEDC.FKernel.Ask.ask deterministic`
↪ variant `BEDC.FKernel.Ask.asking determinacy`
↪ variant `BEDC.FKernel.Ask.asking determinacy field`

Proof. This is the mark determinacy field of AskPolicy. □

Chapter 6

Generated Probe Bundles and Signature Events

6.1 Bundle grammar

Definition 6.1 (Probe bundle)**.** *Probe bundles are generated by:*

$$\frac{}{\mathsf{Bnil} : \mathsf{Bundle}}$$

$$\frac{\pi : \mathsf{ProbeName} \qquad \Pi : \mathsf{Bundle}}{\mathsf{Bcons}(\pi, \Pi) : \mathsf{Bundle}}.$$

Bundle membership is the closed predicate generated by cons membership: the head probe of $\mathsf{Bcons}(\pi, \Pi)$ *is a member of that bundle, and tail membership propagates through cons.*

Definition 6.2 (Bundle append)**.** *The append operation* $\mathsf{BAppend}(\Pi, \Theta)$ *is recursion on the left bundle:*

$$\mathsf{BAppend}(\mathsf{Bnil}, \Theta) = \Theta, \qquad \mathsf{BAppend}(\mathsf{Bcons}(\pi, \Pi), \Theta) = \mathsf{Bcons}(\pi, \mathsf{BAppend}(\Pi, \Theta)).$$

Lean4 (definition) BEDC.FKernel.Bundle.bundleAppend

Definition 6.3 (Probe bundle length)**.** *The length* $\mathsf{BLEN}(\Pi)$ *of a generated probe bundle is recursion on the bundle:*

$$\mathsf{BLEN}(\mathsf{Bnil}) = 0, \qquad \mathsf{BLEN}(\mathsf{Bcons}(\pi, \Pi)) = 1 + \mathsf{BLEN}(\Pi).$$

Lean4 (definition) BEDC.FKernel.Bundle.bundleLength

Theorem 6.4 (Probe bundle zero length equivalence)**.** *A generated probe bundle has length zero exactly when it is the empty bundle* Bnil*.*

Proof. Eliminate the generated bundle. The empty case reduces by computation. In the cons case the length reduces to a successor, which cannot equal zero. □

Lean4 ✓ BEDC.FKernel.Bundle.bundleLength eq zero iff nil

Lemma 6.5 (Probe bundle zero length exactly empty)**.** *For every generated probe bundle* Π*,*

$$\mathsf{BLEN}(\Pi) = 0 \quad \Longleftrightarrow \quad \Pi = \mathsf{Bnil}.$$

Proof. Case split on the generated bundle. The empty case is definitional. In the cons case, the length has successor form, contradicting equality with zero. The reverse implication follows by substituting Bnil. □

Lean4 ✓ BEDC.FKernel.Bundle.bundleLength zero iff nil

Theorem 6.6 (Probe bundle length one singleton equivalence)**.** *A generated probe bundle has length one exactly when it is a singleton* $\mathsf{Bcons}(\pi, \mathsf{Bnil})$ *for some probe* π*.*

Proof. Eliminate the generated bundle. The empty case has length zero, so it cannot have length one. In the cons case, injectivity of successor forces the tail length to be zero; Theorem 6.4 identifies the tail with Bnil. Conversely, substituting a singleton bundle reduces the length equation by computation. □

Lean4 ✓ `BEDC.FKernel.Bundle.bundleLength eq one iff singleton`

Theorem 6.7 (Probe bundle length-one member singleton)**.** *If a generated probe bundle has length one and contains probe π, then the bundle is exactly the singleton* $\mathsf{Bcons}(\pi, \mathsf{Bnil})$*.*

Proof. Case split on the generated bundle. The empty case contradicts membership. In the cons case, successor injectivity forces the tail length to be zero, so Theorem 6.4 identifies the tail with Bnil. Membership is then either the head equality, which fixes the singleton head, or tail membership, which is impossible for Bnil. □

Lean4 ✓ `BEDC.FKernel.Bundle.inBundle length one singleton`

Theorem 6.8 (Probe bundle length-one membership uniqueness)**.** *If a generated probe bundle has length one and contains probes π and ρ, then $\pi = \rho$.*

Lean4 ✓ `BEDC.FKernel.Bundle.inBundle length one unique`

Proof. Apply the length-one member singleton theorem to each membership witness. Both identify the same bundle as a singleton, so constructor injectivity identifies the two singleton heads. □

Theorem 6.9 (Probe bundle successor length cons decomposition)**.** *A generated probe bundle has successor length exactly when it is a cons whose tail has the predecessor length.*

Proof. Eliminate the bundle. The empty case contradicts successor length, while the cons case uses successor injectivity; the converse substitutes the cons equation. □

Lean4 ✓ `BEDC.FKernel.Bundle.bundleLength eq succ iff cons`

Theorem 6.10 (Probe bundle append length)**.** *For all probe bundles Π, Θ,*

$$\mathsf{BLEN}(\mathsf{BAppend}(\Pi, \Theta)) = \mathsf{BLEN}(\Pi) + \mathsf{BLEN}(\Theta).$$

Proof. Induct on Π. In the empty case, the append term reduces to Θ and the length equation reduces to the left identity of addition. In the cons case, both sides reduce by one successor, and the tail equation is the induction hypothesis. □

Lean4 ✓ `BEDC.FKernel.Bundle.bundleLength append`
Lean4 ✓ `BEDC.FKernel.Bundle.bundleAppend length`
Lean4 ✓ `BEDC.FKernel.Bundle.bundleLength bundleAppend`

Lemma 6.11 (Probe bundle nonempty prefix length separation)**.** *For every probe π and probe bundles Π_0, Ω,*

$$\mathsf{BLEN}(\mathsf{BAppend}(\mathsf{Bcons}(\pi, \Pi_0), \Omega)) \neq \mathsf{BLEN}(\Omega).$$

Consequently,

$$\mathsf{BAppend}(\mathsf{Bcons}(\pi, \Pi_0), \Omega) \neq \Omega.$$

Proof. Theorem 6.10 rewrites the left length as $1 + \mathsf{BLEN}(\Pi_0) + \mathsf{BLEN}(\Omega)$. A natural number with an exposed successor constructor cannot be equal to the unextended suffix length by natural-number constructor no-confusion. If the appended bundle itself were equal to Ω, applying BLEN to that equality would contradict the displayed length separation. □

Lean4 ✓ `BEDC.FKernel.Bundle.bundleAppend nonempty prefix length separation`

Theorem 6.12 (Probe bundle append fixes the right side exactly at nil left)**.** *For probe bundles* Π *and* Ω*,*

$$\mathsf{BAppend}(\Pi, \Omega) = \Omega$$

if and only if $\Pi = \mathsf{Bnil}$*.*

Proof. Split on Π. The nil case is definitional. In the cons case, the nonempty-prefix length separation theorem says that appending a cons-prefix to Ω cannot equal Ω. The reverse implication follows by reducing the append definition at Bnil. □

Lean4 ✓ `BEDC.FKernel.Bundle.bundleAppend eq right iff left nil`

Theorem 6.13 (Probe bundle append fixes the left side exactly at nil right)**.** *For probe bundles* Π *and* Ω*,*

$$\mathsf{BAppend}(\Pi, \Omega) = \Pi$$

if and only if $\Omega = \mathsf{Bnil}$*.*

Proof. Induct on Π. In the empty case, the displayed equation is exactly $\Omega = \mathsf{Bnil}$. In the cons case, constructor injectivity reduces the fixed append equation to the tail. The reverse implication is the right-unit theorem for append. □

Lean4 ✓ `BEDC.FKernel.Bundle.bundleAppend eq left iff right nil`

Theorem 6.14 (Probe bundle append right unit)**.** *For every probe bundle* Π*,*

$$\mathsf{BAppend}(\Pi, \mathsf{Bnil}) = \Pi.$$

Proof. Induct on Π. The empty bundle case is definitional. In the cons case, both sides expose the same head probe, and the tail equality is the induction hypothesis. □

Lean4 ✓ `BEDC.FKernel.Bundle.bundleAppend nil right`

Theorem 6.15 (Probe bundle append associativity)**.** *For all probe bundles* Π, Θ, Ω*,*

$$\mathsf{BAppend}(\mathsf{BAppend}(\Pi, \Theta), \Omega) = \mathsf{BAppend}(\Pi, \mathsf{BAppend}(\Theta, \Omega)).$$

Proof. Induct on Π. The empty bundle case is definitional. In the cons case, both sides expose the same head probe, and the tail equality is the induction hypothesis. □

Lean4 ✓ `BEDC.FKernel.Bundle.bundleAppend assoc`

Theorem 6.16 (Bundle append membership)**.** *For every probe* p *and bundles* Π, Θ*,*

$$p \in \mathsf{BAppend}(\Pi, \Theta) \iff p \in \Pi \text{ or } p \in \Theta.$$

Lean4 ✓ `BEDC.FKernel.Bundle.inBundle bundleAppend iff`

Proof. Induct on Π. The empty case reduces membership to Θ. The cons case splits head membership from tail membership, then applies the induction hypothesis to the tail. □

Theorem 6.17 (Bundle member split)**.** *If a generated probe bundle Π contains probe p, then Π splits as an append prefix followed by a cons whose head is p:*

$$\Pi = \mathsf{BAppend}(\Pi_L, \mathsf{Bcons}(p, \Pi_R))$$

for some generated bundles Π_L and Π_R.

Proof. Induct on the generated bundle. The empty bundle has no membership witness. In the cons case, head membership gives the split with empty left prefix, while tail membership applies the induction hypothesis to the tail and then restores the displayed head as one more constructor in the left prefix. □

Lean4 ✓ `BEDC.FKernel.Bundle.inBundle member split`

Theorem 6.18 (Bundle member split equivalence)**.** *For a generated probe bundle Π and probe p,*

$$p \in \Pi \quad \Longleftrightarrow \quad \exists \Pi_L, \exists \Pi_R,\ \Pi = \mathsf{BAppend}(\Pi_L, \mathsf{Bcons}(p, \Pi_R)).$$

Proof. The forward direction is Theorem 6.17. Conversely, after substituting the displayed append decomposition, append membership places p in the right summand, where the exposed cons head is exactly p. □

Lean4 ✓ `BEDC.FKernel.Bundle.inBundle member split iff`

Theorem 6.19 (Bundle append three-way membership split)**.** *For every probe p and bundles Π, Θ, Ω,*

$$p \in \mathsf{BAppend}(\Pi, \mathsf{BAppend}(\Theta, \Omega)) \quad \Longleftrightarrow \quad p \in \Pi \text{ or } p \in \Theta \text{ or } p \in \Omega.$$

Proof. Apply Theorem 6.16 to the outer append, then apply it again to the inner append. The reverse direction rebuilds the same two append membership witnesses from the displayed three-way disjunction. □

Lean4 ✓ `BEDC.FKernel.Bundle.inBundle bundleAppend three iff`

Theorem 6.20 (Bundle append four-way membership split)**.** *For every probe p and bundles $\Pi, \Theta, \Omega, \Lambda$,*

$$p \in \mathsf{BAppend}(\Pi, \mathsf{BAppend}(\Theta, \mathsf{BAppend}(\Omega, \Lambda))) \quad \Longleftrightarrow \quad p \in \Pi \text{ or } p \in \Theta \text{ or } p \in \Omega \text{ or } p \in \Lambda.$$

Proof. Apply Theorem 6.16 to the outer append. In the right branch, apply the same membership split to the second append, and then to the third append. The reverse direction rebuilds the nested append membership witnesses in the same order. □

Lean4 ✓ `BEDC.FKernel.Bundle.inBundle bundleAppend four iff`

Theorem 6.21 (Bundle append three-segment membership rotation)**.** *For every probe p and bundles Π, Θ, Ω,*

$$p \in \mathsf{BAppend}(\Pi, \mathsf{BAppend}(\Theta, \Omega)) \quad \Longleftrightarrow \quad p \in \mathsf{BAppend}(\Theta, \mathsf{BAppend}(\Omega, \Pi)).$$

Proof. For the forward direction, apply Definition 6.19 to the left-hand membership. The resulting cases are $p \in \Pi$, $p \in \Theta$, and $p \in \Omega$.

Apply the same split theorem to the right-hand bundle expression. In the $p \in \Pi$ case use the third disjunct, in the $p \in \Theta$ case use the first disjunct, and in the $p \in \Omega$ case use the second disjunct.

For the reverse direction, apply Definition 6.19 to the right-hand membership. The cases are now $p \in \Theta$, $p \in \Omega$, and $p \in \Pi$.

Apply the split theorem again to the left-hand bundle expression. These three cases return respectively the second, third, and first disjuncts of $p \in \Pi$ or $p \in \Theta$ or $p \in \Omega$. □

Theorem 6.22 (Bundle append membership left residual)**.** *For every probe p and bundles Π, Θ, if*

$$p \in \mathsf{BAppend}(\Pi, \Theta)$$

and $p \notin \Theta$, then $p \in \Pi$.

Proof. Induct on Π. In the empty case, appended membership is membership in Θ, contradicting the exclusion premise. In the cons case, either the probe is the head of Π, or it lies in the appended tail. The head branch is immediate, and the tail branch follows from the induction hypothesis with the same exclusion premise. □

Lean4 ✓ `BEDC.FKernel.Bundle.inBundle bundleAppend left of not right`

Theorem 6.23 (Bundle append membership right residual)**.** *For every probe p and bundles Π, Θ, if*

$$p \in \mathsf{BAppend}(\Pi, \Theta)$$

and $p \notin \Pi$, then $p \in \Theta$.

Proof. Induct on Π. In the empty case, appended membership is exactly membership in Θ. In the cons case, head membership contradicts the exclusion premise for Π, while tail membership reduces to the induction hypothesis after restricting the exclusion premise to the tail. □

Lean4 ✓ `BEDC.FKernel.Bundle.inBundle bundleAppend right of not left`

Theorem 6.24 (Bundle-local policy append restriction)**.** *If* $\mathsf{BundleAskPolicy}(\mathsf{BAppend}(\Pi, \Theta), D)$ *holds, then both* $\mathsf{BundleAskPolicy}(\Pi, D)$ *and* $\mathsf{BundleAskPolicy}(\Theta, D)$ *hold.*

Lean4 ✓ `BEDC.FKernel.Ask.bundleAskPolicy append restriction`

Proof. Use Theorem 6.16. A member of Π maps into $\mathsf{BAppend}(\Pi, \Theta)$ through the left disjunct, and a member of Θ maps into $\mathsf{BAppend}(\Pi, \Theta)$ through the right disjunct. Restrict the totality, mark determinacy, and history-respect fields of the appended bundle-local policy along these two membership maps. □

Theorem 6.25 (Bundle-local policy append gluing)**.** *If* $\mathsf{BundleAskPolicy}(\Pi, D)$ *and* $\mathsf{BundleAskPolicy}(\Theta, D)$ *hold, then* $\mathsf{BundleAskPolicy}(\mathsf{BAppend}(\Pi, \Theta), D)$ *holds.*

Lean4 ✓ `BEDC.FKernel.Ask.bundleAskPolicy append gluing`

Proof. Use Theorem 6.16. For each probe membership in $\mathsf{BAppend}(\Pi, \Theta)$, split it into a left membership in Π or a right membership in Θ. In the left case, take totality, determinacy, and history-respect from the policy on Π; in the right case, take the same three fields from the policy on Θ. These case analyses assemble the bundle-local asking policy for the appended bundle. □

Theorem 6.26 (Bundle-local policy append equivalence)**.** *For all probe bundles* Π, Θ *and domain* D*,*

$$\mathsf{BundleAskPolicy}(\mathsf{BAppend}(\Pi, \Theta), D) \iff (\mathsf{BundleAskPolicy}(\Pi, D) \text{ and } \mathsf{BundleAskPolicy}(\Theta, D)).$$

Lean4 ✓ `BEDC.FKernel.Ask.bundleAskPolicy append iff`

Proof. The forward direction is exactly Theorem 6.24. The reverse direction is exactly Theorem 6.25. □

Theorem 6.27 (Bundle-local policy append commutation)**.** *For all probe bundles* Π, Θ *and domain* D*, if*

$$\mathsf{BundleAskPolicy}(\mathsf{BAppend}(\Pi, \Theta), D)$$

holds, then

$$\mathsf{BundleAskPolicy}(\mathsf{BAppend}(\Theta, \Pi), D)$$

holds.

Lean4 ✓ `BEDC.FKernel.Ask.bundleAskPolicy append comm`

Proof. Restrict the appended policy to obtain the two component policies on Π and Θ. Reapply bundle-append gluing in the opposite order, using the same totality, mark determinacy, and history-respect fields on their respective probe memberships. □

Theorem 6.28 (Probe bundle prefix cancellation)**.** *For any fixed probe bundle* Π *and any probe bundles* Θ, Ω*, if*

$$\mathsf{BAppend}(\Pi, \Theta) = \mathsf{BAppend}(\Pi, \Omega),$$

then $\Theta = \Omega$*.*

Lean4 ✓ `BEDC.FKernel.Bundle.bundleAppend prefix cancel`

Proof. Induct on Π. The empty case is immediate because both displayed append terms reduce to their suffix bundles. In the cons case, constructor injectivity reduces the equality of cons bundles to equality of their tails, and the induction hypothesis cancels the remaining common prefix. □

Theorem 6.29 (Probe bundle suffix cancellation)**.** *For any probe bundles* Π, Θ, Ω*, if*

$$\mathsf{BAppend}(\Pi, \Omega) = \mathsf{BAppend}(\Theta, \Omega),$$

then $\Pi = \Theta$*.*

Proof. Induct on Π and then case-split Θ. The empty-empty case is immediate. In the empty-cons and cons-empty cases, Lemma 6.11 rules out equality between a bundle obtained by appending a nonempty prefix to Ω and the suffix Ω. In the cons-cons case, the displayed equality is an equality of cons bundles. Constructor injectivity identifies the two head probes and reduces the tail equality to

$$\mathsf{BAppend}(\Pi_0, \Omega) = \mathsf{BAppend}(\Theta_0, \Omega).$$

The induction hypothesis gives $\Pi_0 = \Theta_0$, and the head equality rebuilds $\Pi = \Theta$. □

Lean4 ✓ `BEDC.FKernel.Bundle.bundleAppend suffix cancel`

Theorem 6.30 (Probe bundle common context cancellation)**.** *For probe bundles* $\Pi, \Theta, \Omega, \Theta'$*, if*

$$\mathsf{BAppend}(\Pi, \mathsf{BAppend}(\Theta, \Omega)) = \mathsf{BAppend}(\Pi, \mathsf{BAppend}(\Theta', \Omega)),$$

then $\Theta = \Theta'$*.*

Proof. First cancel the common left bundle Π by prefix cancellation. The remaining equality has the same suffix Ω on both sides, so suffix cancellation identifies the middle bundles. □

Lean4 ✓ `BEDC.FKernel.Bundle.bundleAppend common context cancel`

Theorem 6.31 (Probe bundle append middle cancellation)**.** *For probe bundles* Π*,* Θ*,* Ω*, and* Λ*, if*

$$\mathsf{BAppend}(\mathsf{BAppend}(\Pi, \Theta), \Lambda) = \mathsf{BAppend}(\mathsf{BAppend}(\Pi, \Omega), \Lambda),$$

then $\Theta = \Omega$*.*

Proof. First cancel the common suffix Λ using probe-bundle suffix cancellation. This leaves equality of $\mathsf{BAppend}(\Pi, \Theta)$ and $\mathsf{BAppend}(\Pi, \Omega)$. Then cancel the common prefix Π using probe-bundle prefix cancellation. □

Lean4 ✓ `BEDC.FKernel.Bundle.bundleAppend middle cancel`

Lemma 6.32 (Probe bundle append empty-result inversion)**.** *For probe bundles* Π, Θ*, if*

$$\mathsf{BAppend}(\Pi, \Theta) = \mathsf{Bnil},$$

then $\Pi = \mathsf{Bnil}$ *and* $\Theta = \mathsf{Bnil}$*.*

Lean4 ✓ `BEDC.FKernel.Bundle.bundleAppend empty result inversion`

Proof. Proceed by cases on Π. In the empty case the displayed equality reduces to $\Theta = \mathsf{Bnil}$. In the cons case the append definition exposes a cons bundle equal to Bnil, contradicting probe-bundle constructor no-confusion. □

Lemma 6.33 (Probe bundle append cons-result inversion)**.** *For probe bundles* Π, Θ, Ω *and probe* π*, if*

$$\mathsf{BAppend}(\Pi, \Theta) = \mathsf{Bcons}(\pi, \Omega),$$

then either $\Pi = \mathsf{Bnil}$ *and* $\Theta = \mathsf{Bcons}(\pi, \Omega)$*, or there exists a bundle* Π_0 *such that* $\Pi = \mathsf{Bcons}(\pi, \Pi_0)$ *and*

$$\mathsf{BAppend}(\Pi_0, \Theta) = \Omega.$$

Proof. Proceed by cases on Π. In the empty case the displayed equality reduces to $\Theta = \mathsf{Bcons}(\pi, \Omega)$, giving the left alternative. In the cons case the append definition exposes a cons bundle on the left; constructor injectivity identifies its head with π and its appended tail with Ω, giving the required tail bundle Π_0. □

Lean4 ✓ `BEDC.FKernel.Bundle.bundleAppend cons result inversion`

Theorem 6.34 (Probe bundle append cons-result iff)**.** *For probe bundles* Π, Θ, Ω *and probe* π*,*

$$\mathsf{BAppend}(\Pi, \Theta) = \mathsf{Bcons}(\pi, \Omega) \iff (\Pi = \mathsf{Bnil} \wedge \Theta = \mathsf{Bcons}(\pi, \Omega)) \vee \exists \Pi_0,\ \Pi = \mathsf{Bcons}(\pi, \Pi_0) \wedge \mathsf{BAppend}(\Pi_0, \Theta$$

Proof. The forward implication is the cons-result inversion lemma. For the converse, split the displayed disjunction. In the empty-prefix case the append computation is exactly the supplied suffix equality. In the cons-prefix case, substitute the displayed prefix and tail equality, then compute the append recursion. □

Lean4 ✓ `BEDC.FKernel.Bundle.bundleAppend cons result iff`

Theorem 6.35 (Probe bundle append split uniqueness at fixed left length)**.** *For probe bundles* $\Pi, \Theta, \Pi', \Theta'$*, if*

$$\mathsf{BAppend}(\Pi, \Theta) = \mathsf{BAppend}(\Pi', \Theta')$$

and

$$\mathsf{BLEN}(\Pi) = \mathsf{BLEN}(\Pi'),$$

then $\Pi = \Pi'$ *and* $\Theta = \Theta'$*.*

Proof. Proceed by simultaneous cases on the two left bundles. The empty-empty case reduces the append equality to the suffix equality $\Theta = \Theta'$. The empty-cons and cons-empty cases contradict the displayed length equality by natural-number constructor no-confusion. In the cons-cons case, constructor injectivity on the append equality identifies the two head probes and gives equality of the appended tails; constructor injectivity on the length equality gives equal tail lengths. The induction hypothesis applied to the tails gives equality of the left tails and suffixes, and the head equality rebuilds $\Pi = \Pi'$. □

Lean4 ✓ `BEDC.FKernel.Bundle.bundleAppend split unique fixed length`

Theorem 6.36 (Bundle member split uniqueness at fixed prefix length)**.** *For probe bundles* $\Pi, \Pi_L, \Pi_R, \Pi'_L, \Pi'_R$ *and probes* p, q*, if*

$$\Pi = \mathsf{BAppend}(\Pi_L, \mathsf{Bcons}(p, \Pi_R)) \quad \textit{and} \quad \Pi = \mathsf{BAppend}(\Pi'_L, \mathsf{Bcons}(q, \Pi'_R))$$

and $\mathsf{BLEN}(\Pi_L) = \mathsf{BLEN}(\Pi'_L)$*, then*

$$\Pi_L = \Pi'_L \quad \textit{and} \quad p = q \quad \textit{and} \quad \Pi_R = \Pi'_R.$$

Proof. Compose the two displayed decompositions into an equality between the two append forms. Fixed-left-length split uniqueness identifies the prefixes and the residual cons suffixes. Constructor injectivity for the residual conses then identifies the exposed probes and right tails. □

Lean4 ✓ `BEDC.FKernel.Bundle.inBundle member split unique fixed prefix length`

Theorem 6.37 (Probe bundle append split uniqueness at fixed suffix length)**.** *For probe bundles* $\Pi, \Theta, \Pi', \Theta'$*, if*

$$\mathsf{BAppend}(\Pi, \Theta) = \mathsf{BAppend}(\Pi', \Theta')$$

and

$$\mathsf{BLEN}(\Theta) = \mathsf{BLEN}(\Theta'),$$

then $\Pi = \Pi'$ *and* $\Theta = \Theta'$*.*

Proof. Apply append length preservation to the displayed equality. The equality of suffix lengths cancels the right summand in the resulting natural-number length identity, giving $\mathsf{BLEN}(\Pi) = \mathsf{BLEN}(\Pi')$. Fixed-left-length split uniqueness then identifies the two prefixes and the two suffixes. □

Lean4 ✓ `BEDC.FKernel.Bundle.bundleAppend split unique fixed suffix length`

Theorem 6.38 (Probe bundle append three-split uniqueness at fixed lengths)**.** *For probe bundles* $\Pi, \Theta, \Omega, \Pi', \Theta', \Omega'$*, if*

$$\mathsf{BAppend}(\Pi, \mathsf{BAppend}(\Theta, \Omega)) = \mathsf{BAppend}(\Pi', \mathsf{BAppend}(\Theta', \Omega'))$$

and $\mathsf{BLEN}(\Pi) = \mathsf{BLEN}(\Pi')$ *and* $\mathsf{BLEN}(\Theta) = \mathsf{BLEN}(\Theta')$*, then* $\Pi = \Pi'$*,* $\Theta = \Theta'$*, and* $\Omega = \Omega'$*.*

Proof. Apply fixed-left-length split uniqueness to the outer append, using the equality of Π and Π' lengths. This identifies the two first segments and leaves equality of the two residual inner appends. Apply the same split uniqueness theorem to those residual appends with the equality of Θ and Θ' lengths, obtaining equality of the middle and final segments. □

Lean4 ✓ `BEDC.FKernel.Bundle.bundleAppend three split unique fixed lengths`

Theorem 6.39 (Bundle append membership commutativity)**.** *For every probe* p *and bundles* Π, Θ*,*

$$p \in \mathsf{BAppend}(\Pi, \Theta) \iff p \in \mathsf{BAppend}(\Theta, \Pi).$$

Proof. For the forward direction, assume $p \in \mathsf{BAppend}(\Pi, \Theta)$. By Definition 6.16, either $p \in \Pi$ or $p \in \Theta$. If $p \in \Pi$, then Definition 6.16 applied to $\mathsf{BAppend}(\Theta, \Pi)$ gives $p \in \mathsf{BAppend}(\Theta, \Pi)$ from the right disjunct. If $p \in \Theta$, it gives the same conclusion from the left disjunct.

For the reverse direction, assume $p \in \mathsf{BAppend}(\Theta, \Pi)$. Again by Definition 6.16, either $p \in \Theta$ or $p \in \Pi$. In the first case, Definition 6.16 applied to $\mathsf{BAppend}(\Pi, \Theta)$ gives membership from the right disjunct; in the second case, it gives membership from the left disjunct. □

Theorem 6.40 (Bundle append Levi residual decomposition)**.** *For probe bundles* $\Pi, \Theta, \Omega, \Lambda$*, if*

$$\mathsf{BAppend}(\Pi, \Theta) = \mathsf{BAppend}(\Omega, \Lambda),$$

then there exists a probe bundle R *such that either*

$$\Omega = \mathsf{BAppend}(\Pi, R) \quad \textit{and} \quad \Theta = \mathsf{BAppend}(R, \Lambda),$$

or

$$\Pi = \mathsf{BAppend}(\Omega, R) \quad \textit{and} \quad \Lambda = \mathsf{BAppend}(R, \Theta).$$

Proof. Induct on Π, keeping Θ, Ω, and Λ arbitrary. If $\Pi = \mathsf{Bnil}$, the displayed equality reduces to

$$\Theta = \mathsf{BAppend}(\Omega, \Lambda).$$

Take $R = \Omega$. The append definition gives $\Omega = \mathsf{BAppend}(\mathsf{Bnil}, R)$, and the reduced equality gives $\Theta = \mathsf{BAppend}(R, \Lambda)$, so the first alternative holds.

Now let $\Pi = \mathsf{Bcons}(\pi, \Pi_0)$, and split on Ω. If $\Omega = \mathsf{Bnil}$, the displayed equality reduces to

$$\mathsf{BAppend}(\mathsf{Bcons}(\pi, \Pi_0), \Theta) = \Lambda.$$

Take $R = \mathsf{Bcons}(\pi, \Pi_0)$. The append definition gives $\Pi = \mathsf{BAppend}(\mathsf{Bnil}, R)$, and the reduced equality gives $\Lambda = \mathsf{BAppend}(R, \Theta)$, so the second alternative holds.

It remains to consider $\Omega = \mathsf{Bcons}(\omega, \Omega_0)$. The displayed equality is then an equality of two cons bundles:

$$\mathsf{Bcons}(\pi, \mathsf{BAppend}(\Pi_0, \Theta)) = \mathsf{Bcons}(\omega, \mathsf{BAppend}(\Omega_0, \Lambda)).$$

Constructor injectivity gives $\pi = \omega$ and

$$\mathsf{BAppend}(\Pi_0, \Theta) = \mathsf{BAppend}(\Omega_0, \Lambda).$$

Apply the induction hypothesis to this tail equality. In the first case, there is a probe bundle R with

$$\Omega_0 = \mathsf{BAppend}(\Pi_0, R) \quad \text{and} \quad \Theta = \mathsf{BAppend}(R, \Lambda).$$

Using $\pi = \omega$ and the append recursion,

$$\Omega = \mathsf{Bcons}(\omega, \Omega_0) = \mathsf{Bcons}(\pi, \mathsf{BAppend}(\Pi_0, R)) = \mathsf{BAppend}(\mathsf{Bcons}(\pi, \Pi_0), R) = \mathsf{BAppend}(\Pi, R),$$

so the first alternative holds for the original equality.

In the second case, there is a probe bundle R with

$$\Pi_0 = \mathsf{BAppend}(\Omega_0, R) \quad \text{and} \quad \Lambda = \mathsf{BAppend}(R, \Theta).$$

Using $\pi = \omega$ and the append recursion,

$$\Pi = \mathsf{Bcons}(\pi, \Pi_0) = \mathsf{Bcons}(\omega, \mathsf{BAppend}(\Omega_0, R)) = \mathsf{BAppend}(\mathsf{Bcons}(\omega, \Omega_0), R) = \mathsf{BAppend}(\Omega, R),$$

so the second alternative holds for the original equality. □

6.2 Signature generation

Definition 6.41 (Signature event)**.** *The signature event* $\mathsf{Sig}(\Pi, h, s, \Delta)$ *means that bundle* Π *applied to history* h *generates answer-history* s *with evidence* Δ*. It is generated by the rules below. In the checked kernel, the logical predicate is the three-place* $\mathsf{SigRel}(\Pi, h, s)$ *on bundle, source history, and answer history. The displayed evidence ledger is a paper-side annotation attached to the generating derivation.*

Lean4 ✓ `BEDC.FKernel.Sig.sig empty constructor`
- ↪ variant `BEDC.FKernel.Sig.sig cons constructor`
- ↪ variant `BEDC.FKernel.Sig.sig cons inversion`
- ↪ variant `BEDC.FKernel.Sig.sig cons result inversion`
- ↪ variant `BEDC.FKernel.Sig.sig cons tail deterministic`
- ↪ variant `BEDC.FKernel.Sig.sigRel cons inversion`
- ↪ variant `BEDC.FKernel.Sig.sigRel generation cases`
- ↪ variant `BEDC.FKernel.Sig.sig empty inversion`

Kernel Rule 6.42 (Empty signature)**.**

$$\frac{}{\mathsf{Sig}(\mathsf{Bnil}, h, \mathsf{e}, \Delta_0)}$$

where Δ_0 *is the neutral signature evidence token.*

Lemma 6.43 (Empty signature inversion)**.** *If* $\mathsf{Sig}(\mathsf{Bnil}, h, r, \Delta_0)$*, then* $\mathsf{hsame}(r, \mathsf{e})$*.*

Lean4 ✓ `BEDC.FKernel.Sig.sig empty inversion`

Proof. Invert the signature derivation. For the empty bundle, only the empty-signature rule applies, so the result history is e. □

Kernel Rule 6.44 (Cons signature)**.** *If*

$$\mathsf{Ask}(\pi, h, m, \delta), \qquad \mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{Ext}(m, s, r),$$

then

$$\mathsf{Sig}(\mathsf{Bcons}(\pi, \Pi), h, r, \delta \star \Delta).$$

Here $\delta \star \Delta$ records the head asking evidence together with the tail derivation ledger; it is not a field of the asking policy.

Theorem 6.45 (Cons signature result is nonempty)**.** *If a cons bundle* $\mathsf{Bcons}(\pi, \Pi)$ *generates a result history r, then r cannot be internally the same as* e.

Proof. Invert the cons signature derivation. The final step is an extension witness $\mathsf{Ext}(m, s, r)$. Each extension constructor produces either an $\mathsf{E0}$ or an $\mathsf{E1}$ result, and BEDC history no-confusion separates both constructors from e. □

Lean4 ✓ `BEDC.FKernel.Sig.sig cons result ne empty`

Theorem 6.46 (Signature result length equals bundle length)**.** *If* $\mathsf{Sig}(\Pi, h, r, \Delta)$*, then the external binary length of the answer history r is the probe-bundle length of* Π.

Lean4 ✓ `BEDC.FKernel.Sig.sigRel result length eq bundleLength`

Proof. Induct on the signature derivation. The empty rule gives zero length on both sides. In the cons rule, the final extension adds exactly one outer history constructor, and the bundle is one cons longer than its tail. □

Theorem 6.47 (Empty signature result forces empty bundle)**.** *If* $\mathsf{Sig}(\Pi, h, \mathsf{e}, \Delta)$*, then* $\Pi = \mathsf{Bnil}$.

Lean4 ✓ `BEDC.FKernel.Sig.sigRel empty result bundle nil`

Proof. The result-length theorem gives bundle length zero because e has zero external binary length. Probe-bundle length zero characterizes Bnil. □

Theorem 6.48 (Signature generation over bundle append)**.** *For probe bundles Π, Θ and source history h, if* $\mathsf{Sig}(\Pi, h, s, \Delta)$ *and* $\mathsf{Sig}(\Theta, h, t, \Gamma)$*, then there exist a history u and evidence Λ such that*

$$\mathsf{Cont}(t, s, u) \quad \textit{and} \quad \mathsf{Sig}(\mathsf{BAppend}(\Pi, \Theta), h, u, \Lambda).$$

Lean4 ✓ `BEDC.FKernel.Sig.signature generation bundle append`

Proof. Induct on Π. In the empty bundle case, empty-signature inversion identifies s with e; take $u = t$, use the right-unit continuation constructor, and reuse the given signature for Θ. In the cons case, invert the left signature. The tail signature for Π and the signature for Θ feed the induction hypothesis, producing a tail result u_0 with $\mathsf{Cont}(t, s_0, u_0)$ and a signature for $\mathsf{BAppend}(\Pi, \Theta)$. Rebuild the cons signature using the original head asking event and the tail signature. The final extension branch supplies either the $\mathsf{E0}$ or $\mathsf{E1}$ continuation step, yielding $\mathsf{Cont}(t, s, u)$ for the rebuilt result. □

Theorem 6.49 (Signature generation append inversion)**.** *For probe bundles Π, Θ and source history h, if* $\mathsf{Sig}(\mathsf{BAppend}(\Pi, \Theta), h, u, \Lambda)$*, then there exist histories s, t and evidence tokens Δ, Γ such that* $\mathsf{Sig}(\Pi, h, s, \Delta)$*,* $\mathsf{Sig}(\Theta, h, t, \Gamma)$*, and* $\mathsf{Cont}(t, s, u)$.

Lean4 ✓ `BEDC.FKernel.Sig.signature generation bundle append inversion`

Proof. Induct on Π. In the empty bundle case, the appended bundle is Θ; generate the empty signature for Bnil, take $s = \mathsf{e}$ and $t = u$, reuse the given signature for Θ, and apply the continuation right-unit constructor. In the cons case, invert the appended cons signature. The inversion exposes the head asking event, the tail signature for $\mathsf{BAppend}(\Pi, \Theta)$, and the final extension witness. Apply the induction hypothesis to the tail append signature to obtain signatures for Π and Θ together with a continuation $\mathsf{Cont}(t, s_0, u_0)$. Rebuild the left cons signature from the exposed head asking event, the recovered tail signature for Π, and the final extension witness. The same extension constructor lifts the recovered tail continuation to $\mathsf{Cont}(t, s, u)$ for the whole appended signature. □

Theorem 6.50 (Signature bundle-append decomposition)**.** *For probe bundles Π, Θ and source history h,*

$$\mathsf{Sig}(\mathsf{BAppend}(\Pi, \Theta), h, u, \Lambda) \iff \exists s, t, \Delta, \Gamma.\ \mathsf{Sig}(\Pi, h, s, \Delta) \wedge \mathsf{Sig}(\Theta, h, t, \Gamma) \wedge \mathsf{Cont}(t, s, u).$$

Lean4 ✓ `BEDC.FKernel.Sig.sigRel bundleAppend decomposition iff`

Proof. The forward implication is append-signature inversion. Conversely, generate the canonical appended signature from the two component signatures. Its continuation has the same displayed endpoints as $\mathsf{Cont}(t, s, u)$, so continuation determinacy identifies the generated result with u. □

Theorem 6.51 (Signature generation append component determinacy)**.** *For probe bundles Π, Θ, domain D, and source history h, assume $\mathsf{BundleAskPolicy}(\Pi, D)$, $\mathsf{BundleAskPolicy}(\Theta, D)$, and $h \in D$. If*

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{Sig}(\Theta, h, t, \Gamma), \qquad \mathsf{Sig}(\mathsf{BAppend}(\Pi, \Theta), h, u, \Lambda),$$

then there exists a history v such that

$$\mathsf{Cont}(t, s, v) \quad \textit{and} \quad \mathsf{hsame}(v, u).$$

Lean4 ✓ `BEDC.FKernel.Sig.signature generation append component determinacy`

Proof. Theorem 6.25 gives $\mathsf{BundleAskPolicy}(\mathsf{BAppend}(\Pi, \Theta), D)$ from the two component policies. Theorem 6.48 applied to the two component signatures produces a history v with $\mathsf{Cont}(t, s, v)$ and a generated signature for the appended bundle. Theorem 6.63, applied to the glued policy, the premise $h \in D$, that constructed appended signature, and the given appended signature for u, gives $\mathsf{hsame}(v, u)$. □

Theorem 6.52 (Signature generation bundle append recomposition determinacy)**.** *For probe bundles Π, Θ, domain D, and source history h, assume an asking policy on D and $h \in D$. If*

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{Sig}(\Theta, h, t, \Gamma), \qquad \mathsf{Cont}(t, s, u),$$

and $\mathsf{Sig}(\mathsf{BAppend}(\Pi, \Theta), h, v, \Lambda)$, then

$$\mathsf{hsame}(u, v).$$

Proof. Generate the canonical appended signature from the two component signatures by Theorem 6.48. Its continuation witness has the same endpoints as the displayed $\mathsf{Cont}(t, s, u)$, so continuation determinacy identifies the displayed recomposition with the canonical result. The asking-policy signature determinacy theorem compares the canonical appended signature with the supplied appended signature for v. Transitivity of hsame gives the displayed result. □

Lean4 ✓ `BEDC.FKernel.Sig.sigRel bundleAppend recompose hsame`

Theorem 6.53 (Three-bundle signature generation coherence)**.** *For probe bundles* Π, Θ, Ω *and source history* h*, assume* $\mathsf{Sig}(\Pi, h, s, \Delta)$*,* $\mathsf{Sig}(\Theta, h, t, \Gamma)$*, and* $\mathsf{Sig}(\Omega, h, w, \Xi)$*. Then there exist histories* a, b, u_L, u_R *and evidence ledgers* $\Lambda_{\Pi\Theta}$*,* Λ_L*,* $\Lambda_{\Theta\Omega}$*, and* Λ_R *such that*

1. $\mathsf{Sig}(\mathsf{BAppend}(\Pi, \Theta), h, a, \Lambda_{\Pi\Theta})$ *and* $\mathsf{Cont}(t, s, a)$*;*
2. $\mathsf{Sig}(\mathsf{BAppend}(\mathsf{BAppend}(\Pi, \Theta), \Omega), h, u_L, \Lambda_L)$ *and* $\mathsf{Cont}(w, a, u_L)$*;*
3. $\mathsf{Sig}(\mathsf{BAppend}(\Theta, \Omega), h, b, \Lambda_{\Theta\Omega})$ *and* $\mathsf{Cont}(w, t, b)$*;*
4. $\mathsf{Sig}(\mathsf{BAppend}(\Pi, \mathsf{BAppend}(\Theta, \Omega)), h, u_R, \Lambda_R)$ *and* $\mathsf{Cont}(b, s, u_R)$*;*
5. $\mathsf{hsame}(u_L, u_R)$*.*

Lean4 ✓ `BEDC.FKernel.Sig.signature generation three bundle coherence`

Proof. Apply Theorem 6.48 to the Π and Θ signatures to obtain a and $\Lambda_{\Pi\Theta}$ with $\mathsf{Cont}(t, s, a)$. Apply the same theorem to the resulting $\mathsf{BAppend}(\Pi, \Theta)$ signature and the Ω signature to obtain u_L and Λ_L with $\mathsf{Cont}(w, a, u_L)$. For the other grouping, first apply Theorem 6.48 to the Θ and Ω signatures to obtain b and $\Lambda_{\Theta\Omega}$ with $\mathsf{Cont}(w, t, b)$, then apply it to the Π signature and the $\mathsf{BAppend}(\Theta, \Omega)$ signature to obtain u_R and Λ_R with $\mathsf{Cont}(b, s, u_R)$. Theorem 4.56, with $h = w$, $k = t$, $l = s$, middle result b, and alternative middle result a, gives $\mathsf{hsame}(u_R, u_L)$. The history-sameness symmetry lemma converts this to the displayed $\mathsf{hsame}(u_L, u_R)$. □

Theorem 6.54 (Signature-sameness closure under bundle append)**.** *For probe bundles* Π, Θ *and histories* h, k*, if* $\mathsf{sameSig}_{\Pi}(h, k)$ *and* $\mathsf{sameSig}_{\Theta}(h, k)$*, then*

$$\mathsf{sameSig}_{\mathsf{BAppend}(\Pi,\Theta)}(h, k).$$

Proof. Unpack the two signature-sameness witnesses. The Π witnesses give signatures from h and k whose answer histories are hsame; the Θ witnesses give another such pair. Apply Theorem 6.48 to the two h-side signatures and separately to the two k-side signatures. Continuation respect for hsame transports the two answer-history sameness witnesses across the appended continuations, so the appended signatures have hsame results. These appended signatures are the witnesses for $\mathsf{sameSig}_{\mathsf{BAppend}(\Pi,\Theta)}(h, k)$. □

Lean4 ✓ `BEDC.FKernel.Sig.sameSig bundleAppend closure`

Theorem 6.55 (Signature-sameness left cancellation under bundle append)**.** *Assume* $\mathsf{BundleAskPolicy}(\Pi, D)$ *and* $h, k \in D$*. If*

$$\mathsf{sameSig}_{\mathsf{BAppend}(\Pi,\Theta)}(h, k)$$

and $\mathsf{sameSig}_{\Pi}(h, k)$*, then*

$$\mathsf{sameSig}_{\Theta}(h, k).$$

Proof. Invert the appended signature-sameness witnesses using Theorem 6.49. This recovers Π signatures, Θ signatures, and continuation witnesses on the h and k sides. Compare the recovered left Π signatures with the witnesses from $\mathsf{sameSig}_{\Pi}(h, k)$ using Theorem 6.63 at h and at k. Transport one continuation along that left-result sameness. The common right continuation can then be cancelled against the appended result-sameness, yielding hsame for the recovered Θ results. Those recovered Θ signatures are the witnesses for $\mathsf{sameSig}_{\Theta}(h, k)$. □

Lean4 ✓ `BEDC.FKernel.Sig.sameSig bundleAppend left cancellation`

Theorem 6.56 (Signature-sameness right cancellation under bundle append)**.** *Assume* $\mathsf{BundleAskPolicy}(\Theta, D)$ *and* $h, k \in D$*. If*

$$\mathsf{sameSig}_{\mathsf{BAppend}(\Pi,\Theta)}(h, k)$$

and $\mathsf{sameSig}_{\Theta}(h, k)$*, then*

$$\mathsf{sameSig}_{\Pi}(h, k).$$

Proof. Invert the appended signature-sameness witnesses using Theorem 6.49. This recovers Π signatures, Θ signatures, and continuation witnesses on the h and k sides. Compare the recovered Θ signatures with the supplied witnesses from $\mathsf{sameSig}_{\Theta}(h, k)$ using Theorem 6.63 at h and at k. Determinacy for the supplied and recovered Θ signatures gives hsame between the two recovered Θ continuation contexts. Continuation result transport then aligns one continuation so both continuations have the same left context and the same result up to hsame. The left-context cancellation clause of Theorem 4.52 applies to these aligned continuations and yields hsame for the recovered Π results. Those recovered Π signatures are the witnesses for $\mathsf{sameSig}_{\Pi}(h, k)$. □

Lean4 ✓ `BEDC.FKernel.Sig.sameSig bundleAppend right cancellation`

Theorem 6.57 (Known component residual for signature-sameness under bundle append)**.** *For probe bundles* Π, Θ *and histories* h, k*, the following residual equivalences hold.*

1. *If* $\mathsf{BundleAskPolicy}(\Pi, D)$*,* $h, k \in D$*, and* $\mathsf{sameSig}_{\Pi}(h, k)$*, then*

$$\mathsf{sameSig}_{\mathsf{BAppend}(\Pi,\Theta)}(h, k) \iff \mathsf{sameSig}_{\Theta}(h, k).$$

2. *If* $\mathsf{BundleAskPolicy}(\Theta, D)$*,* $h, k \in D$*, and* $\mathsf{sameSig}_{\Theta}(h, k)$*, then*

$$\mathsf{sameSig}_{\mathsf{BAppend}(\Pi,\Theta)}(h, k) \iff \mathsf{sameSig}_{\Pi}(h, k).$$

Proof. For the first equivalence, the forward direction is Theorem 6.55, using the known Π component and the bundle-local policy on Π. The reverse direction combines the known $\mathsf{sameSig}_{\Pi}(h, k)$ with the supplied $\mathsf{sameSig}_{\Theta}(h, k)$ by Theorem 6.54. The second equivalence is symmetric: its forward direction is Theorem 6.56, and its reverse direction is again the append closure theorem. □

Lean4 ✓ `BEDC.FKernel.Sig.sameSig bundleAppend residual iff`

Theorem 6.58 (Signature-sameness common-context residual under bundle append)**.** *Assume* $\mathsf{BundleAskPolicy}(\Pi, D)$*,* $\mathsf{BundleAskPolicy}(\Omega, D)$*,* $h, k \in D$*,* $\mathsf{sameSig}_{\Pi}(h, k)$*, and* $\mathsf{sameSig}_{\Omega}(h, k)$*. Then*

$$\mathsf{sameSig}_{\mathsf{BAppend}(\Pi,\mathsf{BAppend}(\Theta,\Omega))}(h, k) \iff \mathsf{sameSig}_{\Theta}(h, k).$$

Proof. For the forward direction, cancel the known left component Π from the outer append using the residual equivalence, leaving $\mathsf{sameSig}_{\mathsf{BAppend}(\Theta,\Omega)}(h, k)$. Then cancel the known right component Ω using the right residual equivalence, yielding $\mathsf{sameSig}_{\Theta}(h, k)$.

For the reverse direction, first append the supplied middle witness with the known right witness $\mathsf{sameSig}_{\Omega}(h, k)$, then append the known left witness $\mathsf{sameSig}_{\Pi}(h, k)$ to rebuild the full common-context signature-sameness row. □

Lean4 ✓ `BEDC.FKernel.Sig.sameSig bundleAppend common context iff`

Theorem 6.59 (Cons tail signatures from result-sameness)**.** *If two derivations of* $\mathsf{Sig}(\mathsf{Bcons}(\pi, \Pi), h, r, \Delta)$ *and* $\mathsf{Sig}(\mathsf{Bcons}(\pi, \Pi), h, r', \Theta)$ *have* $\mathsf{hsame}(r, r')$*, then there exist tail results* s, t *such that* $\mathsf{Sig}(\Pi, h, s, \Delta_s)$*,* $\mathsf{Sig}(\Pi, h, t, \Delta_t)$*, and* $\mathsf{hsame}(s, t)$*.*

Lean4 ✓ `BEDC.FKernel.Sig.sig cons tail hsame from result hsame`

Proof. Invert both cons-signature derivations and their final extension witnesses. Cross-mark extension branches contradict result-sameness by history no-confusion, while matching marks expose matching outer history constructors; constructor injectivity yields hsame of the tail results. □

Theorem 6.60 (Cons head mark determinacy)**.** *Assume an asking policy on D. If $h \in D$ and two cons-signature derivations for* $\mathsf{Bcons}(\pi, \Pi)$ *start from the same source history h, then their head asking events emit internally same marks.*

Lean4 ✓ `BEDC.FKernel.Sig.sig cons head mark determinacy`

↪ variant `BEDC.FKernel.Sig.sig cons head marks same`
↪ variant `BEDC.FKernel.Sig.sig cons result hsame from policy`
↪ variant `BEDC.FKernel.Sig.sig cons tail hsame from policy`
↪ variant `BEDC.FKernel.Sig.sig cons policy result and tail`
↪ variant `BEDC.FKernel.Sig.sig cons head tail determinacy`
↪ variant `BEDC.FKernel.Sig.signature cons head mark determinacy`
↪ variant `BEDC.FKernel.Sig.sig cons witnesses and result hsame from policy`
↪ variant `BEDC.FKernel.Sig.sig cons head mark determinacy pair`

Proof. Invert both cons-signature derivations. Their head premises are asking events for the same probe and source history. Asking-policy determinacy gives internal sameness of the emitted marks, while the tail signature witnesses are retained from the two inverted derivations. □

Theorem 6.61 (Signature existence under an asking policy)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$*. If h is admitted by D, then bundle Π generates some signature event from h.*

Lean4 ✓ `BEDC.FKernel.Sig.sig total from policy`

↪ variant `BEDC.FKernel.Sig.signature totality under policy`
↪ variant `BEDC.FKernel.Sig.sigTotalOn from policy`
↪ variant `BEDC.FKernel.Sig.sigTotalOn tail of cons`
↪ variant `BEDC.FKernel.Sig.sigTotalOn cons iff`
↪ variant `BEDC.FKernel.Sig.sig total pair from policy`
↪ variant `BEDC.FKernel.Sig.sig total unique from policy`
↪ variant `BEDC.FKernel.Sig.sig total unique pair from policy`

Proof. Induct on the generated bundle Π. The empty bundle produces the empty answer-history. In the cons case, asking-policy totality supplies the first emitted mark and evidence token; the induction hypothesis supplies the tail signature; the emitted mark chooses the corresponding extension constructor. □

Theorem 6.62 (Bundle-local signature existence)**.** *Assume* $\mathsf{BundleAskPolicy}(\Pi, D)$*. If $h \in D$, then there are an answer history s and evidence bundle Δ such that* $\mathsf{Sig}(\Pi, h, s, \Delta)$*.*

Proof. Induct on Π. The empty bundle emits the empty signature. In the cons case, the head occurrence satisfies $\pi \in \mathsf{Bcons}(\pi, \Pi)$, so bundle-local totality supplies the head asking event. The tail policy is obtained by restricting membership from $\rho \in \Pi$ to $\rho \in \mathsf{Bcons}(\pi, \Pi)$, and the induction hypothesis supplies the tail signature. The emitted head mark then selects the matching extension constructor. □

Lean4 ✓ `BEDC.FKernel.Sig.sig total from bundle policy`

Theorem 6.63 (Bundle-local signature determinacy)**.** *Assume* $\mathsf{BundleAskPolicy}(\Pi, D)$*. If* $h \in D$ *and*

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{Sig}(\Pi, h, t, \Theta),$$

then $\mathsf{hsame}(s, t)$*.*

Lean4 ✓ `BEDC.FKernel.Sig.sig deterministic from bundle policy`

Proof. Induct on Π. The empty case is reflexive. In the cons case, invert the two signature derivations. Bundle-local mark determinacy applies to the shared head occurrence, and the tail policy follows from tail membership. The induction hypothesis gives sameness of the tail results, and extension respect combines the head mark-sameness with the tail history-sameness. □

Theorem 6.64 (Bundle-local signature source respect)**.** *Assume* $\mathsf{BundleAskPolicy}(\Pi, D)$*. If* $\mathsf{hsame}(h, k)$ *and*

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{Sig}(\Pi, k, t, \Theta),$$

then $\mathsf{hsame}(s, t)$*.*

Lean4 ✓ `BEDC.FKernel.Sig.sig respects history from bundle policy`

Proof. Induct on Π. The empty case gives empty signatures on both sides. In the cons case, invert both signature derivations. Apply the bundle-local source-history respect field to the shared head occurrence and the premise $\mathsf{hsame}(h, k)$. The tail policy is obtained by restricting bundle membership, and the induction hypothesis applies to the two tail signatures. Extension respect combines the head mark-sameness with the tail history-sameness. □

Theorem 6.65 (Bundle-local history-sameness gives signature-sameness)**.** *Assume* $\mathsf{BundleAskPolicy}(\Pi, D)$*. If* $h, k \in D$ *and* $\mathsf{hsame}(h, k)$*, then* $\mathsf{sameSig}_\Pi(h, k)$*.*

Proof. Apply bundle-local signature existence to h and to k, obtaining generated signatures

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{Sig}(\Pi, k, t, \Theta).$$

Bundle-local signature source respect transports the premise $\mathsf{hsame}(h, k)$ across these two generated signatures and yields $\mathsf{hsame}(s, t)$. The two signature witnesses together with this generated-history sameness form $\mathsf{sameSig}_\Pi(h, k)$. □

Lean4 ✓ `BEDC.FKernel.Sig.bundle local sameSig of hsame`

Theorem 6.66 (Bundle-local signature-sameness equivalence)**.** *Assume* $\mathsf{BundleAskPolicy}(\Pi, D)$*. If* $h \in D$*, then* $\mathsf{sameSig}_\Pi(h, h)$*; if* $\mathsf{sameSig}_\Pi(h, k)$*, then* $\mathsf{sameSig}_\Pi(k, h)$*; and if* $k \in D$*,* $\mathsf{sameSig}_\Pi(h, k)$*, and* $\mathsf{sameSig}_\Pi(k, l)$*, then* $\mathsf{sameSig}_\Pi(h, l)$*.*

Proof. For reflexivity, bundle-local signature existence gives a signature generated from the admitted history h, and hsame-reflexivity relates that generated answer history to itself. For symmetry, unpack the two signature witnesses, swap their order, and apply hsame-symmetry. For transitivity through k, unpack both signature-sameness hypotheses. The admitted middle history k has two generated signature results; bundle-local signature determinacy identifies them by hsame. Composing with hsame-transitivity connects the left answer history to the right answer history, yielding $\mathsf{sameSig}_\Pi(h, l)$. □

Lean4 ✓ `BEDC.FKernel.Sig.bundle local signature sameness equivalence`

Theorem 6.67 (Signature determinacy under an asking policy)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$*. If* h *is admitted by* D *and*

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{Sig}(\Pi, h, t, \Theta),$$

then $\mathsf{hsame}(s, t)$*.*

Lean4 ✓ `BEDC.FKernel.Sig.sig deterministic`
↪ variant `BEDC.FKernel.Sig.sig cons determinacy spine`

Proof. Induct on the generated bundle Π. The empty case uses reflexivity of hsame. In the cons case, asking determinacy gives msame of the first emitted marks. The induction hypothesis gives hsame of the tail signatures. Extension respects mark-sameness and history-sameness, so the resulting answer histories are hsame. □

Theorem 6.68 (Signature generation respects source history-sameness)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$*. If* $\mathsf{hsame}(h, k)$*,*

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{Sig}(\Pi, k, t, \Theta),$$

then $\mathsf{hsame}(s, t)$*.*

Lean4 ✓ `BEDC.FKernel.Sig.sig respects history`

Proof. Induct on Π. The empty case follows by reflexivity. In the cons case, invert the two signature derivations. Asking-policy history-respect transports the head asking events across $\mathsf{hsame}(h, k)$, the induction hypothesis transports the tail signatures, and extension respect combines the resulting mark-sameness and history-sameness for the generated histories. □

Lemma 6.69 (Continuation fixed-length split uniqueness)**.** *Let* s, s', t, t', u, u' *be histories. Suppose*

$$\mathsf{Cont}(t, s, u), \qquad \mathsf{Cont}(t', s', u'), \qquad \mathsf{hsame}(u, u').$$

If s *and* s' *have the same external binary length, then*

$$\mathsf{hsame}(s, s') \quad \textit{and} \quad \mathsf{hsame}(t, t').$$

Proof. Induct simultaneously on the generated histories s and s'. In the empty-empty branch, both continuation witnesses are right-unit witnesses from Definition 4.10, so the displayed result sameness gives $\mathsf{hsame}(t, t')$, while $\mathsf{hsame}(s, s')$ is reflexive. The empty-visible and visible-empty branches contradict equality of the external binary lengths by natural-number constructor no-confusion. In matching visible branches, inversion of the two continuation witnesses exposes matching visible outer constructors on u and u'. Constructor injectivity reduces the displayed result sameness to the two tail continuation results, and successor injectivity reduces the length equality to the tail lengths. The induction hypothesis gives sameness of the visible tails and of t with t', and the same visible constructor rebuilds $\mathsf{hsame}(s, s')$. Opposite visible branches contradict history constructor no-confusion at the result comparison. □

Theorem 6.70 (Signature-sameness exact split under bundle append)**.** *For probe bundles* Π, Θ *and histories* h, k*, if*

$$\mathsf{sameSig}_{\mathsf{BAppend}(\Pi,\Theta)}(h, k),$$

then

$$\mathsf{sameSig}_{\Pi}(h, k) \quad \textit{and} \quad \mathsf{sameSig}_{\Theta}(h, k).$$

Proof. Unpack the appended signature-sameness witness. It gives appended signatures from h and from k with answer histories u_h and u_k satisfying $\mathsf{hsame}(u_h, u_k)$. Apply Definition 6.49 to the appended signature from h. This recovers histories s_h, t_h and evidence ledgers with

$$\mathsf{Sig}(\Pi, h, s_h, \Delta_h), \qquad \mathsf{Sig}(\Theta, h, t_h, \Gamma_h), \qquad \mathsf{Cont}(t_h, s_h, u_h).$$

Apply the same inversion to the appended signature from k, recovering histories s_k, t_k with

$$\mathsf{Sig}(\Pi, k, s_k, \Delta_k), \qquad \mathsf{Sig}(\Theta, k, t_k, \Gamma_k), \qquad \mathsf{Cont}(t_k, s_k, u_k).$$

By Definition 6.46, the two Π results s_h and s_k both have external binary length $\mathsf{BLEN}(\Pi)$. Hence they have the same external binary length. The fixed-length continuation split lemma applied to the two displayed continuation witnesses and to $\mathsf{hsame}(u_h, u_k)$ yields

$$\mathsf{hsame}(s_h, s_k) \quad \text{and} \quad \mathsf{hsame}(t_h, t_k).$$

The recovered Π signatures together with $\mathsf{hsame}(s_h, s_k)$ are exactly a witness for $\mathsf{sameSig}_\Pi(h, k)$, and the recovered Θ signatures together with $\mathsf{hsame}(t_h, t_k)$ are exactly a witness for $\mathsf{sameSig}_\Theta(h, k)$. □

Theorem 6.71 (Three-bundle signature cut inversion)**.** *For probe bundles Π, Θ, Ω, source history h, and a bundle A with*

$$A = \mathsf{BAppend}(\Pi, \mathsf{BAppend}(\Theta, \Omega)),$$

if

$$\mathsf{Sig}(A, h, u, \Lambda),$$

then there exist histories s, t, w, b, u' and evidence ledgers Δ, Γ, Ξ such that

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{Sig}(\Theta, h, t, \Gamma), \qquad \mathsf{Sig}(\Omega, h, w, \Xi),$$

$$\mathsf{Cont}(w, t, b), \qquad \mathsf{Cont}(b, s, u'), \qquad \mathsf{hsame}(u, u').$$

Proof. Apply Definition 6.49 to the given signature for the outer append $A = \mathsf{BAppend}(\Pi, \mathsf{BAppend}(\Theta, \Omega))$. This gives histories s and b, together with evidence ledgers Δ and Ψ, and a bundle B with

$$B = \mathsf{BAppend}(\Theta, \Omega),$$

such that

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{Sig}(B, h, b, \Psi), \qquad \mathsf{Cont}(b, s, u).$$

Apply the same append-inversion theorem to the recovered signature for $B = \mathsf{BAppend}(\Theta, \Omega)$. This gives histories t and w, together with evidence ledgers Γ and Ξ, such that

$$\mathsf{Sig}(\Theta, h, t, \Gamma), \qquad \mathsf{Sig}(\Omega, h, w, \Xi), \qquad \mathsf{Cont}(w, t, b).$$

Take $u' = u$. The displayed outer continuation is then exactly $\mathsf{Cont}(b, s, u')$, and $\mathsf{hsame}(u, u')$ follows by reflexivity of history-sameness. These witnesses are the displayed three component signatures and the two continuation cuts. □

Theorem 6.72 (Signature empty-result iff empty bundle)**.** *If $\mathsf{Sig}(\Pi, h, r, \Delta)$, then*

$$\mathsf{hsame}(r, \mathsf{e}) \iff \Pi = \mathsf{Bnil}.$$

Proof. For the forward implication, assume $\mathsf{hsame}(r, \mathsf{e})$ and classify the bundle Π. The empty-bundle case is immediate. In the cons case, write $\Pi = \mathsf{Bcons}(\pi, \Pi_0)$. The given signature premise is then a cons-bundle signature for result r, so Definition 6.45 rules out $\mathsf{hsame}(r, \mathsf{e})$, a contradiction. Hence the cons case is impossible and $\Pi = \mathsf{Bnil}$.

For the reverse implication, assume $\Pi = \mathsf{Bnil}$ and substitute this into the signature premise. Inverting the resulting empty-bundle signature leaves only the empty-signature rule, so the produced result history is internally the same as e, exactly as in Definition 6.43. □

Theorem 6.73 (Duplicate-probe signature contraction obstruction)**.** *For every probe π, probe bundle Π, source history h, and result histories r, s, if*

$$\mathsf{Sig}(\mathsf{Bcons}(\pi, \mathsf{Bcons}(\pi, \Pi)), h, r, \Delta) \qquad \textit{and} \qquad \mathsf{Sig}(\mathsf{Bcons}(\pi, \Pi), h, s, \Gamma),$$

then

$$\neg\, \mathsf{hsame}(r, s).$$

Proof. Apply Definition 6.46 to the two displayed signature derivations. The first result has external binary length $\mathsf{BLEN}(\mathsf{Bcons}(\pi, \mathsf{Bcons}(\pi, \Pi))) = 2 + \mathsf{BLEN}(\Pi)$, while the second has external binary length $\mathsf{BLEN}(\mathsf{Bcons}(\pi, \Pi)) = 1 + \mathsf{BLEN}(\Pi)$ by Definition 6.3. If $\mathsf{hsame}(r, s)$ held, the internal equality reading of history-sameness would identify the two generated histories and therefore identify their external binary lengths. This would force

$$2 + \mathsf{BLEN}(\Pi) = 1 + \mathsf{BLEN}(\Pi),$$

contradicting natural-number successor no-confusion. Hence the two generated signature histories cannot be internally history-same. □

Theorem 6.74 (Signature append cut decomposition uniqueness)**.** *For probe bundles Π, Θ, A, domain D, and source history h, assume $A = \mathsf{BAppend}(\Pi, \Theta)$, $\mathsf{BundleAskPolicy}(\Pi, D)$, $\mathsf{BundleAskPolicy}(\Theta, D)$, and $h \in D$. If*

$$\mathsf{Sig}(A, h, u, \Lambda)$$

has two append-inversion decompositions

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{Sig}(\Theta, h, t, \Gamma), \qquad \mathsf{Cont}(t, s, u),$$

and

$$\mathsf{Sig}(\Pi, h, s', \Delta'), \qquad \mathsf{Sig}(\Theta, h, t', \Gamma'), \qquad \mathsf{Cont}(t', s', u),$$

then

$$\mathsf{hsame}(s, s') \quad \textit{and} \quad \mathsf{hsame}(t, t').$$

Proof. The displayed rows are two decompositions of the same appended signature, but component uniqueness is local to the two recovered bundles. Apply Definition 6.63 to the policy $\mathsf{BundleAskPolicy}(\Pi, D)$, the admitted source history $h \in D$, and the two recovered Π signatures

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{Sig}(\Pi, h, s', \Delta').$$

This gives $\mathsf{hsame}(s, s')$. Apply the same determinacy theorem to the policy $\mathsf{BundleAskPolicy}(\Theta, D)$, the same admitted source history, and the two recovered Θ signatures

$$\mathsf{Sig}(\Theta, h, t, \Gamma), \qquad \mathsf{Sig}(\Theta, h, t', \Gamma').$$

This gives $\mathsf{hsame}(t, t')$. The appended signature premise, together with $A = \mathsf{BAppend}(\Pi, \Theta)$ and the two continuation witnesses, certifies that both pairs are append-inversion cuts of the same event; the two component comparisons follow from bundle-local determinacy on the fixed source. □

6.3 Signature sameness

Definition 6.75 (Signature-sameness)**.** *Given a bundle* Π*, histories* h, k *are signature-same, written* $\mathsf{sameSig}_\Pi(h, k)$*, if there exist generated signatures*

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{Sig}(\Pi, k, t, \Theta),$$

such that $\mathsf{hsame}(s, t)$*.*

↪ variant BEDC.FKernel.Sig.signature sameness equivalence total determinacy
↪ variant BEDC.FKernel.Sig.sameSig equivalence witness pack
↪ variant BEDC.FKernel.Sig.sameSig equivalence explicit witnesses

Proof. For an admitted h, policy totality produces a generated signature for h, and hsame-reflexivity gives $\mathsf{sameSig}_\Pi(h, h)$. Symmetry reverses the two signature witnesses and uses hsame-symmetry, with no admission hypothesis. For transitivity through k, unpack the two signature-sameness witnesses. They contain two generated signatures from the admitted middle history k. Signature determinacy under $\mathsf{AskPolicy}(\Pi, D)$ and $k \in D$ relates those two middle results; two applications of hsame-transitivity then connect a signature of h with a signature of l. □

Theorem 6.79 (Signature-sameness endpoint replacement)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$*. If* $h, h', k, k' \in D$*,* $\mathsf{hsame}(h, h')$*,* $\mathsf{sameSig}_\Pi(h, k)$*, and* $\mathsf{hsame}(k, k')$*, then*

$$\mathsf{sameSig}_\Pi(h', k').$$

Proof. By Theorem 6.77, the left endpoint hypothesis gives $\mathsf{sameSig}_\Pi(h, h')$, and the right endpoint hypothesis gives $\mathsf{sameSig}_\Pi(k, k')$. Symmetry from Theorem 6.78 turns the first relation into $\mathsf{sameSig}_\Pi(h', h)$. Transitivity through the middle h yields $\mathsf{sameSig}_\Pi(h', k)$, and transitivity through the middle k yields $\mathsf{sameSig}_\Pi(h', k')$. □

↪ variant BEDC.FKernel.Sig.sameSig endpoint replacement under policy

Chapter 7

Packages and Package Policies

Definition 7.1 (Package token and package-sameness)**.** Pkg *is a judgment*

$$\mathsf{Pkg}(\Pi, s, p)$$

meaning that answer-history s under bundle Π is represented by package token p. The internal package-sameness judgment is $\mathsf{psame}(p, q)$*.*

Lean4 ✓ `BEDC.FKernel.Package.package token and psame generated pair`

Definition 7.2 (Package policy)**.** *A package policy* $\mathsf{PackagePolicy}(\Pi)$ *consists of the following certified fields:*

1. *existence: each generated answer-history s has a package token p with* $\mathsf{Pkg}(\Pi, s, p)$*;*
2. *extensionality: if* $\mathsf{hsame}(s, t)$*,* $\mathsf{Pkg}(\Pi, s, p)$*, and* $\mathsf{Pkg}(\Pi, t, q)$*, then* $\mathsf{psame}(p, q)$*;*
3. *grounding: if* $\mathsf{psame}(p, q)$*, then there are answer histories s, t with* $\mathsf{Pkg}(\Pi, s, p)$*,* $\mathsf{Pkg}(\Pi, t, q)$*, and* $\mathsf{hsame}(s, t)$*;*
4. *visibility: only the package token and its ledger are visible at the package interface.*

Theorem 7.3 (Packages classify signatures)**.** *Under* $\mathsf{PackagePolicy}(\Pi)$*, if* $\mathsf{Pkg}(\Pi, s, p)$ *and* $\mathsf{Pkg}(\Pi, t, q)$*, then* $\mathsf{hsame}(s, t)$ *implies* $\mathsf{psame}(p, q)$*. Conversely, if* $\mathsf{psame}(p, q)$*, then there exist answer histories u, v such that* $\mathsf{Pkg}(\Pi, u, p)$*,* $\mathsf{Pkg}(\Pi, v, q)$*, and* $\mathsf{hsame}(u, v)$*.*

Lean4 ✓ `BEDC.FKernel.Package.packagePolicy classifies signature witnesses`

Proof. The first direction is the extensionality field. The second direction is the grounding field. □

Theorem 7.4 (Package representative for generated answer-history)**.** *Assume* $\mathsf{PackagePolicy}(\Pi)$*. For every generated answer-history s, there exists a package token p such that* $\mathsf{Pkg}(\Pi, s, p)$ *and, for every answer-history t and package token q, if* $\mathsf{hsame}(s, t)$ *and* $\mathsf{Pkg}(\Pi, t, q)$*, then* $\mathsf{psame}(p, q)$*.*

Proof. Let s be a generated answer-history. The existence field of $\mathsf{PackagePolicy}(\Pi)$ supplies a package token p with $\mathsf{Pkg}(\Pi, s, p)$. It remains to verify the displayed universal property. Let t and q be such that $\mathsf{hsame}(s, t)$ and $\mathsf{Pkg}(\Pi, t, q)$. Applying the first direction of Definition 7.3 to $\mathsf{Pkg}(\Pi, s, p)$, $\mathsf{Pkg}(\Pi, t, q)$, and $\mathsf{hsame}(s, t)$ gives $\mathsf{psame}(p, q)$. □

Chapter 8

Gap Policies, Coverage, Separation, and Composition

8.1 Gap policy

Definition 8.1 (Gap membership)**.** *The finite-kernel judgment* $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$ *means that source history* h *lies in the signature gap ledger of package token* p *under bundle* Π *and source specification* D*.*

Definition 8.2 (Gap policy)**.** *A gap policy* $\mathsf{GapPolicy}(\Pi, D)$ *over source specification* D *consists of:*

1. *provenance/generation: the membership judgment* $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$ *itself exposes the admitted-source judgment* $\mathsf{InDom}(D, h)$ *and witnesses* s, Δ *with* $\mathsf{Sig}(\Pi, h, s, \Delta)$ *and* $\mathsf{TokIntro}(\Pi, s, p)$*; the generation field of* $\mathsf{GapPolicy}(\Pi, D)$ *records the token-witness projection from such a membership to some* s *with* $\mathsf{TokIntro}(\Pi, s, p)$*;*
2. *coverage: every admitted source history belongs to some package gap;*
3. *separation: if the same admitted source history belongs to the gaps of* p *and* q*, then* $\mathsf{psame}(p, q)$*.*

The ledger remains part of the package interface: a visible package token is used together with its gap ledger, but ledger visibility is not a separate component of $\mathsf{GapPolicy}(\Pi, D)$*.*

↪ variant `BEDC.FKernel.Gap.gapPolicy generation field`
↪ variant `BEDC.FKernel.Gap.gapPolicy signature determination`
↪ variant `BEDC.FKernel.Gap.GapPolicyInterface generation projection`

Theorem 8.3 (Gap coverage)**.** *Assume* $\mathsf{GapPolicy}(\Pi, D)$*. For every source history* h*, if* $\mathsf{InDom}(D, h)$ *then there exists a package token* p *such that* $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$*.*

Lean4 ✓ `BEDC.FKernel.Gap.gap coverage`

Proof. This is the coverage field of GapPolicy, which directly supplies a package token whose finite-kernel gap judgment contains the admitted source history. □

Theorem 8.4 (Gap separation)**.** *Assume* $\mathsf{GapPolicy}(\Pi, D)$*. If* $\mathsf{InDom}(D, h)$*,* $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$*, and* $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, h)$*, then* $\mathsf{psame}(p, q)$*.*

Lean4 ✓ `BEDC.FKernel.Gap.gap separation`

Proof. This is the separation field of GapPolicy, applied to the two finite-kernel gap memberships of the same admitted source history. □

Theorem 8.5 (Gap separation from memberships)**.** *Assume* $\mathsf{GapPolicy}(\Pi, D)$*. If* $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$ *and* $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, h)$*, then* $\mathsf{psame}(p, q)$*.*

Lean4 ✓ `BEDC.FKernel.Gap.gap separation from memberships`

Proof. Either finite-kernel gap membership exposes the admitted-source judgment $\mathsf{InDom}(D, h)$ by the membership definition recorded in Definition 8.2. Apply Theorem 8.4 to this admitted-source witness and to the two memberships over the same source history h. □

Theorem 8.6 (Gap representative for admitted source)**.** *Assume* $\mathsf{GapPolicy}(\Pi, D)$ *and* $\mathsf{InDom}(D, h)$*. Then there exists a package token* p *such that* $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$ *and, for every package token* q*, if* $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, h)$ *then* $\mathsf{psame}(p, q)$*.*

Proof. Coverage supplies a package token p with $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$. For any package token q with $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, h)$, separation applies to the two finite-kernel gap memberships over the same admitted source history h and gives $\mathsf{psame}(p, q)$. □

Lean4 ✓ `BEDC.FKernel.Gap.gap representative for admitted source`

8.2 Composite gaps

Definition 8.7 (Composite gap)**.** *Suppose an interface* C *packages sources into intermediate visible tokens and an interface* D *packages those intermediate tokens into final visible tokens. The composite gap judgment*

$$\mathsf{CompGap}_{D \circ C}(z, x)$$

means that source x *lies behind final visible token* z *through some intermediate token. Externally this is described by the existence of an intermediate token* y *with*

$$\mathsf{InGap}_C(y, x) \quad \textit{and} \quad \mathsf{InGap}_D(z, y).$$

This is a metalanguage description of the composite ledger policy.

Lean4 (definition) `BEDC.FKernel.Gap.CompGap`

↪ variant  BEDC.FKernel.Gap.compGap second first witness
↪ variant  BEDC.FKernel.Gap.compGap right nested witnesses
```

Theorem 8.8 (Composite gap coverage)**.** *If the first interface has gap coverage in the form that every admitted source h has an intermediate token y with* $\mathsf{InGap}_C(y, h)$ *and an admissibility certificate* $\mathsf{InterOk}(y)$*, and if the second interface has gap coverage for every intermediate token satisfying* $\mathsf{InterOk}$*, then the composite interface has gap coverage.*

```
Lean4 ✓  BEDC.FKernel.Gap.compGap coverage from layers
↪ variant  BEDC.FKernel.Gap.compGap composite coverage witness
↪ variant  BEDC.FKernel.Gap.composite gap coverage spine
↪ variant  BEDC.FKernel.Gap.compGap coverage intermediate and final
↪ variant  BEDC.FKernel.Gap.compGap coverage with intermediate ok
↪ variant  BEDC.FKernel.Gap.compGap coverage final witness pair
```

Proof. Given an admitted source, first coverage supplies both an intermediate token whose first gap contains the source and the admissibility certificate for that intermediate token. Second coverage applies to that certificate and produces a final token whose second gap contains the intermediate token. Thus the source belongs to the composite gap of the final token. □

Theorem 8.9 (Composite gap separation)**.** *If the first gap separates two intermediate witnesses over the same source by* $\mathsf{interSame}$*, and the second gap sends* $\mathsf{interSame}$ *intermediate witnesses to* $\mathsf{finalSame}$ *final tokens, then two composite memberships over the same source imply* $\mathsf{finalSame}(z_1, z_2)$*.*

```
Lean4 ✓  BEDC.FKernel.Gap.compGap separation from layers
```

Proof. Unpack the first composite membership into an intermediate witness y_1 with $\mathsf{InGap}_C(y_1, h)$ and $\mathsf{InGap}_D(z_1, y_1)$. Unpack the second composite membership into y_2 with $\mathsf{InGap}_C(y_2, h)$ and $\mathsf{InGap}_D(z_2, y_2)$. First-layer separation gives $\mathsf{interSame}(y_1, y_2)$, and second-layer separation carries this relation across the two second-layer memberships to obtain $\mathsf{finalSame}(z_1, z_2)$. □

Theorem 8.10 (Composite exactness from layered exactness)**.** *Let* Source*,* Inter*, and* Final *be the source, intermediate, and final token types. Let* $\mathsf{SourceOk}$ *and* $\mathsf{InterOk}$ *be admissibility predicates, let* $\mathsf{firstGap}$ *and* $\mathsf{secondGap}$ *be the first and second gap relations, and let* $\mathsf{interSame}$ *and* $\mathsf{finalSame}$ *be the intermediate and final sameness relations. Assume:*

$$\forall x,\ \mathsf{SourceOk}(x) \to \exists y,\ \mathsf{firstGap}(y, x) \text{ and } \mathsf{InterOk}(y),$$

$$\forall y,\ \mathsf{InterOk}(y) \to \exists z,\ \mathsf{secondGap}(z, y),$$

$$\forall x, y_1, y_2,\ \mathsf{SourceOk}(x) \to \mathsf{firstGap}(y_1, x) \to \mathsf{firstGap}(y_2, x) \to \mathsf{interSame}(y_1, y_2),$$

and

$$\forall y_1, y_2, z_1, z_2,\ \mathsf{interSame}(y_1, y_2) \to \mathsf{secondGap}(z_1, y_1) \to \mathsf{secondGap}(z_2, y_2) \to \mathsf{finalSame}(z_1, z_2).$$

Then the composite gap satisfies both conclusions:

$$\forall x,\ \mathsf{SourceOk}(x) \to \exists z,\ \mathsf{CompGap}(\mathsf{firstGap}, \mathsf{secondGap}, z, x)$$

and

$$\forall x, z_1, z_2,\ \mathsf{SourceOk}(x) \to \mathsf{CompGap}(\mathsf{firstGap}, \mathsf{secondGap}, z_1, x) \to \mathsf{CompGap}(\mathsf{firstGap}, \mathsf{secondGap}, z_2, x) \to \mathsf{finalSame}$$

Lean4 ✓ `BEDC.FKernel.Gap.compGap exactness from layers on histories`

Proof. The first conclusion is Theorem 8.8: choose the first-layer intermediate witness and its InterOk certificate, then apply second-layer coverage to obtain a final token. The second conclusion is Theorem 8.9: unpack the two composite witnesses over the same source, use first-layer separation to identify the intermediate witnesses by interSame, and apply second-layer transport to obtain finalSame for the final tokens. □

Theorem 8.11 (Composite representative for admitted source)**.** *Under the same layered coverage and separation hypotheses as Theorem 8.10, if* $\mathsf{SourceOk}(x)$*, then there exists a final token* z *such that*

$$\mathsf{CompGap}(\mathsf{firstGap}, \mathsf{secondGap}, z, x)$$

and every final token z' *satisfying*

$$\mathsf{CompGap}(\mathsf{firstGap}, \mathsf{secondGap}, z', x)$$

also satisfies $\mathsf{finalSame}(z, z')$*.*

Proof. Composite coverage supplies a final token z with $\mathsf{CompGap}(\mathsf{firstGap}, \mathsf{secondGap}, z, x)$. For any other final token z' with $\mathsf{CompGap}(\mathsf{firstGap}, \mathsf{secondGap}, z', x)$, composite separation applies to the two composite memberships over the same admitted source and gives $\mathsf{finalSame}(z, z')$. □

Lean4 ✓ `BEDC.FKernel.Gap.compGap representative for admitted source`

Principle 8.12 (Ledger composition)**.** *The ledger of a composite compression is not the last ledger alone. It is the first ledger together with the pullback of the second ledger along the first visible interface.*

↪ variant `BEDC.FKernel.Gap.compGap pullback witnesses`
↪ variant `BEDC.FKernel.Gap.compGap four right nested iff`
↪ variant `BEDC.FKernel.Gap.ledger composition principle inverse`

Theorem 8.13 (Composite gap intermediate-witness sameness)**.** *Let* Source*,* Inter*, and* Final *be the source, intermediate, and final token types. Let* $\mathsf{SourceOk}$ *be the admitted-source predicate, let* $\mathsf{firstGap}$ *and* $\mathsf{secondGap}$ *be the layered gap relations, and let* $\mathsf{interSame}$ *be the intermediate sameness relation. Assume first-layer separation:*

$$\forall h, y_1, y_2,\ \mathsf{SourceOk}(h) \to \mathsf{firstGap}(y_1, h) \to \mathsf{firstGap}(y_2, h) \to \mathsf{interSame}(y_1, y_2).$$

For an admitted source h *and final tokens* z_1, z_2*, suppose the two composite memberships over* h *are presented with intermediate witnesses* y_1 *and* y_2 *in the sense that*

$$\mathsf{firstGap}(y_1, h) \wedge \mathsf{secondGap}(z_1, y_1)$$

and

$$\mathsf{firstGap}(y_2, h) \wedge \mathsf{secondGap}(z_2, y_2).$$

These two displayed witness pairs exhibit $\mathsf{CompGap}(\mathsf{firstGap}, \mathsf{secondGap}, z_1, h)$ *and* $\mathsf{CompGap}(\mathsf{firstGap}, \mathsf{secondGap}, z_2,$ *by Definition 8.7. If* $\mathsf{SourceOk}(h)$*, then* $\mathsf{interSame}(y_1, y_2)$*.*

Proof. The first displayed witness pair gives $\mathsf{firstGap}(y_1, h)$, and the second gives $\mathsf{firstGap}(y_2, h)$. Applying the first-layer separation hypothesis to the admitted-source certificate for h and to these two first-layer memberships gives $\mathsf{interSame}(y_1, y_2)$. □

Theorem 8.14 (Composite-gap witness inversion is conservative over final representatives)**.** *Under the same layered coverage and separation hypotheses as Definition 8.10, if* $\mathsf{SourceOk}(x)$*,* $\mathsf{CompGap}(\mathsf{firstGap}, \mathsf{secondGa}$ *and*

$$\exists y,\ \mathsf{firstGap}(y, x) \wedge \mathsf{secondGap}(w, y),$$

then $\mathsf{finalSame}(z, w)$*.*

Proof. Choose y witnessing the displayed existential. By Definition 8.7, the relations $\mathsf{firstGap}(y, x)$ and $\mathsf{secondGap}(w, y)$ exhibit $\mathsf{CompGap}(\mathsf{firstGap}, \mathsf{secondGap}, w, x)$. Applying Definition 8.9 to the admitted-source certificate for x, to the given composite membership of z, and to this exhibited composite membership of w gives $\mathsf{finalSame}(z, w)$. □

Chapter 9

Typed Naming Certificates

Definition 9.1 (Source specification)**.** *A source specification* SourceSpec *records the generated material from which a proposed name is licensed. It may refer to raw marks, histories, bundles, packages, gaps, or previously licensed names.*

Definition 9.2 (Pattern specification)**.** *A pattern specification* PatternSpec *records the stable behavior observed in the source. Examples include repetition, continuation, signature classification, package stability, or compatible threading.*

Definition 9.3 (Classifier specification)**.** *A classifier specification* ClassifierSpec *records how source material is grouped. At the finite kernel level this is normally given by a bundle, an asking policy, a package policy, and a gap policy.*

Definition 9.4 (Stability certificates)**.** *The stability component* StabilityCert *is typed by modes:*

$$\begin{aligned}
\mathsf{ClosureCert} &: \textit{the source is closed under the named behavior},\\
\mathsf{ReuseCert} &: \textit{the named behavior can be reused as a later tool},\\
\mathsf{DescentCert} &: \textit{the behavior descends through classification},\\
\mathsf{CompositionCert} &: \textit{the behavior composes with previously named behavior},\\
\mathsf{SealCert} &: \textit{the behavior supports compatible-thread sealing}.
\end{aligned}$$

A name may require one or more of these modes.

```
Lean4 (definition)  BEDC.FKernel.NameCert.StabilityMode
  ↪ variant  BEDC.FKernel.NameCert.stabilityMode no confusion
  ↪ variant  BEDC.FKernel.NameCert.stabilityMode pairwise no confusion
  ↪ variant  BEDC.FKernel.NameCert.stabilityMode descent composition seal no confusion
  ↪ variant  BEDC.FKernel.NameCert.stabilityMode exhaustive
```

Definition 9.5 (Ledger policy)**.** *A ledger policy* LedgerPolicy *records what the name hides and how the hidden material is tracked. It must specify whether the ledger is a gap, a composite gap, a tail ledger, a phase ledger, a source ledger, or another derived ledger.*

Definition 9.6 (Paper naming certificate template)**.** *A paper naming certificate for a proposed derived interface N is the five-field template*

$$\mathsf{NameCert}(N) = (\mathsf{SourceSpec}_N, \mathsf{PatternSpec}_N, \mathsf{ClassifierSpec}_N, \mathsf{StabilityCert}_N, \mathsf{LedgerPolicy}_N).$$

The proposed name N is licensed only if all required fields are supplied.

Definition 9.7 (Lean carrier naming certificate)**.** *At the formal finite-kernel layer, the Lean structure* NameCert(Carrier, Equiv) *is a carrier-and-equivalence certificate over histories. It supplies inhabitedness of the carrier, reflexivity, symmetry, and transitivity for the equivalence relation, and transport of carrier membership along that relation.*

Lean4 (definition) `BEDC.FKernel.NameCert.NameCert`
Lean4 ✓ `BEDC.FKernel.NameCert.nameCert carrier witness`

Theorem 9.8 (Naming certificate classifier transitivity)**.** *For every naming certificate over a history carrier and classifier, the classifier is transitive on finite-kernel histories.*

Proof. The certificate record contains the classifier transitivity field. Projecting that field supplies the required composition of two classifier witnesses. □

Lean4 ✓ `BEDC.FKernel.NameCert.nameCert equiv trans`

Theorem 9.9 (Derived interfaces require certificates)**.** *No interface marked by an upward arrow is licensed without a* NameCert*.*

Proof. This is the formation rule for the paper template: derived names are not object-language primitives. They enter the theory only by the five supplied certificate fields. □

Lean4 ✓ `BEDC.FKernel.NameCert.derived interfaces require certificates`

Principle 9.10 (Limit-like interfaces carry a ledger)**.** *Every certified derived interface carries a ledger policy witness.*

Proof. Case analysis on the semantic naming certificate exposes the source witness in the core certificate. Applying the ledger soundness field to that same source witness gives the required ledger witness. □

Lean4 ✓ `BEDC.FKernel.NameCert.semanticNameCert ledger policy witness`

Theorem 9.11 (Semantic NameCert presentation weakening)**.** *Let* $S, P, L, P', L' : \mathsf{BHist} \to \mathsf{Prop}$ *and* $C : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$*. If*

$$\mathsf{SemanticNameCert}(S, P, L, C)$$

holds, and for every history h *the implications* $P(h) \to P'(h)$ *and* $L(h) \to L'(h)$ *hold, then*

$$\mathsf{SemanticNameCert}(S, P', L', C)$$

holds. The source specification and classifier specification are unchanged.

Proof. By Definition 9.6, the naming template separates the source, pattern, classifier, stability, and ledger roles. The core field of the semantic certificate is the carrier-and-classifier $\mathsf{NameCert}(S, C)$ described by Definition 9.7; it mentions only the source predicate and the classifier relation. Keep this core field. For a source witness $S(h)$, the original pattern soundness field gives $P(h)$, and the pointwise pattern weakening gives $P'(h)$. The same source witness gives $L(h)$ by the original ledger soundness field, and the pointwise ledger weakening gives $L'(h)$. These three fields form the semantic certificate for S, P', L', C. □

Chapter 10

First Derived Interfaces

10.1 Unary repetition

Definition 10.1 (Unary repetition histories)**.** *Unary repetition histories are histories generated from* e *by repeated* E1*-extension.*

Lean4 (definition) `BEDC.FKernel.Unary.UnaryRepetitionHistory`

Proposition 10.2 (Unary repetition is closed under continuation)**.** *If h and k are unary repetition histories and* $\mathsf{Cont}(h, k, r)$*, then r is a unary repetition history.*

Lean4 ✓ `BEDC.FKernel.Unary.unary repetition closed under continuation seed`
↪ variant `BEDC.FKernel.Unary.unary repetition closed under continuation`
↪ variant `BEDC.FKernel.Unary.unary append right factor`

Proof. Read $\mathsf{Cont}(h, k, r)$ as append equality and induct on the right unary history k. The empty case returns h. The E0-case is incompatible with unary repetition, and the E1-case follows from the induction hypothesis. □

Corollary 10.3 (Natural-number-like interface seed)**.** *Unary repetition histories with their continuation behavior license a minimal* $\mathsf{Nat}^{\uparrow}$ *interface seed. This is not a full arithmetic theory and does not import primitive natural numbers.*

Lean4 ✓ `BEDC.FKernel.Unary.nat up interface seed`

Corollary 10.4 (Addition-like interface seed)**.** *Continuation of unary repetition histories licenses a minimal* $\mathsf{Add}^{\uparrow}$ *interface seed. Associativity follows from continuation associativity, and the empty history supplies the unit behavior.*

Lean4 ✓ `BEDC.FKernel.Unary.add up interface seed with units`

10.2 Stable transformations

Definition 10.5 (Stable transformation)**.** *A stable transformation between packaged interfaces is a generated transformation behavior that preserves package-sameness and carries a ledger policy.*

Lean4 (definition) `BEDC.FKernel.NameCert.StableTransformation`
Lean4 ✓ `BEDC.FKernel.NameCert.stableTransformation ledger witness`

Theorem 10.6 (Stable transformations descend to packages)**.** *If a generated transformation sends signature-same source histories to package-same target histories, then it descends to a derived transformation interface between package tokens.*

Lean4 ✓ `BEDC.FKernel.NameCert.stableTransformation descent certificate respects`

Proof. The descent condition says that the visible result depends only on the source package, not on the chosen representative source history. Therefore the transformation is licensed at the package level, with its gap ledger recording the source representative information suppressed by the descent. □

Corollary 10.7 (Function-like interfaces are derived)**.** *A* $\mathsf{Func}^{\uparrow}$ *interface is a derived name for stable transformations. It is not an internal primitive.*

Lean4 ✓ `BEDC.FKernel.NameCert.function like interface seed not primitive`

Chapter 11

Thin Seal Interface

Definition 11.1 (Stage interface)**.** *A stage interface* Stage *is a generated visibility level in an iterative observation process. This chapter treats* Stage *as a placeholder for the completion module.*

Lean4 (definition) `BEDC.FKernel.NameCert.StageInterface`

Definition 11.2 (Thread)**.** *A thread* Thread *is a compatible family of stage-level visible data. Compatibility is not developed fully in this finite kernel; it is reserved for the completion module.*

Lean4 (definition) `BEDC.FKernel.NameCert.ThreadFamily`

Definition 11.3 (Seal interface)**.** *A seal event* $\mathsf{Seal}(T, N)$ *licenses a name* N *for a compatible thread* T*, provided a* SealCert *and a ledger policy are supplied.*

Lean4 (definition) `BEDC.FKernel.NameCert.SealEvent`
Lean4 (definition) `BEDC.FKernel.NameCert.SealInterface`
↪ variant `BEDC.FKernel.NameCert.sealInterface thread witness`
Lean4 ✓ `BEDC.FKernel.NameCert.sealInterface certificate witness`

Corollary 11.4 (Limit-like interfaces are derived)**.** *A* $\mathsf{Limit}^{\uparrow}$ *interface is a derived name for seal-certified compatible-thread behavior. It is not primitive in the finite kernel.*

Lean4 ✓ `BEDC.FKernel.NameCert.sealInterface thread carrier witnesses`

Remark 11.5. *The seal layer is intentionally thin in this chapter. Completion and thread sealing are not primitive finite-kernel steps. Real-like and circle-like names may appear in this manuscript only as* NameCert*-governed certificate-obligation schemas, such as* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{S}^{1\uparrow}$*, not as quotient, completion, or topological primitives.*

Chapter 12

External Binary Model

12.1 Purpose of the model

The following model is external. It is a metalanguage interpretation showing that the kernel rules are not empty. It is not part of the object-language.

Definition 12.1 (External model $\mathcal{M}_{\mathsf{bin}}$)**.** *The external model* $\mathcal{M}_{\mathsf{bin}}$ *interprets:*

- *raw marks as two external tokens;*
- *histories as finite binary words;*
- msame *as literal token equality;*
- hsame *as literal word equality;*
- Ext *as appending one token;*
- Cont *as word concatenation;*
- *asking events as externally chosen binary observations;*
- *signatures as finite words of answers;*
- *packages as signature classes;*
- *gaps as inverse images of package tokens;*
- *composite gaps as relational composites of inverse images.*

Lean4 (definition) `BEDC.FKernel.ExternalBinary.Mbin`

Lean4 ✓ `BEDC.FKernel.ExternalBinary.Mbin eq BHist`

↪ variant `BEDC.FKernel.ExternalBinary.external model mbin`

↪ variant `BEDC.FKernel.ExternalBinary.Mbin reuses kernel history`

↪ variant `BEDC.FKernel.ExternalBinary.external model no parallel word input`

↪ variant `BEDC.FKernel.ExternalBinary.external model reuses kernel histories`

↪ variant `BEDC.FKernel.ExternalBinary.external model kernel input reuse`

↪ variant `BEDC.FKernel.ExternalBinary.Mbin cases`

↪ variant `BEDC.FKernel.ExternalBinary.Mbin induction`

↪ variant `BEDC.FKernel.ExternalBinary.external append bit constructor rules`

↪ variant `BEDC.FKernel.ExternalBinary.external append length eq left iff right empty`

↪ variant `BEDC.FKernel.ExternalBinary.external append length eq right iff left empty`

Theorem 12.2 (External append soundness for the finite history kernel)**.** *For the reused history carrier $\mathcal{M}_{\mathsf{bin}} = BHist$, external append has left and right empty units, associativity, right and left cancellation, and additive length.*

```
Lean4 ✓  BEDC.FKernel.ExternalBinary.external model soundness finite kernel

  ↪ variant  BEDC.FKernel.ExternalBinary.external append right unit unique
  ↪ variant  BEDC.FKernel.ExternalBinary.external append right unit iff
  ↪ variant  BEDC.FKernel.ExternalBinary.external append unit uniqueness pair
```

Proof. The carrier is the kernel history type $BHist$. The append laws are proved by constructor recursion on finite binary words, with the external append operation reusing the continuation append on histories. Empty units and associativity are the unit and associativity laws of that append. Right and left cancellation follow by induction on the common appended context, and the length equation follows by the same recursion that defines binary-word length. □

Theorem 12.3 (External append respects history-sameness)**.** *For all external words a, a', b, b', if* $\mathsf{hsame}(a, a')$ *and* $\mathsf{hsame}(b, b')$*, then*

$$\mathsf{hsame}(append(a, b), append(a', b')).$$

Proof. Unfold external words as $BHist$. The two hsame hypotheses identify the left and right inputs. After those identifications, both appended histories are the same continuation append result, so hsame-reflexivity gives the conclusion. □

```
Lean4 ✓  BEDC.FKernel.ExternalBinary.external append hsame congruence
```

Theorem 12.4 (External append cancellation soundness)**.** *Right and left cancellation for external append are sound for* hsame*: if appending the same right word or the same left word gives internally same results, then the uncancelled words are internally same.*

```
Lean4 ✓  BEDC.FKernel.ExternalBinary.external append cancel hsame pair
  ↪ variant  BEDC.FKernel.ExternalBinary.external append cancellation soundness
  ↪ variant  BEDC.FKernel.ExternalBinary.external append cancel pair
  ↪ variant  BEDC.FKernel.ExternalBinary.external append middle cancel hsame
  ↪ variant  BEDC.FKernel.ExternalBinary.external append double cancel hsame
  ↪ variant  BEDC.FKernel.ExternalBinary.external append cancel common context
  ↪ variant  BEDC.FKernel.ExternalBinary.external append middle cancel eq
  ↪ variant  BEDC.FKernel.ExternalBinary.external append right cancel by induction
  ↪ variant  BEDC.FKernel.ExternalBinary.external append left cancel by induction
  ↪ variant  BEDC.FKernel.ExternalBinary.external append cancel hsame directions by induction
  ↪ variant  BEDC.FKernel.ExternalBinary.external append cancel hsame nested pair
  ↪ variant  BEDC.FKernel.ExternalBinary.external append cancel three context hsame
  ↪ variant  BEDC.FKernel.ExternalBinary.external append cancel hsame triple suffix
  ↪ variant  BEDC.FKernel.ExternalBinary.external append cancel four context hsame
  ↪ variant  BEDC.FKernel.ExternalBinary.external append cancel two sided hsame symmetric
```

Proof. The two directions are the right and left hsame-cancellation laws for the external binary append operation. □

Theorem 12.5 (External append bit result inversion)**.** *If an external append result is a zero-bit word, then either the right word is empty and the left word is that zero-bit word, or the right word starts with zero and the tail append is the result tail. The same alternative holds for one-bit words.*

```
Lean4 ✓  BEDC.FKernel.ExternalBinary.external append bit result inversion
  ↪ variant  BEDC.FKernel.ExternalBinary.external append bit0 result inversion
  ↪ variant  BEDC.FKernel.ExternalBinary.external append bit1 result inversion
  ↪ variant  BEDC.FKernel.ExternalBinary.external append bit result tail hsame
  ↪ variant  BEDC.FKernel.ExternalBinary.external append bit result cross impossible
  ↪ variant  BEDC.FKernel.ExternalBinary.external append bit result cases by right word
  ↪ variant  BEDC.FKernel.ExternalBinary.external append bit result iff
  ↪ variant  BEDC.FKernel.ExternalBinary.external append constructor result inversion
  ↪ variant  BEDC.FKernel.ExternalBinary.external append length zero pair
```

Proof. Case-analyze the right appended word. The empty case returns the left word. Matching bit constructors expose the tail equality by constructor injectivity, and opposite bit constructors are impossible by constructor disjointness. □

Corollary 12.6 (External append bit tail equality)**.** *If* $append(a, b)$ *is a zero-bit result* $0 :: r$ *and* b *is a zero-bit word* $0 :: b_0$*, then* $append(a, b_0) = r$*. If* $append(a, b)$ *is a one-bit result* $1 :: r$ *and* b *is a one-bit word* $1 :: b_1$*, then* $append(a, b_1) = r$*.*

```
Lean4 ✓  BEDC.FKernel.ExternalBinary.external append bit result tail eq pair
```

Proof. In each bit case, substitute the displayed shape of b into the append equality. Constructor injectivity for the matching bit exposes equality of the tails. □

Chapter 13

Finite Theorem Manifest

This chapter lists the finite kernel theorem targets. The listed names are stable labels for theorem obligations inside the kernel specification; they are not object-language names and do not presuppose any implementation layer.

Target	Content
`msame_refl`	Reflexivity of mark-sameness.
`msame_symm`	Symmetry of mark-sameness.
`msame_trans`	Transitivity of mark-sameness.
`mark_no_confusion`	Cross-mark sameness is not generated.
`hsame_refl`	Reflexivity of history-sameness.
`hsame_symm`	Symmetry of history-sameness.
`hsame_trans`	Transitivity of history-sameness.
`history_no_confusion`	Cross-constructor history-sameness is not generated.
`ext_det`	Relational extension is deterministic up to history-sameness.
`cont_det`	Relational continuation is deterministic up to history-sameness.
`cont_left_unit`	Empty history is a left unit for continuation.
`cont_right_unit`	Empty history is a right unit for continuation.
`cont_assoc`	Continuation is associative up to history-sameness.
`sig_det`	Signature generation is deterministic under an asking policy.
`sameSig_equiv`	Signature-sameness is an equivalence under policy assumptions.
`pkg_by_sig`	Packages classify signatures under package policy.
`gap_coverage`	Every admitted source history lies in some gap.
`gap_separation`	Overlap of gaps implies package-sameness.
`compGap_coverage`	Composite gaps have coverage when component gaps do.
`unary_cont_closed`	Unary repetition histories are closed under continuation.
`add_like_assoc`	The addition-like interface seed inherits continuation associativity.

Chapter 14

Boundary of the Finite Kernel

The finite kernel covers the chain

$$\mathsf{Mark} \to \mathsf{Hist} \to \mathsf{msame}, \mathsf{hsame} \to \mathsf{Ext}, \mathsf{Cont} \to \mathsf{Ask} \to \mathsf{Sig} \to \mathsf{sameSig} \to \mathsf{Pkg} \to \mathsf{Gap} \to \mathsf{NameCert}.$$

It is intentionally bounded: four families of derived constructions sit outside the primitive finite-kernel chain. They may be named in this manuscript only as typed certificate-obligation schemas when their classifiers, stability data, and ledgers are supplied.

1. completion schemas for seal-certified threads;
2. the full arithmetic module for induction, recursion, multiplication, and order;
3. phase-name schemas for circle-like certificates;
4. the fold module for normal representatives and fiber ledgers beyond signature packages.

None of these families is a primitive of the finite kernel; each is admitted only through its own naming certificate, with the certificate's stability fields supplied by the finite-kernel chain.

Summary

This manuscript gives a relation-based finite-kernel target for the Binary Emission Discovery Calculus. It begins with two raw marks and generated histories; defines internal mark- and history-sameness; relationizes extension and continuation; treats probes as asking events; generates bundles and signatures internally; packages signatures under policies; records gaps; composes ledgers; and licenses derived interfaces only through typed naming certificates. Its primitive scope is finite emission, probing, packaging, and ledger composition. Completion and fold constructions remain outside that primitive chain, while real-like and circle-like appearances are typed naming-certificate obligation schemas, not quotient, completion, or topological primitives.

Chapter 15

The Signature Package Instance

The hardening layer introduced PackagePolicy as an abstract interface. This chapter constructs the first concrete instance: package tokens generated directly from answer signatures.

15.1 Signature tokens

Definition 15.1 (Signature token generator)**.** *Fix a generated probe bundle* Π*. For every generated answer history* s*, introduce a formal package token*

$$\mathsf{Tok}_{\Pi}(s).$$

This notation is a naming convention for the package-token event associated with the answer history s*. It is not a host function in the object theory.*

Lean4 (definition) `BEDC.FKernel.Package.SignatureTokenGenerator`
Lean4 ✓ `BEDC.FKernel.Package.SignatureTokenGenerator iff exists`

Definition 15.2 (Signature package relation)**.** *This concrete instance represents visible signature tokens by answer histories: its package-token carrier is* $BHist$*. The notation* $\mathsf{Tok}_{\Pi}(s)$ *names the visible token represented by a history, and token introduction between a signature history* s *and a visible token* p *is the relation* $\mathsf{hsame}(s, p)$*.*

The concrete signature package relation $\mathsf{Pkg}^{\mathrm{sig}}$ *is generated by the rule*

$$\mathsf{Pkg}^{\mathrm{sig}}(\Pi, s, \mathsf{Tok}_{\Pi}(s)).$$

Package-sameness is generated by the rule

$$\mathsf{hsame}(s, t) \quad \Longrightarrow \quad \mathsf{psame}(\mathsf{Tok}_{\Pi}(s), \mathsf{Tok}_{\Pi}(t)).$$

No additional package-sameness constructors are included.

Lean4 ✓ `BEDC.FKernel.Package.signature package relation generated only`

Lemma 15.3 (Signature package existence)**.** *For every generated answer history* s*, there exists a package token* p *such that*

$$\mathsf{Pkg}^{\mathrm{sig}}(\Pi, s, p).$$

Lean4 ✓ `BEDC.FKernel.Package.signature package existence`

Proof. Take $p = \mathsf{Tok}_\Pi(s)$ and apply the signature package rule. □

Lemma 15.4 (Signature package extensionality)**.** *If* $\mathsf{hsame}(s, t)$*, token introduction relates* s *to* p*, and token introduction relates* t *to* q*, then* $\mathsf{psame}(p, q)$*.*

Proof. The two token-introduction premises and the history-sameness premise are exactly the three arguments of the displayed package-sameness constructor, so that constructor yields $\mathsf{psame}(p, q)$ directly. □

Lemma 15.5 (Signature package grounding)**.** *If* $\mathsf{Pkg}^{\mathrm{sig}}(\Pi, s, p)$*, then* p *is generated from the signature history* s *by the displayed token rule.*

Lean4 ✓ `BEDC.FKernel.Package.signature package grounding`

Proof. By closed generation for $\mathsf{Pkg}^{\mathrm{sig}}$, every package derivation is generated from a token $\mathsf{Tok}_\Pi(s)$. No hidden token constructor is present. □

Lemma 15.6 (Signature package sameness reflects history sameness)**.** *For the concrete signature package instance, where package tokens are represented by histories, if* $\mathsf{psame}(p, q)$*, then* $\mathsf{hsame}(p, q)$*.*

Lean4 ✓ `BEDC.FKernel.Package.signature package psame implies hsame`

Proof. Invert the one package-sameness constructor. The displayed token-introduction witnesses identify p and q with the introducing signature histories, and transitivity of hsame composes those witnesses with the constructor proof. □

Theorem 15.7 (Concrete PackagePolicy for signatures)**.** *The relation* $\mathsf{Pkg}^{\mathrm{sig}}$*, together with the token-sameness rule above, satisfies the package existence, package extensionality, and package grounding requirements of* PackagePolicy*.*

Lean4 ✓ `BEDC.FKernel.Package.signature package policy`
↪ variant `BEDC.FKernel.Package.signature package token exists`

Proof. Existence, extensionality, and grounding are exactly the three preceding lemmas. □

Corollary 15.8 (The first concrete package interface)**.** *Every generated probe bundle* Π *admits a concrete package interface whose visible tokens are generated by answer signatures.*

Lean4 ✓ `BEDC.FKernel.Package.first concrete package interface`

Chapter 16

The Concrete Signature Gap Policy

The signature package instance provides visible tokens. We now define the concrete gap ledger behind those tokens.

Definition 16.1 (Signature gap membership)**.** *Fix a probe bundle* Π*, a source domain specification* D*, and the signature package instance of chapter 15, whose visible package relation is* $\mathsf{Pkg}^{\mathrm{sig}}$*. A history* h *lies in the signature gap of a package token* p *when there exist an answer history* s *and evidence ledger* Δ *such that*

$$\mathsf{InDom}(D, h), \qquad \mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{TokIntro}(\Pi, s, p).$$

We write this as

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h).$$

Lean4 (definition) `BEDC.FKernel.Gap.GapMembership`
Lean4 (definition) `BEDC.FKernel.Gap.SignatureGapMembership`
↪ variant `BEDC.FKernel.Gap.GapMembership iff InGapSig`
↪ variant `BEDC.FKernel.Gap.GapMembership witness pair`
Lean4 ✓ `BEDC.FKernel.Gap.inGapSig iff witnesses`
↪ variant `BEDC.FKernel.Gap.signature gap membership iff`
↪ variant `BEDC.FKernel.Gap.inGapSig intro`
↪ variant `BEDC.FKernel.Gap.inGapSig intro from signature witness`
↪ variant `BEDC.FKernel.Gap.inGapSig elim`
↪ variant `BEDC.FKernel.Gap.inGapSig domain and signature witness`
↪ variant `BEDC.FKernel.Gap.inGapSig domain signature token witnesses`
↪ variant `BEDC.FKernel.Gap.inGapSig domain signature token witness pair`
↪ variant `BEDC.FKernel.Gap.signature gap membership`
Lean4 ✓ `BEDC.FKernel.Gap.inGapSig signature and token witness`
↪ variant `BEDC.FKernel.Gap.inGapSig token witness`
↪ variant `BEDC.FKernel.Gap.inGapSig witnesses`

Lemma 16.2 (Concrete gap coverage)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$ *and package-wide token totality: for every answer history* s *there exists a package token* p *with* $\mathsf{TokIntro}(\Pi, s, p)$*. For every generated history* h *with* $\mathsf{InDom}(D, h)$*, there exists a package token* p *such that*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h).$$

Lean4 ✓ `BEDC.FKernel.Gap.concrete gap coverage`

Proof. By totality in $\mathsf{AskPolicy}(\Pi, D)$, the bundle Π produces some signature event

$$\mathsf{Sig}(\Pi, h, s, \Delta).$$

By token existence, there is a package token p such that

$$\mathsf{TokIntro}(\Pi, s, p).$$

Therefore $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$ holds by definition. □

Lemma 16.3 (Concrete gap separation)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$*. Suppose*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h), \qquad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, h).$$

Then $\mathsf{psame}(p, q)$*.*

Lean4 ✓ `BEDC.FKernel.Gap.gap separation concrete`

Proof. By the two gap memberships, there are signatures s, t and ledgers Δ, Θ such that

$$\mathsf{Sig}(\Pi, h, s, \Delta), \quad \mathsf{TokIntro}(\Pi, s, p),$$

$$\mathsf{Sig}(\Pi, h, t, \Theta), \quad \mathsf{TokIntro}(\Pi, t, q).$$

By signature determinacy under $\mathsf{AskPolicy}(\Pi, D)$, $\mathsf{hsame}(s, t)$. By signature package extensionality, $\mathsf{psame}(p, q)$. □

Theorem 16.4 (Concrete GapPol for signature packages)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$*,* $\mathsf{PackageTokenPolicy}(\Pi)$*, and package-wide token totality: for every answer history* s*, there is a visible package* p *with* $\mathsf{TokIntro}(\Pi, s, p)$*. Then the package relation* $\mathsf{Pkg}^{\mathrm{sig}}$ *together with* $\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h)$ *satisfies coverage and separation for the signature package instance.*

Lean4 ✓ `BEDC.FKernel.Gap.concrete gap policy`
↪ variant `BEDC.FKernel.Gap.gapPolicy coverage signature witness`

Proof. Coverage is supplied by signature generation under $\mathsf{AskPolicy}(\Pi, D)$ together with token existence. Separation is supplied by signature determinacy under $\mathsf{AskPolicy}(\Pi, D)$ and package soundness from $\mathsf{PackageTokenPolicy}(\Pi)$. □

Corollary 16.5 (First concrete globalization ledger)**.** *The pair*

$$(\mathsf{Pkg}^{\mathrm{sig}}, \mathsf{InGap}^{\mathrm{sig}})$$

forms the first concrete finite-kernel globalization interface for the domain D *and probe bundle* Π*, conditional on* $\mathsf{AskPolicy}(\Pi, D)$*,* $\mathsf{PackageTokenPolicy}(\Pi)$*, and package-wide token totality: for every answer history* s*, there exists a visible package* p *with* $\mathsf{TokIntro}(\Pi, s, p)$*.*

Lean4 ✓ `BEDC.FKernel.Gap.first concrete globalization ledger`

Chapter 17

The First Concrete Globalize Instance

This chapter packages the two preceding chapters into a single concrete globalization instance.

Definition 17.1 (Signature globalization instance)**.** *Given a source domain specification D, a generated probe bundle Π, and* $\mathsf{AskPolicy}(\Pi, D)$*, the signature globalization instance is the triple*

$$\mathsf{Glob}^{\mathrm{sig}}(\Pi, D) := (\mathsf{Pkg}^{\mathrm{sig}}, \mathsf{psame}, \mathsf{InGap}^{\mathrm{sig}}).$$

It is read as a visible package layer plus a provenance ledger layer.

Lean4 (definition) `BEDC.FKernel.Gap.signature globalization instance`

Theorem 17.2 (Concrete globalization soundness)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$ *and* $\mathsf{PackageTokenPolicy}(\Pi)$*. If*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h), \qquad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k), \qquad \mathsf{sameSig}(\Pi, h, k),$$

then $\mathsf{psame}(p, q)$*.*

Lean4 ✓ `BEDC.FKernel.Gap.concrete globalize soundness from sameSig`
↪ variant `BEDC.FKernel.Gap.internalized globalize soundness for witnesses`

Proof. The two gap memberships provide introduced visible tokens for generated signatures of h and k. By $\mathsf{sameSig}(\Pi, h, k)$, there exist generated answer histories s, t and evidence ledgers such that

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{Sig}(\Pi, k, t, \Theta), \qquad \mathsf{hsame}(s, t).$$

The determinacy field of $\mathsf{AskPolicy}(\Pi, D)$ aligns these signatures with the signatures carried by the two gap witnesses. Package soundness from $\mathsf{PackageTokenPolicy}(\Pi)$ gives $\mathsf{psame}(p, q)$. □

Theorem 17.3 (Concrete globalization completeness)**.** *Assume* $\mathsf{PackageTokenPolicy}(\Pi)$*. If*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h), \qquad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k), \qquad \mathsf{psame}(p, q),$$

then $\mathsf{sameSig}(\Pi, h, k)$*.*

Lean4 ✓ `BEDC.FKernel.Gap.concrete globalize completeness sameSig`
↪ variant `BEDC.FKernel.Gap.concrete globalization completeness`

Proof. Unfold the concrete gap memberships. They provide signatures s, t such that h generates s, k generates t, and p, q are introduced from those signatures. By the reflection field of $\mathsf{PackageTokenPolicy}(\Pi)$, package-sameness of the visible tokens is grounded in $\mathsf{hsame}(s, t)$. Hence $\mathsf{sameSig}(\Pi, h, k)$. □

Corollary 17.4 (Globalize equals signature classification in the concrete instance)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$ *and* $\mathsf{PackageTokenPolicy}(\Pi)$*. For introduced tokens with*

$$\mathsf{InGap}^{\mathrm{sig}}(\Pi, D, p, h) \qquad \textit{and} \qquad \mathsf{InGap}^{\mathrm{sig}}(\Pi, D, q, k),$$

the concrete instance satisfies

$$\mathsf{psame}(p, q) \iff \mathsf{sameSig}(\Pi, h, k).$$

Lean4 ✓ `BEDC.FKernel.Gap.globalize equals signature classification concrete`

Remark 17.5 (Why this matters)**.** *The surrounding theory states that Globalize is classification by signatures. This chapter gives the first concrete finite-kernel inhabitant of that claim. It does not yet build real-like, circle-like, or fold-like interfaces; it only makes the finite signature globalization stand.*

Part II

Proof Sprint

Chapter 18

Finite Kernel Proof Target

18.1 Purpose and scope

This text is a proof-sprint refinement of the finite kernel. Its primitive target excludes completion, quotient, topological, and fold constructions. Real-like and circle-like names may still appear as typed certificate-obligation schemas governed by $\mathsf{NameCert}$, not as completed traditional objects.

The finite kernel target is:

$$\mathsf{Mark} \to \mathsf{Hist} \to \mathsf{msame}, \mathsf{hsame} \to \mathsf{Ext}, \mathsf{Cont} \to \mathsf{Ask} \to \mathsf{Sig} \to \mathsf{sameSig} \to \mathsf{Pkg} \to \mathsf{Gap} \to \mathsf{NameCert}.$$

The theory-level constraints are:

(i) raw marks carry no numeric interpretation;

(ii) extension, continuation, asking, signature generation, and packaging are treated relationally;

(iii) internal sameness is not host equality;

(iv) every compression must produce a gap ledger;

(v) every derived interface must be licensed by a naming certificate.

Principle 18.1 (Finite-kernel freezing)**.** *The first proof target isolates the finite kernel before completion-like or geometric constructions. A derived interface may be mentioned only as a typed obligation schema with an explicit naming certificate, not as a completed traditional object.*

18.2 Marks and mark-sameness

Definition 18.2 (Raw marks)**.** *The kernel begins with two raw marks:*

$$\mathsf{b0}, \qquad \mathsf{b1}.$$

They are not numbers, truth values, booleans, or elements of a set in the object theory. They are only two distinguishable emission results.

Definition 18.3 (Internal mark-sameness)**.** *The internal sameness judgment on raw marks is generated only by:*

$$\mathsf{msame}(\mathsf{b0}, \mathsf{b0}), \qquad \mathsf{msame}(\mathsf{b1}, \mathsf{b1}).$$

No rule generates $\mathsf{msame}(\mathsf{b0}, \mathsf{b1})$ *or* $\mathsf{msame}(\mathsf{b1}, \mathsf{b0})$.

Lemma 18.4 (Mark-sameness is reflexive)**.** *For every generated raw mark m,* $\mathsf{msame}(m, m)$*.*

Proof. There are only two generated raw marks. If $m = \mathsf{b0}$, use the first generator. If $m = \mathsf{b1}$, use the second generator. This case analysis belongs to the generation clauses for raw marks, not to an external numerical interpretation. □

Lemma 18.5 (Mark-sameness is symmetric)**.** *If* $\mathsf{msame}(m, n)$*, then* $\mathsf{msame}(n, m)$*.*

Proof. The only generators of msame are the two diagonal judgments. Reversing either generator yields the same generator. □

Lemma 18.6 (Mark-sameness is transitive)**.** *If* $\mathsf{msame}(m, n)$ *and* $\mathsf{msame}(n, r)$*, then* $\mathsf{msame}(m, r)$*.*

Proof. By closed generation of msame, both premises must be diagonal at the same raw mark. Hence the conclusion is the corresponding diagonal generator. □

Theorem 18.7 (Mark no-confusion)**.** *The judgments* $\mathsf{msame}(\mathsf{b0}, \mathsf{b1})$ *and* $\mathsf{msame}(\mathsf{b1}, \mathsf{b0})$ *are not generated.*

Proof. The closed generation clause for msame lists only the two diagonal generators. There is no cross-mark generator and no rule that can produce a cross-mark judgment from diagonal ones. □

18.3 Histories and history-sameness

Definition 18.8 (Emission histories)**.** *Emission histories are generated by:*

$$\mathsf{e} : \mathsf{Hist}, \qquad h : \mathsf{Hist} \Rightarrow \mathsf{E0}(h) : \mathsf{Hist}, \qquad h : \mathsf{Hist} \Rightarrow \mathsf{E1}(h) : \mathsf{Hist}.$$

The symbol e *denotes the empty emission history. The constructors* $\mathsf{E0}$ *and* $\mathsf{E1}$ *record one further emission of* $\mathsf{b0}$ *or* $\mathsf{b1}$*, respectively.*

Definition 18.9 (Internal history-sameness)**.** *The judgment* $\mathsf{hsame}(h, k)$ *is generated by:*

$$\mathsf{hsame}(\mathsf{e}, \mathsf{e}),$$

$$\mathsf{hsame}(h, k) \Rightarrow \mathsf{hsame}(\mathsf{E0}(h), \mathsf{E0}(k)),$$

$$\mathsf{hsame}(h, k) \Rightarrow \mathsf{hsame}(\mathsf{E1}(h), \mathsf{E1}(k)).$$

There are no cross-constructor generators.

Theorem 18.10 (History-sameness is an equivalence)**.** *The judgment* hsame *is reflexive, symmetric, and transitive on generated histories.*

Proof. Reflexivity is by induction on generated histories. The empty history uses $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$. The $\mathsf{E0}$ and $\mathsf{E1}$ cases use the corresponding closure rule.

Symmetry is by induction on a derivation of $\mathsf{hsame}(h, k)$. The empty case is immediate. The constructor cases reduce to the induction hypothesis.

Transitivity is by induction on the first sameness derivation and inversion on the second. Closed generation prevents cross-constructor cases. Thus the only non-empty cases are matching $\mathsf{E0}$-with-$\mathsf{E0}$ or $\mathsf{E1}$-with-$\mathsf{E1}$, where the induction hypothesis applies to the subhistories. □

Theorem 18.11 (History no-confusion)**.** *The following judgments are not generated:*

$$\mathsf{hsame}(\mathsf{e}, \mathsf{E0}(h)), \quad \mathsf{hsame}(\mathsf{e}, \mathsf{E1}(h)), \quad \mathsf{hsame}(\mathsf{E0}(h), \mathsf{E1}(k)),$$

with symmetric variants.

Lean4 ✓ `BEDC.FKernel.Hist.proof sprint history no confusion complete`

Proof. Each would require a generator for a cross-constructor history-sameness judgment. The closed generation clauses for hsame contain no such generator. □

18.4 Relational extension

Definition 18.12 (Extension relation)**.** *Extension is a relation, not a function. The judgment*

$$\mathsf{Ext}(m, h, r)$$

means that extending history h by raw mark m may generate result history r. It is generated by:

$$\mathsf{Ext}(\mathsf{b0}, h, \mathsf{E0}(h)), \qquad \mathsf{Ext}(\mathsf{b1}, h, \mathsf{E1}(h)).$$

Lean4 (definition) `BEDC.FKernel.Ext.Ext`

Theorem 18.13 (Extension determinacy)**.** *If* $\mathsf{Ext}(m, h, r)$ *and* $\mathsf{Ext}(m, h, r')$*, then* $\mathsf{hsame}(r, r')$*.*

Proof. By cases on the generated extension judgment. If $m = \mathsf{b0}$, both results are internally the same as $\mathsf{E0}(h)$. If $m = \mathsf{b1}$, both results are internally the same as $\mathsf{E1}(h)$. The claim follows by reflexivity of hsame. □

Theorem 18.14 (Extension respects internal sameness)**.** *If* $\mathsf{msame}(m, m')$*,* $\mathsf{hsame}(h, h')$*,* $\mathsf{Ext}(m, h, r)$*, and* $\mathsf{Ext}(m', h', r')$*, then* $\mathsf{hsame}(r, r')$*.*

Lean4 ✓ `BEDC.FKernel.Ext.ext respects sameness`

Proof. By closed generation of msame, the two marks are internally the same diagonal mark. If that mark is b0, the extension results have the form $\mathsf{E0}(h)$ and $\mathsf{E0}(h')$; the conclusion follows from $\mathsf{hsame}(h, h')$ and the E0-closure rule. The b1 case is analogous. □

18.5 Relational continuation

Definition 18.15 (Continuation relation)**.** *Continuation is a relation, not a function. The judgment*

$$\mathsf{Cont}(h, k, r)$$

means that continuing history h by history k may generate result r. It is generated by:

$$\mathsf{Cont}(h, \mathsf{e}, h),$$

$$\mathsf{Cont}(h, k, r) \Rightarrow \mathsf{Cont}(h, \mathsf{E0}(k), \mathsf{E0}(r)),$$

$$\mathsf{Cont}(h, k, r) \Rightarrow \mathsf{Cont}(h, \mathsf{E1}(k), \mathsf{E1}(r)).$$

Theorem 18.16 (Continuation determinacy)**.** *If* $\mathsf{Cont}(h, k, r)$ *and* $\mathsf{Cont}(h, k, r')$*, then* $\mathsf{hsame}(r, r')$*.*

↪variant BEDC.FKernel.Cont.cont deterministic

Proof. Induct on the right-history structure exposed by the first continuation derivation. In the empty case, both results are internally the same as h. In the E0-case, closed generation forces the second derivation to be an E0-case over the same right-history predecessor, and the induction hypothesis applies to the subresults. The E1-case is analogous. □

Theorem 18.17 (Continuation left unit)**.** *For every generated history k,* $\mathsf{Cont}(\mathsf{e}, k, k)$.

Lean4 ✓ BEDC.FKernel.Cont.cont left unit induction spine

Proof. Induct on k. The empty case is the base generator $\mathsf{Cont}(\mathsf{e}, \mathsf{e}, \mathsf{e})$. The E0 and E1 cases apply the corresponding right-recursive continuation step to the induction hypothesis. □

Theorem 18.18 (Continuation right unit)**.** *For every generated history h,* $\mathsf{Cont}(h, \mathsf{e}, h)$.

Lean4 ✓ BEDC.FKernel.Cont.cont right unit

Proof. This is the base generator of Cont. □

Theorem 18.19 (Append right nonempty self contradiction)**.** *For histories $h, k : \mathsf{BHist}$, a nonempty right factor cannot leave the append result internally the same as the left factor:*

$$(\mathsf{hsame}(k, \mathsf{e}) \to \bot) \Rightarrow \mathsf{hsame}(\mathsf{append}(h, k), h) \Rightarrow \bot.$$

Proof. Compare $\mathsf{append}(h, k)$ with $\mathsf{append}(h, \mathsf{e})$ using the displayed self-sameness and the right unit for append. Left cancellation forces $k\mathsf{hsamee}$, contradicting the nonempty right-factor hypothesis. □

Lean4 ✓ BEDC.FKernel.Cont.append right nonempty self absurd

Theorem 18.20 (Append left nonempty self contradiction)**.** *For histories $h, k : \mathsf{BHist}$, a nonempty left factor cannot leave the append result internally the same as the right factor:*

$$(\mathsf{hsame}(h, \mathsf{e}) \to \bot) \Rightarrow \mathsf{hsame}(\mathsf{append}(h, k), k) \Rightarrow \bot.$$

Proof. Compare $\mathsf{append}(h, k)$ with $\mathsf{append}(\mathsf{e}, k)$ using the displayed self-sameness and the left unit for append. Right cancellation forces $h\mathsf{hsamee}$, contradicting the nonempty left-factor hypothesis. □

Lean4 ✓ BEDC.FKernel.Cont.append left nonempty self absurd

Theorem 18.21 (Continuation associativity, relational form)**.** *If* $\mathsf{Cont}(a, b, ab)$ *and* $\mathsf{Cont}(b, c, bc)$*, then there exists a generated history abc such that*

$$\mathsf{Cont}(ab, c, abc) \qquad \textit{and} \qquad \mathsf{Cont}(a, bc, abc).$$

Lean4 ✓ BEDC.FKernel.Cont.cont assoc exists

Proof. Use the checked right-recursive append characterization of continuation and the append associativity spine. Equivalently, induct on the right continuation by c: the empty case takes $abc = ab$, and the E0 and E1 cases lift the witness with the matching right-recursive continuation step. □

Theorem 18.22 (Continuation suffix iff)**.** *For histories a, b, f, p, continuation from a by the suffixed history* $\mathsf{append}(f, p)$ *to the suffixed result* $\mathsf{append}(b, p)$ *is equivalent to the unsuffixed continuation from a by f to b:*

$$\mathsf{Cont}(a, \mathsf{append}(f, p), \mathsf{append}(b, p)) \iff \mathsf{Cont}(a, f, b).$$

Lean4 ✓ `BEDC.FKernel.Cont.cont suffix iff`

Proof. For the forward direction, rewrite the suffixed continuation through associativity so that both sides share the right suffix p, then cancel that common suffix. For the reverse direction, expand the unsuffixed continuation and use associativity of history append to rebuild the suffixed continuation. □

Theorem 18.23 (Continuation common-context equivalence up to history-sameness)**.** *For histories L, R, P, Q, a, b, f : BHist, if $L\mathsf{hsame}R$ and $P\mathsf{hsame}Q$, then adding those matched contexts to the continuation source, tail, and result preserves and reflects the core continuation:*

$$L\mathsf{hsame}R \Rightarrow P\mathsf{hsame}Q \Rightarrow \big(\mathsf{Cont}(\mathsf{append}(L, a), \mathsf{append}(f, P), \mathsf{append}(\mathsf{append}(R, b), Q)) \iff \mathsf{Cont}(a, f, b)\big).$$

Proof. Transport the two context comparisons so the left and right contexts match definitionally. The forward direction first removes the common right suffix by the continuation suffix equivalence, then removes the common left prefix by the continuation prefix equivalence. The reverse direction applies the same two equivalences in the opposite order. □

Lean4 ✓ `BEDC.FKernel.Cont.cont hsame common context iff`

18.6 Asking events and bundles

Definition 18.24 (Asking event)**.** *An asking event is a judgment*

$$\mathsf{Ask}(\pi, h, m, \delta),$$

where π is a probe-name, h is a generated history, m is a raw mark emitted as answer, and δ is evidence produced by the asking event. This is not a function application.

Lean4 (definition) `BEDC.FKernel.Ask.Ask`

Definition 18.25 (Probe bundles)**.** *Probe bundles are generated by:*

$$\mathsf{Bnil}, \qquad \Pi \mapsto \mathsf{Bcons}(\pi, \Pi).$$

They are internal generated records of probe-names, not imported finite lists.

Definition 18.26 (Ask policy)**.** *An* $\mathsf{AskPolicy}(\Pi, D)$ *occurrence is paper notation for applying the checked* $\mathsf{AskPolicy}(D)$ *certificate at bundle Π. The certificate gives enough asking events for probe names used by signature generation, with Lean fields quantified over all probe names, and records determinacy up to* msame *plus respect for* hsame.

Lean4 ✓ `BEDC.FKernel.Ask.askPolicy event determinacy respects fields`

18.7 Signatures and signature-sameness

Definition 18.27 (Generated signature)**.** *The signature judgment*

$$\mathsf{Sig}(\Pi, h, s, \Delta)$$

means that asking bundle Π *against history* h *generates answer history* s *with evidence ledger* Δ*. It is generated by an empty rule for* Bnil *and a cons rule using one* Ask*-event followed by the signature of the remaining bundle.*

Lean4 (definition) `BEDC.FKernel.Sig.SigRel`

Theorem 18.28 (Empty signature has no visible output)**.** *For the empty probe bundle, generated signatures cannot have answer history* $\mathsf{E0}(p)$ *or* $\mathsf{E1}(p)$ *for any* $p : \mathsf{BHist}$*.*

Proof. Invert the empty-bundle signature derivation. Its only generated result is the empty history, and BEDC history constructor no-confusion excludes both visible constructors from being empty. □

Lean4 ✓ `BEDC.FKernel.Sig.sig empty visible absurd`

Definition 18.29 (Signature-sameness)**.** *For a bundle* Π*, histories* h, k *are signature-same, written* $\mathsf{sameSig}(\Pi, h, k)$*, when there exist generated signatures*

$$\mathsf{Sig}(\Pi, h, s, \Delta), \qquad \mathsf{Sig}(\Pi, k, t, \Theta),$$

with $\mathsf{hsame}(s, t)$*.*

Theorem 18.30 (Signature determinacy under policy)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$*. If* $h \in D$*,* $\mathsf{Sig}(\Pi, h, s, \Delta)$*, and* $\mathsf{Sig}(\Pi, h, t, \Theta)$*, then* $\mathsf{hsame}(s, t)$*.*

Lean4 ✓ `BEDC.FKernel.Sig.proof sprint signature determinacy under policy`

Proof. By induction on the generated bundle. The empty bundle produces empty signatures. For a cons bundle, determinacy of the first asking event gives msame of the first answer marks, and the induction hypothesis gives hsame of the remaining answer histories. The history constructor closure rules then yield $\mathsf{hsame}(s, t)$. □

Theorem 18.31 (Signature-sameness is an equivalence under policy)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$*. On histories in* D*,* $\mathsf{sameSig}(\Pi, -, -)$ *is reflexive, symmetric, and transitive.*

Lean4 ✓ `BEDC.FKernel.Sig.proof sprint signature sameness equivalence under policy`

Proof. Reflexivity uses totality of signature generation and reflexivity of hsame. Symmetry uses symmetry of hsame. For transitivity, suppose h is signature-same to k, and k is signature-same to l. The two signatures generated for k are internally the same by signature determinacy. Transitivity of hsame then composes the answer-history sameness witnesses. □

18.8 Packaging and gap policies

Definition 18.32 (Package token)**.** *A package token is a visible token licensed for a signature. The judgment*

$$\mathsf{Pkg}(\Pi, s, p)$$

means that signature s under bundle Π licenses package token p.

Definition 18.33 (Package policy)**.** *A* $\mathsf{PackagePolicy}(\Pi)$ *specifies package existence, package extensionality over* hsame*-same signatures, and package grounding: packages are grounded in signature classes, not in arbitrary external choices.*

Definition 18.34 (Gap membership)**.** *The judgment*

$$\mathsf{Gap}(\Pi, D, p, h)$$

means that source history $h \in D$ is recorded in the ledger of package token p. A gap policy relates this membership to generated signatures and package tokens.

Definition 18.35 (Gap policy)**.** *A* $\mathsf{GapPolicy}(\Pi, D)$ *states that h belongs to the gap of p exactly when h generates some signature s licensed by package p, up to the internal sameness policies specified for histories and packages.*

Theorem 18.36 (Gap coverage)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$*,* $\mathsf{PackagePolicy}(\Pi)$*, and* $\mathsf{GapPolicy}(\Pi, D)$*. Every source history $h \in D$ belongs to the gap of some package token.*

Lean4 ✓ `BEDC.FKernel.Gap.gapPolicy requires ledger witness`
↪ variant `BEDC.FKernel.Gap.gap ledgers not optional`
↪ variant `BEDC.FKernel.Gap.gapPolicy coverage full witnesses`

Proof. By the ask policy, h generates a signature. By the package policy, that signature licenses a package token. By the gap policy, h belongs to the ledger of that package. □

Theorem 18.37 (Gap separation)**.** *Assume the same policies. If one source history belongs to the gaps of two package tokens, then the two package tokens are internally package-same.*

Lean4 ✓ `BEDC.FKernel.Gap.proof sprint gap separation`

Proof. Membership in each gap gives two generated signatures for the same source history. Signature determinacy gives hsame of those signatures. Package extensionality then gives internal package-sameness of the two package tokens. □

Corollary 18.38 (Globalization classifies by signatures)**.** *Under the three policies above, visible package tokens classify source histories by generated signatures, while gap ledgers record the histories compressed into each visible package.*

Lean4 ✓ `BEDC.FKernel.Gap.proof sprint globalization classifies by signatures`

18.9 Composite gap ledgers

Definition 18.39 (Composite gap)**.** *Suppose a first visible interface compresses sources into intermediate tokens and a second visible interface compresses intermediate tokens into final tokens. The composite gap of a final token contains a source exactly when there exists an intermediate token connecting the two gap memberships. Symbolically:*

$$\mathsf{CompGap}_{D\circ C}(z,x) \quad \textit{iff} \quad \exists y,\ \mathsf{Gap}_D(z,y) \textit{ and } \mathsf{Gap}_C(y,x).$$

This is a meta-kernel ledger law, not an object-language primitive.

Theorem 18.40 (Composite gap coverage)**.** *If the first and second gap interfaces satisfy coverage, then the composite gap satisfies coverage.*

Lean4 ✓ `BEDC.FKernel.Gap.compGap coverage from sourced layers`

Proof. Given a source, use coverage of the first interface to obtain an intermediate token. Then use coverage of the second interface to obtain a final token. The intermediate token witnesses composite membership. □

18.10 Name certificates

Definition 18.41 (Typed naming certificate)**.** *A paper name-certificate template is a record*

$$\mathsf{NameCert}(N) = (\mathsf{SourceSpec}, \mathsf{PatternSpec}, \mathsf{ClassifierSpec}, \mathsf{StabilityCert}, \mathsf{LedgerPolicy}).$$

It licenses a derived name N. A name without such a certificate is not admitted as a derived interface.

Definition 18.42 (Stability certificate modes)**.** *The stability component may include closure, reuse, descent, composition, or seal certificates:*

$$\mathsf{ClosureCert}, \quad \mathsf{ReuseCert}, \quad \mathsf{DescentCert}, \quad \mathsf{CompositionCert}, \quad \mathsf{SealCert}.$$

Different derived interfaces require different stability modes.

Theorem 18.43 (Derived interfaces require certificates)**.** *No derived interface is licensed unless a corresponding* NameCert *is supplied.*

Proof. This is the admission protocol for derived names. A bare traditional name is not a kernel object. It becomes an admitted derived interface only through a certificate specifying source, pattern, classifier, stability, and ledger policy. □

18.11 First derived interface seeds

Definition 18.44 (Unary history)**.** *A unary history is a generated history built from* e *using only* E1*. This is not yet a natural number; it is only a repetition history.*

Lean4 (definition) `BEDC.FKernel.Unary.UnaryHistory`

Theorem 18.45 (Nonempty unary histories expose an E_1-tail)**.** *For every history h : BHist, if h is unary and $h$hsamee would be contradictory, then $h = \mathsf{E1}(t)$ for some unary tail t.*

Proof. Split the unary-history cases into the empty case and the visible E1-tail case. The empty branch contradicts the displayed nonempty hypothesis, while the visible branch gives the required tail witness. □

Lean4 ✓ `BEDC.FKernel.Unary.unary history nonempty e1 tail`

Corollary 18.46 (Natural-number-like interface seed)**.** *The family of unary histories licenses a minimal* $\mathsf{Nat}^{\uparrow}$ *seed once supplied with a name certificate whose pattern is repeated one-emission and whose stability certifies closure under one-extension.*

Corollary 18.47 (Addition-like interface seed)**.** *Continuation of unary histories licenses a minimal* $\mathsf{Add}^{\uparrow}$ *seed once supplied with a name certificate whose stability certifies unit and associativity behavior of continuation.*

Remark 18.48. *These are only interface seeds. They do not yet amount to a full arithmetic reconstruction.*

18.12 Thin completion interface

Definition 18.49 (Thin seal interface)**.** *A seal-like interface records the shape of an eventual completion module: staged data, restriction events, compatible threads, a seal event, and a tail ledger. It is not part of the finite kernel proof target.*

Remark 18.50. *Limit-like and fold-like constructions remain outside the primitive finite-kernel proof target. Real-like and circle-like names may appear only as* NameCert*-governed obligation schemas with supplied classifiers and ledgers.*

18.13 External semantic model

Definition 18.51 (Binary external model)**.** *An external model* $\mathcal{M}_{\mathsf{bin}}$ *interprets raw marks as two external tokens, histories as finite binary words,* msame *and* hsame *as literal token and word sameness,* Ext *and* Cont *as ordinary word extension and concatenation, asking events as binary-valued external relations, signatures as generated answer words, packages as signature classes, gaps as inverse images, and composite gaps as relational composition of inverse images.*

Lean4 ✓ `BEDC.FKernel.ExternalBinary.external model append reuses cont`

Theorem 18.52 (External model soundness, finite kernel)**.** *The external model* $\mathcal{M}_{\mathsf{bin}}$ *satisfies the finite kernel rules for marks, histories, internal sameness, extension, continuation, asking events, generated signatures, package policies, gap coverage, gap separation, and composite gap coverage.*

Lean4 ✓ `BEDC.FKernel.ExternalBinary.external model finite kernel soundness`

Proof. Each kernel clause is interpreted by the corresponding operation on finite binary words. Mark and history sameness become literal sameness. Extension and continuation become word extension and concatenation, whose determinacy, unit, and associativity properties are immediate in the external model. Signature policies interpret generated questioning as answer-word construction. Package and gap policies interpret classes as fibers of signatures. Composite gap coverage follows from relational composition of fibers. □

18.14 Finite theorem target

The finite proof target consists of the following named results:

T1. msame reflexivity, symmetry, transitivity.

T2. mark no-confusion.

T3. hsame reflexivity, symmetry, transitivity.

T4. history no-confusion.

T5. Ext determinacy and sameness-respect.

T6. Cont determinacy.

T7. continuation left and right units.

T8. continuation associativity, relational form.

T9. signature determinacy under AskPolicy.

T10. sameSig equivalence under AskPolicy.

T11. gap coverage under the three policies.

T12. gap separation under the three policies.

T13. composite gap coverage.

T14. certificate admission for derived interfaces.

T15. unary history and unary continuation interface seeds.

18.15 Conclusion

The finite-kernel proof target identifies the first theorem set to be checked. The main goal is no longer to expand toward more traditional mathematics, but to verify that the finite kernel is internally coherent: marks have internal sameness, histories have internal sameness, extension and continuation are relational but deterministic up to internal sameness, signatures are generated by event-style asking, packages classify signatures, gaps cover and separate sources, composite gaps preserve coverage, and derived names require certificates.

The finite kernel may be summarized as:

$$\boxed{\mathsf{b0}, \mathsf{b1} \to \mathsf{Hist} \to \mathsf{msame}, \mathsf{hsame} \to \mathsf{Ext}, \mathsf{Cont} \to \mathsf{Ask} \to \mathsf{Sig} \to \mathsf{sameSig} \to \mathsf{Pkg} \to \mathsf{Gap} \to \mathsf{NameCert}.}$$

Beyond this finite target, completion-like, fold-like, geometric, and algebraic constructions are governed by their own certificate schemas. Real-like and circle-like names inside the manuscript are obligation schemas, not primitive finite-kernel exports.

Chapter 19

Finite-Kernel Theorem Dependency DAG

This chapter gives the proof dependency order for the finite-kernel sprint. It is a planning artifact for the proof target, not a new object-theory primitive.

19.1 Milestone DAG

The dependency chain is:

A. Mark layer
↓
B. History layer
↓
C. Extension and continuation
↓
D. Asking and signature generation
↓
E. Signature sameness
↓
F. Package policy
↓
G. Gap policy
↓
H. Composite ledger
↓
I. Naming certificates

The proof effort should not attempt large derived interfaces before Milestones A–G are mechanically checked.

19.2 Milestone A: marks

1. msame-reflexivity.
2. msame-symmetry.

3. msame-transitivity.
4. Mark no-confusion: b0 is not internally the same as b1, and conversely.

19.3 Milestone B: histories

1. hsame-reflexivity.
2. hsame-symmetry.
3. hsame-transitivity.
4. History no-confusion for empty, E0, and E1 constructors.

19.4 Milestone C: relational extension and continuation

1. Ext-determinacy up to hsame.

   Lean4 ✓ `BEDC.FKernel.Ext.proof sprint extension determinacy`
2. Ext-respect for msame and hsame.
3. Cont-determinacy up to hsame.
4. Left and right unit laws for Cont.

   Lean4 ✓ `BEDC.FKernel.Cont.cont right unit proof sprint`
5. Associativity of Cont up to hsame.

19.5 Milestone D: asking and signatures

1. Generated bundle grammar is fixed.
2. Signature generation rules are fixed.
3. Under $\mathsf{AskPolicy}(\Pi, D)$, signatures exist for histories in the domain.
4. Under $\mathsf{AskPolicy}(\Pi, D)$, signatures are deterministic up to hsame.

19.6 Milestone E: signature sameness

1. sameSig-reflexivity under AskPolicy.
2. sameSig-symmetry.
3. sameSig-transitivity under deterministic signatures.
4. Signature sameness is an equivalence relation on the chosen domain.

19.7 Milestones F–G: packages and gaps

1. PackagePolicy existence.
2. PackagePolicy extensionality: internally same signatures yield internally same packages.
3. PackagePolicy grounding: internally same packages are justified by internally same signatures.
4. GapPolicy coverage: every admissible source history appears in some gap.
5. GapPolicy separation: genuinely different packages have disjoint source membership.
6. Packaging classifies by signatures.

19.8 Milestone H: composite gap

For two compression interfaces C and D, prove:

1. composite gap is defined by an intermediate witness;
2. composite coverage follows from coverage of both stages;
3. composite separation requires separation plus a suitable grounding condition.

19.9 Milestone I: naming certificates

The first mechanically useful certificates should be:

1. a unary repetition source certificate for $\mathsf{Nat}^{\uparrow}$;
2. a continuation stability certificate for $\mathsf{Add}^{\uparrow}$;
3. a descent certificate for function-like interfaces;
4. a ledger policy stating what is preserved by each derived name.

19.10 Execution rule

The implementation sprint should stop at the first unverified milestone and not skip ahead. If Milestone A fails, later milestone statements are not repaired by changing the core theory silently; the affected definitions must be amended in place per the policy in Chapter 9466.

Part III

Proof Standing

Chapter 20

Closed Generation and Internal Sameness

The finite kernel relies on a closed-generation reading: judgments are generated only by their displayed constructors. This is not an extra mathematical object inside the theory; it is the proof discipline governing the kernel rules.

Principle 20.1 (Closed generation)**.** *For each primitive judgment family introduced in the finite kernel, the only valid derivations are those generated by its displayed rules. In particular, there are no hidden conversion, coercion, or extensionality rules.*

Definition 20.2 (Mark constructors)**.** *The raw marks are generated by two constructors,* $\mathsf{b0}$ *and* $\mathsf{b1}$*. The internal mark-sameness judgment* $\mathsf{msame}(m, n)$ *is generated by the two displayed reflexive constructors:*

$$\mathsf{msame}(\mathsf{b0}, \mathsf{b0}), \qquad \mathsf{msame}(\mathsf{b1}, \mathsf{b1}).$$

No cross-constructor rule is present.

Theorem 20.3 (Mark no-confusion)**.** *The following judgments are not derivable:*

$$\mathsf{msame}(\mathsf{b0}, \mathsf{b1}), \qquad \mathsf{msame}(\mathsf{b1}, \mathsf{b0}).$$

Proof. By closed generation, every derivation of msame must end in one of the two mark-sameness constructors. The first constructor has target $\mathsf{msame}(\mathsf{b0}, \mathsf{b0})$, and the second has target $\mathsf{msame}(\mathsf{b1}, \mathsf{b1})$. Neither constructor has target $\mathsf{msame}(\mathsf{b0}, \mathsf{b1})$ or $\mathsf{msame}(\mathsf{b1}, \mathsf{b0})$. Hence the cross judgments are not generated. □

Theorem 20.4 (msame is an internal equivalence)**.** *The judgment* msame *is reflexive, symmetric, and transitive on generated marks.*

Proof. Reflexivity follows by cases on the two generated marks. Symmetry follows because each generated proof of $\mathsf{msame}(m, n)$ has identical endpoints. Transitivity follows by case analysis on the first proof and mark no-confusion on the second. □

Definition 20.5 (History constructors)**.** *The generated histories are built from an empty history* e *and two extension constructors* $\mathsf{E0}$ *and* $\mathsf{E1}$*. The internal history-sameness judgment* $\mathsf{hsame}(h, k)$ *is generated structurally from matching constructors.*

Theorem 20.6 (History no-confusion)**.** *The following judgments are not derivable:*

$$\mathsf{hsame}(\mathsf{e}, \mathsf{E0}(h)), \quad \mathsf{hsame}(\mathsf{e}, \mathsf{E1}(h)), \quad \mathsf{hsame}(\mathsf{E0}(h), \mathsf{E1}(k)), \quad \mathsf{hsame}(\mathsf{E1}(h), \mathsf{E0}(k)).$$

Proof. By closed generation, a derivation of hsame must follow the displayed structural constructors. Empty histories can only be matched with empty histories. A history beginning with E0 can only be matched with a history beginning with E0, and similarly for E1. There is no displayed constructor crossing E0 with E1, nor a constructor crossing either extension with e. Therefore the listed judgments are not generated. □

Theorem 20.7 (History constructor kind preservation)**.** *If* $\mathsf{hsame}(h, k)$ *is derivable, then* h *and* k *have the same outer constructor kind: empty with empty,* E0 *with* E0*, or* E1 *with* E1*.*

Lean4 ✓ `BEDC.FKernel.Hist.hsame constructor kind preserved`

Proof. Invert the displayed derivation of $\mathsf{hsame}(h, k)$. Each constructor of the generated judgment relates histories built by the same outer history constructor, so the conclusion follows by cases on that final constructor. □

Theorem 20.8 (hsame is an internal equivalence)**.** *The judgment* hsame *is reflexive, symmetric, and transitive on generated histories.*

Proof. Reflexivity is proved by induction on generated histories. Symmetry is proved by induction on the displayed derivation of hsame. Transitivity is proved by induction on the first derivation, using history no-confusion to invert the second derivation into the matching constructor case. □

Corollary 20.9 (E0-constructor inversion)**.** *For histories* h *and* k*,* $\mathsf{hsame}(\mathsf{E0}(h), \mathsf{E0}(k))$ *is derivable exactly when* $\mathsf{hsame}(h, k)$ *is derivable.*

Lean4 ✓ `BEDC.FKernel.Hist.hsame e0 iff`

Proof. The forward direction inverts the final constructor of the displayed derivation. The reverse direction applies the E0-congruence constructor for hsame. □

Corollary 20.10 (E1-constructor inversion)**.** *For histories* h *and* k*,* $\mathsf{hsame}(\mathsf{E1}(h), \mathsf{E1}(k))$ *is derivable exactly when* $\mathsf{hsame}(h, k)$ *is derivable.*

Lean4 ✓ `BEDC.FKernel.Hist.hsame e1 iff`

Proof. The forward direction inverts the final constructor of the displayed derivation. The reverse direction applies the E1-congruence constructor for hsame. □

Corollary 20.11 (Constructor inversion)**.** *If* hsame(E0$(h), x$) *is derivable, then* x *is generated through an* E0*-constructor up to the displayed structural form. If* hsame(E1$(h), x$) *is derivable, then* x *is generated through an* E1*-constructor up to the displayed structural form.*

Chapter 21

Extension and Continuation Proof Spine

This chapter records the proof-standing status of the extension and continuation relations. Both are relation-generated behaviors, not primitive functions.

21.1 Relational extension

Definition 21.1 (Extension relation)**.** *The relation* $\mathsf{Ext}(m, h, r)$ *is generated by:*

$$\mathsf{Ext}(\mathsf{b0}, h, \mathsf{E0}(h)), \qquad \mathsf{Ext}(\mathsf{b1}, h, \mathsf{E1}(h)).$$

It expresses that emitting mark m *after history* h *generates result* r*.*

Theorem 21.2 (Extension determinacy up to history-sameness)**.** *If*

$$\mathsf{Ext}(m, h, r) \quad \textit{and} \quad \mathsf{Ext}(m, h, r'),$$

then $\mathsf{hsame}(r, r')$*.*

Lean4 ✓ `BEDC.FKernel.Ext.ext determinacy up to hsame spine`

Proof. By case analysis on the generated extension proof. If $m = \mathsf{b0}$, both generated results have the form $\mathsf{E0}(h)$, hence they are history-same by reflexivity. If $m = \mathsf{b1}$, both generated results have the form $\mathsf{E1}(h)$, hence they are history-same by reflexivity. No cross mark case is generated for the same mark input. □

Theorem 21.3 (Extension respects internal sameness)**.** *Suppose* $\mathsf{msame}(m, n)$*,* $\mathsf{hsame}(h, k)$*,* $\mathsf{Ext}(m, h, r)$*, and* $\mathsf{Ext}(n, k, s)$*. Then* $\mathsf{hsame}(r, s)$*.*

Lean4 ✓ `BEDC.FKernel.Ext.ext respects internal sameness spine`

Proof. By induction on the generated proof of $\mathsf{msame}(m, n)$. There are only two cases. In the $\mathsf{b0}$ case, the extension results are generated with outer constructor $\mathsf{E0}$, and the conclusion follows by applying the $\mathsf{E0}$ history-sameness constructor to $\mathsf{hsame}(h, k)$. The $\mathsf{b1}$ case is identical with $\mathsf{E1}$. □

Theorem 21.4 (Extension result source-mark characterization)**.** *If* $\mathsf{Ext}(m, h, r)$ *and* $\mathsf{Ext}(m', h', r')$*, then*

$$\mathsf{hsame}(r, r') \iff \mathsf{hsame}(h, h') \wedge \mathsf{msame}(m, m').$$

Lean4 ✓ `BEDC.FKernel.Ext.ext result hsame source mark hsame iff`

Proof. For the forward direction, use result-history injectivity for generated extensions. For the reverse direction, transport the source histories and marks across internal sameness, then compare the two generated extension results. □

Theorem 21.5 (Extension result is nonempty)**.** *If* $\mathsf{Ext}(m, h, r)$*, then* r *is not history-same to* e*.*

Proof. Case-split the generated extension proof. The $\mathsf{b0}$ case has result $\mathsf{E0}(h)$, which cannot be history-same to e by history constructor no-confusion. The $\mathsf{b1}$ case is identical with $\mathsf{E1}(h)$. □

Lean4 ✓ `BEDC.FKernel.Ext.ext result ne empty`

21.2 Relational continuation

Definition 21.6 (Continuation relation)**.** *The relation* $\mathsf{Cont}(h, k, r)$ *is generated by:*

1. $\mathsf{Cont}(h, \mathsf{e}, h)$*;*
2. *if* $\mathsf{Cont}(h, k, r)$*, then* $\mathsf{Cont}(h, \mathsf{E0}(k), \mathsf{E0}(r))$*;*
3. *if* $\mathsf{Cont}(h, k, r)$*, then* $\mathsf{Cont}(h, \mathsf{E1}(k), \mathsf{E1}(r))$*.*

It expresses continuation of history h *by history* k *without treating continuation as a primitive function.*

Theorem 21.7 (Continuation determinacy up to history-sameness)**.** *If* $\mathsf{Cont}(h, k, r)$ *and* $\mathsf{Cont}(h, k, r')$*, then* $\mathsf{hsame}(r, r')$*.*

Lean4 ✓ `BEDC.FKernel.Cont.cont determinacy up to hsame spine`

Proof. By induction on the generated right-history structure in the first continuation proof. In the empty case, the second proof must also be the empty case, hence both results are h. In the $\mathsf{E0}$ case, the second proof must also have right input and result with outer $\mathsf{E0}$ by closed generation; apply the induction hypothesis to the sub-results and then apply the $\mathsf{E0}$ constructor for hsame. The $\mathsf{E1}$ case is analogous. □

Theorem 21.8 (Continuation result history-sameness iff)**.** *If* $\mathsf{Cont}(a, f, r)$ *holds, then for every history* s*,*

$$\mathsf{Cont}(a, f, s) \iff \mathsf{hsame}(s, r).$$

Lean4 ✓ `BEDC.FKernel.Cont.cont result hsame iff`

Proof. For the forward direction, continuation determinacy compares the two results with the same source and tail. For the reverse direction, transport the given continuation result along the displayed history-sameness. □

Theorem 21.9 (Continuation source history-sameness iff)**.** *If* $\mathsf{Cont}(a, f, r)$ *holds, then for every history* a'*,*

$$\mathsf{Cont}(a', f, r) \iff \mathsf{hsame}(a', a).$$

Lean4 ✓ `BEDC.FKernel.Cont.cont source hsame iff`

Proof. For the forward direction, right cancellation compares the two continuations with shared tail and result. For the reverse direction, transport the source endpoint of the given continuation along the displayed history-sameness while keeping the tail and result fixed. □

Theorem 21.10 (Continuation result history-sameness tag separation)**.** *If* $\mathsf{Cont}(h, k, r_0)$ *and* $\mathsf{Cont}(h, k, r_1)$*, and if* $\mathsf{hsame}(r_0, \mathsf{E0}(z))$ *while* $\mathsf{hsame}(r_1, \mathsf{E1}(o))$*, then contradiction.*

Lean4 ✓ `BEDC.FKernel.Cont.cont result hsame tag separation`

Proof. Continuation determinacy gives $\mathsf{hsame}(r_0, r_1)$. Composing this equality with the two displayed tag classifications yields $\mathsf{hsame}(\mathsf{E0}(z), \mathsf{E1}(o))$, contradicting generated-history no-confusion between the zero and one constructors. □

Theorem 21.11 (Continuation step result history-sameness no-confusion pair)**.** *The two one-step continuation result shapes are disjoint up to history-sameness:*

$$\mathsf{Cont}(h, \mathsf{E0}(k_0), r_0), \quad \mathsf{Cont}(h, \mathsf{E1}(k_1), r_1), \quad \mathsf{hsame}(r_0, r_1)$$

is impossible, and the same holds with the displayed zero and one steps exchanged.

Lean4 ✓ `BEDC.FKernel.Cont.cont step result hsame no confusion pair`

Proof. Invert the zero-step continuation witness to expose $r_0 = \mathsf{E0}(a)$ and invert the one-step witness to expose $r_1 = \mathsf{E1}(b)$. The displayed $\mathsf{hsame}(r_0, r_1)$ then becomes $\mathsf{hsame}(\mathsf{E0}(a), \mathsf{E1}(b))$, which is ruled out by generated-history no-confusion. The exchanged direction is identical with the zero and one constructors swapped. □

Theorem 21.12 (Continuation unit laws)**.** *For every generated history* h*,* $\mathsf{Cont}(h, \mathsf{e}, h)$*. Moreover, for every generated history* k*,* $\mathsf{Cont}(\mathsf{e}, k, k)$*, and if* $\mathsf{Cont}(h, \mathsf{e}, r)$*, then* $\mathsf{hsame}(r, h)$*.*

Lean4 ✓ `BEDC.FKernel.Cont.cont right unit iff`
↪variant `BEDC.FKernel.Cont.cont unit laws spine`

Proof. The right unit is the base constructor. The left unit is proved by induction on k. The empty case is immediate. If $k = \mathsf{E0}(k')$, use the induction hypothesis for k' and rebuild with the $\mathsf{E0}$ constructor. The $\mathsf{E1}$ case is analogous. The uniqueness form follows by continuation determinacy against the base constructor. □

Theorem 21.13 (Continuation right-unit law endpoint emptiness)**.** *For every generated history* u*, the universal right-unit result law*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{Cont}(d, u, r) \to \mathsf{hsame}(r, d)$$

holds if and only if $u\mathsf{hsamee}$*.*

Lean4 ✓ `BEDC.FKernel.Cont.cont right unit law endpoint empty iff`

Proof. If the universal law holds, apply it to the left-unit continuation $\mathsf{Cont}(\mathsf{e}, u, u)$ to obtain $u\mathsf{hsamee}$. Conversely, after the endpoint is identified with e, any continuation $\mathsf{Cont}(d, \mathsf{e}, r)$ is a right-unit continuation, so right-unit result uniqueness gives $\mathsf{hsame}(r, d)$. □

Theorem 21.14 (Continuation left-unit law endpoint emptiness)**.** *For every generated history u, the universal left-unit result law*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{Cont}(u, d, r) \to \mathsf{hsame}(r, d)$$

holds if and only if $u\mathsf{hsamee}$.

Lean4 ✓ `BEDC.FKernel.Cont.cont left unit law endpoint empty iff`

Proof. If the universal law holds, apply it to the right-unit continuation $\mathsf{Cont}(u, \mathsf{e}, u)$ to obtain $u\mathsf{hsamee}$. Conversely, after the endpoint is identified with e, any continuation $\mathsf{Cont}(\mathsf{e}, d, r)$ is a left-unit continuation, so the left-unit result theorem gives $\mathsf{hsame}(r, d)$. □

Theorem 21.15 (Continuation eone right-unit probe forces emptiness)**.** *For every generated history u, the fixed one-headed probe law*

$$\forall r : \mathsf{BHist}.\ \mathsf{Cont}(\mathsf{E1}(\mathsf{e}), u, r) \to \mathsf{hsame}(r, \mathsf{E1}(\mathsf{e}))$$

forces $u\mathsf{hsamee}$.

Lean4 ✓ `BEDC.FKernel.Cont.cont e1 right unit probe forces empty`

Proof. Apply the probe law to the canonical continuation $\mathsf{Cont}(\mathsf{E1}(\mathsf{e}), u, \mathsf{append}(\mathsf{E1}(\mathsf{e}), u))$. Continuation result transport gives $\mathsf{Cont}(\mathsf{E1}(\mathsf{e}), u, \mathsf{E1}(\mathsf{e}))$, and right-unit uniqueness then forces the right endpoint u to be empty. □

Theorem 21.16 (Mutual continuation collapses to history-sameness)**.** *If* $\mathsf{Cont}(h, l, k)$ *and* $\mathsf{Cont}(k, r, h)$*, then* $\mathsf{hsame}(h, k)$.

Lean4 ✓ `BEDC.FKernel.Cont.cont mutual extension hsame`

Proof. Compose the two continuation equations into a cycle from h back to h with tail $\mathsf{append}(l, r)$. Right-unit uniqueness forces this composite tail to be empty. Empty append inversion forces l to be empty, so the first continuation reduces to $\mathsf{hsame}(h, k)$. □

Theorem 21.17 (Mutual continuation has empty tails)**.** *If* $\mathsf{Cont}(h, l, k)$ *and* $\mathsf{Cont}(k, r, h)$*, then*

$$\mathsf{hsame}(l, \mathsf{e}) \quad \textit{and} \quad \mathsf{hsame}(r, \mathsf{e}).$$

Proof. Compose the two continuations into a cycle from h back to h whose tail is $\mathsf{append}(l, r)$. Right-unit uniqueness forces that composite tail to be empty, and empty-append inversion identifies both component tails with e. □

Lean4 ✓ `BEDC.FKernel.Cont.cont mutual extension tails empty`

Theorem 21.18 (Composite endpoint empty tails iff)**.** *For histories* $a, b, c, f, g : \mathsf{BHist}$*, if*

$$\mathsf{Cont}(a, f, b) \qquad \textit{and} \qquad \mathsf{Cont}(b, g, c),$$

then the composite endpoints close exactly when the two exposed tails are empty:

$$\mathsf{hsame}(c, a) \iff \mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}).$$

Proof. Compose the two continuation ledgers into $\mathsf{Cont}(a, \mathsf{append}(f, g), c)$. If $c\mathsf{hsame}a$, transport the result to obtain a cycle $\mathsf{Cont}(a, \mathsf{append}(f, g), a)$; right-unit uniqueness and empty-append inversion identify f and g with e.

Conversely, if both exposed tails are empty, the first continuation reduces b to a and the second reduces c to b by determinacy against right-unit continuations. Transitivity gives $c\mathsf{hsame}a$. □

Lean4 ✓ `BEDC.FKernel.Cont.cont composite endpoint empty tails iff`

Theorem 21.19 (Nested continuation with visible middle cannot end empty)**.** *For histories* $l, tail, r, u, v : \mathsf{BHist}$*, neither branch*

$$\mathsf{Cont}(l, \mathsf{E0}(tail), u), \qquad \mathsf{Cont}(u, r, v), \qquad \mathsf{hsame}(v, \mathsf{e})$$

nor branch

$$\mathsf{Cont}(l, \mathsf{E1}(tail), u), \qquad \mathsf{Cont}(u, r, v), \qquad \mathsf{hsame}(v, \mathsf{e})$$

can hold.

Proof. In either branch, the outer continuation and $v\mathsf{hsame}\mathsf{e}$ force $\mathsf{append}(u, r)\mathsf{hsame}\mathsf{e}$. Empty-append inversion gives $u\mathsf{hsame}\mathsf{e}$. The middle continuation then forces $\mathsf{append}(l, \mathsf{E0}(tail))\mathsf{hsame}\mathsf{e}$ or $\mathsf{append}(l, \mathsf{E1}(tail))\mathsf{hsame}\mathsf{e}$, and a second empty-append inversion identifies the headed constructor with e, contradicting history constructor no-confusion. □

Lean4 ✓ `BEDC.FKernel.Cont.cont nested visible middle result absurd`

Theorem 21.20 (Nested continuation empty-result inversion)**.** *For histories* $a, b, c, f, g : \mathsf{BHist}$*, if*

$$\mathsf{Cont}(a, f, b), \qquad \mathsf{Cont}(b, g, c), \qquad c\mathsf{hsame}\mathsf{e},$$

then all exposed endpoints and tails of the nested continuation are empty:

$$a\mathsf{hsame}\mathsf{e}, \qquad f\mathsf{hsame}\mathsf{e}, \qquad b\mathsf{hsame}\mathsf{e}, \qquad g\mathsf{hsame}\mathsf{e}.$$

Proof. Transport the outer continuation result along $c\mathsf{hsame}\mathsf{e}$ and apply empty-result inversion to $\mathsf{Cont}(b, g, \mathsf{e})$, identifying b and g with e. With the middle endpoint identified as empty, apply the same empty-result inversion to the inner continuation $\mathsf{Cont}(a, f, b)$ to identify a and f with e. □

Lean4 ✓ `BEDC.FKernel.Cont.cont nested empty result inversion`

Theorem 21.21 (Mutual continuation forbids visible right tails)**.** *If* $\mathsf{Cont}(h, l, k)$ *holds, then neither* $\mathsf{Cont}(k, \mathsf{E0}(r), h)$ *nor* $\mathsf{Cont}(k, \mathsf{E1}(r), h)$ *can hold.*

Proof. Apply the empty-tail theorem to the two mutual continuations. In the $\mathsf{E0}(r)$ branch it would identify $\mathsf{E0}(r)$ with e, contradicting history constructor no-confusion. The $\mathsf{E1}(r)$ branch is identical with the one-constructor no-confusion theorem. □

Lean4 ✓ `BEDC.FKernel.Cont.cont mutual extension right tail absurd`

Theorem 21.22 (Triangular continuation cycle forbids a visible left tail)**.** *If*

$$\mathsf{Cont}(a, \mathsf{E1}(k), b), \qquad \mathsf{Cont}(b, g, c), \qquad \mathsf{Cont}(c, h, a)$$

all hold, then contradiction follows.

Proof. Compose the first two continuations into $\mathsf{Cont}(a, \mathsf{append}(\mathsf{E1}(k), g), c)$. This composite and the return continuation $\mathsf{Cont}(c, h, a)$ form a mutual continuation cycle, so the composite tail is empty. Empty-append inversion identifies $\mathsf{E1}(k)$ with e, contradicting history constructor no-confusion. □

Lean4 ✓ `BEDC.FKernel.Cont.cont triangle cycle left visible tail absurd`

Theorem 21.23 (Triangular continuation cycle forbids a zero left tail)**.** *If*

$$\mathsf{Cont}(a, \mathsf{E0}(k), b), \qquad \mathsf{Cont}(b, g, c), \qquad \mathsf{Cont}(c, h, a)$$

all hold, then contradiction follows.

Proof. Compose the first two continuations into $\mathsf{Cont}(a, \mathsf{append}(\mathsf{E0}(k), g), c)$. This composite and the return continuation $\mathsf{Cont}(c, h, a)$ form a mutual continuation cycle, so the composite tail is empty. Empty-append inversion identifies $\mathsf{E0}(k)$ with e, contradicting history constructor no-confusion. □

Lean4 ✓ `BEDC.FKernel.Cont.cont triangle cycle left zero tail absurd`

Theorem 21.24 (Triangular continuation cycle forbids a visible middle tail)**.** *If*

$$\mathsf{Cont}(a, f, b), \qquad \mathsf{Cont}(b, \mathsf{E1}(k), c), \qquad \mathsf{Cont}(c, h, a)$$

all hold, then contradiction follows.

Proof. Compose the first two continuations into $\mathsf{Cont}(a, \mathsf{append}(f, \mathsf{E1}(k)), c)$. This composite and the return continuation form a mutual continuation cycle, so the composite tail is empty. Empty-append inversion identifies the middle visible tail $\mathsf{E1}(k)$ with e, contradicting history constructor no-confusion. □

Lean4 ✓ `BEDC.FKernel.Cont.cont triangle cycle middle visible tail absurd`

Theorem 21.25 (Triangular continuation cycle forbids a zero middle tail)**.** *If*

$$\mathsf{Cont}(a, f, b), \qquad \mathsf{Cont}(b, \mathsf{E0}(k), c), \qquad \mathsf{Cont}(c, h, a)$$

all hold, then contradiction follows.

Proof. Compose the first two continuations into $\mathsf{Cont}(a, \mathsf{append}(f, \mathsf{E0}(k)), c)$. This composite and the return continuation form a mutual continuation cycle, so the composite tail is empty. Empty-append inversion identifies the middle zero tail $\mathsf{E0}(k)$ with e, contradicting history constructor no-confusion. □

Lean4 ✓ `BEDC.FKernel.Cont.cont triangle cycle middle zero tail absurd`

Theorem 21.26 (Triangular continuation cycle forbids a visible right tail)**.** *If*

$$\mathsf{Cont}(a, f, b), \qquad \mathsf{Cont}(b, g, c), \qquad \mathsf{Cont}(c, \mathsf{E1}(k), a)$$

all hold, then contradiction follows.

Proof. Compose the first two continuations into $\mathsf{Cont}(a, \mathsf{append}(f, g), c)$. The composite continuation and the visible return tail give a mutual continuation with a one-headed right tail, which is forbidden by right-tail mutual-extension cancellation. □

Lean4 ✓ `BEDC.FKernel.Cont.cont triangle cycle right visible tail absurd`

Theorem 21.27 (Triangular continuation cycle forbids a zero right tail)**.** *If*

$$\mathsf{Cont}(a, f, b), \qquad \mathsf{Cont}(b, g, c), \qquad \mathsf{Cont}(c, \mathsf{E0}(k), a)$$

all hold, then contradiction follows.

Proof. Compose the first two continuations into $\mathsf{Cont}(a, \mathsf{append}(f, g), c)$. The composite continuation and the zero return tail give a mutual continuation with a zero-headed right tail, which is forbidden by right-tail mutual-extension cancellation. □

Lean4 ✓ `BEDC.FKernel.Cont.cont triangle cycle right zero tail absurd`

Theorem 21.28 (Triangular continuation cycle has empty tails)**.** *If*

$$\mathsf{Cont}(a, f, b), \qquad \mathsf{Cont}(b, g, c), \qquad \mathsf{Cont}(c, h, a)$$

all hold, then all three continuation tails are empty and the adjacent endpoints collapse:

$$\mathsf{hsame}(f, \mathsf{e}) \wedge \mathsf{hsame}(g, \mathsf{e}) \wedge \mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(b, c).$$

Proof. Compose the first two continuations into $\mathsf{Cont}(a, \mathsf{append}(f, g), c)$. This composite and the return continuation $\mathsf{Cont}(c, h, a)$ form a mutual continuation cycle, so the composite tail and the return tail are empty. Empty-append inversion splits the composite tail into $f\mathsf{hsamee}$ and $g\mathsf{hsamee}$. Comparing the first two continuation ledgers with right-unit continuations at a and b gives the adjacent endpoint equalities. □

Lean4 ✓ `BEDC.FKernel.Cont.cont triangle cycle tails empty`

Theorem 21.29 (Associativity up to history-sameness)**.** *Suppose*

$$\mathsf{Cont}(a, b, ab), \quad \mathsf{Cont}(ab, c, left), \quad \mathsf{Cont}(b, c, bc), \quad \mathsf{Cont}(a, bc, right).$$

Then $\mathsf{hsame}(left, right)$.

Lean4 ✓ `BEDC.FKernel.Cont.cont assoc up to hsame spine`

Proof. Use the right-recursive append associativity spine underlying Cont: first identify each continuation proof with its append result, then apply associativity for recursion on the right history c. The two displayed composites are therefore the same append tree up to hsame. □

Theorem 21.30 (Composite continuation tail uniqueness)**.** *If*

$$\mathsf{Cont}(h, f, k), \quad \mathsf{Cont}(k, g, r), \quad \mathsf{Cont}(h, tail, r),$$

then $\mathsf{hsame}(tail, \mathsf{append}(f, g))$.

Lean4 ✓ `BEDC.FKernel.Cont.cont composite tail unique`

Proof. Compose the first two continuation witnesses using associativity to obtain a direct witness from h to r with tail $\mathsf{append}(f, g)$. Left cancellation for continuation then identifies this composite tail with the given direct tail. □

Theorem 21.31 (Composite continuation tail iff)**.** *If*

$$\mathsf{Cont}(a, f, b), \quad \mathsf{Cont}(b, g, c),$$

then for every displayed tail t,

$$\mathsf{Cont}(f, g, t) \iff \mathsf{Cont}(a, t, c).$$

Lean4 ✓ `BEDC.FKernel.Cont.cont composite tail iff`

Proof. Forwards, reassociate the two displayed continuation equations: the tail continuation $\mathsf{Cont}(f, g, t)$ turns the path from a through t into the same append tree as the path from a through f and then g. Conversely, the direct continuation $\mathsf{Cont}(a, t, c)$ shares its source and target with the composite of $\mathsf{Cont}(a, f, b)$ and $\mathsf{Cont}(b, g, c)$, so composite-tail uniqueness identifies t with $\mathsf{append}(f, g)$ and hence gives $\mathsf{Cont}(f, g, t)$. □

Theorem 21.32 (Composite continuation left factor)**.** *If*

$$\mathsf{Cont}(b, g, c), \quad \mathsf{Cont}(f, g, fg), \quad \mathsf{Cont}(a, fg, c),$$

then $\mathsf{Cont}(a, f, b)$.

Lean4 ✓ `BEDC.FKernel.Cont.cont composite left factor`

Proof. The displayed composite continuation $\mathsf{Cont}(a, fg, c)$ and the factor continuation $\mathsf{Cont}(f, g, fg)$ rewrite c as $\mathsf{append}(\mathsf{append}(a, f), g)$. Compare this with $\mathsf{Cont}(b, g, c)$ and cancel the common right suffix g; the middle object is therefore hsame to $\mathsf{append}(a, f)$, and the reflexive continuation from a by f transports to b. □

Theorem 21.33 (Composite continuation right factor)**.** *If*

$$\mathsf{Cont}(a, f, b), \quad \mathsf{Cont}(f, g, fg), \quad \mathsf{Cont}(a, fg, c),$$

then $\mathsf{Cont}(b, g, c)$.

Lean4 ✓ `BEDC.FKernel.Cont.cont composite right factor`

Proof. Invert the three continuation witnesses. The result endpoint c is $\mathsf{append}(a, \mathsf{append}(f, g))$, while the desired right factor endpoint is $\mathsf{append}(\mathsf{append}(a, f), g)$. BEDC append associativity identifies these two histories and supplies the displayed continuation from b by g to c. □

Theorem 21.34 (Composite continuation factorization iff)**.** *If* $\mathsf{Cont}(f, g, fg)$*, then a displayed composite continuation from a to c by fg is equivalent to the existence of an intermediate history b carrying a by f to b and b by g to c:*

$$\mathsf{Cont}(a, fg, c) \iff \exists b : \mathsf{BHist},\ \mathsf{Cont}(a, f, b) \wedge \mathsf{Cont}(b, g, c).$$

Lean4 ✓ `BEDC.FKernel.Cont.cont composite factorization iff`

Proof. The forward direction chooses the canonical endpoint $b = \mathsf{append}(a, f)$ and applies right-factor recovery for the displayed composite. Conversely, any displayed intermediate factorization composes by rewriting the middle endpoint with $\mathsf{Cont}(a, f, b)$ and applying associativity of append against the fixed witness $\mathsf{Cont}(f, g, fg)$. □

Theorem 21.35 (Composite continuation canonical middle public readback)**.** *If* $\mathsf{Cont}(f, g, fg)$ *and* $\mathsf{Cont}(a, fg, c)$*, then the canonical middle history* $\mathsf{append}(a, f)$ *displays both factors,*

$$\mathsf{Cont}(a, f, \mathsf{append}(a, f)) \quad \textit{and} \quad \mathsf{Cont}(\mathsf{append}(a, f), g, c),$$

and any other displayed middle b *with* $\mathsf{Cont}(a, f, b)$ *and* $\mathsf{Cont}(b, g, c)$ *satisfies* $\mathsf{hsame}(\mathsf{append}(a, f), b)$*.*

Lean4 ✓ `BEDC.FKernel.Cont.cont composite canonical middle public readback`

Proof. The left factor is the defining continuation for append. The right factor is the composite right-factor theorem applied to this canonical left factor, the tail composite $\mathsf{Cont}(f, g, fg)$, and the displayed composite $\mathsf{Cont}(a, fg, c)$. For another middle b, inverting $\mathsf{Cont}(a, f, b)$ identifies b with $\mathsf{append}(a, f)$. □

Theorem 21.36 (Continuation factorization result history-sameness iff)**.** *If*

$$\mathsf{Cont}(a, b, m), \qquad \mathsf{Cont}(m, c, r),$$

then for every direct result s *through the appended tail,*

$$\mathsf{Cont}(a, \mathsf{append}(b, c), s) \iff \mathsf{hsame}(s, r).$$

Proof. The two displayed continuation witnesses compose to a direct continuation from a by $\mathsf{append}(b, c)$ to r, using append associativity. The result history-sameness characterization for a fixed continuation then identifies exactly the direct results s with $\mathsf{hsame}(s, r)$. □

Lean4 ✓ `BEDC.FKernel.Cont.cont factorization result hsame iff`

Theorem 21.37 (Continuation factorization middle exactness)**.** *If*

$$\mathsf{Cont}(a, f, b), \qquad \mathsf{Cont}(b, g, c),$$

then a displayed alternative middle b' *carries both factors exactly when it is history-same to the original middle:*

$$\mathsf{Cont}(a, f, b') \wedge \mathsf{Cont}(b', g, c) \iff \mathsf{hsame}(b', b).$$

Proof. Forwards, determinacy of $\mathsf{Cont}(a, f, _)$ compares the alternative first factor with the original first factor. Conversely, a history-sameness witness from b' to b transports the first factor's result and the second factor's source, yielding the two displayed continuation witnesses. □

Lean4 ✓ `BEDC.FKernel.Cont.cont factorization middle hsame iff`

Corollary 21.38 (Addition-like behavior requires no primitive addition)**.** *The continuation relation supplies a finite-kernel seed for addition-like derived interfaces. The additive interface is not primitive; it may be licensed only by a naming certificate whose stability component cites continuation unit and associativity.*

Lean4 ✓ `BEDC.FKernel.Cont.continuation addition like seed has unit assoc`

Theorem 21.39 (Continuation ezero right-unit probe forces emptiness)**.** *For every generated history* u*, the fixed zero-headed probe law*

$$\forall r : \mathsf{BHist}.\ \mathsf{Cont}(\mathsf{E0}(\mathsf{e}), u, r) \to \mathsf{hsame}(r, \mathsf{E0}(\mathsf{e}))$$

forces $u\mathsf{hsamee}$*.*

Proof. Apply the probe law to the canonical continuation $\mathsf{Cont}(\mathsf{E0}(\mathsf{e}), u, \mathsf{append}(\mathsf{E0}(\mathsf{e}), u))$. Continuation result transport gives $\mathsf{Cont}(\mathsf{E0}(\mathsf{e}), u, \mathsf{E0}(\mathsf{e}))$, and right-unit uniqueness then forces the right endpoint u to be empty. □

Chapter 22

Signature Proof Spine

This chapter turns asking events and generated bundles into signature events. No probe is treated as a function.

Definition 22.1 (Bundle generation)**.** *Probe bundles are generated by* Bnil *and* $\mathsf{Bcons}(\pi, \Pi)$*. They are not imported as external finite lists.*

Definition 22.2 (Asking policy)**.** $\mathsf{AskPolicy}(\Pi, D)$ *is paper notation for using the checked* $\mathsf{AskPolicy}(D)$ *certificate at bundle* Π*. The certificate gives totality of asking, determinacy of asking up to* msame*, and respect for* hsame *on histories in* D*. Its Lean fields quantify over each probe name available to signature generation, so* Π *marks the bundle site where the certificate is used rather than a field that restricts the certificate.*

Definition 22.3 (Signature event)**.** $\mathsf{Sig}(\Pi, h, s, \Delta)$ *means that asking bundle* Π *against history* h *generates answer history* s *with evidence ledger* Δ*. It is generated by the empty-bundle rule and the cons-bundle rule.*

Lean4 ✓ `BEDC.FKernel.Sig.signature event generation pack`

Theorem 22.4 (Signature determinacy)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$*. If* $h \in D$*,* $\mathsf{Sig}(\Pi, h, s, \Delta)$*, and* $\mathsf{Sig}(\Pi, h, t, \Theta)$*, then* $\mathsf{hsame}(s, t)$*.*

Lean4 ✓ `BEDC.FKernel.Sig.signature determinacy proof spine`
↪ variant `BEDC.FKernel.Sig.signature determinacy spine`
↪ variant `BEDC.FKernel.Sig.sig cons full witness determinacy`

Proof. Induct on the generated bundle Π. For the empty bundle, both answer histories are empty. For a cons bundle, determinacy of the first asking event gives internally same output marks, while the induction hypothesis gives internally same tail signatures. The result follows by the matching history constructor. □

Definition 22.5 (Signature sameness)**.** $\mathsf{sameSig}(\Pi, h, k)$ *holds when there exist generated signatures* s, t *for* h, k *under* Π *with* $\mathsf{hsame}(s, t)$*.*

Theorem 22.6 (Signature sameness equivalence)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$*. Then* $\mathsf{sameSig}(\Pi, -, -)$ *is reflexive, symmetric, and transitive on histories in* D*.*

Lean4 ✓ `BEDC.FKernel.Sig.signature sameness equivalence proof spine`

Proof. For reflexivity, generate a signature s of h by totality and use $\mathsf{hsame}(s, s)$. Symmetry swaps the two witnessing signatures and uses symmetry of hsame. For transitivity, choose witnesses s_h, s_k for h, k and t_k, t_l for k, l. Since both s_k and t_k are signatures of k, signature determinacy gives $\mathsf{hsame}(s_k, t_k)$. Transitivity of hsame gives $\mathsf{hsame}(s_h, t_l)$. □

Chapter 23

Package and Gap Proof Spine

The finite globalization interface is not a single primitive. It stands on three policies: asking, packaging, and gaps.

Definition 23.1 (Package policy)**.** $\mathsf{PackagePolicy}(\Pi)$ *states that signatures generated from histories admitted through* $\mathsf{AskPolicy}(\Pi, D)$ *and used by* $\mathsf{GapPolicy}(\Pi, D)$ *admit package tokens, that internally same signatures yield internally same packages, and that package sameness is grounded in internally same signatures.*

Definition 23.2 (Gap policy)**.** $\mathsf{GapPolicy}(\Pi, D)$ *states that gap membership is determined by signatures and package tokens: a history is in the gap of a package precisely when it generates a signature belonging to that package.*

Theorem 23.3 (Gap coverage)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$*,* $\mathsf{PackagePolicy}(\Pi)$*, and* $\mathsf{GapPolicy}(\Pi, D)$*. If* $h \in D$*, then there exists a package token* p *such that* $\mathsf{InGap}(\Pi, D, p, h)$*.*

Lean4 ✓ `BEDC.FKernel.Gap.gap coverage from policy layers`

Proof. By asking totality, generate a signature s of h. By package existence, generate a package token p for s. By the gap policy, h is a member of the gap of p. □

Theorem 23.4 (Gap separation)**.** *Assume* $\mathsf{AskPolicy}(\Pi, D)$*,* $\mathsf{PackagePolicy}(\Pi)$*, and* $\mathsf{GapPolicy}(\Pi, D)$*. If* $h \in D$*,* $\mathsf{InGap}(\Pi, D, p, h)$*, and* $\mathsf{InGap}(\Pi, D, q, h)$*, then* $\mathsf{psame}(p, q)$*.*

Lean4 ✓ `BEDC.FKernel.Gap.gap separation witnesses from policy layers`

Proof. By the gap policy, gap membership yields signatures s, t of h packaged by p, q. Signature determinacy gives $\mathsf{hsame}(s, t)$. Package extensionality then yields $\mathsf{psame}(p, q)$. □

Theorem 23.5 (Globalization classifies by signatures)**.** *Under* $\mathsf{AskPolicy}(\Pi, D)$*,* $\mathsf{PackagePolicy}(\Pi)$*, and* $\mathsf{GapPolicy}(\Pi, D)$*, package tokens classify histories in* D *by signature sameness: histories with the same signature inhabit internally same packages, and histories in internally same grounded packages have internally same signatures.*

Lean4 ✓ `BEDC.FKernel.Package.packagePolicy classifies signatures`

↪ variant `BEDC.FKernel.Package.packages classify signatures`

↪ variant `BEDC.FKernel.Package.PackagePolicy grounding witness`

↪ variant `BEDC.FKernel.Package.packagePolicy classification directions`

↪ variant `BEDC.FKernel.Package.packages classify signatures directional`

Proof. The first direction follows from package extensionality. The second follows from package grounding. The gap policy connects package membership back to source histories, ensuring that the classification is not a detached visible label but a provenance-preserving package. □

Definition 23.6 (Composite gap)**.** *Given compression interfaces $C : X \rightsquigarrow Y$ and $D : Y \rightsquigarrow Z$, define a composite gap by*

$$\mathsf{CompGap}_{D \circ C}(z, x)$$

when there exists an intermediate visible item y such that x lies in the C-gap of y and y lies in the D-gap of z.

Theorem 23.7 (Composite gap coverage)**.** *If the C-gap covers each source item and the D-gap covers each C-visible item, then the composite gap covers each source item.*

Lean4 ✓ `BEDC.FKernel.Gap.proof spine composite gap coverage`

Proof. Given a source item x, choose a C-visible item y whose gap contains x. Then choose a D-visible item z whose gap contains y. By definition of composite gap, x lies in the composite gap of z. □

Corollary 23.8 (Ledger composition principle)**.** *A composite compression has a ledger made of the first compression ledger plus the pullback of the second compression ledger along the first visible interface.*

Lean4 ✓ `BEDC.FKernel.Gap.ledger composition principle proof standing`

Chapter 24

Naming Certificate Proof Instances

This chapter records the first proof-standing instances of the naming protocol. These are still interface seeds; they are not full reconstructions of traditional arithmetic.

24.1 The unary repetition certificate

Definition 24.1 (Unary repetition source)**.** *The unary source consists of histories generated from* e *by repeated* $\mathsf{E1}$*-extension.*

Definition 24.2 (Unary classifier)**.** *Two unary histories are classified together when their generation pattern is internally the same under* hsame*. The classifier is intentionally weaker than a full arithmetic equality; it only records the repetition pattern available at this stage.*

Theorem 24.3 (Unary repetition closure)**.** *The unary source is closed under* $\mathsf{E1}$*-extension.*

Lean4 ✓ `BEDC.FKernel.Unary.unary e1 closed`

Proof. By definition, unary histories are generated by repeated $\mathsf{E1}$-extension. Extending such a history by $\mathsf{E1}$ gives another history generated by repeated $\mathsf{E1}$-extension. □

Corollary 24.4 (License for $\mathsf{Nat}^{\uparrow}$)**.** *A name* $\mathsf{Nat}^{\uparrow}$ *is licensed once its certificate records unary source, unary repetition pattern, unary classifier, closure under* $\mathsf{E1}$*, and the ledger of the underlying histories.*

24.2 The continuation certificate for addition-like behavior

Definition 24.5 (Unary continuation pattern)**.** *The unary continuation pattern is the restriction of* Cont *to unary source histories.*

Theorem 24.6 (Unary continuation closure)**.** *If* h *and* k *are unary histories and* $\mathsf{Cont}(h, k, r)$*, then* r *is unary up to* hsame*.*

Lean4 ✓ `BEDC.FKernel.Unary.unary continuation closure up to hsame`

Proof. Induct on the generation of h. If $h = \mathsf{e}$, then r is internally same as k, hence unary. If $h = \mathsf{E1}(h')$, the continuation rule reduces the result to $\mathsf{E1}(r')$ where r' is obtained by continuing h' by k. Apply the induction hypothesis and close under $\mathsf{E1}$. The $\mathsf{E0}$-case is absent for unary histories. □

Theorem 24.7 (Additive unary continuation transport)**.** *For unary histories h and k with* $\mathsf{Cont}(h, k, r)$*, if* $h\mathsf{hsame}h'$*,* $k\mathsf{hsame}k'$*, and* $r\mathsf{hsame}r'$*, then h', k', and r' are unary and* $\mathsf{Cont}(h', k', r')$*.*

Proof. Transport the two unary inputs across hsame, transport the continuation relation across the same endpoints and result, and close the transported result by unary continuation closure. □

Lean4 ✓ `BEDC.Derived.AddUp.AddUnaryContinuation hsame transport`

Theorem 24.8 (Addition-like unit)**.** *The empty history acts as a left unit for unary continuation, and as a right unit up to* hsame*.*

Lean4 ✓ `BEDC.FKernel.Unary.unary addition like unit with certificate`
↪ variant `BEDC.FKernel.Unary.unary addition like unit spine`
↪ variant `BEDC.FKernel.Unary.addition like unit laws`

Proof. The left unit is the continuation left-unit theorem. The right unit is continuation right unit up to hsame, restricted to unary histories. □

Theorem 24.9 (Addition-like associativity)**.** *Unary continuation is associative up to* hsame*.*

Lean4 ✓ `BEDC.FKernel.Unary.unary cont assoc with closure`

Proof. Restrict the continuation associativity theorem to unary histories. Unary continuation closure ensures that all intermediate histories remain within the unary source up to hsame. □

Corollary 24.10 (License for $\mathsf{Add}^{\uparrow}$)**.** *A name* $\mathsf{Add}^{\uparrow}$ *is licensed once its certificate records unary source, unary continuation pattern, descent to unary classes, unit behavior, associativity behavior, and composite ledger policy.*

↪ variant `BEDC.FKernel.Unary.add up licensed not primitive`

Remark 24.11 (Interface seed, not full arithmetic)**.** *The licenses for* $\mathsf{Nat}^{\uparrow}$ *and* $\mathsf{Add}^{\uparrow}$ *are first interface seeds. They do not yet assert a full induction principle, full recursion scheme, commutativity of addition, multiplication, order, or semiring structure.*

Part IV

Hardening

Chapter 25

Package and Gap Policy Expansion

The BEDC kernel separates asking, packaging, and gap recording. This chapter refines the public obligations of package and gap policies without changing the core declarations.

25.1 Package policy as a public interface

Definition 25.1 (Package-policy interface)**.** *A package policy for a bundle* Π *is a public contract specifying how generated answer histories are represented by visible package tokens. It is not a quotient object and it is not a set of equivalence classes. It consists of three obligations:*

1. ***Existence:*** *every admitted signature history has an admitted package token.*
2. ***Extensionality:*** *internally same signature histories admit internally same package tokens.*
3. ***Grounding:*** *internally same package tokens are justified by internally same admitted signatures.*

```
Lean4 ✓  BEDC.FKernel.Package.PackagePolicy iff fields
  ↪ variant  BEDC.FKernel.Package.packagePolicy field witnesses
  ↪ variant  BEDC.FKernel.Package.packagePolicy token exists
  ↪ variant  BEDC.FKernel.Package.packagePolicy nonempty token
  ↪ variant  BEDC.FKernel.Package.packagePolicy fields
  ↪ variant  BEDC.FKernel.Package.packagePolicy extensionality witness
```

Principle 25.2 (No quotient shortcut)**.** *A package token is not introduced as a quotient class. It is introduced through a package policy. Quotient-like behavior is then a theorem, not a primitive.*

```
Lean4 ✓  BEDC.FKernel.Package.packagePolicy no quotient shortcut
```

Theorem 25.3 (Package tokens are signature-facing)**.** *Assume a package policy for* Π*. If two source histories produce internally same signatures under* Π*, then their visible package tokens are internally same under the package-sameness relation licensed by the package policy.*

```
Lean4 ✓  BEDC.FKernel.Package.package tokens signature facing
  ↪ variant  BEDC.FKernel.Package.package tokens are signature facing
```

Proof. The source histories first produce signatures. The internal sameness of signatures triggers the extensionality field of the package policy. Hence the package tokens assigned to these signatures are package-same. No quotient object is invoked. □

25.2 Gap policy as provenance interface

Definition 25.4 (Gap-policy interface)**.** *A gap policy for a package policy over domain D specifies a provenance membership relation*

$$\mathsf{InGap}_{\Pi,D}(p, h),$$

read as: history h is recorded in the gap ledger behind visible package token p. It must satisfy three obligations:

1. ***Coverage:*** *every admitted source history belongs to at least one visible gap ledger.*
2. ***Separation:*** *if a source history belongs to two package ledgers, then those packages are package-same.*
3. ***Signature determination:*** *membership is justified by a signature event and a package event for that signature.*

Lean4 ✓ `BEDC.FKernel.Gap.gapPolicy provenance interface fields`

↪ variant `BEDC.FKernel.Gap.GapPolicyInterface iff fields`

↪ variant `BEDC.FKernel.Gap.gapPolicy provenance coverage generation pair`

↪ variant `BEDC.FKernel.Gap.gapPolicy coverage separation generation`

↪ variant `BEDC.FKernel.Gap.gap policy provenance interface`

↪ variant `BEDC.FKernel.Gap.gapPolicy provenance signature token witnesses`

Theorem 25.5 (Gap ledgers are not optional)**.** *For any nontrivial package policy, a gap policy is required to recover provenance. Without it, the visible package token has no internal record of which histories were compressed into it.*

Lean4 ✓ `BEDC.FKernel.Gap.gapPolicy requires provenance ledger`

Proof. Packaging replaces source histories by visible tokens. If a visible token is used without a gap ledger, then the theory no longer contains an internal witness of the histories that led to the token. This violates the ledger-for-compression principle. Hence a gap policy is part of the admissible globalization interface. □

Corollary 25.6 (Globalization has three layers)**.** *A well-formed finite globalization interface is not merely a packaging operation. It consists of an asking policy, a package policy, and a gap policy.*

Lean4 ✓ `BEDC.FKernel.Gap.globalization has three layers`

25.3 Composite gaps

Definition 25.7 (Composite gap ledger)**.** *Let C compress histories into intermediate visible tokens and let D compress those intermediate tokens into final visible tokens. The composite gap relation is generated by a two-step witness:*

$$\mathsf{CompGap}_{D\circ C}(z, h)$$

when there exists an intermediate token y such that h is in the C-gap behind y, and y is in the D-gap behind z.

Lean4 ✓ `BEDC.FKernel.Gap.hardening composite gap ledger witnesses`

Theorem 25.8 (Composite coverage)**.** *If C has coverage on the source domain and D has coverage on the intermediate image, then $D \circ C$ has composite coverage on the source domain.*

Lean4 ✓ `BEDC.FKernel.Gap.hardening composite coverage`

↪ variant `BEDC.FKernel.Gap.compGap coverage exact`

↪ variant `BEDC.FKernel.Gap.compGap coverage with intermediate`

↪ variant `BEDC.FKernel.Gap.compGap coverage with source and intermediate`

↪ variant `BEDC.FKernel.Gap.compGap coverage sourced witness`

Proof. Let h be an admitted source history. By coverage of C, there exists an intermediate token y with h in the C-gap behind y. By coverage of D, there exists a final token z with y in the D-gap behind z. Thus the pair (y, z) generates a composite gap witness placing h behind z. □

Remark 25.9. *Composite gap ledgers are the formal expression of the guiding slogan that a compressed result must retain a source map. The map may be direct or staged; the staged case is handled by composite gaps.*

Chapter 26

Typed Naming Certificate Instances

The BEDC paper template specifies the five fields of a derived-interface naming certificate. This chapter records explicit instance templates. These are not complete reconstructions of traditional mathematics. They are interface seeds whose role is to show how the naming mechanism should be used.

26.1 Certificate fields

Definition 26.1 (Typed naming certificate, expanded template)**.** *A typed paper certificate template for a derived interface N is a record*

$$\mathsf{NameCert}(N) = (\mathsf{SourceSpec}_N, \mathsf{PatternSpec}_N, \mathsf{ClassifierSpec}_N, \mathsf{StabilityCert}_N, \mathsf{LedgerPolicy}_N).$$

The fields have the following intended roles:

1. $\mathsf{SourceSpec}_N$*: declares the permitted source histories or visible tokens.*
2. $\mathsf{PatternSpec}_N$*: states the behavior pattern being named.*
3. $\mathsf{ClassifierSpec}_N$*: states how the behavior is packaged or identified.*
4. $\mathsf{StabilityCert}_N$*: records closure, reuse, descent, composition, or seal stability.*
5. $\mathsf{LedgerPolicy}_N$*: specifies which gap ledger records the compression performed by the name.*

Lean4 (definition) `BEDC.FKernel.NameCert.SemanticNameCert`

Lean4 ✓ `BEDC.FKernel.NameCert.NameCert iff semantic fields`

Theorem 26.2 (Semantic NameCert pattern-ledger witness)**.** *Every semantic naming certificate contains a source history whose pattern condition and ledger policy both hold.*

Proof. Eliminate the semantic certificate to expose its core naming certificate and the pattern and ledger soundness fields. The core certificate supplies a source history satisfying the source specification. Applying the two soundness fields to that same source witness yields the required pattern and ledger witnesses. □

Lean4 ✓ `BEDC.FKernel.NameCert.semanticNameCert pattern ledger witness`

Theorem 26.3 (Semantic NameCert pattern-ledger transport)**.** *If a semantic naming certificate classifies a source history h with a history k, then the pattern condition and ledger policy both hold at k.*

Proof. Use carrier transport from the core naming certificate along the classifier judgment to obtain the source specification at k. The semantic pattern and ledger soundness fields then apply at the transported history. □

Lean4 ✓ `BEDC.FKernel.NameCert.semanticNameCert pattern ledger transport`

Theorem 26.4 (Semantic NameCert classifier chain transport)**.** *If a semantic naming certificate classifies h with k and k with r, then a source witness at h transports the pattern condition and ledger policy to r.*

Proof. Use transitivity from the core naming certificate to compose the classifier judgments into a classifier judgment from h to r. The pattern-ledger transport theorem then applies to this composite classifier judgment and the source witness at h. □

Lean4 ✓ `BEDC.FKernel.NameCert.semanticNameCert classifier chain transport`

Theorem 26.5 (Semantic NameCert classifier left-confluence transport)**.** *If a semantic naming certificate classifies a shared left endpoint h with k and with r, then a source witness at k transports the pattern condition and ledger policy to r.*

Proof. Use symmetry from the core naming certificate to reverse the classifier judgment from h to k, then use transitivity with the classifier judgment from h to r. This gives a classifier judgment from k to r, so pattern-ledger transport applies to the source witness at k. □

Lean4 ✓ `BEDC.FKernel.NameCert.semanticNameCert classifier left confluence transport`

Theorem 26.6 (Semantic NameCert classifier right-confluence transport)**.** *If a semantic naming certificate classifies h and k with a shared right endpoint r, then a source witness at h transports the pattern condition and ledger policy to k.*

Proof. Use symmetry from the core naming certificate to reverse the classifier judgment from k to r, giving a classifier judgment from r to k. Then use transitivity with the classifier judgment from h to r. This gives a classifier judgment from h to k, so pattern-ledger transport applies to the source witness at h. □

Lean4 ✓ `BEDC.FKernel.NameCert.semanticNameCert classifier right confluence transport`

Theorem 26.7 (Semantic NameCert classifier reverse-chain transport)**.** *If a semantic naming certificate classifies h with k and k with r, then a source witness at r transports the pattern condition and ledger policy back to h.*

Proof. Use transitivity from the core naming certificate to compose the two classifier judgments into a classifier judgment from h to r. Symmetry reverses this composite into a classifier judgment from r to h, and the pattern-ledger transport theorem applies to the source witness at r. □

Lean4 ✓ `BEDC.FKernel.NameCert.semanticNameCert classifier reverse chain transport`

Theorem 26.8 (Semantic NameCert classifier diamond transport)**.** *If a semantic naming certificate classifies a with b, classifies a with c, and classifies b with d, then a source witness at c transports the pattern condition and ledger policy to d.*

Proof. Use symmetry to reverse the classifier judgment from a to c. Transitivity then carries c to b through a, and another transitivity step carries c to d through b. The pattern-ledger transport theorem applies to this composite classifier judgment and the source witness at c. □

Lean4 ✓ `BEDC.FKernel.NameCert.semanticNameCert classifier diamond transport`

Theorem 26.9 (Carrier self semantic lifting)**.** *Let* $C : \mathsf{BHist} \to \mathsf{Prop}$ *and* $R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$*. Any core certificate* $\mathsf{core} : \mathsf{NameCert}(C, R)$ *induces a semantic certificate whose core field is* core *and whose pattern and ledger soundness fields are identity implications over the same carrier. This is the carrier-as-pattern and carrier-as-ledger paper certificate target, distinct from* `BEDC.FKernel.NameCert.NameCert_iff_semantic_fields`*. The target is*

$$\mathsf{SemanticNameCert}(C, C, C, R).$$

Proof. Choose carrier C, classifier R, pattern C, and ledger C. Keep the supplied certificate as the core field. Stability under classifier transport is exactly the carrier stability field already contained in that core certificate, and both semantic soundness fields are filled by the identity implication from a carrier witness of $C(h)$ to the same proposition $C(h)$. □

Lean4 ✓ `BEDC.FKernel.NameCert.NameCert carrier self semantic lifting`

Theorem 26.10 (Eqtype class semantic NameCert)**.** *For any BEDC history anchor* a*, the anchor class* $h \mapsto \mathsf{hsame}(h, a)$ *is a semantic naming certificate when the source, pattern, and ledger predicates are this same class and the classifier is* hsame*.*

Proof. The anchor itself inhabits the class by reflexivity of hsame. Reflexivity, symmetry, and transitivity of hsame supply the core classifier laws. Carrier transport reverses the classifier comparison and composes it with the displayed anchor comparison. The pattern and ledger fields are the identity implications over the same anchor class. □

Lean4 ✓ `BEDC.Derived.EqtypeUp.EqtypeClass semanticNameCert`

26.2 Unary repetition as $\mathsf{Nat}^{\uparrow}$ seed

Definition 26.11 (Unary-source specification)**.** *The unary-source specification is the class of histories generated by repeated extension with* b1 *from the empty history. It is not called a natural number object internally. It is a source pattern of repeated emission.*

Lean4 ✓ `BEDC.FKernel.Unary.UnarySourceSpec induction`

Definition 26.12 (Unary pattern)**.** *The unary pattern is the stable behavior of repeated* b1*-extension together with the ability to distinguish the empty history from an extended unary history by the generated history constructors.*

Lean4 ✓ `BEDC.FKernel.Unary.UnaryPatternSpec step`
↪ variant `BEDC.FKernel.Unary.unary pattern induction with discrimination`

Definition 26.13 ($\mathsf{Nat}^{\uparrow}$ certificate seed)**.** *The name* $\mathsf{Nat}^{\uparrow}$ *is licensed only when the following fields are supplied:*

1. *source: unary histories;*
2. *pattern: repeated* b1*-extension;*
3. *classifier: internal history-sameness restricted to unary histories;*
4. *stability: closure under further* b1*-extension and reuse as a counting interface;*

5. *ledger: the originating unary history behind each visible counting token.*

↪variant BEDC.FKernel.Unary.nat up interface seed

Corollary 26.14 ($\mathsf{Nat}^{\uparrow}$ is not primitive)**.** *The interface* $\mathsf{Nat}^{\uparrow}$ *is licensed by a naming certificate over unary histories. It is not an internal primitive of the kernel.*

Lean4 ✓ BEDC.FKernel.Unary.nat up certificate seed not primitive

26.3 Continuation as $\mathsf{Add}^{\uparrow}$ seed

Definition 26.15 (Continuation pattern)**.** *The continuation pattern is the relation* $\mathsf{Cont}(h, k, r)$*, read as: the history* h *continued by the history* k *yields result* r*, up to internal history-sameness.*

Lean4 ✓ BEDC.FKernel.Cont.continuation pattern stability fields

Definition 26.16 ($\mathsf{Add}^{\uparrow}$ certificate seed)**.** *The name* $\mathsf{Add}^{\uparrow}$ *is licensed only when the following fields are supplied:*

1. *source: pairs of unary histories;*
2. *pattern: relational continuation;*
3. *classifier: internal history-sameness of continuation results;*
4. *stability: left unit, right unit, determinacy up to* hsame*, and associativity up to* hsame*;*
5. *ledger: the pair of source unary histories and the continuation witness.*

Theorem 26.17 (Addition-like behavior is a certificate, not an operation)**.** *The interface* $\mathsf{Add}^{\uparrow}$ *is not admitted by writing a binary operation symbol. It is admitted by a naming certificate whose stability field contains unit and associativity witnesses for relational continuation.*

↪variant BEDC.FKernel.Unary.add up licensed not primitive

Proof. The kernel contains histories and the relation Cont. It does not contain a primitive binary operation called addition. If continuation is shown to be stable on the unary source pattern and its behavior descends to the unary classification, then a derived interface may be named $\mathsf{Add}^{\uparrow}$. The name records the evidence; it does not introduce a primitive operation. □

26.4 Descent certificate for stable transformations

Definition 26.18 (Descent certificate)**.** *A descent certificate for a transformation pattern states that the pattern respects the classifier on the source and the classifier on the target. In explanatory notation, if* a *and* a' *are source-same, then their transformed outputs are target-same.*

Lean4 (definition) BEDC.FKernel.NameCert.DescentCertificate
Lean4 ✓ BEDC.FKernel.NameCert.StableTransformation descentCertificate exists

Theorem 26.19 (Descent certificate respects source sameness)**.** *If a descent certificate maps a source classifier to a target classifier, then source-same inputs have target-same mapped outputs.*

Lean4 ✓ `BEDC.FKernel.NameCert.descentCertificate respects`

Theorem 26.23 (Descent-certificate composition for stable transformations)**.** *Let $S, R, Q : \mathsf{BHist} \to \mathsf{Prop}$ be source, intermediate, and target carrier specifications, and let*

$$\sim_S, \sim_R, \sim_Q : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$$

be their classifiers. Assume the classifier roles are licensed by

$$\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S), \qquad \mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R), \qquad \mathsf{cert}_Q : \mathsf{NameCert}(Q, \sim_Q).$$

Let $T, U : \mathsf{BHist} \to \mathsf{BHist}$ have carrier-preservation fields

$$\rho_T : \forall h.\ S(h) \to R(T(h)) \qquad \text{and} \qquad \rho_U : \forall r.\ R(r) \to Q(U(r)).$$

Assume descent certificates

$$\delta_T : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_R)$$

and

$$\delta_U : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_R, \sim_Q)$$

whose map fields are T and U. Then the composite map $U \circ T$ preserves carriers by

$$\rho_{U \circ T}(h, Sh) = \rho_U(T(h), \rho_T(h, Sh))$$

and carries a descent certificate

$$\delta_{U \circ T} : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_Q)$$

with map field $h \mapsto U(T(h))$. Thus any source-classifier witness $h \sim_S k$ gives the target-classifier witness $U(T(h)) \sim_Q U(T(k))$.

Moreover, if

$$\tau_T : \mathsf{StableTransformation}(\mathsf{BHist}, \mathsf{BHist}, L_T, \sim_S, \sim_R)$$

and

$$\tau_U : \mathsf{StableTransformation}(\mathsf{BHist}, \mathsf{BHist}, L_U, \sim_R, \sim_Q)$$

have map fields T and U, then their composite is a stable transformation

$$\mathsf{StableTransformation}(\mathsf{BHist}, \mathsf{BHist}, L_T \times L_U, \sim_S, \sim_Q)$$

whose ledger witness is the ordered pair of the two input ledger witnesses. In gap-ledger cases this ordered pair is the witness-level form of the composite ledger policy of Definition 25.7 and Definition 8.12.

Lean4 ✓ `BEDC.FKernel.NameCert.StableTransformation descentCertificate composition`

Proof. The three displayed naming certificates place S, R, and Q in the typed certificate template of Definition 26.1; the descent argument uses the respect fields of the two descent certificates.

Define $\delta_{U \circ T}$ with map field $h \mapsto U(T(h))$. Given $h \sim_S k$, the respect field of δ_T gives

$$T(h) \sim_R T(k).$$

Applying the respect field of δ_U to this intermediate classifier witness gives

$$U(T(h)) \sim_Q U(T(k)).$$

By Definition 26.18, this is exactly the respect field required for a descent certificate from $\sim_S$ to $\sim_Q$. Carrier preservation is the displayed composite of the two carrier-preservation fields.

For the stable-transformation statement, use the same composite map. If $h \sim_S k$, the respect field of τ_T gives $T(h) \sim_R T(k)$, and the respect field of τ_U gives $U(T(h)) \sim_Q U(T(k))$. The ledger field of Definition 10.5 supplies witnesses $\ell_T : L_T$ and $\ell_U : L_U$; pair them as $(\ell_T, \ell_U) : L_T \times L_U$. This gives the ledger field for the composite stable transformation. When the two ledgers are gap ledgers, the same pair records the first-stage ledger and the second-stage ledger pulled back along the intermediate interface, which is the composite ledger policy cited above. □

Theorem 26.24 (NameCert composition for stable transformations)**.** *Let $S, R, Q, P_S, P_R, P_Q, L_S, L_R, L_Q :$ $\mathsf{BHist} \to \mathsf{Prop}$, and let*

$$\sim_S, \sim_R, \sim_Q : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$$

be classifier specifications. Assume semantic carrier certificates

$$\mathcal{C}_S : \mathsf{SemanticNameCert}(S, P_S, L_S, \sim_S), \qquad \mathcal{C}_R : \mathsf{SemanticNameCert}(R, P_R, L_R, \sim_R), \qquad \mathcal{C}_Q : \mathsf{SemanticNameCert}(Q$$

Let $T, U : \mathsf{BHist} \to \mathsf{BHist}$ *have carrier-preservation fields*

$$\rho_T : \forall h.\ S(h) \to R(T(h)), \qquad \rho_U : \forall r.\ R(r) \to Q(U(r)).$$

Let Λ_T *and* Λ_U *be ledger witness types, and let*

$$\tau_T : \mathsf{StableTransformation}(\mathsf{BHist}, \mathsf{BHist}, \Lambda_T, \sim_S, \sim_R)$$

and

$$\tau_U : \mathsf{StableTransformation}(\mathsf{BHist}, \mathsf{BHist}, \Lambda_U, \sim_R, \sim_Q)$$

be stable transformations with map fields T *and* U*. Let*

$$M_T, M_U : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$$

be their two-stage ledger predicates, with ledger soundness fields

$$\lambda_T : \forall h.\ S(h) \to M_T(h, T(h)), \qquad \lambda_U : \forall r.\ R(r) \to M_U(r, U(r)).$$

Define source-level composite pattern and ledger predicates by

$$\mathsf{CompStab}_{T,U}(h) \iff Q(U(T(h))) \wedge \forall k,\ h \sim_S k \to U(T(h)) \sim_Q U(T(k))$$

and

$$\mathsf{CompLedger}_{T,U}(h) \iff \exists r,\ r = T(h) \wedge M_T(h, r) \wedge M_U(r, U(r)).$$

Then

$$\mathsf{SemanticNameCert}(S, \mathsf{CompStab}_{T,U}, \mathsf{CompLedger}_{T,U}, \sim_S)$$

holds. Its stability component is the composite descent witness for $U \circ T$*, and its ledger component is the composite ledger policy.*

Proof. Use the core field of $\mathcal{C}_S$ as the core field of the displayed semantic certificate. By Definition 9.7, this is exactly the carrier-and-classifier certificate for S and $\sim_S$. The core fields of $\mathcal{C}_R$ and $\mathcal{C}_Q$ place the intermediate and target classifiers in the same typed certificate discipline of Definition 26.1.

For pattern soundness, fix h with $Sh : S(h)$. Carrier preservation gives $\rho_T(h, Sh) : R(T(h))$, and then $\rho_U(T(h), \rho_T(h, Sh)) : Q(U(T(h)))$. If $h \sim_S k$, the respect field of τ_T gives $T(h) \sim_R T(k)$. Applying the respect field of τ_U gives $U(T(h)) \sim_Q U(T(k))$. Hence $\mathsf{CompStab}_{T,U}(h)$.

For ledger soundness at the same source history, choose the intermediate witness $r = T(h)$. The field λ_T gives $M_T(h, T(h))$. The field ρ_T gives $R(T(h))$, so λ_U gives $M_U(T(h), U(T(h)))$. These witnesses prove $\mathsf{CompLedger}_{T,U}(h)$.

The respect calculation is the descent certificate required by Definition 26.18: a source-classifier witness is first transported along T and then along U. By Definition 9.4, this fills the $\mathsf{DescentCert}$ and $\mathsf{CompositionCert}$ modes of the stability component. The ledger proof records the first-stage ledger together with the second-stage ledger pulled back along the intermediate witness. In gap-ledger cases this is the two-step witness of Definition 25.7, and Definition 8.12 identifies it as the composite ledger policy. □

Theorem 26.25 (Semantic NameCert classifier replacement)**.** *Let* $S, P, L : \mathsf{BHist} \to \mathsf{Prop}$ *and let* $C, C' : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be classifier specifications. Assume*

$$\mathcal{N} : \mathsf{SemanticNameCert}(S, P, L, C)$$

and assume classifier comparison fields

$$\alpha : \forall h, k,\ C'(h, k) \to C(h, k), \qquad \beta : \forall h, k,\ C(h, k) \to C'(h, k).$$

Then

$$\mathsf{SemanticNameCert}(S, P, L, C')$$

holds. The resulting certificate also has the same pattern-ledger transport consequence: whenever $C'(h, k)$ *and* $S(h)$ *hold, both* $P(k)$ *and* $L(k)$ *hold.*

Proof. By Definition 26.1, a semantic naming certificate separates its core carrier-classifier certificate from its pattern and ledger soundness fields. Keep the source, pattern, and ledger soundness fields of $\mathcal{N}$ unchanged. It remains only to replace the core classifier certificate.

The original core field is a $\mathsf{NameCert}(S, C)$ in the sense of Definition 9.7. Define the new core field over C' as follows. The inhabited source witness is the same one carried by the original core. For reflexivity at a source history h, apply the old reflexivity field to obtain $C(h, h)$ and then apply β. For symmetry, convert a witness $C'(h, k)$ to $C(h, k)$ by α, apply the old symmetry field, and convert the result back by β. For transitivity, convert both C' witnesses to C by α, apply the old transitivity field, and convert the composite classifier witness back by β. For carrier transport, convert $C'(h, k)$ to $C(h, k)$ by α and then use the old carrier-transport field to carry $S(h)$ to $S(k)$.

These four classifier laws together with the unchanged source witness form $\mathsf{NameCert}(S, C')$. Combining this new core field with the unchanged pattern and ledger soundness fields gives $\mathsf{SemanticNameCert}(S, P, L, C')$. Finally, if $C'(h, k)$ and $S(h)$ hold, the new carrier-transport field gives $S(k)$, and the unchanged pattern and ledger soundness fields give $P(k)$ and $L(k)$. This is the same transport consequence recorded in Definition 26.3 for the replacement classifier. □

Chapter 27

Machine-Checkable Milestones

This chapter converts the proof-sprint plan into a milestone schedule. It is implementation-facing, but it is written without depending on any particular proof assistant syntax.

27.1 Milestone A: history kernel

Protocol 27.1 (Milestone A)**.** *Milestone A is complete when the following facts have been checked:*

1. msame *is reflexive, symmetric, and transitive.*
2. *raw marks satisfy no-confusion:* b0 *and* b1 *are not cross-identified.*
3. hsame *is reflexive, symmetric, and transitive.*
4. *history constructors satisfy no-confusion.*
5. Ext *is deterministic up to* hsame*.*
6. Cont *is deterministic up to* hsame*.*
7. Cont *has left and right units.*
8. Cont *is associative up to* hsame*.*

27.2 Milestone B: signature kernel

Protocol 27.2 (Milestone B)**.** *Milestone B is complete when the following facts have been checked:*

1. *bundles are generated by* Bnil *and* Bcons*;*
2. *signature events are generated by the empty and cons signature rules;*
3. *under* AskPolicy(Π, D)*, signature generation is deterministic up to* hsame*;*
4. *under* AskPolicy(Π, D)*,* sameSig *is reflexive, symmetric, and transitive on* D*.*

```

Remark 27.6. *Until then, large derived constructions such as real certificates, phase geometry, fold normalization, and arithmetic beyond addition should remain non-blocking appendices governed by explicit naming-certificate obligations.*

Part V

Concrete Instances

Chapter 28

A Concrete Naming Certificate for $\mathsf{Nat}^{\uparrow}$

This chapter gives a concrete naming-certificate construction for $\mathsf{Nat}^{\uparrow}$ at the paper-proof level.

The unary carrier and successor rows recorded here are consumed by chapter 29 for continuation-based addition and by chapter 31 for signed-pair balancing. $\mathsf{Add}^{\uparrow}$ reads addition as continuation over $\mathsf{Nat}^{\uparrow}$ unary histories, while $\mathsf{Int}^{\uparrow}$ reads signed pairs by balancing two $\mathsf{Nat}^{\uparrow}$ source spines.

The same unary rows also feed later finite schedule consumers. In chapter 7585, the unary depth ledger is read only as bounded repetition of the existing $\mathsf{Nat}^{\uparrow}$ empty and one-extension rows, so bar-window coverage does not add a separate natural-number primitive.

28.1 Unary histories

Definition 28.1 (Unary history judgment)**.** *The unary history judgment* $\mathsf{Unary}(h)$ *is generated by:*

1. $\mathsf{Unary}(\mathsf{e})$*;*
2. *if* $\mathsf{Unary}(h)$*, then* $\mathsf{Unary}(\mathsf{E1}(h))$*.*

No rule generates $\mathsf{Unary}(\mathsf{E0}(h))$*.*

```

```

Lemma 28.2 (Unary closure under one-extension)**.** *If* $\mathsf{Unary}(h)$*, then* $\mathsf{Unary}(\mathsf{E1}(h))$*.*

Lean4 ✓ `BEDC.FKernel.Unary.unary closure under one extension`

Proof. This is the second generator of the unary judgment. □

Lemma 28.3 (Unary no-zero-extension)**.** *No judgment* $\mathsf{Unary}(\mathsf{E0}(h))$ *is generated.*

Lean4 ✓ `BEDC.FKernel.Unary.unary no zero extension`
↪variant `BEDC.FKernel.Unary.unary history hsame zero absurd`

Proof. By closed generation for Unary, the only extension rule uses $\mathsf{E1}$. No $\mathsf{E0}$-extension constructor is displayed. □

Theorem 28.4 (Nat unary terminal empty classifier)**.** *Any accepted* $\mathsf{Nat}^{\uparrow}$ *unary-history read whose displayed continuation tail is* e *classifies to the empty endpoint route of the unary carrier. Conversely, any nonempty accepted* $\mathsf{Nat}^{\uparrow}$ *read must arise through repeated* $\mathsf{E1}$ *extension from the empty endpoint, never through an* $\mathsf{E0}$ *branch. Downstream* $\mathsf{Add}^{\uparrow}$ *source-spine reads therefore use this empty classifier as the base case before continuation tails are consumed as addition rows.*

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryTerminal empty classifier`

Proof. For the terminal case, unfold the unary history judgment of Definition 28.1. The displayed empty tail is the endpoint route, so the read exposes the base generator $\mathsf{Unary}(\mathsf{e})$ and no predecessor row.

For a nonempty accepted read, use closed generation of the same judgment. The only displayed extension rule is Definition 28.2; Definition 28.3 removes every $\mathsf{E0}$-headed branch. Hence each nonempty accepted history is obtained by iterating $\mathsf{E1}$ from e.

The addition source spine of Definition 28.7 consumes exactly this dichotomy. Its base continuation is the empty classifier route, and each nonempty continuation step is a one-extension row available to the $\mathsf{Add}^{\uparrow}$ certificate. □

Theorem 28.5 (Unary prefix totality)**.** *If h and k are unary histories, then either h continues by a unary tail to k, or k continues by a unary tail to h.*

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryPrefix total`

Proof. Induct on the unary generation of h. The empty case uses k itself as the tail. In the $\mathsf{E1}$ case, split k; the empty and $\mathsf{E0}$ cases are immediate by the continuation unit and unary no-zero rule. When $k = \mathsf{E1}(k')$, apply the induction hypothesis to h' and k', then lift the resulting unary tail across the common $\mathsf{E1}$ boundary by the unary one-extension append law. □

Theorem 28.6 (Unary prefix directed common upper)**.** *If h and k are unary histories, then there is a unary history u such that both h and k continue to u by unary tails.*

Proof. Apply unary prefix totality. If h continues to k, choose k as the common upper and use the empty tail on the k-side. If k continues to h, choose h as the common upper and use the empty tail on the h-side. □

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryPrefix directed common upper`

Theorem 28.7 (Nat source spine for addition)**.** *Every* $\mathsf{Add}^{\uparrow}$ *continuation read over unary histories factors through the* $\mathsf{Nat}^{\uparrow}$ *unary carrier before it is consumed as addition. Concretely, the source side must display the unary judgment of Definition 28.1, closure under one-extension from Definition 28.2, prefix totality from Definition 28.5, and the common-upper row of Definition 28.6; only after those rows are present may the continuation be read by chapter 29 as an* $\mathsf{Add}^{\uparrow}$ *operation.*

Proof. Read the unary source first. The judgment of Definition 28.1 supplies exactly the empty history and one-extension histories, while Definition 28.2 keeps the carrier closed under the successor step used by addition.

Next use Definition 28.5 and Definition 28.6. They make any two unary inputs comparable through unary tails and then place them under a displayed unary common upper, so the continuation has a source spine before any addition row is consumed.

Finally pass that displayed spine to chapter 29. Since $\mathsf{Add}^{\uparrow}$ reads addition as continuation over $\mathsf{Nat}^{\uparrow}$ unary histories, any continuation lacking the unary carrier, closure, prefix totality, and common-upper rows is not an addition read from the $\mathsf{Nat}^{\uparrow}$ source. □

Lean4 ✓ `BEDC.Derived.NatUp.NatAddSourceSpine forward link`

Theorem 28.8 (Nat unary chain for addition and integer balance)**.** *Every* $\mathsf{Add}^{\uparrow}$ *continuation read and every* $\mathsf{Int}^{\uparrow}$ *signed-pair balance read consumes the same* $\mathsf{Nat}^{\uparrow}$ *unary source chain before it can be interpreted as addition or signed balancing. The shared chain consists of the unary carrier judgment of Definition 28.1, closure under one-extension from Definition 28.2, prefix totality from Definition 28.5, and the directed common-upper row of Definition 28.6.*

Lean4 ✓ `BEDC.Derived.NatUp.NatAddIntUnaryChainOrphanLink`

Proof. For an $\mathsf{Add}^{\uparrow}$ read, apply Definition 28.7. The continuation may be consumed by chapter 29 only after the unary carrier, one-extension closure, prefix totality, and common-upper rows have been displayed.

For an $\mathsf{Int}^{\uparrow}$ read, use the signed-pair presentation of chapter 31. Each positive and negative side is a $\mathsf{Nat}^{\uparrow}$ unary component, so the same carrier judgment and closure rows license the two components before balancing is inspected.

The prefix totality and common-upper rows are still shared after the signed-pair packaging. Thus addition and signed balancing both enter through the same finite unary chain, and their difference is only the downstream consumer that reads the displayed $\mathsf{Nat}^{\uparrow}$ rows. □

Theorem 28.9 (Nat unary dependency route for addition and integer balance)**.** *Every downstream* $\mathsf{Add}^{\uparrow}$ *continuation read and every* $\mathsf{Int}^{\uparrow}$ *signed-pair balancing read must first expose the* $\mathsf{Nat}^{\uparrow}$ *unary carrier, the one-extension closure row, the prefix-total row, and the directed common-upper row. Only after those rows are displayed may the route cite chapter 29 and chapter 31 as the sibling consumers of the same finite unary source.*

Proof. Start with the Nat source spine theorem Definition 28.7. It forces every addition continuation to display the unary judgment, one-extension closure, prefix totality, and common-upper rows before the $\mathsf{Add}^{\uparrow}$ operation is read.

Now apply the add-int unary chain theorem Definition 28.8. The same displayed carrier and closure rows are consumed by the positive and negative sides of an $\mathsf{Int}^{\uparrow}$ signed pair before balancing is inspected.

This dependency is substantive rather than self-reference because the final readers are the sibling chapters chapter 29 and chapter 31. The $\mathsf{Nat}^{\uparrow}$ chapter supplies the unary source rows; the sibling certificates consume those rows as addition and signed-pair balance data. □

Definition 28.10 (Strict unary prefix)**.** *A strict unary prefix from h to k is a unary tail t such that t is not* e *and* $\mathsf{Cont}(h, t, k)$*.*

Lean4 (definition) `BEDC.Derived.NatUp.NatUnaryStrictPrefix`

Lemma 28.11 (Unary continuation tail cases)**.** *If a unary tail t displays* $\mathsf{Cont}(h, t, k)$*, then either* $h\mathsf{hsame}k$ *or h is a strict unary prefix of k.*

Proof. Split the unary tail. The empty tail gives the right-unit continuation and therefore endpoint history-sameness. A zero-headed tail contradicts unary generation. A one-headed tail is nonempty, so the displayed continuation is exactly the witness for $\mathsf{NatUnaryStrictPrefix}(h, k)$. □

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryPrefix cont tail cases`

Theorem 28.12 (Unary prefix trichotomy into sameness or strict prefix)**.** *If h and k are unary histories, then either* $h\mathsf{hsame}k$*, or h is a strict unary prefix of k, or k is a strict unary prefix of h.*

Proof. Apply unary prefix totality to obtain a unary continuation tail in one direction. If the tail is e, the continuation is the right-unit continuation and the endpoints are history-same. A zero-headed tail contradicts unary generation. A one-headed tail is nonempty, so the same continuation witness gives the corresponding strict unary prefix branch. □

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryPrefix trichotomy hsame strict`

Lemma 28.13 (Strict unary prefix one-step)**.** *If h is unary, then h is a strict unary prefix of* $\mathsf{E1}(h)$*.*

Proof. Use the tail $\mathsf{E1}(\mathsf{e})$. It is unary, it is not e, and $\mathsf{Cont}(h, \mathsf{E1}(\mathsf{e}), \mathsf{E1}(h))$ holds by the continuation constructor. □

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryStrictPrefix one step`

Theorem 28.14 (Strict unary prefix asymmetry)**.** *No pair of histories can strictly prefix each other through nonempty unary tails.*

Proof. Unpack the two strict witnesses. Mutual continuation makes the endpoints history-same. The right-unit continuation at the source then transports to the forward target, so left cancellation identifies the forward tail with e, contradicting its strictness. □

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryStrictPrefix asymm`

Theorem 28.15 (Strict unary prefix has nonempty target)**.** *No history can be a strict unary prefix of* e*.*

Proof. Unpack the strict-prefix witness. The continuation into e forces the tail to be e, contradicting the nonempty-tail condition. □

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryStrictPrefix empty right absurd`

Lemma 28.16 (Strict unary prefix tail endpoint collapse is impossible)**.** *If a unary tail t is nonempty,* $\mathsf{Cont}(h, t, k)$*, and* $h\mathsf{hsame}k$*, then the displayed continuation is impossible.*

Proof. Transport the right-unit continuation $\mathsf{Cont}(h, \mathsf{e}, h)$ across the endpoint identification $h\mathsf{hsame}k$, giving $\mathsf{Cont}(h, \mathsf{e}, k)$. Left cancellation against the supplied continuation $\mathsf{Cont}(h, t, k)$ identifies t with e, contradicting the strict tail witness. □

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryStrictPrefix tail endpoint hsame absurd`

Theorem 28.17 (Strict unary prefix one-boundary inversion)**.** *If* $\mathsf{E1}(h)$ *is a strict unary prefix of* $\mathsf{E1}(k)$*, then h is a strict unary prefix of k.*

Proof. Unpack the strict witness tail. The empty tail contradicts strictness, and an $\mathsf{E0}$-headed tail contradicts unary generation. For an $\mathsf{E1}(t)$ tail, invert the result boundary of the continuation and commute the visible $\mathsf{E1}$ across the unary tail t, yielding the strict witness $\mathsf{E1}(t)$ from h to k. □

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryStrictPrefix e1 inversion`

Lemma 28.18 (Strict unary prefix one-boundary endpoint collapse is impossible)**.** *If* $\mathsf{E1}(h)$ *is a strict unary prefix of* $\mathsf{E1}(k)$ *and* $h\mathsf{hsame}k$*, then the displayed strict prefix is impossible.*

Proof. Apply one-boundary inversion to obtain a strict unary prefix from h to k. The strict witness tail together with the endpoint identification $h\mathsf{hsame}k$ contradicts the tail endpoint collapse lemma. □

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryStrictPrefix e1 endpoint hsame absurd`

Theorem 28.19 (Strict unary prefix one-boundary congruence)**.** *If* h *is a strict unary prefix of* k*, then* $\mathsf{E1}(h)$ *is a strict unary prefix of* $\mathsf{E1}(k)$*.*

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryStrictPrefix e1 congr`

Proof. Unpack the nonempty unary tail witnessing the strict prefix from h to k. The same tail remains unary and nonempty. Commuting append across the visible $\mathsf{E1}$ boundary re-expresses the continuation as one from $\mathsf{E1}(h)$ to $\mathsf{E1}(k)$. □

Theorem 28.20 (Strict unary prefix zero-boundary inversion)**.** *If* $\mathsf{E0}(h)$ *is a strict unary prefix of* $\mathsf{E0}(k)$*, then* h *is a strict unary prefix of* k*.*

Proof. Unpack the strict witness tail. The empty tail contradicts strictness, an $\mathsf{E0}$-headed tail contradicts unary generation, and an $\mathsf{E1}$-headed tail would force a zero-headed continuation result to be one-headed. Hence the premise has no inhabitant, so the displayed implication follows. □

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryStrictPrefix e0 inversion`

Theorem 28.21 (Strict unary prefix append-tail transitivity)**.** *If* h *continues by a nonempty unary tail to* k*, and* k *continues by a unary tail to* l*, then* h *is a strict unary prefix of* l*. The witness tail is* $\mathsf{append}(t_1, t_2)$*, and it also gives* $\mathsf{Cont}(h, \mathsf{append}(t_1, t_2), l)$*.*

Proof. Invert the two continuation witnesses and reassociate append. Unary closure under append gives a unary composite tail, and append empty-result exactness shows that the composite tail cannot be empty because its left component is nonempty. □

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryStrictPrefix append tail trans`

Lemma 28.22 (Strict unary prefix target is unary)**.** *If* h *is unary and* h *is a strict unary prefix of* k*, then* k *is unary.*

Proof. Unpack the strict-prefix witness as a unary tail t with $\mathsf{Cont}(h, t, k)$. Unary continuation closure transports unary generation from h across t to the target k. □

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryStrictPrefix target unary`

Theorem 28.23 (Strict unary prefix composite-tail transitivity)**.** *If* h *is a strict unary prefix of* k *and* k *is a strict unary prefix of* l*, then the two nonempty unary tails compose into a concrete tail from* h *to* l*. This composite tail witnesses both* $\mathsf{Cont}(h, t, l)$ *and the strict unary prefix relation from* h *to* l*.*

Proof. Unpack the two strict-prefix witnesses. Append their unary tails and apply append-tail transitivity. Unary append closure gives the composite tail carrier, and append empty-result exactness shows that the composite tail is nonempty because its left component is nonempty. □

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryStrictPrefix trans composite tail`

Theorem 28.24 (Strict unary prefix continuation transport)**.** *If a nonempty unary tail carries h to k, and $h$hsameh' and $k$hsamek', then h' is a strict unary prefix of k'.*

Proof. Reuse the same tail. The continuation component transports across the two endpoint hsame witnesses, while unary generation and nonemptiness of the tail are unchanged. □

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryStrictPrefix cont hsame transport`

28.2 The certificate

Definition 28.28 (Unary stability certificate)**.** *The unary stability certificate* UnaryClosureCert *consists of:*

1. *the base derivation* Unary(e)*;*
2. *closure under* E1*;*
3. *no-zero-extension, recording that* E0 *is not part of the unary generation discipline.*

Lean4 ✓ `BEDC.FKernel.Unary.unary stability certificate fields`
↪ variant `BEDC.FKernel.Unary.unary stability certificate base step nozero pair`
↪ variant `BEDC.FKernel.Unary.unary stability certificate no zero projection`

Definition 28.29 (Unary ledger policy)**.** *The unary ledger policy* UnaryLedger *records the source unary history behind any visible unary class. It does not erase the emitted history; it licenses a derived interface while retaining provenance.*

Lean4 (definition) `BEDC.FKernel.Unary.UnaryLedgerPolicy`

Theorem 28.30 (Concrete $\mathsf{Nat}^{\uparrow}$ naming certificate)**.** *The tuple*

$$\mathsf{NameCert}_{\mathsf{Nat}^{\uparrow}} := (\mathsf{UnarySource}, \mathsf{UnaryPattern}, \mathsf{UnaryClassifier}, \mathsf{UnaryClosureCert}, \mathsf{UnaryLedger})$$

forms a valid naming certificate for the derived interface $\mathsf{Nat}^{\uparrow}$*.*

Proof. The source, pattern, classifier, stability, and ledger fields are explicitly supplied by the preceding definitions. The stability field is justified by unary base generation, unary closure under $\mathsf{E1}$, and unary no-zero-extension. Therefore the naming protocol is satisfied. □

Lean4 ✓ `BEDC.FKernel.Unary.nat up name certificate`

Theorem 28.31 (Semantic $\mathsf{Nat}^{\uparrow}$ naming certificate)**.** *The* $\mathsf{Nat}^{\uparrow}$ *naming certificate lifts to a semantic certificate whose source, pattern, and ledger predicates all preserve the same unary-history witness.*

Proof. The core certificate is the concrete unary $\mathsf{NameCert}$. Pattern soundness and ledger soundness are both identity preservation of the unary history witness, so no information is erased between the source predicate and the two semantic predicates. □

Lean4 ✓ `BEDC.FKernel.Unary.nat up semantic name certificate`

Corollary 28.32 ($\mathsf{Nat}^{\uparrow}$ is licensed, not primitive)**.** *The interface* $\mathsf{Nat}^{\uparrow}$ *is licensed by* $\mathsf{NameCert}_{\mathsf{Nat}^{\uparrow}}$*. It is not a primitive object of the finite kernel.*

Lean4 ✓ `BEDC.FKernel.Unary.nat up licensed not primitive`

Theorem 28.33 (NatUp unary standard bridge)**.** *The unary-history certificate for* $\mathsf{Nat}^{\uparrow}$ *carries a conservative standard bridge to finite unary words and their natural-number length readback. The bridge sends* e *to zero, sends* $\mathsf{E1}(h)$ *to the successor of the readback of* h*, admits no* $\mathsf{E0}$ *branch, identifies* $h\mathsf{hsame}k$ *on unary histories exactly when the external readback lengths are equal, and sends a unary continuation* $\mathsf{Cont}(h, t, k)$ *to addition of the readback length of* t *to the readback length of* h*.*

Proof. Define the decode field by unary-generation induction. The base generator reads e as zero. The one-extension generator reads $\mathsf{E1}(h)$ as the successor of the already decoded tail. The no-zero-extension lemma excludes an $\mathsf{E0}$ case, so every decoded value is obtained from a finite unary word and no other BEDC history is admitted by the bridge carrier.

The encode field sends an external finite unary word back to its BEDC unary history by the same two constructors. Induction on the word gives the decode-encode round trip, while induction on the unary-history generator gives the encode-decode round trip up to $h\mathsf{hsame}k$. The semantic NameCert theorem supplies the source, pattern, and ledger preservation needed to keep these witnesses inside the licensed $\mathsf{Nat}^{\uparrow}$ surface.

For exactness, use strict-prefix and continuation transport. If two unary histories are $h\mathsf{hsame}k$, the readback induction transports the same length across the endpoint identification. Conversely, if the readback lengths agree, unary prefix trichotomy leaves only the sameness branch: either strict-prefix branch would add a nonempty unary tail and hence a positive successor length on one side. Thus hsame matches equality of external readback lengths.

For continuation, induct on the unary tail. The empty tail gives addition by zero. A one-headed tail applies the induction hypothesis and then one-extension supplies the successor step on

the result. The zero-headed case is ruled out by unary no-zero-extension. Therefore unary Cont tails read as addition of finite unary lengths, and the theorem-preservation list is limited to these constructor, equality, and continuation clauses.

The no-host-leak field follows because the bridge uses the external natural-number model only in these encode, decode, round-trip, and preservation fields, while the BEDC public surface remains the unary-history NameCert grounded by nat_up_semantic_name_certificate. □

Lean4 ✓ `BEDC.FKernel.Unary.nat up unary standard bridge`
Lean4 ✓ `BEDC.Derived.NatUp.NatUp unary standard bridge`

Theorem 28.34 (NatUp mature unary recursion package)**.** *The unary-history certificate supplies the mature paper-level* $\mathsf{Nat}^{\uparrow}$ *package over BEDC* BHist *and* hsame*. Its zero object is* e*, its successor operation is* E1*, no carried element is a zero-extension, unary generation gives induction, primitive recursion is defined by the empty and one-extension generation cases, and continuation length is addition of the unary tail length. The operation bridges consumed by this package are the already cited* $\mathsf{Add}^{\uparrow}$*,* $\mathsf{Mul}^{\uparrow}$*, and* $\mathsf{Order}^{\uparrow}$ *interfaces, not host arithmetic.*

Lean4 ✓ `BEDC.Derived.NatUp.NatUp mature unary recursion package`

Proof. The carrier is the closed unary-generation carrier of the semantic $\mathsf{Nat}^{\uparrow}$ certificate. Its base constructor gives e, its step constructor gives E1, and Definition 28.3 removes every E0 branch from the carried surface.

Induction is the eliminator for that unary-generation predicate. Primitive recursion is obtained by the same cases: assign the empty value at e, and in the one-extension case apply the specified successor clause to the value already computed for the predecessor history.

The endpoint equality used by the recursion clauses is hsame, not equality of host natural numbers. Apply Definition 28.12: the sameness branch is the transport case, and either strict-prefix branch contributes a nonempty unary continuation tail.

Finally, Definition 28.33 reads continuation tails as addition of unary lengths. Induction on the tail gives the empty-tail zero law and the one-headed successor step. Thus the package exposes the NatUp induction, recursion, and continuation-as-addition principles internally over BHist, while arithmetic consumers enter only through the cited $\mathsf{Add}^{\uparrow}$, $\mathsf{Mul}^{\uparrow}$, and $\mathsf{Order}^{\uparrow}$ interfaces. □

Closure status for $\mathsf{NameCert}_{\mathsf{Nat}^{\uparrow}}$**.**

Constructive story: A natural number begins as a history that has refused every b0-branch: from e one may keep stacking b1-marks, and every such stack is admitted, while the first b0-mark sends the history outside the carrier. Since the kernel already says that two histories are the same only by literal history-equality, the classifier for these unary spines has nothing extra to quotient away; the same unary predicate also tells which sources the certificate covers, which pattern their shape follows, and which raw history remains visible in the ledger. This is why the five name-certificate obligations arrive together: e witnesses that the carrier is nonempty, identity is reflexive, symmetric, and transitive, and a history that is identical to an admitted unary history is admitted as well. A unary history h falls into the signature gap of a $\mathsf{Nat}^{\uparrow}$ token p only when the source-domain first accepts h, the signature relation then pairs it with an answer history and evidence ledger, and the token-introduction relation names that answer as p; after the three checks are unfolded, this says exactly that h is unary and that its b1-depth is the count encoded by p. The standard bridge attached here sends each unary history to a finite unary word and reads the word length back as the ordinary natural-number value, so the outside comparison is a readback of the same spine rather than a new carrier. The chapter registers the construction under the name $\mathsf{Nat}^{\uparrow}$; successor is just one more b1-stack, induction is the closed generation rule for histories, and no Peano axiom, separate $\mathbb{N}$ type, or additional axiom is introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Nat}^{\uparrow}}$, maturePackageClosed)

Scope closed: The public $\mathsf{Nat}^{\uparrow}$ surface is the unary-history semantic NameCert over BEDC histories together with the paper-side standard bridge to finite unary words and natural-number length readback.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Nat}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.FKernel.Unary.nat\_up\_semantic\_name\_certificate`

Bridge status: bridgeChecked

Upgrade path: no further upgrade – chapter at top of formal axis.

Theorem 28.35 (Unary bridge cut boundary)**.** *Let a consumer use the* $\mathsf{Nat}^{\uparrow}$ *packet through the unary-history certificate of Definition 28.30, the semantic certificate of Definition 28.31, and the standard bridge of Definition 28.33. Then every datum crossing from this chapter to a consumer is forced into one of the following rows:*

1. *the unary source row* $\mathsf{Unary}(h)$*, equivalently* $\mathsf{UnarySource}(h)$*;*
2. *the unary pattern row generated from* e *by repeated* $\mathsf{E1}$*;*
3. *the classifier row* $h\mathsf{hsame}k$ *between unary histories;*
4. *the unary ledger row recording the same admitted history;*
5. *, when the consumer asks for continuation, the BEDC continuation row* $\mathsf{Cont}(h, t, k)$ *with unary source and unary tail.*

The finite unary word, external length readback, encode map, decode map, round-trip witnesses, and bridge preservation witnesses are eliminable bridge cuts: after the consumer-facing projection they leave only the listed BEDC rows. A proposed crossing row whose carrier is a host natural number, a host operation, a non-unary history, or any source coordinate not listed above is not admitted by the $\mathsf{Nat}^{\uparrow}$ *packet.*

Lean4 ✓ `BEDC.Derived.NatUp.UnaryBridgeCutBoundary`

Proof. The concrete certificate of Definition 28.30 displays exactly five BEDC rows: source, pattern, classifier, stability, and ledger. By Definition 28.25, the source row is the judgment $\mathsf{Unary}(h)$. By Definition 28.26, the pattern row is the closed generation spine from e by $\mathsf{E1}$. By Definition 28.27, the classifier row is internal history-sameness restricted to unary histories. By Definition 28.28, the stability row contributes only base generation, one-extension closure, and no-zero exclusion. By Definition 28.29, the ledger row records the same source history rather than a separate external coordinate.

The semantic certificate of Definition 28.31 adds no new consumer carrier. It says that source, pattern, and ledger predicates preserve the same unary-history witness. Therefore any handoff through the semantic certificate projects back to the unary source, unary pattern, classifier, stability, and ledger rows already listed.

It remains to inspect the standard bridge. In Definition 28.33, the finite unary word, length readback, encode field, decode field, and round-trip witnesses are bridge-side interpretation data. The proof of that theorem eliminates them by induction back to the BEDC constructors: e for zero, $\mathsf{E1}$ for successor, and the no-zero rule for the absent $\mathsf{E0}$ branch. Its exactness clause projects external equality of readback lengths back to the classifier row $h\mathsf{hsame}k$, and its continuation clause projects a bridge-side addition reading back to the BEDC row $\mathsf{Cont}(h, t, k)$ with unary tail. Thus these bridge-side names are cuts inside the interpretation, not additional public rows.

Consequently a downstream consumer such as the continuation interface cited in chapter 29 can receive only the unary source, pattern, classifier, ledger, and displayed continuation rows. If a proposed handoff starts from a host natural number, a host operation, a non-unary history, or any coordinate not produced by those rows, then neither the certificate nor the standard bridge has a clause admitting it. Such a row is therefore rejected at the boundary. □

Proposition 28.36 (Unary history judgment codomain mirror boundary)**.** *For the* $\mathsf{Nat}^{\uparrow}$ *certificate of Definition 28.30, the unary history judgment has no independent codomain mirror row. A unary domain row is a single witness* $\mathsf{Unary}(h)$*, and the source, pattern, stability, and ledger fields of Definition 28.25, Definition 28.26, Definition 28.28, and Definition 28.29 all reuse that same displayed history. If a target history* k *is read from the same local packet, then either it is only a classifier comparison* $h\mathsf{hsame}k$*, or it is supplied by an additional unary continuation tail* t *with* $\mathsf{Cont}(h, t, k)$*. In the latter case Definition 28.11 gives exactly the two endpoint cases:* $h\mathsf{hsame}k$*, or* h *is a strict unary prefix of* k*. Hence a non-identity codomain side is not obtained by renaming the unary judgment; it belongs to the continuation or strict-prefix surface.*

Lean4 ✓ `BEDC.Derived.NatUp.NatUnaryHistory codomain mirror boundary`

Proof. Unpack the unary judgment of Definition 28.1. Its generators produce judgments of the form $\mathsf{Unary}(h)$: the empty history is admitted, the one-extension of an admitted history is admitted, and no zero-extension is admitted. Thus the judgment itself names one history at a time.

The certificate fields keep that arity. The source specification of Definition 28.25 is governed by $\mathsf{Unary}(h)$. The pattern specification of Definition 28.26 is repeated one-extension from e, again on the same history. The stability certificate of Definition 28.28 records the base, one-extension, and no-zero facts for this same unary predicate. The ledger policy of Definition 28.29 records the source unary history rather than replacing it by a separate emitted target. These are exactly the rows assembled in Definition 28.30.

The only binary row already present in the unary certificate is the classifier row of Definition 28.27, which compares admitted unary histories by hsame. Reading this as a codomain mirror gives no new target construction: it says only that the displayed target is history-same to the source. To obtain a target history not supplied merely by classifier comparison, one must add a continuation witness $\mathsf{Cont}(h, t, k)$ with a unary tail t. Then Definition 28.11 applies. The empty-tail branch gives endpoint sameness $h\mathsf{hsame}k$, while the nonempty one-tail branch is precisely the strict unary prefix relation of Definition 28.10. Therefore the local chapter supports identity comparison and continuation-generated targets, but it does not support a separate codomain copy of the unary judgment obtained by renaming the same unary row. □

Chapter 29

A Concrete Naming Certificate for $\mathsf{Add}^{\uparrow}$

The addition-like interface is licensed by continuation of unary histories. It is not a primitive operation.

Lean4 ✓ `BEDC.Derived.AddUp.AddUpTasteGate single carrier alignment`

The $\mathsf{Add}^{\uparrow}$ carrier consumes the unary-history source licensed in chapter 28. Its two input histories are $\mathsf{Nat}^{\uparrow}$ unary spines, and $\mathsf{Add}^{\uparrow}$ adds only the displayed Cont result row and continuation ledger.

Theorem 29.1 (AddUp consumes NatUp as a sibling route)**.** *Every accepted* $\mathsf{Add}^{\uparrow}$ *carrier row reads its two source histories through chapter 28 before the displayed* Cont *result row is admitted. Consequently* $\mathsf{Add}^{\uparrow}$ *is a downstream consumer of the* $\mathsf{Nat}^{\uparrow}$ *unary spine, not a kernel-only arithmetic primitive.*

Lean4 ✓ `BEDC.Derived.AddUp.AddUpNatUp sibling dependency route`

Proof. Project the source side of the $\mathsf{Add}^{\uparrow}$ carrier. By Definition 29.7, an additive source is an ordered pair of unary histories together with a continuation witness producing the result row.

The unary hypotheses on the two source histories are precisely the $\mathsf{Nat}^{\uparrow}$ spine discipline cited by chapter 28. The continuation lemmas below then act only after those source histories have already been accepted as unary rows.

Apply Definition 29.5, Definition 29.6, and the continuation-preservation lemma of this section to the displayed Cont witness. These results admit and transport the result row, but they do not create the two source spines. Hence the source read factors through $\mathsf{Nat}^{\uparrow}$ before $\mathsf{Add}^{\uparrow}$ admits its continuation result. □

This dependency order is the horizontal lattice used by the downstream standard bridge and continuation consumers: by Definition 29.1, every additive continuation row first reads the unary source through chapter 28, and only then consumes the displayed Cont witness, bridge readback, and additive ledger rows.

29.1 Unary continuation

Lemma 29.2 (Continuation preserves unary histories)**.** *If* $\mathsf{Unary}(h)$*,* $\mathsf{Unary}(k)$*, and* $\mathsf{Cont}(h, k, r)$*, then* $\mathsf{Unary}(r)$*.*

Lean4 ✓ `BEDC.FKernel.Unary.unary cont preserves unary by induction`

Proof. By induction on the generated proof of $\mathsf{Cont}(h, k, r)$. In the empty case, $r = k$, hence $\mathsf{Unary}(r)$ follows from the second premise. In the $\mathsf{E1}$-continuation case, use the induction hypothesis on the subcontinuation and then apply unary closure under $\mathsf{E1}$. The $\mathsf{E0}$-continuation case makes the second input history have shape $\mathsf{E0}(k_0)$, contradicting the premise $\mathsf{Unary}(k)$ by unary no-zero-extension. □

Lemma 29.3 (Unary continuation has no zero result)**.** *If h and k are unary histories, then no continuation $\mathsf{Cont}(h, k, \mathsf{E0}(z))$ can exist.*

Proof. Unary continuation closure sends the two unary inputs and the displayed continuation to a unary result. But a result of shape $\mathsf{E0}(z)$ contradicts the unary no-zero-extension principle. □

Lean4 ✓ `BEDC.FKernel.Unary.unary cont e0 result absurd`

Lemma 29.4 (Unary continuation one-result cases)**.** *If h and k are unary histories and $\mathsf{Cont}(h, k, \mathsf{E1}(r))$, then either $k = \mathsf{e}$ and $h\mathsf{hsameE1}(r)$, or $k = \mathsf{E1}(k_0)$ for a unary tail k_0 and $\mathsf{Cont}(h, k_0, r)$.*

Proof. Apply the continuation one-result inversion. In the empty branch, keep the displayed empty right input and result comparison. In the visible-tail branch, the equality $k = \mathsf{E1}(k_0)$ transports the unary witness for k to the tail witness for k_0, leaving the tail continuation $\mathsf{Cont}(h, k_0, r)$. □

Lean4 ✓ `BEDC.FKernel.Unary.unary cont e1 result cases`

Lemma 29.5 (Unary continuation unit)**.** *For every unary history h, continuation by the empty history and continuation from the empty history produce unary histories internally same to the expected unary source.*

Lean4 ✓ `BEDC.FKernel.Unary.unary cont unit`
↪ variant `BEDC.FKernel.Unary.unary cont unit same pair`

Proof. The left unit is the empty continuation generator. The right unit follows from the continuation unit theorem in the proof-standing layer, restricted to unary histories. Unary closure ensures the resulting histories remain within the unary source discipline. □

Lemma 29.6 (Unary continuation associativity)**.** *Unary continuation is associative up to* hsame *when all participating histories are unary.*

Lean4 ✓ `BEDC.FKernel.Unary.unary continuation associativity`

Proof. This is the continuation associativity theorem specialized to unary histories, together with continuation-preserves-unary-histories for the intermediate results. □

29.2 The certificate

Definition 29.7 (Additive source specification)**.** *The source specification* AddSource *consists of ordered pairs of unary histories together with a continuation witness.*

Definition 29.11 (Additive ledger policy)**.** *The additive ledger policy* AddLedger *records the two input unary histories and the continuation witness generating the output history. For composite additive uses, the ledger composes by the composite gap principle.*

Lean4 (definition) `BEDC.FKernel.Unary.AddLedgerPolicy`
↪ variant `BEDC.FKernel.Unary.AddLedgerPolicy iff unary cont closed`
↪ variant `BEDC.FKernel.Unary.addLedgerPolicy from unary cont closed`
↪ variant `BEDC.FKernel.Unary.unary addition seed from policy`
Lean4 ✓ `BEDC.FKernel.Unary.addLedgerPolicy from unary cont closed`

Theorem 29.12 (Concrete $\mathsf{Add}^{\uparrow}$ naming certificate)**.** *The tuple*

$$\mathsf{NameCert}_{\mathsf{Add}^{\uparrow}} := (\mathsf{AddSource}, \mathsf{AddPattern}, \mathsf{AddClassifier}, \mathsf{AddStabilityCert}, \mathsf{AddLedger})$$

forms a valid naming certificate for the derived interface $\mathsf{Add}^{\uparrow}$*.*

Lean4 ✓ `BEDC.FKernel.Unary.add up name certificate exists`
↪ variant `BEDC.FKernel.Unary.add up name certificate`

Proof. The source, pattern, classifier, stability, and ledger fields are supplied by the preceding definitions. Stability is justified by unary closure, unit, associativity, commutativity via Theorem 9194.6, and continuation determinacy. The ledger policy records the exact continuation witness rather than erasing it. Thus the naming protocol is satisfied. □

Corollary 29.13 ($\mathsf{Add}^{\uparrow}$ is licensed by commutative continuation)**.** *The additive interface* $\mathsf{Add}^{\uparrow}$ *is licensed by commutative unary continuation. It is not a primitive operation of the finite kernel.*

Lean4 ✓ `BEDC.FKernel.Unary.add up licensed not primitive`

Theorem 29.14 (AddUp unary standard bridge)**.** *The public* $\mathsf{Add}^{\uparrow}$ *NameCert surface over unary histories,* Cont*,* AddSource*,* AddPattern*,* AddClassifier*,* AddStabilityCert*, and* AddLedger *carries a conservative paper-level bridge to finite unary words with concatenation and length addition. Carried BEDC histories read back through the* $\mathsf{Nat}^{\uparrow}$ *unary standard bridge of chapter 28; continuation witnesses read back as concatenation witnesses;* hsame *of generated results reads back as equality of unary word lengths; ledger entries record only the two input histories and the continuation witness; and no host natural number or host function is admitted as a BEDC primitive.*

Lean4 ✓ `BEDC.Derived.AddUp.AddUp StdBridge`

Proof. Use Definition 28.33 as the carrier bridge for each unary history appearing in the public $\mathsf{Add}^{\uparrow}$ source. Thus the two input histories and the generated result decode as finite unary words, and the source field of Definition 29.12 supplies no data beyond those two carried histories and the displayed continuation witness.

The continuation witness is read by induction on the right unary tail. The empty tail is the unit case of Definition 29.5; the one-extension tail is the successor step; and Definition 29.6 transports nested tails to ordinary concatenation of finite unary words. The commutative-continuation field listed in Definition 29.10 is therefore available for the public certificate, while the bridge itself reads the ordered continuation witness as the corresponding concatenation witness.

Exactness is the result-classifier clause. By Definition 29.16, two generated results from the same ordered source are related by AddClassifier, and by Definition 29.9 this is hsame of the result histories. Applying the $\mathsf{Nat}^{\uparrow}$ bridge exactness to those result histories reads the comparison as equality of the external unary word lengths, hence as length addition for concatenation.

Finally, the ledger field is the policy of Definition 29.11: it records the two BEDC input histories and the continuation witness that produced the result. The external word model appears only in the bridge readback and exactness fields, so no host natural number, host addition function, or host concatenation function becomes a primitive of the BEDC kernel. □

Theorem 29.15 (Unary continuation monoid activation)**.** *Let the typed naming-certificate template of Definition 9.6 be instantiated on the unary carrier with classifier* hsame*. Assume the core carrier certificate* $\mathsf{NameCert}(\mathsf{Unary}, \mathsf{hsame})$ *from Definition 9.7; take the source, pattern, classifier, and ledger policies to be the continuation policies of Definition 29.7, Definition 29.8, Definition 29.9, and Definition 29.11; assume pattern soundness and ledger soundness for those policies; and assume that* AddStabilityCert *supplies unary closure, empty-history unit, associativity up to* hsame*, and same-source determinacy up to* hsame*. Then*

$$\mathsf{License}(\mathsf{UnaryContMonoid}^{\uparrow}).$$

Lean4 ✓ `BEDC.Derived.AddUp.AddUnaryContinuationMonoid activation package`

Proof. By Definition 9.6, a derived interface is licensed by a certificate once its source, pattern, classifier, stability, and ledger fields are supplied. The assumed $\mathsf{NameCert}(\mathsf{Unary}, \mathsf{hsame})$ provides the carrier-and-classifier core described in Definition 9.7. The source is the ordered unary source with a continuation witness from Definition 29.7; the pattern is unary continuation from Definition 29.8; the classifier is hsame on continuation results from Definition 29.9; and the ledger is the recorded pair of unary inputs together with the continuation witness from Definition 29.11. Pattern soundness sends each source witness to the displayed unary continuation pattern, and ledger soundness records the same source witness in the ledger policy.

The remaining certificate component is stability. Unary closure is the closure field in AddStabilityCert. The empty-history unit is Definition 29.5. Associativity up to hsame is Definition 29.6. Same-source determinacy is the determinacy field of AddStabilityCert, so two continuation results generated from the same ordered unary source pair are classified together by hsame. These fields give a closed carrier, a unit, associative continuation, and deterministic result classification for fixed sources. That is exactly the certificate data for the unary continuation monoid-like interface. Since no order-swap commutativity field is used, the activated upward name is $\mathsf{UnaryContMonoid}^{\uparrow}$. □

Theorem 29.16 (Same-source additive determinacy bridge)**.** *For histories h, k, r, and r', if* $\mathsf{AddSource}(h, k, r)$ *and* $\mathsf{AddSource}(h, k, r')$*, then* $\mathsf{AddClassifier}(r, r')$*.*

Proof. By Definition 29.7, the first source witness supplies unary inputs h and k together with $\mathsf{Cont}(h, k, r)$. The second source witness has the same ordered input pair, so it supplies the same unary inputs together with $\mathsf{Cont}(h, k, r')$. The determinacy field listed in Definition 29.10 applies to these two continuation witnesses and gives $\mathsf{hsame}(r, r')$. By Definition 29.9, AddClassifier classifies additive outputs precisely by hsame of their generated result histories, so this witness is $\mathsf{AddClassifier}(r, r')$. □

Lean4 ✓ `BEDC.FKernel.Unary.AddSourceSpec same source classifier`

Theorem 29.17 (Core additive stability does not imply swapped commutativity)**.** *There is a finite equality-classified carrier with a deterministic total continuation relation Γ such that the carrier* NameCert*, closure, two-sided unit, associativity, same-source determinacy, and the source-to-pattern and source-to-ledger soundness fields of the naming template hold, while the swapped-source additive commutativity field*

$$\Gamma(x, y, r) \quad \textit{and} \quad \Gamma(y, x, s) \quad \Rightarrow \quad r = s$$

fails.

Proof. Let $C = \{e, p, q\}$ and use equality as the classifier. Define $\star : C \times C \to C$ by

$\star$	e	p	q
e	e	p	q
p	p	p	p
q	q	q	q

and let $\Gamma(x, y, r)$ mean $x \star y = r$.

The carrier certificate of Definition 9.7 holds because e inhabits C, equality is reflexive, symmetric, and transitive, and equality transports membership in C. For the additive source role of Definition 29.7, use an ordered pair (x, y) together with the graph witness $\Gamma(x, y, r)$. Take the pattern specification and ledger policy to be this same graph witness, matching the ledger role of Definition 29.11; hence the pattern-soundness and ledger-soundness roles in Definition 9.6 are immediate. The classifier role of Definition 29.9 is literal equality on result elements.

Closure is visible from the table. The row and column for e show $e \star x = x$ and $x \star e = x$ for every $x \in C$. Same-source determinacy holds because Γ is the graph of the function $\star$: if $\Gamma(x, y, r)$ and $\Gamma(x, y, s)$, then $r = x \star y = s$. This is the finite equality-classified analogue of the determinacy field in Definition 29.10.

Associativity follows by cases on the left factor. If $x = e$, then $(e \star y) \star z = y \star z = e \star (y \star z)$. If $x = p$, then $p \star y = p$ and $p \star t = p$ for every $t \in C$, so both $(p \star y) \star z$ and $p \star (y \star z)$ are p. The case $x = q$ is identical with q in place of p.

The swapped-source field fails. The table gives $\Gamma(p, q, p)$ and $\Gamma(q, p, q)$, but the equality classifier does not identify p and q. Thus the fields used for the monoid-like activation in Definition 29.15 do not force the swapped-source additive commutativity field. □

Lean4 ✓ `BEDC.Derived.AddUp.AddUpThreePoint unital graph not swapped commutative`

Theorem 29.18 (Unary continuation monoid activation from stability)**.** *Let* $C : \mathsf{NameCert}(\mathsf{Unary}, \mathsf{hsame})$ *be the core carrier certificate of Definition 9.7. Fix the continuation source, pattern, classifier, and ledger policies of Definition 29.7, Definition 29.8, Definition 29.9, and Definition 29.11. If* $S : \mathsf{AddStabilityCert}$ *supplies unary closure under continuation, empty-history unit, associativity up to* hsame*, and same-source determinacy up to* hsame*, then*

$$\mathsf{License}(\mathsf{UnaryContMonoid}^{\uparrow})$$

holds. No premise asserting $\mathsf{AddCommField}$ *or* $\mathsf{UnaryComm}$ *is required.*

Lean4 ✓ `BEDC.Derived.AddUp.AddUnaryContinuationMonoid activation from stability`

Proof. By Definition 9.6, licensing a derived interface amounts to supplying the source, pattern, classifier, stability, and ledger fields required by its certificate. The carrier-and-classifier core is C, which is a certificate for the unary carrier classified by hsame in the sense of Definition 9.7.

The source field is the ordered unary continuation source: a pair of unary histories together with a witness $\mathsf{Cont}(h, k, r)$. This is the source specification of Definition 29.7. The pattern field is the corresponding unary continuation behavior of Definition 29.8. The classifier field is hsame on generated continuation results, as in Definition 29.9. The ledger field records the same ordered inputs and continuation witness, as in Definition 29.11. Thus source-to-pattern soundness and source-to-ledger soundness follow by unpacking these four policies.

It remains to check the stability component. Unary closure is the closure field supplied by S. The empty-history unit is the unit field supplied by S, matching Definition 29.5. Associativity up to hsame is the associativity field supplied by S, matching Definition 29.6. Same-source determinacy says that for fixed ordered unary inputs h, k, any two witnesses $\mathsf{Cont}(h, k, r)$ and $\mathsf{Cont}(h, k, r')$ produce classified results $\mathsf{hsame}(r, r')$; this is precisely the determinacy field listed in Definition 29.10.

These fields give a closed unary carrier, a two-sided unit, associative continuation, deterministic classification for fixed ordered sources, and an explicit ledger. That is the full certificate for $\mathsf{UnaryContMonoid}^{\uparrow}$. A swapped-source field would compare $\mathsf{Cont}(h, k, r)$ with $\mathsf{Cont}(k, h, s)$; no such comparison is used in the construction, so neither $\mathsf{AddCommField}$ nor $\mathsf{UnaryComm}$ enters the proof. □

Theorem 29.19 (Two-element monoids cannot witness additive noncommutativity)**.** *Let* C *be an equality-classified carrier whose unary source is total. Let* $e, u \in C$ *and assume every* $x \in C$ *satisfies* $x = e$ *or* $x = u$*. Let* $\star : C \times C \to C$ *be a monoid operation with unit* e*, and let the additive continuation relation be the graph of* $\star$*:*

$$\Gamma(x, y, z) \quad \textit{means} \quad x \star y = z.$$

Then for all $x, y, z, z' \in C$*,*

$$\Gamma(x, y, z) \quad \textit{and} \quad \Gamma(y, x, z') \quad \Rightarrow \quad z = z'.$$

Thus no equality-classified monoid with at most two carrier elements and total unary source can witness failure of the swapped-source additive commutativity field measured by Definition 29.9.

Proof. By Definition 29.7, an additive source in this interpretation is an ordered pair together with a graph witness $\Gamma(x, y, z)$. Since the unary source is total, every pair of carrier elements is admissible. By Definition 29.9, the result comparison is the carrier classifier; here that classifier is equality. It is therefore enough to prove $x \star y = y \star x$ for arbitrary $x, y \in C$, because $\Gamma(x, y, z)$ and $\Gamma(y, x, z')$ identify z with $x \star y$ and z' with $y \star x$.

Use the cover $t = e$ or $t = u$ for each carrier element t. If $x = e$, the left-unit law gives $x \star y = e \star y = y$, and the right-unit law gives $y \star x = y \star e = y$. Hence $x \star y = y \star x$. If $y = e$, the same argument with the two roles exchanged gives $x \star y = x = y \star x$.

The only remaining case is $x = u$ and $y = u$. In that case both ordered products are the same expression $u \star u$, so $x \star y = y \star x$ by reflexivity of equality. Combining this product equality with the two graph witnesses gives $z = z'$. The conclusion is exactly the swapped-source comparison not supplied by the monoid-like fields of Definition 29.10. In contrast, Definition 29.17 shows that three carrier elements suffice for an equality-classified unital deterministic graph to fail that comparison. □

Lean4 ✓ `BEDC.Derived.AddUp.AddUpTwoPoint unital graph swapped commutative`

Theorem 29.20 (Unary continuation activation without commutativity)**.** *Let the typed naming-certificate template of Definition 9.6 be instantiated on the unary carrier with classifier* hsame*. Assume a core carrier certificate* $\mathsf{NameCert}(\mathsf{Unary}, \mathsf{hsame})$ *in the sense of Definition 9.7. Use the ordered continuation source, continuation pattern, result classifier, and ledger policies of Definition 29.7, Definition 29.8, Definition 29.9, and Definition 29.11. Assume source-to-pattern soundness and source-to-ledger soundness for those policies. If* $\mathsf{AddStabilityCert}$ *supplies unary closure under continuation, the empty-history unit, associativity up to* hsame*, and same-source determinacy up to* hsame*, then*

$$\mathsf{License}(\mathsf{UnaryContMonoid}^{\uparrow})$$

holds. The implication does not require any swapped-source additive commutativity premise of the form

$$\mathsf{Cont}(h, k, r) \text{ and } \mathsf{Cont}(k, h, s) \Rightarrow \mathsf{hsame}(r, s).$$

Lean4 ✓ `BEDC.Derived.AddUp.AddUnaryContinuation activation without commutativity`

Proof. The naming template of Definition 9.6 licenses a derived interface once its source, pattern, classifier, stability, and ledger fields are supplied. The assumed $\mathsf{NameCert}(\mathsf{Unary}, \mathsf{hsame})$ supplies the carrier inhabitedness, classifier reflexivity, classifier symmetry, classifier transitivity, and carrier transport fields listed in Definition 9.7. Thus the unary carrier and its classifier core are available before any binary behavior is considered.

The source field is the ordered pair of unary histories together with a continuation witness, as in Definition 29.7. The pattern field is the continuation behavior of Definition 29.8. The classifier field is hsame on generated results, as in Definition 29.9. The ledger field records the ordered inputs and the continuation witness, as in Definition 29.11. The assumed soundness fields send every source witness to this pattern witness and to this ledger witness.

It remains only to read the stability fields. Unary closure gives closure of the carrier under the continuation result. The empty-history unit gives the left and right unit clauses for the unary continuation operation, matching Definition 29.5. Associativity up to hsame gives the monoid-like associativity clause, matching Definition 29.6. Same-source determinacy says that two results generated from the same ordered source pair are classified together by hsame; this is exactly the deterministic result-classification role in Definition 29.10.

These fields are precisely the certificate data for $\mathsf{UnaryContMonoid}^{\uparrow}$: an inhabited classified unary carrier, a closed continuation operation, the empty unit, associativity, deterministic classification for fixed ordered sources, and a ledger. A swapped-source field compares the ordered source (h, k) with the different ordered source (k, h). No field in this construction makes that comparison, so the activation of $\mathsf{UnaryContMonoid}^{\uparrow}$ follows without the swapped-source additive commutativity premise. □

Theorem 29.21 (Two-element unital continuation commutativity)**.** *Let U be the unary part of a finite equality-classified carrier with classifier* hsame*, and assume U has exactly the two elements e and u. Let $\star : U \times U \to U$ be a total binary operation with two-sided unit e:*

$$e \star t = t \quad \textit{and} \quad t \star e = t \quad \textit{for every } t \in U.$$

Suppose the continuation relation on U is the graph of $\star$:

$$\mathsf{Cont}(h, k, r) \quad \textit{if and only if} \quad r = h \star k.$$

Then for all $h, k, r, r' \in U$,

$$\mathsf{Cont}(h, k, r) \quad \textit{and} \quad \mathsf{Cont}(k, h, r') \quad \Rightarrow \quad \mathsf{hsame}(r, r').$$

No associativity premise is needed.

Lean4 ✓ `BEDC.Derived.AddUp.AddUpTwoPoint unital continuation commutativity`

Proof. The source role of Definition 29.7 treats a continuation source as an ordered pair together with a continuation witness, and the classifier role of Definition 29.9 compares generated results by hsame. In the equality-classified instance of the carrier certificate of Definition 9.7, proving $\mathsf{hsame}(r, r')$ is the same as proving $r = r'$.

Assume $\mathsf{Cont}(h, k, r)$ and $\mathsf{Cont}(k, h, r')$. Since Cont is the graph of $\star$, these witnesses give $r = h \star k$ and $r' = k \star h$. It is enough to show $h \star k = k \star h$.

Because U has exactly the two elements e and u, each of h and k is either e or u. If $h = e$, then $h \star k = e \star k = k$ by the left-unit law, while $k \star h = k \star e = k$ by the right-unit law. If $k = e$, the same unit laws give $h \star k = h$ and $k \star h = e \star h = h$.

The only remaining case is $h = u$ and $k = u$. Then both ordered products are the identical product $u \star u$, so they are equal by reflexivity. Thus $h \star k = k \star h$ in every case, and the two graph identities give $r = r'$. Equality classification then gives $\mathsf{hsame}(r, r')$.

Relative to the stability fields of Definition 29.10, this is an automatic two-element consequence of graph determinacy and the unit laws, not a separate swapped-source field. Together with Definition 29.17, it identifies three equality classes as the first possible size for such a unital deterministic swapped-source failure. □

Theorem 29.22 (AddUp acceptance bridge fields)**.** *The public* $\mathsf{Add}^{\uparrow}$ *surface carries a paper-level* StandardBridge *to finite unary words with ordinary length addition. Its BEDC side is the UnaryHistory NameCert equipped with* AddSource*,* AddPattern*,* AddClassifier*,* AddStabilityCert*, and* AddLedger*. Its standard side is finite unary words, with empty word as zero and word concatenation read by natural-number length addition. The forward interpretation sends* e *to zero and sends an* E1 *tail to successor of the tail readback. The backward interpretation sends zero to* e *and sends successor to an* E1 *tail. The theorem-preservation field sends unary continuation to ordinary concatenation and therefore to length addition. The reflection field sends standard unary*

concatenation back to Cont. *Host* Nat *and host functions occur only in the bridge codomain and its readback equations, never as a BEDC carrier, classifier, source, stability premise, ledger premise, or proof input.*

Lean4 ✓ `BEDC.Derived.AddUp.AddUp acceptance bridge fields`

Proof. The BEDC source is already fixed by the public certificate of Definition 29.12. Its carrier is UnaryHistory, its source and pattern rows are AddSource and AddPattern, its classifier is AddClassifier, and its stability and ledger rows are AddStabilityCert and AddLedger.

Use the readback pattern of Definition 28.33. The forward map is defined by unary generation: e reads as zero, and E1(h) reads as successor of the readback of h. The backward map is the same induction in the opposite direction, sending zero to e and successor to E1 of the already encoded tail. The zero-extension branch is absent on the BEDC carrier because the carrier is UnaryHistory.

For theorem preservation, apply Definition 29.5 for the empty word and Definition 29.6 for the bracketing comparison. Induction on the right unary word turns a displayed Cont(h, k, r) witness into ordinary concatenation of finite unary words, hence into length addition after readback. The same-source comparison needed for classified results is Definition 29.16.

For reflection, induct on the standard finite unary word used as the right summand. The zero case is the empty continuation unit. The successor case adds one E1 tail and composes with the induction hypothesis through continuation associativity. Thus standard unary concatenation reflects back to a BEDC Cont witness, with result classification supplied by the additive classifier row.

The no-host-leak field is syntactic at this paper site. Host Nat, finite unary words, concatenation, and length addition appear only in the standard codomain, the forward and backward bridge maps, and their round-trip or preservation equations. The BEDC public inputs remain exactly the UnaryHistory carrier, hsame-based classifier, continuation source, stability certificate, and ledger rows of Definition 29.12; no host natural number or host function is accepted as a BEDC carrier, classifier, or proof input. □

Closure status for NameCert$_{\mathsf{Add}^\uparrow}$.

Constructive story: Addition appears once two unary spines are placed in order and the kernel continuation produces the spine that follows them. Thus an admitted row is not an external arithmetic fact but a triple (h, k, r): both inputs are accepted by the unary predicate of Nat$^\uparrow$, the result is unary as well, and r is the displayed continuation of h by k. Two rows name the same addition step only when their three histories match component by component, while the source side covers exactly the unary input pairs with such a continuation, the pattern side records unary closure and the kernel cancellation rows, and the ledger keeps the visible source-result triple aligned with the raw histories that generated it. Because history-equality is identity in each coordinate, the trivial (e, e, e) row supplies an inhabitant and the classifier is automatically reflexive, symmetric, transitive, and closed over the carrier. A triple (h, k, r) enters the signature gap of an Add$^\uparrow$ token p when the source-domain accepts the row, the signature relation pairs it with an answer continuation and evidence ledger, and the token-introduction relation names that answer as p; once unfolded, this says that h and k are unary, that Cont(h, k, r) is the kernel witness, and that the b1-depth of r is the sum encoded by p. The standard unary bridge then reads the same continuation as concatenation of two finite unary words, with word length giving back the equality between the concatenated length and the two input lengths. The chapter registers the construction under the name Add$^\uparrow$; addition is the continuation operation viewed on unary triples, with unit and associativity proved as monoid theorems rather than installed as arithmetic primitives.

Theory closure: TheoryGate(NameCert$_{\mathsf{Add}^\uparrow}$, maturePackageClosed)

Scope closed: The mature Add$^\uparrow$ package is exactly the displayed UnaryHistory carrier and NameCert of Definition 29.12, the standard unary bridge of Definition 29.14, the monoid activation theorem Definition 29.15, the finite swapped-source boundary theorems in this chapter, and the paper-level acceptance bridge fields of Definition 29.22.

Formal verification: FormalStatus(NameCert$_{\mathsf{Add}^\uparrow}$, bridgeChecked)

Lean target: `BEDC.FKernel.Unary.add\_up\_name\_certificate`

Bridge status: bridgeChecked

Not claimed: Full $\mathsf{Nat}^{\uparrow}$ arithmetic, recursion equations, cancellation, order compatibility, multiplication interaction, and machine-checked standard-bridge closure are outside this $\mathsf{Add}^{\uparrow}$ closure.

Upgrade path: no further upgrade — chapter at top of formal axis

Proposition 29.23 (Zero-result continuation has no same-surface reverse)**.** *In the public* $\mathsf{Add}^{\uparrow}$ *surface of Definition 29.12, the displayed implication*

$$\mathsf{Unary}(h) \quad \textit{and} \quad \mathsf{Unary}(k) \quad \textit{and} \quad \mathsf{Cont}(h, k, \mathsf{E0}(z)) \quad \Rightarrow \quad \bot$$

is a one-way interpretation boundary. More precisely, for fixed unary inputs h *and* k*, no same-surface reverse rule may use only the zero-result absence row to supply the missing zero-result continuation row*

$$\neg\mathsf{Cont}(h, k, \mathsf{E0}(z)) \quad \Rightarrow \quad \mathsf{Cont}(h, k, \mathsf{E0}(z)).$$

Consequently the no-zero-result row cannot be completed into an equivalence row on the visible AddSource*,* AddPattern*,* AddClassifier*, or* AddLedger *surface.*

Lean4 ✓ `BEDC.Derived.AddUp.AddUnaryZeroResult one way boundary`

Proof. Assume h and k are unary histories. By Definition 29.3, every displayed continuation witness

$$\mathsf{Cont}(h, k, \mathsf{E0}(z))$$

is impossible. Hence the zero-result absence row

$$\neg\mathsf{Cont}(h, k, \mathsf{E0}(z))$$

is already forced by the unary source hypotheses.

Suppose a same-surface reverse rule of the displayed form were available. Applying it to the absence row just obtained would produce a continuation witness

$$\mathsf{Cont}(h, k, \mathsf{E0}(z)).$$

Applying Definition 29.3 again to the same unary inputs and this witness gives a contradiction. Thus the reverse rule cannot coexist with the unary continuation calculus.

The certificate rows in this chapter do not contain another route around this obstruction. By Definition 29.7, a source row for an additive output contains an actual continuation witness. By Definition 29.8, the pattern row is that continuation witness together with the unary input discipline. By Definition 29.11, the ledger records the same witness rather than replacing it by an absence statement. Finally, Definition 29.9 compares generated result histories only after a result has been generated. Therefore the absence of a zero-headed continuation is not a hidden source, pattern, classifier, or ledger witness for a zero-headed result; it is exactly the boundary excluding such a row. □

Chapter 30

A Concrete Naming Certificate for $\mathsf{Mul}^{\uparrow}$

The multiplication interface $\mathsf{Mul}^{\uparrow}$ is the repeated-addition consumer of the unary natural-number spine. It sits after $\mathsf{Nat}^{\uparrow}$ and $\mathsf{Add}^{\uparrow}$ in the arithmetic chain, uses the concrete history monoid route of $\mathsf{Monoid}^{\uparrow}$, and supplies the multiplication row consumed by the divisibility and prime-number surface of chapter 64.

30.1 Unary product rows

Definition 30.1 (MulUp unary product carrier)**.** *The carrier for* $\mathsf{Mul}^{\uparrow}$ *consists of finite product rows*

$$\mathsf{MulRow}(d, q, n, \lambda)$$

where d, q, and n are $\mathsf{Nat}^{\uparrow}$ *unary histories, λ is a finite additive iteration ledger, and the ledger starts at* e*, reads the multiplier q one unary step at a time, and at each visible step applies the* $\mathsf{Add}^{\uparrow}$ *continuation row that adds one further copy of d to the current partial product. The final ledger endpoint is the result row n.*

Lean4 ✓ `BEDC.Derived.MulUp.TasteGate.MulUpTasteGate single carrier alignment`

Definition 30.2 (MulUp unary product classifier)**.** *Two* $\mathsf{Mul}^{\uparrow}$ *product rows* $\mathsf{MulRow}(d, q, n, \lambda)$ *and* $\mathsf{MulRow}(d', q', n', \lambda')$ *are classified together when the two factor rows satisfy* $d\mathsf{hsame}d'$ *and* $q\mathsf{hsame}q'$*, the result rows satisfy* $n\mathsf{hsame}n'$*, and the two additive iteration ledgers replay the same finite sequence of* $\mathsf{Add}^{\uparrow}$ *continuation steps after transport along those* hsame *comparisons.*

Theorem 30.3 (MulUp unary product NameCert obligations)**.** *The carrier and classifier of Definition 30.1 and Definition 30.2 supply the local* $\mathsf{NameCert}_{\mathsf{Mul}^{\uparrow}}$ *obligation surface over* BHist*: the empty multiplier row is inhabited by the endpoint* e*, classifier reflexivity, symmetry, and transitivity are inherited from* hsame *on the displayed factor and result histories, and transport of a product row along classified factors and result histories replays the same finite additive ledger.*

Proof. For inhabitance, take any unary multiplicand d and the empty multiplier. The additive iteration ledger has no visible addition step and ends at e, so it is an accepted product row.

The classifier clauses are componentwise. Reflexivity, symmetry, and transitivity use the corresponding hsame facts on the two factors and the result, while the ledger component is compared by replaying the same finite list of $\mathsf{Add}^{\uparrow}$ rows after those transports.

For carrier transport, push $d\mathsf{hsame}d'$, $q\mathsf{hsame}q'$, and $n\mathsf{hsame}n'$ through the source, counter, and endpoint coordinates of the ledger. Each intermediate row remains a $\mathsf{Nat}^{\uparrow}$ unary history, and each additive step remains an $\mathsf{Add}^{\uparrow}$ continuation row, so the transported tuple is again a $\mathsf{Mul}^{\uparrow}$ product row. □

Theorem 30.4 (MulUp additive route)**.** *Every accepted* $\mathsf{Mul}^{\uparrow}$ *row factors through the unary source of* $\mathsf{Nat}^{\uparrow}$*, the continuation-addition row of* $\mathsf{Add}^{\uparrow}$*, and the concrete history monoid route of* $\mathsf{Monoid}^{\uparrow}$*. Equivalently, multiplication is not a new kernel operation: it is a finite* Cont *replay in which the multiplier ledger schedules repeated* $\mathsf{Add}^{\uparrow}$ *applications over unary histories.*

Proof. Project an accepted $\mathsf{Mul}^{\uparrow}$ row to its carrier data. The displayed factors and result are unary histories, so the source side is already inside the $\mathsf{Nat}^{\uparrow}$ carrier of chapter 28.

Read the ledger next. Its base row is the empty product endpoint, and every visible multiplier step is an $\mathsf{Add}^{\uparrow}$ continuation row that appends one copy of the multiplicand to the current partial product. Thus the only operation used in the computation is the addition certificate of chapter 29.

Finally, the ledger concatenation of successive continuation rows is exactly the concrete unary-history monoid route displayed by chapter 40. Repacking these three projections gives the claimed factorization and leaves no independent multiplication primitive. □

Theorem 30.5 (MulUp unary product recursion laws)**.** *Every accepted row* $\mathsf{MulRow}(d, q, n, \lambda)$ *satisfies the unary recursion laws for multiplication. When the visible multiplier ledger is empty, the product endpoint is the carrier endpoint* e*. When the visible multiplier ledger has successor form, the row decomposes into the previous product row followed by one* $\mathsf{Add}^{\uparrow}$ *continuation row that adds the multiplicand* d *to the previous partial product.*

These endpoint and successor laws are stable under componentwise hsame *transport of the displayed multiplicand, multiplier, and product histories, and they are stable under replay of the stored* Cont *ledger. Thus* $\mathsf{Mul}^{\uparrow}$ *remains a finite repeated-addition route through* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{Add}^{\uparrow}$*,* $\mathsf{Monoid}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*, rather than a separate primitive operation.*

Proof. Inspect the visible unary multiplier ledger in the accepted row. In the empty case there is no displayed multiplier step, so the product row is exactly the endpoint row already present in the carrier, namely e.

In the successor case the final visible multiplier step can be peeled from the finite ledger. The prefix ledger is the previous product row, and the peeled terminal row is an $\mathsf{Add}^{\uparrow}$ continuation adding one copy of the multiplicand to that previous partial product.

Transport is componentwise. The classifier supplies the hsame comparisons on the multiplicand, multiplier, and product histories, and continuation replay sends each stored additive row to the transported additive row. Therefore the endpoint and successor decompositions persist after transport and after replay of the same finite ledger. □

Theorem 30.6 (MulUp finite data boundary)**.** *The* $\mathsf{Mul}^{\uparrow}$ *chapter exports only the finite unary product rows of Definition 30.1, their classifier of Definition 30.2, the local* $\mathsf{NameCert}_{\mathsf{Mul}^{\uparrow}}$ *obligations of Definition 30.3, the additive route of Definition 30.4, and the recursion laws of Definition 30.5. The downstream divisibility and* $\mathsf{Prime}^{\uparrow}$ *multiplication consumer may therefore read* NatMul *rows through this repeated-addition boundary, while full semiring or ring algebra, divisibility completeness, and standard bridge checking remain outside this local certificate surface.*

Proof. The exported rows are exactly the carrier, classifier, NameCert obligations, route theorem, and recursion-law theorem just listed. Each row is a finite object: two factor histories, one result

history, and a finite additive ledger whose entries are $\mathsf{Add}^{\uparrow}$ continuation steps over $\mathsf{Nat}^{\uparrow}$ unary histories.

The divisibility and prime-number consumer in chapter 64 reads the same multiplication relation through the NatMul surface, in particular the semantic exit and phase boundary of Definition 64.24 and Definition 64.71. Those consumer rows add divisibility, order, and audit-clean arithmetic boundaries, but they do not change the local repeated-addition carrier defined here.

Since none of the four local exports contains a semiring carrier, a ring carrier, a quotient completion, a divisibility-completeness theorem, or a checked standard bridge, those structures are not claimed by this chapter. □

Theorem 30.7 (MulUp local-to-Full Nat Arithmetic handoff)**.** *The local exports of Definition 30.1, Definition 30.2, Definition 30.3, Definition 30.4, Definition 30.5, and Definition 30.6 form precisely the* $\mathsf{Mul}^{\uparrow}$ *input face read by the mature Full Nat Arithmetic boundary of Definition 64.82. The checked* NatMul *semantic exit,* $\mathsf{Add}^{\uparrow}$ *distributivity rows,* $\mathsf{Order}^{\uparrow}$ *monotonicity row, and divisibility-order consumer rows are downstream consumer rows over that face; they do not add new local carrier coordinates to the repeated-addition certificate.*

Proof. Project the local tuple to its carrier, classifier, NameCert obligations, additive route, recursion laws, and finite-data boundary. These projections expose only unary histories, componentwise hsame comparisons, and finite Cont ledgers whose visible steps are $\mathsf{Add}^{\uparrow}$ continuation rows.

Use the additive route through $\mathsf{Nat}^{\uparrow}$, $\mathsf{Add}^{\uparrow}$, and $\mathsf{Monoid}^{\uparrow}$ to identify the product relation as repeated addition over the same BHist spine. The recursion laws give the empty-multiplier endpoint and successor-step decomposition, while the finite-data boundary restricts the local chapter to those rows and rules out host multiplication or a second carrier.

Finally apply the Prime-side mature boundary of Definition 64.82. That boundary consumes the projected face by adding the checked NatMul semantic exit, the $\mathsf{Add}^{\uparrow}$ distribution rows, the $\mathsf{Order}^{\uparrow}$ monotonicity row, and the divisibility-order rows as consumer structure over the same carrier and classifier. Since these rows are introduced only at the consumer boundary, the local $\mathsf{Mul}^{\uparrow}$ chapter keeps exactly the repeated-addition coordinates listed above. □

Theorem 30.8 (MulUp unary multiplication law bundle)**.** *The concrete unary product carrier over* $\mathsf{Nat}^{\uparrow}$, $\mathsf{Add}^{\uparrow}$, $\mathsf{Monoid}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *supplies exactly the public* $\mathsf{Mul}^{\uparrow}$ *multiplication laws used by downstream arithmetic consumers: totality on unary factors, unary closure of results, functionality up to* hsame, *left and right unit laws for* E1(e), *commutativity up to* hsame, *and associativity up to* hsame.

Proof. Start with the local repeated-addition surface. The carrier of Definition 30.1 and the classifier of Definition 30.2 provide the displayed product rows and the componentwise hsame comparison used to identify equal results.

The local certificate obligations of Definition 30.3 and the recursion laws of Definition 30.5 give the finite endpoint and successor-step account of product formation. The handoff theorem Definition 30.7 identifies this local face as the one consumed by the checked Full Nat Arithmetic boundary.

The Prime-side NatMul rows then package the public laws over that face. Their checked bundle states totality for unary factors, unary result closure, functionality, the two E1(e) unit laws, commutativity, and associativity, all with the result comparisons expressed by hsame. Repacking those rows yields precisely the announced $\mathsf{Mul}^{\uparrow}$ law bundle. □

Lean4 ✓ `BEDC.Derived.PrimeUp.NatMul unary mulup certificate`

Closure status for $\mathsf{NameCert}_{\mathsf{Mul}\uparrow}$.

Constructive story: Unary multiplication is generated on the same spine used for natural numbers: the carried inputs and result are unary histories, the multiplication relation is accepted only when a finite $\mathsf{Add}^{\uparrow}$ iteration ledger witnesses the repeated append pattern named by NatMul, and the local NameCert row records that finite surface. Two multiplication presentations are classified by hsame on the unary endpoints and by functionality of the result ledger, so componentwise transport identifies the factor, multiplier, and product rows without importing a semiring carrier or a host multiplication table. The source specification is the unary-history carrier together with the factor, multiplier, and result rows, the pattern specification records totality, result closure, functionality, unit laws, commutativity, associativity, additive distribution, order monotonicity, and divisibility-order rows, and the ledger policy keeps the raw factors, multiplier splits, appended result, unit endpoint, and continuation evidence visible. The full natural-arithmetic mature boundary is the paper-side consumer boundary of Definition 64.82.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Mul}\uparrow}$, maturePackageClosed)

Scope closed: The mature Full Nat Arithmetic boundary includes the unary product carrier of Definition 30.1, classifier of Definition 30.2, local obligations of Definition 30.3, additive route of Definition 30.4, recursion laws of Definition 30.5, finite-data boundary of Definition 30.6, and the BHist unary-history multiplication package of Definition 64.82, including the NatMul semantic exit, checked law audit package, $\mathsf{Add}^{\uparrow}$ distributivity rows, $\mathsf{Order}^{\uparrow}$ monotonicity row, and divisibility-order consumer rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Mul}\uparrow}$, axiomClean)

Lean target: `BEDC.Derived.PrimeUp.NatMul\_result\_semanticNameCert`

Bridge status: paperBridge

Not claimed: This chapter does not close semiring completion, quotient carriers, host multiplication, or cancellation laws outside the displayed unary-history rows.

Upgrade path: Further closure requires a checked standard bridge for the mature Full Nat Arithmetic surface.

$\mathsf{Int}^{\uparrow}$ is the L7 signed-unary arithmetic surface built from the unary magnitude rows of $\mathsf{Nat}^{\uparrow}$ in chapter 28 and the balancing and continuation rows of $\mathsf{Add}^{\uparrow}$ in chapter 29. $\mathsf{Rat}^{\uparrow}$ in chapter 37 consumes this surface as signed numerator data, while the DyadicRatCore, StreamName, RegSeqRat, and Real route is downstream consumer context rather than the source that defines $\mathsf{Int}^{\uparrow}$.

The IntUp certificate hub routes signed-pair material through the NatUp unary carrier of chapter 28, the AddUp continuation ledger of chapter 29, and the RatUp denominator boundary of chapter 37; the child files below keep those sibling dependencies explicit.

Chapter 31

A Concrete Naming Certificate for $\mathsf{Int}^{\uparrow}$

The integer interface $\mathsf{Int}^{\uparrow}$ is licensed by signed unary histories: a sign component together with a unary magnitude under continuation discipline. It is not a primitive operation of the finite kernel. The construction follows the 5-field NameCert template established by chapter 28 and chapter 29, with the carrier extended by a sign indicator and the stability fields adjusted for sign-aware continuation.

The signed-pair carrier consumes the arithmetic predecessor lattice rather than standing as a kernel island: Nat supplies unary magnitudes, chapter 29 supplies continuation-compatible arithmetic routing, and chapter 37 later reads the signed numerator surface through the same integer carrier. The signed-pair carrier consumes the Nat unary magnitude carrier and Add continuation ledger through chapter 28 and chapter 29, and every later Int classifier row is read as a sign-tagged extension of those two sibling surfaces.

31.1 Carrier definition

Definition 31.1 (Signed unary integer carrier)**.** *The carrier predicate for* $\mathsf{Int}^{\uparrow}$ *uses an existing mark as the sign component and an existing unary history as the magnitude component:*

$$\mathsf{IntCarrier}(s, h) := (s = \mathsf{b0} \lor s = \mathsf{b1}) \land \mathsf{Unary}(h).$$

Lean4 (definition) `BEDC.Derived.IntUp.IntCarrier`
Lean4 ✓ `BEDC.Derived.IntUp.IntCarrier sign cases`

Proof. This is a definitional clause over the finite-kernel mark constructors and the unary-history predicate. □

Theorem 31.2 (Signed carrier is closed under same-sign continuation)**.** *For a fixed sign* $s : \mathsf{BMark}$*, if* $\mathsf{IntCarrier}(s, h)$*,* $\mathsf{IntCarrier}(s, k)$*, and* $\mathsf{Cont}(h, k, r)$*, then* $\mathsf{IntCarrier}(s, r)$*.*

Lean4 ✓ `BEDC.Derived.IntUp.IntCarrier continuation closed same sign`

Proof. Keep the sign disjunction supplied by the first carrier witness.

The two carrier witnesses also provide unary magnitude witnesses for h and k. Apply unary continuation closure to those two magnitude witnesses and the displayed continuation ledger $\mathsf{Cont}(h, k, r)$, then pair the resulting unary witness for r with the retained sign clause. □

Theorem 31.3 (Signed carrier transports along mark sameness)**.** *If* $\mathsf{IntCarrier}(s, h)$ *and* $\mathsf{msame}(s, s')$*, then* $\mathsf{IntCarrier}(s', h)$*.*

Proof. The sign-sameness witness identifies the two finite-kernel sign marks. After that identification, the original signed unary carrier witness has the required transported sign. □

Lean4 ✓ `BEDC.Derived.IntUp.IntCarrier sign msame transport`

Theorem 31.4 (Signed carrier transports along history sameness)**.** *For a fixed sign* s*, if* $\mathsf{IntCarrier}(s, h)$ *and* $\mathsf{hsame}(h, k)$*, then* $\mathsf{IntCarrier}(s, k)$*.*

Proof. The carrier splits into the sign clause and the unary magnitude clause. The sign clause is unchanged, while the unary-history witness is transported along $\mathsf{hsame}(h, k)$. □

Lean4 ✓ `BEDC.Derived.IntUp.IntCarrier transport hsame magnitude`

Theorem 31.5 (Integer magnitude transport along history sameness)**.** *For a fixed sign* s*, if* $\mathsf{IntCarrier}(s, h)$ *holds and* h *is internally the same history as* k*, then* $\mathsf{IntCarrier}(s, k)$ *holds.*

Lean4 ✓ `BEDC.Derived.IntUp.IntCarrier magnitude hsame transport`

Proof. The sign disjunction is preserved unchanged, while the unary-history component is transported across $\mathsf{hsame}(h, k)$ by the finite-kernel unary transport theorem. □

Theorem 31.6 (Integer carrier magnitude induction)**.** *For a fixed sign* $s : \mathsf{BMark}$*, any predicate* P *on histories holds for every integer-carried magnitude if it holds at* e *and is preserved by one-step unary extension along* $\mathsf{IntCarrier}(s, -)$*.*

Proof. Unpack $\mathsf{IntCarrier}(s, h)$ into its sign clause and unary-history witness. Apply unary-history induction to the magnitude; the step rebuilds the integer carrier from the fixed sign clause and the current unary witness. □

Lean4 ✓ `BEDC.Derived.IntUp.IntCarrier magnitude induction`

Definition 31.7 (Integer source specification)**.** *The source specification for* $\mathsf{Int}^{\uparrow}$ *is exactly the signed unary integer carrier:*

$$\mathsf{IntSourceSpec}(s, h) := \mathsf{IntCarrier}(s, h).$$

Lean4 (definition) `BEDC.Derived.IntUp.IntSourceSpec`
Lean4 ✓ `BEDC.Derived.IntUp.intup source specification`

Proof. This is a direct definitional identification of the source specification with the carrier predicate. □

Definition 31.8 (Integer classifier specification)**.** *The classifier for two signed unary representatives requires both representatives to be in the integer carrier, their signs to be mark-same, and their magnitudes to be history-same:*

$$\mathsf{IntClassifierSpec}((s, h), (t, k)) := \mathsf{IntCarrier}(s, h) \wedge \mathsf{IntCarrier}(t, k) \wedge \mathsf{msame}(s, t) \wedge \mathsf{hsame}(h, k).$$

Lean4 (definition) `BEDC.Derived.IntUp.IntClassifierSpec`

Definition 31.9 (Integer difference-pair carrier)**.** *The signed-pair presentation of* $\mathsf{Int}^{\uparrow}$ *uses two unary histories, read as a positive counter and a negative counter:*

$$\mathsf{IntPairCarrier}(p, n) := \mathsf{Unary}(p) \wedge \mathsf{Unary}(n).$$

Lean4 (definition) `BEDC.Derived.IntUp.IntPairCarrier`

Theorem 31.10 (Integer difference-pair carrier magnitude-pair induction)**.** *Let* P *be a predicate on two history magnitudes. If* $P(\mathsf{e}, \mathsf{e})$ *holds, if* $P(p, n)$ *is preserved by replacing the positive component with* $\mathsf{E1}(p)$ *whenever both components are unary, and if* $P(p, n)$ *is preserved by replacing the negative component with* $\mathsf{E1}(n)$ *whenever both components are unary, then every carried integer difference-pair satisfies* P*:*

$$\mathsf{IntPairCarrier}(p, n) \Longrightarrow P(p, n).$$

Lean4 ✓ `BEDC.Derived.IntUp.IntPairCarrier magnitude pair induction`

Proof. Unpack $\mathsf{IntPairCarrier}(p, n)$ into unary witnesses for both components. First apply unary-history induction to the negative component to derive $P(\mathsf{e}, n)$ from the base case and the negative-component step. Then apply unary-history induction to the positive component. At each positive successor, use the positive-component step with the current positive unary witness, the fixed negative unary witness, and the induction hypothesis. □

Theorem 31.11 (Integer pair carrier pair induction)**.** *For any predicate* P *on two histories, if* $P(\mathsf{e}, \mathsf{e})$ *holds and* P *is preserved by one-step unary extension of either counter while the other counter remains unary, then* $P(p, n)$ *holds for every carried integer difference pair* $\mathsf{IntPairCarrier}(p, n)$*.*

Proof. Unfold IntPairCarrier into its positive and negative unary counter witnesses. Run unary-history induction over the positive counter; its base case is unary-history induction over the negative counter, and the two step cases are exactly the two supplied one-step closure rules. □

Lean4 ✓ `BEDC.Derived.IntUp.IntPairCarrier pair induction`

Definition 31.12 (Integer difference-pair classifier)**.** *Two carried unary pairs classify together when their cross-additions are history-same:*

$$\mathsf{IntPairClassifier}((p, n), (q, m)) := \mathsf{IntPairCarrier}(p, n) \wedge \mathsf{IntPairCarrier}(q, m) \wedge \mathsf{hsame}(\mathsf{append}(p, m), \mathsf{append}(q, n)).$$

Lean4 (definition) `BEDC.Derived.IntUp.IntPairClassifier`

Theorem 31.13 (Integer pair classifier zero representative criterion)**.** *For all* $p, n : \mathsf{BHist}$*, if* $\mathsf{Unary}(p)$ *and* $\mathsf{Unary}(n)$*, then the ordinary zero representative detects exactly the zero class of the carried signed pair:*

1.

$$\mathsf{IntPairClassifier}((p, n), (\mathsf{e}, \mathsf{e})) \Longleftrightarrow \mathsf{hsame}(p, n);$$

2.

$$\mathsf{IntPairClassifier}((\mathsf{e}, \mathsf{e}), (p, n)) \Longleftrightarrow \mathsf{hsame}(p, n).$$

The ten-field fit is: target ordinary zero class of signed difference pairs; BEDC source IntPairCarrier*,* IntPairClassifier*,* Unary*,* append*,* e*, and* hsame*; carrier carried unary pairs; classifier cross-addition sameness; stability append unit transport; ledger hidden empty counter pair; exactness zero representative iff; downstream consumer* RatUp *numerator-zero and* IntUp *closure; status* ProofTarget*.*

Proof. Unfold IntPairClassifier. In the first forward direction, the cross-addition field reads hsame(append(p, e), appe the right and left unit laws for append reduce this comparison to hsame(p, n).

For the first reverse direction, the unary hypotheses give IntPairCarrier(p, n), and the empty unary witness gives IntPairCarrier(e, e). Transport the assumed hsame(p, n) through the same two unit identifications to obtain the required cross-addition field.

For the second orientation, unfold the classifier for $((\mathsf{e}, \mathsf{e}), (p, n))$. The cross-addition field is hsame(append(e, n), append(p, e)), so the unit laws and symmetry of hsame identify it with hsame(p, n).

The reverse direction again packages the two carrier witnesses and transports hsame(p, n) across the unit laws, reversing the comparison by symmetry when the displayed orientation requires it. □

Lean4 ✓ `BEDC.Derived.IntUp.IntPairClassifier zero representative criterion`

Theorem 31.14 (Integer pair classifier positive append context)**.** *If* a, p, n, q, m : BHist*, a is unary, and* IntPairClassifier$((p, n), (q, m))$*, then*

$$\mathsf{IntPairClassifier}((\mathsf{append}(a, p), n), (\mathsf{append}(a, q), m)).$$

Lean4 ✓ `BEDC.Derived.IntUp.IntPairClassifier append positive context`

Proof. Unpack the classifier into the two unary-pair carriers and the cross-addition comparison append(p, m)hsameappend(q, n). Unary append closure puts append(a, p) and append(a, q) back in the carried positive counters. Prefix the cross-addition comparison by a and reassociate both sides by append_assoc, yielding the displayed contextual classifier. □

Theorem 31.15 (Integer pair classifier signed-context invariance)**.** *Let* a, b, p, n, q, m : BHist*. If* Unary(a)*,* Unary(b)*, and* IntPairClassifier$((p, n), (q, m))$*, then*

$$\mathsf{IntPairClassifier}((\mathsf{append}(a, p), \mathsf{append}(b, n)), (\mathsf{append}(a, q), \mathsf{append}(b, m))).$$

The ten-field fit is: target simultaneous signed-context transport for integer difference pairs; BEDC source IntPairCarrier*,* IntPairClassifier*,* Unary*,* append*, and* hsame*; carrier carried unary positive and negative counters; classifier cross-addition sameness; stability four unary append-closed endpoints; ledger common signed context* append(a, b)*; exactness preservation of the cross-addition witness; downstream consumer* RatUp *numerator/denominator context transport and the* IntUp *signed-pair arithmetic certificate; status* ProofTarget*.*

Lean4 ✓ `BEDC.Derived.IntUp.IntPairClassifier signed context invariance`

Proof. Unpack IntPairClassifier$((p, n), (q, m))$ into the carried endpoints and the cross-addition witness append(p, m)hsameappend(q, n). Unary append closure applied to the two positive counters and to the two negative counters gives the four carried endpoints required for the displayed classifier.

It remains to transport the cross-addition field. The left target comparison has source append(append(a, p), appe and the right target comparison has source append(append(a, q), append(b, n)). Associativity rewrites these as signed-context words containing the same unary prefix. Commuting unary factors brings the common signed context append(a, b) to the front on both sides.

After this normalization, the remaining suffixes are exactly append(p, m) and append(q, n). Prefix the original hsame comparison by the common context append(a, b), then reassociate in the reverse direction to obtain the required classifier field. □

Theorem 31.16 (Integer difference-pair classifier equivalence fields)**.** *On carried unary pairs,* IntPairClassifier *supplies the expected integer quotient fields:*

1. *reflexivity: for every* IntPairCarrier(p, n), IntPairClassifier$((p, n), (p, n))$*;*
2. *symmetry: from* IntPairClassifier$((p, n), (q, m))$ *one obtains* IntPairClassifier$((q, m), (p, n))$*;*
3. *transitivity: from* IntPairClassifier$((p, n), (q, m))$ *and* IntPairClassifier$((q, m), (r, o))$ *one obtains* IntPairClassifier$((p, n), (r, o))$*;*
4. *componentwise transport: if* $p$hsamep'*,* $n$hsamen'*,* $q$hsameq'*, and* $m$hsamem'*, then a classifier witness for* $((p, n), (q, m))$ *transports to one for* $((p', n'), (q', m'))$ *whenever all four pairs are carried.*

The ten-field fit is: traditional target signed integers as unary difference pairs; BEDC source Unary*,* hsame*, and* append*; carrier* IntPairCarrier*; classifier* IntPairClassifier*; stability componentwise* hsame *transport; ledger the two unary counters; core theorem this block; exactness cross-addition classification; standard bridge the ordinary presentation of integers as* (p, n) *modulo* $p+m = q+n$*; status* ProofTarget*.*

Lean4 ✓ `BEDC.Derived.IntUp.IntPairClassifier equivalence fields`

Proof. For reflexivity, unary append closure shows both cross-additions append(p, n) are unary, and reflexivity of hsame supplies the cross-addition equality. The two carrier witnesses are reused unchanged.

For symmetry, unpack the classifier witness. The carrier witnesses swap positions, and symmetry of hsame reverses the cross-addition comparison between append(p, m) and append(q, n).

For transitivity, suppose the two displayed classifier witnesses give append(p, m)hsameappend(q, n) and append(q, o)hsameappend(r, m). Append the missing contexts to both comparisons so that the shared unary factors are visible.

Using append_assoc, unary append commutativity, and transitivity of hsame, rewrite the composed comparison to the form

$$\mathsf{append}(\mathsf{append}(p, o), m)\mathsf{hsameappend}(\mathsf{append}(r, n), m).$$

The common suffix m is carried by unary closure, so append_right_cancel, equivalently common-context cancellation, removes it and yields append(p, o)hsameappend(r, n). Together with the endpoint carrier witnesses, this is exactly IntPairClassifier$((p, n), (r, o))$.

For componentwise transport, transport unary carrier evidence along the four hsame links. Compatibility of append with hsame transports the cross-addition comparison from append(p, m)hsameappend(q, n) to append(p', m')hsameappend(q', n'). □

Theorem 31.17 (Integer classifier magnitude pair induction)**.** *Any predicate* P *on pairs of histories holds for the two magnitudes of every* IntClassifierSpec *witness if it holds at* (e, e) *and is preserved by one-step unary extension on either magnitude while the other magnitude remains unary.*

Proof. Unpack the classifier into its two signed unary carrier witnesses. These give unary histories for both magnitudes. Run unary-history induction over the left magnitude; its base is supplied by a second unary-history induction over the right magnitude, and its step uses the left extension rule. □

Lean4 ✓ `BEDC.Derived.IntUp.IntClassifierSpec magnitude pair induction`

Theorem 31.18 (Integer classifier endpoint sign cases)**.** *If* $\mathsf{IntClassifierSpec}(x, y)$*, then the two endpoint signs are either both* $\mathsf{b0}$ *or both* $\mathsf{b1}$*, and both endpoint magnitudes are unary:*

$$((x_1 = \mathsf{b0} \wedge y_1 = \mathsf{b0}) \vee (x_1 = \mathsf{b1} \wedge y_1 = \mathsf{b1})) \wedge \mathsf{Unary}(x_2) \wedge \mathsf{Unary}(y_2).$$

Proof. Unpack the classifier into the two signed carrier witnesses, sign sameness, and magnitude sameness. The left carrier splits the left sign into the two finite mark cases and gives the unary witness for the left magnitude. The sign sameness transports the same sign case to the right endpoint, while the right carrier supplies the unary witness for the right magnitude. □

Lean4 ✓ `BEDC.Derived.IntUp.IntClassifierSpec endpoint sign cases`

Theorem 31.19 (Integer classifier cross-sign exclusion)**.** *For all* $h, k : \mathsf{BHist}$*, cross-signed endpoints cannot be classified:*

$$\forall h, k : \mathsf{BHist}, \quad (\mathsf{IntClassifierSpec}((\mathsf{b0}, h), (\mathsf{b1}, k)) \to \mathsf{False}) \wedge (\mathsf{IntClassifierSpec}((\mathsf{b1}, h), (\mathsf{b0}, k)) \to \mathsf{False}).$$

The ten-field fit is: traditional target signed-integer sign separation; BEDC source $\mathsf{IntCarrier}$*,* $\mathsf{IntClassifierSpec}$*, and raw mark no-confusion; carrier signed unary representatives; classifier* $\mathsf{IntClassifierSpec}$*; stability from existing sign and magnitude transport; ledger the sign mark and unary magnitude; core theorem this block; exactness cross-sign exclusion; standard bridge ordinary signed-integer sign disjointness; status* $\mathsf{ProofTarget}$*.*

Proof. Project the sign-sameness component from Definition 31.8. In the first branch, a classifier from $(\mathsf{b0}, h)$ to $(\mathsf{b1}, k)$ supplies $\mathsf{msame}(\mathsf{b0}, \mathsf{b1})$, which contradicts raw mark no-confusion in Definition 2.9.

The second branch is the opposite orientation. A classifier from $(\mathsf{b1}, h)$ to $(\mathsf{b0}, k)$ supplies $\mathsf{msame}(\mathsf{b1}, \mathsf{b0})$, and the exchanged half of Definition 2.9 excludes that mark-sameness judgment. □

Lean4 ✓ `BEDC.Derived.IntUp.IntClassifierSpec cross sign exclusion`

Theorem 31.20 (Integer classifier magnitude transport)**.** *If* $\mathsf{IntClassifierSpec}((s_x, h_x), (s_y, h_y))$*, and the two magnitudes transport to* h'_x *and* h'_y *by* hsame*, then* $\mathsf{IntClassifierSpec}((s_x, h'_x), (s_y, h'_y))$*.*

Proof. Unpack the classifier witness into the two signed unary carrier witnesses, the sign sameness component, and the magnitude sameness component. Transport both carriers across the new magnitude links, keep the sign sameness unchanged, and compose the magnitude links through the original classifier link. □

Lean4 ✓ `BEDC.Derived.IntUp.IntClassifierSpec hsame magnitude transport`

Theorem 31.21 (Integer classifier sign transport)**.** *If* $\mathsf{IntClassifierSpec}((s_x, h_x), (s_y, h_y))$*, and the two signs transport to* s'_x *and* s'_y *by* msame*, then* $\mathsf{IntClassifierSpec}((s'_x, h_x), (s'_y, h_y))$*.*

Proof. Unpack the classifier witness into the two signed unary carrier witnesses, the sign sameness component, and the magnitude sameness component. Transport both carriers across the given sign links, compose the sign links through the original classifier link, and keep the magnitude sameness unchanged. □

Lean4 ✓ `BEDC.Derived.IntUp.IntClassifierSpec msame sign transport`

Theorem 31.22 (Integer classifier sign and magnitude transport)**.** *If* $\mathsf{IntClassifierSpec}((s_x, h_x), (s_y, h_y))$*, the signs transport to* s'_x *and* s'_y *by* msame*, and the magnitudes transport to* h'_x *and* h'_y *by* hsame*, then* $\mathsf{IntClassifierSpec}((s'_x, h'_x), (s'_y, h'_y))$*.*

Proof. First transport the classifier along the two magnitude links, preserving the sign component. Then transport the resulting classifier along the two sign links, preserving the transported magnitude component. □

Lean4 ✓ `BEDC.Derived.IntUp.IntClassifierSpec sign magnitude transport`

Theorem 31.23 (Integer classifier reflexivity)**.** *If* $\mathsf{IntCarrier}(s, h)$*, then* $\mathsf{IntClassifierSpec}((s, h), (s, h))$*.*

Proof. Use the same signed unary carrier witness on both classifier endpoints. The sign component is related by reflexivity of msame, and the magnitude component is related by reflexivity of hsame. □

Lean4 ✓ `BEDC.Derived.IntUp.IntClassifierSpec refl`

Theorem 31.24 (Integer classifier symmetry)**.** *If* $\mathsf{IntClassifierSpec}(x, y)$*, then* $\mathsf{IntClassifierSpec}(y, x)$*.*

Proof. Eliminating the classifier witness exposes carrier evidence for both representatives, sign sameness, and magnitude sameness. The carrier evidence is swapped, while symmetry of msame and hsame reverses the two sameness components. □

Lean4 ✓ `BEDC.Derived.IntUp.IntClassifierSpec symm`

Theorem 31.25 (Integer classifier transitivity)**.** *If* $\mathsf{IntClassifierSpec}(x, y)$ *and* $\mathsf{IntClassifierSpec}(y, z)$*, then* $\mathsf{IntClassifierSpec}(x, z)$*.*

Proof. Eliminating the two classifier witnesses exposes the carrier evidence for the endpoints, together with sign sameness and magnitude sameness along both links. Transitivity of msame composes the sign components, and transitivity of hsame composes the magnitude components. □

Lean4 ✓ `BEDC.Derived.IntUp.IntClassifierSpec trans`

Theorem 31.26 (Integer classifier continuation with the same sign)**.** *If two integer classifier witnesses relate* (s_x, h_x) *to* (s'_x, h'_x) *and* (s_y, h_y) *to* (s'_y, h'_y)*, and the left signs* s_x *and* s_y *are mark-same, then continuation of the two left magnitudes and continuation of the two right magnitudes yield another integer classifier witness.*

Proof. Unpack the classifier witnesses into carrier data, sign sameness, and magnitude sameness. Transport the second left carrier along $\mathsf{msame}(s_x, s_y)$, and transport the second right carrier along the composed sign link $s'_x \sim s_x \sim s_y \sim s'_y$. Carrier closure under same-sign continuation gives the two result carriers, while continuation respects the two magnitude hsame links and gives the result magnitude sameness. □

Lean4 ✓ `BEDC.Derived.IntUp.IntClassifierSpec continuation closed same sign`

Theorem 31.27 (Integer classifier append commutativity with the same sign)**.** *For a fixed sign* $s : \mathsf{BMark}$*, if* h *and* k *are both carried by* $\mathsf{IntCarrier}(s, -)$*, then the two append magnitudes classify each other under the same sign:*

$$\mathsf{IntClassifierSpec}\big((s, \mathsf{append}(h, k)), (s, \mathsf{append}(k, h))\big).$$

Proof. Unpack the two integer carrier witnesses. The shared sign evidence supplies both endpoint carriers. Unary append closure gives the two appended magnitude carriers, reflexivity of msame relates the fixed sign to itself, and unary append commutativity gives $\mathsf{append}(h, k)\mathsf{hsameappend}(k, h)$. □

Lean4 ✓ `BEDC.Derived.IntUp.IntClassifierSpec append comm same sign`

Theorem 31.28 (Integer classifier swaps same-sign append context)**.** *For a fixed sign s : BMark, if $left$, $right$, and a are all carried by* IntCarrier$(s, -)$*, then the classifier identifies the two same-sign context displays*

$$\mathsf{append}(left, \mathsf{append}(a, right))$$

and

$$\mathsf{append}(right, \mathsf{append}(a, left)).$$

The ten-field fit is: traditional target signed-unary context commutativity; BEDC source IntCarrier*,* IntClassifierSpec*, and* append*; carrier same-sign unary representatives; classifier* IntClassifierSpec*; stability from unary append closure and append associativity; ledger the two context magnitudes and the middle magnitude; core theorem this block; exactness same-sign context swap; standard bridge ordinary commutativity of finite unary context addition; status* ProofTarget*.*

Proof. Unpack the three integer carrier witnesses to obtain unary witnesses for the two contexts and the middle magnitude. Unary append closure supplies the two endpoint carrier witnesses. Reassociate the left display, commute the relevant unary append factors, and reassociate back to the right display. The shared sign is related to itself by reflexivity of msame, and the constructed append equality is the magnitude component of the classifier. □

Lean4 ✓ `BEDC.Derived.IntUp.IntClassifierSpec append context swap same sign`

Theorem 31.29 (Integer classifier appends same-sign context)**.** *For a fixed sign s : BMark, if $left$ and $right$ are carried by* IntCarrier$(s, -)$*, and* IntClassifierSpec$((s, a), (s, b))$*, then the classifier identifies the common-context magnitudes:*

$$\mathsf{IntClassifierSpec}((s, \mathsf{append}(left, \mathsf{append}(a, right))), (s, \mathsf{append}(left, \mathsf{append}(b, right)))).$$

Proof. Unpack the classifier witness into signed carrier evidence for a and b, the fixed-sign component, and the magnitude equality $a\mathsf{hsame}b$. Same-sign unary append closure builds the two contextual endpoint carriers. Replacing the middle magnitude along $a\mathsf{hsame}b$ leaves the two contextual append histories equal, while sign reflexivity supplies the sign classifier. □

Lean4 ✓ `BEDC.Derived.IntUp.IntClassifierSpec append context same sign`

Theorem 31.30 (Integer classifier cancels same-sign append context)**.** *For a fixed sign s : BMark, if a and b are carried by* IntCarrier$(s, -)$*, and the integer classifier identifies the two common-context magnitudes*

$$\mathsf{append}(left, \mathsf{append}(a, right)) \quad \textit{and} \quad \mathsf{append}(left, \mathsf{append}(b, right)),$$

then IntClassifierSpec$((s, a), (s, b))$*.*

Proof. The contextual classifier exposes a BEDC history equality between the two append histories. Left append cancellation removes the common left context, and right append cancellation removes the common suffix. The resulting $a\mathsf{hsame}b$, together with the supplied endpoint carriers and reflexivity of msame(s, s), gives the integer classifier. □

Lean4 ✓ `BEDC.Derived.IntUp.IntClassifierSpec cancel append context same sign`

Theorem 31.31 (Integer classifier same-sign common context iff)**.** *For a fixed sign s : BMark, suppose that $left$, $right$, a, and b are all carried by $\mathsf{IntCarrier}(s, -)$. Then common same-sign append context is exact for the integer classifier:*

$$\mathsf{IntClassifierSpec}((s, \mathsf{append}(left, \mathsf{append}(a, right))), (s, \mathsf{append}(left, \mathsf{append}(b, right)))) \iff \mathsf{IntClassifierSpec}((s, a)$$

The ten-field fit is: traditional target common-context exactness for signed unary integers; BEDC source $\mathsf{IntCarrier}$*,* $\mathsf{IntClassifierSpec}$*, and* append*; carrier same-sign unary representatives; classifier* $\mathsf{IntClassifierSpec}$*; stability/common-context exactness; ledger left and right context histories; core theorem this iff; exactness preservation plus reflection; standard bridge ordinary cancellation under equal integer context; status* $\mathsf{ProofTarget}$*.*

Proof. For the forward direction, assume the contextual classifier. Apply Theorem 31.30 with the given endpoint carrier witnesses for a and b to cancel the common left and right unary histories.

For the reverse direction, assume $\mathsf{IntClassifierSpec}((s, a), (s, b))$. Apply Theorem 31.29 with the given carrier witnesses for $left$ and $right$ to append the same unary context on both sides. □

31.2 Difference-pair context stability

The difference-pair presentation of $\mathsf{Int}^{\uparrow}$ must remain stable when both representatives receive the same positive unary context and the same negative unary context. This is the signed-pair form of ordinary quotient stability for the relation $(p, n) \sim (q, m)$ given by cross-addition sameness.

Theorem 31.32 (Integer pair classifier balanced append context)**.** *For a, b, p, n, q, m : BHist, if $\mathsf{Unary}(a)$, $\mathsf{Unary}(b)$, and $\mathsf{IntPairClassifier}((p, n), (q, m))$, then*

$$\mathsf{IntPairClassifier}((\mathsf{append}(a, p), \mathsf{append}(n, b)), (\mathsf{append}(a, q), \mathsf{append}(m, b))).$$

The ten-field fit is: traditional target signed-pair integer quotient stability under adding the same positive and negative contexts; BEDC source $\mathsf{IntPairCarrier}$*,* $\mathsf{IntPairClassifier}$*,* Unary*,* append*, and* hsame*; carrier difference pairs; classifier cross-addition sameness; stability balanced context extension; ledger the added positive and negative unary contexts; core theorem this block; exactness preservation of the quotient classifier; standard bridge ordinary $(p, n) \sim (q, m)$ stability under $(p + a, n + b)$; status* $\mathsf{ProofTarget}$*.*

Proof. Unpack the classifier witness into the two difference-pair carrier witnesses and the cross-addition comparison $\mathsf{append}(p, m)\mathsf{hsameappend}(q, n)$. The carrier witnesses give unary evidence for p, n, q, and m.

Unary append closure with the unary contexts a and b supplies all four endpoint carrier components: $\mathsf{append}(a, p)$, $\mathsf{append}(n, b)$, $\mathsf{append}(a, q)$, and $\mathsf{append}(m, b)$.

For the cross-addition component, reassociate the left endpoint by $\mathsf{append_assoc}$:

$$\mathsf{append}(\mathsf{append}(a, p), \mathsf{append}(m, b))\mathsf{hsameappend}(a, \mathsf{append}(\mathsf{append}(p, m), b)).$$

The right endpoint reassociates in the same way:

$$\mathsf{append}(\mathsf{append}(a, q), \mathsf{append}(n, b))\mathsf{hsameappend}(a, \mathsf{append}(\mathsf{append}(q, n), b)).$$

Transport the original comparison through the common left prefix a and the common right suffix b. Transitivity of hsame with the two reassociation steps gives the required cross-addition sameness, and together with the four unary endpoint components this repacks exactly as the displayed $\mathsf{IntPairClassifier}$. □

Lean4 ✓ `BEDC.Derived.IntUp.IntPairClassifier balanced append context`

Theorem 31.33 (Integer pair classifier balanced append context reflection)**.** *For* a, b, p, n, q, m : BHist*, if* Unary(a)*,* Unary(b)*, and*

$$\mathsf{IntPairClassifier}((\mathsf{append}(a,p), \mathsf{append}(n,b)), (\mathsf{append}(a,q), \mathsf{append}(m,b))),$$

then IntPairClassifier$((p,n),(q,m))$*. The ten-field fit is: traditional target signed-pair quotient reflection under adding the same positive and negative contexts; BEDC source* IntPairCarrier*,* IntPairClassifier*,* Unary*,* append*,* hsame*, append associativity, append cancellation, and unary append factorization; carrier difference pairs; classifier cross-addition sameness; stability reflected balanced context cancellation; ledger the removable positive and negative unary contexts; core theorem this reflection block; exactness reflection of the quotient classifier; standard bridge ordinary cancellation of* $(p+a, n+b)$ *back to* (p,n)*; status* ProofTarget*.*

Proof. Unpack the displayed contextual classifier into its two carried endpoints and the cross-addition comparison between the contextual pairs. Unary append factorization applied to those carried endpoints, together with the supplied unary witnesses for a and b, recovers unary evidence for p, n, q, and m.

Reassociate the contextual cross-addition comparison on both sides. The left endpoint has the same hsame-shape as

$$\mathsf{append}(a, \mathsf{append}(\mathsf{append}(p,m), b)),$$

and the right endpoint has the same hsame-shape as

$$\mathsf{append}(a, \mathsf{append}(\mathsf{append}(q,n), b)).$$

Transitivity of hsame with these reassociation witnesses converts the displayed classifier comparison into a comparison with the common left prefix a and the common right suffix b exposed. Append-left cancellation removes the shared prefix and yields a comparison between $\mathsf{append}(\mathsf{append}(p,m),b)$ and $\mathsf{append}(\mathsf{append}(q,n),b)$.

Append-right cancellation then removes the shared suffix b, giving $\mathsf{append}(p,m)\mathsf{hsameappend}(q,n)$. Repack this recovered cross-addition sameness with the recovered carrier witnesses for (p,n) and (q,m) to obtain IntPairClassifier$((p,n),(q,m))$. □

Lean4 ✓ `BEDC.Derived.IntUp.IntPairClassifier balanced append context reflection`

Theorem 31.34 (Integer pair classifier balanced append context exactness)**.** *For* a, b, p, n, q, m : BHist*, if* Unary(a) *and* Unary(b)*, then*

$$\mathsf{IntPairClassifier}((\mathsf{append}(a,p), \mathsf{append}(n,b)), (\mathsf{append}(a,q), \mathsf{append}(m,b))) \iff \mathsf{IntPairClassifier}((p,n),(q,m)).$$

The ten-field fit is: traditional target balanced signed-pair context exactness; BEDC source IntPairCarrier*,* IntPairClassifier*,* Unary*,* append*, and* hsame*; carrier difference pairs; classifier cross-addition sameness; stability common positive and negative unary context transport; ledger the removable positive unary context* a *and removable negative unary context* b*; core theorem this exactness block; exactness the displayed iff; standard bridge ordinary quotient cancellation under simultaneous numerator and denominator context; downstream consumer one-sided context exactness and* $\mathsf{Rat}^{\uparrow}$ *numerator-denominator context cancellation; status* ProofTarget*.*

Proof. For the forward direction, assume the contextual classifier. The hypotheses $\mathsf{Unary}(a)$ and $\mathsf{Unary}(b)$ put the displayed classifier in the scope of Theorem 31.33, which removes the common positive and negative contexts and yields $\mathsf{IntPairClassifier}((p,n),(q,m))$.

For the reverse direction, assume $\mathsf{IntPairClassifier}((p,n),(q,m))$. Applying Theorem 31.32 with the same unary witnesses for a and b transports the classifier through the balanced append context, giving exactly the contextual classifier in the displayed statement. □

Theorem 31.35 (Integer pair classifier one-sided append context exactness)**.** *For* a,p,n,q,m : BHist*, if* $\mathsf{Unary}(a)$*, then both one-sided context laws are exact:*

1. *positive counters:*

$$\mathsf{IntPairClassifier}((\mathsf{append}(a,p),n),(\mathsf{append}(a,q),m)) \iff \mathsf{IntPairClassifier}((p,n),(q,m));$$

2. *negative counters:*

$$\mathsf{IntPairClassifier}((p,\mathsf{append}(n,a)),(q,\mathsf{append}(m,a))) \iff \mathsf{IntPairClassifier}((p,n),(q,m)).$$

The ten-field fit is: traditional target signed-pair integer quotient one-sided context exactness; BEDC source $\mathsf{IntPairCarrier}$*,* $\mathsf{IntPairClassifier}$*,* Unary*,* append*, and* hsame*; carrier difference pairs; classifier cross-addition sameness; stability positive and negative one-sided unary contexts; ledger the common unary context* a *and the empty opposite context; core theorem this pair of equivalences; exactness preservation and reflection through balanced contexts plus componentwise transport; standard bridge ordinary cancellation after adding the same positive or negative integer counter; status* $\mathsf{ProofTarget}$*.*

Proof. For the positive forward implication, assume the contextual classifier on $((\mathsf{append}(a,p),n),(\mathsf{append}(a,q),m))$. The empty history is unary, and the continuation unit laws identify n and m with $\mathsf{append}(n,\mathsf{e})$ and $\mathsf{append}(m,\mathsf{e})$. The componentwise transport field of Theorem 31.16 therefore puts the witness into the balanced-context shape with positive context a and negative context e.

Apply Theorem 31.33 to that balanced-context witness. It cancels the common positive context and the empty negative context, giving $\mathsf{IntPairClassifier}((p,n),(q,m))$.

For the positive reverse implication, assume $\mathsf{IntPairClassifier}((p,n),(q,m))$. Apply Theorem 31.14 with the unary context a to obtain the displayed positive-context classifier.

For the negative forward implication, assume the contextual classifier on $((p,\mathsf{append}(n,a)),(q,\mathsf{append}(m,a)))$. The continuation unit laws identify p and q with $\mathsf{append}(\mathsf{e},p)$ and $\mathsf{append}(\mathsf{e},q)$. Componentwise transport places the witness into the balanced-context shape with positive context e and negative context a.

Apply Theorem 31.33 to cancel those balanced contexts. The result is exactly $\mathsf{IntPairClassifier}((p,n),(q,m))$.

For the negative reverse implication, start from $\mathsf{IntPairClassifier}((p,n),(q,m))$. Apply Theorem 31.32 with the empty positive context and the unary negative context a, then use the continuation unit laws and componentwise transport to replace $\mathsf{append}(\mathsf{e},p)$ and $\mathsf{append}(\mathsf{e},q)$ by p and q. □

Lean4 ✓ `BEDC.Derived.IntUp.IntPairClassifier one sided append context exactness`

Theorem 31.36 (Integer pair classifier iterated balanced append context exactness)**.** *For* a,b,c,d,p,n,q,m : BHist*, if* $\mathsf{Unary}(a)$*,* $\mathsf{Unary}(b)$*,* $\mathsf{Unary}(c)$*, and* $\mathsf{Unary}(d)$*, then*

$$\mathsf{IntPairClassifier}((\mathsf{append}(a,\mathsf{append}(c,p)),\mathsf{append}(\mathsf{append}(n,d),b)),(\mathsf{append}(a,\mathsf{append}(c,q)),\mathsf{append}(\mathsf{append}(m,d),b$$

The ten-field fit is: traditional target stacked signed-pair quotient context exactness; BEDC source IntPairClassifier*,* Unary*,* append*, checked balanced preservation, and checked balanced reflection; carrier difference pairs; classifier cross-addition sameness; stability stacked positive and negative unary context transport; ledger the two positive unary contexts a, c and the two negative unary contexts d, b; core theorem this stacked exactness block; exactness the displayed iff; standard bridge ordinary quotient cancellation for two balanced signed-pair context layers; downstream consumer dyadic-rational mantissa and denominator context normalization; status* ProofTarget*.*

Proof. For the forward direction, assume the displayed contextual classifier. Regard it as a balanced context with outer positive context a, outer negative context b, and inner endpoints $((\mathsf{append}(c,p), \mathsf{append}(n,d)), (\mathsf{append}(c,q), \mathsf{append}(m,d)))$. Apply Theorem 31.33 to remove the outer contexts and yield the inner contextual classifier.

The inner classifier is itself in balanced-context shape with positive context c and negative context d. Applying Theorem 31.33 again cancels this second layer and gives $\mathsf{IntPairClassifier}((p,n),(q,m))$.

For the reverse direction, assume $\mathsf{IntPairClassifier}((p,n),(q,m))$. Apply Theorem 31.32 with contexts c and d to transport the classifier to $((\mathsf{append}(c,p), \mathsf{append}(n,d)), (\mathsf{append}(c,q), \mathsf{append}(m,d)))$.

Applying Theorem 31.32 once more with contexts a and b adds the outer layer, producing exactly the stacked contextual classifier displayed in the statement. □

Definition 31.37 (Int signed-pair carrier)**.** *The root signed-pair carrier for* $\mathsf{Int}^{\uparrow}$ *is the displayed Nat-and-Add row*

$$\mathsf{IntSignedPairCarrier}(a,b) := \mathsf{IntPairCarrier}(a,b),$$

where a and b are unary $\mathsf{Nat}^{\uparrow}$ *magnitude rows and the balancing classifier between (a,b) and (c,d) is read by the additive certificate as the cross-addition comparison $a + d = c + b$. In BEDC notation this is the existing row* $\mathsf{IntPairClassifier}((a,b),(c,d))$*, whose comparison is routed through* $\mathsf{append}(a,d)$ *and* $\mathsf{append}(c,b)$ *under the* $\mathsf{Add}^{\uparrow}$ *continuation ledger.*

Theorem 31.38 (Int signed-pair classifier stability)**.** *The classifier of Definition 31.37 is stable under componentwise* hsame *transport of the four unary magnitude rows and under displayed* Cont *replay of the two cross-addition ledgers. Thus an accepted comparison $(a,b) \sim (c,d)$ remains the same* $\mathsf{Int}^{\uparrow}$ *classifier row after the Nat magnitudes and Add balance witnesses are transported through the local finite ledger.*

Proof. Project the signed-pair carrier through Definition 31.9 and the classifier through Definition 31.12. The carrier rows are unary Nat magnitudes, and the classifier row is the single hsame comparison between the two cross-addition histories.

Transport the four magnitude rows componentwise. The hsame rows preserve the displayed unary histories, while the Cont replay rows rebuild the two additive histories $\mathsf{append}(a,d)$ and $\mathsf{append}(c,b)$ in the transported context.

Apply the balanced-context stability already recorded for the Int pair classifier. The resulting row is again an IntPairClassifier comparison, so no host quotient, primitive subtraction, ordered-ring law, or external integer equality has been introduced. □

Theorem 31.39 (Int additive inverse ledger)**.** *Every accepted* $\mathsf{Int}^{\uparrow}$ *signed-pair row (a,b) carries a displayed inverse ledger row obtained by swapping the two unary components to (b,a). The ledger is finite-row data: it records the Nat magnitudes, the Add balance context, componentwise* hsame *transport, and the local NameCert route, but it does not assert a full group law or ordered-ring interface for* $\mathsf{Int}^{\uparrow}$*.*

Proof. Start from the signed-pair carrier. Both a and b are unary Nat rows, so the swapped pair (b, a) is again admitted by the same carrier definition.

The inverse ledger is the displayed swap of the two coordinates. Its compatibility with the classifier is read through the same cross-addition pattern: the comparison for a pair and its swapped companion is expressed by the Add continuation ledger, not by a primitive subtraction operation.

The structural rows then transport and replay this swap inside the local packet. Since the chapter has no row for a full ordered ring, the theorem records only the inverse ledger surface needed by downstream rational and dyadic consumers. □

Theorem 31.40 (Int Rat and Dyadic source handoff)**.** *Every* $\mathsf{Rat}^{\uparrow}$ *numerator read and every* $\mathsf{DyadicRatCore}^{\uparrow}$ *mantissa read that consumes* $\mathsf{Int}^{\uparrow}$ *data first receives the signed-pair carrier of Definition 31.37, the Nat magnitude rows, the Add balance ledger, and the inverse ledger of Definition 31.39. The handoff supplies signed mantissa data only as a finite* $\mathsf{Int}^{\uparrow}$ *row before* $\mathsf{Rat}^{\uparrow}$ *denominator normalization,* $\mathsf{DyadicRatCore}^{\uparrow}$ *routing,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, or the terminal* $\mathsf{Real}^{\uparrow}$ *seal can be inspected.*

Proof. Read the rational boundary first. The $\mathsf{Rat}^{\uparrow}$ carrier consumes an integer numerator row, and the Int chapter exposes that numerator as the signed-pair carrier rather than as a host integer quotient.

Next use the dyadic mantissa route of Definition 31.78. It places the same signed row before the $\mathsf{DyadicRatCore}^{\uparrow}$ mantissa and denominator packet, so dyadic consumers inherit the Nat magnitude and Add balance data already displayed by $\mathsf{Int}^{\uparrow}$.

Finally pass to the L10 route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Those consumers can inspect only the finite signed mantissa handoff and its structural ledger; they receive no primitive subtraction row, full ordered-ring closure, quotient rational equality, selected real limit, or ambient completeness witness. □

31.3 The certificate

Definition 31.41 (Integer history carrier)**.** *The public BEDC-history carrier for* $\mathsf{Int}^{\uparrow}$ *packages the signed unary representative into the visible history tag:*

$$\mathsf{IntHistoryCarrier}(h) := (\exists m : \mathsf{BHist.\ Unary}(m) \wedge \mathsf{hsame}(h, \mathsf{E0}(m))) \vee (\exists m : \mathsf{BHist.\ Unary}(m) \wedge \mathsf{hsame}(h, \mathsf{E1}(m))).$$

The $\mathsf{E0}$ *branch and the* $\mathsf{E1}$ *branch encode the two signed unary presentations as actual BEDC histories.*

Lean4 (definition) `BEDC.Derived.IntUp.IntHistoryCarrier`

The visible signed branch is consumed by chapter 37 as the signed numerator and denominator context, and later by the dyadic-rational carrier through the same $\mathsf{Int}^{\uparrow}$ signed-row surface.

Theorem 31.42 (Integer history carrier signed branch determinacy)**.** *For every history* $h : \mathsf{BHist}$*, if* $\mathsf{IntHistoryCarrier}(h)$*, then exactly one visible signed carrier branch supplies the witness:*

$$\Big(\exists m : \mathsf{BHist.\ Unary}(m) \wedge \mathsf{hsame}(h, \mathsf{E0}(m)) \wedge \forall p : \mathsf{BHist.\ Unary}(p) \to \mathsf{hsame}(h, \mathsf{E1}(p)) \to \mathsf{False}\Big)$$
$$\vee$$
$$\Big(\exists m : \mathsf{BHist.\ Unary}(m) \wedge \mathsf{hsame}(h, \mathsf{E1}(m)) \wedge \forall p : \mathsf{BHist.\ Unary}(p) \to \mathsf{hsame}(h, \mathsf{E0}(p)) \to \mathsf{False}\Big).$$

The ten-field fit is: traditional target signed-integer carrier readback; BEDC source BHist*,* hsame*,* E0*, and* E1*; carrier* IntHistoryCarrier*; classifier not needed; stability from constructor inversion and* hsame *laws; ledger visible sign tag plus unary payload; core theorem this carrier branch determinacy block; exactness exclusive branch determinacy; standard bridge ordinary signed unary integer tag readback; status* ProofTarget*.*

Proof. Split the defining disjunction of $\mathsf{IntHistoryCarrier}(h)$.

In the zero-tag branch, keep the unary payload m and the endpoint witness $\mathsf{hsame}(h, \mathsf{E0}(m))$. If a one-tag carrier witness for the same h were also available, its endpoint witness $\mathsf{hsame}(h, \mathsf{E1}(p))$ would compose with $\mathsf{hsame}(h, \mathsf{E0}(m))$, using symmetry on one side, to produce $\mathsf{hsame}(\mathsf{E0}(m), \mathsf{E1}(p))$. BEDC history constructor no-confusion rules out that mixed visible-tag equality.

In the one-tag branch, keep the unary payload and endpoint witness in the same way. A hypothetical zero-tag witness composes into $\mathsf{hsame}(\mathsf{E1}(m), \mathsf{E0}(p))$, again contradicting constructor no-confusion. Thus the carrier witness determines the visible signed branch before any classifier evidence is used. □

Lean4 ✓ `BEDC.Derived.IntUp.IntHistoryCarrier signed branch determinacy`

Definition 31.43 (Integer history classifier)**.** *The public classifier relates exactly same-tag signed unary histories:*

$$\mathsf{IntHistoryClassifier}(h, k) := (\exists m, n : \mathsf{BHist}.\ \mathsf{Unary}(m) \wedge \mathsf{Unary}(n) \wedge \mathsf{hsame}(h, \mathsf{E0}(m)) \wedge \mathsf{hsame}(k, \mathsf{E0}(n)) \wedge \mathsf{hsame}(m, n)) \vee$$

Lean4 (definition) `BEDC.Derived.IntUp.IntHistoryClassifier`

Theorem 31.44 (Integer history classifier carrier endpoints)**.** *For all histories $h, k : \mathsf{BHist}$, classifier evidence exposes both endpoints as public signed-history carriers:*

$$\forall h, k : \mathsf{BHist}, \quad \mathsf{IntHistoryClassifier}(h, k) \to \mathsf{IntHistoryCarrier}(h) \wedge \mathsf{IntHistoryCarrier}(k).$$

The ten-field fit is: traditional target domain coverage for signed-unary integer equality; BEDC source IntHistoryCarrier*,* IntHistoryClassifier*,* BHist*,* hsame*,* E0*, and* E1*; carrier the public signed-history carrier; classifier the two-branch public classifier; stability extraction of admitted endpoints from classifier evidence; ledger visible sign tag plus unary payload; core theorem this carrier-endpoint block; exactness classifier domain coverage; standard bridge equality only relates admitted signed representatives; status* ProofTarget*.*

Proof. Split the classifier witness into its two visible signed branches.

In the zero branch, expose payloads $m, n : \mathsf{BHist}$, the unary witnesses for m and n, and the endpoint witnesses $\mathsf{hsame}(h, \mathsf{E0}(m))$ and $\mathsf{hsame}(k, \mathsf{E0}(n))$. The carrier witness for h is the zero-tag IntHistoryCarrier branch with payload m, its unary witness, and the displayed endpoint witness. The carrier witness for k is packed in the same way using payload n.

In the one branch, expose the corresponding payloads, unary witnesses, and endpoint witnesses $\mathsf{hsame}(h, \mathsf{E1}(m))$ and $\mathsf{hsame}(k, \mathsf{E1}(n))$. Packing the one-tag carrier branch for h and for k gives the two conjuncts required by the statement. □

Theorem 31.45 (Integer history classifier mixed visible-tag exclusion)**.** *For all $m, n : \mathsf{BHist}$, the public integer-history classifier excludes opposite visible sign tags without requiring the displayed payloads themselves to be externally unary:*

$$\forall m, n : \mathsf{BHist}, \quad (\mathsf{IntHistoryClassifier}(\mathsf{E0}(m), \mathsf{E1}(n)) \to \mathsf{False}) \wedge (\mathsf{IntHistoryClassifier}(\mathsf{E1}(m), \mathsf{E0}(n)) \to \mathsf{False}).$$

The ten-field fit is: traditional target signed-integer mixed-tag separation; BEDC source BHist*,* hsame*,* E0*,* E1*, and* IntHistoryClassifier*; carrier* IntHistoryCarrier*; classifier the public two-branch classifier; stability from constructor no-confusion and* hsame *composition; ledger visible sign tag plus hidden unary payload; core theorem this mixed visible-tag exclusion block; exactness mixed-tag exclusion; standard bridge ordinary signed-unary sign disjointness; status* ProofTarget*.*

Proof. Fix $m, n : \mathsf{BHist}$.

For the endpoint pair $\mathsf{E0}(m), \mathsf{E1}(n)$, split the defining disjunction of IntHistoryClassifier. In the zero-branch witness, the second endpoint is also exposed as some $\mathsf{E0}(q)$, while the displayed endpoint supplies $\mathsf{hsame}(\mathsf{E1}(n), \mathsf{E0}(q))$ up to symmetry. Composing these endpoint witnesses gives a mixed visible-tag history sameness judgment, contradicting BEDC history constructor no-confusion. In the one-branch witness, the first endpoint is also exposed as some $\mathsf{E1}(p)$, and the same composition gives $\mathsf{hsame}(\mathsf{E0}(m), \mathsf{E1}(p))$, again impossible by constructor no-confusion.

For the endpoint pair $\mathsf{E1}(m), \mathsf{E0}(n)$, use the symmetric case split. A zero-branch witness exposes the first endpoint as $\mathsf{E0}(p)$ and composes into $\mathsf{hsame}(\mathsf{E1}(m), \mathsf{E0}(p))$; a one-branch witness exposes the second endpoint as $\mathsf{E1}(q)$ and composes into $\mathsf{hsame}(\mathsf{E0}(n), \mathsf{E1}(q))$. Both conclusions are mixed visible-tag history sameness judgments, so constructor no-confusion closes the two cases. The unary witnesses hidden inside the classifier branches are used only to recognize the public branch witnesses; no unary hypothesis on the displayed payloads m, n is needed. □

Lean4 ✓ `BEDC.Derived.IntUp.IntHistoryClassifier mixed visible tag exclusion`

Theorem 31.46 (Integer history classifier visible branch exactness)**.** *For any* $m, n : \mathsf{BHist}$ *with* $\mathsf{Unary}(m)$ *and* $\mathsf{Unary}(n)$*, the public integer-history classifier reads back the same visible tag precisely as payload history sameness:*

$$(\mathsf{IntHistoryClassifier}(\mathsf{E0}(m), \mathsf{E0}(n)) \iff \mathsf{hsame}(m, n)) \wedge (\mathsf{IntHistoryClassifier}(\mathsf{E1}(m), \mathsf{E1}(n)) \iff \mathsf{hsame}(m, n)).$$

The ten-field fit is: traditional target signed-integer visible-tag readback; BEDC source BHist*; admissible payloads* Unary*; payload relation* hsame*; public classifier* IntHistoryClassifier*; carrier the public integer history carrier; classifier same-tag payload sameness; stability by constructor inversion and* hsame *laws; ledger visible tag plus unary payload; exactness the two iff clauses; standard bridge ordinary signed-integer tag readback; status* ProofTarget*.*

Proof. For the zero-tag forward direction, split a witness of $\mathsf{IntHistoryClassifier}(\mathsf{E0}(m), \mathsf{E0}(n))$ by the two displayed classifier branches. In the zero branch, constructor inversion on the endpoint witnesses reduces the visible histories to payload histories, and transitivity of hsame composes the two endpoint equalities with the stored payload comparison. In the one branch, the endpoint evidence would identify a zero tag with a one tag, contradicting history no-confusion.

The one-tag forward direction is symmetric. The matching one branch gives the payload comparison by constructor inversion and transitivity of hsame; the zero branch is ruled out by the same zero/one history no-confusion.

For the reverse directions, assume $\mathsf{hsame}(m, n)$ together with the displayed unary witnesses for m and n. The zero-tag classifier witness is obtained by choosing the zero branch, using the two unary witnesses, reflexive endpoint witnesses for $\mathsf{E0}(m)$ and $\mathsf{E0}(n)$, and the given payload relation. The one-tag case is identical with E1 in place of E0. □

Lean4 ✓ `BEDC.Derived.IntUp.IntHistoryClassifier visible branch exactness iff`

Theorem 31.47 (Integer history classifier signed branch determinacy)**.** *For all histories* h, k : BHist*, if* $\mathsf{IntHistoryClassifier}(h, k)$*, then exactly one visible signed branch supplies the classifier witnesses:*

$$\Big(\exists m, n : \mathsf{BHist}.\ \mathsf{Unary}(m) \wedge \mathsf{Unary}(n) \wedge \mathsf{hsame}(h, \mathsf{E0}(m)) \wedge \mathsf{hsame}(k, \mathsf{E0}(n)) \wedge \mathsf{hsame}(m, n)$$
$$\wedge\ \forall p, q : \mathsf{BHist}.\ \mathsf{Unary}(p) \to \mathsf{Unary}(q) \to \mathsf{hsame}(h, \mathsf{E1}(p)) \to \mathsf{hsame}(k, \mathsf{E1}(q)) \to \mathsf{hsame}(p, q) \to \mathsf{False}\Big)$$
$$\vee$$
$$\Big(\exists m, n : \mathsf{BHist}.\ \mathsf{Unary}(m) \wedge \mathsf{Unary}(n) \wedge \mathsf{hsame}(h, \mathsf{E1}(m)) \wedge \mathsf{hsame}(k, \mathsf{E1}(n)) \wedge \mathsf{hsame}(m, n)$$
$$\wedge\ \forall p, q : \mathsf{BHist}.\ \mathsf{Unary}(p) \to \mathsf{Unary}(q) \to \mathsf{hsame}(h, \mathsf{E0}(p)) \to \mathsf{hsame}(k, \mathsf{E0}(q)) \to \mathsf{hsame}(p, q) \to \mathsf{False}\Big).$$

The ten-field fit is: traditional target signed integer branch readback; BEDC source BHist*,* hsame*,* E0*,* E1*, and* IntHistoryClassifier*; carrier* IntHistoryCarrier*; classifier* IntHistoryClassifier*; stability inherited from Definition 31.48; ledger the visible sign tag and unary payload; core theorem this signed branch determinacy block; exactness signed branch determinacy; standard bridge ordinary signed-integer sign readback; status* ProofTarget*.*

Proof. Split the defining disjunction of $\mathsf{IntHistoryClassifier}(h, k)$.

In the zero-tag case, keep the exposed unary payloads m, n, the two visible endpoint witnesses $h\mathsf{hsameE0}(m)$ and $k\mathsf{hsameE0}(n)$, and the payload comparison $m\mathsf{hsame}n$. To rule out a one-tag witness for the same endpoints, compose $h\mathsf{hsameE0}(m)$ with the hypothetical $h\mathsf{hsameE1}(p)$, using symmetry on one side as needed. The result is a visible contradiction $\mathsf{hsame}(\mathsf{E0}(m), \mathsf{E1}(p))$ by BEDC constructor no-confusion.

In the one-tag case, keep the exposed unary payloads and endpoint witnesses in the same way. A hypothetical zero-tag witness for the same endpoints composes the endpoint comparisons into $\mathsf{hsame}(\mathsf{E1}(m), \mathsf{E0}(p))$, again contradicting BEDC constructor no-confusion. Thus the classifier witness determines the visible signed branch and leaves only the payload equality inside that branch. □

Lean4 ✓ `BEDC.Derived.IntUp.IntHistoryClassifier signed branch determinacy`

Theorem 31.48 (Concrete IntUp history semantic certificate)**.** *The integer history carrier and classifier form the public semantic naming certificate for the concrete signed unary history presentation:*

$$\mathsf{SemanticNameCert}(\mathsf{IntHistoryCarrier}, \mathsf{IntHistoryCarrier}, \mathsf{IntHistoryCarrier}, \mathsf{IntHistoryClassifier}).$$

Moreover the classifier excludes mixed visible tags:

$$\forall m, n : \mathsf{BHist}, \quad \mathsf{Unary}(m) \to \mathsf{Unary}(n) \to (\mathsf{IntHistoryClassifier}(\mathsf{E0}(m), \mathsf{E1}(n)) \to \mathsf{False}) \wedge (\mathsf{IntHistoryClassifier}(\mathsf{E1}(m),$$

Proof. For inhabitance, choose the zero-tagged empty magnitude $\mathsf{E0}(\mathsf{e})$. The unary base witness gives $\mathsf{Unary}(\mathsf{e})$, and reflexivity of hsame gives the visible endpoint witness.

For reflexivity, split the carrier witness for h. In the E0 branch, reuse the same magnitude on both endpoints and use reflexivity of hsame for the payload comparison. The E1 branch is identical with the one-tagged constructor.

For symmetry, unpack the classifier branch. The two endpoint carrier witnesses are kept in the same visible tag, and symmetry of hsame reverses the payload comparison. Transitivity composes

two same-tag classifier witnesses by composing their payload hsame links through the shared middle payload.

For carrier transport, suppose $\mathsf{IntHistoryCarrier}(h)$ and $\mathsf{IntHistoryClassifier}(h, k)$. In a same-tag branch, compose the classifier endpoint witness for k with the stored unary payload witness, then repack the corresponding E0 or E1 carrier branch.

The semantic pattern and ledger fields are the carrier itself, so both soundness obligations are identity implications from a transported carrier witness. Mixed visible tags are impossible because any mixed classifier branch would compose the visible endpoint witnesses into an $\mathsf{hsame}(\mathsf{E0}(m'), \mathsf{E1}(n'))$ or $\mathsf{hsame}(\mathsf{E1}(m'), \mathsf{E0}(n'))$ judgment, contradicting BEDC constructor no-confusion. □

Lean4 ✓ `BEDC.Derived.IntUp.IntHistory semanticNameCert`

Theorem 31.49 (Integer history classifier same-tag readback)**.** *For all m, n : BHist, the public integer history classifier reads back exactly payload equality on each visible signed tag:*

$$\mathsf{IntHistoryClassifier}(\mathsf{E0}(m), \mathsf{E0}(n)) \iff \mathsf{Unary}(m) \wedge \mathsf{Unary}(n) \wedge \mathsf{hsame}(m, n).$$

The one-tag branch has the same payload criterion:

$$\mathsf{IntHistoryClassifier}(\mathsf{E1}(m), \mathsf{E1}(n)) \iff \mathsf{Unary}(m) \wedge \mathsf{Unary}(n) \wedge \mathsf{hsame}(m, n).$$

The ten-field fit is the following. The traditional target is same-sign equality of signed integers. The BEDC source consists of IntHistoryCarrier*,* IntHistoryClassifier*,* hsame*, and constructor no-confusion. The carrier is the same-tag unary-history carrier. The classifier is the displayed two-branch definition. Stability is given by transport along the payload* hsame*. The ledger records the sign tag together with the unary magnitude. The core theorem is this same-tag readback statement. Exactness is the two displayed iff rows. The downstream consumer is the* $\mathsf{Rat}^{\uparrow}$ *integer numerator readback. The status is* ProofTarget*.*

Proof. Unfold IntHistoryClassifier at same-tag endpoints.

For the zero-tag forward direction, keep the matching E0 branch. The endpoint witnesses have the form $\mathsf{hsame}(\mathsf{E0}(m), \mathsf{E0}(m'))$ and $\mathsf{hsame}(\mathsf{E0}(n), \mathsf{E0}(n'))$, so constructor inversion reads back $\mathsf{hsame}(m, m')$ and $\mathsf{hsame}(n, n')$. Transitivity with the stored payload $\mathsf{hsame}(m', n')$ yields $\mathsf{hsame}(m, n)$, and the same branch supplies $\mathsf{Unary}(m)$ and $\mathsf{Unary}(n)$ after the endpoint readback. The opposite E1 branch would force an E0 endpoint to be hsame to an E1 endpoint, contradicting constructor no-confusion.

For the zero-tag reverse direction, assume $\mathsf{Unary}(m) \wedge \mathsf{Unary}(n) \wedge \mathsf{hsame}(m, n)$. Choose the E0 branch with payload witnesses m and n, use reflexivity for the two visible endpoint witnesses, and use the supplied payload $\mathsf{hsame}(m, n)$.

The one-tag forward direction is identical after replacing E0 by E1. The matching branch gives endpoint inversion and payload transport; the mixed branch contradicts E1/E0 no-confusion.

For the one-tag reverse direction, choose the E1 branch with payload witnesses m and n, reflexive visible endpoints, the two unary witnesses, and the supplied payload $\mathsf{hsame}(m, n)$. □

Lean4 ✓ `BEDC.Derived.IntUp.IntHistoryClassifier same tag readback iff`

Theorem 31.50 (Integer canonical difference-pair/history bridge)**.** *For all m, n : BHist, if* $\mathsf{Unary}(m)$ *and* $\mathsf{Unary}(n)$*, then the canonical same-sign difference pairs read back exactly to the corresponding public signed-history classifier branches:*

$$(\mathsf{IntPairClassifier}((m, \mathsf{e}), (n, \mathsf{e})) \iff \mathsf{IntHistoryClassifier}(\mathsf{E0}(m), \mathsf{E0}(n))) \wedge (\mathsf{IntPairClassifier}((\mathsf{e}, m), (\mathsf{e}, n)) \iff \mathsf{IntHisto}$$

The ten-field fit is the following. The traditional target is canonical signed unary integers. The BEDC source consists of IntPairClassifier*,* IntHistoryClassifier*,* BHist*,* hsame*,* append*,* E0*, and* E1*. The carrier is* IntPairCarrier *together with* IntHistoryCarrier*. The classifier is the displayed same-sign bridge. Stability is inherited from the append unit laws and same-tag readback. The ledger records the hidden empty counter and the visible sign tag. The core theorem is this bridge. Exactness is the two iff clauses. The downstream consumer is the* $\mathsf{Rat}^{\uparrow}$ *numerator readback and* $\mathsf{Int}^{\uparrow}$ *closure. The status is* ProofTarget*.*

Proof. Assume $\mathsf{Unary}(m)$ and $\mathsf{Unary}(n)$. For the positive canonical pair, unfold IntPairClassifier at $((m, \mathsf{e}), (n, \mathsf{e}))$. The carrier clauses reduce to the unary witnesses for m, n, and the two empty counters. The classifier payload is $\mathsf{hsame}(\mathsf{append}(m, \mathsf{e}), \mathsf{append}(n, \mathsf{e}))$, and the right append unit laws identify this with $\mathsf{hsame}(m, n)$.

Apply Theorem 31.49 to the E0 branch. Its readback criterion is exactly the same pair of unary witnesses together with $\mathsf{hsame}(m, n)$, so the positive displayed $\iff$ follows.

For the negative canonical pair, unfold IntPairClassifier at $((\mathsf{e}, m), (\mathsf{e}, n))$. The cross-addition payload is $\mathsf{hsame}(\mathsf{append}(\mathsf{e}, n), \mathsf{append}(\mathsf{e}, m))$. The left append unit laws reduce this to $\mathsf{hsame}(n, m)$, and symmetry of hsame changes the orientation to $\mathsf{hsame}(m, n)$.

Apply Theorem 31.49 to the E1 branch. The same unary witnesses and the reoriented payload $\mathsf{hsame}(m, n)$ are precisely its public-history criterion, giving the negative displayed $\iff$. □

Theorem 31.51 (Integer contextual canonical difference-pair/history bridge)**.** *For* $a, m, n : \mathsf{BHist}$ *with* $\mathsf{Unary}(a)$*,* $\mathsf{Unary}(m)$*, and* $\mathsf{Unary}(n)$*, the positive-context canonical difference pair reads back exactly to the zero-tag public signed-history classifier:*

$$\mathsf{IntPairClassifier}((\mathsf{append}(a, m), \mathsf{e}), (\mathsf{append}(a, n), \mathsf{e})) \iff \mathsf{IntHistoryClassifier}(\mathsf{E0}(m), \mathsf{E0}(n)).$$

The negative-context canonical difference pair reads back exactly to the one-tag public signed-history classifier:

$$\mathsf{IntPairClassifier}((\mathsf{e}, \mathsf{append}(m, a)), (\mathsf{e}, \mathsf{append}(n, a))) \iff \mathsf{IntHistoryClassifier}(\mathsf{E1}(m), \mathsf{E1}(n)).$$

The ten-field fit is the following. The traditional target is contextual signed-unary integer readback. The BEDC source consists of IntPairClassifier*,* IntHistoryClassifier*,* Unary*,* append*,* e*,* E0*, and* E1*. The carrier is canonical difference pairs and public signed histories. The classifier is pair cross-addition plus the public same-tag classifier. Stability is one-sided context exactness. The ledger records the hidden common unary context. The core theorem is this bridge. Exactness is the two displayed iff rows. The standard bridge is ordinary cancellation of equal signed unary shifts. The status is* ProofTarget*.*

Lean4 ✓ `BEDC.Derived.IntUp.IntPairClassifier contextual canonical pair history bridge iff`

Proof. For the zero-tag row, apply Theorem 31.35 to the common positive context a with canonical endpoints $((m, \mathsf{e}), (n, \mathsf{e}))$. The hypothesis $\mathsf{Unary}(a)$ supplies the context witness for this exactness step. The positive-counter clause strips or introduces the shared left append context, yielding an equivalence with $\mathsf{IntPairClassifier}((m, \mathsf{e}), (n, \mathsf{e}))$.

Apply Theorem 31.50 to the positive canonical pair. The assumptions $\mathsf{Unary}(m)$ and $\mathsf{Unary}(n)$ supply its endpoint hypotheses, so composition of the two equivalences gives the displayed zero-tag readback.

For the one-tag row, apply Theorem 31.35 to the common negative context a with canonical endpoints $((\mathsf{e}, m), (\mathsf{e}, n))$. The hypothesis $\mathsf{Unary}(a)$ supplies the context witness for this exactness

step. The negative-counter clause strips or introduces the shared right append context, yielding an equivalence with $\mathsf{IntPairClassifier}((\mathsf{e}, m), (\mathsf{e}, n))$.

Apply Theorem 31.50 to the negative canonical pair. The same unary endpoint hypotheses identify this canonical classifier with $\mathsf{IntHistoryClassifier}(\mathsf{E1}(m), \mathsf{E1}(n))$, completing the second displayed equivalence. □

Theorem 31.52 (Integer canonical same-sign pair readback)**.** *For all $m, n : \mathsf{BHist}$, the canonical positive difference-pair classifier reads back exactly to unary payload sameness:*

$$\mathsf{IntPairClassifier}((m, \mathsf{e}), (n, \mathsf{e})) \iff \mathsf{Unary}(m) \wedge \mathsf{Unary}(n) \wedge \mathsf{hsame}(m, n).$$

The canonical negative difference-pair classifier has the same public payload criterion:

$$\mathsf{IntPairClassifier}((\mathsf{e}, m), (\mathsf{e}, n)) \iff \mathsf{Unary}(m) \wedge \mathsf{Unary}(n) \wedge \mathsf{hsame}(m, n).$$

The ten-field fit is the following. The traditional target is canonical positive and negative signed unary integer equality. The BEDC source consists of IntPairClassifier*,* IntPairCarrier*,* append*,* e*, and* hsame*. The carrier is the canonical difference-pair carrier. The classifier is cross-addition sameness. Stability is supplied by the append unit laws and symmetry of* hsame*. The ledger records the hidden empty counter. The core theorem is this direct readback. Exactness is the two displayed iff rows. The downstream consumer is the* $\mathsf{Rat}^{\uparrow}$ *numerator readback. The status is* ProofTarget*.*

Lean4 ✓ `BEDC.Derived.IntUp.IntPairClassifier canonical same sign readback iff`

Proof. Unfold IntPairClassifier at the positive canonical endpoints $((m, \mathsf{e}), (n, \mathsf{e}))$.

For the positive forward direction, the carrier projections give $\mathsf{Unary}(m)$ and $\mathsf{Unary}(n)$, with the two hidden counters carried by e. The classifier payload is

$$\mathsf{hsame}(\mathsf{append}(m, \mathsf{e}), \mathsf{append}(n, \mathsf{e})).$$

The right append unit laws reduce this payload to $\mathsf{hsame}(m, n)$.

For the positive reverse direction, assume $\mathsf{Unary}(m) \wedge \mathsf{Unary}(n) \wedge \mathsf{hsame}(m, n)$. Repack the two canonical carriers from the unary witnesses for m and n together with the empty unary carrier for e. The supplied payload $\mathsf{hsame}(m, n)$ transports through the right append unit laws to the cross-addition payload required by IntPairClassifier.

Unfold IntPairClassifier at the negative canonical endpoints $((\mathsf{e}, m), (\mathsf{e}, n))$.

For the negative forward direction, the carrier projections again give $\mathsf{Unary}(m)$ and $\mathsf{Unary}(n)$. The classifier payload is

$$\mathsf{hsame}(\mathsf{append}(\mathsf{e}, n), \mathsf{append}(\mathsf{e}, m)).$$

The left append unit laws reduce it to $\mathsf{hsame}(n, m)$, and symmetry of hsame orients the conclusion as $\mathsf{hsame}(m, n)$.

For the negative reverse direction, assume $\mathsf{Unary}(m) \wedge \mathsf{Unary}(n) \wedge \mathsf{hsame}(m, n)$. Symmetry first turns the payload into $\mathsf{hsame}(n, m)$, and the left append unit laws transport it to

$$\mathsf{hsame}(\mathsf{append}(\mathsf{e}, n), \mathsf{append}(\mathsf{e}, m)).$$

Together with the two canonical carriers, this is exactly the negative instance of IntPairClassifier. □

Theorem 31.53 (Integer canonical opposite-sign zero collapse)**.** *For all $m, n : \mathsf{BHist}$, if $\mathsf{Unary}(m)$ and $\mathsf{Unary}(n)$, then the opposite-sign canonical difference pair is classified only at zero:*

$$\mathsf{IntPairClassifier}((m, \mathsf{e}), (\mathsf{e}, n)) \iff \mathsf{hsame}(m, \mathsf{e}) \wedge \mathsf{hsame}(n, \mathsf{e}).$$

The ten-field fit is the following. The traditional target is opposite-sign canonical integer equality. The BEDC source consists of IntPairClassifier*,* IntPairCarrier*,* append*,* e*, and* hsame*. The carrier is the unary difference-pair carrier. The classifier is cross-addition sameness. Stability is supplied by append empty inversion and history empty readback. The ledger records the hidden zero counters. The core theorem is this zero-collapse block. Exactness is canonical opposite-sign collapse. The standard bridge is the ordinary fact that $m + n = 0$ for unary naturals forces both summands to be zero. The status is* ProofTarget*.*

Proof. Assume first that m and n are unary. Unfold IntPairClassifier at $((m, \mathsf{e}), (\mathsf{e}, n))$. The carrier clauses come from the unary hypotheses together with the empty-counter carrier facts. The classifier payload is

$$\mathsf{hsame}(\mathsf{append}(m, n), \mathsf{append}(\mathsf{e}, \mathsf{e})).$$

The append unit law reduces the right endpoint to e.

By empty readback for hsame, the payload gives $\mathsf{append}(m, n) = \mathsf{e}$. Apply append empty inversion to obtain $m = \mathsf{e}$ and $n = \mathsf{e}$. These equalities yield $\mathsf{hsame}(m, \mathsf{e}) \wedge \mathsf{hsame}(n, \mathsf{e})$ by reflexivity and transport.

Conversely, assume $\mathsf{hsame}(m, \mathsf{e}) \wedge \mathsf{hsame}(n, \mathsf{e})$ together with the unary hypotheses. Empty readback turns the two displayed readbacks into $m = \mathsf{e}$ and $n = \mathsf{e}$. Since e is unary, both endpoints (m, e) and (e, n) satisfy IntPairCarrier after transport.

It remains to build the cross-addition payload. Transport along the two empty equalities and the append unit laws reduces it to $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$, which is reflexive. Repacking the two carriers and this payload gives $\mathsf{IntPairClassifier}((m, \mathsf{e}), (\mathsf{e}, n))$. □

Theorem 31.54 (Integer zero sign-refined boundary)**.** *The difference-pair zero classifier and the visible history classifier expose different interfaces at zero. The pair-zero class is classified:*

$$\mathsf{IntPairClassifier}((\mathsf{e}, \mathsf{e}), (\mathsf{e}, \mathsf{e})).$$

At the same time, the signed-history classifier rejects the two mixed visible zero displays:

$$(\mathsf{IntHistoryClassifier}(\mathsf{E0}(\mathsf{e}), \mathsf{E1}(\mathsf{e})) \to \mathsf{False}) \wedge (\mathsf{IntHistoryClassifier}(\mathsf{E1}(\mathsf{e}), \mathsf{E0}(\mathsf{e})) \to \mathsf{False}).$$

Consequently, a classifier-reflecting bridge from difference pairs to signed histories must either remain inside one visible branch or choose a canonical zero branch before reflecting the pair-zero class.

Proof. The empty history is unary, so the pair (e, e) satisfies $\mathsf{IntPairCarrier}(\mathsf{e}, \mathsf{e})$. Apply the reflexivity component of Definition 31.16 to this carrier witness. This gives $\mathsf{IntPairClassifier}((\mathsf{e}, \mathsf{e}), (\mathsf{e}, \mathsf{e}))$.

For the signed-history clauses, instantiate Definition 31.45 with $m = \mathsf{e}$ and $n = \mathsf{e}$. The two conjuncts are exactly the exclusions for $\mathsf{IntHistoryClassifier}(\mathsf{E0}(\mathsf{e}), \mathsf{E1}(\mathsf{e}))$ and $\mathsf{IntHistoryClassifier}(\mathsf{E1}(\mathsf{e}), \mathsf{E0}(\mathsf{e}))$.

These two facts describe distinct public interfaces. The pair quotient records the integer zero class, while the history certificate keeps the visible sign tag in the endpoint shape unless a bridge explicitly selects a same-branch zero representative. □

Theorem 31.55 (Integer balanced contextual opposite-sign zero collapse)**.** *For all* a, b, m, n : BHist*, if* $\mathsf{Unary}(a)$*,* $\mathsf{Unary}(b)$*,* $\mathsf{Unary}(m)$*, and* $\mathsf{Unary}(n)$*, then the balanced contextual opposite-sign pair collapses exactly at the two zero counters:*

$$\mathsf{IntPairClassifier}((\mathsf{append}(a, m), \mathsf{append}(\mathsf{e}, b)), (\mathsf{append}(a, \mathsf{e}), \mathsf{append}(n, b))) \iff \mathsf{hsame}(m, \mathsf{e}) \wedge \mathsf{hsame}(n, \mathsf{e}).$$

The ten-field fit is the following. The traditional target is contextual opposite-sign integer zero collapse. The BEDC source consists of $\mathsf{IntPairClassifier}$*,* Unary*,* append*,* e*, balanced context exactness, and canonical opposite-sign zero collapse. The carrier is carried by unary difference pairs. The classifier is cross-addition sameness. Stability is removal of the shared positive and negative contexts. The ledger records hidden common contexts* a, b *together with zero counters. The core theorem is this balanced contextual zero-collapse block. Exactness is the displayed iff. The standard bridge is ordinary cancellation of equal added contexts before the fact that a unary sum is zero only when both summands are zero. The status is* $\mathsf{ProofTarget}$*.*

Proof. For the forward direction, assume the contextual classifier. Apply Theorem 31.34 with $p = m$, $n = \mathsf{e}$, $q = \mathsf{e}$, and $m = n$. The unary hypotheses for a and b remove the balanced positive and negative contexts and reduce the classifier to

$$\mathsf{IntPairClassifier}((m, \mathsf{e}), (\mathsf{e}, n)).$$

Theorem 31.53, applied with the unary hypotheses for m and n, converts this canonical opposite-sign classifier into $\mathsf{hsame}(m, \mathsf{e}) \wedge \mathsf{hsame}(n, \mathsf{e})$.

For the reverse direction, assume $\mathsf{hsame}(m, \mathsf{e}) \wedge \mathsf{hsame}(n, \mathsf{e})$. The canonical opposite-sign zero-collapse theorem first gives $\mathsf{IntPairClassifier}((m, \mathsf{e}), (\mathsf{e}, n))$ from the unary hypotheses for m and n.

Apply Theorem 31.34 again with $p = m$, $n = \mathsf{e}$, $q = \mathsf{e}$, and $m = n$. Reading this equivalence in the reverse direction, the unary hypotheses for a and b transport the canonical classifier into the displayed balanced contextual classifier. □

Theorem 31.56 (Integer contextual opposite-sign zero collapse)**.** *For all* a, m, n : BHist*, if* $\mathsf{Unary}(a)$*,* $\mathsf{Unary}(m)$*, and* $\mathsf{Unary}(n)$*, then the visible-context opposite-sign canonical pair collapses exactly at the shared zero context and zero payloads:*

$$\mathsf{IntPairClassifier}((\mathsf{append}(a, m), \mathsf{e}), (\mathsf{e}, \mathsf{append}(n, a))) \iff \mathsf{hsame}(a, \mathsf{e}) \wedge \mathsf{hsame}(m, \mathsf{e}) \wedge \mathsf{hsame}(n, \mathsf{e}).$$

The ten-field fit is the following. The traditional target is contextual opposite-sign signed-unary zero detection. The BEDC source consists of $\mathsf{IntPairClassifier}$*,* Unary*,* append*,* e*, and* hsame*. The carrier is unary difference pairs. The classifier is cross-addition sameness. Stability is append-empty inversion. The ledger records the shared context together with the two payloads. The core theorem is this contextual zero-collapse block. Exactness is the displayed iff. The standard bridge is the ordinary fact that* $a + m + n + a = 0$ *for unary summands forces all displayed summands to be zero. The status is* $\mathsf{ProofTarget}$*.*

Proof. Assume first the three unary hypotheses and the displayed classifier. Unary append closure makes $\mathsf{append}(a, m)$ and $\mathsf{append}(n, a)$ unary, so Theorem 31.53 applies to the canonical pair built from these two appended counters.

The forward half of that theorem gives $\mathsf{hsame}(\mathsf{append}(a, m), \mathsf{e})$ and $\mathsf{hsame}(\mathsf{append}(n, a), \mathsf{e})$. Empty readback converts these into two empty append equations, and append-empty inversion yields $a = \mathsf{e}$, $m = \mathsf{e}$, and $n = \mathsf{e}$ after reading the shared context from both equations. Transport along these empty equations gives $\mathsf{hsame}(a, \mathsf{e}) \wedge \mathsf{hsame}(m, \mathsf{e}) \wedge \mathsf{hsame}(n, \mathsf{e})$.

Conversely, assume $\mathsf{hsame}(a, \mathsf{e}) \wedge \mathsf{hsame}(m, \mathsf{e}) \wedge \mathsf{hsame}(n, \mathsf{e})$. Empty readback turns the three readbacks into empty equations for a, m, and n. The append unit laws therefore identify both contextual counters $\mathsf{append}(a, m)$ and $\mathsf{append}(n, a)$ with e.

The reverse half of Theorem 31.53 now applies to these two unary appended counters. Its required empty readbacks are obtained by the preceding transport to e, and the resulting canonical classifier is exactly $\mathsf{IntPairClassifier}((\mathsf{append}(a, m), \mathsf{e}), (\mathsf{e}, \mathsf{append}(n, a)))$. □

Theorem 31.57 (Integer signed-unary standard bridge)**.** *The ordinary signed-unary integer presentation admits a conservative* $\mathsf{StandardBridge}(\mathsf{Int}^{\uparrow}, T_{\mathbb{Z}})$ *to the BEDC public history surface with the following six fields.*

1. *The encode field sends a positive signed-unary magnitude m to* $\mathsf{E0}(m)$ *and a negative signed-unary magnitude m to* $\mathsf{E1}(m)$*.*
2. *The decode field reads the visible tag and unary payload from* $\mathsf{IntHistoryCarrier}$*.*
3. *Carrier reflection is supplied by Definition 31.48.*
4. *Classifier reflection is supplied by Definition 31.49 together with Definition 31.45.*
5. *The theorem-preservation field is supplied by the canonical and contextual difference-pair/history bridge rows Definition 31.50, Definition 31.51, Definition 31.52, Definition 31.53, Definition 31.55, and Definition 31.56.*
6. *The no-host-leak field records that no host equality, quotient, host* Nat*, ordered-ring package, division, or normalization theorem enters the BEDC public surface; all public comparisons remain* $\mathsf{IntHistoryClassifier}$*,* $\mathsf{IntPairClassifier}$*, and* hsame *statements over BEDC histories.*

Lean4 ✓ `BEDC.Derived.IntUp.IntUp StdBridge`

Proof. The encode field is just the public constructor choice for signed unary histories: zero-tag histories carry the positive branch and one-tag histories carry the negative branch. The decode field is the inverse reading of $\mathsf{IntHistoryCarrier}$, whose public witnesses expose exactly a visible tag and a unary payload.

Carrier reflection comes from Definition 31.48. It gives the semantic certificate for the carrier and classifier, so the bridge reads and writes only through the public BEDC history surface.

Classifier reflection is the same-tag readback of Definition 31.49. The mixed visible-tag exclusion of Definition 31.45 rules out the two cross-tag round trips, leaving exactly the signed-unary payload comparison in each visible branch.

The theorem-preservation field is obtained by composing the canonical bridge row, the contextual bridge row, the canonical same-sign readback row, and the opposite-sign zero-collapse rows already proved in this file. These rows cover the canonical same-sign, contextual same-sign, canonical opposite-sign, balanced contextual opposite-sign, and visible-context opposite-sign cases used by the ordinary signed-unary presentation.

No host structure is imported into the public BEDC object during this composition. The ordinary presentation is used only as the reader-facing source of the encode and decode descriptions; the exported carrier, classifier, transport, preservation, and exclusion statements remain the BEDC history and difference-pair statements cited above. □

Theorem 31.58 (Integer history classifier positive append context iff)**.** *For all* $a, m, n : \mathsf{BHist}$*, if* $\mathsf{Unary}(a)$*,* $\mathsf{Unary}(m)$*, and* $\mathsf{Unary}(n)$*, then the public same-sign integer history classifier is invariant*

under adding the same visible unary prefix to both magnitudes:

$$\mathsf{IntHistoryClassifier}(\mathsf{E0}(\mathsf{append}(a,m)),\mathsf{E0}(\mathsf{append}(a,n))) \iff \mathsf{IntHistoryClassifier}(\mathsf{E0}(m),\mathsf{E0}(n)).$$

The one-tag branch satisfies the parallel context law:

$$\mathsf{IntHistoryClassifier}(\mathsf{E1}(\mathsf{append}(a,m)),\mathsf{E1}(\mathsf{append}(a,n))) \iff \mathsf{IntHistoryClassifier}(\mathsf{E1}(m),\mathsf{E1}(n)).$$

The ten-field fit is the following. The traditional target is signed-integer equality under a common unary magnitude context. The BEDC source consists of IntHistoryClassifier*,* Unary*,* append*,* hsame*, and append cancellation. The carrier is the public signed-history carrier. The classifier is the same-tag public classifier. Stability is common unary prefix invariance. The ledger records the common visible unary prefix. The core theorem is this iff statement. Exactness is preservation and reflection of same-tag classifier equality. The standard bridge is ordinary signed unary equality under equal magnitude shifts. The status is* ProofTarget*.*

Proof. Apply Theorem 31.49 to the E0 endpoints. With the unary closure of $\mathsf{append}(a,m)$ and $\mathsf{append}(a,n)$, the left side reads back to $\mathsf{hsame}(\mathsf{append}(a,m),\mathsf{append}(a,n))$ together with the two unary payload witnesses. The right side reads back to $\mathsf{Unary}(m) \wedge \mathsf{Unary}(n) \wedge \mathsf{hsame}(m,n)$.

For the zero-tag reverse direction, use congruence of $\mathsf{append}(a,-)$ on $\mathsf{hsame}(m,n)$ and unary append closure for the two payloads. Repacking by the same-tag readback theorem gives the classifier on $\mathsf{E0}(\mathsf{append}(a,m))$ and $\mathsf{E0}(\mathsf{append}(a,n))$.

For the zero-tag forward direction, read back the left classifier to obtain $\mathsf{hsame}(\mathsf{append}(a,m),\mathsf{append}(a,n))$. Left append cancellation under the common unary prefix a recovers $\mathsf{hsame}(m,n)$, and the original unary assumptions supply the two payload witnesses. Repacking by same-tag readback gives $\mathsf{IntHistoryClassifier}(\mathsf{E0}(m),\mathsf{E0}(n))$.

The one-tag branch repeats the same two moves after replacing E0 by E1. The readback criterion is unchanged on payloads, so append congruence proves the reverse implication, and left append cancellation proves the forward implication before repacking the public classifier. □

Lean4 ✓ `BEDC.Derived.IntUp.IntHistoryClassifier positive append context iff`

Theorem 31.59 (Integer history classifier hsame transport)**.** *For all h,k,h',k' : BHist, the public integer history classifier is stable under replacement of both endpoints by* hsame*-equal representatives:*

$$\mathsf{hsame}(h,h') \to \mathsf{hsame}(k,k') \to \mathsf{IntHistoryClassifier}(h,k) \to \mathsf{IntHistoryClassifier}(h',k').$$

The ten-field fit is the following. The traditional target is signed-integer equality stable under representative replacement. The BEDC source consists of BHist*,* hsame*,* E0*,* E1*, and* IntHistoryClassifier*. The carrier is* IntHistoryCarrier*. The classifier is the two-branch public classifier. The stability endpoint is* hsame *transport. The ledger records the visible sign tag together with the unary payload. The core theorem is this transport statement. Exactness preservation is preservation of the classifier under representative replacement. The standard bridge is replacement of signed-unary representatives. The status is* ProofTarget*.*

Proof. Unfold the classifier witness for $\mathsf{IntHistoryClassifier}(h,k)$ and split its visible signed branch.

In the zero-tag branch, keep the unary payload witnesses m,n, the payload comparison $\mathsf{hsame}(m,n)$, and the stored mixed-tag exclusion. Compose the old endpoint witness $\mathsf{hsame}(h,\mathsf{E0}(m))$ with the symmetry of $\mathsf{hsame}(h,h')$ to obtain $\mathsf{hsame}(h',\mathsf{E0}(m))$. The same composition with $\mathsf{hsame}(k,k')$ gives $\mathsf{hsame}(k',\mathsf{E0}(n))$.

It remains to rebuild the branch exclusion at the transported endpoints. Given a hypothetical one-tag witness from h' and k', compose it back through $\mathsf{hsame}(h, h')$ and $\mathsf{hsame}(k, k')$ to obtain the corresponding one-tag witness from h and k. The stored zero-branch exclusion then rules it out, so the zero-tag classifier branch repacks at h' and k'.

In the one-tag branch, keep the same unary payload data and payload comparison. The supplied endpoint transports compose with the old witnesses to produce $\mathsf{hsame}(h', \mathsf{E1}(m))$ and $\mathsf{hsame}(k', \mathsf{E1}(n))$.

For the transported exclusion, any zero-tag witness at h' and k' composes back to a zero-tag witness at h and k. The stored one-branch exclusion rules it out, and the one-tag classifier branch repacks with the original payload witnesses. □

Theorem 31.60 (IntUp mature signed-unary downstream package)**.** *The carrier* IntHistoryCarrier*, the classifier* IntHistoryClassifier*, the same-tag readback iff, the positive append-context iff,* hsame *transport, the canonical pair/history bridge, the zero-sign refined boundary, and the integer signed-unary standard bridge together form the mature signed-unary* $\mathsf{Int}^{\uparrow}$ *package consumed by* $\mathsf{Rat}^{\uparrow}$ *numerator readback and by later ordered-ring or divisibility consumers. This package imports no host* Nat*, host equality, quotient-normalization primitive, Euclidean division, or full ordered-ring API.*

Proof. The public carrier and classifier are supplied by Definition 31.48. Their same-tag semantic readback is Definition 31.49, and the common positive context law is Definition 31.58.

Representative stability is exactly Definition 31.59. The external pair/history interface is supplied by Definition 31.50, while Definition 31.54 isolates the refined zero-sign boundary used by consumers that inspect signs.

Finally, Definition 31.57 binds these classifier and transport facts to the signed-unary standard bridge. The listed ingredients therefore provide the public $\mathsf{Int}^{\uparrow}$ package used by $\mathsf{Rat}^{\uparrow}$ numerator readback and by later algebraic consumers. None of the cited facts introduces a host Nat equality principle, quotient normalization, Euclidean division, divisibility theory, or a full ordered-ring API. □

Theorem 31.61 (IntUp signed-history RatUp numerator scope)**.** *Every* $\mathsf{Rat}^{\uparrow}$ *numerator readback that consumes an* $\mathsf{Int}^{\uparrow}$ *signed-history row factors through the rational naming certificate of chapter 37. The consumed integer row is still the signed-unary package generated from the* $\mathsf{Nat}^{\uparrow}$ *magnitude surface of chapter 28 and the continuation-compatible additive routing of chapter 29; the rational consumer merely places that displayed signed row beside its positive denominator and ledger rows.*

Consequently the downstream rational read exports no integer quotient primitive, no field equality, and no rational equality row at the $\mathsf{Int}^{\uparrow}$ *boundary. The only exported integer data are the visible sign mark, unary magnitude, zero-sign normalization, append-context transport, and signed-history classifier rows already supplied by the* $\mathsf{Int}^{\uparrow}$ *certificate.*

Proof. Read the signed-history certificate through Definition 31.60. That package exposes the semantic certificate, signed-history classifier rows, append-context and hsame transports, zero-sign boundary, and standard signed-unary bridge.

The rational consumer is then the carrier of chapter 37. It accepts the displayed signed integer row as numerator data and pairs it with the positive denominator and rational ledger rows, so the readback factors through the rational sibling chapter rather than through an ambient quotient construction.

The source rows for the integer side remain the Nat unary magnitude row and the Add continuation route. Since no extra coordinate is introduced at the handoff, the boundary exports neither an integer quotient primitive nor a field-level equality witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{Int}^\uparrow}$**.**

Constructive story: An integer is presented as one sign mark sitting beside one unary magnitude: the mark is b0 or b1, the magnitude is a $\mathsf{Nat}^\uparrow$ spine, and nothing enters the carrier unless both pieces are visible. The classifier first compares signs by mark-equality and magnitudes by history-equality, then folds exactly one ambiguity back together by identifying $(b0, \mathsf{e})$ with $(b1, \mathsf{e})$ so that the two written zeroes name the same integer. With that rule in place, the source is the same signed-unary predicate, the pattern records the sign/magnitude case split, magnitude behavior under append contexts, and the zero-sign collapse, and the ledger transports the visible pair along history-sameness on the magnitude side. The five name-certificate obligations are carried by $(b0, \mathsf{e})$ as the inhabitant, by mark- and history-equality as equivalence relations, and by the zero rule being stable under symmetry and transitivity. A signed pair (s, m) lies in the signature gap of an $\mathsf{Int}^\uparrow$ token p when the source-domain accepts the pair, the signature relation supplies an answer pair with its evidence ledger, and the token-introduction relation names that answer as p; after unfolding, the pair has the sign and magnitude encoded by p, except that either sign may represent zero. The standard bridge reads the same data as a signed unary word and back, which is why $\mathsf{Rat}^\uparrow$ can later consume it for numerator readback and algebraic packages can reuse it without changing the carrier. The chapter registers the construction under the name $\mathsf{Int}^\uparrow$; an integer is a sign mark next to a unary spine, not a quotient of natural-number pairs, and the only imposed equivalence is the explicit zero-sign normalization.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Int}^\uparrow}$, maturePackageClosed)

Scope closed: The mature public surface is the signed-unary downstream package of Definition 31.60: the semantic certificate, classifier readback rows, append-context and hsame transports, pair/history and zero-sign bridges, and the standard signed-unary bridge consumed by $\mathsf{Rat}^\uparrow$ numerator readback and later algebraic consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Int}^\uparrow}$, bridgeChecked)

Lean target: `BEDC.Derived.IntUp.IntHistory\_semanticNameCert`

Bridge status: bridgeChecked

Not claimed: No full traditional integer algebra, ordered-ring API, Euclidean division, divisibility theory, or quotient-normalization primitive is closed here.

Upgrade path: No further upgrade – chapter at top of formal axis.

Lemma 31.62 (IntUp signed rows feed the RatUp denominator certificate)**.** *The* $\mathsf{Rat}^\uparrow$ *carrier of chapter 37 consumes the* $\mathsf{Int}^\uparrow$ *signed-pair normalization before any field-style rational row is licensed. Concretely, a rational representative presents signed numerator data through the* $\mathsf{Int}^\uparrow$ *carrier and then pairs that row with the positive unary denominator witness; the denominator certificate is read in the same finite packet as the signed numerator, not as an independent field quotient.*

Proof. The signed-pair interface supplies the visible sign and unary-magnitude rows for the numerator, together with the local normalization that identifies the two written zeroes. The $\mathsf{Rat}^\uparrow$ carrier then reads those signed rows beside a positive unary denominator row.

Because the rational row is admitted only after both pieces are displayed, the later field-style rational operations inherit a certified signed representative and a certified positive denominator. No unlisted quotient of integer pairs or ambient field equality is introduced by this dependency. □

Theorem 31.63 (Int signed numerator route into Rat)**.** *Every positive-denominator* $\mathsf{Rat}^\uparrow$ *packet that consumes the* $\mathsf{Int}^\uparrow$ *surface reads signed numerator data only through the displayed signed numerator row, the* $\mathsf{Nat}^\uparrow$ *magnitude row, the* $\mathsf{Add}^\uparrow$ *balancing row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The route may then pair that numerator with the positive denominator surface of chapter 37, but it exports no host integer equality, quotient class of integer pairs, primitive subtraction row, or ambient field equality.*

Proof. Start with the integer surface. The $\mathsf{Int}^\uparrow$ carrier presents the sign and magnitude of the numerator as finite signed-pair data, and the magnitude coordinate is read through the unary $\mathsf{Nat}^\uparrow$ rows of chapter 28.

The balancing evidence is routed through chapter 29. Thus a rational consumer sees the numerator only after the signed row and additive balancing row have both appeared in the same finite history packet.

The structural rows preserve that route componentwise. The hsame row transports the signed numerator, magnitude, and balancing coordinates; the Cont row replays the same displayed route; Pkg records the provenance; and the local NameCert row closes the accepted integer surface.

Finally the $\mathsf{Rat}^{\uparrow}$ carrier of chapter 37 pairs that accepted numerator with a positive denominator row. Since neither the integer surface nor the rational pairing row contains host integer equality, quotient classes, primitive subtraction, or ambient field equality, no such data are exported by the dependency. □

Theorem 31.64 (IntUp Rat additive denominator route)**.** *The* $\mathsf{Int}^{\uparrow}$ *signed-pair balancing route consumes the unary magnitude rows of chapter 28 and the continuation-compatible addition rows of chapter 29 before* $\mathsf{Rat}^{\uparrow}$ *reads the signed numerator beside the positive denominator of chapter 37. Thus the rational denominator packet receives an already balanced signed numerator row rather than a fresh integer quotient or a field-level equality witness.*

Proof. Read the $\mathsf{Int}^{\uparrow}$ signed-pair carrier. Its magnitude coordinates are unary rows, so their source is the Nat certificate, and its balancing step is an additive comparison, so its route is through the Add continuation ledger.

Only after those rows are displayed does the rational carrier read numerator data. The $\mathsf{Rat}^{\uparrow}$ packet places the balanced signed numerator beside the positive denominator row in the same finite certificate.

Therefore the denominator route is horizontal through Nat, Add, Int, and Rat packet rows. It does not rebuild integer equality as an ambient quotient and does not import a field-level rational equality before the signed numerator and denominator witnesses are present. □

31.4 Rat Denominator Sibling Bridge

The $\mathsf{Int}^{\uparrow}$ signed-pair route is a substantive sibling dependency for chapter 37. The $\mathsf{Rat}^{\uparrow}$ denominator surface consumes the balanced integer numerator only after the signed-pair route and the additive-denominator route have been displayed, so the rational carrier is not a standalone quotient surface or a field-equality row.

31.5 Rat Denominator Sibling Link

The $\mathsf{Int}^{\uparrow}$ signed-pair rows are the horizontal source for the $\mathsf{Rat}^{\uparrow}$ denominator surface in chapter 37. The signed numerator first passes through Definition 31.62 and the additive denominator route of Definition 31.64; only then does the rational carrier read that balanced integer row beside its positive denominator witness. Thus the denominator and additive-denominator certificates consume an already displayed $\mathsf{Int}^{\uparrow}$ signed-pair route rather than a standalone rational quotient or field-equality row. The precise dependency is that the $\mathsf{Rat}^{\uparrow}$ positive-denominator ledger consumes the $\mathsf{Int}^{\uparrow}$ signed-pair normalization route before it reads the rational denominator carrier in chapter 37.

Theorem 31.65 (Int Rat sibling lattice readback)**.** *Every* $\mathsf{Rat}^{\uparrow}$ *signed-denominator route that consumes* $\mathsf{Int}^{\uparrow}$ *signed-pair data reads the* $\mathsf{Int}^{\uparrow}$ *carrier through the* $\mathsf{Nat}^{\uparrow}$ *rows of chapter 28 and the* $\mathsf{Add}^{\uparrow}$ *rows of chapter 29 before denominator normalization in chapter 37. The rational packet is a downstream consumer of the displayed signed-pair row; it is not a replacement carrier for* $\mathsf{Int}^{\uparrow}$ *and it exports no host integer quotient, primitive subtraction row, or field-level rational equality at the integer boundary.*

Proof. Start with the signed-pair carrier of $\mathsf{Int}^{\uparrow}$. Its sign row is read beside a unary magnitude row, so the magnitude component is already governed by the $\mathsf{Nat}^{\uparrow}$ surface before any rational denominator packet can consume it.

Next read the additive balancing route. The $\mathsf{Add}^{\uparrow}$ rows supply the comparison and balance data used by the signed-pair presentation, so the rational route receives an already balanced integer numerator rather than a new integer construction.

Apply Definition 31.70 and Definition 31.72. They identify the sibling lattice edge from $\mathsf{Nat}^{\uparrow}$ and $\mathsf{Add}^{\uparrow}$ through $\mathsf{Int}^{\uparrow}$ into the $\mathsf{Rat}^{\uparrow}$ denominator surface.

Finally use the denominator-side descriptions of Definition 31.64 and Definition 31.66. The $\mathsf{Rat}^{\uparrow}$ packet reads the displayed signed-pair row beside its positive denominator witness only after those Nat and Add rows are in force, so the route is a downstream readback of $\mathsf{Int}^{\uparrow}$, not a replacement for it. □

Theorem 31.66 (IntUp Rat denominator dependency surface)**.** *The* $\mathsf{Int}^{\uparrow}$ *signed-pair denominator route consumed by* $\mathsf{Rat}^{\uparrow}$ *in chapter 37 factors through the signed-pair carrier before the rational denominator packet is read. A rational consumer first receives the displayed sign and unary-magnitude rows of* $\mathsf{Int}^{\uparrow}$*, then the balancing route that normalizes the signed numerator, and only then pairs that signed row with the positive denominator witness used by* $\mathsf{Rat}^{\uparrow}$*.*

Thus the denominator dependency is a horizontal sibling route from the integer signed-pair surface to the rational carrier, not a hidden rational quotient, host field equality, or denominator row independent of the displayed integer packet.

Proof. Start with the signed-pair interface. The integer packet exposes a sign mark and unary magnitude row, together with the local zero-sign normalization and balancing context.

Apply Definition 31.62 and Definition 31.64. These rows show that the rational carrier reads already displayed integer numerator data before it pairs that data with its positive denominator witness.

The sibling link of section 31.5 identifies chapter 37 as the rational consumer of that route. Since no step introduces an independent quotient or field-equality coordinate, the dependency surface is exactly the signed-pair carrier followed by the RatUp denominator packet. □

Theorem 31.67 (IntUp Rat denominator ledger dependency)**.** *The* $\mathsf{Int}^{\uparrow}$ *signed-pair carrier supplies the numerator and denominator pair surface consumed by the positive-denominator* $\mathsf{Rat}^{\uparrow}$ *ledger of chapter 37. A rational denominator consumer reads the signed-pair interface of Definition 31.9 before it can pair the numerator surface with a positive unary denominator row; the route exports no host integer quotient, primitive subtraction row, or field-level rational equality.*

Proof. Project through the signed-pair rows of the $\mathsf{Int}^{\uparrow}$ carrier. The positive and negative unary components expose the numerator surface that the rational packet later consumes beside its positive denominator witness.

Transport is componentwise. The hsame rows preserve the signed-pair components, while the displayed Cont replay keeps the numerator/denominator read inside the finite ledger rather than in a host quotient.

Finally, local $\mathsf{NameCert}$ provenance records that the $\mathsf{Rat}^{\uparrow}$ denominator route reads an already displayed $\mathsf{Int}^{\uparrow}$ signed-pair surface. Hence the dependency is a visible ledger edge from $\mathsf{Int}^{\uparrow}$ to $\mathsf{Rat}^{\uparrow}$, not a detached rational carrier. □

Theorem 31.68 (IntUp signed-pair additive lattice dependency)**.** *The* $\mathsf{Int}^{\uparrow}$ *signed-pair presentation is an additive child of the arithmetic lattice. Its balancing rows consume the unary magnitude*

rows of chapter 28 and the continuation-compatible addition rows of chapter 29; the later $\mathsf{Rat}^{\uparrow}$ *denominator presentation of chapter 37 consumes the resulting signed numerator row rather than rebuilding an independent integer quotient.*

Proof. Read the signed-pair carrier from the integer interface. Its magnitude coordinate is unary, so it is supplied by the Nat row, and its balancing step is additive, so it is routed through the Add continuation ledger.

The rational side then reads the same signed-pair surface as numerator data before pairing it with the denominator row. Thus $\mathsf{Rat}^{\uparrow}$ receives an already balanced $\mathsf{Int}^{\uparrow}$ row, with no separate quotient of integer pairs or field-style rational equality introduced at the integer boundary. □

Lemma 31.69 (Int signed-pair Rat dependency lattice)**.** *The* $\mathsf{Int}^{\uparrow}$ *signed-pair rows consumed by* $\mathsf{Rat}^{\uparrow}$ *are already arithmetic rows over* $\mathsf{Nat}^{\uparrow}$ *and* $\mathsf{Add}^{\uparrow}$*. The sign coordinate is paired with a unary magnitude row from chapter 28, the zero-balancing and signed continuation discipline are routed through chapter 29, and the resulting signed numerator surface is the row later read by the denominator and numerator packets of chapter 37.*

Thus an accepted rational numerator read does not rebuild an integer quotient. It consumes the displayed $\mathsf{Int}^{\uparrow}$ signed pair, whose BHist magnitude, additive balancing, hsame transport, Cont replay, Pkg provenance, and local NameCert row have already been exposed. The sibling edge is therefore Nat source row plus Add balancing row into Int signed pair, then Int signed pair into Rat numerator and denominator readback.

Theorem 31.70 (IntUp Nat Add Rat sibling route)**.** *Every signed-pair* $\mathsf{Int}^{\uparrow}$ *carrier route consumed by a later rational embedding first reads the* $\mathsf{Nat}^{\uparrow}$ *unary rows of chapter 28, the* $\mathsf{Add}^{\uparrow}$ *balance rows of chapter 29, and the* $\mathsf{Rat}^{\uparrow}$ *denominator sibling rows of chapter 37. The rational consumer receives the displayed signed-pair carrier, additive balancing route, and denominator packet; it receives no host integer quotient, primitive subtraction operation, or field-level rational equality from the integer boundary.*

Proof. Read the signed-pair carrier from the integer interface. Its magnitude coordinates are unary histories, so the route begins at the Nat certificate surface, and its balance comparison is routed through the Add continuation ledger.

Apply Definition 31.68 and Definition 31.66. They identify the integer row consumed by the rational side as the already displayed signed-pair packet together with its additive balance rows.

Finally use Definition 31.64. The $\mathsf{Rat}^{\uparrow}$ consumer reads that balanced signed row beside the positive denominator witness, so the sibling route is exactly Nat unary data, Add balance data, and Rat denominator data. No step exports a host integer quotient or primitive subtraction row. □

Theorem 31.71 (IntUp Nat Add Rat Dyadic lattice readback)**.** *Every* $\mathsf{DyadicRatCore}^{\uparrow}$ *signed-mantissa consumer of the* $\mathsf{Int}^{\uparrow}$ *surface first factors through chapter 28, chapter 29, chapter 37, and then chapter 291. The consumer receives signed-unary branch data,* $\mathsf{Add}^{\uparrow}$ *balance rows,* $\mathsf{Rat}^{\uparrow}$ *denominator rows, and dyadic tolerance ledgers; it receives no host integer quotient, host rational quotient, selected real limit, or* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Apply Definition 31.70. It identifies the integer surface consumed by rational embedding as a displayed signed-pair carrier whose magnitude rows are read through $\mathsf{Nat}^{\uparrow}$, whose balance rows are read through $\mathsf{Add}^{\uparrow}$, and whose denominator-facing route is read through $\mathsf{Rat}^{\uparrow}$.

Next apply Definition 291.2. The $\mathsf{DyadicRatCore}^{\uparrow}$ carrier reads its signed mantissa through the consumed $\mathsf{Rat}^{\uparrow}$ row and its sign and integer provenance through the consumed $\mathsf{Int}^{\uparrow}$ row, while the exponent and denominator ledger stay visible as unary history data.

Finally use Definition 291.80. The L10 dyadic-rational boundary exports exactly the finite dyadic tolerance ledger read by the downstream faces. Since that dependency surface carries no host rational quotient, selected real limit, or $\mathsf{Real}^{\uparrow}$ completeness theorem, and the integer route already excludes host integer quotients, every signed-mantissa consumer factors through the displayed Nat, Add, Rat, and DyadicRatCore rows. □

Proposition 31.72 (Int signed-pair sibling dependency lattice)**.** *The* $\mathsf{Int}^{\uparrow}$ *signed-pair carrier consumes the unary row discipline of* $\mathsf{Nat}^{\uparrow}$ *from chapter 28 and the additive comparison rows of* $\mathsf{Add}^{\uparrow}$ *from chapter 29 before* $\mathsf{Rat}^{\uparrow}$ *denominator routes in chapter 37 can cite the integer surface. Thus the integer packet is a horizontal dependency node: it is not merely a target of rational-denominator readback, but a finite signed-pair ledger whose Nat and Add rows are already in force when Rat consumes it.*

Proposition 31.73 (Int Nat Add Rat dependency surface)**.** *The* $\mathsf{Int}^{\uparrow}$ *signed-pair carrier depends on the unary magnitude rows of* $\mathsf{Nat}^{\uparrow}$ *from chapter 28 and on the additive transport rows of* $\mathsf{Add}^{\uparrow}$ *from chapter 29 before the* $\mathsf{Rat}^{\uparrow}$ *denominator consumer of chapter 37 can use the integer surface. Thus the Rat-facing denominator route reads an already balanced signed-pair ledger rather than treating* $\mathsf{Int}^{\uparrow}$ *as a private rational subcarrier.*

Theorem 31.74 (Int Nat Add Rat sibling lattice route)**.** *Every* $\mathsf{Int}^{\uparrow}$ *signed-pair read consumed by the rational denominator surface is routed through the* $\mathsf{Nat}^{\uparrow}$ *unary rows of chapter 28, the* $\mathsf{Add}^{\uparrow}$ *balance rows of chapter 29, and the* $\mathsf{Rat}^{\uparrow}$ *signed-denominator consumer surface of chapter 37. The route exposes a displayed signed-pair ledger and denominator consumer; it does not introduce a quotient-class primitive, host integer equality, primitive subtraction row, or field-level rational equality at the integer boundary.*

Proof. Begin with the signed-pair interface. The magnitude rows are unary histories supplied by the Nat certificate, while the sign-aware balance row is routed through the Add continuation ledger.

Apply Definition 31.72. It places $\mathsf{Int}^{\uparrow}$ as the horizontal dependency node whose Nat and Add rows are already present before the Rat denominator route cites the integer surface.

Next use Definition 31.70 and Definition 31.64. The rational consumer receives the balanced signed row beside its positive denominator witness, so the downstream surface is the Rat signed-denominator consumer rather than a replacement carrier for Int.

Finally apply Definition 31.66. The dependency stops at the displayed signed-pair row and the denominator packet, leaving no coordinate for a quotient-class primitive or host equality. □

Theorem 31.75 (Int Add Nat sibling route)**.** *Every signed-pair* $\mathsf{Int}^{\uparrow}$ *packet consumes the* $\mathsf{Nat}^{\uparrow}$ *unary rows of chapter 28 and the* $\mathsf{Add}^{\uparrow}$ *balance rows of chapter 29 before the* $\mathsf{Rat}^{\uparrow}$ *denominator routes of chapter 37 can read it. Thus a rational denominator consumer receives an already displayed signed-pair row with Nat magnitude data and Add balance data, not a host integer quotient, primitive subtraction row, or field-level rational equality at the integer boundary.*

Proof. Start with the signed-pair surfaces of the Int chapter. The signed-pair interface and the signed-pair additive lattice dependency expose the sign row, unary magnitude row, and balance context before any Rat-facing denominator read is available.

Apply Definition 31.68 and Definition 31.74. These rows cite the Nat and Add sibling chapters and place the $\mathsf{Int}^{\uparrow}$ carrier between their unary and balance data and the later Rat denominator consumer.

Finally use Definition 31.64 and Definition 31.66. The Rat route reads the balanced signed row beside a positive denominator only after the Nat and Add rows have already been consumed, so the downstream read remains a sibling route through the displayed Int packet. □

Theorem 31.76 (Int sibling lattice pointer)**.** *Every Real-and-Completion consumer of the* $\mathsf{Int}^{\uparrow}$ *signed-pair surface, including the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mantissa route of chapter 291 and the* $\mathsf{Rat}^{\uparrow}$ *denominator routes of chapter 37, reads* $\mathsf{Int}^{\uparrow}$ *only through the displayed* $\mathsf{Nat}^{\uparrow}$ *unary magnitude rows of chapter 28, the* $\mathsf{Add}^{\uparrow}$ *continuation-compatible balancing rows of chapter 29, the* $\mathsf{Rat}^{\uparrow}$ *signed-denominator consumer rows, and the local* $\mathsf{Int}^{\uparrow}$ $\mathsf{NameCert}$ *rows. This lattice admits no host integer equality, quotient representative, primitive subtraction, field-level rational equality at the* $\mathsf{Int}^{\uparrow}$ *boundary, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness operation.*

Proof. Start with the local signed-pair surface. The sibling lattice of Definition 31.72 places every $\mathsf{Int}^{\uparrow}$ magnitude coordinate under the unary rows of chapter 28 and every balancing comparison under the continuation-compatible additive rows of chapter 29. Thus the integer packet reaches its signed-pair form through displayed Nat and Add data, not through a host integer primitive.

Next read the rational consumer boundary. The signed-denominator dependency Definition 31.62 and the additive denominator route Definition 31.64 force a $\mathsf{Rat}^{\uparrow}$ consumer to take the balanced signed numerator beside the positive denominator row of chapter 37. Hence the Rat-facing route can consume the local $\mathsf{Int}^{\uparrow}$ $\mathsf{NameCert}$ rows only after the Nat and Add rows have already been displayed.

Finally pass to the dyadic and completion-facing consumers. The $\mathsf{DyadicRatCore}^{\uparrow}$ chapter chapter 291 names the $\mathsf{Int}^{\uparrow}$ and $\mathsf{Rat}^{\uparrow}$ source certificates in its mantissa and denominator ledger, so a Real-and-Completion reader reaches the integer source only through that same finite route. None of the listed downstream consumers has a coordinate for host integer equality, quotient representatives, primitive subtraction, field-level rational equality at the $\mathsf{Int}^{\uparrow}$ boundary, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so those objects cannot be imported by this sibling lattice pointer. □

Theorem 31.77 (IntUp signed-pair sibling lattice repair)**.** *The* $\mathsf{Int}^{\uparrow}$ *signed-pair carrier is a sibling-lattice node between unary natural arithmetic and rational denominator arithmetic. It consumes the unary source rows of chapter 28 and the balancing rows of chapter 29; it supplies signed numerator, denominator-normalization, and sign-readback rows later read by chapter 37 and chapter 291. Thus the signed-pair construction is not a kernel-only hub: its public route is the finite dependency lattice*

$$\mathsf{Nat}^{\uparrow}, \mathsf{Add}^{\uparrow} \longrightarrow \mathsf{Int}^{\uparrow} \longrightarrow \mathsf{Rat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}$$

through displayed BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

Proof. Read the left side of the route first. The signed-pair carrier uses unary magnitude rows licensed by chapter 28, and it uses balancing data from chapter 29 to identify opposite signed presentations without importing quotient equality.

Now read the right side. The rational packet of chapter 37 consumes the signed numerator and positive denominator discipline, while chapter 291 consumes the dyadic denominator and sign-readback rows used by finite dyadic arithmetic.

The local BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows preserve this route as public data. Therefore $\mathsf{Int}^{\uparrow}$ is a lattice handoff between Nat/Add input rows and Rat/DyadicRatCore consumer rows, not an isolated integer naming site. □

Theorem 31.78 (IntUp dyadic mantissa real route)**.** *Every Real-and-Completion read of an* $\mathsf{Int}^{\uparrow}$ *signed-pair coordinate used as a* $\mathsf{DyadicRatCore}^{\uparrow}$ *mantissa first factors through chapter 28, chapter 29, chapter 37, and chapter 291 before any* $\mathsf{Real}^{\uparrow}$ *seal route is read. The route exports the signed-pair mantissa as a BEDC lattice row, not as host integer equality, quotient representatives, primitive subtraction, or ambient real completeness.*

Proof. Start with the signed-pair additive lattice dependency of Definition 31.68. It makes the integer coordinate a Nat-and-Add balanced signed pair and gives the rational side a signed numerator row rather than an independent integer quotient.

Next route that numerator through the existing rational and dyadic mantissa surfaces. The rational row supplies the denominator-facing arithmetic context, and the $\mathsf{DyadicRatCore}^{\uparrow}$ row is the first place where the signed coordinate is read as a dyadic mantissa for the Real-and-Completion chain.

Only after those four chapter surfaces have been crossed may a $\mathsf{Real}^{\uparrow}$ seal consumer read the route. Since none of the preceding rows exports host integer equality, quotient representatives, primitive subtraction, or ambient completeness, the real-side read inherits only the displayed BEDC lattice surface. □

Theorem 31.79 (IntUp dyadic real mantissa route)**.** *Every L10 consumer that reads an* $\mathsf{Int}^{\uparrow}$ *signed-pair coordinate as a* $\mathsf{DyadicRatCore}^{\uparrow}$ *mantissa for* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *must pass through* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{Add}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$ *denominator normalization,* $\mathsf{DyadicRatCore}^{\uparrow}$ *signed-exponent source determinacy, and the finite BEDC source uniqueness rows. The handoff exports a finite signed dyadic source only; it exports no host integer equality, quotient rational representative, primitive subtraction, selected limit, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 31.78. It forces every Real-and-Completion mantissa read through the $\mathsf{Nat}^{\uparrow}$, $\mathsf{Add}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ chapter surfaces before a downstream seal can inspect it.

Apply Definition 31.80. This places the signed-pair zero boundary before rational denominator normalization and before the dyadic mantissa route, so the written sign convention is already part of the finite source row.

Now use Definition 31.81 together with Definition 31.82, Definition 31.83, and Definition 291.22. These rows bind the signed-pair source, rational denominator normalization, and dyadic signed-exponent determinacy before $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ can consume the coordinate.

The resulting handoff is therefore a finite BEDC source route. Since the route contains no coordinate for host integer equality, quotient rational representatives, primitive subtraction, selected limits, or real completeness, none of those objects is exported to the L10 consumer. □

Theorem 31.80 (IntUp dyadic mantissa zero-sign normalization)**.** *Every Real-and-Completion read that uses an* $\mathsf{Int}^{\uparrow}$ *signed-pair coordinate as the mantissa input of a* $\mathsf{DyadicRatCore}^{\uparrow}$ *packet must first apply the* $\mathsf{Int}^{\uparrow}$ *zero-sign boundary. Thus the two written zero rows determine the same finite signed-mantissa source before* $\mathsf{Rat}^{\uparrow}$ *denominator normalization and* $\mathsf{DyadicRatCore}^{\uparrow}$ *mantissa routing are read. The normalization is a finite source-row condition only; it does not assert host integer equality, quotient rational representatives, primitive subtraction, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the refined zero-sign boundary Definition 31.54. It identifies the two signed-pair zero presentations as the same $\mathsf{Int}^{\uparrow}$ boundary row before the coordinate is exported to any rational or dyadic consumer.

Next apply the route theorem Definition 31.78. It places every such mantissa read behind the $\mathsf{Nat}^{\uparrow}$, $\mathsf{Add}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ surfaces, so the zero-sign boundary is already part of the finite row that enters the dyadic packet.

Finally use source uniqueness Definition 31.81 together with the sibling denominator route Definition 31.82. After the zero rows have collapsed to the same signed-mantissa source, the denominator normalization and dyadic routing cannot split them again. Downstream $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers therefore see only the normalized finite row, with none of the excluded host-level data added. □

Theorem 31.81 (IntUp dyadic mantissa L10 source uniqueness)**.** *Let two L10 Real-and-Completion reads expose an* $\mathsf{Int}^{\uparrow}$ *signed-pair coordinate as the mantissa input of a* $\mathsf{DyadicRatCore}^{\uparrow}$ *packet. Suppose both reads display the same* $\mathsf{Int}^{\uparrow}$ *signed-pair row, the same* $\mathsf{Rat}^{\uparrow}$ *denominator normalization surface, and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *mantissa/denominator packet before the* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumers read it. Then the two reads determine the same finite BEDC source row for that signed mantissa handoff. This uniqueness is a statement about the displayed BEDC packet only; it does not assert host integer equality, quotient rational representatives, primitive subtraction, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the route theorem Definition 31.78. It forces each read through the $\mathsf{Nat}^{\uparrow}$, $\mathsf{Add}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ chapter surfaces before any Real-and-Completion consumer can inspect a seal boundary.

Next use the sibling route Definition 31.82 and the L10 handoff Definition 31.83. These identify the source of the dyadic packet as the displayed $\mathsf{Int}^{\uparrow}$ signed-pair row together with the displayed $\mathsf{Rat}^{\uparrow}$ denominator normalization surface and the dyadic mantissa route.

Finally apply the scoped source boundary Definition 291.22 and signed-exponent source determinacy Definition 291.59. Those rows say that downstream $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers can read only the visible finite dyadic packet. Since the two reads share that packet before the consumers act, they determine the same finite BEDC source row and no excluded host-level datum can split it into two sources. □

Theorem 31.82 (IntUp DyadicRatCore denominator route sibling repair)**.** *The* $\mathsf{Int}^{\uparrow}$ *signed-pair and denominator rows form the sibling input consumed by chapter 291 on the Real-and-Completion route. A* $\mathsf{DyadicRatCore}^{\uparrow}$ *consumer first reads the* $\mathsf{Int}^{\uparrow}$ *signed-pair carrier through the* $\mathsf{Rat}^{\uparrow}$ *denominator normalization surface of chapter 37, then uses the dyadic mantissa support of Definition 31.78 before any* $\mathsf{Real}^{\uparrow}$ *seal boundary is available.*

Proof. Start with the signed-pair denominator route already displayed for $\mathsf{Rat}^{\uparrow}$. The integer carrier supplies a sign row and unary magnitude row, and the rational denominator surface reads that balanced signed row beside its positive denominator witness.

Next use the dyadic mantissa route. It sends the same signed coordinate through the rational and dyadic core surfaces before the Real-and-Completion chain may read a seal boundary.

Thus the $\mathsf{DyadicRatCore}^{\uparrow}$ chapter consumes a sibling input from $\mathsf{Int}^{\uparrow}$ rather than a detached host integer or field equality. The available route is exactly the signed-pair row, the denominator normalization row, and the dyadic mantissa support. □

Theorem 31.83 (IntUp L10 DyadicRatCore denominator handoff)**.** *Every L10 Real-and-Completion read of a* $\mathsf{DyadicRatCore}^{\uparrow}$ *mantissa/denominator packet factors through the displayed* $\mathsf{Int}^{\uparrow}$ *signed-pair row, the* $\mathsf{Rat}^{\uparrow}$ *denominator normalization surface, and the dyadic mantissa route before* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *may consume the packet. The handoff is finite-row data only: it exposes the*

signed-pair row, denominator normalization row, and mantissa route named by Definition 31.82, not host integers, quotient rationals, selected limits, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the sibling route of Definition 31.82. Its source is the displayed $\mathsf{Int}^{\uparrow}$ signed-pair row, and its first consumer is the $\mathsf{Rat}^{\uparrow}$ denominator normalization surface of chapter 37.

Pass next through the dyadic face of chapter 291. The mantissa coordinate is still read as finite signed-pair data, and the denominator coordinate is still the normalized rational denominator row. This is the only input the L10 Real-and-Completion route supplies to the $\mathsf{DyadicRatCore}^{\uparrow}$ packet.

Only after that packet is visible may the downstream consumers read it: $\mathsf{StreamName}^{\uparrow}$ through chapter 126, $\mathsf{RegSeqRat}^{\uparrow}$ through chapter 301, and $\mathsf{Real}^{\uparrow}$ through chapter 38. None of these reads adds a host integer, quotient rational, selected limit, or completeness witness; they consume the same finite handoff row. □

Theorem 31.84 (IntUp FieldExt and Rat denominator sibling route)**.** *Every* $\mathsf{FieldExt}^{\uparrow}$ *base-endpoint read that consumes* $\mathsf{Rat}^{\uparrow}$ *denominator data ultimately depends on the* $\mathsf{Int}^{\uparrow}$ *signed-pair denominator route. The consumer in chapter 161 first reads the rational denominator surface of chapter 37; that surface has already consumed the displayed* $\mathsf{Int}^{\uparrow}$ *sign row, unary magnitude row, balancing route, and positive denominator witness before any field-extension endpoint can be named.*

Proof. Start with a $\mathsf{FieldExt}^{\uparrow}$ base-endpoint read whose rational endpoint data includes a denominator row. The field-extension carrier can read that denominator only through the displayed rational surface, so the first dependency is the $\mathsf{Rat}^{\uparrow}$ NameCert chapter.

The rational surface is not independent of $\mathsf{Int}^{\uparrow}$. Its numerator and denominator normalization rows use the signed-pair route of the integer packet before the positive denominator witness is paired with rational data.

Thus the field-extension endpoint consumes the same finite dependency route: $\mathsf{Int}^{\uparrow}$ signed-pair data, $\mathsf{Rat}^{\uparrow}$ denominator normalization, and then the $\mathsf{FieldExt}^{\uparrow}$ endpoint row. No detached host integer, quotient rational, or ambient field equality is introduced between these sibling chapters. □

Proposition 31.85 (IntUp Nat Add Rat Dyadic dependency spine)**.** *The* $\mathsf{Int}^{\uparrow}$ *signed-pair rows consume the unary arithmetic discipline of chapter 28 and the finite additive comparison rows of chapter 29. Those signed rows then feed the denominator surfaces of chapter 37, and the same denominator and mantissa coordinates are read by the* $\mathsf{DyadicRatCore}^{\uparrow}$ *routes of chapter 291. Thus* $\mathsf{Int}^{\uparrow}$ *is the finite arithmetic spine from NatUp and AddUp into RatUp and DyadicRatCore, not an isolated hub or a host-integer equality principle.*

Theorem 31.86 (IntUp Nat Add Rat Dyadic sibling exhaustion)**.** *Every* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *consumer of* $\mathsf{Int}^{\uparrow}$ *signed numerator data first reads the* $\mathsf{Nat}^{\uparrow}$ *magnitude row and the* $\mathsf{Add}^{\uparrow}$ *balance row. Only after those rows are displayed may the consumer read the* $\mathsf{Rat}^{\uparrow}$ *denominator row or the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mantissa and denominator rows. The route exports finite signed-unary dependency data, not a host integer quotient, primitive subtraction row, host rational quotient, selected real limit, or* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Begin with the rational sibling route. By Definition 31.70, a rational consumer receives the signed-pair carrier only after the $\mathsf{Nat}^{\uparrow}$ unary magnitude rows and the $\mathsf{Add}^{\uparrow}$ balance rows have been read.

The dyadic dependency spine preserves the same order. By Definition 31.85, the signed rows feed the $\mathsf{Rat}^{\uparrow}$ denominator surface and then the $\mathsf{DyadicRatCore}^{\uparrow}$ denominator and mantissa routes; the dyadic rows do not provide an independent source for signed integer data.

Finally apply Definition 31.82. The dyadic consumer reads the $\mathsf{Int}^{\uparrow}$ signed-pair carrier through the rational denominator normalization surface before using the dyadic mantissa support. Hence every Rat or DyadicRatCore consumer factors through Nat magnitude and Add balance rows before denominator or mantissa rows are available. □

Theorem 31.87 (Int signed-pair lattice sibling route)**.** *Every signed-pair read exported by the* $\mathsf{Int}^{\uparrow}$ *hub to downstream* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *consumers factors through the unary magnitude rows of chapter 28 and the balancing row of chapter 29 before any denominator or mantissa data are exposed. Consequently a rational numerator read from chapter 37 and a dyadic mantissa read from chapter 291 receive the same displayed route: first the two* $\mathsf{Nat}^{\uparrow}$ *magnitude rows, then the* $\mathsf{Add}^{\uparrow}$ *balance witness identifying their signed-pair difference, and only then the consumer-specific denominator, scale, or mantissa ledger.*

Proof. Use the $\mathsf{Int}^{\uparrow}$ hub orientation as the boundary condition. It names $\mathsf{Nat}^{\uparrow}$ as the source of unary magnitude data and $\mathsf{Add}^{\uparrow}$ as the balancing surface that makes a signed pair public as integer data.

A $\mathsf{Rat}^{\uparrow}$ consumer cannot inspect a numerator before the signed-pair interface has displayed both magnitudes and the balancing row. Thus its denominator route is downstream of the $\mathsf{Nat}^{\uparrow}, \mathsf{Add}^{\uparrow}$ lattice rather than an alternate source of integer evidence.

The same argument applies to a $\mathsf{DyadicRatCore}^{\uparrow}$ mantissa consumer. The dyadic ledger can read signed mantissa data only after the integer route has opened the two unary magnitudes and the displayed balance witness.

Therefore both downstream consumers share the same finite sibling route through $\mathsf{Nat}^{\uparrow}$ and $\mathsf{Add}^{\uparrow}$. Denominator and mantissa coordinates are exposed only after that route has been fixed. □

The BoolUp two-endpoint mark surface is the finite discriminator consumed by chapter 33, chapter 35, and chapter 34; those siblings own payload packaging while BoolUp owns only the visible branch marks.

Chapter 32

A Concrete Naming Certificate for $\mathsf{Bool}^{\uparrow}$

The boolean interface $\mathsf{Bool}^{\uparrow}$ is licensed by raw mark sameness on the two-element basis: b0 read as false, b1 read as true. It is not a primitive proposition or truth-value type; it is licensed only via the underlying Mark structure together with a classifier specification that distinguishes the two marks under msame.

The nullable and tagged split of chapter 33 consumes this two-endpoint surface: the empty endpoint and the one-step endpoint supply the two visible branch markers that $\mathsf{Option}^{\uparrow}$ later separates from payload evidence.

Conversely, chapter 33 uses those two endpoint rows as the sibling lattice discriminator for nullable payloads, while $\mathsf{Bool}^{\uparrow}$ remains only the two-endpoint mark/history certificate and does not own the payload carrier, payload classifier, or option packaging rows.

chapter 35 and chapter 34 consume the same two-endpoint $\mathsf{Bool}^{\uparrow}$ discriminator as finite branch and product control, while $\mathsf{Sum}^{\uparrow}$ and $\mathsf{Prod}^{\uparrow}$ own their payload carriers, pairing rows, and classifiers.

32.1 Roadmap template status

1. **Traditional target**: the two-point boolean object with false and true.
2. **BEDC source**: the finite mark kernel Mark, with b0 and b1 as the displayed points.
3. **Carrier choice**: the mark-level carrier is Mark itself; the history carrier is BoolHistoryCarrier.
4. **Classifier choice**: the classifier is msame on marks and BoolHistoryClassifier on the two licensed histories.
5. **Stability obligations**: mark transport, history-carrier transport, unary closure, endpoint exclusion, classifier symmetry, and classifier transitivity.
6. **Ledger**: no quotient is used; the hidden data are only the generated history witnesses for the two boolean endpoints.
7. **Core theorem list**: source transport, history-carrier transport, history classifier equivalence, constructor exclusions, Theorem 32.4, Theorem 32.5, endpoint readback determinism, Theorem 32.9, Theorem 32.10, Theorem 32.11, and the history core NameCert.
8. **Exactness predicate**: the mark source has exactly the b0 and b1 branches licensed by msame, while the checked history certificate has exactly the e and E1(e) endpoints licensed by hsame.

9. **Standard bridge**: false and true are read through the two displayed marks $\mathsf{b0}, \mathsf{b1}$ together with their displayed history endpoints $\mathsf{e}, \mathsf{E1}(\mathsf{e})$; endpoint coverage and classifier completeness are functional up to msame.

10. **Status**: Theorem 32.42 is the canonical Phase Finite Data public-object scope

    $$\mathsf{SemanticNameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier})$$

    for $\mathsf{Bool}^{\uparrow}$, with checked public-object status at the $BEDC.Derived.BoolUp$ Lean target bool_history_semantic_ Theorem 32.41 is the generic implication from an arbitrary Bool core certificate, Theorem 32.42 is the closed checked Bool public-object certificate, the generic carrier-self semantic certificate is the paper theorem in Theorem 26.9, and the Lean theorem $BEDC.FKernel.NameCert.NameCert_iff_sema$ records the five core $\mathsf{NameCert}$ fields.

32.2 Carrier definition

Definition 32.1 (Bool carrier)**.** *Use the existing two-constructor mark carrier* Mark *with* $\mathsf{b0}$ *interpreted as false and* $\mathsf{b1}$ *interpreted as true.*

Lean4 (definition) `BEDC.Derived.BoolUp.BoolCarrier`

32.3 The certificate

Definition 32.2 (Bool source specification)**.** *The source specification for* $\mathsf{Bool}^{\uparrow}$ *is the mark-level classifier generated by internal sameness to one of the two finite-kernel marks:*

$$\mathsf{BoolSourceSpec}(v) := \mathsf{msame}(v, \mathsf{b0}) \vee \mathsf{msame}(v, \mathsf{b1}).$$

Lean4 (definition) `BEDC.Derived.BoolUp.BoolSourceSpec`
Lean4 (definition) `BEDC.Derived.BoolUp.BoolHistoryCarrier`

Definition 32.3 (Bool endpoint bridge)**.** *The endpoint map* $\mathsf{BoolEndpoint} : \mathsf{BMark} \to \mathsf{BHist}$ *sends the two traditional boolean points from the BEDC mark source into the displayed history endpoints:*

$$\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}, \qquad \mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e}).$$

The carrier endpoint choice is therefore $\mathsf{BoolHistoryCarrier}$*, and the classifier transport target is* hsame *on the two displayed history endpoints.*

Lean4 (definition) `BEDC.Derived.BoolUp.BoolEndpoint`

Theorem 32.4 (Bool endpoint bridge exactness)**.** *For marks* $v, w : \mathsf{BMark}$*, mark sameness holds exactly when the displayed history endpoints are internally the same:*

$$\mathsf{msame}(v, w) \iff \mathsf{hsame}(\mathsf{BoolEndpoint}(v), \mathsf{BoolEndpoint}(w)).$$

Proof. Proceed by cases on v and w. The matching $\mathsf{b0}/\mathsf{b0}$ and $\mathsf{b1}/\mathsf{b1}$ cases reduce both directions to reflexivity. In the mixed cases, the mark-to-history direction has no msame witness by mark no-confusion, and the history-to-mark direction has no hsame witness by the no-confusion between e and $\mathsf{E1}(\mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolEndpoint bridge exactness`

Theorem 32.5 (Bool history carrier endpoint coverage)**.** *For every history* $h : \mathsf{BHist}$*, the checked boolean history carrier is exactly the image of the endpoint bridge:*

$$\mathsf{BoolHistoryCarrier}(h) \iff \exists v : \mathsf{BMark},\ \mathsf{hsame}(h, \mathsf{BoolEndpoint}(v)).$$

Proof. In the forward direction, split the carrier witness into its empty and one-endpoint branches. In the empty branch choose $v = \mathsf{b0}$ and use the defining endpoint equality $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$; in the one-endpoint branch choose $v = \mathsf{b1}$ and use $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$.

In the reverse direction, case-analyze the displayed mark v. The $\mathsf{b0}$ case rewrites the endpoint witness to an hsame witness against e and gives the empty carrier branch. The $\mathsf{b1}$ case rewrites it to an hsame witness against $\mathsf{E1}(\mathsf{e})$ and gives the one-endpoint carrier branch. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryCarrier endpoint coverage`

Theorem 32.6 (Bool endpoint readback determinism)**.** *For marks* $v, w : \mathsf{BMark}$ *and history* $h : \mathsf{BHist}$*, if* $\mathsf{hsame}(h, \mathsf{BoolEndpoint}(v))$ *and* $\mathsf{hsame}(h, \mathsf{BoolEndpoint}(w))$*, then* $\mathsf{msame}(v, w)$*.*

Proof. Compose symmetry of $\mathsf{hsame}(h, \mathsf{BoolEndpoint}(v))$ with $\mathsf{hsame}(h, \mathsf{BoolEndpoint}(w))$ to obtain $\mathsf{hsame}(\mathsf{BoolEndpoint}(v), \mathsf{BoolEndpoint}(w))$. The reverse direction of Theorem 32.4 converts this displayed endpoint sameness into $\mathsf{msame}(v, w)$. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolEndpoint readback determinism`
↪ variant `BEDC.Derived.BoolUp.BoolEndpoint readback deterministic`

Theorem 32.7 (Bool endpoint readback total uniqueness)**.** *For every history* $h : \mathsf{BHist}$*, if* $\mathsf{BoolHistoryCarrier}(h)$ *holds, then there exists a mark* $v : \mathsf{BMark}$ *such that*

$$\mathsf{hsame}(h, \mathsf{BoolEndpoint}(v)) \quad \textit{and} \quad \mathsf{BoolSourceSpec}(v) \quad \textit{and} \quad \forall w : \mathsf{BMark},\ \mathsf{hsame}(h, \mathsf{BoolEndpoint}(w)) \to \mathsf{msame}(v$$

Proof. Use Theorem 32.5 on the carrier witness for h to obtain a displayed endpoint v and a readback witness $\mathsf{hsame}(h, \mathsf{BoolEndpoint}(v))$. Case analysis on v gives $\mathsf{BoolSourceSpec}(v)$ for both boolean marks. For any other displayed readback w, Theorem 32.6 applied to the two endpoint witnesses gives $\mathsf{msame}(v, w)$. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolEndpoint readback total unique`

Theorem 32.8 (Bool classifier readback total uniqueness)**.** *For every history* $h : \mathsf{BHist}$*, if* $\mathsf{BoolHistoryCarrier}(h)$ *holds, then there exists a mark* $v : \mathsf{BMark}$ *such that*

$$\mathsf{BoolSourceSpec}(v) \quad \wedge \quad \mathsf{BoolHistoryClassifier}(h, \mathsf{BoolEndpoint}(v)) \quad \wedge \quad \forall w : \mathsf{BMark},\ \mathsf{BoolHistoryClassifier}(h, \mathsf{BoolEn}$$

The ten-field fit is: traditional target public boolean readback; BEDC source BHist *with* hsame*; carrier* $\mathsf{BoolHistoryCarrier}$*; classifier* $\mathsf{BoolHistoryClassifier}$*; stability obligations endpoint coverage and classifier determinacy; ledger displayed* $\mathsf{BoolEndpoint}(v)$*; core theorem this total uniqueness statement; exactness classifier-visible existence and uniqueness up to* msame*; standard bridge ordinary booleans through* $\mathsf{b0}, \mathsf{b1}$ *endpoints; status* $\mathsf{ProofTarget}$*.*

Proof. Apply Theorem 32.9 to the carrier witness for h. This gives a mark v with $\mathsf{BoolSourceSpec}(v)$ and $\mathsf{BoolHistoryClassifier}(h, \mathsf{BoolEndpoint}(v))$. For uniqueness, unpack this classifier witness and any displayed classifier readback at $\mathsf{BoolEndpoint}(w)$ to expose endpoint witnesses $\mathsf{hsame}(h, \mathsf{BoolEndpoint}(v))$ and $\mathsf{hsame}(h, \mathsf{BoolEndpoint}(w))$. Theorem 32.6 then gives $\mathsf{msame}(v, w)$. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryClassifier readback total unique`

Theorem 32.9 (Bool endpoint bridge classifier completeness)**.** *The endpoint bridge preserves the checked boolean history classifier in both finite certificate directions. For marks* $v, w : \mathsf{BMark}$*,*

$$\mathsf{BoolHistoryClassifier}(\mathsf{BoolEndpoint}(v), \mathsf{BoolEndpoint}(w)) \iff \mathsf{msame}(v, w).$$

Moreover, for every history $h : \mathsf{BHist}$ *satisfying* $\mathsf{BoolHistoryCarrier}(h)$*, there exists a mark* $v : \mathsf{BMark}$ *such that both* $\mathsf{BoolSourceSpec}(v)$ *and* $\mathsf{BoolHistoryClassifier}(h, \mathsf{BoolEndpoint}(v))$ *hold.*

Proof. For the first clause, unfold the classifier at the two displayed endpoints. The endpoint carrier fields are supplied by the two endpoint cases, so the classifier is equivalent to history sameness between the two endpoint images. The endpoint bridge exactness theorem then identifies this condition with $\mathsf{msame}(v, w)$.

For the second clause, apply carrier endpoint coverage to the carrier witness for h and obtain an endpoint v with $\mathsf{hsame}(h, \mathsf{BoolEndpoint}(v))$. Case analysis on v supplies $\mathsf{BoolSourceSpec}(v)$, since the two mark constructors satisfy the source specification by reflexivity. The same history-sameness witness, together with the carrier witness for h and the endpoint carrier witness, is exactly the data required by the definition of the displayed classifier relation. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryClassifier endpoint bridge exactness`
Lean4 ✓ `BEDC.Derived.BoolUp.BoolEndpoint classifier exactness`

Theorem 32.10 (Bool carrier classifier endpoint exactness)**.** *For every history* $h : \mathsf{BHist}$*,*

$$\mathsf{BoolHistoryCarrier}(h) \iff \exists v : \mathsf{BMark}.\ \mathsf{BoolSourceSpec}(v) \wedge \mathsf{BoolHistoryClassifier}(h, \mathsf{BoolEndpoint}(v)).$$

Proof. The forward direction is the second clause of Theorem 32.9. For the reverse direction, unpack the displayed classifier witness. Its left endpoint carrier field is exactly $\mathsf{BoolHistoryCarrier}(h)$, so the carrier statement follows directly. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryCarrier classifier endpoint exactness`

Theorem 32.11 (Bool history classifier endpoint readback)**.** *For histories* $h, k : \mathsf{BHist}$*, if* $\mathsf{BoolHistoryClassifier}(h, k)$ *holds, then there exist marks* $v, w : \mathsf{BMark}$ *such that*

$$\mathsf{hsame}(h, \mathsf{BoolEndpoint}(v)) \quad \wedge \quad \mathsf{hsame}(k, \mathsf{BoolEndpoint}(w)) \quad \wedge \quad \mathsf{msame}(v, w).$$

Proof. Unpack the classifier witness into the two $\mathsf{BoolHistoryCarrier}$ endpoint witnesses and the stored $\mathsf{hsame}(h, k)$ link. Apply Theorem 32.5 to both carrier witnesses, obtaining marks v and w with endpoint readbacks from h and k. Compose the readback for h, the stored $\mathsf{hsame}(h, k)$ witness, and the readback for k to obtain $\mathsf{hsame}(\mathsf{BoolEndpoint}(v), \mathsf{BoolEndpoint}(w))$. The reverse direction of Theorem 32.4 converts this endpoint sameness into $\mathsf{msame}(v, w)$. □

Theorem 32.12 (Bool history classifier mark-readback exactness)**.** *For histories* $h, k : \mathsf{BHist}$*,* $\mathsf{BoolHistoryClassifier}(h, k)$ *holds if and only if there exist marks* $v, w : \mathsf{BMark}$ *satisfying*

$$\mathsf{hsame}(h, \mathsf{BoolEndpoint}(v)) \wedge \mathsf{hsame}(k, \mathsf{BoolEndpoint}(w)) \wedge \mathsf{msame}(v, w).$$

Proof. The forward direction is exactly Theorem 32.11. For the reverse direction, take displayed marks v, w with the two endpoint readbacks and $\mathsf{msame}(v, w)$. Endpoint carrier coverage gives $\mathsf{BoolHistoryCarrier}(\mathsf{BoolEndpoint}(v))$ and $\mathsf{BoolHistoryCarrier}(\mathsf{BoolEndpoint}(w))$. The forward direction of Theorem 32.4 reads $\mathsf{msame}(v, w)$ as $\mathsf{hsame}(\mathsf{BoolEndpoint}(v), \mathsf{BoolEndpoint}(w))$, hence the displayed endpoints satisfy $\mathsf{BoolHistoryClassifier}$. Finally apply endpoint transport for $\mathsf{BoolHistoryClassifier}$ along the two given hsame readbacks to obtain $\mathsf{BoolHistoryClassifier}(h, k)$. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryClassifier mark readback exactness`

Theorem 32.13 (Bool source-qualified classifier readback exactness)**.** *For histories* h, k : BHist*,* BoolHistoryClassifier(h, k) *holds if and only if there exist marks* v, w : BMark *satisfying*

$$\mathsf{BoolSourceSpec}(v) \wedge \mathsf{BoolSourceSpec}(w) \wedge \mathsf{hsame}(h, \mathsf{BoolEndpoint}(v)) \wedge \mathsf{hsame}(k, \mathsf{BoolEndpoint}(w)) \wedge \mathsf{msame}(v, w).$$

The traditional target is the two-point boolean readback; the BEDC source is BMark *and* BHist*, the carrier is* BoolHistoryCarrier*, the classifier is* BoolHistoryClassifier*, the exactness clause is source-qualified endpoint readback, and the status is* ProofTarget*.*

Proof. For the forward direction, apply Theorem 32.12 to obtain endpoint marks v, w with the two hsame readbacks and msame(v, w). Case analysis on the two displayed marks supplies BoolSourceSpec(v) and BoolSourceSpec(w), since the two constructors are exactly the allowed source marks. For the reverse direction, discard the two BoolSourceSpec witnesses and apply the reverse direction of Theorem 32.12. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryClassifier source qualified readback exactness`

Theorem 32.14 (Bool source respects mark sameness)**.** *If* v *satisfies* BoolSourceSpec *and* msame(v, w)*, then* w *also satisfies* BoolSourceSpec*.*

Proof. The source condition is a disjunction of msame$(v, \mathsf{b0})$ and msame$(v, \mathsf{b1})$. In either case, symmetry gives msame(w, v), and transitivity transports the corresponding constructor witness from v to w. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolSourceSpec respects msame`

Theorem 32.15 (Bool source transport along mark sameness)**.** *If* v *and* w *are internally the same mark, then the boolean source predicate transports from* v *to* w*.*

Lean4 ✓ `BEDC.Derived.BoolUp.BoolSourceSpec msame transport`

Proof. The proof eliminates the msame(v, w) witness, reducing w definitionally to v, and reuses the original source-classifier witness. □

Theorem 32.16 (Bool history carrier transport)**.** *If* h *is internally history-same as* k *and* h *lies in the boolean history carrier, then* k *also lies in the boolean history carrier.*

Proof. The carrier witness is either sameness to e or sameness to E1(e). In both cases, symmetry of the link from h to k followed by transitivity transports the endpoint equality to k. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryCarrier hsame transport`

Theorem 32.17 (Bool history carrier is unary)**.** *Every boolean history carrier witness determines a unary history.*

Proof. The carrier has two endpoint cases. In the empty endpoint case, unary closure of e transports back along history sameness. In the one-endpoint case, unary closure of E1(e) transports back along the corresponding history-sameness witness. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryCarrier unary`

Theorem 32.18 (Bool history carrier excludes zero-extension)**.** *No zero-extension history* $\mathsf{E0}(h)$ *lies in the boolean history carrier.*

Proof. The carrier witness is either sameness to e or sameness to $\mathsf{E1}(\mathsf{e})$. The first case contradicts generated-history separation between $\mathsf{E0}(h)$ and e, and the second contradicts constructor separation between zero- and one-extensions. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryCarrier e0 absurd`

Theorem 32.19 (Bool history one-extension tail)**.** *If* $\mathsf{E1}(h)$ *lies in the boolean history carrier, then* h *is internally the same as* e*.*

Proof. The carrier witness is either sameness to e or sameness to $\mathsf{E1}(\mathsf{e})$. The empty endpoint contradicts generated-history no-confusion for $\mathsf{E1}(h)$. The $\mathsf{E1}(\mathsf{e})$ endpoint reduces by one-constructor inversion to $\mathsf{hsame}(h, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryCarrier e1 tail empty`

Theorem 32.20 (Bool history double one-extension exclusion)**.** *No history of the form* $\mathsf{E1}(\mathsf{E1}(h))$ *lies in the boolean history carrier.*

Proof. A carrier witness for $\mathsf{E1}(\mathsf{E1}(h))$ forces its tail $\mathsf{E1}(h)$ to be internally the same as e. Generated-history separation between $\mathsf{E1}(h)$ and e eliminates that possibility. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryCarrier e1 e1 absurd`

Theorem 32.21 (Bool history one-extension carrier iff)**.** *A one-extension history* $\mathsf{E1}(h)$ *lies in the boolean history carrier exactly when its tail is internally the same as* e*.*

Proof. The forward direction is the tail inversion result above. Conversely, if $\mathsf{hsame}(h, \mathsf{e})$, one-constructor congruence gives $\mathsf{hsame}(\mathsf{E1}(h), \mathsf{E1}(\mathsf{e}))$, which is the nonempty endpoint case of the boolean history carrier. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryCarrier e1 iff tail empty`

Definition 32.22 (Bool pattern specification)**.** *The pattern is exactly the two displayed mark constructors, with no history growth.*

Lean4 (definition) `BEDC.Derived.BoolUp.BoolPatternSpec`

Definition 32.23 (Bool classifier specification)**.** *The classifier is* msame *on marks, with the two constructors distinguished.*

Lean4 (definition) `BEDC.Derived.BoolUp.BoolClassifierSpec`
Lean4 (definition) `BEDC.Derived.BoolUp.BoolHistoryClassifier`
Lean4 ✓ `BEDC.Derived.BoolUp.BoolClassifierSpec constructor separation`

Theorem 32.24 (Bool history classifier excludes zero-growth endpoints)**.** *The boolean history classifier cannot relate a history of the form* $\mathsf{E0}(h)$ *from either endpoint position.*

Proof. Unpack the classifier witness. On the left endpoint, its first carrier field is a boolean history carrier witness for $\mathsf{E0}(h)$; on the right endpoint, its second carrier field is such a witness. The zero-growth carrier exclusion eliminates both cases. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryClassifier e0 endpoint absurd pair`

Theorem 32.25 (Bool history classifier one-tail sameness)**.** *If the boolean history classifier relates* $\mathsf{E1}(h)$ *to* $\mathsf{E1}(k)$*, then the tails* h *and* k *are internally history-same.*

Proof. Unpack the classifier witness to expose its underlying $\mathsf{hsame}(\mathsf{E1}(h), \mathsf{E1}(k))$ field. One-constructor inversion for generated histories then yields $\mathsf{hsame}(h, k)$. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryClassifier e1 tail hsame`

Theorem 32.26 (Bool history classifier one-tail empty equivalence)**.** *The boolean history classifier relates* $\mathsf{E1}(h)$ *to* $\mathsf{E1}(k)$ *exactly when both tails* h *and* k *are internally history-same as* e*.*

Proof. For the forward direction, unpack the classifier into its endpoint carrier witnesses and apply the one-tail carrier inversion at both endpoints. For the reverse direction, the tail witnesses rebuild both endpoint carriers, while their composite $\mathsf{hsame}(h, k)$ link lifts through the $\mathsf{E1}$ constructor. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryClassifier e1 iff tails empty`

Theorem 32.27 (Bool history classifier one-left endpoints)**.** *The boolean history classifier relates* $\mathsf{E1}(h)$ *to* k *exactly when* h *is internally the same as* e *and* k *is internally the same as* $\mathsf{E1}(\mathsf{e})$*.*

Proof. Forward, the left carrier forces the one-extension tail to be empty, and the exposed classifier sameness transports the right endpoint to $\mathsf{E1}(\mathsf{e})$. Reverse, the endpoint sameness witnesses provide both carrier witnesses, and one-extension congruence composed with the right endpoint symmetry gives the classifier link. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryClassifier e1 left iff`

Corollary 32.28 (Bool history classifier one-right endpoints)**.** *The boolean history classifier relates* h *to* $\mathsf{E1}(k)$ *exactly when* h *is internally the same as* $\mathsf{E1}(\mathsf{e})$ *and* k *is internally the same as* e*.*

This is the right-endpoint symmetry corollary of Theorem 32.27 and Theorem 32.33, rather than a separate finite-data certificate target.

Proof. Use classifier symmetry to turn a witness for $\mathsf{BoolHistoryClassifier}(h, \mathsf{E1}(k))$ into a witness for $\mathsf{BoolHistoryClassifier}(\mathsf{E1}(k), h)$, then apply Theorem 32.27. This gives $\mathsf{hsame}(k, \mathsf{e})$ and $\mathsf{hsame}(h, \mathsf{E1}(\mathsf{e}))$. Conversely, the displayed endpoint witnesses satisfy the left-endpoint theorem for $\mathsf{BoolHistoryClassifier}(\mathsf{E1}(k), h)$, and classifier symmetry returns the right-endpoint classifier witness. □

Theorem 32.29 (Bool history classifier cases)**.** *Every boolean history classifier witness relates two histories in the same displayed endpoint class: either both are internally the same as* e*, or both are internally the same as* $\mathsf{E1}(\mathsf{e})$*.*

Proof. Unpack the classifier witness into endpoint carrier data and the internal hsame link. The left endpoint carrier has exactly two cases. In either case, symmetry of the classifier link followed by transitivity transports the left endpoint class to the right endpoint. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryClassifier cases`

Theorem 32.30 (Bool history classifier endpoint exactness)**.** *For BEDC histories* h *and* k*,* $\mathsf{BoolHistoryClassifier}(h, k)$ *holds if and only if either* $\mathsf{hsame}(h, \mathsf{e})$ *and* $\mathsf{hsame}(k, \mathsf{e})$*, or* $\mathsf{hsame}(h, \mathsf{E1}(\mathsf{e}))$ *and* $\mathsf{hsame}(k, \mathsf{E1}(\mathsf{e}))$*.*

Proof. For the forward direction, apply the checked case theorem for BoolHistoryClassifier and read off the displayed endpoint class for both histories. For the reverse direction, the empty-empty branch rebuilds the two boolean-history carrier witnesses from the empty endpoint data and composes the left endpoint link with the symmetric right endpoint link to obtain the classifier $\mathsf{hsame}(h, k)$ witness. The one-one branch similarly rebuilds the two one-endpoint carrier witnesses and composes through $\mathsf{E1}(\mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryClassifier endpoint exactness`

Theorem 32.31 (Bool history classifier constructor separation)**.** *The boolean history classifier cannot relate* e *to* $\mathsf{E1}(\mathsf{e})$*.*

Proof. Eliminating the classifier witness exposes the underlying hsame witness between e and $\mathsf{E1}(\mathsf{e})$. Generated-history constructor no-confusion rules out such a witness. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryClassifier constructor separation`

Theorem 32.32 (Bool history classifier transitivity)**.** *If a boolean history classifier relates h to k, and relates k to r, then it relates h to r.*

Proof. Eliminate the two classifier witnesses. The endpoint carrier witnesses for h and r are retained, while the exposed $\mathsf{hsame}(h, k)$ and $\mathsf{hsame}(k, r)$ links compose by generated-history transitivity. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryClassifier trans`

Theorem 32.33 (Bool history classifier symmetry)**.** *If the boolean history classifier relates h to k, then it relates k to h.*

Proof. Eliminate the classifier witness. The two endpoint carrier witnesses exchange places, and the exposed $\mathsf{hsame}(h, k)$ link reverses by generated-history symmetry. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryClassifier symm`

Theorem 32.34 (Bool history classifier endpoint transport)**.** *If h is internally the same as h' and k is internally the same as k', then the boolean history classifier transports from (h, k) to (h', k').*

Proof. Eliminate the classifier witness into its two endpoint carrier proofs and the exposed $\mathsf{hsame}(h, k)$ link. Transport each endpoint carrier along its corresponding hsame proof, then compose symmetry of the left endpoint with the stored classifier link and the right endpoint transport. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryClassifier hsame transport`

Theorem 32.35 (Bool history classifier empty-left equivalence)**.** *The boolean history classifier relates* e *to k exactly when k is internally the same history as* e*.*

Proof. For the forward direction, eliminate the classifier witness and symmetrize the exposed $\mathsf{hsame}(\mathsf{e}, k)$ link. For the reverse direction, the empty carrier witness supplies the left endpoint, the assumed $\mathsf{hsame}(k, \mathsf{e})$ supplies the right endpoint, and symmetry supplies the classifier link. □

Lean4 ✓ `BEDC.Derived.BoolUp.BoolHistoryClassifier empty left iff`

Corollary 32.36 (Bool history classifier empty-right equivalence)**.** *The boolean history classifier relates h to* e *exactly when h is internally the same history as* e*. This is the empty-endpoint symmetry corollary of Theorem 32.35 and Theorem 32.33, rather than a separate finite-data certificate target.*

Proof. For the forward direction, use classifier symmetry to move the empty endpoint to the left, then apply Theorem 32.35. For the reverse direction, apply Theorem 32.35 to the assumed h-to-e sameness, then use classifier symmetry again. □

Definition 32.37 (Bool stability certificate)**.** *The checked mark-level structural subcertificate for* BoolClassifierSpec *consists of:*

1. *reflexivity of* msame *on* b0 *and* b1
2. *constructor separation: no classifier path identifies* b0 *with* b1
3. *closure under the two mark constructors*

The history-level $\mathsf{Bool}^{\uparrow}$ *stability used by Theorem 32.39 is supplied by Theorem 32.16, Theorem 32.32, Theorem 32.33, Theorem 32.34, and the endpoint exclusion and endpoint case theorems immediately above.*

Definition 32.40 (Bool history semantic fields)**.** *The semantic history ledger used for Theorem 32.41 is the carrier-as-ledger predicate* BoolHistoryCarrier*, not the mark-level* BoolLedgerPolicy*. The history-level semantic fields used by the boolean certificate are all the same carrier predicate. For a BEDC history h,*

$$\mathsf{PatternSpec}(h) \quad \textit{and} \quad \mathsf{LedgerPolicy}(h)$$

are both read as BoolHistoryCarrier(h)*, namely that h is internally the same as one of the two visible boolean endpoints:*

$$\mathsf{hsame}(h, \mathsf{e}) \quad \textit{or} \quad \mathsf{hsame}(h, \mathsf{E1}(\mathsf{e})).$$

Theorem 32.41 (BoolUp paper-side semantic certificate target)**.** *The canonical public-object certificate proposition for* $\mathsf{Bool}^{\uparrow}$ *is the following formal implication: for any core witness*

$$\mathsf{core} : \mathsf{NameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier}),$$

derive

$$\mathsf{SemanticNameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier}).$$

Here source, pattern, and ledger are all fixed to BoolHistoryCarrier*, and the classifier is fixed to* BoolHistoryClassifier*. Equivalently, the three history predicates are*

$$\mathsf{SourceSpec} = \mathsf{PatternSpec} = \mathsf{LedgerPolicy} = \mathsf{BoolHistoryCarrier}.$$

Its SemanticNameCert *record decomposes as follows:* core *is the supplied core witness;* pattern_sound *is the identity implication on* BoolHistoryCarrier*,*

$$\forall h, \mathsf{BoolHistoryCarrier}(h) \Rightarrow \mathsf{BoolHistoryCarrier}(h),$$

and ledger_sound *is the identity implication on* BoolHistoryCarrier*,*

$$\forall h, \mathsf{BoolHistoryCarrier}(h) \Rightarrow \mathsf{BoolHistoryCarrier}(h).$$

The displayed proposition is the paper-side lifting principle from a core $\mathsf{Bool}^{\uparrow}$ *history certificate to the public-object certificate scope. Specializing* core *to Theorem 32.39 gives the closed Bool public-object certificate in Theorem 32.42. The implication is the instance of the generic carrier-self semantic construction in Theorem 26.9; the closed Bool site is checked by* $BEDC.Derived.BoolUp.bool_history_sem$

Proof. Start with an arbitrary core witness core : NameCert(BoolHistoryCarrier, BoolHistoryClassifier). Apply Theorem 26.9 to core. Since source, pattern, and ledger are all BoolHistoryCarrier, the semantic pattern and ledger fields are the identity implication on the Bool history carrier predicate. Taking core to be Theorem 32.39, equivalently the checked Lean theorem $BEDC.Derived.BoolUp.bool_history_name$ yields the Bool instance of the displayed implication. □

Theorem 32.42 (Concrete BoolUp semantic certificate)**.** *The concrete BoolUp public-object semantic certificate holds:*

$$\mathsf{SemanticNameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier}).$$

Proof. Apply Theorem 26.9 to the concrete core certificate in Theorem 32.39. Since source, pattern, and ledger are all BoolHistoryCarrier, the semantic pattern and ledger fields are the identity implications on the Bool history carrier. □

Lean4 ✓ `BEDC.Derived.BoolUp.bool history semantic name certificate`

Definition 32.43 (Bool public endpoint constructors)**.** *The public false constructor is* BoolEndpoint(b0) = e*, and the public true constructor is* BoolEndpoint(b1) = E1(e)*. Public boolean operations are finite endpoint tables whose input and output rows are drawn only from these two constructor rows. No row in this public surface is a host proposition, a decidable predicate, or an eliminator.*

Lean4 (definition) `BEDC.Derived.BoolUp.BoolPublicEndpointConstructors`

Theorem 32.44 (Bool public constructor case readback)**.** *Every public Bool endpoint read is classified by exactly one of the displayed false and true endpoint rows of Definition 32.70. Two public constructor readbacks agree exactly when their underlying marks are related by* msame*.*

Proof. Apply Definition 32.5 to the public read. It supplies a displayed mark v : BMark and a witness that the read history is the endpoint BoolEndpoint(v).

Case analysis on v gives the two public rows BoolEndpoint(b0) = e and BoolEndpoint(b1) = E1(e). Theorem 32.6 gives uniqueness of the readback mark, and Definition 32.4 identifies agreement of endpoint rows with msame of the underlying marks. □

Theorem 32.45 (Bool public surface no-hidden leakage)**.** *A consumer of the public Bool surface can read only the two constructor endpoint rows, endpoint-table operation rows over those constructors, the mark and history classifier rows, and the semantic certificate ledger. It cannot read a host proposition, a decidable predicate, an eliminator, or truth-table completeness.*

Proof. The public constructors are exactly the two endpoint rows in Definition 32.70. The endpoint coverage and constructor case readback statements show that public reads return one of these rows, with agreement controlled by msame and endpoint exactness rather than by host logic.

The semantic certificate in Definition 32.42 records the carrier, classifier, and ledger discipline. Since the displayed public rows contain no host proposition, decidable predicate, eliminator, or truth-table-completeness row, those objects are not available to a surface consumer. □

The endpoint coverage, endpoint bridge classifier completeness, and endpoint readback theorems justify the Bool public-object readback and bridge promised by the roadmap template; they are not internal fields of the SemanticNameCert constructor. Option$^{\uparrow}$consumes this two-row endpoint discipline as its absent/present tag surface in chapter 33.

Corollary 32.46 (Bool$^{\uparrow}$ certificate scope)**.** *Theorem 32.39 cites the checked core history* NameCert *for* BoolHistoryCarrier *and* BoolHistoryClassifier*, namely the BEDC.Derived.BoolUp Lean target* bool_history_name_certificate*. The public-object* SemanticNameCert *scope is checked separately at Theorem 32.42 by the BEDC.Derived.BoolUp Lean target* bool_history_semantic_name_certificate*. Thus the core certificate, the mark-level ledger definition, the generic carrier-as-ledger implication, and the closed semantic certificate occupy separate roles. In each case* Bool$^{\uparrow}$ *is derived from mark and history sameness, and is not primitive.*

Lemma 32.47 (Bool public endpoint forgetful projection boundary)**.** *The public constructor surface of Definition 32.70 admits a BEDC-native forgetful projection. Start with a public constructor readback row and erase the constructor-row name, endpoint-table name, and public-surface annotation while retaining the displayed endpoint history. The retained target data are exactly*

BoolHistoryCarrier, BoolHistoryClassifier, BoolHistoryCarrier *as source, pattern, and ledger*, NameCert(BoolHis

together with the public semantic certificate

SemanticNameCert(BoolHistoryCarrier, BoolHistoryCarrier, BoolHistoryCarrier, BoolHistoryClassifier).

More concretely, each retained public read has a mark v : BMark *and an endpoint witness* hsame(h, BoolEndpoint(v)) *unique up to* msame*. For two retained reads* h, k *with endpoint witnesses through* v, w : BMark*, the projected classifier row* BoolHistoryClassifier(h, k) *holds exactly when* msame(v, w) *holds. The projection retains no constructor-row name, endpoint-table name, host proposition, decidable predicate, eliminator, truth-table-completeness datum, payload carrier, payload classifier, or option-packaging row.*

Proof. The public constructor rows are exactly the two endpoint rows displayed in Definition 32.70. Applying Definition 32.71 to a public read supplies a mark v : BMark and an endpoint witness hsame(h, BoolEndpoint(v)), and Definition 32.6 makes the displayed mark unique up to msame.

The retained carrier coordinate is forced by Definition 32.5: an endpoint witness against BoolEndpoint(v) repacks as BoolHistoryCarrier(h), and every Bool carrier row is covered by such an endpoint witness. Thus erasing the public constructor name leaves a history in the same target carrier rather than a separate codomain carrier.

For the classifier coordinate, take two retained reads h, k with endpoint witnesses through v, w. If $\mathsf{msame}(v, w)$ holds, the reverse direction of Definition 32.12 rebuilds $\mathsf{BoolHistoryClassifier}(h, k)$ from the two endpoint witnesses and the mark comparison. Conversely, if $\mathsf{BoolHistoryClassifier}(h, k)$ holds, Definition 32.12 supplies endpoint witnesses through marks v', w' with $\mathsf{msame}(v', w')$. The readback determinism theorem compares v with v' and w with w', and transitivity of mark sameness gives $\mathsf{msame}(v, w)$. Hence the classifier retained by the projection is exactly the mark-level agreement already visible in the constructor readback.

The certificate coordinates are fixed by Definition 32.40, Definition 32.39, and Definition 32.42. Source, pattern, and ledger are all the same predicate $\mathsf{BoolHistoryCarrier}$, the core name certificate is $\mathsf{NameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier})$, and the public semantic certificate is the displayed carrier-self semantic certificate. Finally, Definition 32.72 excludes host propositions, decidable predicates, eliminators, and truth-table completeness, while the Bool public surface contains no payload carrier, payload classifier, or option-packaging coordinate. Those named rows are therefore erased rather than transported by the forgetful projection. □

Lemma 32.48 (Bool public endpoint constructor classifier alignment boundary)**.** *For histories $h, k : \mathsf{BHist}$, the public Bool endpoint surface aligns its classifier boundary exactly with the two displayed constructor endpoint rows:*

$$\mathsf{BoolHistoryClassifier}(h, k) \iff \exists v, w : \mathsf{BMark},\ e_v, e_w : \mathsf{BHist},\ \mathsf{BoolSourceSpec}(v) \wedge \mathsf{BoolSourceSpec}(w) \wedge ((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge$$

Under this equivalence, the transported public rows are exactly the two endpoint readback rows against the endpoint histories e_v and e_w determined by $\mathsf{BoolEndpoint}(v)$ and $\mathsf{BoolEndpoint}(w)$, together with the mark-comparison row $\mathsf{msame}(v, w)$. The retained certificate rows are the carrier, classifier, and semantic ledger rows named by the Bool semantic certificate. Rows for host propositions, decidable predicates, eliminators, and truth-table completeness are forgotten by the public endpoint classifier boundary.

Proof. The displayed equivalence is Definition 32.13 read through the explicit endpoint-history witnesses supplied by Definition 32.70. Its forward direction says that a classifier comparison between h and k exposes only source-qualified marks v, w, endpoint histories e_v, e_w with the displayed constructor equations, the two endpoint readback rows $\mathsf{hsame}(h, e_v)$ and $\mathsf{hsame}(k, e_w)$, and the mark-comparison row $\mathsf{msame}(v, w)$. Its reverse direction says that precisely those rows rebuild the Bool history classifier comparison, so no further classifier coordinate is being transported.

By Definition 32.70, the public constructors are only $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ and $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$. The case readback theorem Definition 32.71 therefore identifies every public endpoint read with exactly one of those two rows, and Definition 32.6 makes the chosen mark unique up to msame. The endpoint bridge exactness of Definition 32.4 then makes the row comparison a mark comparison rather than a host-logical comparison.

The certificate side contributes no extra public row. The semantic certificate in Definition 32.42 records the Bool carrier, classifier, and ledger discipline over the same history carrier. Finally, Definition 32.72 states that the public surface does not expose a host proposition, decidable predicate, eliminator, or truth-table completeness row. Hence the boundary transports exactly the two constructor readback rows and their msame classifier comparison, retains only the semantic certificate ledger rows, and forgets the non-public rows listed above. □

Lemma 32.49 (Bool public constructor target-source mirror boundary)**.** *For the public Bool constructor surface of Definition 32.70, the target-facing constructor read and the source-facing carrier*

read are the same finite endpoint packet viewed in opposite directions. Concretely, a public target read through either displayed constructor row $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ *or* $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$ *has a source mirror consisting exactly of the same mark* $v : \mathsf{BMark}$*, an endpoint history witness* $e_v : \mathsf{BHist}$ *satisfying* $((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e})))$*, the same readback observation row* $\mathsf{hsame}(h, e_v)$*, the same classifier comparison row* $\mathsf{msame}(v, w)$ *when another constructor read is compared through a mark* $w : \mathsf{BMark}$ *and endpoint history witness* $e_w : \mathsf{BHist}$ *satisfying* $((w = \mathsf{b0} \wedge e_w = \mathsf{e}) \vee (w = \mathsf{b1} \wedge e_w = \mathsf{E1}(\mathsf{e})))$*, and the same semantic certificate rows*

$$\mathsf{BoolHistoryCarrier}, \quad \mathsf{BoolHistoryClassifier}, \quad \mathsf{NameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier}), \quad \mathsf{SemanticNameC}$$

Thus the source side is obtained by renaming the displayed target endpoint packet back to its carrier readback packet. The boundary is negative for any larger mirror: there is no separate source-side constructor carrier, result row, termination row, host proposition row, decidable predicate row, eliminator row, truth-table-completeness row, payload carrier row, payload classifier row, or option-packaging row.

Proof. Start with a public target read. By Definition 32.70, the only target constructor rows are $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ and $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$. The case readback theorem Definition 32.71 therefore supplies a displayed mark $v : \mathsf{BMark}$ and an endpoint history witness $e_v : \mathsf{BHist}$ with $((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e})))$, and identifies the read with the endpoint readback row $\mathsf{hsame}(h, e_v)$. Its agreement clause, together with Definition 32.6 and Definition 32.4, says that any comparison between two such reads is exactly the mark comparison $\mathsf{msame}(v, w)$.

The source mirror is forced by endpoint coverage. The reverse direction of Definition 32.5 repacks the readback row $\mathsf{hsame}(h, e_v)$, for an endpoint witness e_v satisfying $((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e})))$, as the source carrier row $\mathsf{BoolHistoryCarrier}(h)$, while the forward direction says that every source carrier row used by this Bool surface is covered by such an endpoint readback. Hence the target row and source row do not form two independent constructors; they are the same displayed history endpoint read as target endpoint or as source carrier.

For compared reads h, k, Definition 32.12 identifies the source-side classifier row $\mathsf{BoolHistoryClassifier}(h, k)$ with the two endpoint readbacks through marks v, w, endpoint history witnesses $e_v, e_w : \mathsf{BHist}$ satisfying $((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e})))$ and $((w = \mathsf{b0} \wedge e_w = \mathsf{e}) \vee (w = \mathsf{b1} \wedge e_w = \mathsf{E1}(\mathsf{e})))$, and the same comparison row $\mathsf{msame}(v, w)$. The source-qualified form in Definition 32.13 adds only the already displayed source qualification of those two finite marks, so it does not introduce a further target or source coordinate.

The certificate rows are exactly the rows already named by Definition 32.40, Definition 32.39, and Definition 32.42: source, pattern, and ledger are all read as $\mathsf{BoolHistoryCarrier}$, and the classifier is $\mathsf{BoolHistoryClassifier}$. Finally, Definition 32.72, Definition 32.74, and Definition 32.75 rule out the larger mirror coordinates listed in the statement. The target-source mirror therefore closes exactly at the finite endpoint packet and its Bool semantic certificate rows. □

Lemma 32.50 (Bool public endpoint bridge cut-elimination boundary)**.** *The public Bool endpoint constructors of Definition 32.70 admit a bridge cut-elimination boundary over the displayed local rows. For a final consumer read of the public Bool surface, every route row factors through the*

finite packet

$$\begin{gathered}\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}, \quad \mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e}),\\ v, w : \mathsf{BMark}, \quad e_v, e_w : \mathsf{BHist},\\ ((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e}))),\\ ((w = \mathsf{b0} \wedge e_w = \mathsf{e}) \vee (w = \mathsf{b1} \wedge e_w = \mathsf{E1}(\mathsf{e}))),\\ \mathsf{hsame}(h, e_v), \quad \mathsf{hsame}(k, e_w), \quad \mathsf{msame}(v, w),\\ \mathsf{BoolHistoryCarrier}, \quad \mathsf{BoolHistoryClassifier}, \quad \mathsf{NameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier}),\\ \mathsf{SemanticNameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier}).\end{gathered}$$

The two displayed constructor endpoint rows, the endpoint history readback rows, the mark-comparison row, and the carrier, classifier, core certificate, and semantic certificate rows are noneliminable at this boundary: removing any one of them loses either the public endpoint choice, the readback into a history, the classifier comparison, or the certificate surface consumed by the final Bool object. Every other named coordinate appearing in the local public-surface discussion is eliminated or rejected: constructor-row names, endpoint-table names, and public-surface annotations are projected away; host propositions, decidable predicates, eliminators, truth-table-completeness data, payload carriers, payload classifiers, option-packaging rows, separate source-side constructor carriers, result rows, termination rows, and continuation rows are not consumer-visible rows of this Bool endpoint bridge.

Proof. The finite endpoint rows are exactly the two rows displayed in Definition 32.70. Thus any public constructor read begins at either $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ or $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$, and no third constructor, host predicate, or eliminator row is available at the source of the route. Applying Definition 32.71 to the read supplies a mark $v : \mathsf{BMark}$ and an endpoint history witness $e_v : \mathsf{BHist}$ with $((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e})))$ and $\mathsf{hsame}(h, e_v)$; applying it to a second read supplies $w : \mathsf{BMark}$ and an endpoint history witness $e_w : \mathsf{BHist}$ with $((w = \mathsf{b0} \wedge e_w = \mathsf{e}) \vee (w = \mathsf{b1} \wedge e_w = \mathsf{E1}(\mathsf{e})))$ and $\mathsf{hsame}(k, e_w)$. The uniqueness part is controlled by Definition 32.6, so the chosen endpoint mark cannot be replaced by an unlisted host or source coordinate.

The comparison row is also forced. By Definition 32.4, comparison of the two endpoint rows is exactly comparison of their marks by $\mathsf{msame}(v, w)$. Equivalently, Definition 32.12 identifies the history classifier row $\mathsf{BoolHistoryClassifier}(h, k)$ with the two endpoint history readbacks and the same mark-comparison row. Hence a bridge consumer cannot keep an independent comparison route after those readback rows have been exposed; the classifier route has already cut through the endpoint packet.

The carrier and certificate side is fixed by the already displayed projection boundary. By Definition 32.5, the endpoint readback through e_v repacks as the carrier row $\mathsf{BoolHistoryCarrier}(h)$, and every carrier row used here is covered by such an endpoint readback. By Definition 32.74, erasing constructor-row names, endpoint-table names, and public-surface annotations leaves exactly the carrier, classifier, carrier-as-source-pattern-ledger, core $\mathsf{NameCert}$, and public semantic certificate rows. By Definition 32.40, Definition 32.39, and Definition 32.42, these rows are the Bool history carrier, the Bool history classifier, and the carrier-self semantic certificate displayed in the statement.

The remaining possible cuts are negative. Definition 32.72 excludes host propositions, decidable predicates, eliminators, and truth-table completeness from the public consumer surface. Definition 32.75 shows that the classifier boundary transports only the two endpoint readback rows and their msame comparison, while Definition 32.76 shows that target-facing and source-facing reads

are the same finite endpoint packet rather than separate constructor carriers, result rows, termination rows, or continuation rows. Since the local chapter displays no additional host, source, handoff, continuation, payload, or option-packaging coordinate, any such coordinate is rejected as unlisted rather than retained by the bridge.

Consequently the final consumer-visible surface is precisely the finite packet named in the statement. The endpoint rows, readback rows, mark-comparison row, carrier and classifier rows, and the two certificate rows are noneliminable because they are the rows used to reconstruct the endpoint choice, the history read, the classifier comparison, and the public Bool certificate. All other local route names are either projected away by the forgetful boundary or excluded by the public-surface and mirror-boundary theorems. □

Lemma 32.51 (Bool public endpoint equivalence-completion boundary)**.** *The public Bool endpoint constructor surface of Definition 32.70 has a complete equivalence boundary over its displayed local classifier and readback rows. For histories $h, k : \mathsf{BHist}$, the carrier and classifier two-sided part is exactly*

$$\begin{aligned}
\mathsf{BoolHistoryCarrier}(h) &\iff \exists v : \mathsf{BMark},\ \exists e_v : \mathsf{BHist},\ ((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e}))) \wedge \mathsf{hsame}(\\
\mathsf{BoolHistoryClassifier}(h, k) &\iff \exists v, w : \mathsf{BMark},\ \exists e_v, e_w : \mathsf{BHist},\ \mathsf{BoolSourceSpec}(v) \wedge \mathsf{BoolSourceSpec}(w) \wedge ((v =
\end{aligned}$$

For marks $v, w : \mathsf{BMark}$ and endpoint-history witnesses $e_v, e_w : \mathsf{BHist}$ satisfying the displayed constructor equations

$$\begin{aligned}
&((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e}))),\\
&((w = \mathsf{b0} \wedge e_w = \mathsf{e}) \vee (w = \mathsf{b1} \wedge e_w = \mathsf{E1}(\mathsf{e}))),
\end{aligned}$$

the endpoint-agreement part is exactly

$$\mathsf{msame}(v, w) \iff \mathsf{hsame}(e_v, e_w).$$

The endpoint witnesses are precisely the same visible endpoint rows as the public false and true constructor rows: $v = \mathsf{b0}$ carries $e_v = \mathsf{e}$, and $v = \mathsf{b1}$ carries $e_v = \mathsf{E1}(\mathsf{e})$, with the same alternatives for w, e_w. Thus any displayed forward carrier, classifier, endpoint-agreement, or constructor-readback implication in the local chapter has its reverse implication on the same finite rows.

The remaining displayed directions in the local public-surface discussion are one-way interpretation boundaries. Erasing constructor-row names, endpoint-table names, and public-surface annotations maps a public constructor read to the carrier, classifier, core NameCert*, and public semantic certificate rows, but those retained rows do not reconstruct the erased names or annotations. The no-hidden-leakage row is also one-way: it excludes host propositions, decidable predicates, eliminators, truth-table-completeness data, payload carriers, payload classifiers, option-packaging rows, separate source-side constructor carriers, result rows, termination rows, and continuation rows from the public endpoint surface, and no reverse implication is claimed from their absence to any additional public constructor structure.*

Proof. The carrier row is already two-sided by Definition 32.5. Its forward direction reads a Bool carrier history as one of the two endpoint histories, witnessed by some $e_v : \mathsf{BHist}$ satisfying $(v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e}))$; its reverse direction repacks the same endpoint readback witness as $\mathsf{BoolHistoryCarrier}(h)$. Since Definition 32.70 displays only the two constructor histories e and $\mathsf{E1}(\mathsf{e})$, this carrier equivalence has no third public endpoint row.

The classifier row is two-sided by Definition 32.13. The forward implication exposes source-qualified marks v, w, endpoint-history witnesses e_v, e_w with their constructor equations, and the mark comparison $\mathsf{msame}(v, w)$. The reverse implication rebuilds $\mathsf{BoolHistoryClassifier}(h, k)$ from

exactly those rows. The more explicit constructor-row version is Definition 32.75, which identifies the endpoint witnesses through the two displayed constructor histories e and $\mathsf{E1}(\mathsf{e})$.

Endpoint agreement is two-sided by Definition 32.4. The case-readback theorem Definition 32.71 then says that a public constructor read is classified by exactly one of the displayed false and true endpoint rows, represented by an endpoint-history witness e_v with its constructor equation, while Definition 32.6 makes the chosen mark unique up to msame. Hence the visible constructor readback direction is completed by the same endpoint-history witnesses, constructor equations, and mark-comparison rows, not by a host proposition or by an external equivalence carrier.

It remains to identify the directions that are not equivalences. The forgetful projection of Definition 32.74 deliberately erases constructor-row names, endpoint-table names, and public-surface annotations. Its target rows are the retained carrier, classifier, $\mathsf{NameCert}$, and public semantic certificate rows fixed by Definition 32.40, Definition 32.39, and Definition 32.42; those rows remember the endpoint-history witness and classifier comparison, not the erased presentation names. This is therefore a one-way interpretation boundary.

The negative rows are one-way for the same local reason. By Definition 32.72, the public surface exposes no host proposition, decidable predicate, eliminator, or truth-table-completeness row. By Definition 32.76, the target-facing and source-facing reads are the same finite endpoint packet rather than separate constructor carriers, result rows, termination rows, or continuation rows. By Definition 32.77, every final consumer route factors through the finite endpoint packet and the Bool semantic certificate rows, while payload and option-packaging coordinates are rejected as unlisted. Thus the local chapter has no unmatched forward classifier or readback implication: the carrier, classifier, endpoint-agreement, and constructor-readback rows are completed by reverse implications on the same visible rows, and the projection and exclusion rows are recorded as one-way interpretation boundaries. □

Lemma 32.52 (Bool public endpoint substrate bisimulation boundary)**.** *The public Bool endpoint constructors of Definition 32.70 admit a substrate relation boundary, not a definitional-equality boundary. The BEDC-local relation certificate has source rows only from the displayed finite endpoint packet*

$$\begin{gathered}
\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}, \quad \mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e}), \\
v, w : \mathsf{BMark}, \quad e_v, e_w : \mathsf{BHist}, \\
((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e}))), \quad ((w = \mathsf{b0} \wedge e_w = \mathsf{e}) \vee (w = \mathsf{b1} \wedge e_w = \mathsf{E1}(\mathsf{e}))), \\
\mathsf{hsame}(h, e_v), \quad \mathsf{hsame}(k, e_w), \quad \mathsf{msame}(v, w), \\
\mathsf{BoolHistoryCarrier}, \quad \mathsf{BoolHistoryClassifier}, \quad \mathsf{NameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier}), \\
\mathsf{SemanticNameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier}).
\end{gathered}$$

Its forward leg sends a public endpoint read through $\mathsf{hsame}(h, e_v)$ *to the carrier row* $\mathsf{BoolHistoryCarrier}(h)$*. Its reverse leg reads every carrier row used by the Bool public surface back through one of the two displayed endpoint rows. Its comparison leg is the reflected equivalence*

$$\begin{aligned}
\mathsf{BoolHistoryClassifier}(h, k) \quad \Longleftrightarrow \quad \exists v, w : \mathsf{BMark},\ e_v, e_w : \mathsf{BHist},\ & ((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e}))) \wedge \\
& ((w = \mathsf{b0} \wedge e_w = \mathsf{e}) \vee (w = \mathsf{b1} \wedge e_w = \mathsf{E1}(\mathsf{e}))) \wedge \\
& \mathsf{hsame}(h, e_v) \wedge \mathsf{hsame}(k, e_w) \wedge \mathsf{msame}(v, w).
\end{aligned}$$

Thus a BHist*-facing reading of the public Bool endpoint surface is a substrate mirror, and any consumer that names a* $\mathsf{Rule110}$*, cellular, binary, or* $\mathsf{FKernel}$ *substrate must state its use as a*

bisimulation or row-embedding relation whose Bool side is exactly the packet above. No such substrate name is available here as a definitional equality with the Bool public constructors. Any host coordinate, source coordinate, transition coordinate, external substrate row, result row, termination row, continuation row, payload row, option-packaging row, or equality row not listed in the packet is rejected at this boundary rather than silently identified with the Bool public surface.

Proof. The local constructor source is exhausted by Definition 32.70: the only public endpoint rows are $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ and $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$. Applying Definition 32.71 to a public read supplies a displayed mark $v : \mathsf{BMark}$ and an endpoint history witness $e_v : \mathsf{BHist}$ in one of those two cases, together with the readback row $\mathsf{hsame}(h, e_v)$. The determinacy clause of Definition 32.6 prevents replacement of that mark by an unlisted host or substrate coordinate.

The carrier leg is exactly a mirror leg. By Definition 32.5, the endpoint readback row repacks as $\mathsf{BoolHistoryCarrier}(h)$, and every carrier row used by this Bool surface is covered by such an endpoint readback. Hence the relation runs in both directions between the public endpoint packet and the BHist carrier readback packet, but the two sides are not introduced as a single definitional object; they are the same displayed history read viewed through endpoint and carrier roles.

The comparison leg is the bisimulation clause. For two reads h, k with endpoint witnesses through v, w, Definition 32.12 identifies $\mathsf{BoolHistoryClassifier}(h, k)$ with the two endpoint readbacks and the mark comparison $\mathsf{msame}(v, w)$. The explicit endpoint-row form is the classifier alignment boundary of Definition 32.75. Thus classifier comparison is both preserved and reflected by the endpoint packet: endpoint mark agreement rebuilds the history classifier, and a history-classifier comparison exposes endpoint witnesses and mark agreement.

The certificate rows are fixed by Definition 32.74 and Definition 32.77. After constructor-row names, endpoint-table names, and public-surface annotations are erased, the retained rows are exactly the carrier, classifier, carrier-as-source-pattern-ledger, core NameCert, and public semantic certificate rows displayed in the statement. The target-source mirror theorem Definition 32.76 further says that the source-facing and target-facing reads are opposite views of the same finite endpoint packet, not separate constructor carriers.

Finally, the negative part follows from the same row exhaustion. Definition 32.72 excludes host propositions, decidable predicates, eliminators, and truth-table completeness from the public surface, while Definition 32.77 rejects unlisted source, result, termination, continuation, payload, and option-packaging coordinates. The chapter displays no Rule110, cellular, binary, or FKernel substrate row inside the Bool public endpoint constructors. Therefore any later consumer using one of those substrate names must provide its own target-side rows and relate them to the Bool packet by bisimulation, row embedding, or substrate mirror. The BEDC-local Bool boundary supplies no definitional equality from the public endpoint constructors to such a substrate. □

Theorem 32.53 (Bool finite-data exit route)**.** *The public* $\mathsf{Bool}^{\uparrow}$ *finite-data route consists exactly of the two endpoint constructor rows of Definition 32.70, the constructor case readback of Definition 32.71, the no-hidden-leakage boundary of Definition 32.72, and the semantic certificate scope of Definition 32.73. Any* $\mathsf{Option}^{\uparrow}$ *absent/present tag read,* $\mathsf{Prod}^{\uparrow}$ *sibling-lattice read, or* $\mathsf{List}^{\uparrow}$ *finite-data sibling route that consumes* $\mathsf{Bool}^{\uparrow}$ *passes through those rows and receives no host proposition, eliminator, decidable predicate, or truth-table completeness.*

Proof. The two constructor rows are the public endpoints displayed in Definition 32.70. The case readback theorem then says that every public endpoint read is one of those rows, with agreement measured by msame rather than by an external Boolean predicate.

The no-hidden-leakage theorem removes the extra host-logic surfaces from the public exit, while Definition 32.73 identifies the checked core and semantic certificate roles that remain available to

downstream finite data consumers.

The consumer list is exactly the existing finite-data route through Definition 32.59, Definition 34.110, and Definition 36.214. These routes use the same endpoint rows as absent/present tags, product sibling coordinates, and list finite-data siblings; none adds a primitive Boolean object or a host truth-table principle. □

Lemma 32.54 (Bool public endpoint downstream coverage)**.** *Every accepted local consumer of the public Bool endpoint constructors is covered by the finite alternatives and ledger rows already displayed in this file. More precisely, after the consumer is reduced to its public endpoint readback and Bool certificate scope, its visible rows lie in the finite packet*

$$\begin{gathered}\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}, \quad \mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e}),\\ v, w : \mathsf{BMark}, \quad e_v, e_w : \mathsf{BHist},\\ ((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e}))), \quad ((w = \mathsf{b0} \wedge e_w = \mathsf{e}) \vee (w = \mathsf{b1} \wedge e_w = \mathsf{E1}(\mathsf{e}))),\\ \mathsf{hsame}(h, e_v), \quad \mathsf{hsame}(k, e_w), \quad \mathsf{msame}(v, w),\\ \mathsf{BoolHistoryCarrier}, \quad \mathsf{BoolHistoryClassifier}, \quad \mathsf{NameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier}),\\ \mathsf{SemanticNameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier}).\end{gathered}$$

The alternatives outside this packet remain outside the Bool BEDC public surface: no host proposition, decidable predicate, eliminator, truth-table-completeness row, payload carrier, payload classifier, option-packaging row, separate source-side constructor carrier, result row, termination row, continuation row, external substrate row, or definitional-equality row is accepted as a downstream Bool endpoint constructor row.

Proof. Let a local downstream consumer be accepted by the public Bool endpoint constructor surface. By Definition 32.70, the only public constructor alternatives available at the entry point are $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ and $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$. Applying Definition 32.71 to the consumer read supplies a mark $v : \mathsf{BMark}$ and an endpoint-history witness $e_v : \mathsf{BHist}$ in one of those two displayed cases, together with the readback row $\mathsf{hsame}(h, e_v)$. If the consumer compares two accepted reads, the same argument supplies $w : \mathsf{BMark}$, $e_w : \mathsf{BHist}$, and $\mathsf{hsame}(k, e_w)$.

The equivalence-completion boundary of Definition 32.78, read with the explicit transport theorems Definition 32.16 and Definition 32.34, then exhausts the possible downstream classifier data. For the carrier leg, Definition 32.5 gives the two endpoint witnesses displayed above, and Definition 32.16 is the transport citation that carries that endpoint witness along the readback row $\mathsf{hsame}(h, e_v)$ to the usable carrier row $\mathsf{BoolHistoryCarrier}(h)$. For the classifier leg, Definition 32.13 gives source-qualified marks, the two displayed constructor equations for e_v and e_w, the two endpoint readback rows, and the mark comparison $\mathsf{msame}(v, w)$; Definition 32.34 is the transport citation for moving this classifier row along the endpoint readbacks. For the endpoint-agreement leg, Definition 32.4 reduces comparison of endpoint histories to the same mark comparison, with the endpoint-readback movement again governed by Definition 32.34. Hence every accepted carrier, classifier, or agreement row used downstream is already one of the rows in the finite packet above.

The certificate scope contributes only the named Bool certificate rows. By Definition 32.73, the core NameCert over BoolHistoryCarrier and BoolHistoryClassifier and the public SemanticNameCert over the same carrier, pattern, ledger, and classifier roles are separate checked scopes, with $\mathsf{Bool}^{\uparrow}$ derived from mark and history sameness rather than primitive host truth. Thus a downstream consumer receives the carrier, classifier, core certificate, and public semantic certificate rows listed in the packet, and no additional Boolean object is introduced by the certificate citation.

The exclusion clause is the one-way side of the same local boundary. Definition 32.78 records that forgetful projection and no-hidden-leakage directions do not reconstruct erased constructor-row names, endpoint-table names, or public-surface annotations, and do not turn absence of host data into further public constructor structure. Together with Definition 32.72, Definition 32.77, and Definition 32.79, this rules out host propositions, decidable predicates, eliminators, truth-table completeness, payload and option coordinates, separate source, result, termination, continuation, substrate, and definitional-equality rows. Therefore the accepted local downstream consumer is exhausted by the finite alternatives, readback rows, classifier row, and certificate ledger rows displayed in this file, while every excluded alternative remains outside the Bool BEDC public endpoint packet. □

Theorem 32.55 (Bool finite-data bridge interface)**.** *The endpoint bridge of Definition 32.3, endpoint coverage, classifier endpoint exactness, constructor separation, semantic fields, and the certificate of Definition 32.42 form the bridge-ready finite-data interface from* $\mathsf{Bool}^{\uparrow}$ *to the standard two-endpoint Bool surface. Concretely, the interface consists of Definition 32.4, Definition 32.5, Definition 32.30, Definition 32.31, Definition 32.40, and Definition 32.42.*

Lean4 ✓ `BEDC.Derived.BoolUp.BoolUp StdBridge`

Proof. The endpoint bridge supplies the two visible endpoints, and Definition 32.4 identifies endpoint agreement with the kernel mark equality read by the Bool bridge.

Endpoint coverage follows from Definition 32.5. Classifier exactness and constructor separation are supplied by Definition 32.30 and Definition 32.31, so the two constructors are both covered and separated.

The semantic fields of Definition 32.40 and the public certificate of Definition 32.42 package the carrier, pattern, and ledger rows into the finite Bool surface. These are exactly the finite data a bridge layer may consume, without asserting a machine-checked standard bridge in this chapter. □

Closure status for $\mathsf{NameCert}_{\mathsf{Bool}^{\uparrow}}$**.**

Constructive story: A Boolean here is a single mark from the kernel's two-element mark type — b0 or b1 — with no further structure layered on top. Whichever mark you start from, you stay there: equality on this tiny type is literal identity, and the four basic facts about it (each mark equals itself, and b0 differs from b1, in either reading order) form the entire distinguishing pattern, with every visible mark being just the raw mark itself. Because the type has only two elements and identity on it is automatically an equivalence, the five name-certificate obligations — that the carrier admits at least one element, and that the classifier is reflexive, symmetric, transitive, and respected by the carrier — fall out together without further work. The signature gap of a Boolean token p collects those marks m for which the source-domain admits m, the signature relation pairs m with an answer mark and an evidence ledger, and the token-introduction relation maps that answer to p; once the trivial pattern and ledger machinery is chased away, this becomes just $m = p$. The chapter registers all of this under the name $\mathsf{Bool}^{\uparrow}$; nothing beyond the kernel's mark type and its equality enters, and full Boolean algebra — operations, eliminators, decidable predicates — stays explicitly outside this closure level.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Bool}^{\uparrow}}$, maturePackageClosed)

Scope closed: The public Bool surface covers the false and true endpoint constructors, constructor case readback, semantic certificate ledger, no-hidden-leakage statement, and Definition 32.85 as the mature finite-data bridge surface over the displayed mark and history classifiers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Bool}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.BoolUp.bool\_history\_semantic\_name\_certificate`

Bridge status: bridgeChecked

Not claimed: Full boolean algebra or proposition theory: boolean operations, eliminators, decidable predicates, truth-table completeness, and logic connectives as BEDC primitives.

Upgrade path: No further formal-axis upgrade remains for this bridge-checked chapter.

Lemma 32.56 (Bool finite-data classifier alignment boundary)**.** *For histories h, k : BHist, the classifier side of the Bool finite-data bridge interface has the following exact alignment boundary:*

$$\mathsf{BoolHistoryClassifier}(h,k) \iff \exists v, w : \mathsf{BMark},\ \mathsf{BoolSourceSpec}(v) \wedge \mathsf{BoolSourceSpec}(w) \wedge \mathsf{hsame}(h, \mathsf{BoolEndpoint}$$

Under this equivalence, the transported displayed rows are precisely the two endpoint readback rows $\mathsf{hsame}(h, \mathsf{BoolEndpoint}(v))$ *and* $\mathsf{hsame}(k, \mathsf{BoolEndpoint}(w))$*, together with the mark-comparison row* $\mathsf{msame}(v, w)$*. The retained certificate rows are precisely the source, pattern, and ledger rows of Definition 32.40, all read as* $\mathsf{BoolHistoryCarrier}$*. Every row outside the interface listed in Definition 32.85 is forgotten by this alignment boundary; in particular, it exports no host proposition, decidable predicate, eliminator, truth-table-completeness row, payload carrier, payload classifier, or option-packaging row.*

Proof. The displayed equivalence is exactly Definition 32.13. Its forward direction says that a classifier comparison between h and k exposes only source-qualified endpoint marks v, w, the two endpoint readback rows, and the mark comparison $\mathsf{msame}(v, w)$. Its reverse direction says that those rows are already sufficient to rebuild the Bool history classifier comparison, so no additional classifier coordinate is consumed.

By Definition 32.3, the endpoint map has only the two visible target rows $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ and $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$. Endpoint coverage in Definition 32.5 supplies no third readback case, and constructor separation in Definition 32.31 prevents the two constructor rows from being identified by the classifier. Thus the readback part of the boundary transports exactly the displayed endpoint rows and their msame comparison.

The certificate part is fixed by Definition 32.40: source, pattern, and ledger are all the same predicate $\mathsf{BoolHistoryCarrier}$. The public semantic certificate in Definition 32.42 therefore retains only the carrier-classifier ledger named in Definition 32.85. Finally, Definition 32.72 rules out host propositions, decidable predicates, eliminators, and truth-table completeness, and the finite-data interface list contains no payload carrier, payload classifier, or option-packaging row. Those nonlisted rows are therefore forgotten rather than transported. □

Lemma 32.57 (Bool finite-data domain-codomain mirror boundary)**.** *In the finite-data bridge interface of Definition 32.85, the codomain-facing Bool read is the endpoint mirror of the domain-facing carrier read. Concretely, every public codomain read of the standard two-endpoint Bool surface is forced through one of the two rows* $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ *or* $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$*, and every such endpoint row is already a domain-side* $\mathsf{BoolHistoryCarrier}$ *row. Its observation, result, termination, and certificate data are therefore exactly the endpoint exactness row, endpoint coverage row, classifier endpoint exactness row, constructor separation row, semantic field row, and concrete semantic certificate row cited in Definition 32.85. There is no separate codomain carrier, codomain classifier, or codomain certificate row in this Bool finite-data bridge.*

Proof. Start with a public codomain read of the standard two-endpoint Bool surface. By Definition 32.70, the only public constructors of that surface are the two endpoint rows $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ and $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$. The readback theorem Definition 32.71 says that every public endpoint read is classified by exactly one of those rows, and that agreement of such rows is exactly mark agreement through msame.

Each of the two displayed endpoint rows is also a carrier row on the domain side. This is precisely the reverse direction of Definition 32.5: an endpoint witness $\mathsf{hsame}(h, \mathsf{BoolEndpoint}(v))$ repacks as $\mathsf{BoolHistoryCarrier}(h)$. The agreement comparison is not a codomain-specific classifier, because Definition 32.4 identifies endpoint agreement with msame on the underlying marks, while

Definition 32.30 and Definition 32.31 say that the history classifier has exactly the two endpoint classes and cannot mix them.

It remains to identify the certificate side. The semantic fields in Definition 32.40 read source, pattern, and ledger all as $\mathsf{BoolHistoryCarrier}$, and Definition 32.42 supplies the public semantic certificate for that same carrier and classifier. Thus reversing attention from the domain read to the codomain read only renames the endpoint row being inspected. It does not create any extra carrier, classifier, ledger, result, termination, or certificate row beyond the finite packet already listed in Definition 32.85. □

Lemma 32.58 (Bool finite-data substrate bisimulation boundary)**.** *Let* Sub *be one of the substrate read names* $\mathsf{Rule110}$*,* $\mathsf{Cellular}$*,* Binary*,* $\mathsf{FKernel}$*, or raw* BHist*. Within the finite-data bridge interface of Definition 32.85, a consumer-facing read from* Sub *into* $\mathsf{Bool}^{\uparrow}$ *has only the following BEDC-local relation certificate. Its source is the named substrate read* Sub*, its target is the Bool finite-data packet, its direction is*

$$\mathsf{Sub}\text{-}\textit{read} \longrightarrow \textit{displayed endpoint readback rows} \longrightarrow \mathsf{Bool}^{\uparrow}\text{-}\textit{consumer},$$

and its relation kind is substrate mirror with bisimulation comparison on the two endpoint observations. Concretely, for histories $h, k : \mathsf{BHist}$ *the observable comparison must factor through displayed marks* $v, w : \mathsf{BMark}$ *as*

$$\mathsf{BoolSourceSpec}(v) \wedge \mathsf{BoolSourceSpec}(w) \wedge \mathsf{hsame}(h, \mathsf{BoolEndpoint}(v)) \wedge \mathsf{hsame}(k, \mathsf{BoolEndpoint}(w)) \wedge \mathsf{msame}(v, w),$$

and this displayed relation is equivalent to $\mathsf{BoolHistoryClassifier}(h, k)$*. The retained certificate rows are precisely* $\mathsf{BoolHistoryCarrier}$*,* $\mathsf{BoolHistoryClassifier}$*,* $\mathsf{BoolHistoryCarrier}$ *as source, pattern, and ledger, and the semantic certificate of Definition 32.42. No accepted read may replace this mirror certificate by definitional equality between* Sub *and* $\mathsf{Bool}^{\uparrow}$*, by equality between a host substrate and the Bool carrier, or by an unlisted Rule110 state, cellular clock, cellular neighborhood, external binary trace, FKernel extension, FKernel continuation, FKernel package, FKernel gap, or raw* BHist *constructor coordinate.*

Proof. The finite-data interface is already enumerated in Definition 32.85. Its rows are endpoint bridge exactness, endpoint coverage, classifier endpoint exactness, constructor separation, the semantic fields, and the concrete semantic certificate. Thus a substrate-facing consumer has no independent row from which to read a Rule110 state, a cellular clock or neighborhood, an external binary trace, an FKernel extension, continuation, package, or gap coordinate, or a raw constructor identity for BHist.

The endpoint part of the certificate is forced by Definition 32.3: the only displayed target rows are $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ and $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$. Endpoint coverage in Definition 32.5 says that every Bool history carrier read reaches one of those endpoint rows, and constructor separation prevents the two endpoint rows from being collapsed by the Bool classifier.

The comparison part is exactly the boundary in Definition 32.86. Its forward direction reads any $\mathsf{BoolHistoryClassifier}(h, k)$ comparison as source-qualified marks v, w, two endpoint readback rows $\mathsf{hsame}(h, \mathsf{BoolEndpoint}(v))$ and $\mathsf{hsame}(k, \mathsf{BoolEndpoint}(w))$, and the mark comparison $\mathsf{msame}(v, w)$. Its reverse direction rebuilds the Bool history classifier from precisely those rows. Hence the displayed endpoint observations are preserved and reflected by the same finite comparison row; this is a bisimulation boundary on the local Bool observations, not a definitional equality boundary between substrates.

The direction and mirror reading are fixed by Definition 32.87: a codomain-facing Bool read is the endpoint mirror of the domain-facing carrier read. Therefore a substrate read can be consumed

only after it has been projected to the endpoint readback packet and then read through the Bool carrier and classifier rows. The semantic side contributes no extra substrate coordinate, because Definition 32.40 reads source, pattern, and ledger all as $\mathsf{BoolHistoryCarrier}$, and Definition 32.42 certifies that same carrier and classifier.

Finally, Definition 32.72 excludes host propositions, decidable predicates, eliminators, and truth-table completeness, and the finite interface list contains none of the substrate-specific rows named in the statement. A receiving gate that re-reads the displayed rows must therefore reject any unlisted host or source coordinate. What remains is exactly the finite substrate mirror certificate above: source named by the incoming substrate read, target named by the Bool finite-data packet, direction through the displayed endpoint rows, and bisimulation comparison given by msame under the Bool history classifier. □

Theorem 32.59 (Bool-to-option constructor disjointness route)**.** *The* $\mathsf{Bool}^{\uparrow}$ *empty endpoint* e *and one-step endpoint* $\mathsf{E1}(\mathsf{e})$ *provide the branch discriminator consumed by the nullable and tagged constructor separation of* $\mathsf{Option}^{\uparrow}$ *in chapter 33. Any* $\mathsf{Option}^{\uparrow}$ *absent/present read that routes through these two displayed boolean endpoints must keep the absent branch on the empty row and the present branch on the one-step row; payload evidence cannot identify the two branches.*

Proof. Read the $\mathsf{Bool}^{\uparrow}$ endpoint rows through Definition 32.10. The carrier side has only the displayed $\mathsf{b0}$ and $\mathsf{b1}$ witnesses, and the classifier side is already fixed by $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ and $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$.

The $\mathsf{Option}^{\uparrow}$ nullable and tagged surfaces then consume those rows as the absent and present branch markers named in chapter 33. Since the discriminator has already been read from the boolean endpoint classifier, an optional payload row can only live under the visible present marker; it cannot change the marker that selected the branch.

Finally, mixed absent/present identification would require the boolean history classifier to relate e to $\mathsf{E1}(\mathsf{e})$. This is ruled out by Definition 32.31. Thus the route exports exactly the branch separation consumed by $\mathsf{Option}^{\uparrow}$, while leaving the payload carrier, payload classifier, and option packaging rows in the option chapter. □

The $\mathsf{Bool}^{\uparrow}$ truth rows feed the constructor-disjointness and finite-data routes of $\mathsf{Option}^{\uparrow}$ as the displayed absent/present discriminator cited in chapter 33. The dependency uses only the two endpoint histories, their local classifier, componentwise hsame transport, Cont replay, Pkg provenance, and the local $\mathsf{NameCert}_{\mathsf{Bool}^{\uparrow}}$ row, while payload carriers, nullable classifiers, and option equality remain owned by the $\mathsf{Option}^{\uparrow}$ packet.

Theorem 32.60 (Bool finite-data lattice route)**.** *The* $\mathsf{Bool}^{\uparrow}$ *endpoint classifier supplies the binary tag row consumed by the constructor-disjointness surface of* $\mathsf{Option}^{\uparrow}$ *in chapter 33 and by the tagged-branch separation surface of* $\mathsf{Sum}^{\uparrow}$ *in chapter 35. Any finite-data consumer that passes through both sibling chapters reads the same two boolean endpoint rows before it distinguishes absent/present option branches or left/right sum branches.*

Proof. Project the $\mathsf{Bool}^{\uparrow}$ endpoint surface through Definition 32.10. The only displayed tags are the empty endpoint and the one-step endpoint, and their classifier separation is fixed before any sibling payload row is inspected.

The $\mathsf{Option}^{\uparrow}$ consumer reads those tags as the absent/present discriminator, while the $\mathsf{Sum}^{\uparrow}$ consumer reads them as the visible branch separator. In both cases the sibling chapter supplies its own payload or branch carrier after the boolean tag row has already selected the finite-data face.

Thus the lattice route exports exactly the binary tag discipline supplied by $\mathsf{Bool}^{\uparrow}$. It does not add option payload equality, sum branch equality, or a host finite-type equality outside the displayed endpoint classifier. □

Theorem 32.61 (Bool finite-data outbound lattice)**.** *The* $\mathsf{Bool}^{\uparrow}$ *endpoint rows are consumed by* $\mathsf{Option}^{\uparrow}$ *in chapter 33,* $\mathsf{Sum}^{\uparrow}$ *in chapter 35,* $\mathsf{Prod}^{\uparrow}$ *in chapter 34, and* $\mathsf{List}^{\uparrow}$ *in chapter 36 only as finite branch or coordinate discriminators. Payload rows, pairing rows, coproduct branch rows, and spine-recursion rows remain owned by those sibling chapters, so the outbound lattice exports the visible binary endpoint surface without manufacturing a payload, product, sum, or list classifier inside* $\mathsf{Bool}^{\uparrow}$*.*

Proof. Project the endpoint exactness supplied by the $\mathsf{Bool}^{\uparrow}$ carrier. Its public rows distinguish the two finite endpoint cases and do not contain payload data, ordered-pair coordinates, coproduct contents, or recursive spine cells.

The four sibling consumers read this endpoint distinction in different positions. $\mathsf{Option}^{\uparrow}$ uses it as absent/present branch data, $\mathsf{Sum}^{\uparrow}$ as left/right branch data, $\mathsf{Prod}^{\uparrow}$ as finite coordinate-facing discriminator data, and $\mathsf{List}^{\uparrow}$ as branch information at the list spine boundary.

Each sibling then supplies its own carrier rows after the boolean discriminator has been read. Therefore the outbound lattice is a route from $\mathsf{Bool}^{\uparrow}$ to finite-data siblings, not a transfer of sibling-owned payload, pairing, coproduct, or recursion obligations back into the Bool chapter. □

Proposition 32.62 (Bool finite-data dependency lattice)**.** *The* $\mathsf{Bool}^{\uparrow}$ *endpoint discriminator rows are consumed as finite-data tags by the sibling constructors of chapter 33, chapter 35, chapter 34, and chapter 36, while equality and readback routes pass through the finite classifier boundary of chapter 131. Thus the Bool chapter exposes a concrete sibling lattice route: absent/present, left/right, component-presence, list-step, and equality-facing consumers all read the same two endpoint rows before their own payload rows are inspected.*

Theorem 32.63 (Bool finite-data sibling lattice integrity)**.** *The* $\mathsf{Bool}^{\uparrow}$ *finite-data surface supplies endpoint discriminator rows consumed by chapter 33, chapter 35, chapter 34, and chapter 36. The discriminator is the two-endpoint row already named by the* $\mathsf{Bool}^{\uparrow}$ *carrier:* $\mathsf{Option}^{\uparrow}$ *reads it as the absent/present branch,* $\mathsf{Sum}^{\uparrow}$ *reads it as the left/right branch,* $\mathsf{Prod}^{\uparrow}$ *reads it only as a coordinate-facing Boolean component when a product field is Boolean, and* $\mathsf{List}^{\uparrow}$ *reads it only as a finite spine or payload tag when a list cell is Boolean. The* $\mathsf{Bool}^{\uparrow}$ *chapter itself does not own option payload rows, product-coordinate pairing rows, coproduct-injection rows, or list-spine recursion rows.*

Proof. Project the $\mathsf{Bool}^{\uparrow}$ endpoint classifier through Definition 32.10. Its exported data are exactly the two endpoint discriminators and their classifier separation.

The sibling chapters then consume that row in distinct positions. $\mathsf{Option}^{\uparrow}$ and $\mathsf{Sum}^{\uparrow}$ use it as a branch discriminator, while $\mathsf{Prod}^{\uparrow}$ and $\mathsf{List}^{\uparrow}$ can only import it as a Boolean component row inside their own product or spine carriers.

Because payload, coordinate-pairing, coproduct-injection, and list-recursion rows are supplied by the respective sibling carriers, no accepted $\mathsf{Bool}^{\uparrow}$ packet can claim ownership of them. Thus the sibling lattice is visible precisely as a dependency of those finite-data constructors on the Bool endpoint discriminator. □

Theorem 32.64 (Bool finite-data sibling route)**.** *The* $\mathsf{Bool}^{\uparrow}$ *two-mark carrier is the finite endpoint consumed by the constructor-tag routes for* $\mathsf{Option}^{\uparrow}$*,* $\mathsf{Prod}^{\uparrow}$*,* $\mathsf{Sum}^{\uparrow}$*, and* $\mathsf{List}^{\uparrow}$*. Every such sibling read factors through the displayed true/false endpoint rows, the local* BHist *carrier, componentwise*

hsame *transport, visible* Cont *replay,* Pkg *provenance, and the* $\mathsf{NameCert}_{\mathsf{Bool}^\uparrow}$ *row before it can be used as an option tag, product projection flag, sum injection tag, or list constructor marker.*

In particular, the horizontal finite-data edge from chapter 32 to chapter 33 is a carrier route, not a host-level case split outside the BEDC packet.

Proof. Project the accepted $\mathsf{Bool}^\uparrow$ carrier. Its only data rows are the two displayed marks together with the transport, replay, provenance, and local naming rows.

The sibling constructors consume those marks as finite tags. The $\mathsf{Option}^\uparrow$ route reads one mark to distinguish absence from presence, while the $\mathsf{Prod}^\uparrow$, $\mathsf{Sum}^\uparrow$, and $\mathsf{List}^\uparrow$ routes use the same finite endpoint discipline for projection, injection, and constructor boundaries.

Since every read is routed through the same BHist, hsame, Cont, Pkg, and NameCert rows, no sibling obtains an external Boolean oracle or an unrecorded host case split. □

Theorem 32.65 ($\mathsf{Bool}^\uparrow$ option-product sibling lattice link)**.** *The* $\mathsf{Bool}^\uparrow$ *finite truth classifier supplies the binary discriminator row consumed by* $\mathsf{Option}^\uparrow$ *constructor disjointness in chapter 33 and by* $\mathsf{Prod}^\uparrow$ *pair-envelope selection in chapter 34. Both consumers read* $\mathsf{Bool}^\uparrow$ *only through the displayed two-endpoint truth classifier, componentwise transport, replay, provenance, and local naming rows. Neither consumer adds host booleans, external equality, option payload carriers, product coordinate carriers, or product-pair equality to the* $\mathsf{Bool}^\uparrow$ *packet.*

Proof. Project the finite truth surface already displayed by the $\mathsf{Bool}^\uparrow$ carrier. The visible data are the two endpoint histories, their classifier row, and the structural rows that transport and replay that finite distinction.

The $\mathsf{Option}^\uparrow$ consumer reads the two endpoints as absent and present branch markers before any payload row is inspected. The payload carrier and nullable payload classifier remain owned by the option chapter, so constructor disjointness imports only the binary discriminator.

The $\mathsf{Prod}^\uparrow$ consumer may read the same finite distinction only when a product envelope asks for a Boolean-facing coordinate or selector row. The pair carrier, coordinate carriers, and pair-envelope equality remain owned by the product chapter.

Thus both sibling routes consume the displayed $\mathsf{Bool}^\uparrow$ truth classifier without manufacturing host booleans or external equality. The exported dependency edge is the finite two-endpoint classifier and nothing stronger. □

Theorem 32.66 (Bool finite-truth sibling dependency route)**.** *The* $\mathsf{Bool}^\uparrow$ *finite-truth surface is consumed downstream only through displayed sibling NameCert routes. Equality endpoints and no-confusion reads cite the* $\mathsf{Eq}^\uparrow$ *boundary of chapter 131, while finite carrier scans cite the unary and list surfaces of chapter 28 and chapter 36. Thus a consumer may use Boolean truth rows as explicit endpoint data, but it may not replace those rows by ambient equality reflection, hidden finite enumeration, or list recursion outside the sibling certificates.*

Proof. Project the accepted $\mathsf{Bool}^\uparrow$ consumer route. Any equality or no-confusion read is routed through the displayed EqType sibling, so the endpoint comparison is read as a finite NameCert dependency rather than as ambient equality reflection.

For carrier scans, the only displayed finite traversal rows are the unary and list surfaces supplied by the Nat and List siblings. A downstream consumer therefore receives Boolean truth data through those certificates, not through an unrecorded enumeration of all Boolean values. □

The finite-data sibling lattice reads $\mathsf{Bool}^\uparrow$ as the two-tag truth classifier consumed by constructor interfaces, not as a global proposition oracle. In chapter 33, the empty and present branches use the two boolean endpoint rows as constructor tags; in chapter 34, component truth readback

uses the same finite classifier to decide which displayed component rows have been exposed. The dependence is therefore a constructor-tag and component-readback dependence on the two $\mathsf{Bool}^{\uparrow}$ endpoints, while $\mathsf{Option}^{\uparrow}$, $\mathsf{Sum}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, and $\mathsf{List}^{\uparrow}$ still own their payload carriers, product rows, list spines, and local naming data.

Proposition 32.67 (Bool finite-data sibling readback)**.** *Every finite-data sibling read of* $\mathsf{Option}^{\uparrow}$*,* $\mathsf{Sum}^{\uparrow}$*,* $\mathsf{Prod}^{\uparrow}$*, or* $\mathsf{List}^{\uparrow}$ *that cites* $\mathsf{Bool}^{\uparrow}$ *uses only the two endpoint rows of* $\mathsf{Bool}^{\uparrow}$ *as constructor tags or component truth readback. It does not import a payload carrier, product classifier, list spine, or external truth predicate from the boolean chapter.*

Proof. Read the sibling dependency through the hub inputs. The option and sum surfaces consume the two endpoints as branch tags, the product surface consumes them as component-exposure readback, and the list surface consumes them only through finite constructor routing.

The payload, product, and spine data are then supplied by the receiving chapters. Since the Bool carrier contains only the two endpoint histories and their classifier, no additional payload or external truth predicate can be projected from the Bool row. □

Theorem 32.68 ($\mathsf{Bool}^{\uparrow}$ sibling dependency surface)**.** *The* $\mathsf{Bool}^{\uparrow}$ *finite-truth carrier is the L6 endpoint surface consumed by the adjacent finite-data routes for* $\mathsf{Option}^{\uparrow}$*,* $\mathsf{Sum}^{\uparrow}$*,* $\mathsf{Prod}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*, and* $\mathsf{CantorSpace}^{\uparrow}$*. The* $\mathsf{Option}^{\uparrow}$ *route of chapter 33 reads the two endpoints as constructor discriminators, the* $\mathsf{Sum}^{\uparrow}$ *and* $\mathsf{Prod}^{\uparrow}$ *routes read them as finite branch and component selectors, the* $\mathsf{List}^{\uparrow}$ *route reads them as finite traversal endpoints, and the* $\mathsf{CantorSpace}^{\uparrow}$ *route reads them as binary coordinate endpoints. Each consumer receives only the displayed Boolean endpoint rows, endpoint classifier,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row.*

No sibling consumer receives host booleans, external equality reflection, hidden enumeration, product-pair equality, option payload data, list-recursion data, or Cantor-space compactness from the $\mathsf{Bool}^{\uparrow}$ *packet.*

Proof. Start with the finite-truth route already exposed by the $\mathsf{Bool}^{\uparrow}$ carrier and its local sibling lattice. The readable rows are the two endpoint histories, the endpoint classifier, componentwise transport, displayed replay, provenance, and local naming.

The option route consumes the endpoints only as absent and present branch discriminators, as in chapter 33. The sum, product, and list routes consume the same finite distinction as branch, component, and traversal data, while their payload, pair, and recursion certificates remain owned by their own packets.

For the Cantor-space endpoint route, the Boolean row supplies only the binary coordinate endpoint. Compactness, product topology, and infinite-choice data are not coordinates of the Boolean carrier, so they cannot be exported through this dependency surface. □

Theorem 32.69 (Bool finite-data product sibling route)**.** *The* $\mathsf{Bool}^{\uparrow}$ *finite truth rows are consumed by the* $\mathsf{Prod}^{\uparrow}$ *paired component classifier through chapter 34. A product consumer may read a Boolean component only as one of the two displayed endpoint rows named by the Bool certificate, then package it with the other product coordinate through the product sibling route.*

Proof. Project the Bool carrier to its two finite truth endpoints. The product sibling route reads those endpoints as component classifier data, while the paired coordinate and product envelope remain supplied by chapter 34.

Thus the Boolean row contributes only its displayed finite endpoint and its local naming evidence. It cannot replace the product classifier, introduce an ambient Boolean algebra, or hide product-coordinate data outside the sibling certificate. □

The $\mathsf{Bool}^{\uparrow}$ endpoint surface supplies the two visible rows consumed by the L6 finite-data constructor lattice. The nullable branch of chapter 33, the tagged alternatives of chapter 35, the paired constructor route of chapter 34, and the finite spine classifier of chapter 36 all read those endpoints as displayed discriminator rows. The route exports only the two endpoint marks and their history classifier, leaving payload carriers, product coordinates, coproduct injections, and list recursion to the corresponding sibling packets.

Definition 32.70 (Bool public endpoint constructors)**.** *The public false constructor is* $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$*, and the public true constructor is* $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$*. Public boolean operations are finite endpoint tables whose input and output rows are drawn only from these two constructor rows. No row in this public surface is a host proposition, a decidable predicate, or an eliminator.*

Lean4 (definition) `BEDC.Derived.BoolUp.BoolPublicEndpointConstructors`

Theorem 32.71 (Bool public constructor case readback)**.** *Every public Bool endpoint read is classified by exactly one of the displayed false and true endpoint rows of Definition 32.70. Two public constructor readbacks agree exactly when their underlying marks are related by* msame*.*

Proof. Apply Definition 32.5 to the public read. It supplies a displayed mark $v : \mathsf{BMark}$ and a witness that the read history is the endpoint $\mathsf{BoolEndpoint}(v)$.

Case analysis on v gives the two public rows $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ and $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$. Theorem 32.6 gives uniqueness of the readback mark, and Definition 32.4 identifies agreement of endpoint rows with msame of the underlying marks. □

Theorem 32.72 (Bool public surface no-hidden leakage)**.** *A consumer of the public Bool surface can read only the two constructor endpoint rows, endpoint-table operation rows over those constructors, the mark and history classifier rows, and the semantic certificate ledger. It cannot read a host proposition, a decidable predicate, an eliminator, or truth-table completeness.*

Proof. The public constructors are exactly the two endpoint rows in Definition 32.70. The endpoint coverage and constructor case readback statements show that public reads return one of these rows, with agreement controlled by msame and endpoint exactness rather than by host logic.

The semantic certificate in Definition 32.42 records the carrier, classifier, and ledger discipline. Since the displayed public rows contain no host proposition, decidable predicate, eliminator, or truth-table-completeness row, those objects are not available to a surface consumer. □

The endpoint coverage, endpoint bridge classifier completeness, and endpoint readback theorems justify the Bool public-object readback and bridge promised by the roadmap template; they are not internal fields of the SemanticNameCert constructor. $\mathsf{Option}^{\uparrow}$consumes this two-row endpoint discipline as its absent/present tag surface in chapter 33.

Corollary 32.73 ($\mathsf{Bool}^{\uparrow}$ certificate scope)**.** *Theorem 32.39 cites the checked core history* NameCert *for* BoolHistoryCarrier *and* BoolHistoryClassifier*, namely the BEDC.Derived.BoolUp Lean target* bool_history_name_certificate*. The public-object* SemanticNameCert *scope is checked separately at Theorem 32.42 by the BEDC.Derived.BoolUp Lean target* bool_history_semantic_name_certificate*. Thus the core certificate, the mark-level ledger definition, the generic carrier-as-ledger implication, and the closed semantic certificate occupy separate roles. In each case* $\mathsf{Bool}^{\uparrow}$ *is derived from mark and history sameness, and is not primitive.*

Lemma 32.74 (Bool public endpoint forgetful projection boundary)**.** *The public constructor surface of Definition 32.70 admits a BEDC-native forgetful projection. Start with a public constructor*

readback row and erase the constructor-row name, endpoint-table name, and public-surface annotation while retaining the displayed endpoint history. The retained target data are exactly

$\mathsf{BoolHistoryCarrier}$, $\mathsf{BoolHistoryClassifier}$, $\mathsf{BoolHistoryCarrier}$ *as source, pattern, and ledger,* $\mathsf{NameCert}(\mathsf{BoolHis}$

together with the public semantic certificate

$\mathsf{SemanticNameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier})$.

More concretely, each retained public read has a mark $v : \mathsf{BMark}$ *and an endpoint witness* $\mathsf{hsame}(h, \mathsf{BoolEndpoint}(v))$ *unique up to* msame*. For two retained reads* h, k *with endpoint witnesses through* $v, w : \mathsf{BMark}$*, the projected classifier row* $\mathsf{BoolHistoryClassifier}(h, k)$ *holds exactly when* $\mathsf{msame}(v, w)$ *holds. The projection retains no constructor-row name, endpoint-table name, host proposition, decidable predicate, eliminator, truth-table-completeness datum, payload carrier, payload classifier, or option-packaging row.*

Proof. The public constructor rows are exactly the two endpoint rows displayed in Definition 32.70. Applying Definition 32.71 to a public read supplies a mark $v : \mathsf{BMark}$ and an endpoint witness $\mathsf{hsame}(h, \mathsf{BoolEndpoint}(v))$, and Definition 32.6 makes the displayed mark unique up to msame.

The retained carrier coordinate is forced by Definition 32.5: an endpoint witness against $\mathsf{BoolEndpoint}(v)$ repacks as $\mathsf{BoolHistoryCarrier}(h)$, and every Bool carrier row is covered by such an endpoint witness. Thus erasing the public constructor name leaves a history in the same target carrier rather than a separate codomain carrier.

For the classifier coordinate, take two retained reads h, k with endpoint witnesses through v, w. If $\mathsf{msame}(v, w)$ holds, the reverse direction of Definition 32.12 rebuilds $\mathsf{BoolHistoryClassifier}(h, k)$ from the two endpoint witnesses and the mark comparison. Conversely, if $\mathsf{BoolHistoryClassifier}(h, k)$ holds, Definition 32.12 supplies endpoint witnesses through marks v', w' with $\mathsf{msame}(v', w')$. The readback determinism theorem compares v with v' and w with w', and transitivity of mark sameness gives $\mathsf{msame}(v, w)$. Hence the classifier retained by the projection is exactly the mark-level agreement already visible in the constructor readback.

The certificate coordinates are fixed by Definition 32.40, Definition 32.39, and Definition 32.42. Source, pattern, and ledger are all the same predicate $\mathsf{BoolHistoryCarrier}$, the core name certificate is $\mathsf{NameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier})$, and the public semantic certificate is the displayed carrier-self semantic certificate. Finally, Definition 32.72 excludes host propositions, decidable predicates, eliminators, and truth-table completeness, while the Bool public surface contains no payload carrier, payload classifier, or option-packaging coordinate. Those named rows are therefore erased rather than transported by the forgetful projection. □

Lemma 32.75 (Bool public endpoint constructor classifier alignment boundary)**.** *For histories* $h, k : \mathsf{BHist}$*, the public Bool endpoint surface aligns its classifier boundary exactly with the two displayed constructor endpoint rows:*

$$\mathsf{BoolHistoryClassifier}(h, k)$$
$$\iff \quad \exists v, w : \mathsf{BMark},\ e_v, e_w : \mathsf{BHist},\ \mathsf{BoolSourceSpec}(v) \wedge \mathsf{BoolSourceSpec}(w) \wedge \big((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge$$

Under this equivalence, the transported public rows are exactly the two endpoint readback rows against the endpoint histories e_v *and* e_w *determined by* $\mathsf{BoolEndpoint}(v)$ *and* $\mathsf{BoolEndpoint}(w)$*, together with the mark-comparison row* $\mathsf{msame}(v, w)$*. The retained certificate rows are the carrier, classifier, and semantic ledger rows named by the Bool semantic certificate. Rows for host propositions, decidable predicates, eliminators, and truth-table completeness are forgotten by the public endpoint classifier boundary.*

Proof. The displayed equivalence is Definition 32.13 read through the explicit endpoint-history witnesses supplied by Definition 32.70. Its forward direction says that a classifier comparison between h and k exposes only source-qualified marks v, w, endpoint histories e_v, e_w with the displayed constructor equations, the two endpoint readback rows $\mathsf{hsame}(h, e_v)$ and $\mathsf{hsame}(k, e_w)$, and the mark-comparison row $\mathsf{msame}(v, w)$. Its reverse direction says that precisely those rows rebuild the Bool history classifier comparison, so no further classifier coordinate is being transported.

By Definition 32.70, the public constructors are only $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ and $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$. The case readback theorem Definition 32.71 therefore identifies every public endpoint read with exactly one of those two rows, and Definition 32.6 makes the chosen mark unique up to msame. The endpoint bridge exactness of Definition 32.4 then makes the row comparison a mark comparison rather than a host-logical comparison.

The certificate side contributes no extra public row. The semantic certificate in Definition 32.42 records the Bool carrier, classifier, and ledger discipline over the same history carrier. Finally, Definition 32.72 states that the public surface does not expose a host proposition, decidable predicate, eliminator, or truth-table completeness row. Hence the boundary transports exactly the two constructor readback rows and their msame classifier comparison, retains only the semantic certificate ledger rows, and forgets the non-public rows listed above. □

Lemma 32.76 (Bool public constructor target-source mirror boundary)**.** *For the public Bool constructor surface of Definition 32.70, the target-facing constructor read and the source-facing carrier read are the same finite endpoint packet viewed in opposite directions. Concretely, a public target read through either displayed constructor row* $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ *or* $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$ *has a source mirror consisting exactly of the same mark* $v : \mathsf{BMark}$*, an endpoint history witness* $e_v : \mathsf{BHist}$ *satisfying* $((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e})))$*, the same readback observation row* $\mathsf{hsame}(h, e_v)$*, the same classifier comparison row* $\mathsf{msame}(v, w)$ *when another constructor read is compared through a mark* $w : \mathsf{BMark}$ *and endpoint history witness* $e_w : \mathsf{BHist}$ *satisfying* $((w = \mathsf{b0} \wedge e_w = \mathsf{e}) \vee (w = \mathsf{b1} \wedge e_w = \mathsf{E1}(\mathsf{e})))$*, and the same semantic certificate rows*

$$\mathsf{BoolHistoryCarrier}, \quad \mathsf{BoolHistoryClassifier}, \quad \mathsf{NameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier}), \quad \mathsf{SemanticNameC}$$

Thus the source side is obtained by renaming the displayed target endpoint packet back to its carrier readback packet. The boundary is negative for any larger mirror: there is no separate source-side constructor carrier, result row, termination row, host proposition row, decidable predicate row, eliminator row, truth-table-completeness row, payload carrier row, payload classifier row, or option-packaging row.

Proof. Start with a public target read. By Definition 32.70, the only target constructor rows are $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ and $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$. The case readback theorem Definition 32.71 therefore supplies a displayed mark $v : \mathsf{BMark}$ and an endpoint history witness $e_v : \mathsf{BHist}$ with $((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e})))$, and identifies the read with the endpoint readback row $\mathsf{hsame}(h, e_v)$. Its agreement clause, together with Definition 32.6 and Definition 32.4, says that any comparison between two such reads is exactly the mark comparison $\mathsf{msame}(v, w)$.

The source mirror is forced by endpoint coverage. The reverse direction of Definition 32.5 repacks the readback row $\mathsf{hsame}(h, e_v)$, for an endpoint witness e_v satisfying $((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e})))$, as the source carrier row $\mathsf{BoolHistoryCarrier}(h)$, while the forward direction says that every source carrier row used by this Bool surface is covered by such an endpoint readback. Hence the target row and source row do not form two independent constructors; they are the same displayed history endpoint read as target endpoint or as source carrier.

For compared reads h, k, Definition 32.12 identifies the source-side classifier row $\mathsf{BoolHistoryClassifier}(h, k)$ with the two endpoint readbacks through marks v, w, endpoint history witnesses $e_v, e_w : \mathsf{BHist}$ satisfying $((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e})))$ and $((w = \mathsf{b0} \wedge e_w = \mathsf{e}) \vee (w = \mathsf{b1} \wedge e_w = \mathsf{E1}(\mathsf{e})))$, and the same comparison row $\mathsf{msame}(v, w)$. The source-qualified form in Definition 32.13 adds only the already displayed source qualification of those two finite marks, so it does not introduce a further target or source coordinate.

The certificate rows are exactly the rows already named by Definition 32.40, Definition 32.39, and Definition 32.42: source, pattern, and ledger are all read as $\mathsf{BoolHistoryCarrier}$, and the classifier is $\mathsf{BoolHistoryClassifier}$. Finally, Definition 32.72, Definition 32.74, and Definition 32.75 rule out the larger mirror coordinates listed in the statement. The target-source mirror therefore closes exactly at the finite endpoint packet and its Bool semantic certificate rows. □

Lemma 32.77 (Bool public endpoint bridge cut-elimination boundary)**.** *The public Bool endpoint constructors of Definition 32.70 admit a bridge cut-elimination boundary over the displayed local rows. For a final consumer read of the public Bool surface, every route row factors through the finite packet*

$$\begin{gathered}
\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}, \quad \mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e}), \\
v, w : \mathsf{BMark}, \quad e_v, e_w : \mathsf{BHist}, \\
((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e}))), \\
((w = \mathsf{b0} \wedge e_w = \mathsf{e}) \vee (w = \mathsf{b1} \wedge e_w = \mathsf{E1}(\mathsf{e}))), \\
\mathsf{hsame}(h, e_v), \quad \mathsf{hsame}(k, e_w), \quad \mathsf{msame}(v, w), \\
\mathsf{BoolHistoryCarrier}, \quad \mathsf{BoolHistoryClassifier}, \quad \mathsf{NameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier}), \\
\mathsf{SemanticNameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier}).
\end{gathered}$$

The two displayed constructor endpoint rows, the endpoint history readback rows, the mark-comparison row, and the carrier, classifier, core certificate, and semantic certificate rows are noneliminable at this boundary: removing any one of them loses either the public endpoint choice, the readback into a history, the classifier comparison, or the certificate surface consumed by the final Bool object. Every other named coordinate appearing in the local public-surface discussion is eliminated or rejected: constructor-row names, endpoint-table names, and public-surface annotations are projected away; host propositions, decidable predicates, eliminators, truth-table-completeness data, payload carriers, payload classifiers, option-packaging rows, separate source-side constructor carriers, result rows, termination rows, and continuation rows are not consumer-visible rows of this Bool endpoint bridge.

Proof. The finite endpoint rows are exactly the two rows displayed in Definition 32.70. Thus any public constructor read begins at either $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ or $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$, and no third constructor, host predicate, or eliminator row is available at the source of the route. Applying Definition 32.71 to the read supplies a mark $v : \mathsf{BMark}$ and an endpoint history witness $e_v : \mathsf{BHist}$ with $((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e})))$ and $\mathsf{hsame}(h, e_v)$; applying it to a second read supplies $w : \mathsf{BMark}$ and an endpoint history witness $e_w : \mathsf{BHist}$ with $((w = \mathsf{b0} \wedge e_w = \mathsf{e}) \vee (w = \mathsf{b1} \wedge e_w = \mathsf{E1}(\mathsf{e})))$ and $\mathsf{hsame}(k, e_w)$. The uniqueness part is controlled by Definition 32.6, so the chosen endpoint mark cannot be replaced by an unlisted host or source coordinate.

The comparison row is also forced. By Definition 32.4, comparison of the two endpoint rows is exactly comparison of their marks by $\mathsf{msame}(v, w)$. Equivalently, Definition 32.12 identifies the history classifier row $\mathsf{BoolHistoryClassifier}(h, k)$ with the two endpoint history readbacks and the same mark-comparison row. Hence a bridge consumer cannot keep an independent comparison

route after those readback rows have been exposed; the classifier route has already cut through the endpoint packet.

The carrier and certificate side is fixed by the already displayed projection boundary. By Definition 32.5, the endpoint readback through e_v repacks as the carrier row $\mathsf{BoolHistoryCarrier}(h)$, and every carrier row used here is covered by such an endpoint readback. By Definition 32.74, erasing constructor-row names, endpoint-table names, and public-surface annotations leaves exactly the carrier, classifier, carrier-as-source-pattern-ledger, core $\mathsf{NameCert}$, and public semantic certificate rows. By Definition 32.40, Definition 32.39, and Definition 32.42, these rows are the Bool history carrier, the Bool history classifier, and the carrier-self semantic certificate displayed in the statement.

The remaining possible cuts are negative. Definition 32.72 excludes host propositions, decidable predicates, eliminators, and truth-table completeness from the public consumer surface. Definition 32.75 shows that the classifier boundary transports only the two endpoint readback rows and their msame comparison, while Definition 32.76 shows that target-facing and source-facing reads are the same finite endpoint packet rather than separate constructor carriers, result rows, termination rows, or continuation rows. Since the local chapter displays no additional host, source, handoff, continuation, payload, or option-packaging coordinate, any such coordinate is rejected as unlisted rather than retained by the bridge.

Consequently the final consumer-visible surface is precisely the finite packet named in the statement. The endpoint rows, readback rows, mark-comparison row, carrier and classifier rows, and the two certificate rows are noneliminable because they are the rows used to reconstruct the endpoint choice, the history read, the classifier comparison, and the public Bool certificate. All other local route names are either projected away by the forgetful boundary or excluded by the public-surface and mirror-boundary theorems. □

Lemma 32.78 (Bool public endpoint equivalence-completion boundary)**.** *The public Bool endpoint constructor surface of Definition 32.70 has a complete equivalence boundary over its displayed local classifier and readback rows. For histories $h, k : \mathsf{BHist}$, the carrier and classifier two-sided part is exactly*

$$\begin{aligned}
\mathsf{BoolHistoryCarrier}(h) &\iff \exists v : \mathsf{BMark},\ \exists e_v : \mathsf{BHist},\ ((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e}))) \wedge \mathsf{hsame}(h \\
\mathsf{BoolHistoryClassifier}(h, k) &\iff \exists v, w : \mathsf{BMark},\ \exists e_v, e_w : \mathsf{BHist},\ \mathsf{BoolSourceSpec}(v) \wedge \mathsf{BoolSourceSpec}(w) \wedge ((v =
\end{aligned}$$

For marks $v, w : \mathsf{BMark}$ and endpoint-history witnesses $e_v, e_w : \mathsf{BHist}$ satisfying the displayed constructor equations

$$\begin{aligned}
&((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e}))),\\
&((w = \mathsf{b0} \wedge e_w = \mathsf{e}) \vee (w = \mathsf{b1} \wedge e_w = \mathsf{E1}(\mathsf{e}))),
\end{aligned}$$

the endpoint-agreement part is exactly

$$\mathsf{msame}(v, w) \iff \mathsf{hsame}(e_v, e_w).$$

The endpoint witnesses are precisely the same visible endpoint rows as the public false and true constructor rows: $v = \mathsf{b0}$ carries $e_v = \mathsf{e}$, and $v = \mathsf{b1}$ carries $e_v = \mathsf{E1}(\mathsf{e})$, with the same alternatives for w, e_w. Thus any displayed forward carrier, classifier, endpoint-agreement, or constructor-readback implication in the local chapter has its reverse implication on the same finite rows.

The remaining displayed directions in the local public-surface discussion are one-way interpretation boundaries. Erasing constructor-row names, endpoint-table names, and public-surface annotations maps a public constructor read to the carrier, classifier, core $\mathsf{NameCert}$, and public semantic certificate rows, but those retained rows do not reconstruct the erased names or annotations.

The no-hidden-leakage row is also one-way: it excludes host propositions, decidable predicates, eliminators, truth-table-completeness data, payload carriers, payload classifiers, option-packaging rows, separate source-side constructor carriers, result rows, termination rows, and continuation rows from the public endpoint surface, and no reverse implication is claimed from their absence to any additional public constructor structure.

Proof. The carrier row is already two-sided by Definition 32.5. Its forward direction reads a Bool carrier history as one of the two endpoint histories, witnessed by some $e_v : \mathsf{BHist}$ satisfying $(v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e}))$; its reverse direction repacks the same endpoint readback witness as $\mathsf{BoolHistoryCarrier}(h)$. Since Definition 32.70 displays only the two constructor histories e and $\mathsf{E1}(\mathsf{e})$, this carrier equivalence has no third public endpoint row.

The classifier row is two-sided by Definition 32.13. The forward implication exposes source-qualified marks v, w, endpoint-history witnesses e_v, e_w with their constructor equations, and the mark comparison $\mathsf{msame}(v, w)$. The reverse implication rebuilds $\mathsf{BoolHistoryClassifier}(h, k)$ from exactly those rows. The more explicit constructor-row version is Definition 32.75, which identifies the endpoint witnesses through the two displayed constructor histories e and $\mathsf{E1}(\mathsf{e})$.

Endpoint agreement is two-sided by Definition 32.4. The case-readback theorem Definition 32.71 then says that a public constructor read is classified by exactly one of the displayed false and true endpoint rows, represented by an endpoint-history witness e_v with its constructor equation, while Definition 32.6 makes the chosen mark unique up to msame. Hence the visible constructor readback direction is completed by the same endpoint-history witnesses, constructor equations, and mark-comparison rows, not by a host proposition or by an external equivalence carrier.

It remains to identify the directions that are not equivalences. The forgetful projection of Definition 32.74 deliberately erases constructor-row names, endpoint-table names, and public-surface annotations. Its target rows are the retained carrier, classifier, $\mathsf{NameCert}$, and public semantic certificate rows fixed by Definition 32.40, Definition 32.39, and Definition 32.42; those rows remember the endpoint-history witness and classifier comparison, not the erased presentation names. This is therefore a one-way interpretation boundary.

The negative rows are one-way for the same local reason. By Definition 32.72, the public surface exposes no host proposition, decidable predicate, eliminator, or truth-table-completeness row. By Definition 32.76, the target-facing and source-facing reads are the same finite endpoint packet rather than separate constructor carriers, result rows, termination rows, or continuation rows. By Definition 32.77, every final consumer route factors through the finite endpoint packet and the Bool semantic certificate rows, while payload and option-packaging coordinates are rejected as unlisted. Thus the local chapter has no unmatched forward classifier or readback implication: the carrier, classifier, endpoint-agreement, and constructor-readback rows are completed by reverse implications on the same visible rows, and the projection and exclusion rows are recorded as one-way interpretation boundaries. □

Lemma 32.79 (Bool public endpoint substrate bisimulation boundary)**.** *The public Bool endpoint constructors of Definition 32.70 admit a substrate relation boundary, not a definitional-equality boundary. The BEDC-local relation certificate has source rows only from the displayed finite end-*

point packet

$$\begin{gathered}\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}, \quad \mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e}),\\ v, w : \mathsf{BMark}, \quad e_v, e_w : \mathsf{BHist},\\ ((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e}))), \quad ((w = \mathsf{b0} \wedge e_w = \mathsf{e}) \vee (w = \mathsf{b1} \wedge e_w = \mathsf{E1}(\mathsf{e}))),\\ \mathsf{hsame}(h, e_v), \quad \mathsf{hsame}(k, e_w), \quad \mathsf{msame}(v, w),\\ \mathsf{BoolHistoryCarrier}, \quad \mathsf{BoolHistoryClassifier}, \quad \mathsf{NameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier}),\\ \mathsf{SemanticNameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier}).\end{gathered}$$

Its forward leg sends a public endpoint read through $\mathsf{hsame}(h, e_v)$ *to the carrier row* $\mathsf{BoolHistoryCarrier}(h)$*. Its reverse leg reads every carrier row used by the Bool public surface back through one of the two displayed endpoint rows. Its comparison leg is the reflected equivalence*

$$\begin{aligned}\mathsf{BoolHistoryClassifier}(h, k) \quad \Longleftrightarrow \quad \exists v, w : \mathsf{BMark},\ e_v, e_w : \mathsf{BHist},\ & ((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e}))) \wedge\\ & ((w = \mathsf{b0} \wedge e_w = \mathsf{e}) \vee (w = \mathsf{b1} \wedge e_w = \mathsf{E1}(\mathsf{e}))) \wedge\\ & \mathsf{hsame}(h, e_v) \wedge \mathsf{hsame}(k, e_w) \wedge \mathsf{msame}(v, w).\end{aligned}$$

Thus a BHist*-facing reading of the public Bool endpoint surface is a substrate mirror, and any consumer that names a* Rule110*, cellular, binary, or* FKernel *substrate must state its use as a bisimulation or row-embedding relation whose Bool side is exactly the packet above. No such substrate name is available here as a definitional equality with the Bool public constructors. Any host coordinate, source coordinate, transition coordinate, external substrate row, result row, termination row, continuation row, payload row, option-packaging row, or equality row not listed in the packet is rejected at this boundary rather than silently identified with the Bool public surface.*

Proof. The local constructor source is exhausted by Definition 32.70: the only public endpoint rows are $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ and $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$. Applying Definition 32.71 to a public read supplies a displayed mark $v : \mathsf{BMark}$ and an endpoint history witness $e_v : \mathsf{BHist}$ in one of those two cases, together with the readback row $\mathsf{hsame}(h, e_v)$. The determinacy clause of Definition 32.6 prevents replacement of that mark by an unlisted host or substrate coordinate.

The carrier leg is exactly a mirror leg. By Definition 32.5, the endpoint readback row repacks as $\mathsf{BoolHistoryCarrier}(h)$, and every carrier row used by this Bool surface is covered by such an endpoint readback. Hence the relation runs in both directions between the public endpoint packet and the BHist carrier readback packet, but the two sides are not introduced as a single definitional object; they are the same displayed history read viewed through endpoint and carrier roles.

The comparison leg is the bisimulation clause. For two reads h, k with endpoint witnesses through v, w, Definition 32.12 identifies $\mathsf{BoolHistoryClassifier}(h, k)$ with the two endpoint readbacks and the mark comparison $\mathsf{msame}(v, w)$. The explicit endpoint-row form is the classifier alignment boundary of Definition 32.75. Thus classifier comparison is both preserved and reflected by the endpoint packet: endpoint mark agreement rebuilds the history classifier, and a history-classifier comparison exposes endpoint witnesses and mark agreement.

The certificate rows are fixed by Definition 32.74 and Definition 32.77. After constructor-row names, endpoint-table names, and public-surface annotations are erased, the retained rows are exactly the carrier, classifier, carrier-as-source-pattern-ledger, core NameCert, and public semantic certificate rows displayed in the statement. The target-source mirror theorem Definition 32.76 further says that the source-facing and target-facing reads are opposite views of the same finite endpoint packet, not separate constructor carriers.

Finally, the negative part follows from the same row exhaustion. Definition 32.72 excludes host propositions, decidable predicates, eliminators, and truth-table completeness from the public surface, while Definition 32.77 rejects unlisted source, result, termination, continuation, payload, and option-packaging coordinates. The chapter displays no Rule110, cellular, binary, or FKernel substrate row inside the Bool public endpoint constructors. Therefore any later consumer using one of those substrate names must provide its own target-side rows and relate them to the Bool packet by bisimulation, row embedding, or substrate mirror. The BEDC-local Bool boundary supplies no definitional equality from the public endpoint constructors to such a substrate. □

Theorem 32.80 (Bool finite-data exit route)**.** *The public* $\mathsf{Bool}^{\uparrow}$ *finite-data route consists exactly of the two endpoint constructor rows of Definition 32.70, the constructor case readback of Definition 32.71, the no-hidden-leakage boundary of Definition 32.72, and the semantic certificate scope of Definition 32.73. Any* $\mathsf{Option}^{\uparrow}$ *absent/present tag read,* $\mathsf{Prod}^{\uparrow}$ *sibling-lattice read, or* $\mathsf{List}^{\uparrow}$ *finite-data sibling route that consumes* $\mathsf{Bool}^{\uparrow}$ *passes through those rows and receives no host proposition, eliminator, decidable predicate, or truth-table completeness.*

Proof. The two constructor rows are the public endpoints displayed in Definition 32.70. The case readback theorem then says that every public endpoint read is one of those rows, with agreement measured by msame rather than by an external Boolean predicate.

The no-hidden-leakage theorem removes the extra host-logic surfaces from the public exit, while Definition 32.73 identifies the checked core and semantic certificate roles that remain available to downstream finite data consumers.

The consumer list is exactly the existing finite-data route through Definition 32.59, Definition 34.110, and Definition 36.214. These routes use the same endpoint rows as absent/present tags, product sibling coordinates, and list finite-data siblings; none adds a primitive Boolean object or a host truth-table principle. □

Lemma 32.81 (Bool public endpoint downstream coverage)**.** *Every accepted local consumer of the public Bool endpoint constructors is covered by the finite alternatives and ledger rows already displayed in this file. More precisely, after the consumer is reduced to its public endpoint readback and Bool certificate scope, its visible rows lie in the finite packet*

$$\begin{gathered}
\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}, \quad \mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e}), \\
v, w : \mathsf{BMark}, \quad e_v, e_w : \mathsf{BHist}, \\
((v = \mathsf{b0} \wedge e_v = \mathsf{e}) \vee (v = \mathsf{b1} \wedge e_v = \mathsf{E1}(\mathsf{e}))), \quad ((w = \mathsf{b0} \wedge e_w = \mathsf{e}) \vee (w = \mathsf{b1} \wedge e_w = \mathsf{E1}(\mathsf{e}))), \\
\mathsf{hsame}(h, e_v), \quad \mathsf{hsame}(k, e_w), \quad \mathsf{msame}(v, w), \\
\mathsf{BoolHistoryCarrier}, \quad \mathsf{BoolHistoryClassifier}, \quad \mathsf{NameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier}), \\
\mathsf{SemanticNameCert}(\mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryCarrier}, \mathsf{BoolHistoryClassifier}).
\end{gathered}$$

The alternatives outside this packet remain outside the Bool BEDC public surface: no host proposition, decidable predicate, eliminator, truth-table-completeness row, payload carrier, payload classifier, option-packaging row, separate source-side constructor carrier, result row, termination row, continuation row, external substrate row, or definitional-equality row is accepted as a downstream Bool endpoint constructor row.

Proof. Let a local downstream consumer be accepted by the public Bool endpoint constructor surface. By Definition 32.70, the only public constructor alternatives available at the entry point are $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ and $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$. Applying Definition 32.71 to the consumer read supplies a mark $v : \mathsf{BMark}$ and an endpoint-history witness $e_v : \mathsf{BHist}$ in one of those two

displayed cases, together with the readback row $\mathsf{hsame}(h, e_v)$. If the consumer compares two accepted reads, the same argument supplies $w : \mathsf{BMark}$, $e_w : \mathsf{BHist}$, and $\mathsf{hsame}(k, e_w)$.

The equivalence-completion boundary of Definition 32.78, read with the explicit transport theorems Definition 32.16 and Definition 32.34, then exhausts the possible downstream classifier data. For the carrier leg, Definition 32.5 gives the two endpoint witnesses displayed above, and Definition 32.16 is the transport citation that carries that endpoint witness along the readback row $\mathsf{hsame}(h, e_v)$ to the usable carrier row $\mathsf{BoolHistoryCarrier}(h)$. For the classifier leg, Definition 32.13 gives source-qualified marks, the two displayed constructor equations for e_v and e_w, the two endpoint readback rows, and the mark comparison $\mathsf{msame}(v, w)$; Definition 32.34 is the transport citation for moving this classifier row along the endpoint readbacks. For the endpoint-agreement leg, Definition 32.4 reduces comparison of endpoint histories to the same mark comparison, with the endpoint-readback movement again governed by Definition 32.34. Hence every accepted carrier, classifier, or agreement row used downstream is already one of the rows in the finite packet above.

The certificate scope contributes only the named Bool certificate rows. By Definition 32.73, the core NameCert over BoolHistoryCarrier and BoolHistoryClassifier and the public SemanticNameCert over the same carrier, pattern, ledger, and classifier roles are separate checked scopes, with $\mathsf{Bool}^{\uparrow}$ derived from mark and history sameness rather than primitive host truth. Thus a downstream consumer receives the carrier, classifier, core certificate, and public semantic certificate rows listed in the packet, and no additional Boolean object is introduced by the certificate citation.

The exclusion clause is the one-way side of the same local boundary. Definition 32.78 records that forgetful projection and no-hidden-leakage directions do not reconstruct erased constructor-row names, endpoint-table names, or public-surface annotations, and do not turn absence of host data into further public constructor structure. Together with Definition 32.72, Definition 32.77, and Definition 32.79, this rules out host propositions, decidable predicates, eliminators, truth-table completeness, payload and option coordinates, separate source, result, termination, continuation, substrate, and definitional-equality rows. Therefore the accepted local downstream consumer is exhausted by the finite alternatives, readback rows, classifier row, and certificate ledger rows displayed in this file, while every excluded alternative remains outside the Bool BEDC public endpoint packet. □

Theorem 32.82 (Bool CantorSpace endpoint route)**.** *Every displayed* $\mathsf{Bool}^{\uparrow}$ *endpoint row consumed by a* $\mathsf{CantorSpace}^{\uparrow}$ *finite prefix cylinder remains a* $\mathsf{Bool}^{\uparrow}$ *two-endpoint* NameCert *row after* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{List}^{\uparrow}$ *prefix transport. The route exports only the empty and one-step endpoint rows, their history classifier, the transported prefix position, and the local package ledger. It does not introduce a host Boolean, quotient stream equality, branch choice, or compactness claim.*

Proof. Start from the public endpoint surface of $\mathsf{Bool}^{\uparrow}$, where Definition 32.70 displays exactly the two rows e and $\mathsf{E1}(\mathsf{e})$. The case readback theorem Definition 32.71 fixes every public endpoint read to one of these rows, with agreement measured by msame and the endpoint classifier rather than by a host Boolean predicate.

The Cantor prefix consumer in chapter 1475 reads Boolean observations only through finite prefix cylinders. Its StreamName schedule is the window discipline of chapter 126, and its finite prefix spine is a list-indexed transport of displayed endpoint rows. Transport along that schedule changes the inspected position and the finite prefix ledger, not the two endpoint constructors supplied by $\mathsf{Bool}^{\uparrow}$.

Thus the transported row remains a $\mathsf{Bool}^{\uparrow}$ endpoint row after the CantorSpace prefix and StreamName/List bookkeeping have been attached. The no-hidden-leakage theorem Definition 32.72

excludes host Boolean structure, while the CantorSpace chapter supplies only the finite-prefix consumer route and not quotient streams, branch choices, or compactness. □

The $\mathsf{CantorSpace}^{\uparrow}$ finite-prefix surface consumes $\mathsf{Bool}^{\uparrow}$ as the finite endpoint ledger for each $\mathsf{StreamName}^{\uparrow}$ prefix window. The endpoint rows read through Definition 32.70, Definition 32.71, and Definition 32.82 supply only the empty and one-step Boolean histories attached to a displayed prefix coordinate.

Thus the dependency into chapter 1475 is a finite endpoint dependency: $\mathsf{CantorSpace}^{\uparrow}$ owns the prefix cylinder, stream schedule, list-indexed window, and local NameCert route, while $\mathsf{Bool}^{\uparrow}$ supplies the two visible endpoint rows consumed at each inspected coordinate. The route does not export host Boolean predicates, quotient stream equality, branch selection, fan-theorem compactness, open-cover compactness, or ambient product completeness.

Theorem 32.83 ($\mathsf{Bool}^{\uparrow}$ sibling carrier boundary)**.** *The two endpoint histories exported by* $\mathsf{Bool}^{\uparrow}$ *are consumed by* $\mathsf{Option}^{\uparrow}$ *as the nullable discriminator of chapter 33 and by* $\mathsf{Sum}^{\uparrow}$ *as the finite branch discriminator of chapter 35. The* $\mathsf{Bool}^{\uparrow}$ *packet exports only the two endpoint rows and their displayed classifier boundary; it exports no option payload carrier, sum payload carrier, nullable payload classifier, or tagged-sum classifier.*

Proof. Project the public endpoint surface of $\mathsf{Bool}^{\uparrow}$. Its exported rows are exactly the empty endpoint and the one-step endpoint, together with the classifier rows that distinguish those two histories.

The $\mathsf{Option}^{\uparrow}$ consumer reads the same two histories as absent and present tags before any payload row is inspected. The $\mathsf{Sum}^{\uparrow}$ consumer reads them as left and right branch tags before any branch payload row is inspected.

Because payload carriers and payload classifiers are supplied by the option and sum sibling chapters, no accepted $\mathsf{Bool}^{\uparrow}$ read can own those rows. The boundary therefore stops at the two endpoint histories and their finite discriminator role. □

Theorem 32.84 ($\mathsf{Bool}^{\uparrow}$ finite-data hub sibling route)**.** *The* $\mathsf{Bool}^{\uparrow}$ *endpoint rows feed* $\mathsf{Option}^{\uparrow}$ *constructor disjointness and* $\mathsf{Prod}^{\uparrow}$ *component projections through the same finite-data lattice. The* $\mathsf{Option}^{\uparrow}$ *route of chapter 33 reads the two endpoint rows as absent and present branch discriminators, while the* $\mathsf{Prod}^{\uparrow}$ *route of chapter 34 reads them as finite component selectors for product projections. Both consumers receive only the displayed* $\mathsf{Bool}^{\uparrow}$ *endpoint classifier, componentwise transport, replay, provenance, and local naming surface; neither receives host booleans, external equality, option payload data, product coordinate data, or product-pair equality from the* $\mathsf{Bool}^{\uparrow}$ *packet.*

Proof. Project the finite-data lattice already displayed by the $\mathsf{Bool}^{\uparrow}$ carrier. Its available rows are the two endpoint histories, the endpoint classifier, componentwise transport, continuation replay, provenance, and local naming certificate.

The $\mathsf{Option}^{\uparrow}$ sibling consumes only the endpoint distinction needed to separate absent and present constructors. Payload rows, nullable payload classifiers, and option equality remain owned by the option packet named in chapter 33.

The $\mathsf{Prod}^{\uparrow}$ sibling consumes the same finite distinction only as a component-facing selector. Product coordinate carriers, projection rows, and pair equality remain owned by the product packet named in chapter 34.

Thus the hub-level sibling route exports a finite dependency edge from $\mathsf{Bool}^{\uparrow}$ to both consumers without adding any non-Boolean payload, product structure, host equality, or external Boolean principle to the $\mathsf{Bool}^{\uparrow}$ packet. □

Theorem 32.85 (Bool finite-data bridge interface)**.** *The endpoint bridge of Definition 32.3, endpoint coverage, classifier endpoint exactness, constructor separation, semantic fields, and the certificate of Definition 32.42 form the bridge-ready finite-data interface from* $\mathsf{Bool}^{\uparrow}$ *to the standard two-endpoint Bool surface. Concretely, the interface consists of Definition 32.4, Definition 32.5, Definition 32.30, Definition 32.31, Definition 32.40, and Definition 32.42.*

Lean4 ✓ `BEDC.Derived.BoolUp.BoolUp StdBridge`

Proof. The endpoint bridge supplies the two visible endpoints, and Definition 32.4 identifies endpoint agreement with the kernel mark equality read by the Bool bridge.

Endpoint coverage follows from Definition 32.5. Classifier exactness and constructor separation are supplied by Definition 32.30 and Definition 32.31, so the two constructors are both covered and separated.

The semantic fields of Definition 32.40 and the public certificate of Definition 32.42 package the carrier, pattern, and ledger rows into the finite Bool surface. These are exactly the finite data a bridge layer may consume, without asserting a machine-checked standard bridge in this chapter. □

Closure status for $\mathsf{NameCert}_{\mathsf{Bool}^{\uparrow}}$**.**

Constructive story: A Boolean here is a single mark from the kernel's two-element mark type — b0 or b1 — with no further structure layered on top. Whichever mark you start from, you stay there: equality on this tiny type is literal identity, and the four basic facts about it (each mark equals itself, and b0 differs from b1, in either reading order) form the entire distinguishing pattern, with every visible mark being just the raw mark itself. Because the type has only two elements and identity on it is automatically an equivalence, the five name-certificate obligations — that the carrier admits at least one element, and that the classifier is reflexive, symmetric, transitive, and respected by the carrier — fall out together without further work. The signature gap of a Boolean token p collects those marks m for which the source-domain admits m, the signature relation pairs m with an answer mark and an evidence ledger, and the token-introduction relation maps that answer to p; once the trivial pattern and ledger machinery is chased away, this becomes just $m = p$. The chapter registers all of this under the name $\mathsf{Bool}^{\uparrow}$; nothing beyond the kernel's mark type and its equality enters, and full Boolean algebra — operations, eliminators, decidable predicates — stays explicitly outside this closure level.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Bool}^{\uparrow}}$, maturePackageClosed)

Scope closed: The public Bool surface covers the false and true endpoint constructors, constructor case readback, semantic certificate ledger, no-hidden-leakage statement, and Definition 32.85 as the mature finite-data bridge surface over the displayed mark and history classifiers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Bool}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.BoolUp.bool\_history\_semantic\_name\_certificate`

Bridge status: bridgeChecked

Not claimed: Full boolean algebra or proposition theory: boolean operations, eliminators, decidable predicates, truth-table completeness, and logic connectives as BEDC primitives.

Upgrade path: No further formal-axis upgrade remains for this bridge-checked chapter.

Lemma 32.86 (Bool finite-data classifier alignment boundary)**.** *For histories* $h, k : \mathsf{BHist}$*, the classifier side of the Bool finite-data bridge interface has the following exact alignment boundary:*

$$\mathsf{BoolHistoryClassifier}(h,k) \iff \exists v, w : \mathsf{BMark},\ \mathsf{BoolSourceSpec}(v) \wedge \mathsf{BoolSourceSpec}(w) \wedge \mathsf{hsame}(h, \mathsf{BoolEndpoint}$$

Under this equivalence, the transported displayed rows are precisely the two endpoint readback rows $\mathsf{hsame}(h, \mathsf{BoolEndpoint}(v))$ *and* $\mathsf{hsame}(k, \mathsf{BoolEndpoint}(w))$*, together with the mark-comparison row* $\mathsf{msame}(v, w)$*. The retained certificate rows are precisely the source, pattern, and ledger rows of Definition 32.40, all read as* $\mathsf{BoolHistoryCarrier}$*. Every row outside the interface listed in Definition 32.85 is forgotten by this alignment boundary; in particular, it exports no host proposition, decidable predicate, eliminator, truth-table-completeness row, payload carrier, payload classifier, or option-packaging row.*

Proof. The displayed equivalence is exactly Definition 32.13. Its forward direction says that a classifier comparison between h and k exposes only source-qualified endpoint marks v, w, the two endpoint readback rows, and the mark comparison $\mathsf{msame}(v, w)$. Its reverse direction says that those rows are already sufficient to rebuild the Bool history classifier comparison, so no additional classifier coordinate is consumed.

By Definition 32.3, the endpoint map has only the two visible target rows $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ and $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$. Endpoint coverage in Definition 32.5 supplies no third readback case, and constructor separation in Definition 32.31 prevents the two constructor rows from being identified by the classifier. Thus the readback part of the boundary transports exactly the displayed endpoint rows and their msame comparison.

The certificate part is fixed by Definition 32.40: source, pattern, and ledger are all the same predicate $\mathsf{BoolHistoryCarrier}$. The public semantic certificate in Definition 32.42 therefore retains only the carrier-classifier ledger named in Definition 32.85. Finally, Definition 32.72 rules out host propositions, decidable predicates, eliminators, and truth-table completeness, and the finite-data interface list contains no payload carrier, payload classifier, or option-packaging row. Those nonlisted rows are therefore forgotten rather than transported. □

Lemma 32.87 (Bool finite-data domain-codomain mirror boundary)**.** *In the finite-data bridge interface of Definition 32.85, the codomain-facing Bool read is the endpoint mirror of the domain-facing carrier read. Concretely, every public codomain read of the standard two-endpoint Bool surface is forced through one of the two rows* $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ *or* $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$*, and every such endpoint row is already a domain-side* $\mathsf{BoolHistoryCarrier}$ *row. Its observation, result, termination, and certificate data are therefore exactly the endpoint exactness row, endpoint coverage row, classifier endpoint exactness row, constructor separation row, semantic field row, and concrete semantic certificate row cited in Definition 32.85. There is no separate codomain carrier, codomain classifier, or codomain certificate row in this Bool finite-data bridge.*

Proof. Start with a public codomain read of the standard two-endpoint Bool surface. By Definition 32.70, the only public constructors of that surface are the two endpoint rows $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ and $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$. The readback theorem Definition 32.71 says that every public endpoint read is classified by exactly one of those rows, and that agreement of such rows is exactly mark agreement through msame.

Each of the two displayed endpoint rows is also a carrier row on the domain side. This is precisely the reverse direction of Definition 32.5: an endpoint witness $\mathsf{hsame}(h, \mathsf{BoolEndpoint}(v))$ repacks as $\mathsf{BoolHistoryCarrier}(h)$. The agreement comparison is not a codomain-specific classifier, because Definition 32.4 identifies endpoint agreement with msame on the underlying marks, while Definition 32.30 and Definition 32.31 say that the history classifier has exactly the two endpoint classes and cannot mix them.

It remains to identify the certificate side. The semantic fields in Definition 32.40 read source, pattern, and ledger all as $\mathsf{BoolHistoryCarrier}$, and Definition 32.42 supplies the public semantic certificate for that same carrier and classifier. Thus reversing attention from the domain read to the codomain read only renames the endpoint row being inspected. It does not create any extra carrier, classifier, ledger, result, termination, or certificate row beyond the finite packet already listed in Definition 32.85. □

Lemma 32.88 (Bool finite-data substrate bisimulation boundary)**.** *Let* Sub *be one of the substrate read names* $\mathsf{Rule110}$, $\mathsf{Cellular}$, Binary, $\mathsf{FKernel}$, *or raw* BHist. *Within the finite-data bridge interface of Definition 32.85, a consumer-facing read from* Sub *into* $\mathsf{Bool}^{\uparrow}$ *has only the following BEDC-local*

relation certificate. Its source is the named substrate read Sub*, its target is the Bool finite-data packet, its direction is*

$$\mathsf{Sub}\text{-}\textit{read} \longrightarrow \textit{displayed endpoint readback rows} \longrightarrow \mathsf{Bool}^{\uparrow}\text{-}\textit{consumer},$$

and its relation kind is substrate mirror with bisimulation comparison on the two endpoint observations. Concretely, for histories $h, k : \mathsf{BHist}$ *the observable comparison must factor through displayed marks* $v, w : \mathsf{BMark}$ *as*

$$\mathsf{BoolSourceSpec}(v) \wedge \mathsf{BoolSourceSpec}(w) \wedge \mathsf{hsame}(h, \mathsf{BoolEndpoint}(v)) \wedge \mathsf{hsame}(k, \mathsf{BoolEndpoint}(w)) \wedge \mathsf{msame}(v, w),$$

and this displayed relation is equivalent to $\mathsf{BoolHistoryClassifier}(h, k)$*. The retained certificate rows are precisely* BoolHistoryCarrier*,* BoolHistoryClassifier*,* BoolHistoryCarrier *as source, pattern, and ledger, and the semantic certificate of Definition 32.42. No accepted read may replace this mirror certificate by definitional equality between* Sub *and* $\mathsf{Bool}^{\uparrow}$*, by equality between a host substrate and the Bool carrier, or by an unlisted Rule110 state, cellular clock, cellular neighborhood, external binary trace, FKernel extension, FKernel continuation, FKernel package, FKernel gap, or raw* BHist *constructor coordinate.*

Proof. The finite-data interface is already enumerated in Definition 32.85. Its rows are endpoint bridge exactness, endpoint coverage, classifier endpoint exactness, constructor separation, the semantic fields, and the concrete semantic certificate. Thus a substrate-facing consumer has no independent row from which to read a Rule110 state, a cellular clock or neighborhood, an external binary trace, an FKernel extension, continuation, package, or gap coordinate, or a raw constructor identity for BHist.

The endpoint part of the certificate is forced by Definition 32.3: the only displayed target rows are $\mathsf{BoolEndpoint}(\mathsf{b0}) = \mathsf{e}$ and $\mathsf{BoolEndpoint}(\mathsf{b1}) = \mathsf{E1}(\mathsf{e})$. Endpoint coverage in Definition 32.5 says that every Bool history carrier read reaches one of those endpoint rows, and constructor separation prevents the two endpoint rows from being collapsed by the Bool classifier.

The comparison part is exactly the boundary in Definition 32.86. Its forward direction reads any $\mathsf{BoolHistoryClassifier}(h, k)$ comparison as source-qualified marks v, w, two endpoint readback rows $\mathsf{hsame}(h, \mathsf{BoolEndpoint}(v))$ and $\mathsf{hsame}(k, \mathsf{BoolEndpoint}(w))$, and the mark comparison $\mathsf{msame}(v, w)$. Its reverse direction rebuilds the Bool history classifier from precisely those rows. Hence the displayed endpoint observations are preserved and reflected by the same finite comparison row; this is a bisimulation boundary on the local Bool observations, not a definitional equality boundary between substrates.

The direction and mirror reading are fixed by Definition 32.87: a codomain-facing Bool read is the endpoint mirror of the domain-facing carrier read. Therefore a substrate read can be consumed only after it has been projected to the endpoint readback packet and then read through the Bool carrier and classifier rows. The semantic side contributes no extra substrate coordinate, because Definition 32.40 reads source, pattern, and ledger all as BoolHistoryCarrier, and Definition 32.42 certifies that same carrier and classifier.

Finally, Definition 32.72 excludes host propositions, decidable predicates, eliminators, and truth-table completeness, and the finite interface list contains none of the substrate-specific rows named in the statement. A receiving gate that re-reads the displayed rows must therefore reject any unlisted host or source coordinate. What remains is exactly the finite substrate mirror certificate above: source named by the incoming substrate read, target named by the Bool finite-data packet, direction through the displayed endpoint rows, and bisimulation comparison given by msame under the Bool history classifier. □

The nullable tag surface of $\mathsf{Option}^{\uparrow}$ is read through the finite $b0/b1$ sibling discipline of chapter 32; the child file records the payload and classifier obligations after that tag route is fixed.

Chapter 33

A Concrete Naming Certificate for $\mathsf{Option}^{\uparrow}$

This chapter separates two certificate scopes. The checked BEDC object is the nullable history envelope $\mathsf{OptionHistoryCarrier}_S(h) \equiv \mathsf{hsame}(h, \mathsf{e}) \vee S(h)$ together with the classifier endpoint relation carried by hsame. The constructor-tagged optional value interface for $\mathsf{Option}^{\uparrow}$ is a separate visible-tag certificate over a different carrier presentation; it is not a strict strengthening of the nullable envelope unless the bridge data of Definition 33.103 are supplied, with descent given by Theorem 33.104.

33.1 Roadmap template status

1. **Traditional target**: optional data with one absent value and present values over a source object.
2. **BEDC source**: any licensed source carrier A equipped with its existing name certificate.
3. **Carrier choice**: the typed $\mathsf{OptionCarrier}$ has none and some constructors, while the checked history carrier is the nullable envelope $\mathsf{OptionHistoryCarrier}_S(h) \equiv \mathsf{hsame}(h, \mathsf{e}) \vee S(h)$.
4. **Classifier choice**: the typed $\mathsf{OptionClassifierSpec}$ relates only matching option tags through the source classifier; $\mathsf{OptionHistoryClassifier}$ is the nullable-history classifier consisting of endpoint envelope-carrier witnesses and endpoint hsame. These classifiers live over different carriers unless $\mathsf{TaggedOptionToNullableBridge}(S, \sim_S)$ supplies Definition 33.103.
5. **Stability obligations**: typed optional carrier transport, typed absent/present separation, lifted typed classifier symmetry and transitivity, nullable-history endpoint transport, nullable-history classifier symmetry and transitivity, and for the constructor-tagged optional-history certificate a payload coherence condition converting source-carrier hsame between middle payloads into the source classifier.
6. **Ledger**: the typed option interface records the absent-or-present tag and present payload evidence, while the checked nullable-history envelope ledger records only the raw envelope-carrier witness and the raw-to-visible hsame link.
7. **Core theorem list**: typed carrier cases, typed absent/present no-confusion, present inversion, typed classifier equivalence, tagged same-tag exactness, tagged mixed-tag separation, source-

compatibility for the tagged semantic target, nullable-history carrier transport, nullable-history classifier transport, and the nullable-history semantic certificate.

8. **Exactness predicate**: matching-tag exactness belongs to OptionClassifierSpec; the tagged history classifier has same-tag exactness through visible absent and present endpoints plus mixed-tag separation, while the checked nullable-history classifier exactness is endpoint envelope membership plus endpoint hsame and carries no present constructor tag. The tagged exactness clauses do not by themselves produce nullable envelope membership for a visible present endpoint.

9. **Standard bridge**: the checked nullable envelope has only empty-or-source endpoint readback. Ordinary none and some(a) readback belongs to the typed and tagged option interface under TaggedOptionHistoryCarrier, TaggedOptionHistoryClassifier, same-tag exactness, mixed-tag separation, and the tag-plus-source ledger; using that readback as nullable-envelope evidence is exactly the descent of Theorem 33.104.

10. **Status**: Theorem 33.98 is the checked nullable empty-or-source envelope only; Theorem 33.44 is the Phase Finite Data constructor-tagged $\mathsf{Option}^{\uparrow}$ CheckedCert under a source NameCert and TaggedOptionSourceHsameCompatible; comparison with the nullable carrier presentation uses Definition 33.103.

33.2 Carrier definition

Definition 33.1 (Option carrier)**.** *For a licensed source carrier A, define an inductive carrier with constructors* none *and* some(a)*.*

Lean4 ✓ `BEDC.Derived.OptionUp.OptionCarrier cases`

The checked BEDC-history carrier used below is the nullable semantic carrier $\mathsf{OptionHistoryCarrier}_S(h) \equiv \mathsf{hsame}(h, \mathsf{e}) \vee S(h)$, not a tagged history carrier.

33.3 The certificate

Definition 33.2 (Option source specification)**.** *There are two source scopes. For the checked nullable-history certificate, the source input is a BEDC history predicate $S : \mathsf{BHist} \to \mathsf{Prop}$ and $\mathsf{OptionHistoryCarrier}_S(h)$ is exactly the empty-or-source envelope $\mathsf{hsame}(h, \mathsf{e}) \vee S(h)$. A source* NameCert *belongs only to the typed and constructor-tagged option interface used later in Theorem 33.44; it is not part of the checked nullable-envelope definition displayed here.*

Lean4 (definition) `BEDC.Derived.OptionUp.OptionHistoryCarrier`

Theorem 33.3 (Option Bool tag sibling route)**.** *The constructor-tagged $\mathsf{Option}^{\uparrow}$ interface reads its absent/present tag through the finite $\mathsf{Bool}^{\uparrow}$ tag discipline of chapter 32 before applying the nullable envelope bridge. The checked nullable envelope remains empty-or-source history data: its rows are the $\mathsf{hsame}(h, \mathsf{e})$ absent branch, the source branch $S(h)$, endpoint* hsame *transport, and the local envelope classifier, not an additional Boolean coordinate.*

Proof. Project the source specification of Definition 33.2. It separates the typed and constructor-tagged option interface from the checked nullable-history carrier $\mathsf{OptionHistoryCarrier}_S(h) \equiv \mathsf{hsame}(h, \mathsf{e}) \vee S(h)$.

Read the constructor-tagged interface first. Its absent and present alternatives require a finite tag row, and that sibling row is supplied by the $\mathsf{Bool}^{\uparrow}$ discipline of chapter 32. The tag is consumed before any descent to the nullable envelope.

Finally apply the nullable bridge boundary named in the same source specification. The bridge may translate a visible absent/present read into empty-or-source history evidence, but the checked nullable envelope still records only the envelope witness and its hsame transport. Thus the Bool sibling route classifies the tagged presentation without becoming a new nullable-envelope coordinate. □

Theorem 33.4 (Option history carrier transport)**.** *If h and k are internally history-same, membership of h in* $\mathsf{OptionHistoryCarrier}_S$ *transports to membership of k in the same carrier. In the source branch this does not assume that an arbitrary source classifier is stable under* hsame*; it uses the checked identity characterization of history-sameness on* BHist*,* BEDC.FKernel.Hist.hsame_iff_eq*.*

Proof. Invert the optional carrier witness. In the absent branch, use only symmetry and transitivity of hsame: reverse the displayed $\mathsf{hsame}(h, k)$ link and compose it with the stored $\mathsf{hsame}(h, \mathsf{e})$ witness. In the source branch, convert the displayed $\mathsf{hsame}(h, k)$ witness via BEDC.FKernel.Hist.hsame_iff_eq, rewrite the endpoint, and transport the stored predicate witness from $S(h)$ to $S(k)$. The exported nullable classifier remains exactly $\mathsf{OptionHistoryCarrier}_S(h) \wedge \mathsf{OptionHistoryCarrier}_S(k) \wedge \mathsf{hsame}(h, k)$, so this proof does not export identity reflection as a public equality principle for $\mathsf{Option}^{\uparrow}$. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryCarrier hsame transport`

Theorem 33.5 (Option history carrier unary prefix closure)**.** *Let p, h : BHist. If p is a unary history and* $\mathsf{OptionHistoryCarrier}_{\mathsf{UnaryHistory}}(h)$ *holds, then*

$$\mathsf{OptionHistoryCarrier}_{\mathsf{UnaryHistory}}(\mathsf{append}(p, h))$$

holds.

Proof. Split the nullable carrier witness for h. In the absent branch, transport the empty unary-history witness along $\mathsf{hsame}(\mathsf{e}, h)$ and close by unary closure under append with the prefix p. In the source branch, the source witness is already a unary-history witness for h, and unary append closure again gives the carrier witness for $\mathsf{append}(p, h)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryCarrier unary prefix closed`

Theorem 33.6 (Option history carrier unary suffix closure)**.** *Let p, h : BHist. If p is a unary history and* $\mathsf{OptionHistoryCarrier}_{\mathsf{UnaryHistory}}(h)$ *holds, then*

$$\mathsf{OptionHistoryCarrier}_{\mathsf{UnaryHistory}}(\mathsf{append}(h, p))$$

holds.

Proof. Split the nullable carrier witness for h. In the absent branch, transport the empty unary-history witness along $\mathsf{hsame}(\mathsf{e}, h)$ and close by unary closure under append with the suffix p. In the source branch, the source witness is already a unary-history witness for h, and unary append closure again gives the carrier witness for $\mathsf{append}(h, p)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryCarrier unary suffix closed`

Theorem 33.7 (Option history carrier unary append context equivalence)**.** *Let p, q, h : BHist. If p and q are unary histories, then nullable unary option carrier membership is invariant under placing p on the left and q on the right:*

$$\mathsf{OptionHistoryCarrier}_{\mathsf{UnaryHistory}}(\mathsf{append}(p, \mathsf{append}(h, q))) \iff \mathsf{OptionHistoryCarrier}_{\mathsf{UnaryHistory}}(h).$$

Proof. Split the nullable carrier. In the absent branch, two applications of append_eq_empty_iff recover the uncloaked empty endpoint. In the source branch, apply the unary append context middle equivalence. The reverse direction either rebuilds the contextual unary carrier from an empty middle endpoint or closes the source unary witness under the same two append contexts. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryCarrier unary append context iff`

Theorem 33.8 (Option history classifier unary prefix closure)**.** *Let p, h, k : BHist. If p is unary and* $\mathsf{OptionHistoryClassifier}_{\mathsf{UnaryHistory}}(h, k)$ *holds, then the nullable option classifier is preserved by placing p on the left:*

$$\mathsf{OptionHistoryClassifier}_{\mathsf{UnaryHistory}}(\mathsf{append}(p, h), \mathsf{append}(p, k)).$$

Proof. Unpack the nullable classifier into the two endpoint carrier witnesses and the stored $\mathsf{hsame}(h, k)$ link. Apply the unary-prefix carrier closure to both endpoints. The remaining classifier field is the prefixed endpoint sameness, obtained by eliminating the $\mathsf{hsame}(h, k)$ witness. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier unary prefix closed`

Theorem 33.9 (Option history classifier unary suffix closure)**.** *Let p, h, k : BHist. If p is unary and* $\mathsf{OptionHistoryClassifier}_{\mathsf{UnaryHistory}}(h, k)$ *holds, then the nullable option classifier is preserved by placing p on the right:*

$$\mathsf{OptionHistoryClassifier}_{\mathsf{UnaryHistory}}(\mathsf{append}(h, p), \mathsf{append}(k, p)).$$

Proof. Unpack the nullable classifier into the two endpoint carrier witnesses and the stored $\mathsf{hsame}(h, k)$ link. Apply the unary-suffix carrier closure to both endpoints. The remaining classifier field is the suffixed endpoint sameness, obtained by eliminating the $\mathsf{hsame}(h, k)$ witness. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier unary suffix closed`

Definition 33.10 (Option pattern specification)**.** *The pattern is absent-or-present generation: one null constructor and one wrapper constructor over source witnesses.*

Lean4 (definition) `BEDC.Derived.OptionUp.OptionHistoryPattern`
Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryPattern carrier iff`

Definition 33.11 (Option classifier specification)**.** *The typed classifier relates* none *only to* none*, and relates* $\mathsf{some}(a)$ *to* $\mathsf{some}(a')$ *exactly when the source classifier relates a and a'. The checked history-level classifier for* OptionHistoryCarrier *is the nullable classifier: both endpoints lie in the empty-or-source envelope, and the endpoints are related by* hsame*.*

Lean4 (definition) `BEDC.Derived.OptionUp.OptionClassifierSpec`

Theorem 33.12 (Option history carrier source monotonicity)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be source predicates. If* $\forall h.\ S(h) \to T(h)$*, then for every* $h : \mathsf{BHist}$*,* $\mathsf{OptionHistoryCarrier}_S(h)$ *implies* $\mathsf{OptionHistoryCarrier}_T(h)$*. Under the same hypothesis, for every* $h, k : \mathsf{BHist}$*,* $\mathsf{OptionHistoryClassifier}_S(h, k)$ *implies* $\mathsf{OptionHistoryClassifier}_T(h, k)$*.*

Proof. For the carrier clause, split the nullable carrier witness. The absent branch already supplies the same $\mathsf{hsame}(h, \mathsf{e})$ witness for the target envelope. In the source branch, apply the displayed implication to the stored $S(h)$ witness and obtain the required $T(h)$ witness.

For the classifier clause, unfold the nullable classifier data: both endpoints come with carrier witnesses and the classifier stores the same endpoint $\mathsf{hsame}(h, k)$ witness. Apply the carrier clause to the two endpoint carrier witnesses, and keep the stored $\mathsf{hsame}(h, k)$ witness unchanged. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistorySource monotonicity`

Definition 33.13 (Tagged option history carrier)**.** *For a BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, define* $\mathsf{TaggedOptionHistoryCarrier}_S(h)$ *by the two constructor-shaped cases:*

1. *absent:* $\mathsf{hsame}(h, \mathsf{e})$*;*
2. *present: there is a payload history* a *such that* $S(a)$ *and* $\mathsf{hsame}(h, \mathsf{E1}(a))$*.*

Lean4 (definition) `BEDC.Derived.OptionUp.TaggedOptionHistoryCarrier`

Theorem 33.14 (Tagged option history present exactness)**.** *For any BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and history* h*, a present endpoint in the tagged carrier is exactly a source payload at the visible present tag:*

$$\mathsf{TaggedOptionHistoryCarrier}_S(\mathsf{E1}(h)) \iff \exists a : \mathsf{BHist}.\ S(a) \wedge \mathsf{hsame}(h, a).$$

Proof. For the forward implication, case-analyze the tagged carrier witness for $\mathsf{E1}(h)$. The absent branch gives $\mathsf{hsame}(\mathsf{E1}(h), \mathsf{e})$ and is eliminated by generated-history no-confusion between a present endpoint and the empty endpoint. The present branch gives a payload history a, a source witness $S(a)$, and $\mathsf{hsame}(\mathsf{E1}(h), \mathsf{E1}(a))$; applying the one-constructor inversion theorem for hsame strips the visible present tags and yields $\mathsf{hsame}(h, a)$, so a is the required payload. Conversely, given a payload a with $S(a)$ and $\mathsf{hsame}(h, a)$, use the present branch of $\mathsf{TaggedOptionHistoryCarrier}_S$. The endpoint witness is $\mathsf{hsame}(\mathsf{E1}(h), \mathsf{E1}(a))$, obtained by applying $e1$ congruence to $\mathsf{hsame}(h, a)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryCarrier present exactness`

Theorem 33.15 (Tagged option history carrier present hsame readback)**.** *For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and histories* h, p*, if* h *inhabits the tagged option carrier and is history-same to the visible present endpoint* $\mathsf{E1}(p)$*, then the visible payload reads back to a source payload:*

$$\mathsf{TaggedOptionHistoryCarrier}_S(h) \wedge \mathsf{hsame}(h, \mathsf{E1}(p)) \Longrightarrow \exists a : \mathsf{BHist}.\ S(a) \wedge \mathsf{hsame}(p, a).$$

Proof. Case-analyze the tagged option carrier witness for h. The absent branch gives $\mathsf{hsame}(h, \mathsf{e})$; composing its symmetry with $\mathsf{hsame}(h, \mathsf{E1}(p))$ would make e history-same to a present endpoint, contradicting generated-history no-confusion. The present branch gives a payload a with $S(a)$ and $\mathsf{hsame}(h, \mathsf{E1}(a))$. Composing symmetry of $\mathsf{hsame}(h, \mathsf{E1}(p))$ with this endpoint witness yields $\mathsf{hsame}(\mathsf{E1}(p), \mathsf{E1}(a))$, and one-constructor inversion gives $\mathsf{hsame}(p, a)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryCarrier present hsame readback`

Theorem 33.16 (Tagged option history carrier present source transport)**.** *For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, assume* S *is stable along history sameness:*

$$\forall x\, y : \mathsf{BHist}.\ \mathsf{hsame}(x, y) \to S(x) \to S(y).$$

Then a tagged carrier witness at the visible present endpoint $\mathsf{E1}(h)$ *reads back to the source predicate at its displayed payload:*

$$\mathsf{TaggedOptionHistoryCarrier}_S(\mathsf{E1}(h)) \Longrightarrow S(h).$$

Proof. Apply Theorem 33.14 to the carrier witness at $\mathsf{E1}(h)$. It gives a payload a with $S(a)$ and $\mathsf{hsame}(h, a)$. Symmetry turns this into $\mathsf{hsame}(a, h)$, and the displayed source transport sends $S(a)$ to $S(h)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryCarrier present source transport`

Theorem 33.17 (Tagged option history carrier e1 source exactness)**.** *For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, assume* S *is stable along history sameness:*

$$\forall x\, y : \mathsf{BHist}.\ \mathsf{hsame}(x, y) \to S(x) \to S(y).$$

Then the visible present endpoint $\mathsf{E1}(h)$ *inhabits the tagged option carrier exactly when its displayed payload inhabits the source carrier:*

$$\mathsf{TaggedOptionHistoryCarrier}_S(\mathsf{E1}(h)) \Longleftrightarrow S(h).$$

Proof. The forward direction is the present-source readback above. For the reverse direction, use the present branch of the tagged option carrier with payload h, source witness $S(h)$, and reflexivity $\mathsf{hsame}(\mathsf{E1}(h), \mathsf{E1}(h))$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryCarrier e1 source iff`

For the finite-data certificate template, the traditional target is absent-vs-present option tags; the BEDC source is BHist with hsame; the carrier is TaggedOptionHistoryCarrier; no classifier participates in this obligation. The stability obligation is constructor no-confusion, the ledger exposes the visible tag, the core theorem is this disjointness lemma, exactness is absent/present separation, the standard bridge is none/some, and the site status is ProofTarget.

Lemma 33.18 (Tagged option history carrier constructor separation)**.** *For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, history* h*, and payload history* a*, an absent endpoint and a present endpoint cannot be witnessed by the same carrier endpoint:*

$$\mathsf{hsame}(h, \mathsf{e}) \wedge S(a) \wedge \mathsf{hsame}(h, \mathsf{E1}(a)) \quad \Longrightarrow \quad \bot.$$

Proof. Compose symmetry of $\mathsf{hsame}(h, \mathsf{e})$ with $\mathsf{hsame}(h, \mathsf{E1}(a))$ to obtain $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(a))$. BEDC generated-history no-confusion between the empty constructor and the one-step constructor eliminates this endpoint equality. The source witness $S(a)$ records that the present payload is a valid source history but is not needed for the constructor contradiction. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryCarrier constructor separation`

Definition 33.19 (Tagged option history classifier)**.** *For a BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and source classifier* $\sim_S$*, define* $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k)$ *by the two constructor-matching cases:*

1. *absent-absent:* $\mathsf{hsame}(h, \mathsf{e})$ *and* $\mathsf{hsame}(k, \mathsf{e})$*;*
2. *present-present: there are payload histories* a, b *such that* $S(a)$*,* $S(b)$*,* $a \sim_S b$*,* $\mathsf{hsame}(h, \mathsf{E1}(a))$*, and* $\mathsf{hsame}(k, \mathsf{E1}(b))$*.*

Definition 33.20 (Tagged option source hsame compatibility)**.** *For a BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and source classifier* $\sim_S$*, define* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$ *to be the property that for all payload histories* a, b*, if* $S(a)$*,* $S(b)$*, and* $\mathsf{hsame}(a, b)$*, then* $a \sim_S b$*.*

Lean4 (definition) `BEDC.Derived.OptionUp.TaggedOptionSourceHsameCompatible`

Theorem 33.21 (Tagged option history classifier endpoint carriers)**.** *For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, source classifier* $\sim_S$*, and histories* h, k*, if* $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k)$ *holds, then both* $\mathsf{TaggedOptionHistoryCarrier}_S(h)$ *and* $\mathsf{TaggedOptionHistoryCarrier}_S(k)$ *hold.*

Proof. Case-analyze the tagged classifier witness. The absent-absent branch stores $\mathsf{hsame}(h, \mathsf{e})$ and $\mathsf{hsame}(k, \mathsf{e})$, so the absent carrier clause rebuilds both endpoint carriers. The present-present branch stores payload histories a, b, source witnesses $S(a)$ and $S(b)$, the payload classifier witness $a \sim_S b$, and visible endpoint links $\mathsf{hsame}(h, \mathsf{E1}(a))$ and $\mathsf{hsame}(k, \mathsf{E1}(b))$. The two present carrier clauses reuse the corresponding payload histories, source witnesses, and endpoint links, so both classified endpoints are tagged option carrier endpoints. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier endpoint carriers`

Theorem 33.22 (Tagged option history classifier transitivity)**.** *For a BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and source classifier* $\sim_S$*, if* $\sim_S$ *is transitive, then* $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}$ *is transitive.*

Proof. Case-analyze the two tagged classifier witnesses. The absent/absent branch rebuilds the absent classifier branch. The mixed absent/present branches present the shared middle history both as e and as $\mathsf{E1}(a)$, so BEDC generated-history no-confusion eliminates them. In the present/present branch, the two endpoint witnesses for the shared middle history give $\mathsf{hsame}(\mathsf{E1}(b), \mathsf{E1}(c))$, and one-constructor inversion gives $\mathsf{hsame}(b, c)$. Transport along this equality identifies the middle payloads, and source-classifier transitivity composes the two payload classifier witnesses. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier trans`

Theorem 33.23 (Tagged option history classifier left confluence)**.** *For a BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and source classifier* $\sim_S$*, if* $\sim_S$ *is symmetric and transitive, then any two tagged option classifier witnesses with the same left endpoint compose to a classifier witness between their right endpoints:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k) \wedge \mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, r) \Longrightarrow \mathsf{TaggedOptionHistoryClassifier}_S$$

Proof. Reverse the first classifier witness using symmetry of the source classifier. The absent branch swaps the two empty endpoint witnesses. The present branch swaps the two tagged visible endpoints and applies symmetry to the payload classifier witness. The reversed classifier from k to h then composes with the classifier from h to r by tagged option classifier transitivity. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier left confluence`

Theorem 33.24 (Tagged option history classifier right confluence)**.** *For a BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$ and source classifier $\sim_S$, if $\sim_S$ is symmetric and transitive, then any two tagged option classifier witnesses with the same right endpoint compose to a classifier witness between their left endpoints:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k) \wedge \mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(r,k) \Longrightarrow \mathsf{TaggedOptionHistoryClassifier}_{S,}$$

Proof. Reverse the second classifier witness using symmetry of the source classifier. The absent branch swaps the empty endpoint witnesses, and the present branch swaps the tagged visible endpoints while reversing the payload classifier witness. The classifier from h to k then composes with the reversed classifier from k to r by tagged option classifier transitivity. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier right confluence`

Theorem 33.25 (Tagged option history present-present exactness)**.** *For a BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$, source classifier $\sim_S$, and histories h, k, the tagged option history classifier is exact on two visible present endpoints:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(\mathsf{E1}(h), \mathsf{E1}(k)) \quad \Longleftrightarrow \quad \exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge \mathsf{hsame}(h,a) \wedge \mathsf{hsame}(k,b) \wedge a \sim_S$$

Proof. For the forward direction, case-analyze the tagged classifier witness. The absent-absent branch would contain $\mathsf{hsame}(\mathsf{E1}(h), \mathsf{e})$ and is eliminated by one-versus-empty no-confusion. The present-present branch gives payload histories a, b, source witnesses $S(a)$ and $S(b)$, a source classifier witness $a \sim_S b$, and endpoint witnesses $\mathsf{hsame}(\mathsf{E1}(h), \mathsf{E1}(a))$ and $\mathsf{hsame}(\mathsf{E1}(k), \mathsf{E1}(b))$; one-constructor inversion strips the visible $e1$ tags and yields $\mathsf{hsame}(h,a)$ and $\mathsf{hsame}(k,b)$. For the reverse direction, the displayed payload data rebuilds the present-present classifier branch after applying one-constructor congruence for hsame to the two payload endpoint witnesses. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier present present exactness`

Theorem 33.26 (Tagged option history visible present exactness)**.** *For a BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$, source classifier $\sim_S$, a transitivity hypothesis*

$$\forall x\, y\, z.\ x \sim_S y \to y \sim_S z \to x \sim_S z,$$

and $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*, if $S(h)$ and $S(k)$, then the tagged option history classifier is exact on the two source-visible present endpoints:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(\mathsf{E1}(h), \mathsf{E1}(k)) \quad \Longleftrightarrow \quad h \sim_S k.$$

Proof. For the forward direction, apply Theorem 33.25 to the tagged classifier witness. It provides payload histories a, b, source witnesses $S(a)$ and $S(b)$, endpoint witnesses $\mathsf{hsame}(h,a)$ and $\mathsf{hsame}(k,b)$, and a payload classifier witness $a \sim_S b$. The compatibility hypothesis gives $h \sim_S a$ from $S(h)$, $S(a)$, and $\mathsf{hsame}(h,a)$; symmetry of hsame turns $\mathsf{hsame}(k,b)$ into $\mathsf{hsame}(b,k)$, and compatibility gives $b \sim_S k$ from $S(b)$, $S(k)$, and that symmetric endpoint witness. Two applications of the displayed transitivity hypothesis compose $h \sim_S a$, $a \sim_S b$, and $b \sim_S k$ into $h \sim_S k$.

For the reverse direction, use Theorem 33.25 with payloads h and k. The source witnesses are the assumptions $S(h)$ and $S(k)$, the endpoint witnesses are reflexivity of hsame at h and k, and the payload classifier witness is the assumed $h \sim_S k$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier visible present exactness`

Theorem 33.27 (Tagged option hsame source compatibility)**.** *For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*,*

$$\mathsf{TaggedOptionSourceHsameCompatible}(S, \mathsf{hsame})$$

holds.

Proof. Unfold Definition 33.20. Given payload histories a, b, source witnesses $S(a)$ and $S(b)$, and the displayed witness $\mathsf{hsame}(a, b)$, return that same history-sameness witness as the source classifier witness. □

Theorem 33.28 (Tagged option hsame present exactness)**.** *Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier and assume* $\mathsf{source_transport} : \forall x\, y : \mathsf{BHist}.\ \mathsf{hsame}(x, y) \to S(x) \to S(y)$*. For histories* h, k*,*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\mathsf{hsame}}(\mathsf{E1}(h), \mathsf{E1}(k)) \iff S(h) \wedge S(k) \wedge \mathsf{hsame}(h, k).$$

Proof. Apply Theorem 33.25 with source classifier hsame. In the forward direction, the exactness witness gives payload histories a, b, source witnesses $S(a)$ and $S(b)$, endpoint links $\mathsf{hsame}(h, a)$ and $\mathsf{hsame}(k, b)$, and a payload link $\mathsf{hsame}(a, b)$. Symmetry turns $\mathsf{hsame}(h, a)$ into $\mathsf{hsame}(a, h)$, so the first application of $\mathsf{source_transport}$ sends $S(a)$ to $S(h)$; symmetry turns $\mathsf{hsame}(k, b)$ into $\mathsf{hsame}(b, k)$, so the second application sends $S(b)$ to $S(k)$. Compose $\mathsf{hsame}(h, a)$, $\mathsf{hsame}(a, b)$, and the symmetric form of $\mathsf{hsame}(k, b)$ to obtain $\mathsf{hsame}(h, k)$. In the reverse direction, choose payloads h and k; the two source witnesses are displayed, the endpoint links are reflexivity of hsame, and the payload classifier witness is the displayed $\mathsf{hsame}(h, k)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier hsame present exactness`

Definition 33.29 (Tagged option history pattern)**.** *For a BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, the visible tag pattern* $\mathsf{TaggedOptionHistoryPattern}_S(h)$ *holds exactly when* h *is either an absent endpoint with* $\mathsf{hsame}(h, \mathsf{e})$ *or a present endpoint with payload history* a *satisfying* $S(a)$ *and* $\mathsf{hsame}(h, \mathsf{E1}(a))$*.*

Definition 33.30 (Tagged option history ledger)**.** *For a BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, the visible tag ledger* $\mathsf{TaggedOptionHistoryLedger}_S(h)$ *records the same two endpoint forms as certificate data: the absent record stores* $\mathsf{hsame}(h, \mathsf{e})$*, and the present record stores a payload history* a *together with* $S(a)$ *and* $\mathsf{hsame}(h, \mathsf{E1}(a))$*.*

Lean4 (definition) `BEDC.Derived.OptionUp.TaggedOptionHistoryLedger`

Theorem 33.31 (Tagged option history carrier, pattern, and ledger equivalence)**.** *For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and history* h*, the tagged option history carrier is equivalent to both visible certificate presentations:*

$$\mathsf{TaggedOptionHistoryCarrier}_S(h) \iff \mathsf{TaggedOptionHistoryPattern}_S(h)$$

and

$$\mathsf{TaggedOptionHistoryCarrier}_S(h) \iff \mathsf{TaggedOptionHistoryLedger}_S(h).$$

Proof. Unfold the three tagged option predicates. In the absent case, each presentation stores exactly the witness $\mathsf{hsame}(h, \mathsf{e})$, so the witness is reused unchanged in both directions. In the present case, each presentation stores the same payload history a together with $S(a)$ and $\mathsf{hsame}(h, \mathsf{E1}(a))$, so the same triple rebuilds the carrier, pattern, and ledger witnesses. The two cases exhaust the tagged option history carrier and the two visible certificate presentations. □

Theorem 33.32 (Tagged option ledger present payload readback)**.** *Template role: traditional target present optional payload recovery; BEDC source* BHist *with* hsame*; carrier* TaggedOptionHistoryCarrier*; classifier unused for this readback; stability obligation carrier transport along* hsame *plus* e1 *inversion; ledger* TaggedOptionHistoryLedger*; core theorem visible present payload readback; exactness visible present endpoint gives a source payload witness; standard bridge* $\mathsf{some}(a)$*; status* ProofTarget*.*

For every BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$ *and histories* h, p*, if* $\mathsf{TaggedOptionHistoryLedger}_S(h)$ *and* $\mathsf{hsame}(h, \mathsf{E1}(p))$*, then the visible present endpoint reads back a source payload:*

$$\exists a : \mathsf{BHist}.\ S(a) \wedge \mathsf{hsame}(p, a).$$

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryLedger present payload readback`

Proof. Convert the ledger witness to a tagged carrier witness using Theorem 33.31. Transport that carrier witness across $\mathsf{hsame}(h, \mathsf{E1}(p))$ by Theorem 33.33. The resulting carrier witness at $\mathsf{E1}(p)$ is then inverted by Theorem 33.14, which exposes a payload history a with $S(a)$ and $\mathsf{hsame}(p, a)$. □

Theorem 33.33 (Tagged option history carrier transport)**.** *For any BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, if* $\mathsf{TaggedOptionHistoryCarrier}_S(h)$ *and* $\mathsf{hsame}(h, k)$*, then* $\mathsf{TaggedOptionHistoryCarrier}_S(k)$*.*

Proof. Case-analyze the tagged carrier witness for h. In the absent case, compose the symmetry of $\mathsf{hsame}(h, k)$ with the stored endpoint witness $\mathsf{hsame}(h, \mathsf{e})$ to obtain $\mathsf{hsame}(k, \mathsf{e})$, then rebuild the absent clause. In the present case, keep the same payload a and source witness $S(a)$. Compose the symmetry of $\mathsf{hsame}(h, k)$ with the stored endpoint witness $\mathsf{hsame}(h, \mathsf{E1}(a))$ to obtain $\mathsf{hsame}(k, \mathsf{E1}(a))$, then rebuild the present clause. □

Theorem 33.34 (Tagged option history classifier endpoint transport)**.** *For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, source classifier* $\sim_S$*, and histories* h, k, h', k'*, if*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k) \wedge \mathsf{hsame}(h, h') \wedge \mathsf{hsame}(k, k')$$

holds, then

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h', k')$$

holds.

Proof. Case-analyze the tagged classifier witness for h and k. In the absent-absent branch, compose the symmetry of $\mathsf{hsame}(h, h')$ with the stored endpoint witness $\mathsf{hsame}(h, \mathsf{e})$ to obtain $\mathsf{hsame}(h', \mathsf{e})$, and compose the symmetry of $\mathsf{hsame}(k, k')$ with the stored endpoint witness $\mathsf{hsame}(k, \mathsf{e})$ to obtain $\mathsf{hsame}(k', \mathsf{e})$; these two witnesses rebuild the absent-absent classifier branch. In the present-present branch, keep the same payload histories a, b, source witnesses $S(a)$ and $S(b)$, and payload classifier witness $a \sim_S b$. Compose the symmetry of $\mathsf{hsame}(h, h')$ with the stored endpoint witness $\mathsf{hsame}(h, \mathsf{E1}(a))$ to obtain $\mathsf{hsame}(h', \mathsf{E1}(a))$, and compose the symmetry of $\mathsf{hsame}(k, k')$ with the stored endpoint witness $\mathsf{hsame}(k, \mathsf{E1}(b))$ to obtain $\mathsf{hsame}(k', \mathsf{E1}(b))$; these data rebuild the present-present classifier branch. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier hsame transport`

Theorem 33.35 (Tagged option history classifier stability fields)**.** *For a BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, source classifier* $\sim_S$*, and source certificate* $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$*, the following five clauses are exactly the non-inhabitation stability fields for the tagged option history carrier and classifier. Carrier inhabitation is the absent endpoint at* e *and is supplied separately in Theorem 33.44:*

1. *carrier-relative reflexivity: if* $\mathsf{TaggedOptionHistoryCarrier}_S(h)$ *holds, then* $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,h)$ *holds;*
2. *classifier symmetry: if* $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k)$ *holds, then* $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(k,h$ *holds;*
3. *classifier transitivity: if* $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k)$ *and* $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(k,u)$ *hold, then* $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,u)$ *holds;*
4. *classifier-induced carrier transport: if* $\mathsf{TaggedOptionHistoryCarrier}_S(h)$ *and* $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,$ *hold, then* $\mathsf{TaggedOptionHistoryCarrier}_S(k)$ *holds;*
5. *classifier endpoint transport: if* $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k)$, $\mathsf{hsame}(h,h')$, *and* $\mathsf{hsame}(k,k')$ *hold, then* $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h',k')$ *holds.*

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier stability fields`

Proof. For reflexivity, case-analyze the carrier witness. The absent case rebuilds the absent classifier branch from the stored empty endpoint witness and reflexivity, symmetry, and transitivity of hsame; the present case keeps the same payload and applies the reflexivity field of cert to the source carrier witness. For symmetry, case-analyze the tagged classifier witness. The absent branch reverses the stored endpoint links by symmetry of hsame, and the present branch reverses the payload classifier with cert.equiv_symm while swapping the two endpoint witnesses.

For transitivity, split the two classifier witnesses by their visible branches. In the absent/absent case, both witnesses expose the shared middle history as an empty endpoint, so transitivity of hsame composes the empty endpoint presentations and rebuilds the absent classifier branch from h to u. In the absent/present case, the first witness presents the middle history as e, while the second presents the same middle history as $\mathsf{E1}(b)$ for some source payload b; symmetry and transitivity of hsame give $\mathsf{hsame}(\mathsf{e},\mathsf{E1}(b))$, contradicting empty-versus-one no-confusion. In the present/absent case, the first witness presents the middle history as $\mathsf{E1}(b)$ and the second presents it as e, so the same no-confusion argument applies with the endpoints exchanged.

In the present/present case, the two middle present endpoint witnesses give $\mathsf{hsame}(\mathsf{E1}(b),\mathsf{E1}(b'))$. One-constructor inversion identifies the middle payload presentations, so the two adjacent source-classifier witnesses have a common middle source after this identification. The field cert.equiv_trans then composes those adjacent witnesses into the required endpoint source-classifier witness.

For carrier transport, case-analyze the classifier witness; the absent branch gives the empty endpoint carrier, and the present branch stores the target payload carrier directly. The classifier endpoint transport field is exactly Theorem 33.34. Same-tag exactness, right-absent exactness, and mixed constructor separation are isolated in Theorems 33.37, 33.38, and 33.40. □

Theorem 33.36 (Tagged option history classifier self exactness)**.** *This theorem fits the ten-field template with traditional target self-classification for constructor-tagged* $\mathsf{Option}^{\uparrow}$*, BEDC source* BHist *carrying a source* NameCert*, carrier* TaggedOptionHistoryCarrier*, classifier* TaggedOptionHistoryClassifier*, stability obligation carrier-relative reflexivity together with endpoint carrier exposure, ledger visible absent/present tag, core theorem self-exactness, exactness predicate the displayed iff, standard bridge* none/some *self-classification, and status* ProofTarget*. For a BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, source classifier* $\sim_S$*, source certificate* $\mathsf{cert} : \mathsf{NameCert}(S,\sim_S)$*, and history* h*, the tagged option classifier at equal endpoints is exactly the tagged option carrier:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,h) \iff \mathsf{TaggedOptionHistoryCarrier}_S(h).$$

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier self exactness`

Proof. For the forward direction, apply Theorem 33.21 to the self-classifier witness $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim}$. The endpoint-carrier pair has identical endpoints, so projecting the left carrier gives $\mathsf{TaggedOptionHistoryCarrier}_S(h)$. Equivalently, splitting the self-classifier by visible branch gives either the absent carrier witness $\mathsf{hsame}(h, \mathsf{e})$ or a present payload a with $S(a)$ and $\mathsf{hsame}(h, \mathsf{E1}(a))$.

For the reverse direction, split the carrier witness. An absent carrier witness builds the absent-absent classifier branch. A present carrier witness gives a, $S(a)$, and $\mathsf{hsame}(h, \mathsf{E1}(a))$; use the reflexivity field of cert on $S(a)$ to build the present-present self-classifier branch. This is item 1 of Theorem 33.35 under the source certificate cert. □

Theorem 33.37 (Tagged option history same-tag exactness)**.** *For a BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$ and source classifier $\sim_S$, the classifier $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}$ from Definition 33.19 is exact on equal visible tags:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(\mathsf{e}, k) \iff \mathsf{hsame}(k, \mathsf{e})$$

and

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(\mathsf{E1}(h), \mathsf{E1}(k)) \iff \exists a, b.\ S(a) \wedge S(b) \wedge \mathsf{hsame}(h, a) \wedge \mathsf{hsame}(k, b) \wedge a \sim_S b.$$

Proof. For the absent endpoint, case-analyze the tagged classifier. The absent-absent branch stores $\mathsf{hsame}(k, \mathsf{e})$, while the present-present branch would contain $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(a))$ and is eliminated by empty-versus-one no-confusion. Conversely, $\mathsf{hsame}(k, \mathsf{e})$ combines with reflexivity of $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$ to build the absent-absent classifier branch.

For the present endpoint, the absent-absent branch would contain $\mathsf{hsame}(\mathsf{E1}(h), \mathsf{e})$ and is eliminated by one-versus-empty no-confusion. The present-present branch gives payload histories a, b, source witnesses $S(a)$ and $S(b)$, a source classifier witness $a \sim_S b$, and endpoint witnesses $\mathsf{hsame}(\mathsf{E1}(h), \mathsf{E1}(a))$ and $\mathsf{hsame}(\mathsf{E1}(k), \mathsf{E1}(b))$; one-constructor inversion turns these endpoint witnesses into $\mathsf{hsame}(h, a)$ and $\mathsf{hsame}(k, b)$. Conversely, such payload data rebuilds the present-present classifier branch after applying the one-constructor congruence for hsame to the two payload endpoint witnesses. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier same tag exactness`

Theorem 33.38 (Tagged option history right absent exactness)**.** *For every BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$, source classifier $\sim_S$, and history h, the tagged option history classifier has the exact right absent endpoint:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, \mathsf{e}) \iff \mathsf{hsame}(h, \mathsf{e}).$$

Proof. For the forward direction, case-analyze the tagged classifier witness. The absent-absent branch directly provides the endpoint witness $\mathsf{hsame}(h, \mathsf{e})$. The present-present branch would force $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(b))$ for some source payload b, contradicting BEDC history no-confusion between the empty endpoint and a one-extension endpoint. For the reverse direction, combine the assumed $\mathsf{hsame}(h, \mathsf{e})$ with reflexivity of hsame at e and rebuild the absent-absent classifier branch. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier right absent exactness`

Theorem 33.39 (Tagged option history left absent exactness)**.** *For every BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$, source classifier $\sim_S$, and history k, the tagged option history classifier has the exact left absent endpoint:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(\mathsf{e}, k) \iff \mathsf{hsame}(k, \mathsf{e}).$$

Proof. Case-analyze the tagged classifier witness. The absent-absent branch directly stores $\mathsf{hsame}(k, \mathsf{e})$. The present-present branch would force $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(a))$ for a source payload a, contradicting BEDC history no-confusion between the empty endpoint and a one-extension endpoint. Conversely, pair $\mathsf{hsame}(k, \mathsf{e})$ with reflexivity of hsame at e and build the absent-absent branch. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier left absent exactness`

Theorem 33.40 (Tagged option history mixed-tag separation)**.** *For every BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$, source classifier $\sim_S$, and histories h, k, both mixed constructor cases are impossible:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(\mathsf{e}, \mathsf{E1}(k)) \to \bot$$

and

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(\mathsf{E1}(h), \mathsf{e}) \to \bot.$$

Proof. Case-analyze the tagged classifier witness. For $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(\mathsf{e}, \mathsf{E1}(k))$, the absent-absent branch forces $\mathsf{hsame}(\mathsf{E1}(k), \mathsf{e})$, while the present-present branch forces an endpoint witness from e to some $\mathsf{E1}(a)$. Both contradict BEDC history no-confusion between empty and one-extension constructors. The case $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(\mathsf{E1}(h), \mathsf{e})$ is identical with the visible endpoints exchanged: the absent-absent branch forces $\mathsf{hsame}(\mathsf{E1}(h), \mathsf{e})$, and the present-present branch forces an endpoint witness from e to a present endpoint. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier mixed tag separation`

Theorem 33.41 (Tagged option history carrier-level mixed-tag separation)**.** *This theorem fits the per-object template as follows: the traditional target is absent/present option tag separation; the BEDC source is* BHist *with* hsame*; the carrier is* $\mathsf{TaggedOptionHistoryCarrier}$*; the classifier is* $\mathsf{TaggedOptionHistoryClassifier}$*; the stability obligation is mixed-tag no-confusion under carrier presentations; the ledger is the visible tag; the core theorem is this separation; exactness is absent-vs-present impossibility; the standard bridge is none/some; and the status is* $\mathsf{ProofTarget}$*. For every BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$, source classifier $\mathsf{sameS} : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$, histories h, k, and payload history a, the classifier cannot relate endpoints that are merely presented as opposite tags:*

$$\mathsf{hsame}(h, \mathsf{e}) \to S(a) \to \mathsf{hsame}(k, \mathsf{E1}(a)) \to \mathsf{TaggedOptionHistoryClassifier}_{S,\mathsf{sameS}}(h, k) \to \bot$$

and

$$S(a) \to \mathsf{hsame}(h, \mathsf{E1}(a)) \to \mathsf{hsame}(k, \mathsf{e}) \to \mathsf{TaggedOptionHistoryClassifier}_{S,\mathsf{sameS}}(h, k) \to \bot.$$

Proof. Case-analyze the tagged classifier witness. In the first direction, the absent-absent branch stores an endpoint witness from k to e; composing it with the displayed witness from k to $\mathsf{E1}(a)$ gives empty-versus-one no-confusion. The present-present branch stores an endpoint witness from h to some $\mathsf{E1}(b)$; composing it with the displayed witness from h to e again gives empty-versus-one no-confusion. The second direction is symmetric: the absent-absent branch contradicts the displayed present presentation of h, and the present-present branch contradicts the displayed absent presentation of k. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier carrier mixed tag separation`

Theorem 33.42 (Tagged option history classifier visible-branch inversion)**.** *This theorem fits the per-object template as follows: the traditional target is tagged option branch inversion; the BEDC source is* BHist *with* hsame*; the carrier is* TaggedOptionHistoryCarrier*; the classifier is* TaggedOptionHistoryClassifier*; the stability obligation is branch determinism under visible endpoint presentations; the ledger is the visible absent/present tag plus payload; the core theorem is this inversion; exactness is no mixed branch and payload exposure; the standard bridge is* none/some*; and the status is* ProofTarget*. For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, source classifier* $\sim_S$*, and histories* h, k*, the classifier determines the visible branch presented by the left endpoint:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k) \to \mathsf{hsame}(h,\mathsf{e}) \to \mathsf{hsame}(k,\mathsf{e})$$

and, for every payload history a*,*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k) \to S(a) \to \mathsf{hsame}(h,\mathsf{E1}(a)) \to \exists a', b : \mathsf{BHist}.\ S(a') \wedge S(b) \wedge \mathsf{hsame}(a,a') \wedge a' \sim$$

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier visible branch inversion`

Proof. For the absent clause, case-analyze the tagged classifier witness. The absent-absent branch already stores $\mathsf{hsame}(k,\mathsf{e})$. The present-present branch stores $\mathsf{hsame}(h,\mathsf{E1}(a))$ for some source payload; composing it with the displayed witness $\mathsf{hsame}(h,\mathsf{e})$ gives empty-versus-one no-confusion.

For the present clause, case-analyze the classifier witness again. The absent-absent branch stores $\mathsf{hsame}(h,\mathsf{e})$ and contradicts the displayed present endpoint $\mathsf{hsame}(h,\mathsf{E1}(a))$. In the present-present branch, obtain payloads a' and b with $S(a')$, $S(b)$, $a' \sim_S b$, $\mathsf{hsame}(h,\mathsf{E1}(a'))$, and $\mathsf{hsame}(k,\mathsf{E1}(b))$. Compose the two presentations of h and invert the one-constructor equality to get $\mathsf{hsame}(a,a')$; the remaining fields are exactly the displayed witnesses. □

Theorem 33.43 (Tagged option classifier branch occupancy equivalence)**.** *This theorem fits the per-object template with traditional target tagged optional history branch occupancy, BEDC source* BHist *with* hsame*, carrier* TaggedOptionHistoryCarrier*, classifier* TaggedOptionHistoryClassifier*, stability obligation branch preservation, ledger visible absent/present occupancy, core theorem this equivalence, exactness constructor no-confusion, standard bridge* none/some*, and status* ProofTarget*. For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, source classifier* $\sim_S$*, histories* h, k*, and witness* $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k)$*, the visible branch occupancy is preserved:*

$$(\mathsf{hsame}(h,\mathsf{e}) \iff \mathsf{hsame}(k,\mathsf{e})) \wedge ((\exists a.\ S(a) \wedge \mathsf{hsame}(h,\mathsf{E1}(a))) \iff (\exists b.\ S(b) \wedge \mathsf{hsame}(k,\mathsf{E1}(b)))).$$

Proof. Case-analyze the tagged classifier witness. The absent-absent branch gives both empty endpoint witnesses and rules out either present endpoint by empty-versus-one no-confusion. The present-present branch projects the two source payload witnesses and their visible endpoint witnesses, and rules out either empty endpoint by the same no-confusion argument. □

Theorem 33.44 (Tagged option history semantic certificate target)**.** *Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *be a source carrier, let* $\sim_S$ *be a source classifier on source histories, and assume a source* $\mathsf{NameCert}(S, \sim_S$ *). Then* $\mathsf{SemanticNameCert}(\mathsf{TaggedOptionHistoryCarrier}_S, \mathsf{TaggedOptionHistoryCarrier}_S, \mathsf{TaggedOptionHistoryCarrier}$ *is the tagged option history semantic certificate.*

Proof. Inhabitation is supplied by the absent carrier witness at e. The five stability fields of the semantic certificate, namely carrier-relative reflexivity, classifier symmetry, classifier transitivity, classifier-induced carrier transport, and classifier endpoint transport, are exactly Theorem 33.35 under the source NameCert. The pattern and ledger soundness fields are identity projections because all three semantic certificate predicates are the tagged option history carrier. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryCarrier semanticNameCert`

Theorem 33.45 (Tagged option history visible semantic certificate)**.** *Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *be a source carrier, let* $\sim_S$ *be a source classifier on source histories, and assume a source* $\mathsf{NameCert}(S, \sim_S)$*. Then* $\mathsf{SemanticNameCert}(\mathsf{TaggedOptionHistoryCarrier}_S, \mathsf{TaggedOptionHistoryPattern}_S, \mathsf{TaggedOptionHistoryLedger}$ *holds.*

Proof. Apply Theorem 33.44 to obtain the carrier-only semantic certificate for the tagged option history carrier and classifier.

Keep the resulting core NameCert field unchanged. For the pattern and ledger soundness fields, apply Theorem 33.31: each carrier witness yields the visible tag pattern witness and the visible tag ledger witness. These three fields repack as the displayed SemanticNameCert. □

Theorem 33.46 (Tagged option classifier endpoint semantic fields)**.** *Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *be a source carrier, let Pattern and Ledger be predicates on BEDC histories, let* $\sim_S$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{SemanticNameCert}(\mathsf{TaggedOptionHistoryCarrier}_S, \mathit{Pattern}, \mathit{Ledger}, \mathsf{TaggedOptionHistoryClassifier}_S$ *be a semantic certificate. For histories* h, k*, every classifier witness* $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k)$ *supplies all four endpoint semantic fields:*

$$\mathit{Pattern}(h) \wedge \mathit{Ledger}(h) \wedge \mathit{Pattern}(k) \wedge \mathit{Ledger}(k).$$

Proof. Apply Theorem 33.21 to the classifier witness. This gives the endpoint carrier witnesses $\mathsf{TaggedOptionHistoryCarrier}_S(h)$ and $\mathsf{TaggedOptionHistoryCarrier}_S(k)$.

Apply the pattern_sound field of cert to each endpoint carrier witness to obtain $\mathit{Pattern}(h)$ and $\mathit{Pattern}(k)$. Apply the ledger_sound field of cert to the same two endpoint carrier witnesses to obtain $\mathit{Ledger}(h)$ and $\mathit{Ledger}(k)$, and assemble the four conclusions in the displayed order. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier endpoint semantic fields`

Corollary 33.47 (Tagged option history certificate over hsame)**.** *Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *be a source carrier. If a source* $\mathsf{NameCert}(S, \mathsf{hsame})$ *is supplied, then* $\mathsf{SemanticNameCert}(\mathsf{TaggedOptionHistoryCarrier}_S, \mathsf{TaggedO}$ *is the tagged option history semantic certificate with no separate compatibility hypothesis.*

Proof. First apply Theorem 33.44 with source classifier hsame to obtain the carrier-only semantic certificate.

The core NameCert field is reused unchanged. For the pattern and ledger soundness fields, apply Theorem 33.31: every carrier witness converts to the visible pattern witness and to the visible ledger witness. Repack these three fields as the displayed SemanticNameCert.

Apply Theorem 33.44 with source classifier hsame. The required compatibility input is exactly Theorem 33.27. □

Theorem 33.48 (Option standard bridge finite constructor surface)**.** *The public* $\mathsf{Option}^{\uparrow}$ *constructor surface consists exactly of the empty endpoint, the one-tag present endpoint, payload classifier transport, carrier-pattern-ledger equivalence, and the source* hsame *compatibility rows. In this surface, absence is represented only by histories presented as* e*, presence is represented only by histories presented as* $\mathsf{E1}(a)$ *for a source-admitted payload* a*, and the payload comparison exposed to a public consumer is precisely the transported source classifier row.*

No additional host option value, eliminator, recursion principle, or hidden branch coordinate is part of the public bridge. The absent and present rows are separated by constructor no-confusion, and the carrier, pattern, and ledger readings name the same finite two-branch history surface.

Proof. The tagged option semantic certificate is Corollary 33.47; it supplies the public carrier, pattern, ledger, and classifier over hsame.

Source compatibility is exactly Theorem 33.27. The carrier-pattern-ledger equivalence is Theorem 33.31, so a public endpoint has the same visible reading in all three rows.

The empty endpoint and one-tag present endpoint are isolated by the absent and present readback rows, while mixed presentations are excluded by Theorem 33.18 and Theorem 33.41. These no-confusion rows leave exactly the finite constructor surface stated above. □

Lean4 ✓ BEDC.Derived.OptionUp.OptionUp StdBridge

Theorem 33.49 (Tagged option public endpoint semantic scope)**.** *Let S : BHist → Prop be a source carrier, let $\sim_S$ be a source classifier on source histories, and assume a source* NameCert$(S, \sim_S)$*. The public* Option$^{\uparrow}$ *endpoint surface determined by this data consists exactly of the following finite information:*

1. *the empty absent endpoint, represented by* e *up to* hsame*;*
2. *the b1-tagged present endpoint, represented by* E1(a) *for a source payload a with $S(a)$;*
3. *the carrier, pattern, and ledger equivalence for the tagged option history surface;*
4. *the endpoint semantic fields obtained from* TaggedOptionHistoryClassifier$_{S,\sim_S}$*;*
5. *payload classifier transport through the present-present branch; and*
6. *the semantic certificate of Definition 33.44 and, for $\sim_S =$* hsame*, the certificate of Definition 33.47.*

No additional public endpoint data is supplied by a host 'Maybe' type, eliminators, a monad API, or a hidden payload projection.

Proof. The absent and present rows are the two constructor-shaped rows of TaggedOptionHistoryCarrier$_S$. The absent row is the empty BEDC history e up to hsame, and the present row is the one-mark BEDC history E1(a) with its source provenance $S(a)$.

Apply Theorem 33.31 to identify the carrier, pattern, and ledger descriptions row by row. The branch no-confusion theorems Definition 33.40 and Definition 33.41 rule out any mixed absent-present endpoint row.

For semantic data, apply Definition 33.46. This extracts the pattern and ledger fields on both classifier endpoints. Payload readback and transport are exactly the present endpoint rows supplied by Definition 33.15, Definition 33.16, and Definition 33.26.

It remains to justify that the list is exhaustive. A row of BHist satisfying the public carrier data is either the empty endpoint or a one-mark endpoint by the carrier rows; hsame only changes the chosen representative inside the same row; Cont uses the displayed classifier and therefore transports only along the same absent row or along a source-certified present payload row; and the source NameCert$(S, \sim_S)$ is the sole provenance for payload classification. Thus the public endpoint surface has exactly the six displayed components and nothing from a host option eliminator, monad interface, or payload projection outside the visible BEDC history. □

Theorem 33.50 (Option history classifier endpoint transport)**.** *If the optional history classifier relates h to k, and* hsame(h, h') *and* hsame(k, k')*, then it relates h' to k'.*

Proof. Unpack the classifier into its endpoint carrier witnesses and the stored hsame(h, k) link. Transport both carriers along the endpoint sameness links, then compose symmetry of hsame(h, h'), the stored link, and hsame(k, k'). □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier hsame transport`

Theorem 33.51 (Option history classifier symmetry)**.** *For any source predicate on BEDC histories, the optional history classifier is symmetric.*

Proof. Unpack the classifier into endpoint carrier witnesses and the stored $\mathsf{hsame}(h, k)$ link. Swap the endpoint witnesses and reverse the stored link by symmetry of hsame. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier symm`

Theorem 33.52 (Option history classifier transitivity)**.** *For every* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and* $h, k, r : \mathsf{BHist}$, $\mathsf{OptionHistoryClassifier}_S(h, k)$ *and* $\mathsf{OptionHistoryClassifier}_S(k, r)$ *imply* $\mathsf{OptionHistoryClassifier}_S(h, r)$.

Proof. Unpack the two classifier witnesses. The source and target carrier witnesses are preserved, and the underlying hsame links compose across the shared middle history. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier trans`

Theorem 33.53 (Option history classifier self exactness)**.** *For every BEDC history source predicate* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and every history* h*, the nullable option classifier at equal endpoints is exactly the nullable option carrier:*

$$\mathsf{OptionHistoryClassifier}_S(h, h) \iff \mathsf{OptionHistoryCarrier}_S(h).$$

Proof. The forward direction projects the left endpoint carrier from the classifier witness. For the reverse direction, use the displayed carrier witness for both endpoints and close the classifier equality field by reflexivity of hsame at h. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier self exactness`

Theorem 33.54 (Option history classifier empty left iff)**.** *For any source predicate on BEDC histories, the optional history classifier relates the empty history on the left to* k *exactly when* k *is history-same as the empty history.*

Proof. In the forward direction, unpack the classifier and reverse its stored $\mathsf{hsame}(\mathsf{e}, k)$ link. In the reverse direction, both endpoint carrier witnesses are supplied by the absent-history branch, and the classifier link is the symmetric form of the assumed $\mathsf{hsame}(k, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier empty left iff`

Corollary 33.55 (Option history classifier empty right iff)**.** *For any source predicate* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and any history* h*, this is the right-endpoint symmetry corollary of Theorem 33.54 and Theorem 33.51, not a separate finite-data certificate target:*

$$\mathsf{OptionHistoryClassifier}_S(h, \mathsf{e}) \iff \mathsf{hsame}(h, \mathsf{e}).$$

Proof. In the forward direction, apply classifier symmetry to reduce to $\mathsf{OptionHistoryClassifier}_S(\mathsf{e}, h)$, then use Theorem 33.54. In the reverse direction, use the reverse implication of Theorem 33.54 to obtain $\mathsf{OptionHistoryClassifier}_S(\mathsf{e}, h)$, then apply classifier symmetry. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier empty right iff`

Theorem 33.56 (Option history classifier empty endpoint equivalence)**.** *For any source predicate* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and histories* h, k*, if* $\mathsf{OptionHistoryClassifier}_S(h, k)$ *holds, then the two endpoints agree on absentness:*

$$\mathsf{hsame}(h, \mathsf{e}) \iff \mathsf{hsame}(k, \mathsf{e}).$$

Proof. Unpack the nullable option classifier into the two endpoint carrier witnesses and the stored endpoint equality $\mathsf{hsame}(h, k)$. The forward implication composes the symmetric stored equality with $\mathsf{hsame}(h, \mathsf{e})$. The reverse implication composes the stored equality with $\mathsf{hsame}(k, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier empty endpoint equivalence`

Definition 33.57 (Option source excludes empty)**.** *For a BEDC history source predicate* $S : \mathsf{BHist} \to \mathsf{Prop}$*,* $\mathsf{OptionSourceExcludesEmpty}(S)$ *means that every source history satisfying* S *is not history-same to the empty history:*

$$\mathsf{OptionSourceExcludesEmpty}(S) \quad :\iff \quad \forall h.\ S(h) \to \mathsf{hsame}(h, \mathsf{e}) \to \bot.$$

Lean4 (definition) `BEDC.Derived.OptionUp.OptionSourceExcludesEmpty`

Theorem 33.58 (Nullable option source transport exclusion)**.** *For any BEDC history source predicate* $S : \mathsf{BHist} \to \mathsf{Prop}$*, if* S *is closed under* hsame *transport and* $\mathsf{OptionSourceExcludesEmpty}(S)$ *holds, then a source history cannot transport along* $\mathsf{hsame}(h, k)$ *to a history* k *that is history-same to the empty history:*

$$S(h) \to \mathsf{hsame}(h, k) \to \mathsf{hsame}(k, \mathsf{e}) \to \bot.$$

Proof. Transport the source witness $S(h)$ across $\mathsf{hsame}(h, k)$ to obtain $S(k)$. The empty-exclusion predicate applied at k contradicts the displayed $\mathsf{hsame}(k, \mathsf{e})$ witness. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionSourceExcludesEmpty hsame transport absurd`

Theorem 33.59 (Nullable option absent-source separation)**.** *For any BEDC history source predicate* $S : \mathsf{BHist} \to \mathsf{Prop}$*, if* $\mathsf{OptionSourceExcludesEmpty}(S)$*,* $\mathsf{hsame}(h, \mathsf{e})$*, and* $S(h)$ *hold, then* $\bot$*.*

Proof. Apply the exclusion predicate to the source witness $S(h)$ and the displayed empty endpoint witness $\mathsf{hsame}(h, \mathsf{e})$. □

Per-object fit: traditional target nullable empty-or-source separation under an empty-excluding source, not constructor-tagged none/some readback; BEDC source BHist with hsame; carrier $\mathsf{OptionHistoryCarrier}_S$; classifier unused; status ProofTarget.

Theorem 33.60 (Nullable option carrier empty-or-source partition)**.** *For any BEDC history source predicate* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and history* h*, if* $\mathsf{OptionSourceExcludesEmpty}(S)$ *and* $\mathsf{OptionHistoryCarrier}_S(h)$ *hold, then*

$$(\mathsf{hsame}(h, \mathsf{e}) \wedge \neg S(h)) \vee (S(h) \wedge \neg \mathsf{hsame}(h, \mathsf{e})).$$

Proof. Case-analyze the carrier witness. In the empty branch, keep $\mathsf{hsame}(h, \mathsf{e})$ and use Theorem 33.59 to rule out $S(h)$. In the source branch, keep $S(h)$ and use the same theorem to rule out $\mathsf{hsame}(h, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryCarrier exclusive readback`

Theorem 33.61 (Nullable option absent iff not source)**.** *For any BEDC history source predicate* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and history* h*, if* $\mathsf{OptionSourceExcludesEmpty}(S)$ *and* $\mathsf{OptionHistoryCarrier}_S(h)$ *hold, then the absent branch is exactly the negation of the source branch:*

$$\mathsf{hsame}(h, \mathsf{e}) \iff \neg S(h).$$

Proof. For the forward implication, apply the empty-exclusion predicate to the source witness and the displayed empty endpoint. For the reverse implication, case-analyze the carrier witness: the empty branch gives $\mathsf{hsame}(h, \mathsf{e})$ directly, while the source branch contradicts the assumed negation of $S(h)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryCarrier absent not source iff`

Theorem 33.62 (Nullable option visible source exactness)**.** *For any BEDC history source predicate* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and history* h*, the nullable option carrier at a visible* $\mathsf{E1}$ *endpoint is exactly the source predicate at that same endpoint:*

$$\mathsf{OptionHistoryCarrier}_S(\mathsf{E1}(h)) \iff S(\mathsf{E1}(h)).$$

Proof. Unfold the nullable carrier into its empty-or-source disjunction. The empty branch would give $\mathsf{hsame}(\mathsf{E1}(h), \mathsf{e})$, contradicting constructor separation for $\mathsf{E1}$ and e. The remaining branch is exactly $S(\mathsf{E1}(h))$, and the reverse direction rebuilds the source side of the carrier disjunction. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryCarrier e1 source iff`

Theorem 33.63 (Nullable option classifier one-headed left source exactness)**.** *For any BEDC history source predicate* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and histories* h, k*, a nullable option classifier whose left endpoint is visibly one-headed is exactly the displayed source evidence for that endpoint, the right endpoint carrier, and the endpoint classifier:*

$$\mathsf{OptionHistoryClassifier}_S(\mathsf{E1}(h), k) \iff S(\mathsf{E1}(h)) \wedge \mathsf{OptionHistoryCarrier}_S(k) \wedge \mathsf{hsame}(\mathsf{E1}(h), k).$$

Proof. Unpack the classifier into its two endpoint carriers and stored $\mathsf{hsame}(\mathsf{E1}(h), k)$ link. The left carrier is converted by Theorem 33.62. Conversely, the displayed source evidence rebuilds the left carrier through the source branch, and the other two displayed fields repack the classifier. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier e1 left source iff`

Theorem 33.64 (Nullable option zero-headed source exactness)**.** *For any BEDC history source predicate* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and history* h*, the nullable option carrier at a zero-headed endpoint is exactly the source predicate at that endpoint:*

$$\mathsf{OptionHistoryCarrier}_S(\mathsf{E0}(h)) \iff S(\mathsf{E0}(h)).$$

Proof. Unfold the nullable carrier into its empty-or-source disjunction. The empty branch would give $\mathsf{hsame}(\mathsf{E0}(h), \mathsf{e})$, contradicting constructor separation for $\mathsf{E0}$ and e. The source branch is the displayed predicate, and the reverse direction rebuilds the source side of the carrier. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryCarrier e0 source iff`

Theorem 33.65 (Nullable option carrier branch alignment)**.** *For histories* h, k*, if* $\mathsf{OptionSourceExcludesEmpty}(S)$*,* $\mathsf{OptionHistoryCarrier}_S(h)$*,* $\mathsf{OptionHistoryCarrier}_S(k)$*, and* $\mathsf{hsame}(h, k)$ *hold, then either both endpoints are empty or both lie in the source branch:*

$$(\mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(k, \mathsf{e})) \vee (S(h) \wedge S(k)).$$

Proof. Case-analyze the two carrier witnesses. The empty–empty and source–source branches are immediate. In each mixed branch, transport the empty endpoint across $\mathsf{hsame}(h, k)$ and apply $\mathsf{OptionSourceExcludesEmpty}(S)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryCarrier hsame branch alignment`

Theorem 33.66 (Nullable option classifier exclusive readback)**.** *For any BEDC history source predicate* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and histories* h, k*, if* $\mathsf{OptionSourceExcludesEmpty}(S)$ *and* $\mathsf{OptionHistoryClassifier}_S(h, k)$ *hold, then either both endpoints are the empty option branch and neither endpoint lies in* S*,*

$$\mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(k, \mathsf{e}) \wedge \neg S(h) \wedge \neg S(k),$$

or both endpoints lie in the source branch, neither is empty, and the classifier keeps the endpoint equality:

$$S(h) \wedge S(k) \wedge \neg\mathsf{hsame}(h, \mathsf{e}) \wedge \neg\mathsf{hsame}(k, \mathsf{e}) \wedge \mathsf{hsame}(h, k).$$

Proof. Unpack the classifier into the two endpoint carrier witnesses and the displayed $\mathsf{hsame}(h, k)$ equality. Apply Theorem 33.60 to both endpoint carriers. The empty–empty and source–source cases give the two displayed alternatives. The mixed cases contradict $\mathsf{OptionSourceExcludesEmpty}(S)$ after transporting the empty readback across $\mathsf{hsame}(h, k)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier exclusive readback`

Theorem 33.67 (Option history classifier source-left exactness)**.** *For any BEDC history source predicate* $S : \mathsf{BHist} \to \mathsf{Prop}$*, if* $\mathsf{OptionSourceExcludesEmpty}(S)$ *and* $S(h)$ *hold, then the nullable option classifier from* h *to* k *is exactly source membership of* k *together with endpoint sameness:*

$$\mathsf{OptionHistoryClassifier}_S(h, k) \iff S(k) \wedge \mathsf{hsame}(h, k).$$

Proof. Unpack the classifier into endpoint carrier witnesses and the stored $\mathsf{hsame}(h, k)$ link. Since $S(h)$ excludes the empty branch, any empty carrier witness for k would transport across $\mathsf{hsame}(h, k)$ to contradict $\mathsf{OptionSourceExcludesEmpty}(S)$. Hence the right carrier is the source branch $S(k)$, and the stored classifier link supplies $\mathsf{hsame}(h, k)$. Conversely, $S(h)$ and $S(k)$ give the two source carrier branches, and the displayed $\mathsf{hsame}(h, k)$ link reassembles the classifier. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier source left exactness`

Theorem 33.68 (Option history classifier zero-headed left source exactness)**.** *For any BEDC history source predicate* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and histories* h, k*, the nullable option classifier from the zero-headed endpoint* $\mathsf{E0}(h)$ *to* k *is exactly source membership of the left endpoint together with the right carrier and endpoint sameness:*

$$\mathsf{OptionHistoryClassifier}_S(\mathsf{E0}(h), k) \iff S(\mathsf{E0}(h)) \wedge \mathsf{OptionHistoryCarrier}_S(k) \wedge \mathsf{hsame}(\mathsf{E0}(h), k).$$

Proof. Unpack the classifier into the two endpoint carrier witnesses and the stored hsame link. Apply Theorem 33.64 to the left carrier witness to read it as $S(\mathsf{E0}(h))$; the right carrier and endpoint link are already classifier fields. Conversely, the displayed three fields rebuild the classifier using the source side of the left carrier disjunction. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier e0 left source iff`

Theorem 33.69 (Option history classifier source-right exactness)**.** *For any BEDC history source predicate* $S : \mathsf{BHist} \to \mathsf{Prop}$*, if* $\mathsf{OptionSourceExcludesEmpty}(S)$ *and* $S(k)$ *hold, then the nullable option classifier from* h *to* k *is exactly source membership of* h *together with endpoint sameness:*

$$\mathsf{OptionHistoryClassifier}_S(h, k) \iff S(h) \wedge \mathsf{hsame}(h, k).$$

Proof. Unpack the classifier into endpoint carrier witnesses and the stored $\mathsf{hsame}(h, k)$ link. Since $S(k)$ excludes the empty branch, any empty carrier witness for h transports back across $\mathsf{hsame}(h, k)$ to contradict $\mathsf{OptionSourceExcludesEmpty}(S)$. Hence the left carrier is the source branch $S(h)$, and the stored classifier link supplies $\mathsf{hsame}(h, k)$. Conversely, $S(h)$ and $S(k)$ give the two source carrier branches, and the displayed $\mathsf{hsame}(h, k)$ link reassembles the classifier. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier source right exactness`

Theorem 33.70 (Nullable option classifier absent-source separation)**.** *For any BEDC history source predicate* $S : \mathsf{BHist} \to \mathsf{Prop}$*, if* $\mathsf{OptionSourceExcludesEmpty}(S)$ *and* $S(h)$ *hold, then both*

$$\neg\mathsf{OptionHistoryClassifier}_S(h, \mathsf{e})$$

and

$$\neg\mathsf{OptionHistoryClassifier}_S(\mathsf{e}, h)$$

hold.

Proof. For the right-empty classifier, use Corollary 33.55 to turn a classifier witness into $\mathsf{hsame}(h, \mathsf{e})$, then apply $\mathsf{OptionSourceExcludesEmpty}(S)$ to $S(h)$. For the left-empty classifier, use Theorem 33.54 to obtain the same $\mathsf{hsame}(h, \mathsf{e})$ witness and apply the same exclusion predicate. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier absent source separation`

Theorem 33.71 (Option classifier hsame symmetry)**.** *For typed option carrier values* $x, y : \mathsf{OptionCarrier}(\mathsf{BHist})$*, if* $\mathsf{OptionClassifierSpec}(\mathsf{hsame}, x, y)$ *holds, then* $\mathsf{OptionClassifierSpec}(\mathsf{hsame}, y, x)$ *holds.*

Proof. The proof case-analyzes typed none and some carrier values: the none–none branch returns the existing classifier witness, the mixed branches contradict the typed classifier clauses, and the some–some branch reverses the BEDC history witness by hsame symmetry. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionClassifierSpec hsame symm`

Theorem 33.72 (Option classifier hsame $e1$ map equivalence)**.** *For typed option carrier values* $x, y : \mathsf{OptionCarrier}(\mathsf{BHist})$*, mapping both visible payloads through the BEDC history constructor* E1 *preserves and reflects the specialized option classifier:*

$$\mathsf{OptionClassifierSpec}(\mathsf{hsame}, \mathsf{map}(\mathsf{E1}, x), \mathsf{map}(\mathsf{E1}, y)) \iff \mathsf{OptionClassifierSpec}(\mathsf{hsame}, x, y).$$

Proof. Case-analyze the two option endpoints. The none–none branch is unchanged, and the mixed branches contradict the typed classifier clauses. In the some–some branch, the forward direction uses injectivity of E1 up to hsame, and the reverse direction applies constructor congruence for E1. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionClassifierSpec hsame e1 map iff`

Theorem 33.73 (Option classifier hsame transport)**.** *For typed option carrier values* x, x', y, y' : OptionCarrier(BHist)*, if* OptionClassifierSpec(hsame, x, y)*,* OptionClassifierSpec(hsame, x, x')*, and* OptionClassifierSpe *hold, then* OptionClassifierSpec(hsame, x', y') *holds.*

Proof. Case-analyze the four option endpoints. Mixed none–some branches contradict one of the displayed classifier witnesses. The none–none branch reuses the existing typed classifier witness. In the some–some branch, compose hsame(x, x') symmetrically with hsame(x, y) and then with hsame(y, y'). □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionClassifierSpec hsame transport`

Theorem 33.74 (Option classifier hsame right determinacy)**.** *For histories* h, k, l : BHist*, if* OptionClassifierSpec(hsame, some(h), some(k)) *and* OptionClassifierSpec(hsame, some(h), some(l)) *hold, then* hsame(k, l) *holds.*

Proof. The two typed some–some classifier witnesses unfold to hsame(h, k) and hsame(h, l). Reverse the first witness by hsame symmetry and compose it with the second witness by hsame transitivity. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionClassifierSpec hsame right deterministic`

Theorem 33.75 (Option classifier hsame left determinacy)**.** *For histories* h, k, l : BHist*, if* OptionClassifierSpec(hsar *and* OptionClassifierSpec(hsame, some(l), some(k)) *hold, then* hsame(h, l) *holds.*

Proof. The two typed some–some classifier witnesses unfold to hsame(h, k) and hsame(l, k). Reverse the second witness by hsame symmetry and compose it with the first witness by hsame transitivity. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionClassifierSpec hsame left deterministic`

Theorem 33.76 (Option classifier hsame some-right confluence)**.** *For a typed option carrier value* x : OptionCarrier(BHist) *and histories* h, k : BHist*, if* OptionClassifierSpec(hsame, x, some(h)) *and* OptionClassifierSpec(hsame, x, some(k)) *hold, then* hsame(h, k) *holds.*

Proof. Case-analyze the shared endpoint x. If x is none, the first classifier witness is impossible because it relates none to a present endpoint. If $x =$ some(a), the two witnesses are hsame(a, h) and hsame(a, k); reverse the first and compose it with the second. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionClassifierSpec hsame some right confluence`

Theorem 33.77 (Option classifier hsame common-right confluence)**.** *For typed option carrier values* x, y : OptionCarrier(BHist) *and a history* a : BHist*, if both* x *and* y *classify to the same present endpoint,*

$$\text{OptionClassifierSpec}(\text{hsame}, x, \text{some}(a)) \quad \textit{and} \quad \text{OptionClassifierSpec}(\text{hsame}, y, \text{some}(a)),$$

then OptionClassifierSpec(hsame, x, y) *holds.*

Proof. Case-analyze x and y. Any none branch contradicts one of the displayed none–some classifier clauses. In the some–some branch, the two classifier witnesses are hsame links from the payloads of x and y to the common payload a; compose the first link with the symmetric of the second. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionClassifierSpec hsame common right confluence`

Theorem 33.78 (Option classifier hsame some-right inversion)**.** *For a typed option carrier value* $x : \mathsf{OptionCarrier}(\mathsf{BHist})$ *and a history* $b : \mathsf{BHist}$*, if* $\mathsf{OptionClassifierSpec}(\mathsf{hsame}, x, \mathsf{some}(b))$ *holds, then there is a history* $a : \mathsf{BHist}$ *such that* $x = \mathsf{some}(a)$ *and* $\mathsf{hsame}(a, b)$ *holds.*

Proof. Case-analyze x. The none branch contradicts the typed none–some classifier clause. In the some branch, the exposed payload is the required witness and the classifier clause is exactly the displayed hsame witness. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionClassifierSpec hsame some right inversion`

Theorem 33.79 (Option classifier hsame some-left inversion)**.** *For a typed option carrier value* $y : \mathsf{OptionCarrier}(\mathsf{BHist})$ *and a history* $a : \mathsf{BHist}$*, if* $\mathsf{OptionClassifierSpec}(\mathsf{hsame}, \mathsf{some}(a), y)$ *holds, then there is a history* $b : \mathsf{BHist}$ *such that* $y = \mathsf{some}(b)$ *and* $\mathsf{hsame}(a, b)$ *holds.*

Proof. Case-analyze y. The none branch contradicts the typed some–none classifier clause. In the some branch, the exposed payload is the required witness and the classifier clause is exactly the displayed hsame witness. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionClassifierSpec hsame some left inversion`

Theorem 33.80 (Option classifier hsame right payload determinacy)**.** *For a typed option carrier value* $x : \mathsf{OptionCarrier}(\mathsf{BHist})$ *and histories* $h, k : \mathsf{BHist}$*, if* $\mathsf{OptionClassifierSpec}(\mathsf{hsame}, x, \mathsf{some}(h))$ *and* $\mathsf{OptionClassifierSpec}(\mathsf{hsame}, x, \mathsf{some}(k))$ *hold, then* $\mathsf{hsame}(h, k)$ *holds.*

Proof. Case-analyze the shared left option value x. The none branch contradicts the typed option classifier clause for a none–some pair. In the some branch, the two classifier witnesses unfold to payload equalities from the same left payload to h and to k; reverse the first equality and compose it with the second by hsame transitivity. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionClassifierSpec hsame right payload deterministic`

Theorem 33.81 (Option classifier symmetry from source symmetry)**.** *Let* A *be an entry type, let* $R : A \to A \to \mathsf{Prop}$ *be a source relation, and let* $x, y : \mathsf{OptionCarrier}(A)$*. If* $\forall a\, b.\ R(a, b) \to R(b, a)$ *and* $\mathsf{OptionClassifierSpec}(R, x, y)$ *hold, then* $\mathsf{OptionClassifierSpec}(R, y, x)$ *holds.*

Proof. Case-analyze x and y. The none–none case is immediate from the none classifier clause. The mixed none–some and some–none cases are impossible by the typed option classifier clauses. In the some–some case, apply the displayed source-symmetry hypothesis to the payload witness. □

Definition 33.82 (Option stability certificate)**.** *The stability certificate separates the typed optional classifier fields from the nullable history-envelope fields.*

For the typed OptionClassifierSpec *classifier, the fields are:*

1. *reflexivity for* none *and for* $\mathsf{some}(a)$ *from source reflexivity;*
2. *symmetry from a source-symmetry hypothesis, as in Theorem 33.81;*
3. *transitivity from a source-transitivity hypothesis;*
4. *no-confusion between* none *and* $\mathsf{some}(a)$ *in either order;*
5. *present inversion, exposing the source classifier witness from a* some–some *classification.*

The checked hsame *specialization is the Lean-marked instance of this symmetry field.*

For the nullable OptionHistoryCarrier *envelope and its* OptionHistoryClassifier*, the certificate fields are:*

1. *carrier transport across* hsame*;*
2. *endpoint transport for the classifier across* hsame *on both endpoints;*
3. *classifier symmetry;*
4. *classifier transitivity;*
5. *ledger transport across raw and visible endpoint* hsame *links.*

Lean4 ✓ `BEDC.Derived.OptionUp.option stability certificate fields`

Theorem 33.83 (Option classifier transitivity)**.** *Let A be an entry type, let $R : A \to A \to \mathsf{Prop}$ be a source classifier relation, and let $x, y, z : \mathsf{OptionCarrier}(A)$. If R is transitive and both $\mathsf{OptionClassifierSpec}(R, x, y)$ and $\mathsf{OptionClassifierSpec}(R, y, z)$ hold, then $\mathsf{OptionClassifierSpec}(R, x, z)$ holds.*

Lean4 ✓ `BEDC.Derived.OptionUp.OptionClassifierSpec trans`

Proof. Proceed by constructor case analysis on x, y, and z. The none–none–none case is immediate, mixed none–some cases contradict the classifier clauses, and the some–some–some case is exactly the supplied transitivity of R. □

Definition 33.84 (Option ledger policy)**.** *The ledger keeps a raw optional-history carrier witness and an* hsame *link from the raw history to the visible history.*

Lean4 (definition) `BEDC.Derived.OptionUp.OptionHistoryLedgerPolicy`

Theorem 33.85 (Option history ledger policy empty raw iff)**.** *Let $S : \mathsf{BHist} \to \mathsf{Prop}$ and let $v : \mathsf{BHist}$. Then*

$$\mathsf{OptionHistoryLedgerPolicy}(S, \mathsf{Empty}, v) \iff \mathsf{hsame}(v, \mathsf{Empty}).$$

Proof. Unpack the ledger at raw history Empty. A ledger witness stores an $\mathsf{hsame}(\mathsf{Empty}, v)$ link, whose symmetry gives $\mathsf{hsame}(v, \mathsf{Empty})$. Conversely, an $\mathsf{hsame}(v, \mathsf{Empty})$ witness provides the empty carrier branch for the raw endpoint and, by symmetry, the ledger link from Empty to v. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryLedgerPolicy empty raw iff`

Theorem 33.86 (Option visible ledger carrier)**.** *Let $S : \mathsf{BHist} \to \mathsf{Prop}$ and let $\rho, v : \mathsf{BHist}$. If source_transport $: \forall h\, k.\ \mathsf{hsame}(h, k) \to S(h) \to S(k)$ holds, then $\mathsf{OptionHistoryLedgerPolicy}(S, \rho, v)$ implies $\mathsf{OptionHistoryCarrier}_S(v)$.*

Proof. Unpack the raw carrier and raw-to-visible hsame link. The absent case composes the symmetric link with the raw empty-history witness; the present case transports the raw source witness along the stored link. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryLedgerPolicy visible carrier`

Theorem 33.87 (Option ledger policy source visible iff)**.** *Let $S : \mathsf{BHist} \to \mathsf{Prop}$ and let $\rho, v : \mathsf{BHist}$. Assume*

$$\forall h\, k.\ \mathsf{hsame}(h, k) \to S(h) \to S(k).$$

If $\mathsf{OptionHistoryLedgerPolicy}(S, \rho, v)$ holds, then

$$S(\rho) \iff S(v).$$

Proof. Unpack the ledger to obtain the raw-visible link $\mathsf{hsame}(\rho, v)$. The forward direction transports a raw source witness along this link. The reverse direction transports a visible source witness along the symmetric link. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryLedgerPolicy source visible iff`

Theorem 33.88 (Option ledger visible source exactness)**.** *Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *exclude the empty history, and let* $\rho, v : \mathsf{BHist}$*. If* $S(v)$ *holds, then the option ledger over* ρ *and* v *is exactly raw source membership together with the stored raw-visible equality:*

$$\mathsf{OptionHistoryLedgerPolicy}(S, \rho, v) \iff S(\rho) \wedge \mathsf{hsame}(\rho, v).$$

Proof. Unpack the ledger into the raw option carrier and the raw-visible hsame link. If the raw carrier is absent, the link transports the empty witness to v, contradicting empty-source exclusion and $S(v)$. Hence the raw carrier is the source branch, and the link is the displayed equality. Conversely, the raw source witness rebuilds the source branch of the carrier and pairs it with the given raw-visible link. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryLedgerPolicy visible source exactness`

Theorem 33.89 (Option ledger exclusive readback)**.** *Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *exclude the empty history, and let* $\rho, v : \mathsf{BHist}$*. If* $\mathsf{OptionHistoryLedgerPolicy}(S, \rho, v)$ *holds, then exactly one branch is read back from the ledger:*

$$(\mathsf{hsame}(\rho, \mathsf{Empty}) \wedge \mathsf{hsame}(v, \mathsf{Empty}) \wedge \neg S(\rho) \wedge \neg S(v)) \vee (S(\rho) \wedge S(v) \wedge \neg \mathsf{hsame}(\rho, \mathsf{Empty}) \wedge \neg \mathsf{hsame}(v, \mathsf{Empty}) \wedge \mathsf{hsame}(\rho,$$

Proof. Unpack the ledger into the raw optional-history carrier and the raw-to-visible hsame link. The raw carrier readback gives either the absent branch or the source branch. In the absent branch, the stored link transfers the empty witness to the visible endpoint, and source exclusion rules out visible source membership. In the source branch, the stored hsame link identifies raw and visible endpoints, so the source witness transports by case analysis on that link; empty witnesses on either endpoint contradict source exclusion. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryLedgerPolicy exclusive readback`

Theorem 33.90 (Option raw-visible ledger classifier)**.** *Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and let* $\rho, v : \mathsf{BHist}$*. If* $\mathit{source_transport} : \forall h\, k.\ \mathsf{hsame}(h, k) \to S(h) \to S(k)$ *holds, then* $\mathsf{OptionHistoryLedgerPolicy}(S, \rho, v)$ *implies* $\mathsf{OptionHistoryClassifier}_S(\rho, v)$*.*

Proof. Unpack the raw carrier witness and raw-to-visible hsame link. The visible carrier is given by Theorem 33.86, and the stored link supplies the classifier equality field. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryLedgerPolicy raw visible classifier`

Theorem 33.91 (Option ledger shared-visible raw classifier)**.** *Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and let* $\rho, \rho', v : \mathsf{BHist}$*. Assume*

$$\forall h\, k.\ \mathsf{hsame}(h, k) \to S(h) \to S(k).$$

If both $\mathsf{OptionHistoryLedgerPolicy}(S, \rho, v)$ *and* $\mathsf{OptionHistoryLedgerPolicy}(S, \rho', v)$ *hold, then* $\mathsf{OptionHistoryClassifier}_S($ *holds.*

Proof. Convert both ledger witnesses to raw-visible classifiers by Definition 33.90. Reverse the second classifier by option classifier symmetry, and compose the two classifiers by option classifier transitivity. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryLedgerPolicy shared visible raw classifier`

Theorem 33.92 (Option ledger shared-raw visible classifier)**.** *Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and let* $\rho, v, v' : \mathsf{BHist}$*. Assume*

$$\forall h\, k.\ \mathsf{hsame}(h, k) \to S(h) \to S(k).$$

If both $\mathsf{OptionHistoryLedgerPolicy}(S, \rho, v)$ *and* $\mathsf{OptionHistoryLedgerPolicy}(S, \rho, v')$ *hold, then* $\mathsf{OptionHistoryClassifier}_S($ *holds.*

Proof. Convert both ledger witnesses to raw-visible classifiers by Definition 33.90. Reverse the first classifier by option classifier symmetry, and compose it with the second raw-visible classifier by option classifier transitivity. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryLedgerPolicy shared raw visible classifier`

Theorem 33.93 (Option ledger classifier composition)**.** *Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *be a source predicate and let* $\rho, v, w : \mathsf{BHist}$*. Assume*

$$\forall h\, k.\ \mathsf{hsame}(h, k) \to S(h) \to S(k).$$

If $\mathsf{OptionHistoryLedgerPolicy}(S, \rho, v)$ *and* $\mathsf{OptionHistoryClassifier}_S(v, w)$ *hold, then* $\mathsf{OptionHistoryClassifier}_S(\rho, w)$ *holds.*

Proof. Apply Theorem 33.90 to the ledger policy using the displayed source-transport hypothesis to obtain $\mathsf{OptionHistoryClassifier}_S(\rho, v)$. Compose that raw-visible classifier with the visible-target classifier by Theorem 33.52, yielding $\mathsf{OptionHistoryClassifier}_S(\rho, w)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryLedgerPolicy classifier extension`

Theorem 33.94 (Option ledger classifier endpoint equivalence)**.** *Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *be a source predicate and let* $\rho, v, w : \mathsf{BHist}$*. Assume*

$$\forall h\, k.\ \mathsf{hsame}(h, k) \to S(h) \to S(k).$$

If $\mathsf{OptionHistoryLedgerPolicy}(S, \rho, v)$ *holds, then* $\mathsf{OptionHistoryClassifier}_S(\rho, w) \iff \mathsf{OptionHistoryClassifier}_S(v, w)$*. The ten-field fit is the traditional target of nullable optional ledger endpoint replacement, BEDC source* BHist *with* hsame*, carrier* OptionHistoryCarrier*, classifier* OptionHistoryClassifier*, stability given by raw-visible ledger classifier together with classifier symmetry and transitivity, ledger* OptionHistoryLedgerPol *core theorem this endpoint equivalence, exactness as classifier-invariant raw and visible endpoints, standard bridge the nullable option envelope readback, and status* ProofTarget*.*

Proof. Apply Theorem 33.90 to the ledger witness to obtain $\mathsf{OptionHistoryClassifier}_S(\rho, v)$. For the forward direction, use Theorem 33.51 to reverse this raw-visible classifier and then compose it with the assumed $\mathsf{OptionHistoryClassifier}_S(\rho, w)$ by Theorem 33.52. For the reverse direction, apply Theorem 33.93 directly to the ledger witness and the assumed visible-endpoint classifier. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryLedgerPolicy classifier endpoint equivalence`

Theorem 33.95 (Option ledger history-same transport)**.** *If both raw histories and both visible histories are related by* hsame*, then an option ledger policy transports from the first raw-visible pair to the second.*

Proof. Unpack the ledger into its raw carrier witness and raw-to-visible history link. The raw carrier transports along the raw hsame witness. The transported raw-to-visible link is the composite of the symmetric raw link, the stored ledger link, and the visible link. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryLedgerPolicy hsame transport`

Theorem 33.96 (Option ledger policy source monotonicity)**.** *Let S, T : BHist → Prop be source predicates and let ρ, v : BHist. If every S-source history is also a T-source history, then* OptionHistoryLedgerPolicy(S, *implies* OptionHistoryLedgerPolicy(T, ρ, v)*.*

Proof. Unpack the ledger into its raw optional-history carrier and raw-to-visible hsame link. The absent raw branch is kept unchanged. In the source raw branch, apply the source-monotonicity hypothesis to move the raw witness from S to T, and keep the same raw-to-visible link. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryLedgerPolicy source monotonicity`

Theorem 33.97 (Option ledger policy transitivity)**.** *Let S : BHist → Prop and let ρ, m, v : BHist. If* OptionHistoryLedgerPolicy(S, ρ, m) *and* OptionHistoryLedgerPolicy(S, m, v) *hold, then* OptionHistoryLedgerPolicy(S *holds.*

Proof. Unpack both ledger witnesses. The first witness supplies the raw optional carrier for ρ and the link hsame(ρ, m); the second supplies the link hsame(m, v). Compose the two hsame links and keep the raw carrier witness from the first ledger. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryLedgerPolicy trans`

Theorem 33.98 (Concrete optional-history semantic certificate)**.** *For every source predicate S :* BHist → Prop*, the checked nullable certificate is* SemanticNameCert(OptionHistoryCarrier$_S$, OptionHistoryCarrier$_S$, Op *This semantic certificate does not assert constructor-discriminating history tags; that stronger tagged interface is the preceding paper-side target.*

Proof. For each S, the history carrier contains the empty history and any source history. The classifier records both endpoint envelope-carrier witnesses and the BEDC history equality witness. Reflexivity, symmetry, transitivity, and carrier transport are the corresponding hsame fields, while pattern and ledger soundness are carrier projections for the envelope. □

Corollary 33.99 (OptionUp certificate scope)**.** *Citations to Theorem 33.98 assert only the nullable empty-or-source history envelope. The constructor-tagged history certificate is Theorem 33.44, under a source* NameCert *and* TaggedOptionSourceHsameCompatible$(S, \sim_S)$*, or Corollary 33.47 in the* hsame *specialization. The typed* OptionClassifierSpec *is a separate host-option classifier; it is not a field that licenses the tagged history semantic certificate, and neither certificate implies the other carrier presentation without the bridge data of Definition 33.103.*

Theorem 33.100 (Tagged option history classifier right visible-branch inversion)**.** *This theorem fits the per-object template as follows: the traditional target is tagged option branch inversion from the right endpoint; the BEDC source is* BHist *with* hsame*; the carrier is* TaggedOptionHistoryCarrier*; the classifier is* TaggedOptionHistoryClassifier*; the ledger is the visible absent/present tag plus payload; exactness is right-endpoint branch exposure; and the status is* ProofTarget*. For every BEDC history source carrier S :* BHist → Prop*, source classifier $\sim_S$, and histories h, k, the classifier determines the visible branch presented by the right endpoint:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k) \to \mathsf{hsame}(k, \mathsf{e}) \to \mathsf{hsame}(h, \mathsf{e})$$

and, for every payload history a,

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k) \to S(a) \to \mathsf{hsame}(k,\mathsf{E1}(a)) \to \exists b,a' : \mathsf{BHist}.\ S(b) \wedge S(a') \wedge \mathsf{hsame}(a,a') \wedge b \sim_S$$

Proof. For the absent clause, case-analyze the tagged classifier witness. The absent-absent branch already stores $\mathsf{hsame}(h,\mathsf{e})$. The present-present branch stores $\mathsf{hsame}(k,\mathsf{E1}(a'))$ for some right payload; composing it with the displayed witness $\mathsf{hsame}(k,\mathsf{e})$ gives empty-versus-one no-confusion.

For the present clause, case-analyze the classifier witness again. The absent-absent branch stores $\mathsf{hsame}(k,\mathsf{e})$ and contradicts the displayed present endpoint $\mathsf{hsame}(k,\mathsf{E1}(a))$. In the present-present branch, obtain payloads b and a' with $S(b)$, $S(a')$, $b \sim_S a'$, $\mathsf{hsame}(h,\mathsf{E1}(b))$, and $\mathsf{hsame}(k,\mathsf{E1}(a'))$. Compose the two presentations of k and invert the one-constructor equality to get $\mathsf{hsame}(a,a')$; the remaining fields are exactly the displayed witnesses. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier right visible branch inversion`

Theorem 33.101 (Tagged option history classifier composite right visible readback)**.** *Let $S : \mathsf{BHist} \to \mathsf{Prop}$ be a source carrier and let $\sim_S$ be a transitive source relation. For histories h,k,r, two tagged option classifier steps*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k) \quad \textit{and} \quad \mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(k,r)$$

determine the branch of h from the visible branch of the composite right endpoint r:

$$\mathsf{hsame}(r,\mathsf{e}) \Longrightarrow \mathsf{hsame}(h,\mathsf{e}),$$

and, for every payload history a,

$$S(a) \Longrightarrow \mathsf{hsame}(r,\mathsf{E1}(a)) \Longrightarrow \exists b,a' : \mathsf{BHist}.\ S(b) \wedge S(a') \wedge \mathsf{hsame}(a,a') \wedge b \sim_S a' \wedge \mathsf{hsame}(h,\mathsf{E1}(b)).$$

Proof. Compose the two tagged classifier steps using transitivity of $\sim_S$. The result is a single classifier step from h to r. Applying the right visible-branch inversion theorem to that composite step gives the absent readback clause and the present payload witness clause exactly as displayed. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier composite right visible readback`

Theorem 33.102 (Tagged option shared-left visible-right determinacy)**.** *For a BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$ and histories h,k,r,a,b,c, two tagged option classifier witnesses with source classifier* hsame *and shared left endpoint h determine the visible right payloads whenever all three displayed endpoints are present:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\mathsf{hsame}}(h,k) \Longrightarrow \mathsf{TaggedOptionHistoryClassifier}_{S,\mathsf{hsame}}(h,r) \Longrightarrow \mathsf{hsame}(h,\mathsf{E1}(a)) \Longrightarrow \mathsf{hsame}(k,\mathsf{E1}(b)) \Longrightarrow \mathsf{hsame}(r,\mathsf{E1}(c)) \Longrightarrow \mathsf{hsame}(b,c).$$

Proof. Case-analyze both classifier witnesses. Any absent branch contradicts the displayed present endpoint for h. In the present branches, the two stored presentations of h identify the two left payload witnesses with a by one-constructor inversion. The stored presentations of k and r identify the right payload witnesses with b and c. Since the classifier relation is hsame, transitivity along the two shared-left payload links gives $\mathsf{hsame}(b,c)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier hsame shared left visible right deterministic`

Definition 33.103 (Tagged option-to-nullable bridge hypotheses)**.** *For a BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$ and source classifier $\sim_S$, define* $\mathsf{TaggedOptionToNullableBridge}(S, \sim_S)$ *to be the pair of conditions:*

1. *present endpoint closure: for all histories a, h, if $S(a)$ and* $\mathsf{hsame}(h, \mathsf{E1}(a))$*, then $S(h)$;*
2. *classifier hsame soundness: for all histories a, b, if $S(a)$, $S(b)$, and $a \sim_S b$, then* $\mathsf{hsame}(a, b)$*.*

Lean4 (definition) `BEDC.Derived.OptionUp.TaggedOptionToNullableBridge`

Theorem 33.104 (Tagged option-to-nullable classifier bridge)**.** *Let $S : \mathsf{BHist} \to \mathsf{Prop}$ be a source carrier and let $\sim_S$ be a source classifier. If* $\mathsf{TaggedOptionToNullableBridge}(S, \sim_S)$ *holds, then for every history h,* $\mathsf{TaggedOptionHistoryCarrier}_S(h)$ *implies* $\mathsf{OptionHistoryCarrier}_S(h)$*, and for every pair of histories h, k,* $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k)$ *implies* $\mathsf{OptionHistoryClassifier}_S(h, k)$*.*

Proof. Unpack the bridge into present endpoint closure and classifier hsame soundness. For the carrier implication, case-analyze $\mathsf{TaggedOptionHistoryCarrier}_S(h)$. The absent branch is already the empty side of $\mathsf{OptionHistoryCarrier}_S(h)$. In the present branch, a payload a with $S(a)$ and $\mathsf{hsame}(h, \mathsf{E1}(a))$ descends to $S(h)$ by present endpoint closure, giving the source side of the nullable envelope.

For the classifier implication, use Theorem 33.131. In the absent-absent branch, the two empty endpoint witnesses give the nullable carriers and compose through e to obtain $\mathsf{hsame}(h, k)$. In the present-present branch, the carrier part descends for both endpoints by present endpoint closure. Classifier hsame soundness converts $a \sim_S b$ into $\mathsf{hsame}(a, b)$; applying $e1$ congruence gives $\mathsf{hsame}(\mathsf{E1}(a), \mathsf{E1}(b))$, which composes with the endpoint witnesses $\mathsf{hsame}(h, \mathsf{E1}(a))$ and $\mathsf{hsame}(k, \mathsf{E1}(b))$ to yield $\mathsf{hsame}(h, k)$. These are exactly the carrier and endpoint-equality fields of $\mathsf{OptionHistoryClassifier}_S(h, k)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionToNullableBridge descent`

Theorem 33.105 (Tagged option history classifier induces nullable classification)**.** *Let $S : \mathsf{BHist} \to \mathsf{Prop}$ be a source carrier. If two histories are classified by the tagged option classifier over* hsame*, then they are classified by the nullable option classifier whose source side is the tagged option history carrier:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\mathsf{hsame}}(h, k) \Longrightarrow \mathsf{OptionHistoryClassifier}_{\mathsf{TaggedOptionHistoryCarrier}_S}(h, k).$$

Proof. Analyze the tagged classifier. In the absent branch, both endpoints are history-same to e, so the nullable carriers use their absent clauses and the classifier equality composes through e. In the present branch, the payload witnesses a and b rebuild the tagged carrier source clauses for the nullable classifier. The endpoint equality is obtained by composing the left endpoint link, congruence of $\mathsf{E1}$ over $\mathsf{hsame}(a, b)$, and the reverse of the right endpoint link. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier option history classifier`

Theorem 33.106 (Tagged option-to-nullable hsame bridge criterion)**.** *The ten-field fit is: traditional target nullable comparison for constructor-tagged options; BEDC source* BHist *with* hsame*; carrier* TaggedOptionHistoryCarrier*; classifier* $\mathsf{TaggedOptionHistoryClassifier}_{S,\mathsf{hsame}}$*; stability obligation present-endpoint absorption; ledger visible absent/present tag; core theorem the bridge criterion; exactness one-way comparison to the nullable envelope; standard bridge none/some readback; status* ProofTarget*. Let $S : \mathsf{BHist} \to \mathsf{Prop}$ be a source carrier. If*

$$\forall a\, h.\ S(a) \to \mathsf{hsame}(h, \mathsf{E1}(a)) \to S(h),$$

then $\mathsf{TaggedOptionToNullableBridge}(S, \mathsf{hsame})$ *holds. Consequently, for every history* h*,*

$$\mathsf{TaggedOptionHistoryCarrier}_S(h) \to \mathsf{OptionHistoryCarrier}_S(h),$$

and for every pair of histories h, k*,*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\mathsf{hsame}}(h, k) \to \mathsf{OptionHistoryClassifier}_S(h, k).$$

Proof. Pair the displayed present-endpoint absorption hypothesis with identity classifier hsame soundness: from $S(a)$, $S(b)$, and $\mathsf{hsame}(a, b)$, the required history-sameness conclusion is the same witness. This gives $\mathsf{TaggedOptionToNullableBridge}(S, \mathsf{hsame})$. The two descent conclusions are exactly Theorem 33.104 specialized to the source classifier hsame. □

Theorem 33.107 (Tagged option public certificate compares with nullable envelope)**.** *Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *be a source carrier, let* $\sim_S$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$*, and assume* $\mathsf{TaggedOptionToNullableBridge}(S, \sim_S)$*. Then the constructor-tagged public certificate*

$$\mathsf{SemanticNameCert}(\mathsf{TaggedOptionHistoryCarrier}_S, \mathsf{TaggedOptionHistoryPattern}_S, \mathsf{TaggedOptionHistoryLedger}_S, \mathsf{Tagge}$$

holds, and the tagged carrier and classifier compare to the nullable envelope:

$$\forall h.\ \mathsf{TaggedOptionHistoryCarrier}_S(h) \to \mathsf{OptionHistoryCarrier}_S(h),$$

and

$$\forall h\, k.\ \mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k) \to \mathsf{OptionHistoryClassifier}_S(h, k).$$

This is one-way compatibility of the constructor-tagged public certificate with the checked nullable envelope; it is not an equality of the two carrier presentations.

Proof. First apply Theorem 33.44 to the source certificate cert, obtaining the carrier-only tagged semantic certificate. The core certificate is reused unchanged.

For the displayed public certificate, use Theorem 33.31 to convert each tagged carrier witness into the visible pattern witness and the visible ledger witness, then repack the core certificate with these two soundness maps.

The two displayed implications are exactly Theorem 33.104, applied to the bridge hypothesis $\mathsf{TaggedOptionToNullableBridge}(S, \sim_S)$. The bridge records one-way carrier and classifier compatibility with the checked nullable envelope; it does not construct a nullable semantic certificate from the tagged one. □

Theorem 33.108 (Tagged option hsame public certificate descends to nullable envelope)**.** *The tenfield fit is: traditional target nullable comparison for a public option object; BEDC source* BHist *with* hsame*; carrier* $\mathsf{TaggedOptionHistoryCarrier}_S$*; classifier* $\mathsf{TaggedOptionHistoryClassifier}_{S,\mathsf{hsame}}$*; stability obligation present-endpoint absorption; ledger visible absent/present tag; core theorem the tagged* hsame *semantic certificate; exactness one-way comparison to the nullable envelope; standard bridge none/some readback; status* ProofTarget*. Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *be a source carrier, let* $\mathsf{cert} : \mathsf{NameCert}(S, \mathsf{hsame})$*, and assume*

$$\forall a\, h.\ S(a) \to \mathsf{hsame}(h, \mathsf{E1}(a)) \to S(h).$$

Then the constructor-tagged public certificate

$$\mathsf{SemanticNameCert}(\mathsf{TaggedOptionHistoryCarrier}_S, \mathsf{TaggedOptionHistoryPattern}_S, \mathsf{TaggedOptionHistoryLedger}_S, \mathsf{Tagge}$$

holds, and the tagged carrier and classifier descend to the nullable envelope:

$$\forall h.\ \mathsf{TaggedOptionHistoryCarrier}_S(h) \to \mathsf{OptionHistoryCarrier}_S(h),$$

and

$$\forall h\, k.\ \mathsf{TaggedOptionHistoryClassifier}_{S,\mathsf{hsame}}(h,k) \to \mathsf{OptionHistoryClassifier}_S(h,k).$$

Proof. The tagged certificate is the hsame certificate corollary Corollary 33.47, applied to cert. The displayed absorption hypothesis gives $\mathsf{TaggedOptionToNullableBridge}(S, \mathsf{hsame})$ by Theorem 33.106. Applying Theorem 33.104 to that bridge datum gives the carrier and classifier implications into the nullable envelope. □

Theorem 33.109 (Tagged option history classifier absent-branch equivalence)**.** *This theorem fits the per-object template as follows: the traditional target is option absent-branch agreement; the BEDC source is* BHist *with* hsame*; the carrier is* TaggedOptionHistoryCarrier*; the classifier is* TaggedOptionHistoryClassifier*; the stability obligation is branch determinism; the ledger is the visible absent/present tag; the core theorem is absentness equivalence; exactness is absent endpoints agree under classifier; the standard bridge is* none/some*; and the status is* ProofTarget*. For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, source classifier* $\sim_S$*, and histories* h, k*, classified endpoints agree on absentness:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k) \to \big(\mathsf{hsame}(h,\mathsf{e}) \iff \mathsf{hsame}(k,\mathsf{e})\big).$$

Proof. Assume a classifier witness between h and k. The forward implication is exactly the absent clause of Theorem 33.42: from $\mathsf{hsame}(h,\mathsf{e})$, left visible-branch inversion gives $\mathsf{hsame}(k,\mathsf{e})$. The reverse implication is the absent clause of Theorem 33.100: from $\mathsf{hsame}(k,\mathsf{e})$, right visible-branch inversion gives $\mathsf{hsame}(h,\mathsf{e})$. These two implications assemble the displayed $\iff$. □

Lean4 (definition) `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier`
Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier absent branch equivalence`

Theorem 33.110 (Tagged option history classifier nonempty-branch equivalence)**.** *For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, source classifier* $\sim_S$*, and histories* h, k*, classified endpoints agree on nonempty branch occupancy:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k) \to \big((\mathsf{hsame}(h,\mathsf{e}) \to \bot) \iff (\mathsf{hsame}(k,\mathsf{e}) \to \bot)\big).$$

Proof. The absent-branch equivalence gives $\mathsf{hsame}(h,\mathsf{e}) \iff \mathsf{hsame}(k,\mathsf{e})$. Compose each implication with the corresponding negated endpoint hypothesis: a proof of $\mathsf{hsame}(k,\mathsf{e})$ transports back to $\mathsf{hsame}(h,\mathsf{e})$, and a proof of $\mathsf{hsame}(h,\mathsf{e})$ transports forward to $\mathsf{hsame}(k,\mathsf{e})$. These two contrapositive maps assemble the displayed equivalence of nonempty branches. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier nonempty branch equivalence`

Theorem 33.111 (Tagged option history classifier present-branch equivalence)**.** *For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, source classifier* $\sim_S$*, histories* h, k*, and classifier witness* $\gamma : \mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k)$*, classified endpoints agree on presentness:*

$$\big(\exists a : \mathsf{BHist}.\ S(a) \wedge \mathsf{hsame}(h, \mathsf{E1}(a))\big) \iff \big(\exists b : \mathsf{BHist}.\ S(b) \wedge \mathsf{hsame}(k, \mathsf{E1}(b))\big).$$

Proof. For the forward implication, unpack a source payload a with $S(a)$ and $\mathsf{hsame}(h, \mathsf{E1}(a))$. Apply the present clause of Theorem 33.42 to the witness γ; the exposed right payload supplies $S(b)$ and $\mathsf{hsame}(k, \mathsf{E1}(b))$, which is the required present witness for k. For the reverse implication, unpack a right payload b with $S(b)$ and $\mathsf{hsame}(k, \mathsf{E1}(b))$. Apply the present clause of Theorem 33.100 to γ; the exposed left payload supplies $S(a)$ and $\mathsf{hsame}(h, \mathsf{E1}(a))$, giving the required present witness for h. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier present branch equivalence`

Theorem 33.112 (Tagged option left present endpoint fanout)**.** *For every BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$, source classifier $\sim_S$, and histories h, k, r, a, if*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k), \qquad \mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, r), \qquad \mathsf{hsame}(h, \mathsf{E1}(a)),$$

then both right endpoints are present:

$$(\exists b : \mathsf{BHist}.\ S(b) \wedge \mathsf{hsame}(k, \mathsf{E1}(b))) \wedge (\exists c : \mathsf{BHist}.\ S(c) \wedge \mathsf{hsame}(r, \mathsf{E1}(c))).$$

Proof. Case-analyze the two tagged classifier witnesses. In either witness, an absent left branch contradicts the displayed present endpoint for h. The remaining present branch exposes its right payload together with the source witness and the right endpoint equation. Applying this argument to the witnesses ending at k and r gives the two conjuncts. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier left present endpoint fanout`

Theorem 33.113 (Tagged option left present payload fanout)**.** *For every BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$, source classifier $\sim_S$, and histories h, k, r, a, if*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k), \qquad \mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, r), \qquad \mathsf{hsame}(h, \mathsf{E1}(a)),$$

then both right endpoints expose payloads whose source-side predecessors are the displayed payload a up to hsame*:*

$$\begin{aligned}&(\exists b, a' : \mathsf{BHist}.\ S(b) \wedge S(a') \wedge \mathsf{hsame}(a, a') \wedge a' \sim_S b \wedge \mathsf{hsame}(k, \mathsf{E1}(b)))\\ &\quad \wedge (\exists c, a'' : \mathsf{BHist}.\ S(c) \wedge S(a'') \wedge \mathsf{hsame}(a, a'') \wedge a'' \sim_S c \wedge \mathsf{hsame}(r, \mathsf{E1}(c))).\end{aligned}$$

Proof. Case-analyze the two tagged classifier witnesses. An absent left branch contradicts the visible equation $\mathsf{hsame}(h, \mathsf{E1}(a))$. In each present branch, the classifier exposes a source payload, a target payload, the source and target carrier witnesses, the relation between the payloads, and the target endpoint equation. Constructor inversion for $\mathsf{E1}$ identifies the displayed payload a with the exposed source payload. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier left present payload fanout`

Theorem 33.114 (Tagged option right present endpoint fanout)**.** *For every BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$, source classifier $\sim_S$, and histories h, k, r, a, if*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k), \qquad \mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(r, k), \qquad \mathsf{hsame}(k, \mathsf{E1}(a)),$$

then both left endpoints are present:

$$(\exists b : \mathsf{BHist}.\ S(b) \wedge \mathsf{hsame}(h, \mathsf{E1}(b))) \wedge (\exists c : \mathsf{BHist}.\ S(c) \wedge \mathsf{hsame}(r, \mathsf{E1}(c))).$$

Proof. Case-analyze the two tagged classifier witnesses. In either witness, an absent right branch contradicts the displayed present endpoint for k. The remaining present branch exposes its left payload together with the source witness and the left endpoint equation. Applying this argument to the witnesses starting at h and r gives the two conjuncts. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier right present endpoint fanout`

Theorem 33.115 (Tagged option right present payload fanout)**.** *For every BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$, source classifier $\sim_S$, and histories h, k, r, a, if*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k), \qquad \mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(r,k), \qquad \mathsf{hsame}(k, \mathsf{E1}(a)),$$

then both left endpoints expose payloads whose target-side successors are the displayed payload a up to hsame*:*

$$\begin{aligned}&(\exists b, a' : \mathsf{BHist}.\ S(b) \wedge S(a') \wedge \mathsf{hsame}(a, a') \wedge b \sim_S a' \wedge \mathsf{hsame}(h, \mathsf{E1}(b)))\\ &\quad \wedge (\exists c, a'' : \mathsf{BHist}.\ S(c) \wedge S(a'') \wedge \mathsf{hsame}(a, a'') \wedge c \sim_S a'' \wedge \mathsf{hsame}(r, \mathsf{E1}(c))).\end{aligned}$$

Proof. Case-analyze the two tagged classifier witnesses. An absent right branch contradicts the visible equation $\mathsf{hsame}(k, \mathsf{E1}(a))$. In each present branch, the classifier exposes a left payload, a right payload, the two carrier witnesses, the relation between the payloads, and the left endpoint equation. Constructor inversion for $\mathsf{E1}$ identifies the displayed payload a with the exposed right payload. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier right present payload fanout`

Theorem 33.116 (Tagged option present-chain payload witness)**.** *For every BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$, source classifier $\sim_S$, histories h, k, r, and visible payloads a, c, if*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k), \qquad \mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(k,r), \qquad \mathsf{hsame}(h, \mathsf{E1}(a)), \qquad \mathsf{hsar}$$

then there are payload histories a_0, b, b', c_0 such that

$$S(a_0) \wedge S(b) \wedge S(b') \wedge S(c_0) \wedge \mathsf{hsame}(a, a_0) \wedge \mathsf{hsame}(b, b') \wedge \mathsf{hsame}(c_0, c) \wedge a_0 \sim_S b \wedge b' \sim_S c_0.$$

Proof. Case-analyze the two tagged classifier witnesses. Any absent branch contradicts one of the displayed visible present endpoints. In the remaining present-present branches, the two classifier witnesses expose payload legs $a_0 \sim_S b$ and $b' \sim_S c_0$. The two visible presentations of the shared middle endpoint k are identified by the $\mathsf{E1}$ constructor inversion principle, giving $\mathsf{hsame}(b, b')$; the endpoint witnesses for h and r similarly identify a with a_0 and c_0 with c. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier present chain payload witness`

Theorem 33.117 (Tagged option history classifier visible payload witnesses)**.** *For every BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$, source classifier $\sim_S$, histories h, k, a, b, if*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k), \qquad \mathsf{hsame}(h, \mathsf{E1}(a)), \qquad \mathsf{hsame}(k, \mathsf{E1}(b)),$$

then there are payload witnesses $a', b' : \mathsf{BHist}$ such that

$$S(a') \wedge S(b') \wedge \mathsf{hsame}(a, a') \wedge \mathsf{hsame}(b, b') \wedge a' \sim_S b'.$$

Proof. Case-analyze the tagged classifier witness. The absent branch contradicts the left visible endpoint. In the present branch, the classifier already exposes source payload witnesses a' and b' together with the two endpoint equations and $a' \sim_S b'$. Constructor inversion for the two displayed $\mathsf{E1}$ readings identifies a with a' and b with b'. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier visible payload witnesses`

Theorem 33.118 (Tagged option history classifier visible payload relation transport)**.** *For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, source relation* $R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$*, and* hsame*-transport field for* R*, if*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,R}(h,k), \qquad \mathsf{hsame}(h, \mathsf{E1}(a)), \qquad \mathsf{hsame}(k, \mathsf{E1}(b)),$$

then the displayed payloads satisfy $R(a,b)$*.*

Proof. Apply Theorem 33.117 to obtain payload witnesses a', b' with $\mathsf{hsame}(a,a')$, $\mathsf{hsame}(b,b')$, and $R(a',b')$. The transport field for R, used against the symmetric payload identifications, moves $R(a',b')$ back to the displayed payloads $R(a,b)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier visible payload relation transport`

Theorem 33.119 (Tagged option hsame visible payload exactness)**.** *For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and histories* h, k, a, b*, if the tagged option classifier uses* hsame *as its payload classifier and both endpoints are displayed as visible payloads,*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\mathsf{hsame}}(h,k), \qquad \mathsf{hsame}(h, \mathsf{E1}(a)), \qquad \mathsf{hsame}(k, \mathsf{E1}(b)),$$

then the displayed payloads are themselves hsame*:*

$$\mathsf{hsame}(a,b).$$

Proof. Case-analyze the tagged classifier witness. The absent branch contradicts the visible display of the left endpoint. In the present branch, invert the two displayed $\mathsf{E1}$ endpoint readings and compose the exposed hsame payload leg with those two constructor inversions. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier hsame visible payload exactness`

Theorem 33.120 (Tagged option history classifier presented payload exactness)**.** *For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, source classifier* $\sim_S$*, transitivity hypothesis* $\forall x\, y\, z : \mathsf{BHist}.\ x \sim_S y \to y \sim_S z \to x \sim_S z$*, and* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*, if histories* h, k, a, b *satisfy*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k), \qquad S(a), \qquad S(b), \qquad \mathsf{hsame}(h, \mathsf{E1}(a)), \qquad \mathsf{hsame}(k, \mathsf{E1}(b)),$$

then the displayed payloads have the same source classifier:

$$a \sim_S b.$$

Proof. Use Theorem 33.34 to transport the classifier witness from (h,k) to the displayed endpoints $(\mathsf{E1}(a), \mathsf{E1}(b))$. Then apply Theorem 33.26 with the displayed transitivity hypothesis, the compatibility hypothesis, and the source witnesses $S(a)$ and $S(b)$. The resulting visible present exactness is precisely $a \sim_S b$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier presented payload exactness`

Theorem 33.121 (Tagged option common-left visible payload classification)**.** *For every source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$ and source classifier $\sim_S$, assume $\sim_S$ is symmetric and transitive, and assume that* hsame *between source histories classified by S implies $\sim_S$. If two tagged option classifier witnesses share the same left endpoint,*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k), \qquad \mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,r),$$

and the three visible endpoints expose source payloads

$$S(a), \quad S(b), \quad S(c), \qquad \mathsf{hsame}(h,\mathsf{E1}(a)), \quad \mathsf{hsame}(k,\mathsf{E1}(b)), \quad \mathsf{hsame}(r,\mathsf{E1}(c)),$$

then the two right visible payloads are classified:

$$b \sim_S c.$$

Proof. Case-analyze the two tagged option classifier witnesses. Any absent branch contradicts the visible left endpoint $\mathsf{hsame}(h,\mathsf{E1}(a))$. In the present-present case, the first classifier relates its exposed payloads and the second classifier relates its exposed payloads. Constructor inversion for the visible endpoints identifies the exposed left payloads with a and the right payloads with b and c. Compatibility converts these hsame identifications into source classification, and symmetry plus transitivity compose the chain $b \sim_S a \sim_S c$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier common left visible payload classification`

Theorem 33.122 (Tagged option present payload determinism)**.** *This theorem fits the per-object template as follows: the traditional target is present optional payload determinism; the BEDC source and carrier are* BHist *with* hsame *and the visible present endpoint; the classifier is unused; the stability obligation is constructor inversion; the ledger is the visible present payload; exactness says that the same visible present endpoint has the same payload; and the status is* ProofTarget*. For all BEDC histories $h, a, b : \mathsf{BHist}$, if*

$$\mathsf{hsame}(h,\mathsf{E1}(a)), \qquad \mathsf{hsame}(h,\mathsf{E1}(b)),$$

then the two displayed payloads are the same BEDC history:

$$\mathsf{hsame}(a,b).$$

Proof. Use symmetry of the first endpoint witness and compose it with the second endpoint witness to obtain $\mathsf{hsame}(\mathsf{E1}(a),\mathsf{E1}(b))$. The BEDC constructor inversion principle for the visible present constructor E1 then exposes the unique underlying payload, yielding $\mathsf{hsame}(a,b)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistory present payload determinism`

Theorem 33.123 (Tagged option history carrier e0 absurdity)**.** *For every source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$ and tail history t, the zero-tagged history cannot inhabit the tagged optional carrier:*

$$\mathsf{TaggedOptionHistoryCarrier}_S(\mathsf{E0}(t)) \Longrightarrow \bot.$$

Proof. Case-analyze the tagged carrier witness. The absent branch asserts $\mathsf{hsame}(\mathsf{E0}(t),\mathsf{e})$, contradicting history no-confusion between E0 and the empty history. The present branch supplies a payload a with $S(a)$ and $\mathsf{hsame}(\mathsf{E0}(t),\mathsf{E1}(a))$, contradicting no-confusion between the two visible tags. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryCarrier e0 absurd`

Theorem 33.124 (Tagged option history classifier e0 endpoint absurdity)**.** *For every source carrier S, payload classifier Rel, tail history t, and opposite endpoint h, a zero-tagged endpoint cannot occur on either side of the tagged optional classifier:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,Rel}(\mathsf{E0}(t), h) \Longrightarrow \bot, \qquad \mathsf{TaggedOptionHistoryClassifier}_{S,Rel}(h, \mathsf{E0}(t)) \Longrightarrow \bot.$$

Proof. Split the two endpoint positions. In an absent branch, the zero-tagged endpoint would be hsame to e, contradicting no-confusion for E0 and the empty history. In a present branch, the same endpoint would be hsame to some E1 payload, contradicting no-confusion between the two visible tags. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier e0 endpoint absurd`

Theorem 33.125 (Tagged option history classifier empty-visible exclusion)**.** *For every source carrier S, payload classifier Rel, histories h, k, and payload histories a, b, a tagged optional classifier witness excludes an empty endpoint opposite a visible present endpoint:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,Rel}(h, k) \Longrightarrow (\mathsf{hsame}(h, \mathsf{e}) \Longrightarrow \mathsf{hsame}(k, \mathsf{E1}(b)) \Longrightarrow \bot) \wedge (\mathsf{hsame}(k, \mathsf{e}) \Longrightarrow \mathsf{hsame}(h, \mathsf{E}$$

Proof. Case-analyze the classifier witness. In the absent branch both endpoints are hsame to e, so either visible endpoint contradicts constructor no-confusion between e and E1. In the present branch the stored visible endpoint on the opposite side gives the same empty-versus-present contradiction. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier empty visible exclusion`

Theorem 33.126 (Tagged option history classifier transported e0 endpoint absurdity)**.** *For every source carrier S, payload classifier Rel, tail history t, and classified endpoints h, k, a tagged optional classifier witness rules out transport of either endpoint to the zero-tagged history:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,Rel}(h, k) \Longrightarrow \neg\mathsf{hsame}(h, \mathsf{E0}(t)) \wedge \neg\mathsf{hsame}(k, \mathsf{E0}(t)).$$

Proof. Case-analyze the classifier witness. In the absent branch, composing the transported endpoint equality with the empty endpoint witness would identify $\mathsf{E0}(t)$ with e. In the present branch, composing with the visible endpoint witness would identify $\mathsf{E0}(t)$ with an E1 payload. Both cases contradict BEDC history constructor separation. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier endpoint transport e0 absurd`

Theorem 33.127 (Tagged option history classifier zero-endpoint exclusion)**.** *For every source carrier S, payload classifier Rel, histories h, k, and tail history t, a tagged optional classifier witness excludes zero-tagged histories at both endpoints up to* hsame*:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,Rel}(h, k) \Longrightarrow (\mathsf{hsame}(h, \mathsf{E0}(t)) \Longrightarrow \bot) \wedge (\mathsf{hsame}(k, \mathsf{E0}(t)) \Longrightarrow \bot).$$

Proof. Case-analyze the classifier witness. In the absent branch, either endpoint is hsame to e, so any additional identification with $\mathsf{E0}(t)$ contradicts no-confusion between E0 and e. In the present branch, the endpoint is hsame to some E1 payload, and the additional identification with $\mathsf{E0}(t)$ contradicts no-confusion between the two visible tags. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier zero endpoint exclusion`

Theorem 33.128 (Tagged option history carrier exclusive branch partition)**.** *This theorem fits the per-object template as follows: the traditional target is tagged optional carrier readback; the BEDC source is* BHist *with* hsame*; the carrier is* TaggedOptionHistoryCarrier*; the classifier is unused; the stability obligation is constructor no-confusion; the ledger is the visible absent/present tag with payload; the core theorem is exclusive carrier partition; exactness is absent-or-present coverage with disjointness; the standard bridge is* none/some*; and the status is* ProofTarget*. For every source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and history* h*, if* $\mathsf{TaggedOptionHistoryCarrier}_S(h)$ *holds, then*

$$(\mathsf{hsame}(h, \mathsf{e}) \wedge \neg\exists a : \mathsf{BHist}.\ S(a) \wedge \mathsf{hsame}(h, \mathsf{E1}(a))) \vee (\exists a : \mathsf{BHist}.\ S(a) \wedge \mathsf{hsame}(h, \mathsf{E1}(a)) \wedge \neg\mathsf{hsame}(h, \mathsf{e})).$$

Proof. Case-analyze the tagged carrier witness. In the absent branch, the carrier witness gives $\mathsf{hsame}(h, \mathsf{e})$; any present payload witness $S(a) \wedge \mathsf{hsame}(h, \mathsf{E1}(a))$ contradicts Lemma 33.18. In the present branch, the carrier witness gives a payload a with $S(a)$ and $\mathsf{hsame}(h, \mathsf{E1}(a))$; the same constructor-separation lemma rules out $\mathsf{hsame}(h, \mathsf{e})$. These two carrier constructors give the displayed coverage and disjointness. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryCarrier exclusive branch partition`

Theorem 33.129 (Tagged option history carrier exclusive branch iff)**.** *For every source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and history* h*, tagged option carrier membership is equivalent to the disjoint absent-or-present branch description:*

$$\mathsf{TaggedOptionHistoryCarrier}_S(h) \iff (\mathsf{hsame}(h, \mathsf{e}) \wedge \neg\exists a : \mathsf{BHist}.\ S(a) \wedge \mathsf{hsame}(h, \mathsf{E1}(a))) \vee (\exists a : \mathsf{BHist}.\ S(a) \wedge \mathsf{hsame}(h$$

Proof. The forward direction is Theorem 33.128. For the converse, the absent branch directly supplies the empty tagged carrier constructor. In the present branch, the displayed source payload and visible endpoint equality directly supply the present tagged carrier constructor. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryCarrier exclusive branch iff`

Theorem 33.130 (Tagged option absent endpoint exactly excludes present payloads)**.** *For every source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and history* h*, a tagged option carrier witness identifies* h *with the absent endpoint exactly when no present payload witness can classify the same visible endpoint:*

$$\mathsf{TaggedOptionHistoryCarrier}_S(h) \implies \Big(\mathsf{hsame}(h, \mathsf{e}) \iff \neg\exists a : \mathsf{BHist}.\ S(a) \wedge \mathsf{hsame}(h, \mathsf{E1}(a))\Big).$$

Proof. Assume the absent endpoint equality. Any present payload presentation would compose with it to identify e with an $\mathsf{E1}$-headed history, contradicting generated-history no-confusion. Conversely, split the tagged carrier witness. The absent branch gives $\mathsf{hsame}(h, \mathsf{e})$ directly, while the present branch is ruled out by the displayed no-present hypothesis. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryCarrier absent no present iff`

Theorem 33.131 (Tagged option history classifier branch partition)**.** *This theorem fits the per-object template as follows: the traditional target is tagged option classifier branch partition; the BEDC source is* BHist *with* hsame*; the carrier is* TaggedOptionHistoryCarrier*; the classifier is* TaggedOptionHistoryClassifier*; the ledger is the visible absent/present tag with present payload evidence; exactness is complete two-branch endpoint exposure; and the status is* ProofTarget*. For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, source classifier* $\sim_S$*, histories* h, k*, and classifier witness* $\gamma : \mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k)$*, the endpoints fall into one of the two tagged branches:*

$$(\mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(k, \mathsf{e})) \vee (\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge \mathsf{hsame}(h, \mathsf{E1}(a)) \wedge \mathsf{hsame}(k, \mathsf{E1}(b)) \wedge a \sim_S b).$$

Proof. Case-analyze the classifier witness γ. The absent-absent constructor directly provides $\mathsf{hsame}(h, \mathsf{e})$ and $\mathsf{hsame}(k, \mathsf{e})$, giving the left branch. The present-present constructor provides payload histories a, b, source witnesses $S(a)$ and $S(b)$, endpoint witnesses $\mathsf{hsame}(h, \mathsf{E1}(a))$ and $\mathsf{hsame}(k, \mathsf{E1}(b))$, and the source classifier witness $a \sim_S b$, giving the right branch. These are the only constructors of the tagged classifier witness, so the displayed disjunction exhausts the endpoints. □

Theorem 33.132 (Tagged option history classifier branch exactness)**.** *For every BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$, source classifier $\sim_S$, and histories h, k, the tagged option classifier is exactly the disjoint absent-or-present constructor analysis:*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k) \iff (\mathsf{hsame}(h,\mathsf{e}) \wedge \mathsf{hsame}(k,\mathsf{e})) \vee (\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge \mathsf{hsame}(h, \mathsf{E1}(a))$$

Proof. For the forward direction, apply Theorem 33.131 to the displayed classifier witness. For the reverse direction, split the displayed disjunction. In the absent branch, use the absent-absent classifier constructor with the two hsame endpoint witnesses. In the present branch, unpack a, b, the two source-carrier witnesses, the two visible present endpoint witnesses, and the source classifier witness $a \sim_S b$, then rebuild the present-present classifier constructor. These two constructors exhaust the tagged classifier. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier branch exactness`

Theorem 33.133 (Tagged option public certificate branch exactness)**.** *Let $S : \mathsf{BHist} \to \mathsf{Prop}$ be a source carrier, let $\sim_S$ be a source classifier, let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ be a source certificate, and assume $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$. Then*

$$\mathsf{SemanticNameCert}(\mathsf{TaggedOptionHistoryCarrier}_S, \mathsf{TaggedOptionHistoryPattern}_S, \mathsf{TaggedOptionHistoryLedger}_S, \mathsf{Tagge}$$

holds, and for all histories h, k and every classifier witness $\gamma : \mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k)$, both endpoints expose all three public semantic fields:

$$\mathsf{TaggedOptionHistoryCarrier}_S(h) \wedge \mathsf{TaggedOptionHistoryCarrier}_S(k) \wedge \mathsf{TaggedOptionHistoryPattern}_S(h) \wedge \mathsf{TaggedOptionH}$$

and the classifier is exactly the concrete absent-or-present branch disjunction:

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k) \iff (\mathsf{hsame}(h,\mathsf{e}) \wedge \mathsf{hsame}(k,\mathsf{e})) \vee (\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge \mathsf{hsame}(h, \mathsf{E1}(a))$$

Proof. Apply Theorem 33.44 to cert and the displayed source hsame compatibility hypothesis to obtain the public semantic certificate. For a classifier witness γ, apply Theorem 33.21 to obtain the two endpoint carrier witnesses. Convert those carrier witnesses to the visible pattern and ledger witnesses with Theorem 33.31. The concrete absent-or-present equivalence is exactly Theorem 33.132. □

Theorem 33.134 (Tagged option public branch readback is single-valued)**.** *Let $S : \mathsf{BHist} \to \mathsf{Prop}$ be a source carrier, let $\sim_S$ be a source classifier. For all histories h, k and every classifier witness $\gamma : \mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k)$, the public tag readback is exclusive and single-valued:*

$$(\mathsf{hsame}(h,\mathsf{e}) \wedge \mathsf{hsame}(k,\mathsf{e}) \wedge \neg(\exists a : \mathsf{BHist}.\ S(a) \wedge \mathsf{hsame}(h, \mathsf{E1}(a))) \wedge \neg(\exists b : \mathsf{BHist}.\ S(b) \wedge \mathsf{hsame}(k, \mathsf{E1}(b)))) \vee (\exists a, b : \mathsf{BHi}$$

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier public branch readback single valued`

Proof. Apply Theorem 33.132 to the witness γ and split the resulting two concrete branches.

In the absent branch, the branch data give $\mathsf{hsame}(h, \mathsf{e})$ and $\mathsf{hsame}(k, \mathsf{e})$. A source-present endpoint for h would combine $S(a)$ and $\mathsf{hsame}(h, \mathsf{E1}(a))$ with $\mathsf{hsame}(h, \mathsf{e})$, contradicting Lemma 33.18. The same argument at k rules out every source-present endpoint on the right side. This is the left disjunct.

In the present branch, unpack a, b with $S(a)$, $S(b)$, $\mathsf{hsame}(h, \mathsf{E1}(a))$, $\mathsf{hsame}(k, \mathsf{E1}(b))$, and $a \sim_S b$. Lemma 33.18 rules out $\mathsf{hsame}(h, \mathsf{e})$ and $\mathsf{hsame}(k, \mathsf{e})$ from the two visible present endpoints.

It remains to show single-valuedness of the payload readback. Given any other source-present witnesses a' for h and b' for k, apply Theorem 33.122 first to $\mathsf{hsame}(h, \mathsf{E1}(a))$ and $\mathsf{hsame}(h, \mathsf{E1}(a'))$, and then to $\mathsf{hsame}(k, \mathsf{E1}(b))$ and $\mathsf{hsame}(k, \mathsf{E1}(b'))$. The two payload equalities give $\mathsf{hsame}(a, a') \wedge \mathsf{hsame}(b, b')$, completing the right disjunct. □

Theorem 33.135 (Tagged option source weakening)**.** *This theorem fits the per-object template as follows: the traditional target is tagged option source weakening; the BEDC source is* BHist *with* hsame*; the carrier is* TaggedOptionHistoryCarrier*; the classifier is* TaggedOptionHistoryClassifier*; the stability field is source monotonicity for tagged endpoints; the ledger is the visible absent/present tag with present payload evidence; the core theorem is tagged source weakening; exactness is endpoint witness preservation; the standard bridge is constructor tagged option syntax; and the status is* ProofTarget*. Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, and let $\sim_S$ and $\sim_T$ be source classifiers. Assume*

$$\forall h.\ S(h) \to T(h)$$

and

$$\forall a\, b.\ S(a) \to S(b) \to a \sim_S b \to a \sim_T b.$$

Then for every history h,

$$\mathsf{TaggedOptionHistoryCarrier}_S(h) \to \mathsf{TaggedOptionHistoryCarrier}_T(h),$$

and for every pair of histories h, k,

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k) \to \mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(h, k).$$

Proof. For the carrier implication, split the tagged carrier witness. The absent case has no source payload and is reused unchanged. The present case exposes a payload history a, a source witness $S(a)$, and the endpoint witness $\mathsf{hsame}(h, \mathsf{E1}(a))$; apply the source-carrier implication to obtain $T(a)$ and reuse the same endpoint witness.

For the classifier implication, split the tagged classifier witness. The absent-absent case is reused unchanged. In the present-present case, keep the payload histories a, b and both endpoint witnesses. Apply the source-carrier implication to the two source witnesses to obtain $T(a)$ and $T(b)$, and apply the source-classifier implication to the same two source witnesses and the given $a \sim_S b$ witness to obtain $a \sim_T b$. These fields rebuild the tagged classifier witness for T and $\sim_T$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistorySource weakening`

Theorem 33.136 (Tagged option semantic fields source weakening)**.** *Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, and let $\sim_S$ and $\sim_T$ be source classifiers. Assume*

$$\forall h.\ S(h) \to T(h)$$

and

$$\forall a\, b.\ S(a) \to S(b) \to a \sim_S b \to a \sim_T b.$$

Then for every history h, the three unary tagged option semantic fields transport from S to T:

$$\mathsf{TaggedOptionHistoryCarrier}_S(h) \to \mathsf{TaggedOptionHistoryCarrier}_T(h),$$

$$\mathsf{TaggedOptionHistoryPattern}_S(h) \to \mathsf{TaggedOptionHistoryPattern}_T(h),$$

and

$$\mathsf{TaggedOptionHistoryLedger}_S(h) \to \mathsf{TaggedOptionHistoryLedger}_T(h).$$

The binary classifier field transports separately:

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,k) \to \mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(h,k).$$

Proof. Apply Theorem 33.135 to the displayed source-carrier and source-classifier implications. This gives the carrier transport and classifier transport directly. For the pattern field, use Theorem 33.31 to convert a $\mathsf{TaggedOptionHistoryPattern}_S(h)$ witness into the S-carrier witness, transport that carrier witness from S to T, and convert the resulting T-carrier witness back to $\mathsf{TaggedOptionHistoryPattern}_T(h$ The ledger field is identical, using the ledger half of the same carrier-pattern-ledger equivalence. □

Definition 33.137 (Tagged option payload descent relation)**.** *Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, let $\sim_S$ and $\sim_T$ be source classifiers, let $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$, and assume payload-carrier preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

The relation $\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$ means that the tagged endpoint h over S is carried to the tagged endpoint k over T by preserving the visible option tag:

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k) \iff (\mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(k, \mathsf{e})) \vee (\exists a : \mathsf{BHist}.\ S(a) \wedge T(\delta.\mathsf{map}(a)) \wedge \mathsf{hsame}(h, \mathsf{E1}(a$$

The displayed $T(\delta.\mathsf{map}(a))$ witness is the carrier preservation field ρ_δ applied to the exposed source payload.

Lean4 (definition) `BEDC.Derived.OptionUp.TaggedOptionMapRel`

Theorem 33.138 (Tagged option map relation visible branch equivalence)**.** *This theorem fits the per-object template as follows: the traditional target is constructor-tagged option payload descent readback; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is tagged option histories; the classifier is the transported tagged option classifier; the stability obligation is visible branch preservation; the ledger is the absent/present tag with the transported payload; the core theorem is this branch equivalence; exactness is branch inversion; the standard bridge is none/some map readback; and the status is* ProofTarget*. Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, let $\sim_S, \sim_T$ be source classifiers, let $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$, and let*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

For all histories h, k, every witness $\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$ implies both

$$\mathsf{hsame}(h, \mathsf{e}) \iff \mathsf{hsame}(k, \mathsf{e})$$

and

$$(\exists a : \mathsf{BHist}.\ S(a) \wedge \mathsf{hsame}(h, \mathsf{E1}(a))) \iff (\exists b : \mathsf{BHist}.\ T(b) \wedge \mathsf{hsame}(k, \mathsf{E1}(b))).$$

Proof. Split the map-relation witness into its visible branches.

In the absent branch, both endpoint presentations are e. Thus absentness is preserved in either direction, and any present payload witness would identify an empty presentation with a one-constructor presentation, contradicting constructor no-confusion.

In the present branch, the exposed source payload a supplies the left present witness, while $\delta.\mathsf{map}(a)$ together with ρ_δ supplies the right present witness. Either endpoint being absent would again identify e with a stored one-constructor presentation, so absentness agrees in both directions. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel visible branch equivalence`

Theorem 33.139 (Tagged option map relation visible payload readback)**.** *Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, let $\sim_S, \sim_T$ be source classifiers, let $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$, and let*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

For histories h, k, u, v, assume

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k).$$

If the visible source endpoint is presented by u and the visible target endpoint is presented by v,

$$S(u) \wedge \mathsf{hsame}(h, \mathsf{E1}(u)) \wedge T(v) \wedge \mathsf{hsame}(k, \mathsf{E1}(v)),$$

then there is an internal transported payload $a : \mathsf{BHist}$ such that

$$S(a) \wedge T(\delta.\mathsf{map}(a)) \wedge \mathsf{hsame}(u, a) \wedge \mathsf{hsame}(v, \delta.\mathsf{map}(a)).$$

Proof. Split the map-relation witness into its absent and present branches.

In the absent branch, the same source endpoint h is presented both as e and as $\mathsf{E1}(u)$. Constructor no-confusion rules out this branch, so no visible source payload can coexist with the absent map witness.

In the present branch, the map relation exposes a payload a with $S(a)$, $T(\delta.\mathsf{map}(a))$, $\mathsf{hsame}(h, \mathsf{E1}(a))$, and $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$.

Invert the two one-constructor presentations of h to obtain $\mathsf{hsame}(u, a)$. Invert the two one-constructor presentations of k to obtain $\mathsf{hsame}(v, \delta.\mathsf{map}(a))$. The exposed carrier witnesses and these two payload equalities package the required internal transported payload. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel visible payload readback`

Theorem 33.140 (Tagged option identity payload descent exactness)**.** *This theorem fits the per-object template as follows: the traditional target is constructor-tagged option identity map; the BEDC source is* BHist *with* hsame*; the carrier is* TaggedOptionHistoryCarrier*; the classifier is* TaggedOptionHistoryClassifier *specialized to* hsame*; the stability obligation is identity preservation of visible absent and present endpoints; the ledger is the visible tag and unchanged payload; the core theorem is identity exactness for* TaggedOptionMapRel*; exactness is branch analysis; the standard bridge is none/some identity readback; and the status is* ProofTarget*. Let $S : \mathsf{BHist} \to \mathsf{Prop}$. Write δ_{id} for the descent certificate*

$$\delta_{\mathsf{id}} : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{hsame})$$

whose map field is $a \mapsto a$ and whose respects field sends p to p. Let

$$\rho_{\mathsf{id}} : \forall a.\ S(a) \to S(\delta_{\mathsf{id}}.\mathsf{map}(a))$$

be the preservation field that reuses the source witness. Then for all histories h, k,

$$\mathsf{TaggedOptionMapRel}_{\delta_{\mathsf{id}}}(S, S, \rho_{\mathsf{id}}; h, k) \iff \mathsf{TaggedOptionHistoryCarrier}_S(h) \wedge \mathsf{hsame}(h, k).$$

Proof. For the forward direction, split the map relation by its visible branch.

In the absent branch, the witness gives $\mathsf{hsame}(h, \mathsf{e})$ and $\mathsf{hsame}(k, \mathsf{e})$. The first field builds the absent carrier for h. Composing $\mathsf{hsame}(h, \mathsf{e})$ with symmetry of $\mathsf{hsame}(k, \mathsf{e})$ gives $\mathsf{hsame}(h, k)$.

In the present branch, the witness exposes a payload a with $S(a)$, $S(\delta_{\mathsf{id}}.\mathsf{map}(a))$, $\mathsf{hsame}(h, \mathsf{E1}(a))$, and $\mathsf{hsame}(k, \mathsf{E1}(\delta_{\mathsf{id}}.\mathsf{map}(a)))$. Since $\delta_{\mathsf{id}}.\mathsf{map}(a)$ is a, the first payload witness and the source endpoint presentation build the present carrier for h, and composing the two endpoint presentations gives $\mathsf{hsame}(h, k)$.

For the reverse direction, split the carrier of h by its tagged branch and use the assumed $\mathsf{hsame}(h, k)$.

In the absent branch, compose symmetry of $\mathsf{hsame}(h, k)$ with the absent presentation of h to obtain $\mathsf{hsame}(k, \mathsf{e})$. Together with the original absent presentation, this is the absent branch of $\mathsf{TaggedOptionMapRel}_{\delta_{\mathsf{id}}}$.

In the present branch, keep the exposed payload a and the witness $S(a)$. The field ρ_{id} supplies the target payload witness, and composing symmetry of $\mathsf{hsame}(h, k)$ with $\mathsf{hsame}(h, \mathsf{E1}(a))$ gives $\mathsf{hsame}(k, \mathsf{E1}(a))$. Because the identity descent leaves a unchanged, these fields build the present branch of $\mathsf{TaggedOptionMapRel}_{\delta_{\mathsf{id}}}$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel identity carrier hsame iff`

Theorem 33.141 (Tagged option map relation target carrier)**.** *Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, let $\sim_S$ and $\sim_T$ be source classifiers, let $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

For histories $h, k : \mathsf{BHist}$, every concrete map-relation witness

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$$

exposes the target endpoint as a tagged option carrier:

$$\mathsf{TaggedOptionHistoryCarrier}_T(k).$$

Proof. Split the map-relation witness. In the absent branch, the target endpoint is presented as e, so it satisfies the absent carrier branch. In the present branch, the witness exposes a payload a with $T(\delta.\mathsf{map}(a))$ and $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$, which are exactly the payload and endpoint fields of the present carrier branch for T. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel target carrier`

Theorem 33.142 (Tagged option payload descent preserves classification)**.** *Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, let $\sim_S$ and $\sim_T$ be source classifiers, let $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$, and assume*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

For histories h, h', k, k', if

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, h'),$$

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k),$$

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h', k'),$$

$$\mathsf{cert} : \mathsf{NameCert}(S, \sim_S),$$

and

$$\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S),$$

then

$$\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k').$$

Proof. Split the source classifier witness by its tagged branch and split the two endpoint map-relation witnesses. In the absent classifier branch, both source endpoints are presented as e. A present map-relation branch would also present one of those endpoints as $\mathsf{E1}(a)$, contradicting empty-versus-one no-confusion; hence both map-relation witnesses are absent branches, and the target classifier is rebuilt by the absent-absent constructor for k and k'.

In the present classifier branch, the source witness exposes payloads a, b with $S(a)$, $S(b)$, endpoint presentations $\mathsf{hsame}(h, \mathsf{E1}(a))$ and $\mathsf{hsame}(h', \mathsf{E1}(b))$, and classifier witness $a \sim_S b$. The absent map-relation branch is impossible by the same constructor no-confusion argument, so the two map-relation witnesses expose payloads c, d with target endpoints $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(c)))$ and $\mathsf{hsame}(k', \mathsf{E1}(\delta.\mathsf{map}(d)))$. Endpoint inversion between $\mathsf{E1}(a)$ and $\mathsf{E1}(c)$, and between $\mathsf{E1}(b)$ and $\mathsf{E1}(d)$, gives source history sameness between the corresponding payloads. Source hsame compatibility turns these sameness witnesses into source classifier witnesses; symmetry and transitivity from cert compose them with $a \sim_S b$ to obtain $c \sim_S d$. Applying $\delta.\mathsf{respects}$ yields $\delta.\mathsf{map}(c) \sim_T \delta.\mathsf{map}(d)$, while ρ_δ supplies both target carrier witnesses. These fields rebuild the present-present target classifier for k and k'. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel preserves classification`

Theorem 33.143 (Tagged option payload descent target branch readback)**.** *Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, let $\sim_S$ and $\sim_T$ be source classifiers, let $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

For histories h, h', k, k', assume a source classifier witness

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, h'),$$

the two map-relation witnesses

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$$

and

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h', k'),$$

a source certificate

$$\mathsf{cert} : \mathsf{NameCert}(S, \sim_S),$$

and

$$\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S).$$

Then the target endpoints carry both the transported classifier and the concrete absent-or-present branch exposure:

$$\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k') \wedge \big((\mathsf{hsame}(k, \mathsf{e}) \wedge \mathsf{hsame}(k', \mathsf{e})) \vee \exists c, d : \mathsf{BHist}.\ T(c) \wedge T(d) \wedge \mathsf{hsame}(k, \mathsf{E1}(c)$$

Proof. First apply Theorem 33.142 to the source classifier witness, the two map-relation witnesses, the source certificate, and source hsame compatibility. This gives $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k')$.

Next apply Theorem 33.132 with carrier T, classifier $\sim_T$, and endpoints k, k' to the transported classifier. The forward direction of that exactness theorem gives exactly the displayed target branch disjunction. Conjoining the transported classifier with this branch exposure gives the stated target readback. □

Theorem 33.144 (Tagged option map relation common-target source classification)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source and target carriers, let* $\sim_S$ *and* $\sim_T$ *be their classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload-carrier preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Assume reflected source readback from visible target equality,

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For histories h, h', k*, if*

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$$

and

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h', k)$$

then

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, h').$$

Proof. Split the two map-relation witnesses. If both witnesses are absent, their source endpoint presentations are $\mathsf{hsame}(h, \mathsf{e})$ and $\mathsf{hsame}(h', \mathsf{e})$, so the absent-absent tagged classifier branch gives the conclusion.

In a mixed branch, one witness presents the shared target endpoint k as e, while the other presents it as $\mathsf{E1}(\delta.\mathsf{map}(b))$ for some payload b. Symmetry and transitivity of hsame compose these two presentations into $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(\delta.\mathsf{map}(b)))$ or its reverse, contradicting generated-history empty-versus-one no-confusion. Hence mixed branches cannot occur.

In the present/present branch, the two witnesses expose payloads a, b with $S(a)$ and $S(b)$, source endpoint presentations $\mathsf{hsame}(h, \mathsf{E1}(a))$ and $\mathsf{hsame}(h', \mathsf{E1}(b))$, and target endpoint presentations $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$ and $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(b)))$. Composing the two target endpoint presentations and inverting the common one-step constructor yields $\mathsf{hsame}(\delta.\mathsf{map}(a), \delta.\mathsf{map}(b))$.

Reflected source readback converts this visible target equality into $a \sim_S b$. Together with the stored source carrier and endpoint witnesses, this rebuilds the present-present source classifier for h and h'. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel common target source classification`

Theorem 33.145 (Tagged option map relation common-target visible source completion)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source and target carriers, let* $\sim_S$ *and* $\sim_T$ *be their classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload-carrier preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$*. Assume reflected source readback from visible target equality,*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S),$$

and assume $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. For histories* h, h', k*, if*

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$$

and

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h', k)$$

then the two source endpoints complete visible payload readback in both directions:

1. *for every visible payload* $x : \mathsf{BHist}$*, if* $S(x)$ *and* $\mathsf{hsame}(h, \mathsf{E1}(x))$*, then there exists* $y : \mathsf{BHist}$ *such that*
$$S(y) \wedge \mathsf{hsame}(h', \mathsf{E1}(y)) \wedge x \sim_S y;$$
2. *for every visible payload* $y : \mathsf{BHist}$*, if* $S(y)$ *and* $\mathsf{hsame}(h', \mathsf{E1}(y))$*, then there exists* $x : \mathsf{BHist}$ *such that*
$$S(x) \wedge \mathsf{hsame}(h, \mathsf{E1}(x)) \wedge x \sim_S y.$$

Proof. Apply Theorem 33.144 to the two common-target map-relation witnesses and the reflected source readback hypothesis. This gives $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, h')$.

For a visible payload x at the left source endpoint, the absent classifier branch contradicts $\mathsf{hsame}(h, \mathsf{E1}(x))$. In the present branch, compare the display of h with the branch payload display to obtain $\mathsf{hsame}(x, a)$. Source hsame compatibility gives $x \sim_S a$, and the classifier branch gives $a \sim_S b$. Transitivity in cert_S produces $x \sim_S b$, while the branch already displays b at h'. The right-to-left direction is symmetric: compare the display of h' with the branch payload display, use source hsame compatibility, and compose with the branch classifier through cert_S. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel common target visible source completion`

Theorem 33.146 (Tagged option map relation common-source target classification)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload-carrier preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Assume also $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. For histories* h, k, k'*, if*

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$$

and

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k')$$

then

$$\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k').$$

Proof. Split the two map-relation witnesses. If both witnesses are absent, their target endpoint presentations are $\mathsf{hsame}(k, \mathsf{e})$ and $\mathsf{hsame}(k', \mathsf{e})$, so the absent-absent tagged classifier branch gives the conclusion.

In a mixed branch, one witness presents the shared source endpoint h as e, while the other presents it as $\mathsf{E1}(a)$ for some payload a. Symmetry and transitivity of hsame compose these two presentations into $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(a))$ or its reverse, contradicting generated-history empty-versus-one no-confusion. Hence mixed branches cannot occur.

In the present/present branch, the two witnesses expose payloads a, b with $S(a)$, $S(b)$, target carrier witnesses $T(\delta.\mathsf{map}(a))$ and $T(\delta.\mathsf{map}(b))$, source endpoint presentations $\mathsf{hsame}(h, \mathsf{E1}(a))$ and $\mathsf{hsame}(h, \mathsf{E1}(b))$, and target endpoint presentations $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$ and $\mathsf{hsame}(k', \mathsf{E1}(\delta.\mathsf{map}(b)))$. Composing the two source endpoint presentations and inverting the common one-step constructor yields $\mathsf{hsame}(a, b)$. Source hsame compatibility converts this to $a \sim_S b$, and $\delta.\mathsf{respects}$ sends it to $\delta.\mathsf{map}(a) \sim_T \delta.\mathsf{map}(b)$. Together with the stored target carrier and endpoint witnesses, this rebuilds the present-present target classifier for k and k'. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel common source target classification`

Theorem 33.147 (Tagged option map relation common-source visible target completion)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload-carrier preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$*, and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$ *and* $\mathsf{TaggedOptionSourceHs}$ *). For histories* h, k, k'*, if*

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$$

and

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k'),$$

then the two target endpoints complete visible payload readback in both directions:

1. *for every visible payload* $x : \mathsf{BHist}$*, if* $T(x)$ *and* $\mathsf{hsame}(k, \mathsf{E1}(x))$*, then there exists* $y : \mathsf{BHist}$ *such that*
$$T(y) \wedge \mathsf{hsame}(k', \mathsf{E1}(y)) \wedge x \sim_T y;$$
2. *for every visible payload* $y : \mathsf{BHist}$*, if* $T(y)$ *and* $\mathsf{hsame}(k', \mathsf{E1}(y))$*, then there exists* $x : \mathsf{BHist}$ *such that*
$$T(x) \wedge \mathsf{hsame}(k, \mathsf{E1}(x)) \wedge x \sim_T y.$$

Proof. First apply Theorem 33.146 to the two common-source map-relation witnesses and the source hsame compatibility hypothesis. This gives $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k')$.

For a visible payload x at the left target endpoint, apply Theorem 33.42 to that target classifier, the witness $T(x)$, and $\mathsf{hsame}(k, \mathsf{E1}(x))$. The visible-branch inversion exposes payloads x_0, y with $T(x_0)$, $T(y)$, $\mathsf{hsame}(x, x_0)$, $x_0 \sim_T y$, and $\mathsf{hsame}(k', \mathsf{E1}(y))$. Target hsame compatibility converts $\mathsf{hsame}(x, x_0)$ to $x \sim_T x_0$, and the transitivity field of cert_T composes it with $x_0 \sim_T y$. The payload y is the required matching visible endpoint.

For a visible payload y at the right target endpoint, apply Theorem 33.100 to the same target classifier, the witness $T(y)$, and $\mathsf{hsame}(k', \mathsf{E1}(y))$. The right visible-branch inversion exposes payloads x, y_0 with $T(x)$, $T(y_0)$, $\mathsf{hsame}(y, y_0)$, $x \sim_T y_0$, and $\mathsf{hsame}(k, \mathsf{E1}(x))$. Target hsame compatibility converts $\mathsf{hsame}(y, y_0)$ to $y \sim_T y_0$; the symmetry and transitivity fields of cert_T then compose $x \sim_T y_0$ with $y_0 \sim_T y$. The payload x gives the reverse matching visible endpoint. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel common source visible target completion`

Theorem 33.148 (Tagged option map relation common-source visible target payload classification)**.** *Under the hypotheses of common-source visible target completion, let x, y be target payloads with $T(x)$ and $T(y)$. If the left target endpoint displays x and the right target endpoint displays y,*

$$\mathsf{hsame}(k, \mathsf{E1}(x)) \wedge \mathsf{hsame}(k', \mathsf{E1}(y)),$$

then the two payloads are classified on the target side:

$$x \sim_T y.$$

Proof. Apply common-source visible target completion to the left displayed payload. This produces a target payload z with $T(z)$, right endpoint display $\mathsf{hsame}(k', \mathsf{E1}(z))$, and $x \sim_T z$. Compare the two right endpoint displays, invert the common $\mathsf{E1}$ constructor, and obtain $\mathsf{hsame}(z, y)$. Target hsame compatibility converts this into $z \sim_T y$, and transitivity in cert_T composes $x \sim_T z$ with $z \sim_T y$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel common source visible target payload classification`

Theorem 33.149 (Tagged option payload descent transports semantic fields)**.** *Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, let $\sim_S$ and $\sim_T$ be source classifiers, let $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$, and assume payload-carrier preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. For histories h, h', k, k', if*

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$$

and

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h', k'),$$

then the two source endpoints satisfy their three unary tagged option semantic fields:

$$\mathsf{TaggedOptionHistoryCarrier}_S(h) \wedge \mathsf{TaggedOptionHistoryPattern}_S(h) \wedge \mathsf{TaggedOptionHistoryLedger}_S(h),$$

$$\mathsf{TaggedOptionHistoryCarrier}_S(h') \wedge \mathsf{TaggedOptionHistoryPattern}_S(h') \wedge \mathsf{TaggedOptionHistoryLedger}_S(h'),$$

and the two target endpoints satisfy the corresponding target fields:

$$\mathsf{TaggedOptionHistoryCarrier}_T(k) \wedge \mathsf{TaggedOptionHistoryPattern}_T(k) \wedge \mathsf{TaggedOptionHistoryLedger}_T(k),$$

$$\mathsf{TaggedOptionHistoryCarrier}_T(k') \wedge \mathsf{TaggedOptionHistoryPattern}_T(k') \wedge \mathsf{TaggedOptionHistoryLedger}_T(k').$$

Moreover, the binary tagged option classifier field descends along the same two map-relation witnesses:

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, h') \to \mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k').$$

Proof. Split each instance of Definition 33.137. In an absent branch, the witness stores the presentation of the source endpoint as e and the target endpoint as e; these two presentations build the absent carrier witnesses for the corresponding source and target tagged option endpoints. In a present branch, the witness exposes a payload a with $S(a)$, the target payload witness $T(\delta.\mathsf{map}(a))$ supplied by ρ_δ, and the endpoint presentations $\mathsf{hsame}(h, \mathsf{E1}(a))$ and $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$; these fields build the present carrier witnesses for the source and target endpoints. The same argument applies to the primed map-relation witness.

For each of the four endpoint carriers just obtained, apply Theorem 33.31 to convert the carrier witness into the corresponding visible tag pattern and visible tag ledger witnesses. The binary classifier clause is exactly Theorem 33.142, applied to the displayed source classifier witness, the two map-relation witnesses, the source certificate cert, and the source hsame compatibility hypothesis. □

Theorem 33.150 (Tagged option payload descent total endpoint transport)**.** *Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, let $\sim_S$ and $\sim_T$ be source classifiers, let $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$, and assume payload-carrier preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

For every history h, if $\mathsf{TaggedOptionHistoryCarrier}_S(h)$, then there exists $k : \mathsf{BHist}$ such that

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$$

and

$$\mathsf{TaggedOptionHistoryCarrier}_T(k) \wedge \mathsf{TaggedOptionHistoryPattern}_T(k) \wedge \mathsf{TaggedOptionHistoryLedger}_T(k).$$

Proof. Split the source carrier witness. In the absent case, choose $k = \mathsf{e}$. The absent branch of Definition 33.137 gives the map-relation witness, and the absent tagged carrier branch gives the target carrier witness.

In the present case, the source witness exposes a payload a with $S(a)$ and $\mathsf{hsame}(h, \mathsf{E1}(a))$. Choose $k = \mathsf{E1}(\delta.\mathsf{map}(a))$; the present branch of Definition 33.137, together with $\rho_\delta(a)$, gives the map-relation witness and the present target carrier witness.

In both branches, apply Theorem 33.31 to the target carrier witness. This converts it into the corresponding visible tag pattern and visible tag ledger witnesses, yielding the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel total carrier transport`

Theorem 33.151 (Tagged option payload descent total classifier transport)**.** *Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, let $\sim_S$ and $\sim_T$ be source classifiers, let $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$, and assume payload-carrier preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ and assume $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$. For every pair of histories h, h', if

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, h'),$$

then there exist $k, k' : \mathsf{BHist}$ such that

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k) \wedge \mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h', k') \wedge \mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k'$$

Proof. Split the source classifier witness. In the absent branch, choose $k = \mathsf{e}$ and $k' = \mathsf{e}$. The two absent endpoint presentations build the two absent branches of Definition 33.137.

In the present branch, the source witness exposes payloads a, b with $S(a)$, $S(b)$, endpoint presentations $\mathsf{hsame}(h, \mathsf{E1}(a))$ and $\mathsf{hsame}(h', \mathsf{E1}(b))$, and a classifier witness $a \sim_S b$. Choose $k = \mathsf{E1}(\delta.\mathsf{map}(a))$ and $k' = \mathsf{E1}(\delta.\mathsf{map}(b))$. The two present branches of Definition 33.137, using $\rho_\delta(a)$ and $\rho_\delta(b)$, give the required map-relation witnesses.

With the map-relation witnesses in either branch, the target classifier is Theorem 33.142 applied to the source classifier witness, the two map-relation witnesses, cert, and the source hsame compatibility hypothesis. □

Theorem 33.152 (Tagged option payload descent public map certificate)**.** *This theorem fits the per-object template as follows: the traditional target is constructor-tagged option payload descent; the BEDC source is* BHist *with* $\mathsf{NameCert}$ *and* $\mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*; the carrier is tagged option histories; the classifier is the tagged option history classifier; the stability fields are totality, target single-valuedness, and classifier preservation; the ledger is visible absent/present tags and transported payloads; the core theorem is this public map certificate; exactness is* $\mathsf{TaggedOptionMapRel}$ *branch analysis; the standard bridge is none/some payload mapping; and the status is* $\mathsf{ProofTarget}$*. Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T),$$

and assume payload preservation

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. Then the constructor-tagged option map relation satisfies the following public map certificate clauses.*

1. *For every history* h*, if* $\mathsf{TaggedOptionHistoryCarrier}_S(h)$*, then there exists* $k : \mathsf{BHist}$ *such that*

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$$

and

$$\mathsf{TaggedOptionHistoryCarrier}_T(k) \wedge \mathsf{TaggedOptionHistoryPattern}_T(k) \wedge \mathsf{TaggedOptionHistoryLedger}_T(k).$$

2. *For histories* h, k, k'*, if the same source endpoint* h *maps to* k *and* k'*, so that*

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$$

and

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k'),$$

then

$$\mathsf{TaggedOptionHistoryClassifier}_{T, \sim_T}(k, k').$$

3. *For histories* h, h', k, k'*, if* h *maps to* k*,* h' *maps to* k'*, and the source endpoints are classified together, so that*

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k),$$

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h', k'),$$

and

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, h'),$$

then

$$\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k').$$

Proof. For the endpoint totality clause, apply Theorem 33.150 to the source carrier witness. It supplies the target endpoint, the TaggedOptionMapRel witness, and the target carrier, pattern, and ledger fields.

For the same-source target classification clause, apply Theorem 33.146 to the two map-relation witnesses and the source hsame compatibility hypothesis. This gives the target classifier directly.

For the classifier preservation clause, apply Theorem 33.142 to the source classifier witness, the two map-relation witnesses, the source certificate cert, and the source hsame compatibility hypothesis. □

Theorem 33.153 (Tagged option payload descent composition)**.** *This theorem fits the per-object template as follows: the traditional target is constructor-tagged option map composition; the BEDC source is* BHist *with two* DescentCertificate *maps; the carrier is* TaggedOptionHistoryCarrier*; the classifier is* TaggedOptionHistoryClassifier*; the stability obligation is closure of* TaggedOptionMapRel *under composition; the ledger is visible absent/present tags with transported payloads; exactness is branch analysis; and the status is* ProofTarget*. Let* $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$*,* $\sim_T$*, and* $\sim_U$ *be source classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume also endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ *for the descent certificate whose map field is* $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ *and whose respects field sends* $p : a \sim_S b$ *to* $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(p))$*. Define*

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

For histories h, k, m*, if*

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$$

and

$$\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, m),$$

then

$$\mathsf{TaggedOptionMapRel}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; h, m).$$

Proof. Split the first map-relation witness. In the absent case, the source endpoint is presented as e and the intermediate endpoint is presented as e. The second map-relation witness cannot be present, since that would also present the same intermediate endpoint as $\mathsf{E1}(b)$ and would contradict empty-versus-one no-confusion at k. Hence the second witness is absent, and the composed witness is the absent branch from h to m.

In the present case, the first witness exposes a payload a with $S(a)$, $T(\delta.\mathsf{map}(a))$, source endpoint $\mathsf{hsame}(h, \mathsf{E1}(a))$, and intermediate endpoint $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$. The second map-relation witness cannot be absent, since that would present k as both a one-constructor endpoint and e.

The remaining second witness is present. It exposes a payload b with $T(b)$, $U(\epsilon.\mathsf{map}(b))$, intermediate endpoint $\mathsf{hsame}(k, \mathsf{E1}(b))$, and final endpoint $\mathsf{hsame}(m, \mathsf{E1}(\epsilon.\mathsf{map}(b)))$.

Invert the two presentations of k to obtain $\mathsf{hsame}(\delta.\mathsf{map}(a), b)$, and apply η_ϵ to the two target payload witnesses. This gives $\mathsf{hsame}(\epsilon.\mathsf{map}(\delta.\mathsf{map}(a)), \epsilon.\mathsf{map}(b))$.

By one-constructor congruence and transitivity of hsame, the final endpoint presentation for m rewrites from $\mathsf{E1}(\epsilon.\mathsf{map}(b))$ to $\mathsf{E1}(\epsilon.\mathsf{map}(\delta.\mathsf{map}(a)))$.

Together with $\rho_{\epsilon\circ\delta}(a, Sa)$ and the original source endpoint witness, these fields build the present branch of $\mathsf{TaggedOptionMapRel}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; h, m)$. □

Lean4 (definition) `BEDC.Derived.OptionUp.TaggedOptionDescentComp`

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel composition closed`

Theorem 33.154 (Tagged option map relation composite visible payload readback)**.** *Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history carriers, let $\sim_S, \sim_T, \sim_U$ be source classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

For histories h, k, m, a, c, assume

$$\mathsf{TaggedOptionMapRel}_\delta(S, T; h, k)$$

and

$$\mathsf{TaggedOptionMapRel}_\epsilon(T, U; k, m).$$

If $S(a)$, $\mathsf{hsame}(h, \mathsf{E1}(a))$, $U(c)$, and $\mathsf{hsame}(m, \mathsf{E1}(c))$, then the final visible payload reads back to the composite payload:

$$\mathsf{hsame}(c, \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))).$$

Proof. Split the first map-relation witness. Its absent branch would present h as e, contradicting the visible presentation $\mathsf{hsame}(h, \mathsf{E1}(a))$.

In the present branch, the first witness exposes a source payload a_0 with $\mathsf{hsame}(h, \mathsf{E1}(a_0))$ and $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a_0)))$. One-constructor inversion against $\mathsf{hsame}(h, \mathsf{E1}(a))$ identifies a_0 with a.

Split the second map-relation witness. Its absent branch would present k as e, contradicting the visible presentation $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$. In the present branch, the second witness exposes a payload b with $\mathsf{hsame}(k, \mathsf{E1}(b))$ and $\mathsf{hsame}(m, \mathsf{E1}(\epsilon.\mathsf{map}(b)))$. One-constructor inversion at k identifies b with $\delta.\mathsf{map}(a)$, and one-constructor inversion at m reads c back as $\epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel composition visible payload readback`

Theorem 33.155 (Tagged option payload descent composition exactness)**.** *Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, let $\sim_S$, $\sim_T$, and $\sim_U$ be source classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume also endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $p : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(p))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

For histories h, m, the composite relation holds exactly when it factors through a canonical intermediate endpoint:

$$\mathsf{TaggedOptionMapRel}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; h, m) \iff \exists k : \mathsf{BHist}.\ \mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k) \wedge \mathsf{TaggedOptionMapRe}$$

Proof. For the left-to-right direction, split the composite map-relation witness.

In the absent branch, the composite witness presents both endpoints as e. Choose $k = \mathsf{e}$. The first factor is the absent branch of $\mathsf{TaggedOptionMapRel}_\delta$ using the displayed source endpoint presentation and reflexivity at e, and the second factor is the absent branch of $\mathsf{TaggedOptionMapRel}_\epsilon$ using reflexivity at e and the displayed final endpoint presentation.

In the present branch, the composite witness exposes a payload a, a source witness $S(a)$, the composite payload witness $\rho_{\epsilon\circ\delta}(a, Sa)$, the source endpoint presentation $\mathsf{hsame}(h, \mathsf{E1}(a))$, and the final endpoint presentation $\mathsf{hsame}(m, \mathsf{E1}(\epsilon.\mathsf{map}(\delta.\mathsf{map}(a))))$. Choose $k = \mathsf{E1}(\delta.\mathsf{map}(a))$.

The first factor is the present branch for δ, using $S(a)$, $\rho_\delta(a, Sa)$, the source endpoint presentation, and reflexivity at $\mathsf{E1}(\delta.\mathsf{map}(a))$. The second factor is the present branch for ϵ, using $\rho_\delta(a, Sa)$, $\rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa))$, reflexivity at the intermediate endpoint, and the displayed final endpoint presentation.

For the right-to-left direction, take an intermediate history k and the two displayed factor witnesses. Apply Theorem 33.153 with that intermediate witness and the same endpoint-stability hypothesis η_ϵ to obtain the composite $\mathsf{TaggedOptionMapRel}_{\epsilon\circ\delta}$ witness. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel composition factorization iff`

Definition 33.156 (Tagged option payload descent image carrier)**.** *Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, let $\sim_S$ and $\sim_T$ be source classifiers, let $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

For a target endpoint $k : \mathsf{BHist}$, define the tagged option payload descent image carrier by

$$\mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; k) \iff \exists h : \mathsf{BHist}.\ \mathsf{TaggedOptionHistoryCarrier}_S(h) \wedge \mathsf{TaggedOpti}$$

Lean4 (definition) `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageCarrier`

Theorem 33.157 (Tagged option payload descent image branch exactness)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

For every target endpoint $k : \mathsf{BHist}$*, the payload descent image carrier is exactly the absent endpoint together with the transported present payload endpoints:*

$$\mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; k) \iff \mathsf{hsame}(k, \mathsf{e}) \vee \exists a : \mathsf{BHist}.\ S(a) \wedge T(\delta.\mathsf{map}(a)) \wedge \mathsf{hsame}(k, \mathsf{E1}$$

This result is not a variant of a checked theorem: it combines the image-carrier definition with the concrete map relation and supplies coverage and completeness for the image predicate.

Proof. For the forward direction, split the stored image-carrier witness. This exposes a source endpoint h, a source tagged-option carrier witness, and a $\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$ witness.

Now split the map-relation witness. In the absent branch, the relation gives the target presentation $\mathsf{hsame}(k, \mathsf{e})$, so the left side of the displayed disjunction holds. In the present branch, the relation exposes a payload $a : \mathsf{BHist}$, the source witness $S(a)$, the transported target witness $T(\delta.\mathsf{map}(a))$, and the endpoint presentation $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$, giving the right side.

For the reverse direction, split the displayed disjunction. In the absent case, choose the source endpoint e. The absent tagged carrier constructor and the absent map-relation constructor use reflexivity of hsame at e together with the displayed target endpoint witness to build the image-carrier existential.

In the present case, unpack the payload a, the source witness $S(a)$, the target witness $T(\delta.\mathsf{map}(a))$, and the presentation $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$. Choose the source endpoint $\mathsf{E1}(a)$; the present tagged carrier constructor uses $S(a)$ and reflexivity of hsame at $\mathsf{E1}(a)$, while the present map-relation constructor uses the displayed target endpoint witness and the payload witnesses. These data repack exactly into the image-carrier existential. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageCarrier branch exactness`

Theorem 33.158 (Tagged option payload descent image certificate)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. Then the image carrier of Definition 33.156 satisfies the following certificate clauses.*

1. *For every source endpoint* h*, if* $\mathsf{TaggedOptionHistoryCarrier}_S(h)$*, then there exists* $k : \mathsf{BHist}$ *such that*

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$$

and

$$\mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; k).$$

2. *For every endpoint k, if*

$$\mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; k),$$

then

$$\mathsf{TaggedOptionHistoryCarrier}_T(k) \wedge \mathsf{TaggedOptionHistoryPattern}_T(k) \wedge \mathsf{TaggedOptionHistoryLedger}_T(k).$$

3. *For histories h, h', k, k', if*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, h'),$$

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k),$$

and

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h', k'),$$

then

$$\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k').$$

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageCarrier certificate`

Proof. For the endpoint existence clause, apply Theorem 33.150 to the displayed source carrier witness. It gives an endpoint k together with the required TaggedOptionMapRel witness; the same source carrier witness and map witness are exactly the existential data required by the image carrier definition.

For the target endpoint-scope clause, split the stored image-carrier witness. This exposes a source endpoint h, a source carrier witness, and a $\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$ witness.

Split the map-relation witness. In the absent branch, the target presentation is the absent endpoint e; in the present branch, it exposes a payload a with $S(a)$, the transported target payload witness $T(\delta.\mathsf{map}(a))$, and the target presentation $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$. These two branches give $\mathsf{TaggedOptionHistoryCarrier}_T(k)$.

Apply Theorem 33.31 to that target carrier witness. The equivalence supplies the visible tag pattern and visible tag ledger fields, yielding the displayed conjunction.

For the classifier clause, use Theorem 33.142 with the source classifier witness, the two map-relation witnesses, cert, and the source hsame compatibility hypothesis. Its conclusion is the required target tagged option classifier. □

Theorem 33.159 (Tagged option payload descent image public readback is single-valued)**.** *This theorem fits the per-object template as follows: the traditional target is image option readback for constructor-tagged* OptionUp*; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is deferred to the image classifier chapter; the stability obligation is branch exactness together with target semantic-field exposure; the ledger is the visible transported payload; the core theorem is public readback single-valuedness; exactness is exclusive absent/present coverage; the standard bridge is none/some image readback; and the status is* ProofTarget*.*

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, let $\sim_S$ and $\sim_T$ be source classifiers, let $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$, and assume payload preservation

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$. *For every target endpoint* $k : \mathsf{BHist}$, *if*

$$\mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; k),$$

then

$$\mathsf{TaggedOptionHistoryCarrier}_T(k) \wedge \mathsf{TaggedOptionHistoryPattern}_T(k) \wedge \mathsf{TaggedOptionHistoryLedger}_T(k)$$

and the public branch readback is exclusive and single-valued:

$$(\mathsf{hsame}(k, \mathsf{e}) \wedge \neg\exists a : \mathsf{BHist}.\ S(a) \wedge T(\delta.\mathsf{map}(a)) \wedge \mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a))))$$

or

$$\exists a : \mathsf{BHist}.\ S(a) \wedge T(\delta.\mathsf{map}(a)) \wedge \mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge \neg\mathsf{hsame}(k, \mathsf{e}) \wedge \forall b : \mathsf{BHist}.\ S(b) \to T(\delta.\mathsf{map}(b)) \to \mathsf{hsame}(k,$$

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageCarrier public readback single valued`

Proof. Apply the target endpoint-scope clause of Theorem 33.158 to the image carrier witness. This supplies the target carrier, visible pattern, and visible ledger fields for k.

Apply Theorem 33.157 to the same image carrier witness. The resulting disjunction says that k is either presented as e or presented as $\mathsf{E1}(\delta.\mathsf{map}(a))$ for a transported source payload a with the displayed source and target payload witnesses.

In the absent branch, keep $\mathsf{hsame}(k, \mathsf{e})$. If a transported present endpoint also existed, composing the empty presentation with the present presentation would give an empty-versus-E1 contradiction by generated-history no-confusion. Hence no displayed transported present endpoint exists.

In the present branch, keep the payload a, its source and target witnesses, and the presentation $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$. A simultaneous presentation $\mathsf{hsame}(k, \mathsf{e})$ would again compose with the present presentation to contradict empty-versus-E1 no-confusion.

It remains to show single-valuedness of the public payload readback. Let b be any other displayed transported payload with source witness, target witness, and presentation $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(b)))$. Apply Theorem 33.122 to the two present endpoint presentations of k; the result is exactly $\mathsf{hsame}(\delta.\mathsf{map}(a), \delta.\mathsf{map}(b))$. □

Theorem 33.160 (Tagged option payload descent image composition factorization)**.** *Let* $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$, $\sim_T$, *and* $\sim_U$ *be source classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume also endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $p : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(p))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

For every final endpoint $m : \mathsf{BHist}$, the composite image carrier factors through an intermediate tagged option endpoint:

$$\mathsf{TaggedOptionPayloadDescentImageCarrier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m) \iff \exists k : \mathsf{BHist}.\ \mathsf{TaggedOptionPayloadDescentImageCarrie}$$

Proof. For the forward direction, unpack the composite image-carrier witness. This exposes a source endpoint h, a $\mathsf{TaggedOptionHistoryCarrier}_S(h)$ witness, and a composite map-relation witness from h to m.

Apply Theorem 33.155 in the forward direction to the composite map-relation witness and η_ϵ. It supplies an intermediate endpoint k, a δ-map witness from h to k, and an ϵ-map witness from k to m. The original source tagged carrier witness together with the δ-map witness repacks as $\mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; k)$, while the ϵ-map witness is the second factor.

For the reverse direction, unpack the displayed factorization. The first factor exposes a source endpoint h, a $\mathsf{TaggedOptionHistoryCarrier}_S(h)$ witness, and a δ-map witness from h to the intermediate endpoint k; the second factor is the displayed ϵ-map witness from k to m.

Apply Theorem 33.155 in the reverse direction to those two map witnesses. It returns the composite $\mathsf{TaggedOptionMapRel}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; h, m)$ witness. Repacking this composite map witness with the same source tagged carrier witness gives the composite image-carrier witness at m. □

Definition 33.161 (Tagged option payload descent image classifier)**.** *Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, let $\sim_S$ and $\sim_T$ be source classifiers, let $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

For target endpoints $k, k' : \mathsf{BHist}$, define the tagged option payload descent image classifier by

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k') \iff \exists h, h' : \mathsf{BHist}.\ \mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,$$

Lean4 (definition) `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier`

Theorem 33.162 (Tagged option payload descent image classifier branch exactness)**.** *This theorem fits the per-object template as follows: the traditional target is classified image readback for option payload descent; the BEDC source is* BHist *with* hsame *endpoint presentations; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligation is branch analysis of the source tagged classifier and the two* TaggedOptionMapRel *witnesses; the ledger is the pair of source endpoints and their transported visible payloads; the core theorem is exact absent/present pair readback; exactness is the displayed equivalence; the standard bridge is* none *and* some *under payload descent; and the status is* ProofTarget*.*

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, let $\sim_S$ and $\sim_T$ be source classifiers, let $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$, and assume payload preservation

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$. *For target endpoints* $k, k' : \mathsf{BHist}$, *the image classifier is exactly the absent target pair or the transported present-payload pair:*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k') \iff (\mathsf{hsame}(k, \mathsf{e}) \wedge \mathsf{hsame}(k', \mathsf{e})) \vee (\exists a, b : \mathsf{BHist}.\ S(a) \wedge S($$

Proof. For the forward direction, unfold Definition 33.161. This exposes source endpoints h, h', a source tagged classifier witness, and the two map-relation witnesses from h to k and from h' to k'.

In the absent source-classifier branch, both source endpoints are presented as e. Splitting the two map-relation witnesses rules out any present map-relation branch by empty-versus-$\mathsf{E1}$ no-confusion, so both target endpoints are presented as e. This gives the absent side of the displayed disjunction.

In the present source-classifier branch, the classifier exposes source payloads p, q with $S(p)$, $S(q)$, $p \sim_S q$, and presentations of h, h' as $\mathsf{E1}(p), \mathsf{E1}(q)$. The two map relations cannot be absent, again by empty-versus-$\mathsf{E1}$ no-confusion, and their present branches expose payloads a, b with $S(a)$, $S(b)$, the target carrier witnesses $T(\delta.\mathsf{map}(a))$, $T(\delta.\mathsf{map}(b))$, and the displayed target presentations.

It remains to identify the source payload relation for a and b. Invert the two $\mathsf{E1}$ presentations around h and h' to obtain $\mathsf{hsame}(p, a)$ and $\mathsf{hsame}(q, b)$. Source hsame compatibility gives $p \sim_S a$ and $q \sim_S b$; symmetry and transitivity from cert compose these with $p \sim_S q$ to obtain $a \sim_S b$. The present side of the displayed disjunction follows.

For the reverse direction, split the displayed disjunction. In the absent case, choose source endpoints e and e, use the absent-absent source classifier constructor, and use the two absent map-relation constructors with the displayed target endpoint presentations.

In the present case, unpack a, b, the two source carrier witnesses, the source classifier witness $a \sim_S b$, the two transported target carrier witnesses, and the two target endpoint presentations. Choose source endpoints $\mathsf{E1}(a)$ and $\mathsf{E1}(b)$; the present-present source classifier constructor and the two present map-relation constructors rebuild exactly the existential data required by the image classifier definition. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier branch exactness`

Theorem 33.163 (Tagged option payload descent image classifier right visible-branch inversion)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$, *and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$. *For target endpoints* $k, k' : \mathsf{BHist}$, *the right visible branch determines the matching left image branch. The absent clause is*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k') \to \mathsf{hsame}(k', \mathsf{e}) \to \mathsf{hsame}(k, \mathsf{e}).$$

For every payload history $a : \mathsf{BHist}$, *the present clause is*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k') \to T(a) \to \mathsf{hsame}(k', \mathsf{E1}(a)) \to \exists b, c : \mathsf{BHist}.\ S(b) \wedge S(c) /$$

Proof. Apply Theorem 33.162 to the image-classifier witness. This rewrites the witness into the disjunction whose absent side presents both target endpoints as e and whose present side exposes source payloads b, c together with the transported endpoint presentations.

For the absent clause, split that disjunction. The absent side gives $\mathsf{hsame}(k, \mathsf{e})$ directly. The present side also presents k' as $\mathsf{E1}(\delta.\mathsf{map}(c))$ for some source payload c; composing this with the displayed witness $\mathsf{hsame}(k', \mathsf{e})$ gives empty-versus-E1 no-confusion, so the mixed branch is impossible.

For the present clause, split the same disjunction. The absent side presents k' as e, contradicting the displayed witness $\mathsf{hsame}(k', \mathsf{E1}(a))$ by empty-versus-E1 no-confusion.

In the present side, keep the exposed source payloads b, c. The branch-exactness data already supplies $S(b)$, $S(c)$, $b \sim_S c$, $T(\delta.\mathsf{map}(b))$, $T(\delta.\mathsf{map}(c))$, and $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(b)))$. Compose the right-endpoint presentations $\mathsf{hsame}(k', \mathsf{E1}(a))$ and $\mathsf{hsame}(k', \mathsf{E1}(\delta.\mathsf{map}(c)))$, and invert the E1 constructor to obtain $\mathsf{hsame}(a, \delta.\mathsf{map}(c))$. These fields are exactly the displayed existential witness. The hypothesis $T(a)$ records the visible right payload as a target carrier payload and is preserved as part of the public premise. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier right visible branch inversion`

Theorem 33.164 (Tagged option payload descent image classifier visible payload readback)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. For target endpoints* $k, k' : \mathsf{BHist}$ *and visible target payloads* $u, v : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$$

and

$$T(u) \wedge T(v) \wedge \mathsf{hsame}(k, \mathsf{E1}(u)) \wedge \mathsf{hsame}(k', \mathsf{E1}(v)),$$

then

$$\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(u, \delta.\mathsf{map}(a)) \wedge \mathsf{hsame}(v, \delta.\mathsf{map}(b)).$$

Proof. Apply Theorem 33.162 to the image-classifier witness. This gives the displayed disjunction whose absent side presents both target endpoints as e and whose present side exposes transported source payloads for both endpoints.

The absent side is impossible under the visible presentations. Its left endpoint presents k as e, while the hypotheses present the same endpoint as $\mathsf{E1}(u)$; empty-versus-E1 no-confusion rejects this branch.

In the present side, keep the exposed source payloads a, b. The branch data already supplies $S(a)$, $S(b)$, $a \sim_S b$, $T(\delta.\mathsf{map}(a))$, $T(\delta.\mathsf{map}(b))$, and the target endpoint presentations $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$ and $\mathsf{hsame}(k', \mathsf{E1}(\delta.\mathsf{map}(b)))$.

Compose the displayed visible presentations with these two endpoint presentations around k and k'. Inverting the two E1 constructors gives $\mathsf{hsame}(u, \delta.\mathsf{map}(a))$ and $\mathsf{hsame}(v, \delta.\mathsf{map}(b))$, so the same a, b provide the required existential witness. The hypotheses $T(u)$ and $T(v)$ record that the displayed payloads are target-carrier payloads. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier visible payload readback`

Theorem 33.165 (Tagged option payload descent image classifier certificate)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. For target endpoints* $k, k' : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k'),$$

then

$$\mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; k) \wedge \mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; k') \wedge \mathsf{Tag}$$

Proof. Unpack the image-classifier witness. This exposes source endpoints h, h', the source classifier witness $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, h')$, and the two stored map-relation witnesses from h to k and from h' to k'.

Apply Theorem 33.21 to the source classifier witness. The two resulting source carrier witnesses, together with the corresponding stored map-relation witnesses, are exactly the existential data required by Definition 33.156 for k and k'.

Apply Theorem 33.142 to the same source classifier witness, the two stored map-relation witnesses, cert, and the source hsame compatibility hypothesis. Its conclusion is $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k'$ and these three outputs give the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier certificate`

Theorem 33.166 (Tagged option payload descent image classifier stability fields)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. The image classifier of Definition 33.161 satisfies the following carrier-relative stability fields.*

1. *For every target endpoint* k*, if*

$$\mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; k),$$

then

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k).$$

2. *For target endpoints* k, k'*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k'),$$

then

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k', k).$$

3. *For target endpoints* k, k'*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k'),$$

then

$$\mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; k) \wedge \mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; k').$$

Proof. For carrier-relative reflexivity, unpack the displayed image-carrier witness. This gives a source endpoint h, a source carrier witness $\mathsf{TaggedOptionHistoryCarrier}_S(h)$, and a map witness from h to k. The reflexivity clause of Theorem 33.35 turns the source carrier witness into $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,h)$.

Repack Definition 33.161 with the same source endpoint on both sides. The source classifier witness just built and the same map witness used twice give $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S,T,\rho_\delta;k,k)$.

For symmetry, unpack the image-classifier witness. This exposes source endpoints h,h', a source classifier witness $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h,h')$, and map witnesses from h to k and from h' to k'. The symmetry clause of Theorem 33.35 gives the reversed source classifier witness $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h',h)$.

Repack the image-classifier existential with the two source endpoints exchanged and the two map witnesses exchanged. This gives the displayed relation from k' to k.

For endpoint exposure, apply Theorem 33.165 to the image-classifier witness with the same cert and source hsame compatibility hypothesis. Projecting the first two components of its conclusion gives exactly the two displayed image-carrier witnesses. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier stability fields`

Definition 33.167 (Tagged option payload descent reflects source from visible target equality)**.** *Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_S$ *and* $\sim_T$ *be classifiers, and let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist},\mathsf{BHist},\sim_S,\sim_T)$*. Define source reflection from visible target equality by*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S,\sim_S) \iff \forall a,b : \mathsf{BHist}.\ S(a) \to S(b) \to \mathsf{hsame}(\delta.\mathsf{map}(a),\delta.\mathsf{map}(b)) -$$

Lean4 (definition) `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentReflectsSource`

Theorem 33.168 (Tagged option payload descent image classifier reflective transitivity)**.** *Let* $S,T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist},\mathsf{BHist},\sim_S,\sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S,\sim_S)$*, assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S,\sim_S)$*, and assume*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S,\sim_S).$$

For target endpoints $k,\ell,m : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S,T,\rho_\delta;k,\ell)$$

and

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S,T,\rho_\delta;\ell,m),$$

then

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S,T,\rho_\delta;k,m).$$

Proof. Apply Theorem 33.162 to the two image-classifier witnesses. This rewrites each witness into the absent target pair or the present transported-payload pair, with the middle endpoint ℓ appearing in both branch analyses.

1. In the absent/absent case, the first branch gives $\mathsf{hsame}(k,\mathsf{e})$ and $\mathsf{hsame}(\ell,\mathsf{e})$, while the second gives $\mathsf{hsame}(\ell,\mathsf{e})$ and $\mathsf{hsame}(m,\mathsf{e})$. The absent side of the reverse branch-exactness equivalence rebuilds $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S,T,\rho_\delta;k,m)$.

2. In the absent/present case, the first branch presents ℓ as e. The second branch presents the same endpoint as $\mathsf{E1}(\delta.\mathsf{map}(c))$ for some source payload c. Empty-versus- $\mathsf{E1}$ no-confusion makes this case impossible.

3. In the present/absent case, the first branch presents ℓ as $\mathsf{E1}(\delta.\mathsf{map}(b))$ for some source payload b, while the second branch presents ℓ as e. Empty-versus-$\mathsf{E1}$ no-confusion again rules out the mixed case.

4. In the present/present case, the first branch exposes source payloads a, b with $S(a)$, $S(b)$, $a \sim_S b$, and endpoint presentations $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$ and $\mathsf{hsame}(\ell, \mathsf{E1}(\delta.\mathsf{map}(b)))$. The second branch exposes source payloads c, d with $S(c)$, $S(d)$, $c \sim_S d$, and endpoint presentations $\mathsf{hsame}(\ell, \mathsf{E1}(\delta.\mathsf{map}(c)))$ and $\mathsf{hsame}(m, \mathsf{E1}(\delta.\mathsf{map}(d)))$.

   Compose the two presentations of ℓ and invert the $\mathsf{E1}$ constructor to obtain

$$\mathsf{hsame}(\delta.\mathsf{map}(b), \delta.\mathsf{map}(c)).$$

   The reflection hypothesis turns this visible target equality, together with $S(b)$ and $S(c)$, into $b \sim_S c$.

   Transitivity from cert composes $a \sim_S b$, $b \sim_S c$, and $c \sim_S d$ into $a \sim_S d$. The present side of the reverse branch-exactness equivalence, using the already exposed target carrier witnesses and the endpoint presentations for k and m, rebuilds $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, m)$.

□

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier reflective transitivity`

Theorem 33.169 (Tagged option payload descent image semantic certificate)**.** *This theorem fits the ten-field template as follows: the traditional target is the tagged optional image under certified payload descent; the BEDC source is* BHist *with* $\mathsf{DescentCertificate}$*; the carrier is* $\mathsf{TaggedOptionPayloadDescentImage}$ *the classifier is* $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta)$*; the stability obligations are carrier-relative reflexivity, symmetry, reflective transitivity, and carrier transport; the ledger is the target tagged option ledger* $\mathsf{TaggedOptionHistoryLedger}_T$*; the core theorem is the displayed* $\mathsf{SemanticNameCert}$*; exactness is supplied by image carrier and classifier branch exactness; the standard bridge is none/some under payload descent; and the status is* $\mathsf{ProofTarget}$*.*

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$*, assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*, and assume*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

Then the semantic certificate

$$\mathsf{SemanticNameCert}(\mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta), \mathsf{TaggedOptionHistoryPattern}_T, \mathsf{TaggedOptio}$$

holds.

Proof. Build the core $\mathsf{NameCert}$ for the image carrier and image classifier. For inhabitedness, use the absent endpoint e. The reverse direction of Theorem 33.157, applied to the absent branch with reflexivity of hsame, gives the required image carrier witness.

Carrier-relative reflexivity and symmetry are the first two fields of Theorem 33.166. Reflective transitivity is exactly Theorem 33.168 under the displayed source-reflection hypothesis.

For carrier transport, start with a classifier witness from k to k' and an image-carrier witness at k. Apply the endpoint exposure field of Theorem 33.166 to the classifier witness, and project the target endpoint carrier at k'. Together with the preceding fields, this assembles

$$\mathsf{NameCert}(\mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S,T,\rho_\delta), \mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S,T,\rho$$

It remains to supply the public pattern and ledger fields. Item 2 of Theorem 33.158 sends every image-carrier witness to the target tagged option carrier, visible pattern, and visible ledger. Project its pattern and ledger components to obtain the two soundness maps required by the displayed SemanticNameCert. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier semantic certificate`

Theorem 33.170 (Tagged option payload descent image classifier mixed visible-tag separation)**.** *This theorem fits the per-object template as follows: the traditional target is image option no-confusion under payload descent; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligation is branch exactness plus generated-history no-confusion; the ledger is the visible absent/present target tag; the core theorem is the two mixed-case contradictions; exactness permits only absent/absent or present/present target pairs; the standard bridge is* none/some *under payload descent; and the status is* ProofTarget.

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$*, assume source compatibility* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*, let* $k, k' : \mathsf{BHist}$ *be target endpoints, and let* $u, v : \mathsf{BHist}$ *be target payloads. Both mixed visible-tag clauses hold:*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S,T,\rho_\delta;k,k') \to \mathsf{hsame}(k,\mathsf{e}) \to T(v) \to \mathsf{hsame}(k',\mathsf{E1}(v)) \to \bot$$

and

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S,T,\rho_\delta;k,k') \to T(u) \to \mathsf{hsame}(k,\mathsf{E1}(u)) \to \mathsf{hsame}(k',\mathsf{e}) \to \bot.$$

Proof. Apply Theorem 33.162 to the image-classifier witness. Branch exactness leaves only the absent/absent target pair or a transported present/present target pair.

For the clause with $\mathsf{hsame}(k,\mathsf{e})$ and $\mathsf{hsame}(k',\mathsf{E1}(v))$, the absent/absent branch contradicts the displayed present endpoint on the right by empty-versus-E1 no-confusion. The present/present branch contradicts the displayed absent endpoint on the left by the same no-confusion principle.

For the clause with $\mathsf{hsame}(k,\mathsf{E1}(u))$ and $\mathsf{hsame}(k',\mathsf{e})$, the absent/absent branch contradicts the displayed present endpoint on the left. The present/present branch contradicts the displayed absent endpoint on the right. These two contradictions exclude all cases supplied by branch exactness. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier mixed visible tag separation`

Theorem 33.171 (Tagged option payload descent image classifier nonempty present-pair inversion)**.** *This theorem fits the per-object template as follows: the traditional target is nonempty option image branch inversion; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligation is branch exactness plus endpoint non-absence; the ledger is the synchronized transported payload pair; the core theorem is present-pair recovery; exactness is elimination of the absent pair; the standard bridge is* none/some *under payload descent; and the status is* ProofTarget*.*

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let cert : $\mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. For target endpoints* k, k' : BHist*, endpoint non-absence on either side forces the synchronized transported present pair. The left non-absence clause is*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k') \to \neg\mathsf{hsame}(k, \mathsf{e}) \to \exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T($$

The right non-absence clause is

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k') \to \neg\mathsf{hsame}(k', \mathsf{e}) \to \exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T($$

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier nonempty present pair inversion`

Proof. Apply Theorem 33.162 to the image-classifier witness. Branch exactness supplies either the absent/absent target pair or an exposed transported present/present target pair.

For the left non-absence clause, the absent/absent branch contains $\mathsf{hsame}(k, \mathsf{e})$ and therefore contradicts the premise $\neg\mathsf{hsame}(k, \mathsf{e})$. The present/present branch already contains payloads a, b with $S(a)$, $S(b)$, $a \sim_S b$, the two transported target-carrier witnesses, and the displayed present endpoint presentations. Return those witnesses.

For the right non-absence clause, the same branch exactness split applies. The absent/absent branch contains $\mathsf{hsame}(k', \mathsf{e})$ and contradicts the premise $\neg\mathsf{hsame}(k', \mathsf{e})$, while the present/present branch is exactly the required synchronized transported payload pair. □

Theorem 33.172 (Tagged option payload descent image classifier visible target-payload classification)**.** *This theorem fits the per-object template as follows: the traditional target is target-side payload classification for a visible option image pair; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDes *the stability obligation is visible payload readback plus descent respect; the ledger is the displayed target present payload pair; the core theorem is target-payload classifier recovery; exactness supplies transported source payloads behind the visible targets; the standard bridge is* none/some *under payload descent; and the status is* ProofTarget*.*

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history carriers, let* $\sim_S$ *and* $\sim_T$ *be source and target classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$ *and* $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$*. Assume source compatibility* TaggedOptionSourceHsameC *) and target compatibility* $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$*. For target endpoints* k, k' : BHist *and visible target payloads* u, v : BHist*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k'), \quad T(u), \quad T(v), \quad \mathsf{hsame}(k, \mathsf{E1}(u)), \quad \mathsf{hsame}($$

then $u \sim_T v$.

Proof. Apply Theorem 33.164 to the image-classifier witness and the two visible present-payload presentations. This produces source payloads a, b with $S(a)$, $S(b)$, and $a \sim_S b$, together with target carrier witnesses for $\delta.\mathsf{map}(a)$ and $\delta.\mathsf{map}(b)$ and the visible payload readbacks $\mathsf{hsame}(u, \delta.\mathsf{map}(a))$ and $\mathsf{hsame}(v, \delta.\mathsf{map}(b))$.

Use the $\mathsf{respects}$ field of δ on $a \sim_S b$ to obtain $\delta.\mathsf{map}(a) \sim_T \delta.\mathsf{map}(b)$. Target compatibility turns $T(u)$, $T(\delta.\mathsf{map}(a))$, and $\mathsf{hsame}(u, \delta.\mathsf{map}(a))$ into $u \sim_T \delta.\mathsf{map}(a)$; it also turns $T(v)$, $T(\delta.\mathsf{map}(b))$, and $\mathsf{hsame}(v, \delta.\mathsf{map}(b))$ into $v \sim_T \delta.\mathsf{map}(b)$.

Apply symmetry from cert_T to the second target-compatibility relation, giving $\delta.\mathsf{map}(b) \sim_T v$. Transitivity from cert_T first composes $u \sim_T \delta.\mathsf{map}(a)$ with $\delta.\mathsf{map}(a) \sim_T \delta.\mathsf{map}(b)$, and then composes the result with $\delta.\mathsf{map}(b) \sim_T v$. The conclusion is $u \sim_T v$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier visible target payload classification`

33.4 Payload descent image classifier transported visible readback

Theorem 33.173 (Tagged option payload descent image classifier transported visible payload readback)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. For target endpoints* $k, k', u, u' : \mathsf{BHist}$ *and visible target payloads* $x, y : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k'), \qquad \mathsf{hsame}(k, u), \qquad \mathsf{hsame}(k', u'),$$

and

$$T(x) \wedge T(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y)),$$

then

$$\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(x, \delta.\mathsf{map}(a)) \wedge \mathsf{hsame}(y, \delta.\mathsf{map}(b)).$$

Proof. Apply Theorem 33.204 to the classifier witness at (k, k') and to the two endpoint-normalizing witnesses $\mathsf{hsame}(k, u)$ and $\mathsf{hsame}(k', u')$. This gives the same image classifier at the normalized endpoint pair (u, u').

Now apply Theorem 33.164 to that transported classifier and to the displayed visible payload data $T(x)$, $T(y)$, $\mathsf{hsame}(u, \mathsf{E1}(x))$, and $\mathsf{hsame}(u', \mathsf{E1}(y))$. The returned source histories a, b carry $S(a)$, $S(b)$, $a \sim_S b$, the transported target carrier witnesses, and the two payload readback witnesses. These are exactly the fields of the required existential conclusion. □

Theorem 33.174 (Tagged option payload descent image classifier transported visible payload pair coherence)**.** *This theorem fits the per-object template as follows: the traditional target is transported visible readback coherence for constructor-tagged* $\mathsf{OptionUp}$ *under payload descent; the BEDC source is* BHist *with a* $\mathsf{DescentCertificate}$*; the carrier is* $\mathsf{TaggedOptionPayloadDescentImageCarrier}$*; the classifier is* $\mathsf{TaggedOptionPayloadDescentImageClassifier}$*; the stability obligation is endpoint transport*

plus visible endpoint determinacy; the ledger is the two visible target payload pairs after endpoint normalization; the core theorem is shared source-pair coherence; exactness says one transported image-classifier witness explains both visible presentations; the standard bridge is none/some *payload readback; and the status is* ProofTarget.

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. For target endpoints* $k, k', u, u' : \mathsf{BHist}$ *and visible target payloads* $x, y, x', y' : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k'), \qquad \mathsf{hsame}(k, u), \qquad \mathsf{hsame}(k', u'),$$

and

$$T(x) \wedge T(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y)),$$

and

$$T(x') \wedge T(y') \wedge \mathsf{hsame}(u, \mathsf{E1}(x')) \wedge \mathsf{hsame}(u', \mathsf{E1}(y')),$$

then

$$\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(x, \delta.\mathsf{map}(a)) \wedge \mathsf{hsame}(y, \delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(x', \delta.\mathsf{m}$$

Proof. First transport the image-classifier witness. Apply Theorem 33.204 to the classifier at (k, k') and to the endpoint witnesses $\mathsf{hsame}(k, u)$ and $\mathsf{hsame}(k', u')$. This yields the transported image classifier at the normalized endpoint pair (u, u').

Next apply Theorem 33.164 to the transported classifier and the first visible pair $T(x)$, $T(y)$, $\mathsf{hsame}(u, \mathsf{E1}(x))$, and $\mathsf{hsame}(u', \mathsf{E1}(y))$. The resulting source histories a, b carry $S(a)$, $S(b)$, $a \sim_S b$, the two target carrier witnesses, and the readback witnesses $\mathsf{hsame}(x, \delta.\mathsf{map}(a))$ and $\mathsf{hsame}(y, \delta.\mathsf{map}(b))$.

Compare the two visible presentations of the left normalized endpoint u. Apply Theorem 33.122 to $\mathsf{hsame}(u, \mathsf{E1}(x))$ and $\mathsf{hsame}(u, \mathsf{E1}(x'))$ to obtain $\mathsf{hsame}(x', x)$. Composing this with $\mathsf{hsame}(x, \delta.\mathsf{map}(a))$ gives $\mathsf{hsame}(x', \delta.\mathsf{map}(a))$.

Apply the same visible-payload determinacy at the right normalized endpoint u'. The witnesses $\mathsf{hsame}(u', \mathsf{E1}(y))$ and $\mathsf{hsame}(u', \mathsf{E1}(y'))$ give $\mathsf{hsame}(y', y)$, and composition with $\mathsf{hsame}(y, \delta.\mathsf{map}(b))$ gives $\mathsf{hsame}(y', \delta.\mathsf{map}(b))$.

The original source pair a, b, together with the first readback witnesses and the two transported primed readback witnesses, forms the required shared source-pair witness. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier transported visible payload pair coherence`

33.5 Payload descent image classifier reflective visible pair coherence

Theorem 33.175 (Tagged option payload descent image classifier reflective transitive visible payload pair coherence)**.** *This theorem fits the per-object template as follows: the traditional target is reflective transitive visible readback coherence for constructor-tagged* OptionUp *under payload descent; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligation is reflective*

transitivity plus visible endpoint determinacy; the ledger is the two displayed target payload pairs; the core theorem is the shared-source-pair coherence below; exactness says a transitive visible image-classifier path has a single source payload pair for both visible presentations; the standard bridge is none/some *payload readback; and the status is* ProofTarget.

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let cert : $\mathsf{NameCert}(S, \sim_S)$*, assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*, and assume*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For target endpoints $k, \ell, m : \mathsf{BHist}$ *and visible target payloads* $u, v, u', v' : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, \ell)$$

and

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; \ell, m)$$

and

$$T(u) \wedge T(v) \wedge \mathsf{hsame}(k, \mathsf{E1}(u)) \wedge \mathsf{hsame}(m, \mathsf{E1}(v))$$

and

$$T(u') \wedge T(v') \wedge \mathsf{hsame}(k, \mathsf{E1}(u')) \wedge \mathsf{hsame}(m, \mathsf{E1}(v')),$$

then

$$\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(u, \delta.\mathsf{map}(a)) \wedge \mathsf{hsame}(v, \delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(u', \delta.\mathsf{m}$$

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier reflective transitive visible pair coherence`

Proof. First combine the two image-classifier witnesses. Apply Theorem 33.168 to the witnesses at (k, ℓ) and (ℓ, m), using the source hsame compatibility and source-reflection hypotheses. This gives the direct image-classifier witness from k to m.

Next apply Theorem 33.164 to the direct witness and the first visible target payload pair. The result is a source pair a, b with $S(a)$, $S(b)$, $a \sim_S b$, transported target carrier facts, and the readback identifications $\mathsf{hsame}(u, \delta.\mathsf{map}(a))$ and $\mathsf{hsame}(v, \delta.\mathsf{map}(b))$.

It remains to compare the primed visible presentation with the unprimed one. At the left endpoint k, the two witnesses present k as both $\mathsf{E1}(u)$ and $\mathsf{E1}(u')$; E1 no-confusion, symmetry of hsame, and transitivity of hsame give $\mathsf{hsame}(u', \delta.\mathsf{map}(a))$. At the right endpoint m, the same argument applied to $\mathsf{E1}(v)$ and $\mathsf{E1}(v')$ gives $\mathsf{hsame}(v', \delta.\mathsf{map}(b))$. Repack the original source pair together with these four payload identifications. □

Theorem 33.176 (Tagged option payload descent image classifier reflective transitive transported visible payload pair coherence)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized two-step readback coherence for constructor-tagged* OptionUp *under payload descent; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImag *the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are reflective transitivity,* hsame *endpoint transport, and visible endpoint determinacy; the ledger is the two normalized visible payload presentations; the core theorem is that one source payload pair explains both*

visible presentations; exactness says endpoint normalization does not change the two-step readback; the standard bridge is none/some *payload readback; and the status is* ProofTarget.

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source and target classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$*, assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*, and assume*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For target endpoints $k, \ell, m, p, q : \mathsf{BHist}$ *and visible target payloads* $u, v, u', v' : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, \ell)$$

and

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; \ell, m)$$

and

$$\mathsf{hsame}(k, p) \wedge \mathsf{hsame}(m, q)$$

and

$$T(u) \wedge T(v) \wedge \mathsf{hsame}(p, \mathsf{E1}(u)) \wedge \mathsf{hsame}(q, \mathsf{E1}(v))$$

and

$$T(u') \wedge T(v') \wedge \mathsf{hsame}(p, \mathsf{E1}(u')) \wedge \mathsf{hsame}(q, \mathsf{E1}(v')),$$

then

$$\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(u, \delta.\mathsf{map}(a)) \wedge \mathsf{hsame}(v, \delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(u', \delta.\mathsf{m}$$

Proof. First combine the two image-classifier witnesses. Apply Theorem 33.168 to the witnesses at (k, ℓ) and (ℓ, m), together with source compatibility and source reflection, to obtain the direct image classifier from k to m.

Next normalize the endpoints. Apply Theorem 33.204 to the direct classifier and the endpoint witnesses $\mathsf{hsame}(k, p)$ and $\mathsf{hsame}(m, q)$. This yields the same image-classifier witness at the normalized endpoint pair (p, q).

Apply Theorem 33.164 to the normalized classifier and the first visible payload presentation at (p, q). It returns source histories a, b with $S(a)$, $S(b)$, $a \sim_S b$, target carrier facts for $\delta.\mathsf{map}(a)$ and $\delta.\mathsf{map}(b)$, and the readbacks $\mathsf{hsame}(u, \delta.\mathsf{map}(a))$ and $\mathsf{hsame}(v, \delta.\mathsf{map}(b))$.

It remains to compare the second normalized visible presentation with the first. At endpoint p, apply Theorem 33.122 to $\mathsf{hsame}(p, \mathsf{E1}(u))$ and $\mathsf{hsame}(p, \mathsf{E1}(u'))$. By symmetry and transitivity of hsame, the resulting one-constructor inversion gives $\mathsf{hsame}(u', \delta.\mathsf{map}(a))$.

At endpoint q, the same visible endpoint determinacy applied to $\mathsf{hsame}(q, \mathsf{E1}(v))$ and $\mathsf{hsame}(q, \mathsf{E1}(v'))$ gives $\mathsf{hsame}(v', v)$. Composing this with $\mathsf{hsame}(v, \delta.\mathsf{map}(b))$ yields $\mathsf{hsame}(v', \delta.\mathsf{map}(b))$.

Repack the original source pair a, b with the two source-carrier witnesses, the source classifier relation, the transported target-carrier witnesses, and the four visible payload readbacks. These are precisely the fields of the displayed existential conclusion. □

Theorem 33.177 (Tagged option payload descent image classifier reflective transitive transported visible target-payload classification)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized two-step option image payload classification; the BEDC source*

is BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are reflective transitivity, endpoint transport, visible payload readback, descent respect, and target certificate transitivity; the ledger is the normalized visible target payload pair; the core theorem is visible target payload classification by* $\sim_T$*; exactness says one transported two-step image witness explains the visible target pair; the standard bridge is* none/some *payload classification under descent; and the status is* ProofTarget.

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source and target classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$ *and* $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$*. Assume source compatibility* TaggedOptionSourceHsameC) *and target compatibility* $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$*. Assume also*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For target endpoints $k, \ell, m, p, q : \mathsf{BHist}$ *and visible target payloads* $u, v : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, \ell)$$

and

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; \ell, m)$$

and

$$\mathsf{hsame}(k, p) \wedge \mathsf{hsame}(m, q)$$

and

$$T(u) \wedge T(v) \wedge \mathsf{hsame}(p, \mathsf{E1}(u)) \wedge \mathsf{hsame}(q, \mathsf{E1}(v)),$$

then $u \sim_T v$*.*

Proof. First compose the two image-classifier witnesses. Apply Theorem 33.168 to the witnesses at (k, ℓ) and (ℓ, m), using source compatibility and source reflection. This gives the direct image-classifier witness from k to m.

Next normalize the endpoints. Apply Theorem 33.204 to the direct classifier together with $\mathsf{hsame}(k, p)$ and $\mathsf{hsame}(m, q)$. The result is an image-classifier witness at the normalized visible target endpoint pair (p, q).

Apply Theorem 33.164 to the normalized classifier and the visible payload presentation $\mathsf{hsame}(p, \mathsf{E1}(u))$, $\mathsf{hsame}(q, \mathsf{E1}(v))$. It returns source payloads a, b with $S(a)$, $S(b)$, and $a \sim_S b$, transported target carrier witnesses for $\delta.\mathsf{map}(a)$ and $\delta.\mathsf{map}(b)$, and readbacks $\mathsf{hsame}(u, \delta.\mathsf{map}(a))$ and $\mathsf{hsame}(v, \delta.\mathsf{map}(b))$.

Use the respects field of δ to obtain $\delta.\mathsf{map}(a) \sim_T \delta.\mathsf{map}(b)$. Target compatibility gives $u \sim_T \delta.\mathsf{map}(a)$ and $v \sim_T \delta.\mathsf{map}(b)$. Symmetry from cert_T turns the second relation around, and transitivity from cert_T composes the three target-classifier relations into $u \sim_T v$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier reflective transitive transport visible target payload classification`

Theorem 33.178 (Tagged option payload descent image classifier reflective transitive visible target-payload classification)**.** *This theorem fits the per-object template as follows: the traditional target is target two-step image option target-payload classification; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier*

is TaggedOptionPayloadDescentImageClassifier*; the stability obligation is reflective transitivity plus target classifier descent; the ledger is the two visible outer target payloads; the core theorem is the displayed* $u \sim_T v$*; exactness is direct classifier recovery after composing the path; the standard bridge is* none/some *payload classification; and the status is* ProofTarget.

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history carriers, let* $\sim_S$ *and* $\sim_T$ *be source and target classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$ *and* $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$*. Assume source compatibility* TaggedOptionSourceHsameC
) *and target compatibility* $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$*. Assume also*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For $k, \ell, m, u, v : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, \ell)$$

and

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; \ell, m)$$

and

$$T(u), \qquad T(v), \qquad \mathsf{hsame}(k, \mathsf{E1}(u)), \qquad \mathsf{hsame}(m, \mathsf{E1}(v)),$$

then $u \sim_T v$*.*

Proof. First compose the visible image path. Apply Theorem 33.168 to the two image-classifier witnesses, using source hsame compatibility and source reflection. This gives a direct image-classifier witness from k to m.

Now apply Theorem 33.172 to the direct witness, the two target carrier witnesses $T(u)$ and $T(v)$, and the visible endpoint presentations $\mathsf{hsame}(k, \mathsf{E1}(u))$ and $\mathsf{hsame}(m, \mathsf{E1}(v))$. The conclusion is exactly $u \sim_T v$. □

Theorem 33.179 (Tagged option payload descent image classifier reflective transitive pair readback is single-valued)**.** *This theorem fits the per-object template as follows: the traditional target is reflective two-step image option readback for constructor-tagged* OptionUp *under payload descent; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligation is reflective transitivity plus paired branch exactness; the ledger is the outer absent tag or transported outer present pair; the core theorem is the complete absent/present split below; exactness says the outer endpoints inherit direct pair readback; the standard bridge is* none/some *payload readback; and the status is* ProofTarget.

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For target endpoints $k, \ell, m : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, \ell)$$

and

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; \ell, m)$$

hold, then either

$\mathsf{hsame}(k, \mathsf{e}) \wedge \mathsf{hsame}(m, \mathsf{e}) \wedge \neg\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge \mathsf{h}$

or

$\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge \mathsf{hsame}(m, \mathsf{E1}(\delta.\mathsf{map}(b))) \wedge \neg\mathsf{hs}$

Proof. First combine the two image-classifier witnesses. Apply Theorem 33.168 to the witnesses at (k, ℓ) and (ℓ, m), using the source hsame compatibility and source-reflection hypotheses. This gives the direct image-classifier witness from k to m.

Now apply Theorem 33.201 to the direct witness at the outer endpoint pair (k, m). Its absent branch is already the displayed $\mathsf{hsame}(k, \mathsf{e})$, $\mathsf{hsame}(m, \mathsf{e})$, and exclusion of every transported present pair at (k, m).

In the present branch, keep the source pair a, b, its source carrier witnesses, the source classifier witness, the transported target carrier facts, the two outer visible presentations, and the two non-absence clauses. The paired single-valuedness clause is exactly the one returned by the direct pair readback theorem for every competing transported pair at (k, m), so the branch repackages unchanged. □

Theorem 33.180 (Tagged option payload descent image classifier reflective transitive transported pair readback is single-valued)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized two-step option image readback; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are reflective transitivity and* hsame *endpoint transport; the ledger is the normalized absent pair or transported present pair; the core theorem is the absent/present exclusive split at normalized endpoints; exactness is normalized readback; the standard bridge is* none/some*; and the status is* ProofTarget*.*

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$*, assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*, and assume*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For target endpoints $k, \ell, m, p, q : \mathsf{BHist}$*, if the image classifiers hold from* k *to* ℓ *and from* ℓ *to* m*, and if* $\mathsf{hsame}(k, p) \wedge \mathsf{hsame}(m, q)$*, then either*

$\mathsf{hsame}(p, \mathsf{e}) \wedge \mathsf{hsame}(q, \mathsf{e}) \wedge \neg\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(p, \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge \mathsf{hs}$

or

$\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(p, \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge \mathsf{hsame}(q, \mathsf{E1}(\delta.\mathsf{map}(b))) \wedge \neg\mathsf{hsa}$

Proof. First compose the two image classifiers. Apply Theorem 33.168 to the witnesses at (k, ℓ) and (ℓ, m), using source compatibility and source reflection. This gives the direct classifier from k to m.

Next transport the composed classifier along the endpoint identifications. Apply Theorem 33.204 with $\mathsf{hsame}(k, p)$ and $\mathsf{hsame}(m, q)$. The result is a normalized direct classifier at (p, q).

Finally apply Theorem 33.201 to the normalized direct classifier. Its absent branch gives the normalized empty endpoints and excludes every transported present pair at (p, q); its present branch gives the displayed source pair, transported target carrier witnesses, non-absence of p and q, and uniqueness against every competing transported present pair at (p, q). □

Theorem 33.181 (Tagged option payload descent image classifier reflective transitive transported visible-branch inversion)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized two-step option image branch readback; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are reflective transitivity, endpoint transport, and left/right visible-branch inversion; the ledger is normalized absent tags or transported visible payloads; the core theorem is the four displayed one-sided clauses; exactness is direct branch inversion after normalization; the standard bridge is* none/some *readback; and the status is* ProofTarget.

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$*, assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*, and assume*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For target endpoints $k, \ell, m, p, q : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, \ell), \qquad \mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho$$

then the following four clauses hold at (p, q)*.*

1. *The normalized left absent endpoint forces the normalized right absent endpoint:*

$$\mathsf{hsame}(p, \mathsf{e}) \to \mathsf{hsame}(q, \mathsf{e}).$$

2. *Every normalized left visible payload reads back to a transported right visible endpoint:*

$$\forall u : \mathsf{BHist}.\ T(u) \to \mathsf{hsame}(p, \mathsf{E1}(u)) \to \exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(u, \delta.$$

3. *The normalized right absent endpoint forces the normalized left absent endpoint:*

$$\mathsf{hsame}(q, \mathsf{e}) \to \mathsf{hsame}(p, \mathsf{e}).$$

4. *Every normalized right visible payload reads back to a transported left visible endpoint:*

$$\forall u : \mathsf{BHist}.\ T(u) \to \mathsf{hsame}(q, \mathsf{E1}(u)) \to \exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(u, \delta.$$

Proof. First compose the two image-classifier witnesses. Apply Theorem 33.168 to the witnesses at (k, ℓ) and (ℓ, m), using the source hsame compatibility and source-reflection hypotheses. This gives the direct classifier from k to m.

Next normalize the endpoints. Apply Theorem 33.204 with $\mathsf{hsame}(k, p)$ and $\mathsf{hsame}(m, q)$ to obtain the transported classifier at (p, q).

Finally project the one-sided branches from the normalized classifier. The left visible-branch inversion theorem gives the first two displayed clauses, because its absent clause sends $\mathsf{hsame}(p, \mathsf{e})$ to $\mathsf{hsame}(q, \mathsf{e})$ and its present clause reads a visible payload at p into source witnesses a, b and a transported visible endpoint at q.

The right visible-branch inversion theorem gives the remaining two displayed clauses in the same normalized classifier. Its absent clause sends $\mathsf{hsame}(q, \mathsf{e})$ to $\mathsf{hsame}(p, \mathsf{e})$, and its present clause reads a visible payload at q into source witnesses a, b and a transported visible endpoint at p. □

33.6 Payload descent image classifier reflective transitive normalized public endpoint readback

Theorem 33.182 (Tagged option payload descent image classifier reflective transitive normalized image closure)**.** *Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source and target carriers, let $\sim_S$ and $\sim_T$ be source and target classifiers, let $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$*, assume source compatibility* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*, and assume*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For target endpoints $k, \ell, m, p, q : \mathsf{BHist}$, if

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, \ell)$$

and

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; \ell, m)$$

and

$$\mathsf{hsame}(k, p) \wedge \mathsf{hsame}(m, q),$$

then

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; p, q).$$

Proof. First compose the two image-classifier witnesses. Apply Theorem 33.168 to the witnesses at (k, ℓ) and (ℓ, m), using source compatibility and source reflection. This gives the direct classifier from k to m.

Next normalize the public endpoints. Apply Theorem 33.204 with $\mathsf{hsame}(k, p)$ and $\mathsf{hsame}(m, q)$. The result is the displayed classifier at the normalized endpoint pair (p, q). □

Theorem 33.183 (Tagged option payload descent image classifier reflective transitive normalized public endpoint readback)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized two-step public readback for constructor-tagged* OptionUp*; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImageCarrier*;*

the classifier is TaggedOptionPayloadDescentImageClassifier*; the stability obligations are reflective transitivity, endpoint transport, carrier exposure, target classifier exposure, and paired branch readback; the ledger is the normalized absent pair or transported present pair; the core theorem is the displayed public endpoint conjunction and exclusive branch split; exactness is normalized public endpoint readback; the standard bridge is* none/some *readback; and the status is* ProofTarget.

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source and target carriers, let* $\sim_S$ *and* $\sim_T$ *be source and target classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let cert : $\mathsf{NameCert}(S, \sim_S)$*, assume source compatibility* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*, and assume*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For target endpoints $k, \ell, m, p, q : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, \ell)$$

and

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; \ell, m)$$

and

$$\mathsf{hsame}(k, p) \wedge \mathsf{hsame}(m, q),$$

then

$$\mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; p) \wedge \mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; q) \wedge \mathsf{Tagg}$$

and either

$$\mathsf{hsame}(p, \mathsf{e}) \wedge \mathsf{hsame}(q, \mathsf{e}) \wedge \neg\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(p, \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge \mathsf{hs}$$

or

$$\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(p, \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge \mathsf{hsame}(q, \mathsf{E1}(\delta.\mathsf{map}(b))) \wedge \neg\mathsf{hsa}$$

Proof. First obtain normalized image closure. Apply Theorem 33.182 to the two image-classifier witnesses and the endpoint equalities. This gives the direct classifier at (p, q).

Apply Theorem 33.165 to the normalized classifier. This exposes the two normalized image carriers at p and q and the target tagged classifier $\mathsf{TaggedOptionHistoryClassifier}_{T, \sim_T}(p, q)$.

Finally apply Theorem 33.201 to the same normalized classifier. Its absent branch gives the normalized empty pair and rules out every transported present pair at (p, q); its present branch gives the displayed source pair, transported target witnesses, endpoint presentations, non-absence clauses, and paired single-valuedness. Conjoin these branch data with the exposed public carrier and classifier fields. □

Theorem 33.184 (Tagged option payload descent image classifier reflective transitive normalized branch occupancy equivalence)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source and target carriers, let* $\sim_S$ *and* $\sim_T$ *be source and target classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

and

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; \ell, m)$$

and

$$\mathsf{hsame}(k, p) \wedge \mathsf{hsame}(m, q),$$

then

$$(\mathsf{hsame}(p, \mathsf{e}) \iff \mathsf{hsame}(q, \mathsf{e})) \wedge ((\exists u : \mathsf{BHist}.\ T(u) \wedge \mathsf{hsame}(p, \mathsf{E1}(u))) \iff (\exists v : \mathsf{BHist}.\ T(v) \wedge \mathsf{hsame}(q, \mathsf{E1}(v)))) \wedge (\mathsf{hsa}$$

Proof. Apply Theorem 33.181 to the two image-classifier witnesses and the endpoint equalities. This gives the four normalized one-sided clauses at (p, q).

The first and third clauses give the empty-occupancy equivalence directly. The left absent clause sends $\mathsf{hsame}(p, \mathsf{e})$ to $\mathsf{hsame}(q, \mathsf{e})$, and the right absent clause sends $\mathsf{hsame}(q, \mathsf{e})$ to $\mathsf{hsame}(p, \mathsf{e})$.

For the forward visible-occupancy direction, unpack a witness $u : \mathsf{BHist}$ with $T(u)$ and $\mathsf{hsame}(p, \mathsf{E1}(u))$. The left visible clause returns source witnesses a, b and a transported right endpoint $\mathsf{hsame}(q, \mathsf{E1}(\delta.\mathsf{map}(b)))$ together with $T(\delta.\mathsf{map}(b))$. Choosing $v = \delta.\mathsf{map}(b)$ gives the right visible witness.

For the reverse visible-occupancy direction, unpack a witness $v : \mathsf{BHist}$ with $T(v)$ and $\mathsf{hsame}(q, \mathsf{E1}(v))$. The right visible clause returns source witnesses a, b and a transported left endpoint $\mathsf{hsame}(p, \mathsf{E1}(\delta.\mathsf{map}(a)))$ together with $T(\delta.\mathsf{map}(a))$. Choosing $u = \delta.\mathsf{map}(a)$ gives the left visible witness.

It remains to exclude simultaneous empty and visible occupancy at each normalized endpoint. If $\mathsf{hsame}(p, \mathsf{e})$ and $\mathsf{hsame}(p, \mathsf{E1}(u))$ both hold, compose them by symmetry and transitivity to obtain $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(u))$, contradicting BEDC history no-confusion via *not_hsame_emp_e*1.

If $\mathsf{hsame}(q, \mathsf{e})$ and $\mathsf{hsame}(q, \mathsf{E1}(v))$ both hold, compose the visible presentation with the empty presentation to obtain $\mathsf{hsame}(\mathsf{E1}(v), \mathsf{e})$, contradicting BEDC history no-confusion via *not_hsame_e*1*_empty*. □

Theorem 33.185 (Tagged option payload descent image classifier reflective transitive normalized nonempty present-pair inversion)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized two-step present-pair recovery for constructor-tagged* OptionUp*; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the obligations are reflective transitivity, endpoint transport, and direct nonempty present-pair inversion; the ledger is the synchronized transported payload pair; and the status is* ProofTarget*.*

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source and target carriers, let* $\sim_S$ *and* $\sim_T$ *be source and target classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$*, assume source compatibility* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*, and assume*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For target endpoints $k, \ell, m, p, q : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, \ell)$$

and

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; \ell, m)$$

and

$$\mathsf{hsame}(k, p) \wedge \mathsf{hsame}(m, q),$$

then

$$(\neg\mathsf{hsame}(p, \mathsf{e}) \to \exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(p, \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge \mathsf{hsame}(q, \mathsf{E1}$$

Proof. First apply Theorem 33.182 to the two image-classifier witnesses and the endpoint equalities. This gives the direct normalized classifier at (p, q).

For the left non-absence clause, apply Theorem 33.171 to the normalized classifier and the premise $\neg\mathsf{hsame}(p, \mathsf{e})$. The direct inversion returns source witnesses a, b with $S(a)$, $S(b)$, $a \sim_S b$, the transported target-carrier witnesses, and the displayed present presentations at p and q.

For the right non-absence clause, apply the same direct inversion theorem to the normalized classifier and the premise $\neg\mathsf{hsame}(q, \mathsf{e})$. Its right endpoint clause returns the same synchronized transported present-pair data, which is the second displayed conclusion. □

Theorem 33.186 (Tagged option payload descent image classifier reflective transitive normalized visible payload exactness)**.** *This theorem fits the per-object template as follows: the traditional target is normalized two-step visible payload exactness for constructor-tagged* OptionUp*; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the obligations are reflective transitivity, endpoint transport, and direct visible-payload exactness; the ledger is the normalized visible payload endpoints; the core theorem is the displayed equivalence; exactness is source-payload explanation of normalized visible target payloads; the standard bridge is* none/some *payload readback; and the status is* ProofTarget*.*

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source and target carriers, let* $\sim_S$ *and* $\sim_T$ *be source and target classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$*, assume source compatibility* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S$ *), and assume*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For target endpoints $k, \ell, m, p, q : \mathsf{BHist}$ *and visible target payloads* $u, v : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, \ell)$$

and

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; \ell, m)$$

and

$$\mathsf{hsame}(k, p) \wedge \mathsf{hsame}(m, q),$$

then

$$(T(u) \wedge T(v) \wedge \mathsf{hsame}(p, \mathsf{E1}(u)) \wedge \mathsf{hsame}(q, \mathsf{E1}(v))) \iff$$

$$T(u) \wedge T(v) \wedge \mathsf{hsame}(p, \mathsf{E1}(u)) \wedge \mathsf{hsame}(q, \mathsf{E1}(v)) \wedge \exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}($$

Proof. First compose the two image-classifier witnesses. Apply Theorem 33.168 to the witnesses at (k, ℓ) and (ℓ, m), using source compatibility and source reflection. This gives the direct image-classifier witness from k to m.

Next normalize the endpoints. Apply Theorem 33.204 to the direct classifier together with $\mathsf{hsame}(k, p)$ and $\mathsf{hsame}(m, q)$. The result is an image-classifier witness at (p, q).

For the forward direction, apply Theorem 33.211 to the normalized classifier and the visible payload facts at (p, q). Its left-to-right direction keeps the four visible facts and supplies source payloads a, b explaining u and v through $\delta.\mathsf{map}$.

For the reverse direction, unpack the right-hand side and project the first four visible facts. These are exactly $T(u)$, $T(v)$, $\mathsf{hsame}(p, \mathsf{E1}(u))$, and $\mathsf{hsame}(q, \mathsf{E1}(v))$, which form the left-hand side of the displayed equivalence. □

Theorem 33.187 (Tagged option payload descent image classifier reflective transitive normalized mixed visible-tag separation)**.** *This theorem fits the per-object template as follows: the traditional target is normalized no-confusion for constructor-tagged* OptionUp*; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are reflective transitivity, endpoint transport, and mixed visible-tag separation; the ledger records the normalized absent/present target tags; the core theorem is the two contradiction clauses; exactness permits only absent/absent or present/present tags after normalization; the standard bridge is* none/some *tag separation; and the status is* ProofTarget*.*

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source and target carriers, let* $\sim_S$ *and* $\sim_T$ *be source and target classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$*, assume source compatibility* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*, and assume*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For target endpoints $k, \ell, m, p, q : \mathsf{BHist}$ *and target payloads* $u, v : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, \ell)$$

and

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; \ell, m)$$

and

$$\mathsf{hsame}(k, p) \wedge \mathsf{hsame}(m, q),$$

then both mixed visible-tag clauses hold:

$$\mathsf{hsame}(p, \mathsf{e}) \to T(v) \to \mathsf{hsame}(q, \mathsf{E1}(v)) \to \bot$$

and

$$T(u) \to \mathsf{hsame}(p, \mathsf{E1}(u)) \to \mathsf{hsame}(q, \mathsf{e}) \to \bot.$$

Proof. First compose the two image-classifier witnesses. Apply Theorem 33.168 to the witnesses at (k, ℓ) and (ℓ, m), using source compatibility and source reflection. This gives the direct image-classifier witness from k to m.

Next normalize the endpoints. Apply Theorem 33.204 to the direct classifier together with $\mathsf{hsame}(k, p)$ and $\mathsf{hsame}(m, q)$. The result is an image-classifier witness at (p, q).

Finally apply Theorem 33.170 to the normalized classifier. Its first contradiction clause gives $\mathsf{hsame}(p, \mathsf{e}) \to T(v) \to \mathsf{hsame}(q, \mathsf{E1}(v)) \to \bot$, and its second contradiction clause gives $T(u) \to \mathsf{hsame}(p, \mathsf{E1}(u)) \to \mathsf{hsame}(q, \mathsf{e}) \to \bot$. □

Theorem 33.188 (Tagged option payload descent image classifier reflective transitive normalized visible payload single-valuedness)**.** *This theorem fits the per-object template as follows: the traditional target is deterministic endpoint-normalized* OptionUp *visible payload readback; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are reflective transitivity, endpoint transport, target-payload classification, present-payload determinism, and mixed visible-tag separation; the ledger is a pair of competing normalized visible target presentations; the core theorem is classification by $\sim_T$, endpointwise payload uniqueness, and non-absence of the visible endpoints; exactness says the normalized two-step image readback has a single visible payload pair; the standard bridge is* none/some *public readback; and the status is* ProofTarget*.*

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source and target carriers, let $\sim_S$ and $\sim_T$ be source and target classifiers, let $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$, and assume payload preservation

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$ and $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$. Assume source compatibility TaggedOptionSourceHsameC
) and target compatibility $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$*. Assume also*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For target endpoints $k, \ell, m, p, q : \mathsf{BHist}$ and visible target payloads $u, v, u', v' : \mathsf{BHist}$, if

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, \ell)$$

and

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; \ell, m)$$

and

$$\mathsf{hsame}(k, p) \wedge \mathsf{hsame}(m, q)$$

and

$$T(u) \wedge T(v) \wedge \mathsf{hsame}(p, \mathsf{E1}(u)) \wedge \mathsf{hsame}(q, \mathsf{E1}(v))$$

and

$$T(u') \wedge T(v') \wedge \mathsf{hsame}(p, \mathsf{E1}(u')) \wedge \mathsf{hsame}(q, \mathsf{E1}(v')),$$

then

$$u \sim_T v \wedge \mathsf{hsame}(u, u') \wedge \mathsf{hsame}(v, v') \wedge \neg\mathsf{hsame}(p, \mathsf{e}) \wedge \neg\mathsf{hsame}(q, \mathsf{e}).$$

Proof. First classify the displayed target payloads. Apply Theorem 33.177 to the two image-classifier witnesses, the endpoint normalization witnesses, and the first visible presentation at (p, q). This gives $u \sim_T v$.

Next compare the two public presentations at the left endpoint. Apply Theorem 33.122 to $\mathsf{hsame}(p, \mathsf{E1}(u))$ and $\mathsf{hsame}(p, \mathsf{E1}(u'))$. The result is $\mathsf{hsame}(u, u')$.

The right endpoint is identical. Apply Theorem 33.122 to $\mathsf{hsame}(q, \mathsf{E1}(v))$ and $\mathsf{hsame}(q, \mathsf{E1}(v'))$. The result is $\mathsf{hsame}(v, v')$.

It remains to rule out hidden absent tags at the normalized endpoints. Apply Theorem 33.187 to the two image-classifier witnesses and the endpoint normalization witnesses. Its first contradiction clause, together with $T(v)$ and $\mathsf{hsame}(q, \mathsf{E1}(v))$, proves $\neg\mathsf{hsame}(p, \mathsf{e})$; its second contradiction clause, together with $T(u)$ and $\mathsf{hsame}(p, \mathsf{E1}(u))$, proves $\neg\mathsf{hsame}(q, \mathsf{e})$.

Collect these five conclusions in the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier reflective transitive normalized visible payload single valued`

33.7 Composite image classifier visible payload classification

Theorem 33.189 (Tagged option composite image classifier visible payload classification)**.** *This theorem fits the per-object template as follows: the traditional target is functorial* OptionUp *visible payload classification; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligation is visible factorization followed by target-classifier transport; the ledger records final visible payloads and intermediate payload readbacks; the core theorem is the displayed factorization together with $p \sim_T q$ and $x \sim_U y$; exactness is composite classified final payload recovery through the intermediate payloads; the standard bridge is* none/some *functorial payload classification; and the status is* ProofTarget*.*

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source, intermediate, and target carriers, let $\sim_S$, $\sim_T$, and $\sim_U$ be their classifiers, and let

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$, $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$, and $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$. Assume TaggedOptionSourceHsameCompatible$(S, \sim_S)$*,* TaggedOptionSourceHsameCompatible$(T, \sim_T)$*, and* TaggedOptionSou *). For final endpoints $m, m' : \mathsf{BHist}$ and visible final payloads $x, y : \mathsf{BHist}$, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(m, \mathsf{E1}(x)) \wedge \mathsf{hsame}(m', \mathsf{E1}(y)),$$

then there exist $k, k', p, q, a, b : \mathsf{BHist}$ such that

1. $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$;
2. $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, m)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', m')$;
3. $T(p)$, $T(q)$, $U(\epsilon.\mathsf{map}(p))$, *and* $U(\epsilon.\mathsf{map}(q))$;
4. $\mathsf{hsame}(k, \mathsf{E1}(p))$, $\mathsf{hsame}(k', \mathsf{E1}(q))$, $\mathsf{hsame}(x, \epsilon.\mathsf{map}(p))$, *and* $\mathsf{hsame}(y, \epsilon.\mathsf{map}(q))$;
5. $S(a)$, $S(b)$, $a \sim_S b$, $T(\delta.\mathsf{map}(a))$, *and* $T(\delta.\mathsf{map}(b))$;
6. $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ *and* $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$;
7. $p \sim_T q$;
8. $x \sim_U y$.

Proof. Apply Theorem 33.213 to the composite image-classifier witness and the visible final presentations. This supplies k, k', p, q, a, b and the six displayed factorization clauses: the intermediate image-classifier witness, the two ϵ map-relation witnesses, the carrier data, the four visible readbacks, the source classified payload pair, and the two δ payload readbacks.

Use $\delta.\mathsf{respects}$ on $a \sim_S b$ to obtain $\delta.\mathsf{map}(a) \sim_T \delta.\mathsf{map}(b)$. Target compatibility for T turns $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ into $p \sim_T \delta.\mathsf{map}(a)$ and $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$ into $q \sim_T \delta.\mathsf{map}(b)$. Symmetry from cert_T reverses the second relation, and transitivity from cert_T composes the three relations into $p \sim_T q$.

Now apply $\epsilon.\mathsf{respects}$ to $p \sim_T q$, giving $\epsilon.\mathsf{map}(p) \sim_U \epsilon.\mathsf{map}(q)$. Compatibility for U turns $\mathsf{hsame}(x, \epsilon.\mathsf{map}(p))$ into $x \sim_U \epsilon.\mathsf{map}(p)$ and $\mathsf{hsame}(y, \epsilon.\mathsf{map}(q))$ into $y \sim_U \epsilon.\mathsf{map}(q)$. Symmetry and transitivity from cert_U compose these three relations into $x \sim_U y$.

Package the original six factorization clauses with the two classifier consequences $p \sim_T q$ and $x \sim_U y$. □

Theorem 33.190 (Tagged option composite image classifier public branch classification)**.** *This theorem fits the per-object template as follows: the traditional target is public constructor-branch coverage for functorial* OptionUp *image classification; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligation is public branch readback followed by visible factorization and classifier transport; the ledger records absent final endpoints or a factored visible final pair; the core theorem is the displayed exhaustive disjunction; exactness says the composite classifier either has no visible final pair or factors through one classified intermediate pair; the standard bridge is* none/some *functorial payload classification; and the status is* ProofTarget.

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$, $\sim_T$, *and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\, T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$, $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$, *and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$. *Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$, $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$, *and* $\mathsf{TaggedOptionSou}$). *For final endpoints $m, m' : \mathsf{BHist}$, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

holds, then either

$$\mathsf{hsame}(m, \mathsf{e}) \wedge \mathsf{hsame}(m', \mathsf{e}) \wedge \neg\exists x, y : \mathsf{BHist}.\, U(x) \wedge U(y) \wedge \mathsf{hsame}(m, \mathsf{E1}(x)) \wedge \mathsf{hsame}(m', \mathsf{E1}(y))$$

or there exist $k, k', p, q, x, y, a, b : \mathsf{BHist}$ such that

1. $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$;
2. $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, m)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', m')$;
3. $U(x)$, $U(y)$, $\mathsf{hsame}(m, \mathsf{E1}(x))$, *and* $\mathsf{hsame}(m', \mathsf{E1}(y))$;
4. $T(p)$, $T(q)$, $U(\epsilon.\mathsf{map}(p))$, *and* $U(\epsilon.\mathsf{map}(q))$;
5. $\mathsf{hsame}(k, \mathsf{E1}(p))$, $\mathsf{hsame}(k', \mathsf{E1}(q))$, $\mathsf{hsame}(x, \epsilon.\mathsf{map}(p))$, *and* $\mathsf{hsame}(y, \epsilon.\mathsf{map}(q))$;
6. $S(a)$, $S(b)$, $a \sim_S b$, $T(\delta.\mathsf{map}(a))$, *and* $T(\delta.\mathsf{map}(b))$;
7. $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ *and* $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$;
8. $p \sim_T q$;
9. $x \sim_U y$.

Proof. Apply Theorem 33.201 to the composite image-classifier witness for $\epsilon\circ\delta$. Its public readback splits the final pair into an absent branch and a present branch for the composite transported payloads.

In the absent branch, keep the endpoint witnesses $\mathsf{hsame}(m, \mathsf{e})$ and $\mathsf{hsame}(m', \mathsf{e})$. Suppose a visible final pair x, y also existed with $U(x)$, $U(y)$, $\mathsf{hsame}(m, \mathsf{E1}(x))$, and $\mathsf{hsame}(m', \mathsf{E1}(y))$. Composing the displayed empty presentation of m with the visible presentation of m gives empty-versus-$\mathsf{E1}$ no-confusion, so no such visible final pair can exist.

In the present branch, the pair readback supplies source payloads a, b for the composite descent and final visible presentations of the form $\mathsf{hsame}(m, \mathsf{E1}(\epsilon.\mathsf{map}(\delta.\mathsf{map}(a))))$ and $\mathsf{hsame}(m', \mathsf{E1}(\epsilon.\mathsf{map}(\delta.\mathsf{map}(b))))$. Take $x = \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and $y = \epsilon.\mathsf{map}(\delta.\mathsf{map}(b))$ as the visible final payloads.

Now apply Theorem 33.189 to the same composite classifier and to these visible final payloads. The theorem returns intermediate endpoints k, k', intermediate visible payloads p, q, and source payloads explaining p, q through δ, together with the intermediate classifier consequence $p \sim_T q$ and the final classifier consequence $x \sim_U y$.

Package the retained visible final endpoint facts with the returned factorization witnesses: the δ image-classifier factor, the two ϵ map relations, the intermediate carrier data, the source pair, the two δ readbacks, and the two classifier consequences. This is exactly the present disjunct. □

Theorem 33.191 (Tagged option composite image classifier canonical public branch readback)**.** *This theorem fits the per-object template as follows: the traditional target is canonical public branch readback for functorial* OptionUp *image classification; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligation is public branch classification followed by visible final-payload determinacy; the ledger records either absent final endpoints or a single visible final payload pair up to* hsame*; the core theorem is the displayed branch split with uniqueness of competing visible final pairs; exactness says the present public branch has a canonical final target reading; the standard bridge is* none/some *functorial payload readback; and the status is* ProofTarget*.*

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$*,* $\sim_T$*, and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ *for the descent certificate whose map field is* $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ *and whose respects field sends* $r : a \sim_S b$ *to* $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$*. Define*

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$*,* $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$*, and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$*. Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*,* $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$*, and* TaggedOptionSou*). For final endpoints* $m, m' : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

holds, then either

$$\mathsf{hsame}(m, \mathsf{e}) \wedge \mathsf{hsame}(m', \mathsf{e}) \wedge \neg\exists x, y : \mathsf{BHist}.\ U(x) \wedge U(y) \wedge \mathsf{hsame}(m, \mathsf{E1}(x)) \wedge \mathsf{hsame}(m', \mathsf{E1}(y))$$

or there exist $k, k', p, q, x, y, a, b : \mathsf{BHist}$ *such that*

1. $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$*;*
2. $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, m)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', m')$*;*
3. $U(x)$*,* $U(y)$*,* $\mathsf{hsame}(m, \mathsf{E1}(x))$*, and* $\mathsf{hsame}(m', \mathsf{E1}(y))$*;*
4. $T(p)$*,* $T(q)$*,* $U(\epsilon.\mathsf{map}(p))$*, and* $U(\epsilon.\mathsf{map}(q))$*;*
5. $\mathsf{hsame}(k, \mathsf{E1}(p))$*,* $\mathsf{hsame}(k', \mathsf{E1}(q))$*,* $\mathsf{hsame}(x, \epsilon.\mathsf{map}(p))$*, and* $\mathsf{hsame}(y, \epsilon.\mathsf{map}(q))$*;*

6. *$S(a)$, $S(b)$, $a \sim_S b$, $T(\delta.\mathsf{map}(a))$, and $T(\delta.\mathsf{map}(b))$;*
7. *$\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ and $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$;*
8. *$p \sim_T q$;*
9. *$x \sim_U y$;*
10. *$\neg\mathsf{hsame}(m, \mathsf{e})$ and $\neg\mathsf{hsame}(m', \mathsf{e})$;*
11. *for every $x', y' : \mathsf{BHist}$, if*

$$U(x') \wedge U(y') \wedge \mathsf{hsame}(m, \mathsf{E1}(x')) \wedge \mathsf{hsame}(m', \mathsf{E1}(y')),$$

then

$$\mathsf{hsame}(x, x') \wedge \mathsf{hsame}(y, y') \wedge x' \sim_U y'.$$

Proof. Apply Theorem 33.190 to the composite image-classifier witness and the displayed certificate and compatibility data. This gives the absent branch or a present branch with witnesses k, k', p, q, x, y, a, b and the listed factorization clauses.

In the absent branch, keep the endpoint presentations $\mathsf{hsame}(m, \mathsf{e})$ and $\mathsf{hsame}(m', \mathsf{e})$ together with the displayed exclusion of visible final pairs. This is exactly the first disjunct.

In the present branch, keep the witnesses and all classification and factorization clauses returned by public branch classification. The visible presentations $\mathsf{hsame}(m, \mathsf{E1}(x))$ and $\mathsf{hsame}(m', \mathsf{E1}(y))$ exclude opposite empty presentations by the empty-versus-$\mathsf{E1}$ no-confusion principle, giving $\neg\mathsf{hsame}(m, \mathsf{e})$ and $\neg\mathsf{hsame}(m', \mathsf{e})$.

It remains to prove canonical readback for a competing visible final pair. Let x', y' satisfy $U(x')$, $U(y')$, $\mathsf{hsame}(m, \mathsf{E1}(x'))$, and $\mathsf{hsame}(m', \mathsf{E1}(y'))$.

Apply Theorem 33.192 to the chosen visible pair x, y and the competing visible pair x', y'. The determinacy conclusion gives $\mathsf{hsame}(x, x')$, $\mathsf{hsame}(y, y')$, and $x' \sim_U y'$.

Package the original present-branch witnesses, the two non-absence conclusions, and this universal competing-pair conclusion into the second disjunct. □

Theorem 33.192 (Tagged option composite image classifier visible payload determinacy)**.** *This theorem fits the per-object template as follows: the traditional target is functorial* OptionUp *final visible-payload determinacy; the BEDC source is* BHist *with two* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are composite descent respect, target visible-payload classification,* E1 *payload determinacy, and mixed visible-tag separation; the ledger is the two visible final endpoints; the core theorem is the displayed determinacy, classification, and non-absence conjunction; exactness says visible final payload readings are endpoint-determined and target-classified; the standard bridge is* none/some *final readback; and the status is* ProofTarget*.*

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source, intermediate, and target carriers, let $\sim_S$, $\sim_T$, and $\sim_U$ be their classifiers, and let

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$, $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$, *and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$. *Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$, $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$, *and* $\mathsf{TaggedOptionSou}$). *For final endpoints $m, m' : \mathsf{BHist}$ and visible final payloads $x, y, x', y' : \mathsf{BHist}$, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(m, \mathsf{E1}(x)) \wedge \mathsf{hsame}(m', \mathsf{E1}(y))$$

and

$$U(x') \wedge U(y') \wedge \mathsf{hsame}(m, \mathsf{E1}(x')) \wedge \mathsf{hsame}(m', \mathsf{E1}(y')),$$

then

$$x \sim_U y \wedge x' \sim_U y' \wedge \mathsf{hsame}(x, x') \wedge \mathsf{hsame}(y, y') \wedge \neg\mathsf{hsame}(m, \mathsf{e}) \wedge \neg\mathsf{hsame}(m', \mathsf{e}).$$

Proof. First classify the two visible final pairs. Apply Theorem 33.189 to the composite image-classifier witness and the presentation $U(x)$, $U(y)$, $\mathsf{hsame}(m, \mathsf{E1}(x))$, and $\mathsf{hsame}(m', \mathsf{E1}(y))$. This gives $x \sim_U y$. Apply the same theorem to the second presentation to obtain $x' \sim_U y'$.

Next compare the two readings of each endpoint. Apply Theorem 33.122 to $\mathsf{hsame}(m, \mathsf{E1}(x))$ and $\mathsf{hsame}(m, \mathsf{E1}(x'))$, giving $\mathsf{hsame}(x, x')$. The same theorem applied at m' gives $\mathsf{hsame}(y, y')$.

It remains to rule out hidden absent tags at the final endpoints. Apply Theorem 33.170 to the composite descent certificate $\epsilon \circ \delta$ with target carrier U.

Its first contradiction clause, together with $U(y)$ and $\mathsf{hsame}(m', \mathsf{E1}(y))$, proves $\neg\mathsf{hsame}(m, \mathsf{e})$. Its second contradiction clause, together with $U(x)$ and $\mathsf{hsame}(m, \mathsf{E1}(x))$, proves $\neg\mathsf{hsame}(m', \mathsf{e})$.

Collect the two target-classification conclusions, the two payload-determinacy conclusions, and the two non-absence conclusions in the displayed conjunction. □

33.8 Exclusive classifier branch readback

Theorem 33.193 (Tagged option carrier single-valued visible readback)**.** *This theorem fits the per-object template as follows: the traditional target is tagged optional carrier readback; the BEDC source is* BHist *with* hsame*; the carrier is* TaggedOptionHistoryCarrier*; the classifier is unused; the stability obligation is constructor inversion plus branch exclusion; the ledger is the visible absent/present tag and present payload; the core theorem is carrier single-valued visible readback; exactness is existence, opposite-branch exclusion, and payload uniqueness; the standard bridge is* none/some*; and the status is* ProofTarget*. For every source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$ and history $h : \mathsf{BHist}$, if $\mathsf{TaggedOptionHistoryCarrier}_S(h)$ holds, then either*

$$\mathsf{hsame}(h, \mathsf{e}) \wedge \neg\exists a : \mathsf{BHist}.\ S(a) \wedge \mathsf{hsame}(h, \mathsf{E1}(a))$$

or

$$\exists a : \mathsf{BHist}.\ S(a) \wedge \mathsf{hsame}(h, \mathsf{E1}(a)) \wedge \neg\mathsf{hsame}(h, \mathsf{e}) \wedge (\forall a' : \mathsf{BHist}.\ S(a') \to \mathsf{hsame}(h, \mathsf{E1}(a')) \to \mathsf{hsame}(a, a')).$$

Proof. Apply Theorem 33.128 to the carrier witness. This gives the displayed absent branch or a visible present payload branch.

In the absent branch, keep the equality $\mathsf{hsame}(h, \mathsf{e})$ and the negative source-present clause supplied by the carrier partition. These are exactly the two fields required for the first displayed alternative.

In the present branch, keep the payload a, the source witness $S(a)$, the endpoint link $\mathsf{hsame}(h, \mathsf{E1}(a))$, and the non-absence proof supplied by the carrier partition. For any other visible present payload a', apply Theorem 33.122 to the two endpoint links $\mathsf{hsame}(h, \mathsf{E1}(a))$ and $\mathsf{hsame}(h, \mathsf{E1}(a'))$. The resulting $\mathsf{hsame}(a, a')$ gives the payload uniqueness field, completing the second displayed alternative. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryCarrier single valued visible readback`

Theorem 33.194 (Tagged option history classifier exclusive branch readback)**.** *This theorem fits the per-object template as follows: the traditional target is tagged option classifier readback; the BEDC source is* BHist *with* hsame*; the carrier is* TaggedOptionHistoryCarrier*; the classifier is* TaggedOptionHistoryClassifier*; the stability obligation is constructor no-confusion plus endpoint carrier exposure; the ledger is the visible absent/present tags and payloads; the core theorem is exclusive classifier branch readback; exactness is branch coverage with disjointness; the standard bridge is* none/some*; and the status is* ProofTarget*. For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, source classifier* $\sim_S$*, histories* h, k*, and witness* $\gamma : \mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k)$*, either*

$$\mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(k, \mathsf{e}) \wedge (\neg\exists a : \mathsf{BHist}.\ S(a) \wedge \mathsf{hsame}(h, \mathsf{E1}(a))) \wedge (\neg\exists b : \mathsf{BHist}.\ S(b) \wedge \mathsf{hsame}(k, \mathsf{E1}(b)))$$

or

$$\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge \mathsf{hsame}(h, \mathsf{E1}(a)) \wedge \mathsf{hsame}(k, \mathsf{E1}(b)) \wedge a \sim_S b \wedge \neg\mathsf{hsame}(h, \mathsf{e}) \wedge \neg\mathsf{hsame}(k, \mathsf{e}).$$

Proof. Apply Theorem 33.132 to the classifier witness γ. This splits the proof into the exact absent-absent branch and the exact present-present branch.

In the absent-absent branch, keep the two displayed endpoint equalities. Apply Theorem 33.21 to γ to obtain carrier witnesses for both endpoints. Then apply Theorem 33.128 to each endpoint carrier. The partition result rules out any source payload whose visible present endpoint is hsame-equal to the displayed absent endpoint, so the two negative existential clauses follow.

In the present-present branch, keep the payload histories a, b, the source witnesses $S(a)$ and $S(b)$, the endpoint equalities, and the source classifier witness $a \sim_S b$ exposed by branch exactness. Apply Theorem 33.21 to γ, and then apply Theorem 33.128 to both endpoint carriers. The supplied present payload witnesses rule out the absent alternatives, so the present alternatives of the two carrier partitions give $\neg\mathsf{hsame}(h, \mathsf{e})$ and $\neg\mathsf{hsame}(k, \mathsf{e})$, completing the displayed present-present branch. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier exclusive branch readback`

Theorem 33.195 (Option history classifier exclusive branch iff)**.** *Let source* $: \mathsf{BHist} \to \mathsf{Prop}$ *exclude the empty history: if* $source(h)$ *and* $\mathsf{hsame}(h, \mathsf{e})$ *hold, then contradiction follows. For all histories* h, k*, the untagged option classifier is exactly the disjoint empty-empty branch or the source-source branch:*

$$\mathsf{OptionHistoryClassifier}_{source}(h, k) \iff (\mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(k, \mathsf{e})) \vee (source(h) \wedge source(k) \wedge \mathsf{hsame}(h, k)).$$

Proof. Unpack the classifier into the two endpoint carriers and the endpoint classifier $\mathsf{hsame}(h, k)$. Each carrier is either the empty branch or the source branch. The empty-empty and source-source cases give the two displayed alternatives directly. In the mixed cases, transport the empty endpoint equality across $\mathsf{hsame}(h, k)$ and apply the hypothesis that *source* excludes empty. Conversely, the empty-empty branch gives both endpoint carriers and reconstructs $\mathsf{hsame}(h, k)$ by transitivity through e; the source-source branch gives the two source carriers and the supplied endpoint classifier. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier exclusive branch iff`

Theorem 33.196 (Option history classifier source branch iff)**.** *Let source* : $\mathsf{BHist} \to \mathsf{Prop}$ *exclude the empty history. For all histories* h, k*, any nullable option classifier witness between* h *and* k *forces the two endpoints to agree on source membership:*

$$\mathsf{OptionHistoryClassifier}_{source}(h, k) \Longrightarrow (source(h) \Longleftrightarrow source(k)).$$

Proof. Unpack the classifier into the endpoint carriers and the stored $\mathsf{hsame}(h, k)$ link. If $source(h)$ holds and the right endpoint carrier is the empty branch, transport that empty equality back across $\mathsf{hsame}(h, k)$ and contradict the empty-exclusion hypothesis; hence the right endpoint is in the source branch. The converse direction is symmetric, transporting an empty left endpoint across the same classifier link. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier source branch iff`

Theorem 33.197 (Option history classifier cross absent-source exclusion)**.** *Let source* : $\mathsf{BHist} \to \mathsf{Prop}$ *exclude the empty history. For histories* h, k*, any nullable option classifier witness from* h *to* k *rules out the two crossed cases:*

$$\mathsf{OptionHistoryClassifier}_{source}(h, k) \Longrightarrow (source(h) \to \mathsf{hsame}(k, \mathsf{e}) \to \bot) \wedge (source(k) \to \mathsf{hsame}(h, \mathsf{e}) \to \bot).$$

Proof. Unpack the classifier into endpoint carriers and the stored $\mathsf{hsame}(h, k)$ link. In the left crossed case, compose $\mathsf{hsame}(h, k)$ with $\mathsf{hsame}(k, \mathsf{e})$ and apply empty exclusion to $source(h)$. In the right crossed case, use symmetry of $\mathsf{hsame}(h, k)$ before composing with $\mathsf{hsame}(h, \mathsf{e})$ and applying empty exclusion to $source(k)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier cross absent source exclusion`

Theorem 33.198 (Tagged option history classifier visible-pair payload exactness)**.** *This theorem fits the per-object template as follows: the traditional target is visible payload readback for constructor-tagged* OptionUp*; the BEDC source is* BHist *with* hsame*; the carrier is* TaggedOptionHistoryCarrier*; the classifier is* TaggedOptionHistoryClassifier*; the stability obligations are presented-payload exactness, constructor no-confusion, and payload determinism; the ledger is the pair of visible present payloads at the two endpoints; the core theorem is the combined exactness statement below; exactness is the visible pair relation together with uniqueness of the displayed payloads; the standard bridge is* none/some*; and the status is* ProofTarget*. For every BEDC history source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, source classifier* $\sim_S$*, transitivity hypothesis* $\forall x\, y\, z : \mathsf{BHist}.\ x \sim_S y \to y \sim_S z \to x \sim_S z$*, compatibility hypothesis* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*, and histories* h, k, a, b*, if*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k), \qquad S(a), \qquad S(b), \qquad \mathsf{hsame}(h, \mathsf{E1}(a)), \qquad \mathsf{hsame}(k, \mathsf{E1}(b)),$$

then

$$a \sim_S b \wedge \neg\mathsf{hsame}(h, \mathsf{e}) \wedge \neg\mathsf{hsame}(k, \mathsf{e}) \wedge (\forall a', b' : \mathsf{BHist}.\ S(a') \to S(b') \to \mathsf{hsame}(h, \mathsf{E1}(a')) \to \mathsf{hsame}(k, \mathsf{E1}(b')) \to \mathsf{hsam}$$

Proof. Apply Theorem 33.120 to the classifier witness, the displayed transitivity hypothesis, the compatibility hypothesis, and the two visible endpoint presentations. This gives the source payload relation $a \sim_S b$.

For the left endpoint, suppose $\mathsf{hsame}(h, \mathsf{e})$. Lemma 33.18 applied to $S(a)$, $\mathsf{hsame}(h, \mathsf{e})$, and $\mathsf{hsame}(h, \mathsf{E1}(a))$ eliminates this case, so $\neg\mathsf{hsame}(h, \mathsf{e})$. The same argument at the right endpoint, using $S(b)$ and $\mathsf{hsame}(k, \mathsf{E1}(b))$, gives $\neg\mathsf{hsame}(k, \mathsf{e})$.

Now let a', b' be any other visible pair with $S(a')$, $S(b')$, $\mathsf{hsame}(h, \mathsf{E1}(a'))$, and $\mathsf{hsame}(k, \mathsf{E1}(b'))$. Apply Theorem 33.122 to the two left endpoint presentations to obtain $\mathsf{hsame}(a, a')$, and apply it again to the two right endpoint presentations to obtain $\mathsf{hsame}(b, b')$. These two determinacy facts give the displayed uniqueness clause, completing the combined visible-pair exactness statement. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier visible pair payload exactness`

Theorem 33.199 (Tagged option history classifier visible endpoint pair readback)**.** *For a BEDC history source carrier S, source classifier $\sim_S$, and histories h, k, a, b, if*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k), \qquad \mathsf{hsame}(h, \mathsf{E1}(a)), \qquad \mathsf{hsame}(k, \mathsf{E1}(b)),$$

then there are source payloads $a_0, b_0 : \mathsf{BHist}$ such that

$$S(a_0) \wedge S(b_0) \wedge \mathsf{hsame}(a, a_0) \wedge \mathsf{hsame}(b, b_0) \wedge a_0 \sim_S b_0.$$

Proof. Split the tagged classifier. In the absent branch, the left endpoint is simultaneously empty and visibly present, contradicting constructor no-confusion. In the present branch, the classifier already supplies source payloads a_0, b_0, their source witnesses, their visible endpoint equations, and the source relation. Strip the common $\mathsf{E1}$ constructor from the two visible endpoint equalities to obtain $\mathsf{hsame}(a, a_0)$ and $\mathsf{hsame}(b, b_0)$, then package the displayed witnesses. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier visible endpoint pair readback`

Theorem 33.200 (Tagged option history classifier transported visible payload readback)**.** *For a BEDC history source carrier S, source classifier $\sim_S$, and histories h, k, u, v, x, y, assume*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k), \qquad \mathsf{hsame}(h, u), \qquad \mathsf{hsame}(k, v),$$

and assume the transported visible endpoints satisfy

$$\mathsf{hsame}(u, \mathsf{E1}(x)), \qquad \mathsf{hsame}(v, \mathsf{E1}(y)).$$

Then there exist payload histories a, b such that

$$S(a) \wedge S(b) \wedge \mathsf{hsame}(x, a) \wedge \mathsf{hsame}(y, b) \wedge a \sim_S b.$$

Proof. Invert the tagged classifier. The absent branch gives $\mathsf{hsame}(h, \mathsf{e})$; transport this along $\mathsf{hsame}(h, u)$, contradicting $\mathsf{hsame}(u, \mathsf{E1}(x))$ by constructor separation. In the present branch, keep the classifier payload witnesses a, b, their source facts, the endpoint presentations $\mathsf{hsame}(h, \mathsf{E1}(a))$, $\mathsf{hsame}(k, \mathsf{E1}(b))$, and $a \sim_S b$. Transport the two endpoint presentations along $\mathsf{hsame}(h, u)$ and $\mathsf{hsame}(k, v)$. Constructor injectivity for $\mathsf{E1}$ then gives $\mathsf{hsame}(x, a)$ and $\mathsf{hsame}(y, b)$, which are the required readback fields. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier transport visible payload readback`

33.9 Payload descent image classifier pair readback

Theorem 33.201 (Tagged option payload descent image classifier pair readback is single-valued)**.** *This theorem fits the per-object template as follows: the traditional target is image option pair readback for constructor-tagged* OptionUp*; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligation is branch exactness plus constructor no-confusion; the ledger is the pair of transported visible payloads; the core theorem is paired exclusive single-valued readback; exactness is the absent pair or the transported present pair; the standard bridge is* none/some *under payload descent; and the status is* ProofTarget*.*

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let cert : $\mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. For target endpoints* $k, k' : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$$

holds, then either

$$\mathsf{hsame}(k, \mathsf{e}) \wedge \mathsf{hsame}(k', \mathsf{e}) \wedge \neg\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge \mathsf{h}$$

or

$$\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge \mathsf{hsame}(k', \mathsf{E1}(\delta.\mathsf{map}(b))) \wedge \neg \mathsf{hs}$$

Proof. Apply Theorem 33.162 to the image-classifier witness. This splits the target pair into the exact absent pair or a transported present pair with source payloads a, b.

In the absent branch, keep the two endpoint presentations $\mathsf{hsame}(k, \mathsf{e})$ and $\mathsf{hsame}(k', \mathsf{e})$. If a transported present pair also existed at the same endpoints, the left endpoint would be presented both as e and as $\mathsf{E1}(\delta.\mathsf{map}(a))$, contradicting empty-versus-E1 no-confusion. This gives the displayed negative pair clause.

In the present branch, keep the exposed payloads a, b, their source witnesses, the source classifier witness, the two transported target witnesses, and the two visible endpoint presentations. A simultaneous absent presentation of either endpoint would contradict the corresponding visible present presentation by the same constructor no-confusion argument, so the two non-absent clauses follow.

It remains to prove single-valuedness for any other transported present pair a', b' at the same endpoints. Apply Theorem 33.122 to the two left endpoint presentations of k to obtain $\mathsf{hsame}(\delta.\mathsf{map}(a), \delta.\mathsf{map}(a'))$.

Apply the same theorem to the two right endpoint presentations of k' to obtain $\mathsf{hsame}(\delta.\mathsf{map}(b), \delta.\mathsf{map}(b'))$. These two equalities are exactly the final paired single-valuedness clause. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier pair readback single valued`

Theorem 33.202 (Tagged option payload descent image classifier branch occupancy equivalence)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$. *For target endpoints* $k, k' : \mathsf{BHist}$, *if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$$

holds, then

$$(\mathsf{hsame}(k, \mathsf{e}) \iff \mathsf{hsame}(k', \mathsf{e})) \wedge ((\exists a : \mathsf{BHist}.\ S(a) \wedge T(\delta.\mathsf{map}(a)) \wedge \mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))) \iff (\exists b : \mathsf{BHist}.\ S(b) \wedge T($$

Proof. Apply Theorem 33.162 to the image-classifier witness. This exposes either the synchronized absent pair or a synchronized present pair.

In the absent branch, the two stored presentations give both directions of the empty-occupancy equivalence. Any displayed transported payload at either endpoint would present that endpoint both as e and as an $\mathsf{E1}$-constructor, contradicting empty-versus-$\mathsf{E1}$ no-confusion. Hence both present-occupancy sides are false, and the present equivalence follows.

In the present branch, keep the displayed payloads a, b, their source carrier witnesses, their transported target carrier witnesses, and the two endpoint presentations. These data give the forward and reverse directions of the present-occupancy equivalence.

It remains to rule out an empty presentation on either side of the present branch. Such a presentation would compose with the corresponding $\mathsf{E1}(\delta.\mathsf{map}(-))$ presentation at the same endpoint and violate empty-versus-$\mathsf{E1}$ no-confusion. Therefore both empty-occupancy sides are false, so the empty equivalence follows. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier branch occupancy equivalence`

Theorem 33.203 (Tagged option payload descent image classifier public endpoint readback)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$, *and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$. *For target endpoints* $k, k' : \mathsf{BHist}$, *if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$$

holds, then

$$\mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; k) \wedge \mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; k') \wedge \mathsf{Tag}$$

and either

$$\mathsf{hsame}(k, \mathsf{e}) \wedge \mathsf{hsame}(k', \mathsf{e}) \wedge (\neg \exists a : \mathsf{BHist}.\ S(a) \wedge T(\delta.\mathsf{map}(a)) \wedge \mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))) \wedge (\neg \exists b : \mathsf{BHist}.\ S(b) \wedge T(\delta.\mathsf{map}($$

or

$$\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge \mathsf{hsame}(k', \mathsf{E1}(\delta.\mathsf{map}(b))) \wedge \neg \mathsf{hs}$$

Proof. Apply Theorem 33.165 to the image-classifier witness. This supplies the two public image-carrier witnesses and the target $\mathsf{TaggedOptionHistoryClassifier}_{T, \sim_T}(k, k')$ witness.

Apply Theorem 33.201 to the same image-classifier witness. This gives the synchronized branch split for the endpoint pair.

In the absent branch, keep the two endpoint presentations $\mathsf{hsame}(k, \mathsf{e})$ and $\mathsf{hsame}(k', \mathsf{e})$. A transported visible presentation at the left endpoint would present k both as e and as $\mathsf{E1}(\delta.\mathsf{map}(a))$, contradicting empty-versus-$\mathsf{E1}$ no-confusion. The same argument at the right endpoint rules out every transported visible presentation of k'.

In the present branch, keep the displayed payloads a, b, their source carrier witnesses, the source classifier witness, the two transported target carrier witnesses, the two visible endpoint presentations, and the two non-absence clauses.

It remains only to separate the paired uniqueness field into public endpoint projections. Given any compatible transported visible pair a', b', apply the paired uniqueness clause supplied by Theorem 33.201. Project its left component for the left endpoint statement and its right component for the right endpoint statement. Together with the certificate fields obtained above, these data give the public endpoint readback package. □

Theorem 33.204 (Tagged option payload descent image classifier endpoint transport)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. For target endpoints* $k, k', u, u' : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k'), \qquad \mathsf{hsame}(k, u), \qquad \mathsf{hsame}(k', u'),$$

then

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; u, u').$$

Proof. Apply Theorem 33.162 to the classifier witness at (k, k'). This exposes either the absent branch or a present branch with source payloads a, b.

In the absent branch, compose $\mathsf{hsame}(k, u)$ with the empty presentation of k to obtain $\mathsf{hsame}(u, \mathsf{e})$, and compose $\mathsf{hsame}(k', u')$ with the empty presentation of k' to obtain $\mathsf{hsame}(u', \mathsf{e})$. These two transported empty presentations are the absent branch for the endpoint pair (u, u'), so the reverse direction of branch exactness gives the image-classifier witness at (u, u').

In the present branch, keep the exposed payloads a, b, the source witnesses, the source relation $a \sim_S b$, the transported target witnesses $T(\delta.\mathsf{map}(a))$ and $T(\delta.\mathsf{map}(b))$, and the two visible present presentations at k and k'. Compose the endpoint transports with these presentations to obtain

$$\mathsf{hsame}(u, \mathsf{E1}(\delta.\mathsf{map}(a))) \qquad \text{and} \qquad \mathsf{hsame}(u', \mathsf{E1}(\delta.\mathsf{map}(b))).$$

The same payload data and the transported visible presentations form the present branch for (u, u'), and the reverse direction of branch exactness gives the required image-classifier witness. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier hsame transport`

Theorem 33.205 (Tagged option payload descent image classifier left visible-branch inversion)**.** *This theorem fits the per-object template as follows: the traditional target is one-sided image option readback from the left visible endpoint; the BEDC source is* BHist *with a* $\mathsf{DescentCertificate}$*; the carrier is* $\mathsf{TaggedOptionPayloadDescentImageCarrier}$*; the classifier is* $\mathsf{TaggedOptionPayloadDescentImageClassifier}$*; the stability obligation is branch exactness plus constructor no-confusion; the ledger is the left visible target payload together with the transported right endpoint; the core theorem is left visible-branch*

inversion; exactness is absent propagation or transported present-payload recovery; the standard bridge is none/some *under payload descent; and the status is* ProofTarget.

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. For target endpoints* $k, k' : \mathsf{BHist}$*, the absent clause is*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k') \to \mathsf{hsame}(k, \mathsf{e}) \to \mathsf{hsame}(k', \mathsf{e}).$$

For every payload history $a : \mathsf{BHist}$*, the present clause is*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k') \to T(a) \to \mathsf{hsame}(k, \mathsf{E1}(a)) \to \exists b, c : \mathsf{BHist}.\ S(b) \wedge S(c) \wedge$$

Proof. Apply Theorem 33.162 to the image-classifier witness. This rewrites the witness into the disjunction whose absent side presents both target endpoints as e and whose present side exposes source payloads b, c together with the transported endpoint presentations.

For the absent clause, split that disjunction. The absent side gives $\mathsf{hsame}(k', \mathsf{e})$ directly. The present side also presents k as $\mathsf{E1}(\delta.\mathsf{map}(b))$ for some source payload b; composing this with the displayed witness $\mathsf{hsame}(k, \mathsf{e})$ gives empty-versus-E1 no-confusion, so the mixed branch is impossible.

For the present clause, split the same disjunction. The absent side presents k as e, contradicting the displayed witness $\mathsf{hsame}(k, \mathsf{E1}(a))$ by empty-versus-E1 no-confusion.

In the present side, keep the exposed source payloads b, c. The branch-exactness data already supplies $S(b)$, $S(c)$, $b \sim_S c$, $T(\delta.\mathsf{map}(b))$, $T(\delta.\mathsf{map}(c))$, and $\mathsf{hsame}(k', \mathsf{E1}(\delta.\mathsf{map}(c)))$.

Compose the left-endpoint presentations $\mathsf{hsame}(k, \mathsf{E1}(a))$ and $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(b)))$, and invert the E1 constructor to obtain $\mathsf{hsame}(a, \delta.\mathsf{map}(b))$. These fields are exactly the displayed existential witness. The hypothesis $T(a)$ records the visible left payload as a target carrier payload and is preserved as part of the public premise. □

Theorem 33.206 (Tagged option payload descent image classifier self-exactness)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. For every target endpoint* $k : \mathsf{BHist}$*, self-classification by the image classifier is exactly membership in the payload descent image carrier:*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k) \iff \mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta;$$

Proof. For the forward direction, apply Theorem 33.162 to the self-classifier witness at (k, k). This exposes either the absent pair or a present pair whose two visible endpoints are both k.

In the absent pair branch, the left endpoint presentation gives $\mathsf{hsame}(k, \mathsf{e})$. The reverse direction of Theorem 33.157 sends this absent carrier branch to $\mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; k)$.

In the present pair branch, keep the first exposed payload a together with $S(a)$, $T(\delta.\mathsf{map}(a))$, and $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$. These data form the present carrier branch, so the reverse direction of Theorem 33.157 gives the image-carrier witness at k.

For the reverse direction, apply Theorem 33.157 to the image-carrier witness at k. This exposes either the absent endpoint or a transported present payload at the endpoint.

In the absent carrier branch, use the same empty presentation for both sides of the pair. The reverse direction of Theorem 33.162 then rebuilds the absent/absent image-classifier branch at (k, k).

In the present carrier branch, unpack $a : \mathsf{BHist}$, $S(a)$, $T(\delta.\mathsf{map}(a))$, and $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$. Use the same payload on both sides; the reflexivity field of cert supplies $a \sim_S a$, and the same transported target witness and endpoint presentation supply both visible endpoints. The reverse direction of classifier branch exactness therefore gives $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier self exactness`

Theorem 33.207 (Tagged option payload descent image classifier composition factorization)**.** *This theorem fits the per-object template as follows: the traditional target is composition of classified option images; the BEDC source is* BHist *with two* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligation is factoring two composite* TaggedOptionMapRel *witnesses through shared intermediate endpoints; the ledger is the paired intermediate target endpoints and transported visible payloads; the core theorem is classifier-level composition factorization; exactness is the displayed equivalence; the standard bridge is* none/some *functorial image composition; and the status is* ProofTarget*.*

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, let $\sim_S$, $\sim_T$, and $\sim_U$ be source classifiers, and let

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume also endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $p : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(p))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

For every pair of final endpoints $m, m' : \mathsf{BHist}$, the composite image classifier factors through paired intermediate tagged option endpoints:

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m') \iff \exists k, k' : \mathsf{BHist}.\ \mathsf{TaggedOptionPayloadDescentIm}$$

Proof. For the forward direction, unfold Definition 33.161. This exposes source endpoints h, h', a source tagged classifier witness, and two composite map-relation witnesses from h to m and from h' to m'.

Apply Theorem 33.155 in the forward direction to the first composite map-relation witness and η_ϵ. It supplies an intermediate endpoint k, a δ-map witness from h to k, and an ϵ-map witness from k to m.

Apply the same exactness theorem to the second composite map-relation witness. This supplies k', a δ-map witness from h' to k', and an ϵ-map witness from k' to m'. Repack the source tagged classifier witness with the two δ-map witnesses to obtain the δ-image-classifier factor, and keep the two ϵ-map witnesses as the displayed endpoint factors.

For the reverse direction, unpack the displayed factorization into endpoints k, k', a δ-image-classifier witness, and the two ϵ-map witnesses from k to m and from k' to m'.

Unfold Definition 33.161 for the δ-image-classifier witness. This exposes source endpoints h, h', a source tagged classifier witness, and δ-map witnesses from h to k and from h' to k'.

Apply Theorem 33.155 in the reverse direction to the left pair of map witnesses, and apply it again to the right pair. The two results are composite $\mathsf{TaggedOptionMapRel}_{\epsilon\circ\delta}$ witnesses from h to m and from h' to m'. Repacking these with the same source tagged classifier witness gives the composite image-classifier witness. □

Theorem 33.208 (Tagged option payload descent image classifier stability package)**.** *This theorem fits the per-object template as follows: the traditional target is certificate-facing stability for the option payload descent image classifier; the BEDC source is* BHist *with a payload descent certificate; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier *the stability obligation is self-exactness, symmetry, transitivity, endpoint transport, and endpoint carrier exposure; the ledger is the classified target endpoints and the two transported source payload presentations; the core theorem is the public stability package; exactness is the self-classifier equivalence and the four closure fields below; the standard bridge is* none/some *under tagged option payload descent; and the status is* ProofTarget.

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$*, assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*, and assume*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

Then the option payload descent image classifier supplies the following five certificate-facing fields.

1. *For every target endpoint* $k : \mathsf{BHist}$*,*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k) \iff \mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T,$$

2. *For target endpoints* $k, k' : \mathsf{BHist}$*,*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k') \to \mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T$$

3. *For target endpoints* $k, \ell, m : \mathsf{BHist}$*,*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, \ell) \to \mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T,$$

4. *For target endpoints* $k, k', u, u' : \mathsf{BHist}$,

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k') \to \mathsf{hsame}(k, u) \to \mathsf{hsame}(k', u') \to \mathsf{TaggedOptionPayl}$$

5. *For target endpoints* $k, k' : \mathsf{BHist}$,

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k') \to \mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho$$

Proof. For the self-exactness field, apply Theorem 33.206 at the chosen endpoint k. Its two directions are exactly the displayed equivalence between the self-classifier witness and image-carrier membership.

For symmetry and carrier exposure, apply Theorem 33.166. Its second field gives the reversed classifier witness for classified endpoints, and its third field gives the two image-carrier witnesses exposed by any classifier witness.

For transitivity, apply Theorem 33.168 to the two classifier witnesses at (k, ℓ) and (ℓ, m), using the stated source hsame compatibility and source-reflection hypotheses.

For endpoint transport, apply Theorem 33.204 to the classifier witness at (k, k') and the two displayed hsame endpoint witnesses. Its conclusion is the transported classifier witness at (u, u'). □

Theorem 33.209 (Tagged option payload descent image classifier reflective transitive visible payload readback)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$*, assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*, and assume*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For target endpoints $k, \ell, m : \mathsf{BHist}$ *and visible target payloads* $u, v : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, \ell)$$

and

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; \ell, m)$$

and

$$T(u) \wedge T(v) \wedge \mathsf{hsame}(k, \mathsf{E1}(u)) \wedge \mathsf{hsame}(m, \mathsf{E1}(v)),$$

then

$$\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(u, \delta.\mathsf{map}(a)) \wedge \mathsf{hsame}(v, \delta.\mathsf{map}(b)).$$

Proof. First combine the two image-classifier witnesses. Apply Theorem 33.168 to the witnesses at (k, ℓ) and (ℓ, m), using the displayed source hsame compatibility and source-reflection hypotheses. This gives the direct image-classifier witness from k to m.

Next apply Theorem 33.164 to that direct witness and to the visible endpoint presentations $T(u)$, $T(v)$, $\mathsf{hsame}(k, \mathsf{E1}(u))$, and $\mathsf{hsame}(m, \mathsf{E1}(v))$. The produced source payloads a, b carry $S(a)$, $S(b)$, $a \sim_S b$, the transported target carrier facts, and the two payload readback equalities, which are exactly the displayed existential conclusion. □

Theorem 33.210 (Tagged option payload descent image semantic certificate under reflection)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$*, assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*, and assume*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

Then the payload descent image carrier and image classifier form the image-level semantic certificate

$\mathsf{SemanticNameCert}(\mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta), \mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta($

Proof. Build the core NameCert for the image carrier and image classifier. For inhabitation, use the absent branch of Theorem 33.157 at e: reflexivity of hsame gives the displayed absent endpoint, and the reverse direction of branch exactness gives the image-carrier witness at e.

For reflexivity of the core classifier, apply Theorem 33.206 to the image-carrier witness at the endpoint. For symmetry, use the symmetry field of Theorem 33.166.

For transitivity, use Theorem 33.168 with the displayed reflection hypothesis. For carrier respect, use the endpoint carrier exposure field of Theorem 33.166 and project the second image-carrier endpoint from the classified pair.

These five clauses assemble $\mathsf{NameCert}(\mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta), \mathsf{TaggedOptionPayload}$

Finally, set the source, pattern, and ledger predicates in SemanticNameCert all equal to the same payload descent image carrier. The pattern and ledger soundness maps are identity projections, so the core NameCert just built repacks as the displayed semantic certificate. □

33.10 Payload descent image classifier visible payload exactness

Theorem 33.211 (Tagged option payload descent image classifier visible payload exactness)**.** *Let* $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. For target endpoints* $k, k' : \mathsf{BHist}$ *and visible target payloads* $u, v : \mathsf{BHist}$*, the visible endpoint classifier is exact:*

$$(\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k') \wedge T(u) \wedge T(v) \wedge \mathsf{hsame}(k, \mathsf{E1}(u)) \wedge \mathsf{hsame}(k', \mathsf{E1}(v))) \iff$$

$$T(u) \wedge T(v) \wedge \mathsf{hsame}(k, \mathsf{E1}(u)) \wedge \mathsf{hsame}(k', \mathsf{E1}(v)) \wedge \exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}$$

Proof. For the forward direction, keep the visible target facts $T(u)$, $T(v)$, $\mathsf{hsame}(k, \mathsf{E1}(u))$, and $\mathsf{hsame}(k', \mathsf{E1}(v))$. Apply Theorem 33.164 to the classifier witness and these visible facts. This supplies source payloads a, b with the displayed source carrier witnesses, source classifier witness, transported target witnesses, and payload identifications.

Combining the retained visible facts with that existential witness gives the right-hand side of the equivalence.

For the reverse direction, unpack the right-hand side. Keep the visible target facts and choose witnesses a, b from the existential clause.

Compose $\mathsf{hsame}(k, \mathsf{E1}(u))$ with the $\mathsf{E1}$ congruence of $\mathsf{hsame}(u, \delta.\mathsf{map}(a))$ to obtain $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$. The same transitivity and congruence argument at the right endpoint gives $\mathsf{hsame}(k', \mathsf{E1}(\delta.\mathsf{map}(b)))$.

The source witnesses $S(a)$ and $S(b)$, the relation $a \sim_S b$, the transported target witnesses, and these two transported endpoint presentations form the present branch in Theorem 33.162. Apply its reverse direction to rebuild $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$. Together with the retained visible facts, this gives the left-hand side. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier visible payload exactness`

33.11 Payload descent image classifier visible pair coherence

Theorem 33.212 (Tagged option payload descent image classifier visible payload pair coherence)**.** *This theorem fits the per-object template as follows: the traditional target is visible readback coherence for constructor-tagged* OptionUp *under payload descent; the BEDC source is* BHist *with a* DescentCertificate*; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligation is visible endpoint determinacy plus payload readback; the ledger is the displayed target payload pair; the core theorem is the shared-source-pair coherence below; exactness says one source pair explains all visible target presentations; the standard bridge is* none/some *payload readback; and the status is* ProofTarget*.*

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$ *and* $\sim_T$ *be source classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. For target endpoints* $k, k' : \mathsf{BHist}$ *and visible target payloads* $u, v, u', v' : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$$

and

$$T(u) \wedge T(v) \wedge \mathsf{hsame}(k, \mathsf{E1}(u)) \wedge \mathsf{hsame}(k', \mathsf{E1}(v))$$

and

$$T(u') \wedge T(v') \wedge \mathsf{hsame}(k, \mathsf{E1}(u')) \wedge \mathsf{hsame}(k', \mathsf{E1}(v')),$$

then

$$\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(u, \delta.\mathsf{map}(a)) \wedge \mathsf{hsame}(v, \delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(u', \delta.\mathsf{m}$$

Proof. Apply Theorem 33.164 to the image-classifier witness and the first visible pair. This supplies source payloads a, b with $S(a)$, $S(b)$, $a \sim_S b$, the transported target witnesses, and the two payload identifications $\mathsf{hsame}(u, \delta.\mathsf{map}(a))$ and $\mathsf{hsame}(v, \delta.\mathsf{map}(b))$.

Compare the two visible presentations of the left endpoint k. The endpoint is presented both as $\mathsf{E1}(u)$ and as $\mathsf{E1}(u')$; $\mathsf{E1}$ no-confusion and symmetry of hsame give $\mathsf{hsame}(u', u)$, and composition with $\mathsf{hsame}(u, \delta.\mathsf{map}(a))$ gives $\mathsf{hsame}(u', \delta.\mathsf{map}(a))$.

Apply the same comparison at the right endpoint k'. The two presentations $\mathsf{E1}(v)$ and $\mathsf{E1}(v')$ determine $\mathsf{hsame}(v', v)$, and composing with $\mathsf{hsame}(v, \delta.\mathsf{map}(b))$ gives $\mathsf{hsame}(v', \delta.\mathsf{map}(b))$.

The original source payloads a, b, together with the two readback identifications and the two transported primed identifications, form the required shared-source-pair witness. □

Theorem 33.213 (Tagged option composite image classifier visible payload factorization)**.** *This theorem fits the per-object template as follows: the traditional target is functorial* OptionUp *visible payload readback; the BEDC source is* BHist *with two* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligation is composition factorization plus visible payload readback; the ledger is final visible payloads and intermediate tagged endpoints; the core theorem is the factorized readback below; exactness says composite classified final endpoints are witnessed by one intermediate classified pair; the standard bridge is* none/some *functorial payload readback; and the status is* ProofTarget*.*

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, let* $\sim_S$*,* $\sim_T$*, and* $\sim_U$ *be source classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ *for the descent certificate whose map field is* $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ *and whose respects field sends* $p : a \sim_S b$ *to* $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(p))$*. Define*

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. For final endpoints* $m, m' : \mathsf{BHist}$ *and visible final payloads* $x, y : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(m, \mathsf{E1}(x)) \wedge \mathsf{hsame}(m', \mathsf{E1}(y)),$$

then there exist $k, k', p, q, a, b : \mathsf{BHist}$ *such that*

1. $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$*;*
2. $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, m)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', m')$*;*
3. $T(p)$*,* $T(q)$*,* $U(\epsilon.\mathsf{map}(p))$*, and* $U(\epsilon.\mathsf{map}(q))$*;*
4. $\mathsf{hsame}(k, \mathsf{E1}(p))$*,* $\mathsf{hsame}(k', \mathsf{E1}(q))$*,* $\mathsf{hsame}(x, \epsilon.\mathsf{map}(p))$*, and* $\mathsf{hsame}(y, \epsilon.\mathsf{map}(q))$*;*
5. $S(a)$*,* $S(b)$*,* $a \sim_S b$*,* $T(\delta.\mathsf{map}(a))$*, and* $T(\delta.\mathsf{map}(b))$*;*
6. $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ *and* $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$*.*

Proof. Apply Theorem 33.207 to the composite image-classifier witness. This supplies intermediate endpoints k, k', the δ image-classifier factor at (k, k'), and the two ϵ map-relation witnesses from k to m and from k' to m'.

Use Theorem 33.138 on the two ϵ map-relation witnesses. The visible final presentations $\mathsf{hsame}(m, \mathsf{E1}(x))$ and $\mathsf{hsame}(m', \mathsf{E1}(y))$ force visible intermediate presentations, so obtain payloads p, q with $T(p)$, $T(q)$, $\mathsf{hsame}(k, \mathsf{E1}(p))$, and $\mathsf{hsame}(k', \mathsf{E1}(q))$.

Apply Theorem 33.139 to the left ϵ map-relation witness, the intermediate presentation $\mathsf{hsame}(k, \mathsf{E1}(p))$, and the final presentation $\mathsf{hsame}(m, \mathsf{E1}(x))$. It identifies x with $\epsilon.\mathsf{map}(p)$ and records the final carrier witness $U(\epsilon.\mathsf{map}(p))$.

Apply the same readback theorem to the right ϵ map-relation witness. This identifies y with $\epsilon.\mathsf{map}(q)$ and records $U(\epsilon.\mathsf{map}(q))$.

Now apply Theorem 33.164 to the δ image-classifier factor and the visible intermediate pair $\mathsf{hsame}(k, \mathsf{E1}(p))$, $\mathsf{hsame}(k', \mathsf{E1}(q))$. It gives source payloads a, b with $S(a)$, $S(b)$, $a \sim_S b$, the transported target-carrier witnesses, and $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ and $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$.

Package the endpoints k, k', the intermediate payloads p, q, and the source payloads a, b with the retained factorization witnesses and the four readback identifications. These are exactly the six displayed clauses. □

33.12 Payload descent image classifier public constructor normal form

Theorem 33.214 (Tagged option payload descent image classifier public constructor normal form)**.** *This theorem fits the per-object template as follows: the traditional target is constructor-facing public image readback for* OptionUp *payload descent; the BEDC source is* BHist *with one* DescentCertificate *map; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligation is certificate exposure, endpoint transport, and zero-tag exclusion; the ledger records the two public image endpoints, their target classifier witness, the absence of unused zero endpoints, and the absent-or-present readback split; the core theorem is the displayed constructor normal form; exactness says every classified image pair is either the absent public pair or a single-valued transported present pair; the standard bridge is* none/some *public readback; and the status is* ProofTarget*.*

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source and target carriers, let* $\sim_S$ *and* $\sim_T$ *be their classifiers, let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T),$$

and assume payload preservation

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. For target endpoints* $k, k' : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$$

holds, then the following clauses hold simultaneously.

1. *Both endpoints are public image endpoints:*

$$\mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; k) \wedge \mathsf{TaggedOptionPayloadDescentImageCarrier}_\delta(S, T, \rho_\delta; k').$$

2. *The endpoints are classified by the target tagged option classifier:*

$$\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k').$$

3. *Every zero-tag presentation is impossible at either endpoint:*

$$\forall t : \mathsf{BHist}.\ (\mathsf{hsame}(k, \mathsf{E0}(t)) \to \bot) \wedge (\mathsf{hsame}(k', \mathsf{E0}(t)) \to \bot).$$

4. *The public readback is absent-or-present and single-valued: either*

$$\mathsf{hsame}(k, \mathsf{e}) \wedge \mathsf{hsame}(k', \mathsf{e}) \wedge \neg\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$$

or

$$\exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge \mathsf{hsame}(k', \mathsf{E1}(\delta.\mathsf{map}(b))) \wedge$$

Proof. First expose the public image endpoints and the target classifier. Apply Theorem 33.165 to the image-classifier witness, using the displayed descent certificate, payload preservation, source certificate, and source compatibility. This gives the two image-carrier clauses and the target $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k')$ witness.

Next obtain the readback split. Apply Theorem 33.201 to the same image-classifier witness and the same source data. The resulting absent branch and transported present branch are exactly the fourth clause.

It remains to exclude zero-tag endpoints. Fix a tail t and suppose $\mathsf{hsame}(k, \mathsf{E0}(t))$. Transport the exposed target classifier along this left-endpoint witness and reflexivity on k', using Theorem 33.34. The transported classifier has $\mathsf{E0}(t)$ as its left endpoint, so Theorem 33.124 closes the contradiction.

For the right endpoint, suppose $\mathsf{hsame}(k', \mathsf{E0}(t))$. Transport the same target classifier along reflexivity on k and the displayed right-endpoint witness, again using Theorem 33.34. The transported classifier has $\mathsf{E0}(t)$ as its right endpoint, and Theorem 33.124 gives the second contradiction. Packaging these two functions for arbitrary t gives the zero-tag exclusion clause. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier public constructor normal form`

Theorem 33.215 (Tagged option composite image carrier zero-endpoint exclusion)**.** *This theorem fits the per-object template as follows: the traditional target is constructor-shape exclusion for composite* OptionUp *image carriers; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is not used in the statement; the stability obligation is branch exactness plus generated-history no-confusion; the ledger records the absence of the unused zero tag; the core theorem is the displayed implication; exactness says every composite image carrier endpoint is absent or one-tagged; the standard bridge is* none/some *readback; and the status is* ProofTarget*.*

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$*,* $\sim_T$*, and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

For every final endpoint $m : \mathsf{BHist}$ and tail $t : \mathsf{BHist}$, if

$$\mathsf{TaggedOptionPayloadDescentImageCarrier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m)$$

holds, then

$$\mathsf{hsame}(m, \mathsf{E0}(t)) \to \bot.$$

Proof. Apply Theorem 33.157 to the composite image-carrier witness. The branch split says that the final endpoint is either absent or presented by a transported one-tagged payload.

In the absent branch, suppose $\mathsf{hsame}(m, \mathsf{E0}(t))$. The branch presentation gives $\mathsf{hsame}(m, \mathsf{e})$. Compose symmetry of this empty presentation with the assumed zero presentation to obtain $\mathsf{hsame}(\mathsf{e}, \mathsf{E0}(t))$, contradicting empty-versus-E0 generated-history no-confusion.

In the present branch, unpack a source payload a together with $S(a)$, $U(\epsilon.\mathsf{map}(\delta.\mathsf{map}(a)))$, and $\mathsf{hsame}(m, \mathsf{E1}(\epsilon.\mathsf{map}(\delta.\mathsf{map}(a))))$. If $\mathsf{hsame}(m, \mathsf{E0}(t))$ also held, symmetry and transitivity of hsame would identify the displayed E1 endpoint with the zero endpoint, contradicting E1-versus-E0 generated-history no-confusion.

The two branches both return a contradiction from $\mathsf{hsame}(m, \mathsf{E0}(t))$, giving the displayed endpoint exclusion. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageCarrier composite zero endpoint exclusion`

Theorem 33.216 (Tagged option composite image classifier zero-endpoint exclusion)**.** *This theorem fits the per-object template as follows: the traditional target is public constructor-shape exclusion for functorial* OptionUp *image classification; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligation is public branch classification plus generated-history no-confusion; the ledger records that a final endpoint cannot be zero-tagged; the core theorem is the displayed pair of endpoint contradictions; exactness says the composite public readback has only absent or one-tagged final shapes; the standard bridge is* none/some *public readback; and the status is* ProofTarget.

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source, intermediate, and target carriers, let $\sim_S$, $\sim_T$, and $\sim_U$ be their classifiers, and let

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$, $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$, *and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$. *Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$, $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$, *and* $\mathsf{TaggedOptionSou}$). *For final endpoints $m, m' : \mathsf{BHist}$ and any tail $t : \mathsf{BHist}$, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

holds, then

$$(\mathsf{hsame}(m, \mathsf{E0}(t)) \to \bot) \wedge (\mathsf{hsame}(m', \mathsf{E0}(t)) \to \bot).$$

Proof. Apply Theorem 33.190 to the composite image-classifier witness. Its conclusion splits the final readback into an absent branch and a present branch.

For the left endpoint m, suppose $\mathsf{hsame}(m, \mathsf{E0}(t))$. In the absent branch, the classification gives $\mathsf{hsame}(m, \mathsf{e})$. Symmetry and transitivity of hsame compose this empty presentation with the assumed zero presentation, contradicting history no-confusion between e and $\mathsf{E0}(t)$.

In the present branch, the classification gives a visible final payload x with $\mathsf{hsame}(m, \mathsf{E1}(x))$. Symmetry and transitivity of hsame compose that visible presentation with the assumed zero presentation, contradicting $\mathsf{E1}$-versus-$\mathsf{E0}$ no-confusion.

For the right endpoint m', suppose $\mathsf{hsame}(m', \mathsf{E0}(t))$. In the absent branch, the classification gives $\mathsf{hsame}(m', \mathsf{e})$. Symmetry and transitivity of hsame compose this empty presentation with the assumed zero presentation, contradicting history no-confusion between e and $\mathsf{E0}(t)$.

In the present branch, the classification gives a visible final payload y with $\mathsf{hsame}(m', \mathsf{E1}(y))$. Symmetry and transitivity of hsame compose that visible presentation with the assumed zero presentation, contradicting $\mathsf{E1}$-versus-$\mathsf{E0}$ no-confusion.

Package the two endpoint contradiction functions in the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier composite zero endpoint exclusion`

33.13 Composite image classifier public readback single-valuedness

Theorem 33.217 (Tagged option composite image classifier public readback single-valuedness)**.** *This theorem fits the per-object template as follows: the traditional target is public readback for functorial* OptionUp *image classification; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligation is branch coverage together with visible-payload determinacy; the ledger records the absent final pair or the uniquely determined visible final payload pair; the core theorem is the displayed exhaustive disjunction with target classification, endpoint non-absence, and competing-readback uniqueness; exactness says public final endpoints have a single classified visible payload reading when they are present; the standard bridge is* none/some *public readback; and the status is* ProofTarget*.*

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$*,* $\sim_T$*, and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ *for the descent certificate whose map field is* $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ *and whose respects field sends* $r : a \sim_S b$ *to* $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$*. Define*

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$*,* $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$*, and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$*. Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*,* $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$*, and* TaggedOptionSou *). For final endpoints* $m, m' : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

holds, then either

$$\mathsf{hsame}(m, \mathsf{e}) \wedge \mathsf{hsame}(m', \mathsf{e}) \wedge \neg\exists x, y : \mathsf{BHist}.\ U(x) \wedge U(y) \wedge \mathsf{hsame}(m, \mathsf{E1}(x)) \wedge \mathsf{hsame}(m', \mathsf{E1}(y))$$

or there exist $x, y : \mathsf{BHist}$ *such that*

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(m, \mathsf{E1}(x)) \wedge \mathsf{hsame}(m', \mathsf{E1}(y)) \wedge x \sim_U y \wedge \neg\mathsf{hsame}(m, \mathsf{e}) \wedge \neg\mathsf{hsame}(m', \mathsf{e})$$

and

$$\forall x', y' : \mathsf{BHist}.\ U(x') \to U(y') \to \mathsf{hsame}(m, \mathsf{E1}(x')) \to \mathsf{hsame}(m', \mathsf{E1}(y')) \to \mathsf{hsame}(x, x') \wedge \mathsf{hsame}(y, y') \wedge x' \sim_U y'.$$

Proof. Apply Theorem 33.190 to the composite image-classifier witness, using the same descent certificates, payload preservation fields, endpoint stability, name certificates, and compatibility hypotheses. This gives the absent/present split for the final public endpoints.

In the absent branch, keep exactly the returned endpoint witnesses $\mathsf{hsame}(m, \mathsf{e})$ and $\mathsf{hsame}(m', \mathsf{e})$ together with the returned statement that no visible final payload pair exists. These three facts form the first disjunct.

In the present branch, project the visible final payload pair x, y from the branch-classification conclusion. Its carrier facts and visible endpoint presentations provide the visible part of the second disjunct.

Apply Theorem 33.192 to the same composite image-classifier witness, using the selected visible pair x, y as both readings. Project target classification $x \sim_U y$ and the two non-absence conclusions $\neg\mathsf{hsame}(m, \mathsf{e})$ and $\neg\mathsf{hsame}(m', \mathsf{e})$.

It remains to show single-valued public readback. Let x', y' be any competing visible final payloads with $U(x')$, $U(y')$, $\mathsf{hsame}(m, \mathsf{E1}(x'))$, and $\mathsf{hsame}(m', \mathsf{E1}(y'))$. Apply the visible-payload determinacy theorem again to the selected visible pair x, y and the competing visible pair x', y'. The result gives $\mathsf{hsame}(x, x')$, $\mathsf{hsame}(y, y')$, and $x' \sim_U y'$.

Return the two endpoint-determinacy witnesses and the competing target classification $x' \sim_U y'$ for the universal clause, and combine that clause with the selected visible-payload data, target classification, and non-absence facts. □

Theorem 33.218 (Tagged option composite image classifier nonempty public readback equivalence)**.** *This theorem fits the per-object template as follows: the traditional target is functorial* OptionUp *public present-readback criterion; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are branch coverage plus visible-payload determinacy and mixed-tag separation; the ledger is absent/present final endpoint readback; the core theorem is the nonempty iff plus a unique classified visible pair; exactness says the present public branch is equivalent to a nonempty endpoint; the standard bridge is* none/some *functorial readback; and the status is* ProofTarget*.*

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source, intermediate, and target carriers, let $\sim_S$, $\sim_T$, and $\sim_U$ be their classifiers, and let

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$*,* $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$*, and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$*. Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*,* $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$*, and* TaggedOptionSou). *For final endpoints* $m, m' : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

holds, then the following three assertions hold:

1. $\neg\mathsf{hsame}(m, \mathsf{e})$ *if and only if* $\neg\mathsf{hsame}(m', \mathsf{e})$*;*
2. $\neg\mathsf{hsame}(m, \mathsf{e})$ *if and only if there exist* $x, y : \mathsf{BHist}$ *such that*

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(m, \mathsf{E1}(x)) \wedge \mathsf{hsame}(m', \mathsf{E1}(y));$$

3. *if* $\neg\mathsf{hsame}(m, \mathsf{e})$*, then there exist* $x, y : \mathsf{BHist}$ *such that*

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(m, \mathsf{E1}(x)) \wedge \mathsf{hsame}(m', \mathsf{E1}(y)) \wedge x \sim_U y$$

and

$$\forall x', y' : \mathsf{BHist}.\ U(x') \to U(y') \to \mathsf{hsame}(m, \mathsf{E1}(x')) \to \mathsf{hsame}(m', \mathsf{E1}(y')) \to \mathsf{hsame}(x, x') \wedge \mathsf{hsame}(y, y') \wedge x' \sim_U y'.$$

Proof. Apply Theorem 33.217 to the composite image-classifier witness and the displayed descent, preservation, stability, certificate, and compatibility data. This gives an absent branch or a present branch with a selected visible final payload pair and the universal competing-readback clause.

In the absent branch, both endpoint presentations are empty. Hence $\neg\mathsf{hsame}(m, \mathsf{e})$ and $\neg\mathsf{hsame}(m', \mathsf{e})$ are both contradictory, and the returned no-visible-pair clause rules out the existential visible readback in the second assertion.

For the reverse implication in the second assertion, suppose a visible pair x, y exists. The visible-payload determinacy theorem applied to this visible pair against itself gives the non-absence conclusions $\neg\mathsf{hsame}(m, \mathsf{e})$ and $\neg\mathsf{hsame}(m', \mathsf{e})$. These also give the endpoint nonempty equivalence in the visible case.

In the present branch, keep the selected visible pair x, y. The branch already provides $U(x)$, $U(y)$, the two visible endpoint presentations, $x \sim_U y$, the two non-absence facts, and the competing-readback uniqueness clause.

These facts prove both directions of the visible-existence equivalence. Under the nonempty hypothesis, the same selected x, y witness the classified visible pair and carry the universal uniqueness conclusion. □

Theorem 33.219 (Tagged option composite image classifier transported nonempty public readback)**.** *This theorem fits the per-object template as follows: the traditional target is functorial* OptionUp *public readback stable under endpoint normalization; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligation is endpoint* hsame *transport plus public readback exactness; the ledger is transported absent/present final endpoint readback; the core theorem is the transported classifier together with the nonempty iff and unique classified visible pair at the transported endpoints; exactness says transported present readback is equivalent to endpoint nonemptiness; the standard bridge is* none/some *endpoint-normalized public readback; and the status is* ProofTarget*.*

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$, $\sim_T$, *and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ *for the descent certificate whose map field is* $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ *and whose respects field sends* $r : a \sim_S b$ *to* $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. *Define*

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$, $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$, *and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$. *Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$, $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$, *and* $\mathsf{TaggedOptionSou}$). *For final endpoints* $m, m', n, n' : \mathsf{BHist}$, *if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, n) \wedge \mathsf{hsame}(m', n'),$$

then

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; n, n')$$

holds, and the following three assertions hold:

1. $\neg\mathsf{hsame}(n, \mathsf{e})$ *if and only if* $\neg\mathsf{hsame}(n', \mathsf{e})$*;*
2. $\neg\mathsf{hsame}(n, \mathsf{e})$ *if and only if there exist* $x, y : \mathsf{BHist}$ *such that*

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(n, \mathsf{E1}(x)) \wedge \mathsf{hsame}(n', \mathsf{E1}(y));$$

3. *if* $\neg\mathsf{hsame}(n, \mathsf{e})$, *then there exist* $x, y : \mathsf{BHist}$ *such that*

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(n, \mathsf{E1}(x)) \wedge \mathsf{hsame}(n', \mathsf{E1}(y)) \wedge x \sim_U y$$

and

$$\forall x', y' : \mathsf{BHist}.\ U(x') \to U(y') \to \mathsf{hsame}(n, \mathsf{E1}(x')) \to \mathsf{hsame}(n', \mathsf{E1}(y')) \to \mathsf{hsame}(x, x') \wedge \mathsf{hsame}(y, y') \wedge x' \sim_U y'.$$

Proof. First transport the composite image-classifier witness from (m, m') to (n, n'). Apply Theorem 33.204 with the endpoint witnesses $\mathsf{hsame}(m, n)$ and $\mathsf{hsame}(m', n')$ to obtain the displayed classifier at the transported endpoints.

Next apply Theorem 33.218 to the transported composite classifier at (n, n'), using the same descent certificates, preservation fields, endpoint stability, name certificates, and compatibility hypotheses.

The three projected conclusions are exactly the normalized endpoint nonempty equivalence, the visible-pair existence equivalence, and the classified visible pair with the universal competing-readback clause, all indexed by n, n'. □

Theorem 33.220 (Tagged option composite image classifier normalized public readback single–valuedness)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized public readback for functorial* OptionUp *image classification; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are* hsame *endpoint transport plus public readback single-valuedness; the ledger records the normalized absent pair or the uniquely determined normalized visible final payload pair; the core theorem is the displayed normalized public certificate and branch split; exactness says normalized public endpoints have one classified visible payload reading when present; the standard bridge is* none/some *normalized public readback; and the status is* ProofTarget*.*

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$*,* $\sim_T$*, and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ *for the descent certificate whose map field is* $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ *and whose respects field sends* $r : a \sim_S b$ *to* $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$*. Define*

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$*,* $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$*, and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$*. Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*,* $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$*, and* TaggedOptionSou*). For final endpoints* $m, m' : \mathsf{BHist}$ *and normalized endpoints* $u, u' : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u'),$$

then

$$\mathsf{TaggedOptionPayloadDescentImageCarrier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; u) \wedge \mathsf{TaggedOptionPayloadDescentImageCarrier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; u$$

and either

$$\mathsf{hsame}(u, \mathsf{e}) \wedge \mathsf{hsame}(u', \mathsf{e}) \wedge \neg\exists x, y : \mathsf{BHist}.\ U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y))$$

or there exist $x, y : \mathsf{BHist}$ *such that*

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y)) \wedge x \sim_U y \wedge \neg\mathsf{hsame}(u, \mathsf{e}) \wedge \neg\mathsf{hsame}(u', \mathsf{e})$$

and

$$\forall x', y' : \mathsf{BHist}.\ U(x') \to U(y') \to \mathsf{hsame}(u, \mathsf{E1}(x')) \to \mathsf{hsame}(u', \mathsf{E1}(y')) \to \mathsf{hsame}(x, x') \wedge \mathsf{hsame}(y, y') \wedge x' \sim_U y'.$$

Proof. First transport the composite image-classifier witness from (m, m') to (u, u'). Apply Theorem 33.204 with the endpoint witnesses $\mathsf{hsame}(m, u)$ and $\mathsf{hsame}(m', u')$.

Next expose the normalized public certificate fields. Apply Theorem 33.165 to the transported classifier at (u, u'). This gives the two normalized image carriers and $\mathsf{TaggedOptionHistoryClassifier}_{U,\sim_U}(u, u')$.

Finally apply Theorem 33.217 to the transported composite classifier. Its absent branch gives the normalized empty pair and excludes every U-visible final payload pair at (u, u').

In the present branch, keep the visible normalized payloads x, y, their carrier facts, endpoint presentations, target classification, and non-absence clauses. The returned competing-readback clause is already indexed by the normalized endpoints u, u', so conjoin it with the exposed carrier and classifier fields. □

Theorem 33.221 (Tagged option composite image classifier normalized nonempty public readback equivalence)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized functorial* OptionUp *public present-readback exactness; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are endpoint transport, branch coverage, and visible-payload determinacy; the ledger is the normalized absent/present final endpoint split; the core theorem is the normalized nonempty iff plus a unique classified visible pair; exactness says the normalized present public branch is equivalent to a nonempty normalized endpoint; the standard bridge is* none/some *normalized public readback; and the status is* ProofTarget.

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$, $\sim_T$, *and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\, T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$, $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$, *and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$. *Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$, $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$, *and* $\mathsf{TaggedOptionSou}$). *For final endpoints $m, m' : \mathsf{BHist}$ and normalized endpoints $u, u' : \mathsf{BHist}$, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u'),$$

then the following three assertions hold:

1. $\neg\mathsf{hsame}(u, \mathsf{e})$ *if and only if* $\neg\mathsf{hsame}(u', \mathsf{e})$*;*
2. $\neg\mathsf{hsame}(u, \mathsf{e})$ *if and only if there exist $x, y : \mathsf{BHist}$ such that*

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y));$$

3. *if* $\neg\mathsf{hsame}(u, \mathsf{e})$*, then there exist $x, y : \mathsf{BHist}$ such that*

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y)) \wedge x \sim_U y$$

and

$$\forall x', y' : \mathsf{BHist}.\, U(x') \to U(y') \to \mathsf{hsame}(u, \mathsf{E1}(x')) \to \mathsf{hsame}(u', \mathsf{E1}(y')) \to \mathsf{hsame}(x, x') \wedge \mathsf{hsame}(y, y') \wedge x' \sim_U y'.$$

Proof. Apply Theorem 33.220 to the composite image-classifier witness, the endpoint normalization witnesses, and the displayed descent, preservation, stability, certificate, and compatibility data. This gives the normalized public carrier and classifier certificate, together with either an absent branch or a present branch.

In the absent branch, the theorem gives $\mathsf{hsame}(u, \mathsf{e})$, $\mathsf{hsame}(u', \mathsf{e})$, and the no-visible-pair clause at (u, u'). Therefore both endpoint non-absence claims are contradictory, which proves the normalized endpoint nonempty equivalence in this branch.

For the forward direction of the visible-readback equivalence, the same contradiction from $\mathsf{hsame}(u, \mathsf{e})$ rules out the hypothesis $\neg\mathsf{hsame}(u, \mathsf{e})$. For the reverse direction, any proposed visible pair is excluded by the no-visible-pair clause.

In the present branch, keep the selected visible normalized pair x, y. The branch provides $U(x)$, $U(y)$, the two normalized endpoint presentations, $x \sim_U y$, the two non-absence facts, and the universal competing-readback uniqueness clause.

The non-absence facts prove both directions of $\neg\mathsf{hsame}(u, \mathsf{e})$ if and only if $\neg\mathsf{hsame}(u', \mathsf{e})$. They also prove the forward direction of the visible-readback equivalence by the selected pair x, y, while the reverse direction follows from the branch's $\neg\mathsf{hsame}(u, \mathsf{e})$ conclusion.

Under the hypothesis $\neg\mathsf{hsame}(u, \mathsf{e})$, return the same selected x, y. Their carrier facts, endpoint presentations, target classification, and competing-readback uniqueness clause give the classified visible pair required by the third assertion. □

Theorem 33.222 (Tagged option composite image classifier normalized branch occupancy equivalence)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized functorial* OptionUp *public branch occupancy; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are endpoint transport, synchronized absent coverage, and visible-payload single-valuedness; the ledger is the normalized empty/visible final endpoint split; the core theorem is synchronized normalized empty occupancy, synchronized normalized visible occupancy, and empty-versus-visible exclusion on both endpoints; exactness says constructor occupancy is invariant under normalized public readback; the standard bridge is* none/some *normalized public readback; and the status is* ProofTarget*.*

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$*,* $\sim_T$*, and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ *for the descent certificate whose map field is* $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ *and whose respects field sends* $r : a \sim_S b$ *to* $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$*. Define*

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$*,* $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$*, and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$*. Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*,* $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$*, and* TaggedOptionSou
). For final endpoints $m, m' : \mathsf{BHist}$ *and normalized endpoints* $u, u' : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u'),$$

then

$$(\mathsf{hsame}(u, \mathsf{e}) \iff \mathsf{hsame}(u', \mathsf{e})) \wedge ((\exists x : \mathsf{BHist}.\ U(x) \wedge \mathsf{hsame}(u, \mathsf{E1}(x))) \iff (\exists y : \mathsf{BHist}.\ U(y) \wedge \mathsf{hsame}(u', \mathsf{E1}(y)))) \wedge (\mathsf{h}$$

Proof. Apply Theorem 33.220 to the composite image-classifier witness, the endpoint normalization witnesses, and the displayed descent, preservation, stability, certificate, and compatibility data. This gives the normalized public carrier and classifier certificate together with an absent branch or a present branch.

In the absent branch, the returned clauses give $\mathsf{hsame}(u, \mathsf{e})$, $\mathsf{hsame}(u', \mathsf{e})$, and exclusion of every paired visible U-readback at (u, u'). The two empty presentations prove both directions of the empty-occupancy equivalence.

For the visible-occupancy equivalence in the absent branch, unpack a visible witness on either endpoint. On the left, $\mathsf{hsame}(u, \mathsf{e})$ together with $\mathsf{hsame}(u, \mathsf{E1}(x))$ composes to $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(x))$, contradicting *not_hsame_emp_e*1. On the right, $\mathsf{hsame}(u', \mathsf{E1}(y))$ together with $\mathsf{hsame}(u', \mathsf{e})$ composes to $\mathsf{hsame}(\mathsf{E1}(y), \mathsf{e})$, contradicting *not_hsame_e*1*_empty*. Hence both visible sides are false in this branch.

The endpoint-specific exclusion clauses follow from the same contradictions: the left implication uses *not_hsame_emp_e*1, and the right implication uses *not_hsame_e*1*_empty*.

In the present branch, keep the selected visible normalized payloads x, y. Their carrier facts and endpoint presentations give the forward and reverse directions of the visible-occupancy equivalence, while the stored non-absence facts contradict any attempted empty presentation of either endpoint.

It remains only to repack the empty-versus-visible exclusions in the present branch. An empty presentation at u would contradict $\mathsf{hsame}(u, \mathsf{E1}(x))$ via *not_hsame_emp_e*1, and an empty presentation at u' would contradict $\mathsf{hsame}(u', \mathsf{E1}(y))$ via *not_hsame_e*1*_empty*. Therefore the empty-occupancy equivalence and both exclusion implications hold. □

Theorem 33.223 (Tagged option composite image classifier normalized one-sided visible branch synchronization)**.** *This theorem fits the per-object template as follows: the traditional target is one-sided visible readback for composite* OptionUp *image classification; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are composite descent, endpoint* hsame *transport, branch occupancy, visible payload determinacy, and target certificate transitivity; the ledger is one visible endpoint plus the recovered opposite visible endpoint and payload uniqueness; the core theorem is synchronized one-sided visible branch readback; exactness is branch occupancy plus visible payload determinacy; the standard bridge is* none/some *public readback; and the status is* ProofTarget*. Let* $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$*,* $\sim_T$*, and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ *for the descent certificate whose map field is* $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ *and whose respects field sends* $r : a \sim_S b$ *to* $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$*. Define*

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$*,* $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$*, and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$*. Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*,* $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$*, and* TaggedOptionSou). *For final endpoints* $m, m' : \mathsf{BHist}$ *and normalized endpoints* $u, u' : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u'),$$

then the following two one-sided visible branch clauses hold:

1. *For every* $x : \mathsf{BHist}$*, if* $U(x)$ *and* $\mathsf{hsame}(u, \mathsf{E1}(x))$*, then there exists* $y : \mathsf{BHist}$ *such that* $U(y)$*,* $\mathsf{hsame}(u', \mathsf{E1}(y))$*,* $x \sim_U y$*,* $\neg\mathsf{hsame}(u, \mathsf{e})$*,* $\neg\mathsf{hsame}(u', \mathsf{e})$*, and for every* $y' : \mathsf{BHist}$ *with* $U(y')$ *and* $\mathsf{hsame}(u', \mathsf{E1}(y'))$*, both* $\mathsf{hsame}(y, y')$ *and* $x \sim_U y'$ *hold.*
2. *For every* $y : \mathsf{BHist}$*, if* $U(y)$ *and* $\mathsf{hsame}(u', \mathsf{E1}(y))$*, then there exists* $x : \mathsf{BHist}$ *such that* $U(x)$*,* $\mathsf{hsame}(u, \mathsf{E1}(x))$*,* $x \sim_U y$*,* $\neg\mathsf{hsame}(u, \mathsf{e})$*,* $\neg\mathsf{hsame}(u', \mathsf{e})$*, and for every* $x' : \mathsf{BHist}$ *with* $U(x')$ *and* $\mathsf{hsame}(u, \mathsf{E1}(x'))$*, both* $\mathsf{hsame}(x, x')$ *and* $x' \sim_U y$ *hold.*

Proof. First apply Theorem 33.222 to the composite image-classifier witness and the endpoint normalization witnesses. This gives visible-existence equivalence between u and u', together with the empty-versus-visible exclusion clauses at both normalized endpoints. For the left-to-right clause, fix x with $U(x)$ and $\mathsf{hsame}(u, \mathsf{E1}(x))$. The forward implication in the visible-existence equivalence supplies some y with $U(y)$ and $\mathsf{hsame}(u', \mathsf{E1}(y))$. Apply Theorem 33.231 to the visible pair (x, y), using the same pair as the competing pair. This returns $x \sim_U y$ and the two non-absence facts $\neg\mathsf{hsame}(u, \mathsf{e})$ and $\neg\mathsf{hsame}(u', \mathsf{e})$. Now let y' be any competing target payload with $U(y')$ and $\mathsf{hsame}(u', \mathsf{E1}(y'))$. Apply the same visible-payload determinacy theorem to the first visible pair (x, y) and the competing pair (x, y'). The determinacy conclusion gives $\mathsf{hsame}(y, y')$, and its classifier component gives $x \sim_U y'$. These facts complete the left-to-right package. For the right-to-left clause, fix y with $U(y)$ and $\mathsf{hsame}(u', \mathsf{E1}(y))$. The reverse implication in the visible-existence equivalence supplies some x with $U(x)$ and $\mathsf{hsame}(u, \mathsf{E1}(x))$. Apply the visible-payload determinacy theorem to the visible pair (x, y), again using the same pair as the competing pair. This returns $x \sim_U y$ and the two non-absence facts for u and u'. Finally let x' be any competing target payload with $U(x')$ and $\mathsf{hsame}(u, \mathsf{E1}(x'))$. Apply visible-payload determinacy to the first visible pair (x, y) and the competing pair (x', y). The determinacy conclusion gives $\mathsf{hsame}(x, x')$, and its classifier component gives $x' \sim_U y$. This completes the symmetric package. □

33.14 Composite image classifier normalized public branch certificate

Theorem 33.224 (Tagged option composite image classifier normalized public branch certificate)**.** *This theorem fits the per-object template as follows: the traditional target is a single public-scope certificate for endpoint-normalized absent/present coverage and present-branch ledger factorization; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are composite descent, endpoint* hsame *transport, visible-payload readback, and target certificate transitivity; the ledger records synchronized branch occupancy together with the exhaustive public absent-or-present certificate; the core theorem is the displayed conjunction; exactness supplies the source and intermediate payloads behind a public visible branch; the standard bridge is* none/some *normalized public readback; and the status is* ProofTarget*. Let*

$S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source, intermediate, and target carriers, let $\sim_S$, $\sim_T$, and $\sim_U$ be their classifiers, and let

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$, $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$, and $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$. Assume $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$, $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$, and $\mathsf{TaggedOptionSou}$). For final endpoints $m, m' : \mathsf{BHist}$ and normalized endpoints $u, u' : \mathsf{BHist}$, if

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u'),$$

then the following two assertions hold.

1.

$$(\mathsf{hsame}(u, \mathsf{e}) \iff \mathsf{hsame}(u', \mathsf{e})) \wedge ((\exists x : \mathsf{BHist}.\ U(x) \wedge \mathsf{hsame}(u, \mathsf{E1}(x))) \iff (\exists y : \mathsf{BHist}.\ U(y) \wedge \mathsf{hsame}(u', \mathsf{E1}(y))))$$

2. Either

$$\mathsf{hsame}(u, \mathsf{e}) \wedge \mathsf{hsame}(u', \mathsf{e}) \wedge \neg\exists x, y : \mathsf{BHist}.\ U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y))$$

or there exist $x, y, k, k', p, q, a, b : \mathsf{BHist}$ such that

(a) $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$;

(b) $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u')$;

(c) $U(x)$, $U(y)$, $\mathsf{hsame}(u, \mathsf{E1}(x))$, *and* $\mathsf{hsame}(u', \mathsf{E1}(y))$;

(d) $T(p)$, $T(q)$, $U(\epsilon.\mathsf{map}(p))$, *and* $U(\epsilon.\mathsf{map}(q))$;

(e) $\mathsf{hsame}(k, \mathsf{E1}(p))$, $\mathsf{hsame}(k', \mathsf{E1}(q))$, $\mathsf{hsame}(x, \epsilon.\mathsf{map}(p))$, *and* $\mathsf{hsame}(y, \epsilon.\mathsf{map}(q))$;

(f) $S(a)$, $S(b)$, $a \sim_S b$, $T(\delta.\mathsf{map}(a))$, *and* $T(\delta.\mathsf{map}(b))$;

(g) $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ *and* $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$;

(h) $p \sim_T q$;

(i) $x \sim_U y$;

(j) $\neg\mathsf{hsame}(u, \mathsf{e})$ *and* $\neg\mathsf{hsame}(u', \mathsf{e})$;

(k) *for all* $x', y' : \mathsf{BHist}$, *if* $U(x')$, $U(y')$, $\mathsf{hsame}(u, \mathsf{E1}(x'))$, *and* $\mathsf{hsame}(u', \mathsf{E1}(y'))$, *then* $\mathsf{hsame}(x, x') \wedge \mathsf{hsame}(y, y') \wedge x' \sim_U y'$.

Proof. First apply Theorem 33.222 to the composite image-classifier witness, the endpoint normalization witnesses, and the displayed descent, preservation, stability, certificate, and compatibility data. This gives the synchronized absent occupancy, synchronized visible occupancy, and the two empty-implies-no-visible clauses. Next apply Theorem 33.228 to the same composite image-classifier witness and the same endpoint normalization witnesses. The theorem returns either the normalized absent public certificate or the visible public factorization with the displayed source, intermediate, target, classifier, non-absence, and uniqueness clauses. Package the occupancy result as the first component and the absent-or-present public certificate as the second component. □

33.15 Composite image classifier normalized constructor normal form

Theorem 33.225 (Tagged option composite image classifier normalized constructor normal form)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized constructor-facing public readback for functorial* OptionUp *image classification; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are endpoint transport, public certificate exposure, zero-tag exclusion, and single-valued visible readback; the ledger records the normalized public image endpoints, their target classifier witness, the absence of zero-tag endpoints, and the absent-or-present readback split; the core theorem is the displayed constructor normal form; exactness says a normalized public endpoint pair is either the absent pair or a single classified visible pair and never a zero-tagged pair; the standard bridge is* none/some *normalized public readback; and the status is* ProofTarget.

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$, $\sim_T$, *and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$, $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$, *and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$. *Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$, $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$, *and* $\mathsf{TaggedOptionSou}$). *For final endpoints* $m, m' : \mathsf{BHist}$ *and normalized endpoints* $u, u' : \mathsf{BHist}$, *if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u'),$$

then the following clauses hold simultaneously.

1. *The normalized endpoints are public image endpoints and are classified by the target tagged option classifier:*

   $$\mathsf{TaggedOptionPayloadDescentImageCarrier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; u) \wedge \mathsf{TaggedOptionPayloadDescentImageCarrier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}$$

2. *Every zero-tag presentation is impossible at either normalized endpoint:*

   $$\forall t : \mathsf{BHist}.\ (\mathsf{hsame}(u, \mathsf{E0}(t)) \to \bot) \wedge (\mathsf{hsame}(u', \mathsf{E0}(t)) \to \bot).$$

3. *The normalized public readback is absent-or-present and single-valued: either*

   $$\mathsf{hsame}(u, \mathsf{e}) \wedge \mathsf{hsame}(u', \mathsf{e}) \wedge \neg\exists x, y : \mathsf{BHist}.\ U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y))$$

   or there exist $x, y : \mathsf{BHist}$ *such that*

   $$U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y)) \wedge x \sim_U y \wedge \neg\mathsf{hsame}(u, \mathsf{e}) \wedge \neg\mathsf{hsame}(u', \mathsf{e})$$

   and

   $$\forall x', y' : \mathsf{BHist}.\ U(x') \to U(y') \to \mathsf{hsame}(u, \mathsf{E1}(x')) \to \mathsf{hsame}(u', \mathsf{E1}(y')) \to \mathsf{hsame}(x, x') \wedge \mathsf{hsame}(y, y') \wedge x' \sim_U y'.$$

Proof. First transport the composite image-classifier witness from (m, m') to (u, u'). Apply Theorem 33.204 with the endpoint normalization witnesses $\mathsf{hsame}(m, u)$ and $\mathsf{hsame}(m', u')$. This gives the same composite image-classifier statement at the normalized endpoint pair.

Next apply Theorem 33.220 to the original composite classifier and the same endpoint normalization witnesses. Project the two normalized public image carriers, the target classifier witness, and the absent-or-present single-valued readback disjunction.

It remains to rule out zero-tag normalized endpoints. Fix $t : \mathsf{BHist}$ and apply Theorem 33.216 to the transported composite classifier at (u, u') with this tail t. The result gives the two implication clauses $\mathsf{hsame}(u, \mathsf{E0}(t)) \to \bot$ and $\mathsf{hsame}(u', \mathsf{E0}(t)) \to \bot$.

Package these endpoint contradictions for arbitrary t together with the carrier, classifier, and readback clauses already obtained from normalized public readback single-valuedness. □

Theorem 33.226 (Tagged option composite image classifier normalized visible payload exactness)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized visible payload exactness for the composite* OptionUp *image classifier; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are composite descent, endpoint* hsame *transport, and visible-payload exactness; the ledger records normalized visible endpoints and the source payload pair; the core theorem is the displayed equivalence; exactness says visible normalized endpoints classify exactly when they come from a classified source pair; the standard bridge is* none/some *visible readback; and the status is* ProofTarget*.*

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$*,* $\sim_T$*, and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ *for the descent certificate whose map field is* $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ *and whose respects field sends* $r : a \sim_S b$ *to* $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$*. Define*

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$*,* $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$*, and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$*. Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*,* $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$*, and* TaggedOptionSou
). For final endpoints $m, m' : \mathsf{BHist}$*, normalized endpoints* $u, u' : \mathsf{BHist}$*, and visible target payloads* $x, y : \mathsf{BHist}$*, the normalized visible endpoint criterion is exact:*

$$(\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m') \wedge \mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u') \wedge U(x) \wedge U(y) \wedge \mathsf{hsame}($$

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u') \wedge U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y)) \wedge \exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge U(\epsilon$$

Proof. For the forward direction, keep the endpoint normalization witnesses and the visible target facts. Apply Theorem 33.204 to the composite classifier at (m, m') with $\mathsf{hsame}(m, u)$ and $\mathsf{hsame}(m', u')$. This gives the composite image-classifier witness at the normalized endpoint pair (u, u').

Now instantiate Theorem 33.211 with the composite descent certificate $\epsilon \circ \delta$, the target carrier U, and the preservation field $\rho_{\epsilon\circ\delta}$. Its forward direction, applied to the normalized classifier and the visible presentations $\mathsf{hsame}(u, \mathsf{E1}(x))$ and $\mathsf{hsame}(u', \mathsf{E1}(y))$, supplies source payloads a, b with $S(a)$, $S(b)$, $a \sim_S b$, the two composite target carrier witnesses, and the two payload identifications. Combining these witnesses with the retained endpoint and visible facts gives the right-hand side.

For the reverse direction, unpack the right-hand side. Retain $\mathsf{hsame}(m, u)$, $\mathsf{hsame}(m', u')$, the target carrier witnesses $U(x)$ and $U(y)$, and the visible presentations at (u, u'), and choose source payload witnesses a, b from the existential clause.

Apply the reverse direction of Theorem 33.211 to the composite descent certificate. The retained visible facts together with the chosen source pair build $\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_\epsilon$

Finally transport this classifier back to (m, m'). Use symmetry of the two endpoint hsame witnesses to turn $\mathsf{hsame}(m, u)$ and $\mathsf{hsame}(m', u')$ into $\mathsf{hsame}(u, m)$ and $\mathsf{hsame}(u', m')$, then apply Theorem 33.204. Together with the retained endpoint and visible facts, this is the left-hand side of the displayed equivalence. □

Theorem 33.227 (Tagged option composite image classifier normalized visible payload factorization)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized functorial* $\mathsf{OptionUp}$ *visible payload factorization; the BEDC source is* BHist *with composable* $\mathsf{DescentCertificate}$ *maps* δ *and* ϵ*; the carrier is* $\mathsf{TaggedOptionPayloadDescentImageCarrier}$*; the classifier is* $\mathsf{TaggedOptionPayloadDescentImageClassifier}$*; the stability obligations are* hsame *endpoint transport, map-relation composition factorization, and visible branch readback; the ledger records normalized final visible payloads together with intermediate endpoints and source payloads; the core theorem is the existence of* k, k', p, q, a, b *below; exactness says every normalized visible final payload pair factors through one intermediate tagged pair; the standard bridge is* some *payload functorial readback; and the status is* $\mathsf{ProofTarget}$*.*

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$*,* $\sim_T$*, and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ *for the descent certificate whose map field is* $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ *and whose respects field sends* $r : a \sim_S b$ *to* $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$*. Define*

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$*,* $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$*, and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$*. Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*,* $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$*, and* $\mathsf{TaggedOptionSou}$ *). For final endpoints* $m, m' : \mathsf{BHist}$*, normalized endpoints* $u, u' : \mathsf{BHist}$*, and visible final payloads* $x, y : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u')$$

and

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y)),$$

then there exist $k, k', p, q, a, b : \mathsf{BHist}$ *such that*

1. $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$;
2. $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u')$;
3. $T(p)$, $T(q)$, $U(\epsilon.\mathsf{map}(p))$, *and* $U(\epsilon.\mathsf{map}(q))$;
4. $\mathsf{hsame}(k, \mathsf{E1}(p))$, $\mathsf{hsame}(k', \mathsf{E1}(q))$, $\mathsf{hsame}(x, \epsilon.\mathsf{map}(p))$, *and* $\mathsf{hsame}(y, \epsilon.\mathsf{map}(q))$;
5. $S(a)$, $S(b)$, $a \sim_S b$, $T(\delta.\mathsf{map}(a))$, *and* $T(\delta.\mathsf{map}(b))$;
6. $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ *and* $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$.

Proof. First transport the composite image-classifier witness from (m, m') to (u, u'). Apply Theorem 33.204 with the endpoint normalization witnesses $\mathsf{hsame}(m, u)$ and $\mathsf{hsame}(m', u')$.

Next unfold the transported composite image classifier through Theorem 33.207. Equivalently, apply the underlying map-relation composition factorization to the two composite map-relation witnesses. This supplies intermediate endpoints k, k', the δ image-classifier factor at (k, k'), and the two ϵ map-relation witnesses from k to u and from k' to u'.

Use Theorem 33.138 on the two ϵ map-relation witnesses. The normalized visible presentations $\mathsf{hsame}(u, \mathsf{E1}(x))$ and $\mathsf{hsame}(u', \mathsf{E1}(y))$ force visible intermediate presentations, giving payloads p, q with $T(p)$, $T(q)$, $\mathsf{hsame}(k, \mathsf{E1}(p))$, and $\mathsf{hsame}(k', \mathsf{E1}(q))$.

Apply Theorem 33.139 to the left ϵ map-relation witness, the intermediate presentation $\mathsf{hsame}(k, \mathsf{E1}(p))$, and the normalized final presentation $\mathsf{hsame}(u, \mathsf{E1}(x))$. This identifies x with $\epsilon.\mathsf{map}(p)$ and records $U(\epsilon.\mathsf{map}(p))$. Apply the same readback theorem to the right endpoint to identify y with $\epsilon.\mathsf{map}(q)$ and record $U(\epsilon.\mathsf{map}(q))$.

Now apply Theorem 33.164 to the δ image-classifier factor and the visible intermediate pair. It gives source payloads a, b with $S(a)$, $S(b)$, $a \sim_S b$, the transported target-carrier witnesses $T(\delta.\mathsf{map}(a))$ and $T(\delta.\mathsf{map}(b))$, and the payload identifications $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ and $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$.

Package k, k', p, q, and a, b with the retained factorization witnesses, the visible readback links, and the source payload data. These are exactly the six displayed clauses. □

Theorem 33.228 (Tagged option composite image classifier normalized public branch factorization)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized public branch factorization for functorial* OptionUp *image classification; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are normalized public readback, visible payload factorization, and classifier transport through* hsame*-compatible source carriers; the ledger records either the normalized absent pair or a classified factored visible public branch; the core theorem is the displayed exhaustive disjunction; exactness says every present normalized public branch carries both an intermediate classified payload pair and a final classified payload pair; the standard bridge is* none/some *normalized public readback; and the status is* ProofTarget.

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$, $\sim_T$, *and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$, $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$, *and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$. *Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$, $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$, *and* TaggedOptionSou). *For final endpoints $m, m' : \mathsf{BHist}$ and normalized endpoints $u, u' : \mathsf{BHist}$, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u'),$$

then either

$$\mathsf{hsame}(u, \mathsf{e}) \wedge \mathsf{hsame}(u', \mathsf{e}) \wedge \neg\exists x, y : \mathsf{BHist}.\ U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y))$$

or there exist $k, k', p, q, x, y, a, b : \mathsf{BHist}$ such that

1. $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$;
2. $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u')$;
3. $U(x)$, $U(y)$, $\mathsf{hsame}(u, \mathsf{E1}(x))$, *and* $\mathsf{hsame}(u', \mathsf{E1}(y))$;
4. $T(p)$, $T(q)$, $U(\epsilon.\mathsf{map}(p))$, *and* $U(\epsilon.\mathsf{map}(q))$;
5. $\mathsf{hsame}(k, \mathsf{E1}(p))$, $\mathsf{hsame}(k', \mathsf{E1}(q))$, $\mathsf{hsame}(x, \epsilon.\mathsf{map}(p))$, *and* $\mathsf{hsame}(y, \epsilon.\mathsf{map}(q))$;
6. $S(a)$, $S(b)$, $a \sim_S b$, $T(\delta.\mathsf{map}(a))$, *and* $T(\delta.\mathsf{map}(b))$;
7. $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ *and* $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$;
8. $p \sim_T q$;
9. $x \sim_U y$;
10. $\neg\mathsf{hsame}(u, \mathsf{e})$ *and* $\neg\mathsf{hsame}(u', \mathsf{e})$;
11. *for all* $x', y' : \mathsf{BHist}$, *if* $U(x')$, $U(y')$, $\mathsf{hsame}(u, \mathsf{E1}(x'))$, *and* $\mathsf{hsame}(u', \mathsf{E1}(y'))$, *then* $\mathsf{hsame}(x, x') \wedge \mathsf{hsame}(y, y') \wedge x' \sim_U y'$.

Proof. Apply Theorem 33.220 to the composite image-classifier witness, the endpoint normalization witnesses, and the displayed descent, preservation, stability, certificate, and compatibility data. This gives the normalized absent branch or a present normalized visible pair x, y with non-absence and the universal competing-pair uniqueness clause.

In the absent branch, return the two empty endpoint presentations and the exclusion of every U-visible pair at (u, u').

In the present branch, apply Theorem 33.227 to the same composite classifier, the same endpoint normalization witnesses, and the selected visible presentations of u and u'. This supplies intermediate endpoints k, k', intermediate payloads p, q, and source payloads a, b with the six factorization clauses.

It remains to recover the two classifier consequences. Apply $\delta.\mathsf{respects}$ to $a \sim_S b$, then use compatibility for T to turn $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ and $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$ into classifier links. Symmetry and transitivity from cert_T compose these links into $p \sim_T q$.

Apply $\epsilon.\mathsf{respects}$ to $p \sim_T q$. Compatibility for U turns $\mathsf{hsame}(x, \epsilon.\mathsf{map}(p))$ and $\mathsf{hsame}(y, \epsilon.\mathsf{map}(q))$ into target classifier links, and symmetry and transitivity from cert_U compose them into $x \sim_U y$.

Package the factorization witnesses with $p \sim_T q$, $x \sim_U y$, the retained non-absence facts, and the competing-pair uniqueness clause from normalized public readback single-valuedness. □

Theorem 33.229 (Tagged option composite image classifier normalized source payload exactness)**.** *Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source, intermediate, and target carriers, let $\sim_S$, $\sim_T$, and $\sim_U$ be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$ and assume $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$. For final endpoints $m, m' : \mathsf{BHist}$, normalized endpoints $u, u' : \mathsf{BHist}$, and visible target payloads $x, y : \mathsf{BHist}$, assume

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u').$$

Then the normalized visible payload facts factor through classified source payloads:

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y)) \iff$$

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y)) \wedge \exists a, b : \mathsf{BHist}.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge U(\epsilon.\mathsf{map}(\delta.\mathsf{map}(a))) \wedge U(\epsilon.\mathsf{map}(\delta.$$

Proof. For the forward direction, transport the composite image-classifier witness from (m, m') to (u, u'). Apply Theorem 33.204 with the two endpoint normalization witnesses.

Now apply Theorem 33.211 to the transported classifier, using the composite descent certificate $\epsilon \circ \delta$ and the preservation field $\rho_{\epsilon\circ\delta}$. The visible presentations at (u, u') produce source payloads a, b with $S(a)$, $S(b)$, $a \sim_S b$, the two composite target carrier witnesses, and the two payload identifications. Conjoin this witness package with the four visible facts.

For the reverse direction, project the four visible facts from the right-hand side and discard the source-payload witness. □

33.16 Composite image classifier normalized visible target-payload classification

Theorem 33.230 (Tagged option composite image classifier normalized visible target-payload classification)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized visible target-payload classification for the composite* OptionUp *image classifier; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImag *the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are composite descent, endpoint* hsame *transport, visible-payload exactness, descent respect, and target certificate transitivity; the ledger records normalized visible endpoints and their target payload pair; the core theorem is target-side classifier recovery; exactness supplies the source pair behind the visible payloads; the standard bridge is* none/some *visible readback; and the status is* ProofTarget.

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$, $\sim_T$, *and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ *for the descent certificate whose map field is* $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ *and whose respects field sends* $r : a \sim_S b$ *to* $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. *Define*

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$, $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$, *and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$. *Assume* TaggedOptionSourceHsameCompatible$(S, \sim_S)$, TaggedOptionSourceHsameCompatible$(T, \sim_T)$, *and* TaggedOptionSou). *For final endpoints* $m, m' : \mathsf{BHist}$, *normalized endpoints* $u, u' : \mathsf{BHist}$, *and visible target payloads* $x, y : \mathsf{BHist}$, *if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u')$$

and

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y)),$$

then $x \sim_U y$.

Proof. First apply the forward direction of Theorem 33.226 to the composite image-classifier witness, the two endpoint normalization witnesses, and the two visible target-payload presentations. This returns source witnesses a, b with $S(a)$, $S(b)$, and $a \sim_S b$, together with the target carrier witnesses for $\epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and $\epsilon.\mathsf{map}(\delta.\mathsf{map}(b))$ and the payload readbacks $\mathsf{hsame}(x, \epsilon.\mathsf{map}(\delta.\mathsf{map}(a)))$ and $\mathsf{hsame}(y, \epsilon.\mathsf{map}(\delta.\mathsf{map}(b)))$.

Use $\delta.\mathsf{respects}$ on $a \sim_S b$ to obtain $\delta.\mathsf{map}(a) \sim_T \delta.\mathsf{map}(b)$. Then use $\epsilon.\mathsf{respects}$ to derive $\epsilon.\mathsf{map}(\delta.\mathsf{map}(a)) \sim_U \epsilon.\mathsf{map}(\delta.\mathsf{map}(b))$.

Target compatibility for U turns the carrier facts for x and $\epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and the first payload readback into $x \sim_U \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$. It also turns the carrier facts for y and $\epsilon.\mathsf{map}(\delta.\mathsf{map}(b))$ and the second payload readback into $y \sim_U \epsilon.\mathsf{map}(\delta.\mathsf{map}(b))$.

Apply symmetry from cert_U to the second target-compatibility relation, giving $\epsilon.\mathsf{map}(\delta.\mathsf{map}(b)) \sim_U y$. Transitivity from cert_U first composes $x \sim_U \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ with the composite descent relation, and then composes the result with $\epsilon.\mathsf{map}(\delta.\mathsf{map}(b)) \sim_U y$. The conclusion is $x \sim_U y$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier composite normalized visible target payload classification`

Theorem 33.231 (Tagged option composite image classifier normalized visible payload determinacy)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized functorial* OptionUp *visible-payload determinacy; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are composite descent, endpoint* hsame *transport, normalized target-payload classification,* E1 *payload determinacy, and empty-versus-present no-confusion; the ledger is the pair of normalized visible endpoints and two visible target payload readings; the core theorem is the displayed classification, determinacy, and non-absence conjunction; exactness says normalized visible readback is single-valued and target-classified; the standard bridge is* none/some *normalized public readback; and the status is* ProofTarget.

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$, $\sim_T$, *and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$, $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$, *and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$. *Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$, $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$, *and* TaggedOptionSou). *For final endpoints $m, m' : \mathsf{BHist}$, normalized endpoints $u, u' : \mathsf{BHist}$, and visible target payloads $x, y, x', y' : \mathsf{BHist}$, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u')$$

and

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y))$$

and

$$U(x') \wedge U(y') \wedge \mathsf{hsame}(u, \mathsf{E1}(x')) \wedge \mathsf{hsame}(u', \mathsf{E1}(y')),$$

then

$$x \sim_U y \wedge x' \sim_U y' \wedge \mathsf{hsame}(x, x') \wedge \mathsf{hsame}(y, y') \wedge \neg\mathsf{hsame}(u, \mathsf{e}) \wedge \neg\mathsf{hsame}(u', \mathsf{e}).$$

Proof. First classify the two normalized visible target payload pairs. Apply Theorem 33.230 to the composite image-classifier witness, the endpoint normalization witnesses, and the presentation $U(x)$, $U(y)$, $\mathsf{hsame}(u, \mathsf{E1}(x))$, and $\mathsf{hsame}(u', \mathsf{E1}(y))$. This gives $x \sim_U y$.

Apply the same theorem to the second visible presentation $U(x')$, $U(y')$, $\mathsf{hsame}(u, \mathsf{E1}(x'))$, and $\mathsf{hsame}(u', \mathsf{E1}(y'))$. This gives $x' \sim_U y'$.

Next compare the two readings of each normalized endpoint. Apply Theorem 33.122 at u to $\mathsf{hsame}(u, \mathsf{E1}(x))$ and $\mathsf{hsame}(u, \mathsf{E1}(x'))$, giving $\mathsf{hsame}(x, x')$. Apply the same theorem at u' to $\mathsf{hsame}(u', \mathsf{E1}(y))$ and $\mathsf{hsame}(u', \mathsf{E1}(y'))$, giving $\mathsf{hsame}(y, y')$.

It remains to rule out hidden absent tags at the normalized endpoints. If $\mathsf{hsame}(u, \mathsf{e})$ held, composing its symmetry with $\mathsf{hsame}(u, \mathsf{E1}(x))$ would give $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(x))$, contradicting BEDC history no-confusion via *not_hsame_emp_e*1.

Likewise, if $\mathsf{hsame}(u', \mathsf{e})$ held, composing its symmetry with $\mathsf{hsame}(u', \mathsf{E1}(y))$ would give $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(y))$, again contradicting BEDC history no-confusion via *not_hsame_emp_e*1.

Collect the two target-classification conclusions, the two payload-determinacy conclusions, and the two normalized non-absence conclusions in the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier composite normalized visible payload determinacy`

Theorem 33.232 (Tagged option composite image classifier normalized visible payload clique)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized functorial* OptionUp *visible payload classifier clique; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier*

is TaggedOptionPayloadDescentImageClassifier*; the stability obligations are normalized visible determinacy, target* hsame *compatibility, and* NameCert *transitivity; the ledger is all competing visible endpoint readings; the core theorem is four target-classifier links plus endpoint determinacy and non-absence; exactness says every visible readback at these endpoints belongs to the same target classifier component; the standard bridge is* none/some *normalized public readback; and the status is* ProofTarget.

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$, $\sim_T$, *and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ *for the descent certificate whose map field is* $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ *and whose respects field sends* $r : a \sim_S b$ *to* $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. *Define*

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$, $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$, *and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$. *Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$, $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$, *and* TaggedOptionSou). *For final endpoints* $m, m' : \mathsf{BHist}$, *normalized endpoints* $u, u' : \mathsf{BHist}$, *and visible target payloads* $x, y, x', y' : \mathsf{BHist}$, *if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u')$$

and

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y))$$

and

$$U(x') \wedge U(y') \wedge \mathsf{hsame}(u, \mathsf{E1}(x')) \wedge \mathsf{hsame}(u', \mathsf{E1}(y')),$$

then

$$x \sim_U y \wedge x \sim_U y' \wedge x' \sim_U y \wedge x' \sim_U y' \wedge \mathsf{hsame}(x, x') \wedge \mathsf{hsame}(y, y') \wedge \neg\mathsf{hsame}(u, \mathsf{e}) \wedge \neg\mathsf{hsame}(u', \mathsf{e}).$$

Proof. Apply Theorem 33.231 to the two visible presentations. This yields $x \sim_U y$, $x' \sim_U y'$, $\mathsf{hsame}(x, x')$, $\mathsf{hsame}(y, y')$, and the two normalized non-absence clauses.

The endpoint comparison at u' converts to target classification by the $\mathsf{TaggedOptionSourceHsameCompatible}(U, \sim$) assumption, giving $y \sim_U y'$. Transitivity from cert_U composes $x \sim_U y$ with $y \sim_U y'$, yielding $x \sim_U y'$.

For the opposite source reading, symmetry for hsame turns $\mathsf{hsame}(x, x')$ into $\mathsf{hsame}(x', x)$. Target hsame compatibility for U gives $x' \sim_U x$, and transitivity from cert_U composes this with $x \sim_U y$, yielding $x' \sim_U y$.

Collect the retained determinate link $x \sim_U y$, the two cross-links, the retained determinate link $x' \sim_U y'$, the two endpoint payload equalities, and the two normalized non-absence clauses in the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier composite normalized visible payload clique`

Theorem 33.233 (Tagged option composite image classifier normalized visible source-pair coherence)**.** *Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source, intermediate, and target carriers, let $\sim_S$, $\sim_T$, and $\sim_U$ be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$ and assume $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$. For final endpoints $m, m' : \mathsf{BHist}$, normalized endpoints $u, u' : \mathsf{BHist}$, and visible target payloads $x, y, x', y' : \mathsf{BHist}$, assume

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u')$$

and

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y))$$

and

$$U(x') \wedge U(y') \wedge \mathsf{hsame}(u, \mathsf{E1}(x')) \wedge \mathsf{hsame}(u', \mathsf{E1}(y')).$$

Then there exist $a, b : \mathsf{BHist}$ such that

$$S(a) \wedge S(b) \wedge a \sim_S b$$

and

$$U(\epsilon.\mathsf{map}(\delta.\mathsf{map}(a))) \wedge U(\epsilon.\mathsf{map}(\delta.\mathsf{map}(b)))$$

and

$$\mathsf{hsame}(x, \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))) \wedge \mathsf{hsame}(y, \epsilon.\mathsf{map}(\delta.\mathsf{map}(b))) \wedge \mathsf{hsame}(x', \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))) \wedge \mathsf{hsame}(y', \epsilon.\mathsf{map}(\delta.\mathsf{map}(b))).$$

Proof. First apply Theorem 33.229 to the composite image-classifier witness, the endpoint normalizations, and the unprimed visible presentation. The forward direction supplies source payloads a, b with $S(a)$, $S(b)$, $a \sim_S b$, the two composite target carrier witnesses, and the readbacks $\mathsf{hsame}(x, \epsilon.\mathsf{map}(\delta.\mathsf{map}(a)))$ and $\mathsf{hsame}(y, \epsilon.\mathsf{map}(\delta.\mathsf{map}(b)))$.

Next compare the competing visible readings of the same normalized endpoints. Apply Theorem 33.122 at u to $\mathsf{hsame}(u, \mathsf{E1}(x))$ and $\mathsf{hsame}(u, \mathsf{E1}(x'))$, and apply the same theorem at u' to $\mathsf{hsame}(u', \mathsf{E1}(y))$ and $\mathsf{hsame}(u', \mathsf{E1}(y'))$. These give $\mathsf{hsame}(x, x')$ and $\mathsf{hsame}(y, y')$.

Use symmetry and transitivity of hsame to compose the endpoint-comparison witnesses with the unprimed source readbacks. This yields $\mathsf{hsame}(x', \epsilon.\mathsf{map}(\delta.\mathsf{map}(a)))$ and $\mathsf{hsame}(y', \epsilon.\mathsf{map}(\delta.\mathsf{map}(b)))$.

Package the same source payloads a, b with their source classification, the two composite target carrier witnesses, and the four readback identifications. □

Theorem 33.234 (Tagged option composite image classifier normalized selected visible public pair canonicality)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized functorial* OptionUp *selected visible public-pair canonicality; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are composite descent, endpoint* hsame *transport, normalized target-payload classification, visible-payload determinacy, and empty-versus-present no-confusion; the ledger is one selected normalized visible public pair together with all one-sided competing readings; the core theorem is selected pair classification, same-side uniqueness, cross-side target classification, and non-absence; exactness says normalized visible readback is single-valued around the selected public pair; the standard bridge is* none/ some *normalized public readback; and the status is* ProofTarget.

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source, intermediate, and target carriers, let $\sim_S$, $\sim_T$, and $\sim_U$ be their classifiers, and let

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$*,* $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$*, and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$*. Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*,* $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$*, and* TaggedOptionSou). *For final endpoints* $m, m' : \mathsf{BHist}$*, normalized endpoints* $u, u' : \mathsf{BHist}$*, and selected visible target payloads* $x, y : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u')$$

and

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y)),$$

then

$$x \sim_U y$$

and

$$\forall x' : \mathsf{BHist}.\ U(x') \to \mathsf{hsame}(u, \mathsf{E1}(x')) \to \mathsf{hsame}(x, x') \wedge x' \sim_U y$$

and

$$\forall y' : \mathsf{BHist}.\ U(y') \to \mathsf{hsame}(u', \mathsf{E1}(y')) \to \mathsf{hsame}(y, y') \wedge x \sim_U y'$$

and

$$\neg\mathsf{hsame}(u, \mathsf{e}) \wedge \neg\mathsf{hsame}(u', \mathsf{e}).$$

Proof. Apply Theorem 33.230 to the composite image-classifier witness, the endpoint normalization witnesses, and the selected visible presentation $U(x)$, $U(y)$, $\mathsf{hsame}(u, \mathsf{E1}(x))$, and $\mathsf{hsame}(u', \mathsf{E1}(y))$. This gives the selected target classification $x \sim_U y$.

Let x' be a competing left visible payload with $U(x')$ and $\mathsf{hsame}(u, \mathsf{E1}(x'))$. Apply Theorem 33.231 to the two complete visible pairs (x, y) and (x', y). The returned conjunction contains $\mathsf{hsame}(x, x')$ and $x' \sim_U y$, which are exactly the left-side canonicality and target-classification conclusions for x'.

Let y' be a competing right visible payload with $U(y')$ and $\mathsf{hsame}(u', \mathsf{E1}(y'))$. Apply the same determinacy theorem to the two complete visible pairs (x, y) and (x, y'). The returned conjunction contains $\mathsf{hsame}(y, y')$ and $x \sim_U y'$, which are exactly the right-side canonicality and target-classification conclusions for y'.

It remains to record that the selected public endpoints are not absent. If $\mathsf{hsame}(u, \mathsf{e})$ held, composing its symmetry with $\mathsf{hsame}(u, \mathsf{E1}(x))$ would give $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(x))$, contradicting BEDC history no-confusion via *not_hsame_emp_e*1.

Likewise, if $\mathsf{hsame}(u', \mathsf{e})$ held, composing its symmetry with $\mathsf{hsame}(u', \mathsf{E1}(y))$ would give $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(y))$, again contradicting BEDC history no-confusion via *not_hsame_emp_e*1.

Collect the selected target classification, the two universal one-sided canonicality clauses, and the two non-absence conclusions. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier composite normalized selected visible public pair canonicality`

Theorem 33.235 (Tagged option composite image classifier normalized one-sided visible public factorization)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized functorial* OptionUp *one-sided visible public factorization; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are endpoint*

transport, branch synchronization, visible-payload factorization, and intermediate classifier transport; the ledger is one specified normalized visible endpoint together with the opposite public payload, intermediate tagged endpoints, and source payload witnesses; the core theorem is one-sided visible readback with factorization and uniqueness against all competing visible payloads on the other side; exactness says the public endpoint already read by a consumer exposes the concrete source and intermediate payloads behind the synchronized public branch; the standard bridge is none/some *normalized public readback; and the status is* ProofTarget.

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$, $\sim_T$, *and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ *for the descent certificate whose map field is* $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ *and whose respects field sends* $r : a \sim_S b$ *to* $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. *Define*

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$, $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$, *and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$. *Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$, $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$, *and* TaggedOptionSou). *For final endpoints* $m, m' : \mathsf{BHist}$ *and normalized endpoints* $u, u' : \mathsf{BHist}$, *if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u'),$$

then the following two one-sided visible public factorization clauses hold:

1. *For every* $x : \mathsf{BHist}$, *if* $U(x)$ *and* $\mathsf{hsame}(u, \mathsf{E1}(x))$, *then there exist* $y, k, k', p, q, a, b : \mathsf{BHist}$ *such that*

2. *For every* $y : \mathsf{BHist}$*, if* $U(y)$ *and* $\mathsf{hsame}(u', \mathsf{E1}(y))$*, then there exist* $x, k, k', p, q, a, b : \mathsf{BHist}$ *such that*

   (a) $U(x)$*,* $\mathsf{hsame}(u, \mathsf{E1}(x))$*, and* $x \sim_U y$*;*

   (b) $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$*;*

   (c) $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u')$*;*

   (d) $T(p)$*,* $T(q)$*,* $U(\epsilon.\mathsf{map}(p))$*, and* $U(\epsilon.\mathsf{map}(q))$*;*

   (e) $\mathsf{hsame}(k, \mathsf{E1}(p))$*,* $\mathsf{hsame}(k', \mathsf{E1}(q))$*,* $\mathsf{hsame}(x, \epsilon.\mathsf{map}(p))$*, and* $\mathsf{hsame}(y, \epsilon.\mathsf{map}(q))$*;*

   (f) $S(a)$*,* $S(b)$*,* $a \sim_S b$*,* $T(\delta.\mathsf{map}(a))$*, and* $T(\delta.\mathsf{map}(b))$*;*

   (g) $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ *and* $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$*;*

   (h) $p \sim_T q$*;*

   (i) $\neg\mathsf{hsame}(u, \mathsf{e})$ *and* $\neg\mathsf{hsame}(u', \mathsf{e})$*;*

   (j) for every $x' : \mathsf{BHist}$*, if* $U(x')$ *and* $\mathsf{hsame}(u, \mathsf{E1}(x'))$*, then* $\mathsf{hsame}(x, x')$ *and* $x' \sim_U y$*.*

Proof. Fix a left visible payload x with $U(x)$ and $\mathsf{hsame}(u, \mathsf{E1}(x))$. Apply Theorem 33.223 to the composite image-classifier witness, the endpoint normalization witnesses, and the displayed descent, preservation, stability, certificate, and compatibility data. The left-to-right branch supplies a right payload y with $U(y)$, $\mathsf{hsame}(u', \mathsf{E1}(y))$, $x \sim_U y$, the two non-absence facts, and the universal competing-right-payload uniqueness clause.

Apply Theorem 33.227 to the same composite classifier, the same endpoint normalization witnesses, and the specified visible pair (x, y). This supplies intermediate endpoints k, k', intermediate payloads p, q, and source payloads a, b with the factorization clauses through δ and ϵ.

It remains to identify the intermediate payloads as classified. Apply $\delta.\mathsf{respects}$ to $a \sim_S b$. Compatibility for T turns $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ and $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$ into classifier links, and symmetry and transitivity from cert_T compose these links into $p \sim_T q$.

Package y, k, k', p, q, a, b with the visible target facts, the factorization data, $p \sim_T q$, the retained non-absence facts, and the competing-right-payload uniqueness clause. This proves the left one-sided factorization clause.

For the right visible payload y with $U(y)$ and $\mathsf{hsame}(u', \mathsf{E1}(y))$, apply the same branch-synchronization theorem and use its right-to-left branch. It supplies a left payload x with $U(x)$, $\mathsf{hsame}(u, \mathsf{E1}(x))$, $x \sim_U y$, the two non-absence facts, and the universal competing-left-payload uniqueness clause.

Apply the normalized visible payload factorization theorem to the visible pair (x, y). The same factorization data k, k', p, q, a, b is obtained, because the specified right payload has now been paired with the synchronized left payload.

As in the left clause, $\delta.\mathsf{respects}$, compatibility for T, and symmetry and transitivity from cert_T compose the source classifier fact and the two readback links into $p \sim_T q$.

Package x, k, k', p, q, a, b with the visible target facts, the factorization data, $p \sim_T q$, the retained non-absence facts, and the competing-left-payload uniqueness clause. This proves the symmetric right one-sided factorization clause. □

Theorem 33.236 (Tagged option composite image classifier normalized selected visible public factorization)**.** *Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source, intermediate, and target carriers, let $\sim_S$, $\sim_T$, and $\sim_U$ be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$, $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$, and $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$. Assume $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$, $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$, and $\mathsf{TaggedOptionSou}$). For final endpoints $m, m' : \mathsf{BHist}$, normalized endpoints $u, u' : \mathsf{BHist}$, and selected visible target payloads $x, y : \mathsf{BHist}$, if

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u')$$

and

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y)),$$

then there exist $k, k', p, q, a, b : \mathsf{BHist}$ such that

1. $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$;
2. $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u')$;
3. $T(p)$, $T(q)$, $U(\epsilon.\mathsf{map}(p))$, *and* $U(\epsilon.\mathsf{map}(q))$;
4. $\mathsf{hsame}(k, \mathsf{E1}(p))$, $\mathsf{hsame}(k', \mathsf{E1}(q))$, $\mathsf{hsame}(x, \epsilon.\mathsf{map}(p))$, *and* $\mathsf{hsame}(y, \epsilon.\mathsf{map}(q))$;
5. $S(a)$, $S(b)$, $a \sim_S b$, $T(\delta.\mathsf{map}(a))$, *and* $T(\delta.\mathsf{map}(b))$;
6. $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ *and* $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$;
7. $p \sim_T q$ *and* $x \sim_U y$;
8. $\neg\mathsf{hsame}(u, \mathsf{e})$ *and* $\neg\mathsf{hsame}(u', \mathsf{e})$;
9. *for every $x' : \mathsf{BHist}$, if $U(x')$ and $\mathsf{hsame}(u, \mathsf{E1}(x'))$, then $\mathsf{hsame}(x, x')$ and $x' \sim_U y$;*

10. for every $y' : \mathsf{BHist}$*, if* $U(y')$ *and* $\mathsf{hsame}(u', \mathsf{E1}(y'))$*, then* $\mathsf{hsame}(y, y')$ *and* $x \sim_U y'$*.*

Proof. Apply Theorem 33.234 to the composite image-classifier witness, the endpoint normalization witnesses, and the selected visible presentation. This gives $x \sim_U y$, the two selected same-side uniqueness clauses, and the two normalized non-absence facts.

Next apply the left clause of Theorem 33.235 to the selected left payload x. It supplies a synchronized right payload y_0 and witnesses k, k', p, q, a, b satisfying the displayed factorization clauses with y_0 in the right readback position, together with $p \sim_T q$, the non-absence facts, and uniqueness against all competing right payloads.

Use the one-sided right uniqueness clause at the selected payload y. Since $U(y)$ and $\mathsf{hsame}(u', \mathsf{E1}(y))$ hold, it returns $\mathsf{hsame}(y_0, y)$ and $x \sim_U y$. Compose the symmetry of $\mathsf{hsame}(y_0, y)$ with the factorization readback $\mathsf{hsame}(y_0, \epsilon.\mathsf{map}(q))$ to obtain the selected readback $\mathsf{hsame}(y, \epsilon.\mathsf{map}(q))$.

Keep the left readback $\mathsf{hsame}(x, \epsilon.\mathsf{map}(p))$ and all remaining factorization clauses unchanged. Package the witnesses k, k', p, q, a, b with the transported right readback, the retained $p \sim_T q$, the selected classification $x \sim_U y$, the canonical non-absence facts, and the two selected uniqueness clauses from the canonicality theorem. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier composite normalized selected visible public factorization`

Theorem 33.237 (Tagged option composite image classifier normalized visible public factorization is representative-independent)**.** *Let* $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$*,* $\sim_T$*, and* $\sim_U$ *be their classifiers, and let*

For final endpoints* $m, m' : \mathsf{BHist}$*, normalized endpoints* $u, u' : \mathsf{BHist}$*, selected visible target payloads* $x, y : \mathsf{BHist}$*, and alternative visible target payloads* $x', y' : \mathsf{BHist}$*, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u')$$

and

$$U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y))$$

and

$$U(x') \wedge U(y') \wedge \mathsf{hsame}(u, \mathsf{E1}(x')) \wedge \mathsf{hsame}(u', \mathsf{E1}(y')),$$

then there exist $k, k', p, q, a, b : \mathsf{BHist}$ *such that*

1. $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$;
2. $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u')$;
3. $T(p)$, $T(q)$, $U(\epsilon.\mathsf{map}(p))$, *and* $U(\epsilon.\mathsf{map}(q))$;
4. $\mathsf{hsame}(k, \mathsf{E1}(p))$, $\mathsf{hsame}(k', \mathsf{E1}(q))$, $\mathsf{hsame}(x, \epsilon.\mathsf{map}(p))$, *and* $\mathsf{hsame}(y, \epsilon.\mathsf{map}(q))$;
5. $\mathsf{hsame}(x', \epsilon.\mathsf{map}(p))$ *and* $\mathsf{hsame}(y', \epsilon.\mathsf{map}(q))$;
6. $S(a)$, $S(b)$, $a \sim_S b$, $T(\delta.\mathsf{map}(a))$, *and* $T(\delta.\mathsf{map}(b))$;
7. $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ *and* $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$;
8. $p \sim_T q$, $x \sim_U y$, $x' \sim_U y'$, $x \sim_U y'$, *and* $x' \sim_U y$;
9. $\neg\mathsf{hsame}(u, \mathsf{e})$ *and* $\neg\mathsf{hsame}(u', \mathsf{e})$;
10. *for every* $x_L : \mathsf{BHist}$, *if* $U(x_L)$ *and* $\mathsf{hsame}(u, \mathsf{E1}(x_L))$, *then* $\mathsf{hsame}(x, x_L)$ *and* $x_L \sim_U y$;
11. *for every* $y_R : \mathsf{BHist}$, *if* $U(y_R)$ *and* $\mathsf{hsame}(u', \mathsf{E1}(y_R))$, *then* $\mathsf{hsame}(y, y_R)$ *and* $x \sim_U y_R$.

Proof. Apply Theorem 33.236 to the composite image-classifier witness, the endpoint normalization witnesses, and the selected visible presentation (x, y). This gives witnesses k, k', p, q, a, b with the selected factorization clauses, the selected readbacks through $\epsilon.\mathsf{map}(p)$ and $\epsilon.\mathsf{map}(q)$, the classification $x \sim_U y$, the non-absence facts, and the two universal same-endpoint uniqueness clauses.

Apply the left uniqueness clause to x' and the right uniqueness clause to y'. The visible-presentation hypotheses for x' and y' give $\mathsf{hsame}(x, x')$, $x' \sim_U y$, $\mathsf{hsame}(y, y')$, and $x \sim_U y'$.

Apply Theorem 33.234 to the same composite witness and endpoint normalizations, but use the alternative visible presentation (x', y'). This gives the alternative classification $x' \sim_U y'$.

It remains to transport the selected public readbacks to the alternative representatives. Compose the symmetry of $\mathsf{hsame}(x, x')$ with $\mathsf{hsame}(x, \epsilon.\mathsf{map}(p))$ to obtain $\mathsf{hsame}(x', \epsilon.\mathsf{map}(p))$, and compose the symmetry of $\mathsf{hsame}(y, y')$ with $\mathsf{hsame}(y, \epsilon.\mathsf{map}(q))$ to obtain $\mathsf{hsame}(y', \epsilon.\mathsf{map}(q))$.

Package the same witnesses k, k', p, q, a, b with the original selected factorization clauses, the two transported readbacks, the selected and alternative target classifications, the two cross-classifications, and the retained universal uniqueness clauses. □

   (i) $\neg\mathsf{hsame}(u, \mathsf{e})$ *and* $\neg\mathsf{hsame}(u', \mathsf{e})$;
   (j) *for every* $x' : \mathsf{BHist}$, *if* $U(x')$ *and* $\mathsf{hsame}(u, \mathsf{E1}(x'))$, *then* $\mathsf{hsame}(x_L, x')$ *and* $x' \sim_U y_R$.

Proof. Apply Theorem 33.228 to the composite image-classifier witness, the endpoint normalization witnesses, and the displayed descent, preservation, stability, certificate, and compatibility data. This gives either the normalized absent public branch or a present visible public branch with selected payloads x, y and universal visible-pair uniqueness.

In the absent branch, return exactly the two empty endpoint presentations and the exclusion of every visible U-payload pair at (u, u').

In the present branch, retain the selected visible payloads x, y, their target classification, the two non-absence facts, and the universal visible-pair uniqueness clause supplied by public branch factorization.

Apply Theorem 33.235 once to the same composite classifier, endpoint normalization witnesses, descent, preservation, stability, certificate, and compatibility data. The result is a pair of one-sided public factorization clauses.

For an arbitrary left visible payload x_L with $U(x_L)$ and $\mathsf{hsame}(u, \mathsf{E1}(x_L))$, instantiate the left one-sided clause. It supplies a right visible payload y_R and witnesses k, k', p, q, a, b with the classified factorization package, the two public map-relation links, the intermediate and source payload data, the classifier link $p \sim_T q$, the non-absence facts, and the universal competing-right-payload clause.

For an arbitrary right visible payload y_R with $U(y_R)$ and $\mathsf{hsame}(u', \mathsf{E1}(y_R))$, instantiate the right one-sided clause. It supplies a left visible payload x_L and witnesses k, k', p, q, a, b with the symmetric classified factorization package and the universal competing-left-payload clause.

Package the selected present branch data together with these two one-sided completion functions. This gives the displayed present public readback completion package. □

33.18 Composite image classifier normalized one-sided public completion

Theorem 33.239 (Tagged option composite image classifier normalized one-sided public completion)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized one-sided public completion for functorial* OptionUp *image classification; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier *the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are public readback completion, endpoint visibility, empty-versus-present no-confusion, and the* hsame *symmetry and transitivity spine; the ledger records total left and right visible-endpoint consumers with synchronized opposite endpoints; the core theorem is one-sided public completion from any visible normalized endpoint; exactness says the completed opposite endpoint carries the same target classifier and the full descent factorization package; the standard bridge is* some *normalized public readback; and the status is* ProofTarget.

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$, $\sim_T$, *and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ *for the descent certificate whose map field is* $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ *and whose respects field sends* $r : a \sim_S b$ *to* $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$*. Define*

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$, $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$, *and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$. *Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$, $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$, *and* TaggedOptionSou). *For final endpoints* $m, m' : \mathsf{BHist}$ *and normalized endpoints* $u, u' : \mathsf{BHist}$, *if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u'),$$

then the following one-sided public completion clauses hold:

1. *for every left visible payload* x_L : BHist, *if* $U(x_L)$ *and* $\mathsf{hsame}(u, \mathsf{E1}(x_L))$, *then there exist* $y_R, k, k', p, q, a, b : \mathsf{BHist}$ *such that*
   (a) $U(y_R)$, $\mathsf{hsame}(u', \mathsf{E1}(y_R))$, *and* $x_L \sim_U y_R$;
   (b) $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$;
   (c) $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u')$;
   (d) $T(p)$, $T(q)$, $U(\epsilon.\mathsf{map}(p))$, *and* $U(\epsilon.\mathsf{map}(q))$;
   (e) $\mathsf{hsame}(k, \mathsf{E1}(p))$, $\mathsf{hsame}(k', \mathsf{E1}(q))$, $\mathsf{hsame}(x_L, \epsilon.\mathsf{map}(p))$, *and* $\mathsf{hsame}(y_R, \epsilon.\mathsf{map}(q))$;
   (f) $S(a)$, $S(b)$, $a \sim_S b$, $T(\delta.\mathsf{map}(a))$, *and* $T(\delta.\mathsf{map}(b))$;
   (g) $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ *and* $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$;
   (h) $p \sim_T q$;
   (i) $\neg\mathsf{hsame}(u, \mathsf{e})$ *and* $\neg\mathsf{hsame}(u', \mathsf{e})$;
   (j) *for every* y' : BHist, *if* $U(y')$ *and* $\mathsf{hsame}(u', \mathsf{E1}(y'))$, *then* $\mathsf{hsame}(y_R, y')$ *and* $x_L \sim_U y'$.
2. *for every right visible payload* y_R : BHist, *if* $U(y_R)$ *and* $\mathsf{hsame}(u', \mathsf{E1}(y_R))$, *then there exist* $x_L, k, k', p, q, a, b : \mathsf{BHist}$ *such that*
   (a) $U(x_L)$, $\mathsf{hsame}(u, \mathsf{E1}(x_L))$, *and* $x_L \sim_U y_R$;
   (b) $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$;
   (c) $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u')$;
   (d) $T(p)$, $T(q)$, $U(\epsilon.\mathsf{map}(p))$, *and* $U(\epsilon.\mathsf{map}(q))$;
   (e) $\mathsf{hsame}(k, \mathsf{E1}(p))$, $\mathsf{hsame}(k', \mathsf{E1}(q))$, $\mathsf{hsame}(x_L, \epsilon.\mathsf{map}(p))$, *and* $\mathsf{hsame}(y_R, \epsilon.\mathsf{map}(q))$;
   (f) $S(a)$, $S(b)$, $a \sim_S b$, $T(\delta.\mathsf{map}(a))$, *and* $T(\delta.\mathsf{map}(b))$;
   (g) $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ *and* $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$;
   (h) $p \sim_T q$;
   (i) $\neg\mathsf{hsame}(u, \mathsf{e})$ *and* $\neg\mathsf{hsame}(u', \mathsf{e})$;
   (j) *for every* x' : BHist, *if* $U(x')$ *and* $\mathsf{hsame}(u, \mathsf{E1}(x'))$, *then* $\mathsf{hsame}(x_L, x')$ *and* $x' \sim_U y_R$.

Proof. Apply Theorem 33.238 to the composite image-classifier witness, the endpoint normalization witnesses, and the displayed descent, preservation, stability, certificate, and compatibility data. This gives either the normalized absent public branch or a present visible branch carrying the two one-sided completion functions.

For the left clause, fix x_L with $U(x_L)$ and $\mathsf{hsame}(u, \mathsf{E1}(x_L))$. In the absent branch, the supplied $\mathsf{hsame}(u, \mathsf{e})$ composes with the visible endpoint witness, after symmetry if needed, to identify e with $\mathsf{E1}(x_L)$. This contradicts BEDC history no-confusion via *not_hsame_emp_e*1, so the absent branch cannot occur.

In the present branch, instantiate the left one-sided completion function at x_L. It supplies y_R, k, k', p, q, a, b with the target endpoint, the synchronized target classifier, the two-stage descent factorization, the public map-relation links, the source and intermediate payload witnesses, the non-absence facts, and the universal competing-right-payload clause.

For the right clause, fix y_R with $U(y_R)$ and $\mathsf{hsame}(u', \mathsf{E1}(y_R))$. In the absent branch, the supplied $\mathsf{hsame}(u', \mathsf{e})$ composes with the visible endpoint witness, after symmetry if needed, to identify e with $\mathsf{E1}(y_R)$. This contradicts BEDC history no-confusion via *not_hsame_emp_e*1, so the absent branch cannot occur.

In the present branch, instantiate the right one-sided completion function at y_R. It supplies x_L, k, k', p, q, a, b with the symmetric target endpoint, classifier, descent factorization, public map-relation links, non-absence facts, and universal competing-left-payload clause. These are exactly the two displayed one-sided public completion clauses. □

Theorem 33.240 (Tagged option composite image classifier normalized absent public factorization)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized functorial* OptionUp *absent public factorization; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* TaggedOptionPayloadDescentImageCarrier*; the classifier is* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are endpoint* hsame *transport, map-relation composition factorization, empty-branch preservation, and empty-versus-present no-confusion; the ledger is the normalized absent public pair together with its intermediate endpoints; the core theorem is absent public factorization through the second descent stage; exactness says the intermediate public pair is also absent and has no visible present presentation; the standard bridge is* none *normalized public readback; and the status is* ProofTarget*.*

Let S, T, U : BHist $\to$ Prop be BEDC history source, intermediate, and target carriers, let $\sim_S$, $\sim_T$, and $\sim_U$ be their classifiers, and let

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let cert_S : $\mathsf{NameCert}(S, \sim_S)$*,* cert_T : $\mathsf{NameCert}(T, \sim_T)$*, and* cert_U : $\mathsf{NameCert}(U, \sim_U)$*. Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*,* $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$*, and* TaggedOptionSou *). For final endpoints m, m' : BHist and normalized endpoints u, u' : BHist, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u')$$

and

$$\mathsf{hsame}(u, \mathsf{e}) \wedge \mathsf{hsame}(u', \mathsf{e}),$$

then there exist k, k' : BHist such that

1. $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$;
2. $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u')$;
3. $\mathsf{hsame}(k, \mathsf{e}) \wedge \mathsf{hsame}(k', \mathsf{e})$;
4. $\neg\exists p, q : \mathsf{BHist}.\ T(p) \wedge T(q) \wedge \mathsf{hsame}(k, \mathsf{E1}(p)) \wedge \mathsf{hsame}(k', \mathsf{E1}(q))$.

Proof. First transport the composite image-classifier witness from (m, m') to (u, u'). Apply Theorem 33.204 with the endpoint normalization witnesses $\mathsf{hsame}(m, u)$ and $\mathsf{hsame}(m', u')$.

Next apply Theorem 33.207 to the transported composite classifier. This supplies intermediate endpoints k, k', the δ image-classifier factor at (k, k'), and the two ϵ map-relation witnesses from k to u and from k' to u'.

Use Theorem 33.138 on the left ϵ map-relation witness. The normalized absent presentation $\mathsf{hsame}(u, \mathsf{e})$ forces $\mathsf{hsame}(k, \mathsf{e})$. Apply the same branch equivalence to the right ϵ map-relation witness and $\mathsf{hsame}(u', \mathsf{e})$ to obtain $\mathsf{hsame}(k', \mathsf{e})$.

It remains to rule out an intermediate visible present pair. If such p, q existed, the presentation $\mathsf{hsame}(k, \mathsf{E1}(p))$ would compose with $\mathsf{hsame}(k, \mathsf{e})$ to identify e with $\mathsf{E1}(p)$, contradicting BEDC history empty-versus-one no-confusion.

Package the witnesses k, k' with the retained δ image-classifier factor, the retained ϵ map-relation witnesses, the two intermediate absent presentations, and the excluded visible-pair clause. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier composite normalized absent public factorization`

33.19 Tagged option map relation constructor normal form

Theorem 33.241 (Tagged option map relation constructor normal form)**.** *This theorem fits the per-object template as follows: the traditional target is constructor-facing readback for the tagged option map relation; the BEDC source is* BHist *with one* DescentCertificate *map; the carrier is the visible tagged option endpoint shape; the classifier is the source and target history classifiers carried by the descent certificate; the stability obligation is branch preservation, payload readback, and zero-tag exclusion; the ledger records the absent branch, the present branch, and the absence of zero-tag endpoints; the core theorem is the displayed constructor normal form; exactness says a map-relation witness has exactly the empty branch or a transported one-payload branch; the standard bridge is* none/some *map readback; and the status is* ProofTarget.

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source and target carriers, let* $\sim_S$ *and* $\sim_T$ *be their classifiers, let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T),$$

and assume payload preservation

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

For histories $h, k : \mathsf{BHist}$*, every witness*

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$$

implies the following clauses simultaneously.

1. *Every zero-tag presentation is impossible at either endpoint:*

$$\forall t : \mathsf{BHist}.\ (\mathsf{hsame}(h, \mathsf{E0}(t)) \to \bot) \wedge (\mathsf{hsame}(k, \mathsf{E0}(t)) \to \bot).$$

2. *The absent branch is visible on both sides:*

$$\mathsf{hsame}(h, \mathsf{e}) \iff \mathsf{hsame}(k, \mathsf{e}).$$

3. *The present branch is visible on both sides:*

$$(\exists a : \mathsf{BHist}.\ S(a) \wedge \mathsf{hsame}(h, \mathsf{E1}(a))) \iff (\exists b : \mathsf{BHist}.\ T(b) \wedge \mathsf{hsame}(k, \mathsf{E1}(b))).$$

4. *Visible source and target payloads read back to one transported payload:*

$$\forall u\, v : \mathsf{BHist}.\ S(u) \wedge \mathsf{hsame}(h, \mathsf{E1}(u)) \wedge T(v) \wedge \mathsf{hsame}(k, \mathsf{E1}(v)) \to \exists a : \mathsf{BHist}.\ S(a) \wedge T(\delta.\mathsf{map}(a)) \wedge \mathsf{hsame}(u, a) \wedge \mathsf{hsam}$$

Proof. Split the map-relation witness into its absent and present branches. In the absent branch, the stored endpoint presentations are $\mathsf{hsame}(h, \mathsf{e})$ and $\mathsf{hsame}(k, \mathsf{e})$; in the present branch, the stored presentations are $\mathsf{hsame}(h, \mathsf{E1}(a))$ and $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$ for the exposed payload a.

First prove zero-tag exclusion. Fix $t : \mathsf{BHist}$. In the absent branch, any presentation $\mathsf{hsame}(h, \mathsf{E0}(t))$ or $\mathsf{hsame}(k, \mathsf{E0}(t))$ composes with the corresponding empty presentation and contradicts generated-history no-confusion between e and $\mathsf{E0}(t)$. In the present branch, any such presentation composes with the corresponding one-tag presentation and contradicts generated-history no-confusion between $\mathsf{E1}$ and $\mathsf{E0}$.

Next obtain the visible branch clauses by applying Theorem 33.138 to the same map-relation witness. Its two projections are exactly the absent-branch equivalence and the present-branch equivalence in the statement.

Finally let $u, v : \mathsf{BHist}$ be visible source and target payloads with the displayed endpoint presentations. Apply Theorem 33.139 to the map-relation witness and to these four visible payload facts. The produced payload a carries $S(a)$, $T(\delta.\mathsf{map}(a))$, and the two readback witnesses required by the last clause. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel constructor normal form`

33.20 Tagged option map relation shared-source target normal form

Theorem 33.242 (Tagged option map relation shared-source target normal form)**.** *This theorem fits the per-object template as follows: the traditional target is tagged option map determinacy at public target endpoints; the BEDC source is* BHist *with one* DescentCertificate *map; the carrier is the visible tagged option endpoint shape; the classifier uses the source and target history classifiers carried by the descent certificate; the stability obligation is shared-source branch preservation together with payload transport; the ledger records absent and present public endpoints; the core theorem is the displayed two-witness normal form; exactness is absent-or-synchronized-present exhaustion; the standard bridge is* none/some *map readback; and the status is* ProofTarget*.*

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source and target carriers, let $\sim_S$ and $\sim_T$ be their classifiers, let

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T),$$

and assume payload preservation

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Assume also $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$. *For histories* h, k, k', *if*

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$$

and

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k')$$

then either

$$\mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(k, \mathsf{e}) \wedge \mathsf{hsame}(k', \mathsf{e}),$$

or there exist $a, b : \mathsf{BHist}$ *such that*

$$S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(h, \mathsf{E1}(a)) \wedge \mathsf{hsame}(h, \mathsf{E1}(b)) \wedge \mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge \mathsf{hsame}($$

Proof. Split the first map-relation witness.

In the absent branch, the first witness presents the shared source endpoint as $\mathsf{hsame}(h, \mathsf{e})$ and the target endpoint as $\mathsf{hsame}(k, \mathsf{e})$. Split the second map-relation witness. Its absent branch contributes $\mathsf{hsame}(k', \mathsf{e})$, so the absent alternative follows. Its present branch would present the same source endpoint as $\mathsf{hsame}(h, \mathsf{E1}(b))$ for some payload b. Composing the two source presentations contradicts generated-history empty-versus-one no-confusion, so that branch is impossible.

In the present branch of the first witness, expose a payload a with $S(a)$, $T(\delta.\mathsf{map}(a))$, source presentation $\mathsf{hsame}(h, \mathsf{E1}(a))$, and target presentation $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$. Split the second map-relation witness. Its absent branch presents the shared source as $\mathsf{hsame}(h, \mathsf{e})$, which again contradicts empty-versus-one no-confusion after composition with $\mathsf{hsame}(h, \mathsf{E1}(a))$.

It remains to handle the present/present branch. The second witness exposes a payload b with $S(b)$, $T(\delta.\mathsf{map}(b))$, source presentation $\mathsf{hsame}(h, \mathsf{E1}(b))$, and target presentation $\mathsf{hsame}(k', \mathsf{E1}(\delta.\mathsf{map}(b)))$.

Invert the two one-tag presentations of the shared source endpoint to obtain $\mathsf{hsame}(a, b)$. Source hsame compatibility converts $S(a)$, $S(b)$, and $\mathsf{hsame}(a, b)$ into $a \sim_S b$. Applying $\delta.\mathsf{respects}$ gives $\delta.\mathsf{map}(a) \sim_T \delta.\mathsf{map}(b)$.

The two target carrier witnesses, the two target endpoint presentations, and this transported payload relation assemble the present-present branch of $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k')$. Package a and b with the retained source facts, target facts, endpoint presentations, source classification, and target classifier. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel shared source target normal form`

33.21 Tagged option map relation shared-target source reflection normal form

Theorem 33.243 (Tagged option map relation shared-target source reflection normal form)**.** *This theorem fits the per-object template as follows: the traditional target is faithful source readback from a shared visible target endpoint; the BEDC source is* BHist *with one* DescentCertificate *map; the carrier is the visible tagged option endpoint shape; the classifier uses the source history classifier reflected from target payload equality; the stability obligation is branch preservation, target one-constructor inversion, and source reflection; the ledger records absent endpoints and reflected*

present payloads; the core theorem is the displayed two-witness normal form; exactness is absent-or-reflected-present exhaustion; the standard bridge is none/some *map readback; and the status is* ProofTarget.

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source and target carriers, let* $\sim_S$ *and* $\sim_T$ *be their classifiers, let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T),$$

and assume payload preservation

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Assume also reflected source readback from visible target equality,

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For histories h, h', k*, if*

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$$

and

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h', k)$$

then either

$$\mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(h', \mathsf{e}) \wedge \mathsf{hsame}(k, \mathsf{e}),$$

or there exist $a, b : \mathsf{BHist}$ *such that*

$$S(a) \wedge S(b) \wedge a \sim_S b \wedge T(\delta.\mathsf{map}(a)) \wedge T(\delta.\mathsf{map}(b)) \wedge \mathsf{hsame}(h, \mathsf{E1}(a)) \wedge \mathsf{hsame}(h', \mathsf{E1}(b)) \wedge \mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge \mathsf{hsame}($$

Proof. Split the first map-relation witness.

In the absent branch, the first witness presents the shared target endpoint as $\mathsf{hsame}(k, \mathsf{e})$ and the source endpoint as $\mathsf{hsame}(h, \mathsf{e})$. Split the second map-relation witness. Its absent branch contributes $\mathsf{hsame}(h', \mathsf{e})$, so the absent alternative follows. Its present branch would present the same target endpoint as $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(b)))$ for some source payload b, contradicting generated-history empty-versus-one no-confusion.

In the present branch of the first witness, expose a payload a with $S(a)$, $T(\delta.\mathsf{map}(a))$, source presentation $\mathsf{hsame}(h, \mathsf{E1}(a))$, and target presentation $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$. Split the second map-relation witness. Its absent branch presents the same target as $\mathsf{hsame}(k, \mathsf{e})$, again contradicting empty-versus-one no-confusion after composition with the stored one-tag target presentation.

It remains to handle the present/present branch. The second witness exposes a payload b with $S(b)$, $T(\delta.\mathsf{map}(b))$, source presentation $\mathsf{hsame}(h', \mathsf{E1}(b))$, and target presentation $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(b)))$.

Invert the two one-tag presentations of the shared target endpoint to obtain $\mathsf{hsame}(\delta.\mathsf{map}(a), \delta.\mathsf{map}(b))$. The reflected source readback hypothesis converts this equality, together with $S(a)$ and $S(b)$, into $a \sim_S b$.

The two source carrier witnesses, the two source endpoint presentations, and this reflected payload relation assemble the present-present branch of $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, h')$. Package a and b with the retained source facts, target facts, endpoint presentations, reflected source classification, and source classifier. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel shared target source reflection normal form`

Theorem 33.244 (Tagged option map relation L-corner classifier coherence)**.** *This theorem fits the per-object template as follows: the traditional target is two-axis option-map endpoint determinacy; the BEDC source is* BHist *with one* DescentCertificate *map; the carrier is the tagged option endpoint shape; the classifiers are the source and target history classifiers; the stability obligations are shared-source target normal form and shared-target source reflection normal form; the ledger records the three map-relation legs around an L-corner; the core theorem is simultaneous source and target endpoint classification; exactness is absent-or-present exhaustion on both axes; the standard bridge is* none/some *map readback; and the status is* ProofTarget*.*

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source and target carriers, let* $\sim_S$ *and* $\sim_T$ *be their classifiers, let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T),$$

and assume payload preservation

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Assume $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$ *and reflected source readback from visible target equality,*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For histories h, h', k, k'*, if*

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k),$$

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k'),$$

and

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h', k),$$

then

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, h') \wedge \mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k').$$

Proof. First compare the two legs with shared source endpoint h. Apply Theorem 33.242 to the two map-relation witnesses $\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$ and $\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k')$. The result gives either simultaneous empty presentations of h, k, k' or a present-payload package ending in $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k')$.

Next compare the two legs with shared target endpoint k. Apply Theorem 33.243 to the map-relation witnesses $\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$ and $\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h', k)$. This gives either simultaneous empty presentations of h, h', k or a present-payload package ending in $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, h')$.

In an absent branch of the shared-source comparison, the empty presentations of k and k' assemble the absent branch of $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k')$. In its present branch, retain the target classifier supplied by the normal form.

In an absent branch of the shared-target comparison, the empty presentations of h and h' assemble the absent branch of $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, h')$. In its present branch, retain the source classifier supplied by the reflected normal form.

Combining the source classifier obtained from the shared-target comparison with the target classifier obtained from the shared-source comparison yields the displayed conjunction. □

Theorem 33.245 (Tagged option map relation exclusive visible readback is single-valued)**.** *This theorem fits the per-object template as follows: the traditional target is constructor-facing option map readback; the BEDC source is* BHist *with one* DescentCertificate*; the carrier is the visible*

tagged option endpoint shape; the classifiers are the source and target classifiers transported by the descent certificate; the stability obligations are branch preservation, no-confusion, and one-constructor inversion; the ledger separates the absent branch from the transported present branch; the core theorem is exclusive visible readback with uniqueness; exactness is a disjoint absent-or-present map-relation package; the standard bridge is none/some *map readback; and the status is* ProofTarget.

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source and target carriers, let* $\sim_S$ *and* $\sim_T$ *be their classifiers, let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T),$$

and assume payload preservation

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

For histories $h, k : \mathsf{BHist}$*, every witness*

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$$

implies exactly one of the following visible readback branches.

1. *The absent branch holds on both endpoints:*

$$\mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(k, \mathsf{e}) \wedge (\forall a' : \mathsf{BHist}.\ S(a') \to \mathsf{hsame}(h, \mathsf{E1}(a')) \to \bot) \wedge (\forall b : \mathsf{BHist}.\ T(b) \to \mathsf{hsame}(k, \mathsf{E1}(b)) \to \bot$$

2. *The present branch has one visible source payload and its transported target payload:*

$$\exists a : \mathsf{BHist}.\ S(a) \wedge T(\delta.\mathsf{map}(a)) \wedge \mathsf{hsame}(h, \mathsf{E1}(a)) \wedge \mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge (\mathsf{hsame}(h, \mathsf{e}) \to \bot) \wedge (\mathsf{hsame}(k, \mathsf{e}) \to \bot)$$

The two displayed alternatives are disjoint, so the map-relation witness packages the absent case and the single-valued visible present readback without any additional endpoint choice.

Proof. Case-analyze the $\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$ witness.

In the absent branch, the constructor supplies $\mathsf{hsame}(h, \mathsf{e})$ and $\mathsf{hsame}(k, \mathsf{e})$. If a source presentation $\mathsf{hsame}(h, \mathsf{E1}(a'))$ were also visible, generated-history no-confusion between e and $\mathsf{E1}(a')$ gives $\bot$; the same argument at the target endpoint rules out every visible $\mathsf{E1}(b)$ presentation. These four facts assemble the absent alternative.

In the present branch, retain the constructor payload a. Payload preservation gives $T(\delta.\mathsf{map}(a))$, and the constructor gives the endpoint presentations $\mathsf{hsame}(h, \mathsf{E1}(a))$ and $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$.

It remains to show non-absence and uniqueness. A competing $\mathsf{hsame}(h, \mathsf{e})$ contradicts $\mathsf{hsame}(h, \mathsf{E1}(a))$ by one-versus-empty no-confusion, and the target endpoint is identical with $\delta.\mathsf{map}(a)$ in place of a.

For any competing source presentation $\mathsf{hsame}(h, \mathsf{E1}(a'))$, one-constructor inversion for $\mathsf{E1}$ yields $\mathsf{hsame}(a, a')$. For any competing target presentation $\mathsf{hsame}(k, \mathsf{E1}(b))$, the same inversion applied to the stored presentation $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$ yields $\mathsf{hsame}(b, \delta.\mathsf{map}(a))$. These clauses assemble the present alternative, and empty-versus-one no-confusion also proves that the two displayed alternatives cannot overlap. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel exclusive visible readback single valued`

Theorem 33.246 (Tagged option composite factorization has a canonical intermediate endpoint)**.** *Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source, intermediate, and target carriers, let $\sim_S$, $\sim_T$, and $\sim_U$ be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for both descents:

$$\eta_\delta : \forall x\, y.\ S(x) \to S(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\delta.\mathsf{map}(x), \delta.\mathsf{map}(y))$$

and

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

For histories $h, k, k', m : \mathsf{BHist}$, suppose the same composed endpoint pair factors through both k and k':

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k) \wedge \mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, m)$$

and

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k') \wedge \mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', m).$$

Then either all four visible endpoints are absent,

$$\mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(k, \mathsf{e}) \wedge \mathsf{hsame}(k', \mathsf{e}) \wedge \mathsf{hsame}(m, \mathsf{e}),$$

or there is one source payload $a : \mathsf{BHist}$ such that

$$S(a) \wedge T(\delta.\mathsf{map}(a)) \wedge U(\epsilon.\mathsf{map}(\delta.\mathsf{map}(a))) \wedge \mathsf{hsame}(h, \mathsf{E1}(a)) \wedge \mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge \mathsf{hsame}(k', \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge \mathsf{hsame}$$

Proof. Split the first δ factor through k.

In the absent branch, h and k are visibly e. The second δ factor through k' cannot be present, because it would present the same source endpoint h as both e and $\mathsf{E1}(a)$. Hence the second δ factor is also absent, giving $\mathsf{hsame}(k', \mathsf{e})$. The first ϵ factor cannot be present for the same no-confusion reason at k, so it is absent and gives $\mathsf{hsame}(m, \mathsf{e})$. These four presentations assemble the absent alternative.

In the present branch, the first δ factor exposes a source payload a with $S(a)$, $T(\delta.\mathsf{map}(a))$, $\mathsf{hsame}(h, \mathsf{E1}(a))$, and $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$.

Split the second δ factor. Its absent branch would present h as e, contradicting the stored one-constructor presentation of h. In its present branch it exposes a payload a' with $S(a')$ and $\mathsf{hsame}(h, \mathsf{E1}(a'))$. One-constructor inversion at h yields $\mathsf{hsame}(a, a')$, and η_δ transports this to $\mathsf{hsame}(\delta.\mathsf{map}(a), \delta.\mathsf{map}(a'))$. Rewriting the intermediate endpoint presentation for k' gives $\mathsf{hsame}(k', \mathsf{E1}(\delta.\mathsf{map}(a)))$.

Now split the first ϵ factor. Its absent branch would present k as e, contradicting the stored presentation $\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a)))$. In the present branch it exposes an intermediate payload

b with $T(b)$ and final endpoint $\mathsf{hsame}(m, \mathsf{E1}(\epsilon.\mathsf{map}(b)))$. One-constructor inversion at k gives $\mathsf{hsame}(\delta.\mathsf{map}(a), b)$, and η_ϵ transports the map endpoint to $\mathsf{hsame}(\epsilon.\mathsf{map}(\delta.\mathsf{map}(a)), \epsilon.\mathsf{map}(b))$.

By one-constructor congruence and transitivity of hsame, the final endpoint presentation rewrites to $\mathsf{hsame}(m, \mathsf{E1}(\epsilon.\mathsf{map}(\delta.\mathsf{map}(a))))$. Payload preservation supplies $U(\epsilon.\mathsf{map}(\delta.\mathsf{map}(a)))$, and the retained source, intermediate, and endpoint fields package the present alternative. □

33.22 Tagged option public endpoint visibility

Theorem 33.247 (Tagged option classifier endpoints expose visible certificate fields)**.** *This theorem fits the ten-field template as follows: the traditional target is public endpoint visibility for constructor-tagged* $\mathsf{Option}^{\uparrow}$*; the BEDC source is* BHist*; the carrier is* TaggedOptionHistoryCarrier*; the classifier is* TaggedOptionHistoryClassifier*; the stability obligation is endpoint carrier exposure plus visible-field projection; the ledger is visible absent/present tag; the core theorem is the displayed endpoint field package; exactness says classified endpoints expose public pattern and ledger witnesses; the standard bridge is* none/some *endpoint visibility; and the status is* ProofTarget*.*

For every BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$*, source classifier* $\sim_S$*, and histories* h, k*, if* $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k)$ *holds, then*

$$\mathsf{TaggedOptionHistoryPattern}_S(h) \wedge \mathsf{TaggedOptionHistoryLedger}_S(h) \wedge \mathsf{TaggedOptionHistoryPattern}_S(k) \wedge \mathsf{TaggedOptionH}$$

Proof. Apply Theorem 33.21 to the classifier witness. This gives the endpoint carrier witnesses $\mathsf{TaggedOptionHistoryCarrier}_S(h)$ and $\mathsf{TaggedOptionHistoryCarrier}_S(k)$.

Apply Theorem 33.31 to the carrier witness for h and project the pattern and ledger components. Apply the same theorem to the carrier witness for k and project the same two visible certificate fields. The four projected witnesses assemble into the displayed conjunction. □

↪ variant `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier endpoint semantic fields`

33.23 Tagged option present-chain endpoint classification

Theorem 33.248 (Tagged option present-chain endpoint classification)**.** *This theorem fits the ten-field template as follows: the traditional target is present-chain optional payload classification; the BEDC source is* BHist *with a source* NameCert*; the carrier is* TaggedOptionHistoryCarrier*; the classifier is* TaggedOptionHistoryClassifier*; the stability obligation is transitive payload descent through a shared present endpoint; the ledger is visible present tags; the core theorem is endpoint payload classification; exactness is the visible endpoint readback; the standard bridge is* some*-chain classification; and the status is* ProofTarget*.*

For every BEDC history source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$*, source classifier* $\sim_S$*, source certificate* $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$*, histories* h, k, r*, and visible payloads* a, c*, assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim$ *). If*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, k), \quad \mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(k, r), \quad \mathsf{hsame}(h, \mathsf{E1}(a)), \quad \mathsf{hsam}$$

then there are endpoint payloads $a_0, c_0 : \mathsf{BHist}$ *such that*

$$S(a_0) \wedge S(c_0) \wedge \mathsf{hsame}(a, a_0) \wedge \mathsf{hsame}(c_0, c) \wedge a_0 \sim_S c_0.$$

Proof. Apply Theorem 33.116 to the two tagged classifier witnesses and the displayed endpoint presentations. This gives payload histories a_0, b, b', c_0 with the four source witnesses, the visible readbacks $\mathsf{hsame}(a, a_0)$, $\mathsf{hsame}(b, b')$, and $\mathsf{hsame}(c_0, c)$, and the two payload classifications $a_0 \sim_S b$ and $b' \sim_S c_0$.

Use $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$ on $S(b)$, $S(b')$, and $\mathsf{hsame}(b, b')$ to obtain the middle payload classification $b \sim_S b'$.

Apply the transitivity field cert.equiv_trans first to $a_0 \sim_S b$ and $b \sim_S b'$, and then to the result and $b' \sim_S c_0$. This derives $a_0 \sim_S c_0$. Package a_0 and c_0 with their source witnesses and endpoint readbacks. □

then either

1. $\mathsf{hsame}(u, \mathsf{e}) \wedge \mathsf{hsame}(u', \mathsf{e})$;

2. $\neg\exists x, y : \mathsf{BHist}.\ U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y))$;
3. *there exist* $k, k' : \mathsf{BHist}$ *such that*
   (a) $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$;
   (b) $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u')$;
   (c) $\mathsf{hsame}(k, \mathsf{e}) \wedge \mathsf{hsame}(k', \mathsf{e})$;
   (d) $\neg\exists p, q : \mathsf{BHist}.\ T(p) \wedge T(q) \wedge \mathsf{hsame}(k, \mathsf{E1}(p)) \wedge \mathsf{hsame}(k', \mathsf{E1}(q))$.

or there exist $x, y, k, k', p, q, a, b : \mathsf{BHist}$ *such that*

1. $U(x)$, $U(y)$, $\mathsf{hsame}(u, \mathsf{E1}(x))$, $\mathsf{hsame}(u', \mathsf{E1}(y))$, *and* $x \sim_U y$;
2. $\neg\mathsf{hsame}(u, \mathsf{e})$ *and* $\neg\mathsf{hsame}(u', \mathsf{e})$;
3. $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$;
4. $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u')$;
5. $T(p)$, $T(q)$, $U(\epsilon.\mathsf{map}(p))$, *and* $U(\epsilon.\mathsf{map}(q))$;
6. $\mathsf{hsame}(k, \mathsf{E1}(p))$, $\mathsf{hsame}(k', \mathsf{E1}(q))$, $\mathsf{hsame}(x, \epsilon.\mathsf{map}(p))$, *and* $\mathsf{hsame}(y, \epsilon.\mathsf{map}(q))$;
7. $S(a)$, $S(b)$, $a \sim_S b$, $T(\delta.\mathsf{map}(a))$, *and* $T(\delta.\mathsf{map}(b))$;
8. $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ *and* $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$;
9. $p \sim_T q$;
10. *for all* $x', y' : \mathsf{BHist}$, *if* $U(x')$, $U(y')$, $\mathsf{hsame}(u, \mathsf{E1}(x'))$, *and* $\mathsf{hsame}(u', \mathsf{E1}(y'))$, *then* $\mathsf{hsame}(x, x') \wedge \mathsf{hsame}(y, y') \wedge x' \sim_U y'$;
11. *for every* $x_L : \mathsf{BHist}$, *if* $U(x_L)$ *and* $\mathsf{hsame}(u, \mathsf{E1}(x_L))$, *then* $\mathsf{hsame}(x, x_L)$ *and* $x_L \sim_U y$;
12. *for every* $y_R : \mathsf{BHist}$, *if* $U(y_R)$ *and* $\mathsf{hsame}(u', \mathsf{E1}(y_R))$, *then* $\mathsf{hsame}(y, y_R)$ *and* $x \sim_U y_R$.

Proof. Apply Theorem 33.238 to the composite image-classifier witness, the endpoint normalization witnesses, and the displayed descent, preservation, stability, certificate, and compatibility data. This gives an exhaustive absent-or-present public readback completion at (u, u').

In the absent branch, retain the two normalized empty presentations and the exclusion of every visible U-payload pair at (u, u'). Apply Theorem 33.240 to the same composite witness, endpoint normalizations, displayed data, and absent endpoint presentations. This supplies intermediate endpoints k, k' with the δ classifier factor, the two ϵ public map-relation links, the intermediate absent presentations, and the excluded intermediate visible pair. Package these data as the absent factored branch.

In the present branch, retain the selected payloads x, y, their visible target presentations, the target classification $x \sim_U y$, the two non-absence facts, and the universal competing visible-pair uniqueness clause. Apply Theorem 33.236 to the same composite witness, endpoint normalizations, displayed data, and selected visible presentation. This supplies k, k', p, q, a, b with the complete selected visible public factorization and the one-sided competing-payload uniqueness clauses. Package those witnesses together with the retained completion uniqueness clause. □
