Proof. Begin with the finite-cover row F. It supplies only a finite net, finite cover request, and finite subcover ledger over the compact-metric source K.

Use the stream window S to record the finite source positions inspected by the consumer. The row W then records the selected finite windows and their monotonicity evidence; it is packet data, not a choice functional supplied from outside the carrier.

Finally apply R, D, and Q. The regular rational readback consumes the selected windows, the dyadic row records the cover-radius and tolerance comparisons, and the Real row seals only those accepted finite reads. Therefore the route remains inside the displayed packet and exports none of the excluded host principles. □

Theorem 4681.4 (Subsequence-window data yields a finite-net cover route)**.** *Let*

$$E = (K, F, B, S, W, R, D, Q, H, C, P, N)$$

be an accepted CompactnessSequentialEquivalence$^{\uparrow}$ *carrier. If a downstream compact-metric consumer reads the sequential side through B, S, W, R, then the same packet exposes a finite-net cover route through*

$$K, \quad B, \quad S, \quad W, \quad R, \quad D, \quad F, \quad Q$$

without adding a global open-cover compactness theorem, an unrestricted sequential compactness principle, quotient stream equality, countable choice, or ambient Real completeness row.

Proof. Read the sequential rows first. The bounded-subsequence row B, stream row S, subsequence-window row W, and regular rational row R expose only finite windows and regular readback data.

The dyadic row D transports that finite readback into the tolerance scale used by the finite-net cover ledger. It records mesh, radius, and slack comparisons; it does not create a second compactness principle.

The finite-net route is then the already carried row F, sealed by Q over the same compact-metric source K. Since all rows are components of the same accepted carrier and are replayed by H and C, the consumer obtains a finite-net cover route without any appeal to the excluded host principles. □

Closure status for NameCert$_{\text{CompactnessSequentialEquivalence}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{CompactnessSequentialEquivalence}^{\uparrow}}$, seed)

Scope closed: Definition 5854.1, Definition 5854.2, Definition 5854.3, and Definition 5854.4 seed the finite comparison boundary between finite-cover compactness and sequential compactness for compact-metric consumers.

Formal verification: FormalStatus(NameCert$_{\text{CompactnessSequentialEquivalence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host compactness-equivalence theorem, unrestricted sequential compactness, countable choice, quotient stream equality, external subsequence selection, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-cover and subsequence-window classifier exposure, dyadic tolerance exactness, RegSeqRat handoff exactness, RealUp seal nonescape, and host-principle refusal proofs for BEDC.Derived.CompactnessSequentialEquivalenceUp.

Constructive story: A CompactnessSequentialEquivalence$^{\uparrow}$ packet is generated from CompactMetric source data, HeineBorelFiniteNet finite-cover data, BolzanoWeierstrass bounded-subsequence data, StreamName windows, subsequence windows, RegSeqRat readback, DyadicRatCore tolerance checks, Real seal, componentwise transport, continuation replay, provenance, and a local NameCert row.

Chapter 4682

A Concrete Naming Certificate for $\mathsf{ArensEellsSpace}^{\uparrow}$

Following Arens–Eells and Weaver on Lipschitz-free spaces, the $\mathsf{ArensEellsSpace}^{\uparrow}$ packet names the finite molecule ledger by which a pointed metric source is linearized before normed-space and completion consumers read it. It sits beside the metric carrier of chapter 57, the Lipschitz map surface of chapter 410, the normed-space carrier of chapter 1950, the vector-space rows of chapter 47, the Real seal of chapter 38, and the completion boundary of chapter 95. The packet records only displayed molecules, zero-sum accounting, norm budgets, linear handoff rows, transport, replay, provenance, and local naming; it does not quotient a free vector space, select representatives, invoke duality, or assert an ambient Banach completion.

Definition 4682.1 (Arens–Eells space carrier)**.** *An* $\mathsf{ArensEellsSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, b, L, Z, Q, N, H, C, P, R)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the finite distance reads used by molecule budgets.*
2. *b is the basepoint row, naming the distinguished source point against which zero-sum molecules are displayed.*
3. *L is the finite molecule ledger, listing signed point-coefficient rows whose support is finite.*
4. *Z is the zero-sum coefficient row, recording that the displayed coefficients in L balance over the basepoint boundary.*
5. *Q is the Arens–Eells norm budget, read through* $\mathsf{Real}^{\uparrow}$ *rows as a finite infimum ledger over decompositions into elementary molecules.*
6. *N is the* $\mathsf{NormedSpace}^{\uparrow}$*-facing handoff row, with vector-space operations routed through* $\mathsf{VecSpace}^{\uparrow}$ *and norm exposure routed through Q.*
7. *H records componentwise* hsame *transport for the metric source, basepoint, molecule ledger, zero-sum row, norm budget, normed-space handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from metric-source inspection through molecule formation, zero-sum checking, norm-budget accounting, and the normed-space handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{ArensEellsSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. R is the local $\mathsf{NameCert}_{\mathsf{ArensEellsSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a quotient presentation, selected molecule representative, unrestricted dual space, host linearization theorem, completed Banach envelope, or choice of an optimal decomposition.

Lean4 ✓ `BEDC.Derived.ArensEellsSpaceUp.ArensEellsSpaceTasteGate single carrier alignment`

Theorem 4682.2 (Arens–Eells NameCert obligations)**.** *For every accepted* $\mathsf{ArensEellsSpace}^{\uparrow}$ *carrier* $A = (M, b, L, Z, Q, N, H, C, P, R)$*, the local* $\mathsf{NameCert}_{\mathsf{ArensEellsSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric source row, basepoint row, finite molecule ledger, zero-sum coefficient row, Arens–Eells norm budget, normed-space handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row. In particular, every accepted molecule read must first expose* M, b, L, Z*, every accepted norm read must pass through the Real-valued budget* Q*, and every normed-space consumer must enter through* N, H, C, P, R*.*

Proof. Project the carrier of Definition 5855.1. The metric source M and basepoint b are the only rows from which point distances and pointed molecule data can be read.

The molecule ledger is finite. The row L lists the signed point-coefficient entries, while Z records the zero-sum boundary that permits the ledger to behave as an Arens–Eells molecule rather than as an arbitrary formal sum.

The norm budget is likewise displayed. The row Q reads Real-valued distance budgets over finite decompositions of the molecule ledger, and the handoff row N exposes only the resulting vector-space and normed-space interface.

Finally the structural rows H, C, P, R transport, replay, source, and name the same packet. Since no other coordinate occurs in the carrier, the NameCert surface cannot import quotient equality, a selected representative, unrestricted duality, a host linearization theorem, ambient completion, or an optimal-decomposition choice principle. □

Theorem 4682.3 (Arens–Eells Lipschitz linearization handoff)**.** *Let* $A = (M, b, L, Z, Q, N, H, C, P, R)$ *be an accepted* $\mathsf{ArensEellsSpace}^{\uparrow}$ *carrier. Any downstream* $\mathsf{LipschitzMap}^{\uparrow}$ *consumer that asks for a linearized normed-space route must factor through the finite handoff*

$$M, b, L, Z, Q \longmapsto N \longmapsto H, C, P, R.$$

The handoff records only that Lipschitz reads from the pointed metric source may be replayed against finite molecules and their Real-valued norm budgets before entering the $\mathsf{NormedSpace}^{\uparrow}$ *and* $\mathsf{VecSpace}^{\uparrow}$ *surfaces; it does not assert a completed free Banach space, host universal property, quotient by molecule equality, selected extension, or dual representation.*

Proof. Start with a Lipschitz-facing request. The source data are the pointed metric rows M, b, so the request cannot inspect a linear object before the finite molecule ledger is exposed.

Replay the molecule rows by C. The ledger L supplies finite signed point-coefficient data, and the zero-sum row Z supplies the balancing boundary required for molecule consumption.

The normed-space handoff is reached only after the budget row Q has been read. That row supplies the Real-valued Arens–Eells norm account over displayed decompositions, and N is the only row that passes this account to $\mathsf{NormedSpace}^{\uparrow}$ and $\mathsf{VecSpace}^{\uparrow}$ consumers.

The transport, provenance, and local naming rows H, P, R preserve this same route. Therefore the linearization handoff is a finite BEDC route from pointed metric and Lipschitz data to a normed-space interface, not a quotient construction, selected extension, ambient completion, or host universal-property theorem. □

Theorem 4682.4 (Arens–Eells molecule zero-sum transport)**.** *Let $A = (M, b, L, Z, Q, N, H, C, P, R)$ and $A' = (M', b', L', Z', Q', N', H', C', P', R')$ be accepted* $\mathsf{ArensEellsSpace}^{\uparrow}$ *carriers. If the pointed metric rows M, b, the finite molecule ledger L, and the zero-sum row Z transport componentwise through the displayed* hsame *rows, then the transported packet preserves both the displayed molecule ledger and the zero-sum boundary over the pointed* $\mathsf{Met}^{\uparrow}$ *source. In particular, no transported read may replace L by an unlisted formal sum or replace Z by a host equality proof.*

Proof. Project the two carriers through Definition 5855.1. The only rows that expose molecule data are M, b, L, Z, and the only transport coordinate is the componentwise row H.

Use the NameCert obligations of Definition 5855.2. Molecule admission reads the signed point-coefficient ledger L, while zero-sum admission reads the balancing row Z over the same pointed metric source M, b.

Transport is componentwise. Hence a valid hsame replay can rename or move the displayed rows, but it must carry M, b, L, Z together. Since the carrier has no coordinate for host formal sums or quotient equality, the transported molecule remains the finite displayed ledger with the displayed zero-sum boundary. □

Theorem 4682.5 (Arens–Eells norm-budget stability)**.** *For every accepted* $\mathsf{ArensEellsSpace}^{\uparrow}$ *carrier $A = (M, b, L, Z, Q, N, H, C, P, R)$, each* $\mathsf{Real}^{\uparrow}$*-valued norm-budget read through Q remains tied to the displayed molecule decomposition rows M, b, L, Z. The read may expose finite decomposition budgets and their Real comparisons, but it cannot select an optimal decomposition, choose a quotient representative, or detach the budget from the molecule ledger named by L.*

Proof. Begin with the carrier projection. The row Q is introduced only after the pointed source, molecule ledger, and zero-sum rows M, b, L, Z have already been displayed.

Apply Definition 5855.2. The theorem makes every accepted norm read pass through Q, and it makes Q the Real-valued account over displayed decompositions rather than an external norm primitive.

Finally use the handoff theorem Definition 5855.3. Downstream normed-space and vector-space consumers reach N only after Q is read. Thus the budget remains attached to the finite molecule data, with no coordinate for an optimal-decomposition selector or quotient representative. □

Theorem 4682.6 (Arens–Eells Lipschitz-free universal window)**.** *Let $A = (M, b, L, Z, Q, N, H, C, P, R)$ be an accepted* $\mathsf{ArensEellsSpace}^{\uparrow}$ *carrier. Every finite consumer window that treats A as a Lipschitz-free handoff factors through*

$$\mathsf{LipschitzMap}^{\uparrow},\ \mathsf{NormedSpace}^{\uparrow},\ \mathsf{VecSpace}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{Completion}^{\uparrow}$$

only by reading the displayed route $M, b, L, Z, Q, N, H, C, P, R$. The packet supplies the finite universal-window data needed by Lipschitz, normed-space, vector-space, Real, and completion-facing consumers, but it refuses the classical ambient Banach-space universal property.

Proof. Start with a consumer that asks for a Lipschitz-free route. By Definition 5855.3, the request must first pass through the pointed metric rows M, b, the molecule ledger L, the zero-sum row Z, and the norm-budget row Q.

The consumer then reaches the normed and vector interfaces through N. The rows H, C, P, R preserve the same finite route by componentwise transport, displayed replay, provenance, and local naming.

The completion-facing boundary has no additional coordinate in the carrier. Therefore a $\mathsf{Completion}^{\uparrow}$ read can only receive the already displayed Lipschitz-to-normed-space window, not a

completed Banach envelope, unrestricted extension theorem, selected quotient representative, or host universal property. □

Falsifiable prediction: Any consumer that claims an $\mathsf{ArensEellsSpace}^{\uparrow}$ molecule, norm, Lipschitz-linearization, normed-space, vector-space, Real, or Completion read while omitting $M, b, L, Z, Q, N, H, C, P$, or the local NameCert row refutes the carrier of Definition 5855.1.

Independence witness: metric, lipschitzmap, normedspace, vecspace, real, completion: $\mathsf{ArensEellsSpace}^{\uparrow}$ is not bijective to any listed sibling because it carries a pointed metric source, finite molecule ledger, zero-sum coefficient boundary, Arens–Eells norm budget, and a normed-space linearization handoff before any completion-facing consumer may read the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ArensEellsSpace}^{\uparrow}}$.

Constructive story: An $\mathsf{ArensEellsSpace}^{\uparrow}$ packet is generated from a pointed metric source, finite molecule ledger, zero-sum coefficient row, Real-valued norm budget, normed-space handoff, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArensEellsSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5855.1, Definition 5855.2, and Definition 5855.3 seed the finite molecule and norm-budget route from pointed metric data to Lipschitz and normed-space consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArensEellsSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient vector-space equality, a selected molecule representative, unrestricted duality, a completed free Banach space, an ambient universal property, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, molecule ledger replay, zero-sum boundary, Real-valued norm-budget exactness, and Lipschitz-to-normed-space handoff for BEDC.Derived.ArensEellsSpaceUp.

Chapter 4683

A Concrete Naming Certificate for $\mathsf{BanachFixedPointStability}^{\uparrow}$

Following Banach and Bishop–Bridges constructive metric analysis, the $\mathsf{BanachFixedPointStability}^{\uparrow}$ packet records the finite stability surface by which a displayed contraction orbit keeps its fixed-point seal attached to explicit Picard and Cauchy-modulus data. It sits after the fixed-point certificate of chapter 396, the iteration ledger of chapter 2359, the contraction surface of chapter 1418, the complete-metric boundary of chapter 128, the modulus schedule of chapter 292, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a stability handoff for fixed-point consumers; it is not ambient real completeness, a selected host fixed point, a quotient orbit, a global contraction theorem, or a choice principle.

Definition 4683.1 (Banach fixed point stability carrier)**.** *A* $\mathsf{BanachFixedPointStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, I, T, M, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{BanachFixedPoint}^{\uparrow}$ *source row naming the fixed-point certificate whose stability is being inspected.*
2. *I is the* $\mathsf{PicardIteration}^{\uparrow}$ *orbit row, recording the finite prefix and tail schedule consumed by the stability packet.*
3. *T is the* $\mathsf{ContractionMapping}^{\uparrow}$ *row that exposes the displayed contraction constant, comparison window, and contraction replay surface.*
4. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *dependency row, available only as the completion boundary used by the Picard orbit and not as ambient completeness for* $\mathsf{Real}^{\uparrow}$*.*
5. *Q is the* $\mathsf{CauchyModulus}^{\uparrow}$ *stability schedule for the orbit tail and perturbation tolerance.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached only after I, T, M, Q have been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the fixed-point source, Picard orbit, contraction row, completion boundary, modulus schedule, and regular-rational readback have been read.*
8. *H records componentwise* hsame *transport for the displayed source, orbit, contraction, completion, modulus, readback, real-seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from the fixed-point source through $F, I, T, M, Q, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{BanachFixedPointStability}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BanachFixedPointStability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, I, T, M, Q, R, E, H, C, P, N$. It has no coordinate for a selected host fixed point, quotient orbit equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, global contraction soundness, trichotomy, or countable choice.*

Lean4 ✓ `BEDC.Derived.BanachFixedPointStabilityUp.BanachFixedPointStabilityTasteGate single carrier alignment`

Theorem 4683.2 (Banach fixed point stability NameCert obligations)**.** *For every accepted* BanachFixedPointStabili *carrier $B = (F, I, T, M, Q, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BanachFixedPointStability}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed fixed-point source F, Picard orbit I, contraction row T, complete-metric dependency M, Cauchy-modulus schedule Q, regular-rational readback R, terminal real seal E, componentwise transport H, displayed replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 5856.1. The analytic rows visible to a stability consumer are exactly F, I, T, M, Q, R, E, followed by transport, replay, provenance, and naming.

The fixed-point source is not read alone. The Picard row I and contraction row T display the orbit and contraction comparison before the complete-metric dependency M and modulus schedule Q can be consumed.

The Real-facing endpoint is downstream from the same finite route. The regular-rational row R is read only from the displayed orbit, contraction, completion, and modulus rows, and the terminal seal E is read only after R.

Finally H, C, P, N transport, replay, source, and name this packet. Since the carrier has no excluded coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 4683.3 (Banach fixed point stability Picard-Cauchy handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BanachFixedPointStability}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{BanachFixedPoint}^{\uparrow} \longmapsto \mathsf{PicardIteration}^{\uparrow} \longmapsto \mathsf{ContractionMapping}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{Re}$$

The handoff exposes only the displayed fixed-point source, Picard orbit, contraction comparison, complete-metric dependency, Cauchy-modulus schedule, regular-rational readback, terminal real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. It exports no selected host fixed point, quotient orbit equality, hidden completion theorem, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, global contraction soundness, trichotomy, or countable-choice schedule.*

Proof. Begin with Definition 5856.2. It places every stability read behind the fixed-point source, Picard orbit, contraction comparison, complete-metric dependency, and explicit modulus schedule.

Next open the handoff to regular-rational data. The rows I, T, M, Q determine the displayed Cauchy tail route, so the $\mathsf{RegSeqRat}^{\uparrow}$ row R is a finite readback from those rows rather than a quotient orbit or host-selected fixed point.

The terminal real seal is last. The $\mathsf{Real}^{\uparrow}$ row E is consumed only after R has been displayed, while H, C, P, N preserve the same dependency order under transport, replay, provenance, and local naming.

Thus any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer sees exactly the stated Picard-Cauchy route and cannot bypass it through an ambient completeness or choice object. □

Theorem 4683.4 (Banach fixed point stability modulus nonescape)**.** *Let $B = (F, I, T, M, Q, R, E, H, C, P, N)$ be an accepted* $\mathsf{BanachFixedPointStability}^{\uparrow}$ *carrier. Every perturbation consumer and every tail-stability consumer of B must read the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule Q before it can read the regular-rational row R or the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E.*

Consequently no such consumer can obtain a selected host fixed point, quotient orbit equality, hidden completion theorem, ambient $\mathsf{Real}^{\uparrow}$ *completeness, global contraction soundness, trichotomy, or countable-choice schedule from R or E without first exposing the displayed modulus row Q.*

Proof. Project the carrier of Definition 5856.1. The rows are ordered so that Q is the displayed Cauchy-modulus schedule for the orbit tail and perturbation tolerance, while R and E are downstream readback and seal rows.

Apply Definition 5856.2. It says that the local NameCert surface contains the fixed-point source, Picard orbit, contraction row, complete-metric dependency, Cauchy-modulus schedule, regular-rational readback, and terminal real seal as listed carrier rows, with no excluded coordinate.

Next apply Definition 5856.3. The displayed route reaches $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ only after $\mathsf{CauchyModulus}^{\uparrow}$, so a perturbation or tail-stability request that tries to read R or E has already passed through Q.

The refusal clauses follow because the carrier and handoff theorems export no selected host fixed point, quotient orbit equality, hidden completion theorem, ambient Real completeness, global contraction theorem, trichotomy, or countable-choice row. Thus Q is a nonescape boundary for all tail-stability and perturbation reads. □

Closure status for $\mathsf{NameCert}_{\mathsf{BanachFixedPointStability}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachFixedPointStability}^{\uparrow}$ packet is generated from a BanachFixedPoint source row, PicardIteration orbit, ContractionMapping comparison, CompleteMetric dependency, CauchyModulus schedule, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachFixedPointStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5856.1, Definition 5856.2, and Definition 5856.3 seed the finite stability handoff from Banach fixed-point data through Picard, contraction, completion, modulus, regular-rational, and real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachFixedPointStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected host fixed points, quotient orbit equality, hidden completion theorems, ambient RealUp completeness, global contraction soundness, trichotomy, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Picard orbit ordering, contraction comparison stability, complete-metric dependency confinement, Cauchy-modulus exactness, RegSeqRat handoff, RealUp seal confinement, transport stability, continuation replay, and provenance nonescape for BEDC.Derived.BanachFixedPointStabilityUp.

Chapter 4684

A Concrete Naming Certificate for $\mathsf{RealTriangleInequality}^{\uparrow}$

Following Bishop and Bridges' constructive treatment of metric real names, the $\mathsf{RealTriangleInequality}^{\uparrow}$ packet records the finite three-leg route by which a displayed real distance estimate is assembled without importing quotient real equality or an ambient completeness theorem. It sits beside the real-name seal of chapter 38, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, and the stream-window discipline of chapter 126.

Definition 4684.1 (Real triangle inequality carrier)**.** *A* $\mathsf{RealTriangleInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, B, M, D, W, H, C, P, N)$$

with the following displayed coordinates:

1. *A and B are the two endpoint* $\mathsf{Real}^{\uparrow}$ *equality rows whose distance comparison is being bounded.*
2. *M is the intermediate* $\mathsf{RegSeqRat}^{\uparrow}$ *row that supplies the middle leg of the finite rational comparison.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carrying the three displayed radii and the exact middle-leg budget.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family through which the two endpoints and the intermediate row are inspected.*
5. *H stores componentwise* hsame *transport for endpoint rows, the middle readback row, dyadic budgets, windows, replay, provenance, and local naming rows.*
6. *C stores displayed* Cont *replay from a consumer request through A, B, M, D, W, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{RealTriangleInequality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RealTriangleInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite coordinates. It has no coordinate for host real equality, quotient streams, selected limits, trichotomy, or ambient completeness.

Theorem 4684.2 (Real triangle inequality NameCert obligations)**.** *For an accepted* $\mathsf{RealTriangleInequality}^{\uparrow}$ *carrier $T = (A, B, M, D, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealTriangleInequality}^{\uparrow}}$ *surface consists exactly of endpoint admission through the two displayed* $\mathsf{Real}^{\uparrow}$ *equality rows A, B, dyadic middle-leg*

exactness through the ledger D, $\mathsf{RegSeqRat}^{\uparrow}$ *replay through M,* $\mathsf{StreamName}^{\uparrow}$ *window inspection through W, terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff for the three-leg comparison, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row N. No consumer can escape from this surface to host real equality, quotient streams, selected limits, trichotomy, or ambient completeness.*

Proof. Project the carrier of Definition 5857.1. The two endpoint rows A, B, the intermediate readback row M, the dyadic ledger D, the stream windows W, transport, replay, provenance, and naming row are all displayed coordinates of the finite packet.

Endpoint admission is therefore read only through A and B. The middle leg is read through M, while D records the exact dyadic budget that joins the two endpoint comparisons through the displayed intermediate row.

Replay the consumer request through C after transporting coordinates with H. The replay order exposes the $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{RegSeqRat}^{\uparrow}$ middle row, and the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger before any terminal $\mathsf{Real}^{\uparrow}$ seal is inspected.

The exclusions are the carrier inventory. Since no coordinate stores host real equality, a quotient stream object, a selected limit, trichotomy data, or an ambient completeness theorem, the local naming certificate cannot export any of them. □

Lean4 ✓ `BEDC.Derived.RealTriangleInequalityUp.RealTriangleInequalityTasteGate single carrier alignment`

Closure status for $\mathsf{NameCert}_{\mathsf{RealTriangleInequality}^{\uparrow}}$.

Constructive story: A $\mathsf{RealTriangleInequality}^{\uparrow}$ packet is generated from two endpoint $\mathsf{Real}^{\uparrow}$ equality rows, one intermediate $\mathsf{RegSeqRat}^{\uparrow}$ row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, finite $\mathsf{StreamName}^{\uparrow}$ windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealTriangleInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5857.1 and Definition 5857.2 seed the finite three-leg real route over RealUp, RegSeqRatUp, DyadicRatCoreUp, StreamNameUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealTriangleInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real equality, quotient stream equality, selected limits, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint admission, dyadic middle-leg exactness, RegSeqRat replay, RealUp seal handoff, and non-escape for BEDC.Derived.RealTriangleInequalityUp.

$\mathsf{LowerDarbouxSum}^{\uparrow}$ is the lower finite-sum side consumed by chapter 1880 and paired with chapter 4083.

Chapter 4685

A Concrete Naming Certificate for $\mathsf{LowerDarbouxSum}^{\uparrow}$

Following Darboux and Riemann, the $\mathsf{LowerDarbouxSum}^{\uparrow}$ packet isolates the lower-sum side of Darboux integration before the full upper/lower gap is read. It is the lower companion to chapter 4083 and supplies the missing finite half used by chapter 1880. The packet reads the integrability boundary of chapter 1960, the displayed finite partition mesh of chapter 3496, and the step-function bracket rows of chapter 428; it exports no host infimum, selected mesh limit, quotient function equality, open-cover compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate.

Definition 4685.1 (Lower Darboux sum carrier)**.** *A* $\mathsf{LowerDarbouxSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (P, B, D, S, I, R, H, C, Q, N)$$

with the following displayed rows:

1. *P is the finite partition-mesh row, naming the ordered displayed cells, endpoint ledger, width ledger, and refinement handle used by every lower-sum read.*
2. *B is the cell lower-bound ledger. For each displayed cell it records the chosen lower value row and the comparison proof that the carried value is below every admitted sample value in that cell.*
3. *D is the* $\mathsf{DyadicStepFunction}^{\uparrow}$ *row over the same partition cells, carrying the step values used to display the lower envelope.*
4. *S is the finite lower Darboux-sum row computed from the displayed widths in P and the lower values exposed by B and D.*
5. *I is the* $\mathsf{RiemannIntegrable}^{\uparrow}$ *and* $\mathsf{DarbouxSum}^{\uparrow}$ *handoff row, recording that the lower-sum read is available before any upper-sum, gap, or integral seal is requested.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *comparison row, exposing only the finite real-name comparison needed by lower-bound consumers.*
7. *H records componentwise* hsame *transport for the partition mesh, lower-bound ledger, dyadic step row, finite lower sum, handoff, comparison row, replay, provenance, and local naming row.*
8. *C records displayed* Cont *replay from partition cells to lower-bound reads, from lower-bound reads to the dyadic step row, from the dyadic step row to the finite lower sum, and from the lower sum to the handoff row.*

9. *Q is the* Pkg *provenance over* $\mathsf{LowerDarbouxSum}^{\uparrow}$, *??*, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegrable}^{\uparrow}$, $\mathsf{FinitePartitionMesh}^{\uparrow}$, $\mathsf{DyadicStepFunction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LowerDarbouxSum}^{\uparrow}}$ *row.*

The classifier reads accepted packets only through $P, B, D, S, I, R, H, C, Q, N$. It has no coordinate for a host infimum, a selected mesh limit, an upper Darboux sum, an upper-minus-lower gap, quotient equality of functions, open-cover compactness, or ambient real completeness.

Theorem 4685.2 (Lower Darboux sum NameCert obligations)**.** *For every accepted* $\mathsf{LowerDarbouxSum}^{\uparrow}$ *carrier*

$$L = (P, B, D, S, I, R, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{LowerDarbouxSum}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the displayed partition mesh, cell lower-bound ledger, dyadic step row, finite lower sum, Darboux and Riemann handoff, comparison row, transport, replay, provenance, and local naming row;*
2. *partition-mesh stability, requiring each transported refinement of P to preserve the displayed cell-width ledger and to route lower-bound reads through the same refinement handle;*
3. *lower-bound ledger transport, requiring B and D to move componentwise by* hsame *while preserving the stated lower relation on every displayed cell;*
4. *finite lower-sum replay, requiring S to be recomputed from the transported cell widths and transported lower values before any handoff row can be consumed;*
5. *ledger non-escape, requiring I, R, H, C, Q, N to expose only the displayed lower-sum route and to exclude host infima, selected mesh limits, quotient function equality, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, upper-sum rows, and gap rows.*

Proof. Carrier admission is the projection of Definition 5858.1. The accepted packet displays exactly the partition mesh, lower-bound ledger, dyadic step row, finite lower sum, handoff, comparison, transport, replay, provenance, and local naming rows.

Partition-mesh stability is read before any numerical sum. The row P fixes the displayed cells and widths, so a transported refinement can only expose a lower-bound read through the same finite mesh ledger and refinement handle.

The lower-bound ledger is then transported componentwise. The rows B and D move together under H, while replay through C rebuilds the lower envelope and then the finite lower sum row S.

The handoff and non-escape clauses are exhausted by S, I, R, H, C, Q, N. Since no carrier coordinate stores a host infimum, selected mesh limit, quotient function equality, open-cover compactness theorem, ambient completeness row, upper-sum row, or gap row, the local NameCert surface is exactly the five listed obligations. □

Theorem 4685.3 (Lower Darboux finite partition handoff)**.** *Every* $\mathsf{DarbouxSum}^{\uparrow}$ *or* $\mathsf{RiemannIntegrable}^{\uparrow}$ *consumer of an accepted* $\mathsf{LowerDarbouxSum}^{\uparrow}$ *carrier $L = (P, B, D, S, I, R, H, C, Q, N)$ must first read the finite partition mesh P, the lower-bound ledger B, the* $\mathsf{DyadicStepFunction}^{\uparrow}$ *row D, the finite lower sum S, and the comparison row R, with transport, replay, provenance, and local naming supplied by H, C, Q, N. The consumer therefore receives a finite partition-and-lower-envelope route rather than a host infimum, a selected mesh limit, quotient function equality, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The rows upstream of every exported lower-sum read are P, B, D, S, R together with the structural rows H, C, Q, N.

For a $\mathsf{DarbouxSum}^{\uparrow}$ read, the handoff row I is reachable only after the partition mesh, lower-bound ledger, dyadic step row, and finite lower sum have been replayed. For a $\mathsf{RiemannIntegrable}^{\uparrow}$ read, the same row S is the lower finite half that a later upper/lower gap comparison must consume.

Coordinate exhaustion closes the handoff. The packet has no analytic coordinate beyond the displayed rows, so the consumer cannot bypass the finite route through a host infimum, selected mesh limit, quotient equality, compactness theorem, or ambient completeness row. □

Theorem 4685.4 (Lower Darboux gap boundary)**.** *Let $L = (P, B, D, S, I, R, H, C, Q, N)$ be an accepted* $\mathsf{LowerDarbouxSum}^{\uparrow}$ *carrier. Any later* $\mathsf{DarbouxSum}^{\uparrow}$ *upper-minus-lower gap row that uses L must take S as its lower finite sum over the displayed partition mesh P and the displayed lower envelope B, D. The lower-sum side of the gap therefore remains fixed by the finite lower packet and cannot be replaced by a host infimum, quotient function equality, selected limiting mesh, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or an independently chosen lower bracket.*

Proof. Start with the finite partition handoff of Definition 5858.3. Any Darboux-facing consumer already reads P, B, D, S with H, C, Q, N before it can ask for a gap row.

Compare this lower half with the upper half named by chapter 4083 and the combined surface of chapter 1880. The gap row can combine a transported upper finite sum with the transported lower finite sum, but the lower input remains the row S replayed from the displayed mesh and lower envelope.

The boundary is therefore finite and local. Since L contains no coordinate for an alternate lower bracket, host infimum, selected mesh limit, quotient equality, compactness theorem, or ambient completeness row, no later gap consumer can replace the lower side without leaving the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{LowerDarbouxSum}^{\uparrow}}$.

Constructive story: A $\mathsf{LowerDarbouxSum}^{\uparrow}$ packet is generated from finite partition-mesh rows, cell lower-bound ledgers, dyadic step-function rows, finite lower-sum rows, Darboux and Riemann handoff rows, Real comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LowerDarbouxSum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5858.1, Definition 5858.2, Definition 5858.3, and Definition 5858.4 seed the finite lower-sum packet over displayed partition meshes, cell lower-bound reads, dyadic-step rows, finite-sum rows, Darboux and Riemann handoff, $\mathsf{Real}^{\uparrow}$ comparison, transport, replay, provenance, local naming, and Darboux gap-boundary rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LowerDarbouxSum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host infima, selected mesh limits, quotient function equality, open-cover compactness, upper Darboux sums, upper-minus-lower gap construction, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, partition-mesh stability, lower-bound ledger transport, finite lower-sum replay, finite partition handoff, Darboux gap boundary, componentwise transport, displayed replay, provenance, local naming, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.LowerDarbouxSumUp.

The $\mathsf{LowerDarbouxSum}^{\uparrow}$ packet consumes the shared $\mathsf{DarbouxSum}^{\uparrow}$ partition ledger of chapter 1880 and is paired with **??** through the same finite interval, cell-width, and partition rows of chapter 4083. A lower-sum consumer therefore reads the lower envelope as one half of the displayed Darboux partition lattice rather than as an isolated kernel row.

Chapter 4686

A Concrete Naming Certificate for $\mathsf{BoundedMetricSpace}^{\uparrow}$

Following Hausdorff and Kelley metric-space practice, the $\mathsf{BoundedMetricSpace}^{\uparrow}$ packet records the bounded metric-space interface as finite BEDC NameCert data. It sits between the metric carrier of chapter 4230, the center-radius containment row of chapter 1450, the bounded-subset surface of chapter 1757, the diameter handoff of chapter 1503, the ordered-real bound route of chapter 766, the terminal real-name seal of chapter 38, and the completion-facing consumers of chapter 95 and chapter 1506. The packet supplies finite-net, Cauchy, compact-metric, and diameter consumers with a displayed bounded metric source without importing compactness, host suprema, selected centers, quotient equality, or ambient completeness.

Definition 4686.1 (BoundedMetricSpace carrier)**.** *A* $\mathsf{BoundedMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, B, D, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *carrier row. It supplies the point classifier, metric-source data, real-valued distance route, zero-distance classifier, symmetry row, and triangle row.*
2. *B is the bounded-containment row. It records the* $\mathsf{MetricBall}^{\uparrow}$ *center-radius ledger together with the* $\mathsf{BoundedSet}^{\uparrow}$ *membership classifier that every admitted point must read before boundedness is exposed.*
3. *D is the* $\mathsf{MetricDiameter}^{\uparrow}$ *row. It names the finite diameter-bound handoff consumed by diameter, finite-net, Cauchy, and compact-metric readers.*
4. *R is the real-bound readback row. It routes the radius and diameter bounds through* $\mathsf{Real}^{\uparrow}$ *and the ordered comparison surface of* $\mathsf{RealAlgOrder}^{\uparrow}$*.*
5. *H records componentwise* hsame *transport for the metric carrier, containment row, diameter row, real-bound readback, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a bounded-metric request through metric admission, bounded-set containment, metric-ball comparison, diameter-bound readback, ordered-real comparison, and completion-facing handoff.*
7. *P is the* Pkg *provenance over* $\mathsf{BoundedMetricSpace}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{MetricBall}^{\uparrow}$*,* $\mathsf{BoundedSet}^{\uparrow}$*,* $\mathsf{MetricDiameter}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RealAlgOrder}^{\uparrow}$*,* $\mathsf{Completion}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*

8. N is the local $\mathsf{NameCert}_{\mathsf{BoundedMetricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through X, B, D, R, H, C, P, N. It has no coordinate for a host subset, host supremum, selected bounding center, selected diameter witness, compactness theorem, quotient completion, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedMetricSpaceUp.BoundedMetricSpaceTasteGate single carrier alignment`

Theorem 4686.2 (BoundedMetricSpace NameCert obligations)**.** *For every accepted* $\mathsf{BoundedMetricSpace}^{\uparrow}$ *carrier $Q = (X, B, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BoundedMetricSpace}^{\uparrow}}$ *surface consists exactly of the following obligation families:*

1. *metric-source admission for the displayed* $\mathsf{Met}^{\uparrow}$ *row X;*
2. *bounded-containment admission for the* $\mathsf{MetricBall}^{\uparrow}$ *and* $\mathsf{BoundedSet}^{\uparrow}$ *rows stored in B;*
3. *diameter-bound admission for the* $\mathsf{MetricDiameter}^{\uparrow}$ *row D;*
4. *real-bound readback through* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RealAlgOrder}^{\uparrow}$ *in R;*
5. *componentwise transport, displayed replay, provenance, and local naming through H, C, P, N.*

Consequently a downstream finite-net, Cauchy, compact-metric, diameter, or completion-facing consumer may read bounded metric-space data only through the displayed metric, containment, diameter, ordered-real, and structural rows. The packet exports no host supremum, compactness theorem, selected bound, quotient completion, countable-choice selector, or ambient real completeness coordinate.

Proof. Project the carrier of Definition 5859.1. The only analytic rows are the metric source X, the bounded-containment row B, the diameter row D, and the real-bound readback row R.

The containment side is read first. The row B combines the center-radius ledger of chapter 1450 with the bounded-subset classifier of chapter 1757, so membership containment is visible before any bounded-space consumer receives the packet.

The diameter and real-bound rows are downstream from that containment. The row D supplies the sibling handoff of chapter 1503, and R records that the bound is read through $\mathsf{Real}^{\uparrow}$ and $\mathsf{RealAlgOrder}^{\uparrow}$ rather than through a host supremum.

Finally H, C, P, N transport, replay, source, and name the same displayed rows. Since no excluded analytic object is a coordinate of Q, the listed obligation families exhaust the local NameCert surface. □

Theorem 4686.3 (BoundedMetricSpace diameter-bound handoff)**.** *Every diameter, finite-net, Cauchy, compact-metric, or completion-facing read accepted from a* $\mathsf{BoundedMetricSpace}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{MetricBall}^{\uparrow}, \mathsf{BoundedSet}^{\uparrow} \longmapsto \mathsf{MetricDiameter}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}, \mathsf{RealAlgOrder}^{\uparrow} \longmapsto \mathsf{Completion}^{\uparrow}, \mathsf{MetricCompletio}$$

The exported handoff is a displayed bounded metric source with containment and diameter-bound rows already visible. It does not provide compactness, a host supremum, a selected bounding center, a selected maximum pair, quotient completion equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from an accepted packet $Q = (X, B, D, R, H, C, P, N)$. A consumer first opens the metric row X, so every subsequent boundedness or diameter read remains attached to the same point classifier and distance route.

Read containment through B. This exposes the center-radius and bounded-subset rows before any finite-net or Cauchy consumer can treat the source as bounded.

Next read the diameter row D and the ordered-real readback R. These rows hand the displayed bound to the sibling diameter packet and to the $\mathsf{Real}^{\uparrow}$ and $\mathsf{RealAlgOrder}^{\uparrow}$ comparison surfaces, with no host supremum or selected maximum pair.

The completion-facing route is only a consumer of that finite surface. The structural rows H, C, P, N preserve the same path under transport and replay, so no quotient completion, choice schedule, or ambient completeness principle is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedMetricSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5859.1, Definition 5859.2, and Definition 5859.3 seed the finite bounded metric-space packet over metric, ball-containment, bounded-subset, diameter, ordered-real, and completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedMetricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim compactness, host suprema, selected bounds, quotient completions, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked metric admission, bounded-containment admission, diameter-bound handoff, real-bound readback, transport, replay, provenance, and local naming for BEDC.Derived.BoundedMetricSpaceUp.

Constructive story: A $\mathsf{BoundedMetricSpace}^{\uparrow}$ packet is generated from a MetricSpaceUp carrier, MetricBallUp and BoundedSetUp containment rows, a MetricDiameterUp bound row, RealUp and RealAlgOrderUp readback, completion-facing handoff data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The Legendre–Fenchel envelope concrete instance is housed in its thematic spine so the root concrete-instance index stays structural; its convex-optimization route is read through chapter 208, chapter 321, chapter 3713, chapter 3563, and chapter 300.

Chapter 4687

A Concrete Naming Certificate for $\mathsf{LegendreFenchelEnvelope}^{\uparrow}$

Following Rockafellar, the $\mathsf{LegendreFenchelEnvelope}^{\uparrow}$ packet names the finite convex-envelope surface obtained by reading epigraph windows, supporting affine minorants, convex-conjugate data, and biconjugate comparison rows before any optimization consumer may inspect the result. It sits after the convex-set carrier of chapter 208, the Fenchel-duality ledger of chapter 321, and the proximal-resolvent handoff of chapter 3713; it also exposes KKT-facing and convex-conjugate-facing rows for certificates that need a displayed envelope without importing an ambient lower-semicontinuous hull, host supremum operator, quotient function space, or choice-selected minimizer.

Definition 4687.1 (Legendre–Fenchel envelope carrier)**.** *A* $\mathsf{LegendreFenchelEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (W, A, D, B, R, K, H, C, P, N)$$

with the following displayed rows:

1. *W is the epigraph window row, read through the* $\mathsf{ConvexSet}^{\uparrow}$ *carrier and recording the finite domain, value, and order comparisons visible to the envelope request.*
2. *A is the supporting affine minorant ledger, listing the finitely displayed affine lower bounds and their compatibility with the same epigraph window.*
3. *D is the convex conjugate readback row, exposing the pairing, dual-vector, and budgeted conjugacy data that a* $\mathsf{ConvexConjugate}^{\uparrow}$ *or* $\mathsf{FenchelDuality}^{\uparrow}$ *consumer may inspect.*
4. *B is the biconjugate-envelope row, recording the displayed comparison between the primal epigraph window and the conjugate readback route.*
5. *R is the proximal consumer row, allowing a* $\mathsf{ProximalMap}^{\uparrow}$ *request to read the envelope only after the window, minorant, conjugate, and biconjugate rows have been displayed.*
6. *K is the KKT and Fenchel ledger row, tying stationarity, supporting minorants, and dual comparison data to the* $\mathsf{KKT}^{\uparrow}$ *and* $\mathsf{FenchelDuality}^{\uparrow}$ *packets.*
7. *H records componentwise* hsame *transport for the epigraph window, affine minorants, conjugate readback, biconjugate envelope, proximal consumer, KKT and Fenchel ledger, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from epigraph admission through supporting minorants, conjugate readback, biconjugate comparison, proximal consumption, and KKT/Fenchel ledger inspection.*

9. *P is the* Pkg *provenance over* $\mathsf{LegendreFenchelEnvelope}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{ConvexConjugate}^{\uparrow}$, $\mathsf{FenchelDuality}^{\uparrow}$, $\mathsf{ProximalMap}^{\uparrow}$, $\mathsf{KKT}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LegendreFenchelEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, A, D, B, R, K, H, C, P, N$. It has no coordinate for an external lower-semicontinuous hull, host biconjugation theorem, selected supremum witness, quotient equality of functions, ambient locally convex topology, or global minimization principle.

Falsifiable prediction: Every accepted $\mathsf{LegendreFenchelEnvelope}^{\uparrow}$ consumer read factors through an epigraph window, supporting affine minorant ledger, convex conjugate readback, biconjugate-envelope row, proximal consumer row, KKT/Fenchel ledger row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Independence witness: convexset, fenchelduality, proximal-map, convex-conjugate, kkt: LegendreFenchelEnvelop is not bijective to any listed sibling because it jointly carries an epigraph window, supporting affine minorants, conjugate readback, biconjugate envelope comparison, proximal consumer route, and KKT/Fenchel ledger in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LegendreFenchelEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{LegendreFenchelEnvelope}^{\uparrow}$ packet is generated from an epigraph window, supporting affine minorant ledger, convex conjugate readback, biconjugate-envelope row, proximal consumer row, KKT and Fenchel ledger row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LegendreFenchelEnvelope}^{\uparrow}}$, seed)

Scope closed: Definition 5860.1 seeds the finite envelope certificate surface over convex-set, convex-conjugate, Fenchel-duality, proximal-map, and KKT rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LegendreFenchelEnvelope}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a host biconjugation theorem, lower-semicontinuous hull existence, selected supporting functional, quotient function equality, ambient locally convex topology, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, affine-minorant ledger exactness, conjugate readback, biconjugate-envelope comparison, proximal consumer boundary, KKT/Fenchel ledger visibility, transport, replay, provenance, and local naming for BEDC.Derived.LegendreFenchelEnvelopeUp.

Chapter 4688

A Concrete Naming Certificate for $\mathsf{PrefixTree}^{\uparrow}$

Following Brouwer and Kleene on spreads and finite choice sequences, the $\mathsf{PrefixTree}^{\uparrow}$ packet records the finite prefix-tree carrier used before StreamName and compact fan routes ask for branch-facing data. It sits between the finite window discipline of chapter 126, the binary obstruction route of chapter 1622, the fan boundary of chapter 400, and the Cantor prefix reads of chapter 1475. The packet names a finite frontier and branch-window surface; it is not an infinite branch selector, host tree equality, countable choice, bar induction, compactness, or ambient stream equality.

Definition 4688.1 (PrefixTree frontier carrier)**.** *A* $\mathsf{PrefixTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (V, E, F, W, H, C, P, N)$$

with the following displayed rows:

1. *V is the prefix-closed* BHist *node row. It lists the root, every displayed node, every displayed parent-prefix row, and the finite prefix relation used by the packet.*
2. *E is the finite child* $\mathsf{ProbeBundle}$ *row. For each displayed node in V, it records the listed child probes, the edge labels, and the finite immediate-extension checks.*
3. *F is the frontier row. It lists the exposed leaves and boundary nodes whose child probes are not opened by this packet, together with their parent-prefix witnesses in V.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *branch-window row. It records exactly the finite stream-name windows read along displayed root-to-frontier paths before any fan, Cantor, or compact route may consume the tree.*
5. *H records componentwise* hsame *transport for prefix nodes, child probes, frontier rows, branch windows, replay rows, provenance rows, and local naming rows.*
6. *C records displayed* Cont *replay from a tree request through V, E, F, W and then into the downstream* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{FanTheorem}^{\uparrow}$*,* $\mathsf{KleeneTree}^{\uparrow}$*, or* $\mathsf{CantorSpace}^{\uparrow}$ *consumer route that asked for the prefix data.*
7. *P is the* Pkg *provenance over* $\mathsf{PrefixTree}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{FanTheorem}^{\uparrow}$*,* $\mathsf{KleeneTree}^{\uparrow}$*,* $\mathsf{CantorSpace}^{\uparrow}$*,* BHist*,* $\mathsf{ProbeBundle}$*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{PrefixTree}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through V, E, F, W, H, C, P, N. It has no coordinate for selected infinite branches, quotient stream equality, host tree equality, countable choice, open-cover compactness, or ambient fan compactness.

Lean4 (definition) `BEDC.Derived.PrefixTreeUp.PrefixTreeUp`

Theorem 4688.2 (PrefixTree frontier NameCert obligation surface)**.** *For every accepted* $\mathsf{PrefixTree}^{\uparrow}$ *carrier*

$$T = (V, E, F, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrefixTree}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the prefix-closed node row, child probe bundle, frontier row, branch-window row, componentwise transport, continuation replay, provenance, and local naming;*
2. *prefix closure, requiring every non-root node in V to display its parent-prefix chain inside V before any child probe in E is consumed;*
3. *finite branching, requiring each child request to be read from the finite* ProbeBundle *row E attached to the currently displayed node;*
4. *frontier coverage, requiring every exposed leaf or boundary node in F to be reached by a displayed finite path through V and E;*
5. *branch-window stability, requiring every* $\mathsf{StreamName}^{\uparrow}$ *window in W to be attached to a displayed root-to-frontier path and to transport through H and replay through C without changing the prefix path;*
6. *non-escape from selected infinite branches, requiring P and N to export no selected branch, quotient stream equality, host tree equality, countable choice, open-cover compactness, or ambient fan compactness.*

Thus any downstream $\mathsf{StreamName}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{KleeneTree}^{\uparrow}$, *or* $\mathsf{CantorSpace}^{\uparrow}$ *consumer receives only compact finite prefix data.*

Proof. Carrier admission is projection from Definition 5861.1. The accepted packet displays exactly the prefix-node row, finite child probes, frontier ledger, branch windows, and structural rows.

Prefix closure is read from V. A non-root node has no entry point except its displayed parent-prefix chain, so a consumer cannot jump to an unlisted node or compare nodes by host tree equality.

Finite branching is read from E. For a displayed node, the packet exposes only the listed child probes and edge labels, and each such probe is attached to the node already admitted by V.

Frontier coverage is read from F. Every exposed leaf or boundary node carries a finite path back through the node and child rows, so the frontier is a finite BEDC ledger rather than a completed branch object.

Branch-window stability is read from W, H, C. The $\mathsf{StreamName}^{\uparrow}$ window is attached to the same displayed root-to-frontier path, componentwise hsame transport preserves that path, and displayed Cont replay repeats the same finite route for fan, Kleene-tree, and Cantor-space consumers.

Finally, provenance and local naming in P, N add no excluded coordinate. Since selected infinite branches, quotient streams, host tree equality, countable choice, open-cover compactness, and ambient fan compactness are absent from the carrier, the local NameCert surface cannot export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrefixTree}^{\uparrow}}$.

Constructive story: A $\mathsf{PrefixTree}^{\uparrow}$ packet is generated from prefix-closed BHist node rows, finite ProbeBundle child rows, frontier rows, finite $\mathsf{StreamName}^{\uparrow}$ branch windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrefixTree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5861.1 and Definition 5861.2 seed the finite prefix-tree frontier route for StreamName, fan, Kleene-tree, and Cantor-space consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrefixTree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close infinite branch selection, quotient stream equality, host tree equality, countable choice, bar induction, compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix closure, finite branching, frontier coverage, branch-window stability, replay, provenance, local naming, and non-escape for BEDC.Derived.PrefixTreeUp.

$\mathsf{ChomskyNormalForm}^{\uparrow}$ reads its grammar-normalization route through chapter 356, finite word rows through chapter 36, and language-preservation comparison through chapter 351; the child files below keep the carrier and proof rows separate.

Chapter 4689

A Concrete Naming Certificate for $\mathsf{ChomskyNormalForm}^{\uparrow}$

Following Hopcroft–Ullman and Sipser, the $\mathsf{ChomskyNormalForm}^{\uparrow}$ packet records the finite normal-form handoff for a context-free grammar as BEDC NameCert data. It sits beside the grammar carrier of chapter 356, the finite word rows of chapter 36, and the regular-language comparison surface of chapter 351, with parse-tree rows consumed by downstream grammar chapters. The packet names the displayed nonterminal, terminal, production, start, nullable, unit-production, binarization, and language-preservation rows before any consumer may read a grammar as a Chomsky-normal-form grammar. The language-preservation row L is the shared boundary read consumed by the regular-language surface of chapter 351 and by parse-tree or CFG consumers through chapter 356.

Definition 4689.1 (ChomskyNormalForm carrier)**.** *A* $\mathsf{ChomskyNormalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (G, N, T, S, P, E, U, B, L, H, C, K, A)$$

with the following displayed rows:

1. *G is the source* $\mathsf{ContextFreeGrammar}^{\uparrow}$ *row whose variables, terminals, productions, start symbol, derivation relation, and language surface are visible to the packet.*
2. *N is the nonterminal vocabulary row for the normal-form grammar, including the finite renamed variables introduced by binarization.*
3. *T is the terminal vocabulary row inherited from the source grammar and exposed through finite word rows.*
4. *S is the start-symbol row, including the displayed fresh-start handling used when the source grammar derives the empty word.*
5. *P is the production-shape row, requiring every displayed production to be terminal, binary nonterminal, or the admitted start-empty row.*
6. *E is the nullable and empty-word ledger, recording exactly where the construction retains or removes empty productions.*
7. *U is the unit-production elimination ledger, recording the finite route by which unit edges are replaced by ordinary productions.*

8. *B is the binarization ledger, recording the finite chain of helper variables used to replace long right-hand sides.*
9. *L is the language-preservation row comparing the source grammar and the normal-form grammar through finite derivation trees and finite word reads.*
10. *H records componentwise* hsame *transport for the source grammar, vocabulary rows, start row, production-shape row, elimination ledgers, binarization ledger, language-preservation row, replay, provenance, and naming rows.*
11. *C records displayed* Cont *replay from a grammar consumer through $G, N, T, S, P, E, U, B, L$.*
12. *K is the* Pkg *provenance over* $\mathsf{ChomskyNormalForm}^{\uparrow}$, $\mathsf{ContextFreeGrammar}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{RegularLanguage}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
13. *A is the local* $\mathsf{NameCert}_{\mathsf{ChomskyNormalForm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an unrestricted grammar quotient, an erased derivation equivalence, a host parser, countable grammar enumeration, or ambient language equality.

Theorem 4689.2 (ChomskyNormalForm NameCert obligations)**.** *For every accepted* $\mathsf{ChomskyNormalForm}^{\uparrow}$ *carrier*

$$F = (G, N, T, S, P, E, U, B, L, H, C, K, A),$$

the local $\mathsf{NameCert}_{\mathsf{ChomskyNormalForm}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed grammar rows, production-shape certification, empty-production handling, unit-production elimination, binarization, language-preservation readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside the finite rows of F.*

Proof. Carrier admission is projection from Definition 5862.1. The packet displays the source grammar, the normal-form vocabulary, the start row, the production-shape row, the nullable and unit ledgers, the binarization ledger, the language-preservation row, and the structural rows.

Production-shape certification is read from P. The row admits only terminal productions, binary nonterminal productions, and the displayed start-empty case, so the local certificate has no remaining route to arbitrary grammar productions.

Empty-production and unit-production handling are read from E and U. These ledgers record the finite eliminations before L may compare languages, preventing a consumer from replacing the construction by an erased grammar equivalence.

Binarization is read from B, and language preservation is read from L. The structural rows H, C, K, A transport, replay, source, and name the same finite route, while no carrier coordinate contains a quotient grammar, host parser, countable enumeration, or ambient language equality. □

Theorem 4689.3 (ChomskyNormalForm CFG handoff)**.** *Every* $\mathsf{ContextFreeGrammar}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{ChomskyNormalForm}^{\uparrow}$ *packet must pass through the displayed route*

$$G \longrightarrow E, U, B \longrightarrow P \longrightarrow L$$

and then through H, C, K, A. Thus the packet hands a context-free grammar to downstream normal-form consumers only after the empty-production ledger, unit-production ledger, binarization ledger, production-shape row, and language-preservation row have been displayed. It does not export a host

parser, a quotient grammar equality, an erased derivation equivalence, a countable-choice grammar selector, or ambient language extensionality.

Proof. Begin with a consumer read of the source grammar row G. The carrier does not expose the normal-form grammar as a bare replacement; it orders the read through the finite ledgers E, U, B.

The production-shape row P is downstream of those ledgers. It verifies that the resulting productions have the Chomsky-normal-form shape before a language-facing read is available.

The language-preservation row L then compares only finite derivation-tree and finite word reads. Finally H, C, K, A transport, replay, source, and name that route for CFG consumers. Since the excluded parser, quotient, erased-equivalence, selector, and ambient-extensionality objects are absent from the carrier, the handoff is exactly the displayed finite BEDC route. □

Closure status for $\mathsf{NameCert}_{\mathsf{ChomskyNormalForm}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChomskyNormalForm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5862.1, Definition 5862.2, and Definition 5862.3 seed the finite context-free grammar route from source grammar rows through Chomsky-normal-form ledgers to language-preservation readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChomskyNormalForm}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close parser implementation, quotient grammar equality, erased derivation equivalence, countable grammar selection, ambient language extensionality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, production-shape exactness, empty-production handling, unit-production elimination, binarization, language-preservation readback, transport, replay, provenance, and local naming for BEDC.Derived.ChomskyNormalFormUp.

Constructive story: A $\mathsf{ChomskyNormalForm}^{\uparrow}$ packet is generated from a source CFG row, normal-form vocabulary rows, a start row, production-shape evidence, nullable and unit-production ledgers, a binarization ledger, language-preservation readback, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Chapter 4690

A Concrete Naming Certificate for $\mathsf{FiniteFanTheorem}^{\uparrow}$

Following Brouwer and Bishop-style finite fan practice, the $\mathsf{FiniteFanTheorem}^{\uparrow}$ packet records the bounded bar evidence that a Cantor or Baire prefix consumer may inspect before it exports a finite branch-window conclusion. It sits after the $\mathsf{StreamName}^{\uparrow}$ finite-window interface of chapter 126, the binary prefix carrier of chapter 1475, the countable prefix carrier of chapter 334, the endpoint rows of chapter 32, and the unary depth ledger of chapter 28. The chapter names a finite prefix-bar packet; it does not claim open-cover compactness, countable choice, selected branches, quotient stream equality, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4690.1 (Finite fan theorem carrier)**.** *A* $\mathsf{FiniteFanTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathcal{B} = (S, C, B, I, W, H, T, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *prefix-window row, exposing the finite observation schedule read by every branch-facing consumer.*
2. *C is the* $\mathsf{CantorSpace}^{\uparrow}$ *tree row, recording binary prefix extensions, Boolean endpoint labels, and the Cantor branch rows retained by the fan packet.*
3. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *branch row, recording the countable prefix route through which Baire-style consumers reuse the same finite observation window.*
4. *I is the* $\mathsf{Bool}^{\uparrow}$ *and* $\mathsf{Nat}^{\uparrow}$ *finite prefix ledger, pairing endpoint decisions with unary prefix-depth indices and branch-length comparisons.*
5. *W is the finite bar-window row. It lists the prefixes inspected at the displayed depths and the bar decision read at each retained prefix.*
6. *H records componentwise* hsame *transport for the StreamName, CantorSpace, BaireSpace, prefix-ledger, bar-window, traversal, provenance, and local naming rows.*
7. *T records displayed* Cont *traversal from a branch request through S, C, B, I, W, H and into the local certificate.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteFanTheorem}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{CantorSpace}^{\uparrow}$*,* $\mathsf{BaireSpace}^{\uparrow}$*,* $\mathsf{Bool}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{FiniteFanTheorem}^{\uparrow}}$ *row.*
The carrier has no coordinate for an infinite branch, a selected bar witness, countable choice, open-cover compactness, quotient stream equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FiniteFanTheoremUp.FiniteFanTheoremTasteGate single carrier alignment`

Theorem 4690.2 (Finite fan theorem NameCert obligations)**.** *For every accepted* $\mathsf{FiniteFanTheorem}^{\uparrow}$ *carrier*

$$\mathcal{B} = (S, C, B, I, W, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteFanTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed StreamName prefix windows, CantorSpace tree rows, BaireSpace branch rows, Bool and Nat finite prefix ledger, finite bar-window row, componentwise* hsame *transport, displayed* Cont *traversal,* Pkg *provenance, and local naming. Every public read of the packet must inspect S before C or B, must read the finite prefix ledger I before the bar window W, and must pass through H, T, P, N before export.*

Thus a downstream fan, Cantor, Baire, Real, or Completion consumer receives only finite prefix-bar evidence. The packet exports no open-cover compactness theorem, countable-choice selector, selected branch, quotient stream equality, or $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Carrier admission is projection from Definition 5863.1. The accepted packet displays exactly the StreamName window, Cantor tree, Baire branch, finite prefix ledger, bar window, transport, traversal, provenance, and local naming rows.

The prefix order is forced by the carrier. A branch-facing request first reads S as the finite observation schedule, then reads the Cantor and Baire rows C, B only through the prefixes exposed by that schedule.

The bar evidence is finite because I and W are displayed ledgers. The Bool endpoint rows and Nat depth rows in I determine which retained prefixes are inspected, and W records the corresponding bar decisions without adding an infinite branch or a choice-selected witness.

Finally H, T, P, N transport, replay, source, and name the same finite route. Since the carrier contains no coordinate for open covers, countable choice, selected branches, quotient streams, or completed real data, the listed rows exhaust the local NameCert surface. □

Theorem 4690.3 (Finite fan prefix-order exactness)**.** *Let*

$$\mathcal{B} = (S, C, B, I, W, H, T, P, N)$$

be an accepted $\mathsf{FiniteFanTheorem}^{\uparrow}$ *carrier. Every accepted branch-facing read exposes the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row S before it can read either the* $\mathsf{CantorSpace}^{\uparrow}$ *prefix row C or the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix row B, and exposes the* $\mathsf{Nat}^{\uparrow}$ *depth ledger inside I before it can read the finite bar-window row W.*

Consequently the public prefix order of the packet is exactly

$$S \longrightarrow C, B \quad \textit{and} \quad I \longrightarrow W$$

with all exported reads then transported and named through H, T, P, N.

Proof. Project the accepted packet through Definition 5863.1. The row S is the only displayed finite observation schedule for branch-facing consumers, while C and B are retained as tree and branch prefix rows read through that schedule.

The depth order is also a carrier projection. The row I pairs Boolean endpoint decisions with Nat depth indices and branch-length comparisons, while W only lists the prefixes inspected at the displayed depths. Thus W cannot be read before the depth coordinates in I have been exposed.

Finally H, T, P, N preserve the same ordered rows under transport, traversal, provenance, and local naming. No listed carrier row supplies an alternate prefix order. □

Theorem 4690.4 (Finite fan bar-window coverage)**.** *For every accepted* $\mathsf{FiniteFanTheorem}^{\uparrow}$ *carrier*

$$\mathcal{B} = (S, C, B, I, W, H, T, P, N),$$

each accepted finite bar window in W *is covered by a displayed finite prefix family read from* S, C, B, I*. The bar-window read cannot inspect a branch outside the recorded* $\mathsf{Bool}^{\uparrow}/\mathsf{Nat}^{\uparrow}$ *finite ledger* I*, and every prefix used by the read is one of the prefixes retained by the finite observation schedule* S *and the Cantor or Baire prefix rows* C, B*.*

Proof. Use the carrier rows from Definition 5863.1. The finite observation schedule S records the inspected windows, the Cantor and Baire rows C, B retain the branch prefixes available to the packet, and I records the Boolean endpoint labels and Nat depth comparisons.

The bar row W is defined only as a finite bar-window row over those displayed depths. Hence an accepted read of W is already indexed by the prefixes and depths carried by S, C, B, I; there is no carrier coordinate for a branch outside that finite ledger.

The transport and replay rows do not add new branches. They move the same finite family through H, T, P, N, so coverage remains exactly the displayed finite prefix family. □

Theorem 4690.5 (Finite fan nonescape)**.** *Let*

$$\mathcal{B} = (S, C, B, I, W, H, T, P, N)$$

be an accepted $\mathsf{FiniteFanTheorem}^{\uparrow}$ *carrier. Any consumer reaching the local* $\mathsf{NameCert}_{\mathsf{FiniteFanTheorem}^{\uparrow}}$ *row* N *factors through* $S, C, B, I, W, H, T, P, N$ *and therefore exports no open-cover compactness, countable choice, selected infinite branch, or quotient stream equality.*

Proof. Carrier admission gives the complete row list $S, C, B, I, W, H, T, P, N$. A consumer that reaches N must first pass through the displayed traversal row T, provenance row P, and transport row H attached to the same finite prefix-bar packet.

The source rows are exhausted by S, C, B, I, W. These rows carry finite windows, prefix trees, branch rows, endpoint and depth ledgers, and finite bar decisions only. None of them contains an open cover, a countable-choice selector, an infinite branch choice, or a quotient equality of streams.

Thus the local naming row can export only the displayed finite packet. The nonlisted principles are outside the carrier and cannot be recovered by a NameCert consumer. □

Falsifiable prediction: Every $\mathsf{FiniteFanTheorem}^{\uparrow}$ branch-facing read factors through one $\mathsf{StreamName}^{\uparrow}$ finite-window row, one $\mathsf{CantorSpace}^{\uparrow}$ binary tree row, one $\mathsf{BaireSpace}^{\uparrow}$ branch row, one combined $\mathsf{Bool}^{\uparrow}$ and $\mathsf{Nat}^{\uparrow}$ finite prefix ledger, one finite bar-window row, componentwise hsame transport, displayed Cont traversal, Pkg provenance, and local naming.

Independence witness: streamname, cantorspace, bairespace, bool, nat: $\mathsf{FiniteFanTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries binary and countable prefix rows with a finite bar-window ledger as one branch-facing packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteFanTheorem}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteFanTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5863.1 and Definition 5863.2 seed the finite prefix-bar route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, and $\mathsf{Nat}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteFanTheorem}^{\uparrow}}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, selected branches, quotient stream equality, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-order exactness, finite bar-window coverage, componentwise transport, traversal replay, provenance, local naming, and non-escape for BEDC.Derived.FiniteFanTheoremUp.

Constructive story: A $\mathsf{FiniteFanTheorem}^{\uparrow}$ packet is generated from finite StreamName windows, CantorSpace tree rows, BaireSpace branch rows, Bool endpoint decisions, Nat depth indices, a finite bar-window ledger, componentwise transport, displayed traversal, package provenance, and a local NameCert row.

Chapter 4691

A Concrete Naming Certificate for $\mathsf{SpecializationOrder}^{\uparrow}$

Following Alexandroff and standard topology, the specialization preorder of a topological space is read through open-neighbourhood implication rather than host point equality. The $\mathsf{SpecializationOrder}^{\uparrow}$ packet sits after the indexed-open topology of chapter 88, the observable-open truth classifier of chapter 1860, the membership discipline of chapter 3668, and the separated order surface of chapter 53. It is also the topology-side order interface consumed by the metric-generated topology handoff of chapter 1655. The packet names only finite open-set implication data; it does not import quotient point equality, selected representatives, powerset extensionality, excluded middle over opens, or choice-based separation.

Definition 4691.1 (SpecializationOrder carrier)**.** *A* $\mathsf{SpecializationOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, O, R, H, C, P, N)$$

with the following displayed rows:

1. *T is the topology row, carrying the accepted indexed-open source, finite open-neighbourhood requests, and topology closure witnesses read from chapter 88.*
2. *O is the open-set membership classifier, recording for each displayed point and accepted open index whether the point is observed inside that open through the local open-row interface.*
3. *R is the specialization relation row. A displayed comparison $x \leq_{\mathsf{spec}} y$ is admitted only when every open-membership read true at x in O is replayed as true at y through the same topology row T.*
4. *H records componentwise* hsame *transport for the topology row, open-set membership classifier, specialization relation row, replay, provenance, and local naming rows.*
5. *C records displayed* Cont *replay from an open-neighbourhood request through T and O into the specialization relation row R.*
6. *P is the* Pkg *provenance over* $\mathsf{SpecializationOrder}^{\uparrow}$*, the topology, Sierpinski, SetLike, Poset, metric-topology,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *surfaces.*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{SpecializationOrder}^{\uparrow}}$ *row.*

The carrier has no coordinate for host point equality, quotient points, selected separated representatives, powerset equality of opens, excluded middle over open membership, or choice-based separation.

Lean4 ✓ `BEDC.Derived.SpecializationOrderUp.SpecializationOrderTasteGate single carrier alignment`

Theorem 4691.2 (SpecializationOrder NameCert obligations)**.** *For every accepted* $\mathsf{SpecializationOrder}^{\uparrow}$ *carrier* $K = (T, O, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SpecializationOrder}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the topology row, open-set membership classifier, specialization relation row, transport, replay, provenance, and local naming;*
2. *classifier transport, requiring* H *to preserve every open-membership read in* O *along displayed* hsame *moves;*
3. *reflexivity, read by replaying each open-membership observation for a point back to the same point through* O*;*
4. *transitivity, read by composing two displayed open-neighbourhood implication rows inside* R*;*
5. *topology handoff, requiring every public order comparison to factor through the indexed-open row* T *before it reaches* R*;*
6. *sibling nonescape, forbidding quotient point equality, host separation, selected representatives, powerset extensionality, excluded middle, and choice data not displayed in* K*;*
7. *local naming through the provenance row* P *and the local certificate row* N*.*

These rows exhaust the packet obligations. A downstream T0-reflection, formal-topology, metric-topology, or separated-order consumer receives only the displayed open-neighbourhood implication route.

Proof. Carrier admission is projection from Definition 5864.1. The packet exposes only T, O, R, H, C, P, N, so each local obligation must be read from the topology row, the open-membership classifier, the specialization relation, or the structural rows.

Classifier transport is componentwise. The H row moves topology indices, point reads, open-membership observations, and specialization comparisons together, so an accepted classifier read cannot detach from the topology row that generated it.

Reflexivity and transitivity are internal to R. Reflexivity reuses the same open-membership read at the same point, while transitivity composes the two displayed implication routes through the common open index. No quotient or host equality coordinate is involved.

The topology handoff and sibling nonescape follow from the carrier boundary. Every public order read passes through T and O before R, and the rows P, N name only that route. Since quotient points, selected representatives, powerset extensionality, excluded middle, and choice-based separation are absent from the packet, none can be exported as a NameCert obligation. □

Theorem 4691.3 (SpecializationOrder topology handoff)**.** *Every accepted* $\mathsf{SpecializationOrder}^{\uparrow}$ *packet reads its preorder only from open-set implication:*

$x \leq_{\mathsf{spec}} y$ *means that every displayed open-neighbourhood read true at* x *is replayed as true at* y*.*

The handoff exports no quotient point equality, no selected representative, and no choice-based separation principle.

Proof. Start with an accepted carrier $K = (T, O, R, H, C, P, N)$. The topology row T supplies the only accepted open indices, and O supplies the only membership reads for those opens.

The specialization row R is defined as the replay of those membership reads from source point to target point. Thus a preorder comparison can be inspected by checking the displayed implication from each open-neighbourhood observation at x to the corresponding observation at y.

Finally H, C, P, N preserve, replay, source, and name that same implication route. The carrier has no coordinate for quotient points, selected representatives, host equality, or choice-based separation, so the topology handoff cannot export any of them. □

Closure status for $\mathsf{NameCert}_{\mathsf{SpecializationOrder}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SpecializationOrder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5864.1, Definition 5864.2, and Definition 5864.3 seed the open-neighbourhood implication interface between topology rows and order-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SpecializationOrder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient point equality, T0 reflection, formal topology, metric separation, choice-based separation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, open-membership classifier transport, reflexivity, transitivity, topology handoff, sibling nonescape, provenance, and local naming for BEDC.Derived.SpecializationOrderUp.

Constructive story: A $\mathsf{SpecializationOrder}^{\uparrow}$ packet is generated from a topology row, an open-set membership classifier, a specialization relation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4692

A Concrete Naming Certificate for $\mathsf{FiniteModulusReal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteModulusReal}^{\uparrow}$ packet records a real-name route whose modulus ledger is finite and explicit at every consumer read. It sits between the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the real-modulus criterion of chapter 3415. The packet gives Real and Completion consumers a modulus-visible carrier without quotienting Cauchy streams, selecting host limits, invoking countable choice, or asserting ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4692.1 (FiniteModulusReal carrier)**.** *A* $\mathsf{FiniteModulusReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, R, D, M, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, naming exactly the finite observation windows read by the carrier at the requested precision.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, translating the inspected stream windows into regular rational approximation data.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic scales and comparison rows used by the displayed approximations.*
4. *M is the explicit finite modulus ledger, assigning to each retained precision request the finite window of S and dyadic tolerance data in D required before the readback row R may be consumed.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after S, R, D, M have been displayed.*
6. *H records componentwise* hsame *transport for the stream windows, regular readback, dyadic tolerance ledger, finite modulus ledger, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite Real or Completion read through S, R, D, M, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteModulusReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *the real-modulus criterion,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteModulusReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, M, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected host limits, countable choice, undecorated Real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FiniteModulusRealUp.FiniteModulusRealTasteGate single carrier alignment`

Theorem 4692.2 (FiniteModulusReal NameCert obligations)**.** *For every accepted* $\mathsf{FiniteModulusReal}^{\uparrow}$ *carrier*

$$F = (S, R, D, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteModulusReal}^{\uparrow}}$ *surface consists exactly of carrier admission for stream windows, regular rational readback, dyadic tolerances, explicit finite modulus rows, terminal Real seal routing, componentwise transport, displayed continuation replay, package provenance, and local naming. Every Real or Completion consumer read of the packet must expose the finite modulus row M before it consumes R or E.*

Proof. Project the carrier of Definition 5865.1. The analytic rows are S, R, D, M, E, and the structural rows H, C, P, N transport, replay, source, and name the same packet.

The read order is finite. A precision request first selects the window named in S and the dyadic tolerance data recorded in D. The finite modulus ledger M binds those two rows to the requested read before the regular rational row R may be consumed.

The terminal seal E is downstream of S, R, D, M. Componentwise transport through H and continuation replay through C preserve the same displayed rows, while P and N record provenance and local naming. Since the carrier has no additional coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 4692.3 (FiniteModulusReal RegSeqRat handoff)**.** *For every accepted* $\mathsf{FiniteModulusReal}^{\uparrow}$ *carrier $F = (S, R, D, M, E, H, C, P, N)$, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R is consumed only after the finite stream windows S, dyadic tolerance ledger D, and explicit modulus ledger M have been displayed. Thus downstream regular rational consumers receive a finite modulus-indexed approximation route, not a quotient Cauchy stream or selected host limit.*

Proof. Project Definition 5865.1. The row R is the only regular rational readback coordinate, and it is listed after the stream-window row S, dyadic tolerance ledger D, and explicit finite modulus ledger M.

Apply Definition 5865.2. A consumer read must expose M before consuming R, so the demanded regular rational approximation is tied to a displayed finite window and a displayed dyadic tolerance row.

Transport and replay add no hidden readback source. The rows H, C, P, N preserve and name the same finite route, so a downstream $\mathsf{RegSeqRat}^{\uparrow}$ consumer cannot inspect quotient stream equality, a selected limit, countable choice, or ambient Real completeness through this handoff. □

Theorem 4692.4 (FiniteModulusReal Real seal nonescape)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *seal read of an accepted* $\mathsf{FiniteModulusReal}^{\uparrow}$ *carrier factors through*

$$S, D, M \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

No Real or Completion consumer can bypass the explicit finite modulus ledger before reading the terminal seal.

Proof. Start with an accepted packet $F = (S, R, D, M, E, H, C, P, N)$. By Definition 5865.1, the only terminal Real boundary is the row E.

Use Definition 5865.2. The seal row E is downstream of the stream windows, dyadic tolerance ledger, explicit modulus ledger, and regular rational readback. Therefore a consumer that has not displayed S, D, M, R has not reached the packet's terminal seal.

The structural rows do not create another Real-facing boundary. They transport, replay, source, and name the same finite packet, so the seal route cannot escape to quotient equality, selected host limits, countable choice, undecorated Real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: An accepted $\mathsf{FiniteModulusReal}^{\uparrow}$ consumer that reaches $\mathsf{RegSeqRat}^{\uparrow}$ readback or the terminal $\mathsf{Real}^{\uparrow}$ seal without the displayed finite modulus ledger M refutes the carrier surface.

Independence witness: streamname, regseqrat, dyadicratcore, real, real-modulus-criterion: no listed sibling supplies the whole nine-row packet $F = (S, R, D, M, E, H, C, P, N)$, because each sibling contributes finite windows, regular readback, dyadic tolerance data, terminal Real sealing, or a modulus criterion while this chapter binds them into one local NameCert carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteModulusReal}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteModulusReal}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, an explicit finite modulus ledger, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteModulusReal}^{\uparrow}}$, seed)

Scope closed: Definition 5865.1, Definition 5865.2, Definition 5865.3, and Definition 5865.4 seed the finite explicit-modulus Real carrier over StreamName, RegSeqRat, DyadicRatCore, Real, and real-modulus criterion rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteModulusReal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected host limits, countable choice, undecorated Real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, dyadic tolerance exactness, explicit modulus routing, RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteModulusRealUp.

Chapter 4693

A Concrete Naming Certificate for $\mathsf{CompactUniformSubordinateCover}^{\uparrow}$

Following Heine–Cantor and Bishop–Bridges constructive analysis, the $\mathsf{CompactUniformSubordinateCover}^{\uparrow}$ packet records the subordinate finite cover used before the compact-uniform-continuity lower-bound fold in chapter 9237. It sits over the compact source of chapter 60, the metric source of chapter 57, the continuous-map pointwise modulus rows of chapter 59, the rational positivity surface of chapter 37, and the sibling subordinate-cover packets of chapter 596 and chapter 3937. The packet names the finite ProbeBundle cover and its lower-bound handoff; it does not export open-cover compactness, a host Lebesgue number, a selected subcover, quotient point equality, or an external modulus function.

Definition 4693.1 (Compact-uniform subordinate-cover carrier)**.** *A* $\mathsf{CompactUniformSubordinateCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, G, Q, F, L, M, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact metric source row, combining the* $\mathsf{Compact}^{\uparrow}$ *admission and the* $\mathsf{Met}^{\uparrow}$ *distance carrier over the same source.*
2. *G is the continuous graph row, exposing pointwise modulus requests for the same source and target metric carriers.*
3. *Q is the positive* $\mathsf{Rat}^{\uparrow}$ *tolerance row read by the pointwise-modulus requests.*
4. *F is the finite* ProbeBundle *subordinate-cover row, naming bundled centers, coverage witnesses, and the source-distance windows attached to those centers.*
5. *L is the rational lower-bound fold over the displayed subordinate radii in F.*
6. *M is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced only after K, G, Q, F, L have been displayed.*
7. *H records componentwise* hsame *transport for K, G, Q, F, L, M and for the replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from compact-source inspection through pointwise-modulus reads, finite-cover coverage, rational lower-bound folding, and uniform-modulus handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactUniformSubordinateCover}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, Pkg, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{CompactUniformSubordinateCover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, G, Q, F, L, M, H, C, P, N$. It has no coordinate for open-cover compactness, host lower-bound extraction, a selected infinite subcover, quotient point equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactUniformSubordinateCoverUp.CompactUniformSubordinateCoverTasteGate single carrier alignment`

Theorem 4693.2 (Compact-uniform subordinate cover handoff)**.** *For every accepted* CompactUniformSubordinateC *carrier $U = (K, G, Q, F, L, M, H, C, P, N)$, the finite* ProbeBundle *row F is the unique subordinate-cover input to the uniform-modulus handoff. A consumer reaches M only by first reading the compact metric source K, the continuous graph row G, the positive rational tolerance row Q, the bundled center and coverage row F, and the rational lower-bound fold L, with H, C, P, N preserving that route.*

Consequently the packet supplies the ProbeBundle modulus-fold route used in chapter 9237 without exposing open-cover compactness, a host Lebesgue-number choice, a selected subcover, quotient point equality, or an external modulus selector.

Proof. Project the carrier of Definition 5866.1. The compact metric source is K, the continuous graph row is G, the tolerance row is Q, the finite subordinate cover is F, the rational lower-bound fold is L, and the uniform-modulus handoff is M.

The cover row F is the only coordinate carrying bundled centers and coverage witnesses. Thus every local pointwise-modulus read used by the handoff is tied to a displayed probe name and to the same source metric row in K.

The fold row L is read after F and before M. It computes the tolerance-only radius through finite rational data rather than through a host minimum or an external Lebesgue-number selector.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no coordinate for the excluded host objects, every $\mathsf{UniformModulus}^{\uparrow}$ consumer of M factors through the displayed subordinate cover. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformSubordinateCover}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactUniformSubordinateCover}^{\uparrow}$ packet is generated from CompactUp and MetricUp source rows, ContinuousUp pointwise-modulus rows, RatUp tolerance rows, a finite ProbeBundle subordinate-cover row, a rational lower-bound fold, a UniformModulusUp handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactUniformSubordinateCover}^{\uparrow}}$, seed)

Scope closed: Definition 5866.1 and Definition 5866.2 seed the finite subordinate-cover carrier used before compact-uniform-continuity lower-bound folding.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactUniformSubordinateCover}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.CompactUniformSubordinateCoverUp.CompactUniformSubordinateCoverTasteGate\_single\_carri`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host lower-bound extraction, selected infinite subcovers, quotient point equality, countable choice, ambient RealUp completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact metric source exposure, continuous graph exposure, RatUp tolerance exposure, ProbeBundle coverage exactness, rational lower-bound folding, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformSubordinateCoverUp.

Chapter 4694

A Concrete Naming Certificate for $\mathsf{BishopIntervalContraction}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopIntervalContraction}^{\uparrow}$ packet records a finite interval-contraction handoff from located bisection data to regular Cauchy names. It consumes the located bisection route of chapter 1711, the dyadic arithmetic ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite L10 neighbor of interval bisection and regular Cauchy handoff; it is not a quotient real construction, a selected infinite branch, a host fixed-point theorem, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4694.1 (Bishop interval contraction carrier)**.** *A* $\mathsf{BishopIntervalContraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, F, L, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the located source interval row, carrying endpoints, locator evidence, and the admitted interval boundary as BEDC data.*
2. *F is the contraction self-map row, recording the displayed map on the interval together with its contraction witness.*
3. *L is the Lipschitz or shrinkage ledger, exposing the dyadic contraction budget and the requested depth.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *midpoint and error ledger used by the retained interval windows.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row recording which contraction stages are inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows and dyadic tolerances.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after I, F, L, D, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the interval, contraction, dyadic, stream, regular-rational, real-seal, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the interval-contraction request through I, F, L, D, W, R, E, H.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalContraction}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalContraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient real equality, a chosen infinite branch, a host contraction theorem, selected limits, countable choice, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.BishopIntervalContractionUp.BishopIntervalContractionTasteGate single carrier alignment`

Theorem 4694.2 (Bishop interval contraction NameCert obligations)**.** *For every accepted* BishopIntervalContractio *carrier*

$$B = (I, F, L, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopIntervalContraction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed located interval, contraction self-map, dyadic shrinkage ledger, finite windows, regular rational readback, terminal real seal, transport, replay, provenance, and local naming rows;*
2. *contraction stability, requiring every replayed self-map read to preserve the located source interval through I and to expose its shrinkage budget through L, D;*
3. *bisection compatibility, requiring the retained interval windows to factor through the located interval bisection route before any* $\mathsf{StreamName}^{\uparrow}$ *window or* $\mathsf{RegSeqRat}^{\uparrow}$ *readback is consumed;*
4. *dyadic budget exactness, requiring every tolerance request to read the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *midpoint and error ledger D before it reaches W, R, E;*
5. *Cauchy handoff, requiring the completion-facing consumer to pass through W, R, E, H, C, P, N after the interval and contraction rows have been displayed.*

No NameCert obligation is stored outside $I, F, L, D, W, R, E, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.BishopIntervalContractionUp.BishopIntervalContractionCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 5867.1. The accepted packet displays the located interval, contraction, dyadic ledger, finite windows, regular readback, real seal, transport, replay, provenance, and local naming rows.

Contraction stability is read through I, F, L, D. The self-map row F is not a host function detached from the interval; it is paired with the located interval row I and with the shrinkage ledger L, D.

Bisection compatibility follows from the dependency route. A retained interval window must be displayed before a stream or regular-rational readback can be consumed, so the packet reaches W and R only after the located bisection and dyadic rows have been read.

Finally, the handoff rows E, H, C, P, N preserve the same finite route. Since the carrier contains no quotient equality, selected branch, host contraction theorem, selected limit, countable-choice row, or ambient completeness coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 4694.3 (Bishop interval contraction Cauchy handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{BishopIntervalContraction}^{\uparrow}$ *packet must read the finite route*

$$I, F, L, D \longmapsto W, R, E \longmapsto H, C, P, N$$

before it can treat the contraction stages as a regular Cauchy real name. The consumer receives located interval data, a displayed contraction self-map, dyadic shrinkage budgets, finite stream windows, regular rational readback, a terminal real seal, componentwise transport, continuation replay, provenance, and local naming. It receives no quotient completion, selected limit, chosen infinite branch, countable choice, host fixed-point object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.BishopIntervalContractionUp.BishopIntervalContractionCauchyHandoff`

Proof. Start with the interval-contraction request. The source interval is read through I, while the self-map and contraction budget are read through F, L, D.

The finite windows then expose the Cauchy route. The row W records the inspected contraction stages, and R reads the corresponding regular rational approximants against the same dyadic tolerance ledger.

The terminal seal E is reached only after those rows are present. The structural rows H, C, P, N transport, replay, source, and name the same route for downstream completion consumers.

Thus the packet hands off a regular Cauchy name through displayed BEDC rows. No quotient completion, selected limit, chosen infinite branch, countable-choice row, host fixed-point object, or ambient real-completeness coordinate is present in the carrier. □

Theorem 4694.4 (Bishop interval contraction RegSeqRat endpoint stability)**.** *Let* $B = (I, F, L, D, W, R, E, H, C,$ *be an accepted* $\mathsf{BishopIntervalContraction}^{\uparrow}$ *carrier. If the contraction route preserves the located interval row* I *and the shrinkage ledger rows* L, D*, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R *is stable under componentwise* hsame *transport before the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *is passed to fixed-point endpoint consumers.*

Lean4 ✓ `BEDC.Derived.BishopIntervalContractionUp.BishopIntervalContractionRegSeqRatEndpointStability`

Proof. Project the carrier definition Definition 5867.1. The regular readback row R is downstream of the located interval, contraction, shrinkage, dyadic, and finite-window rows.

Apply the NameCert obligations of Definition 5867.2. They require contraction stability through I, F, L, D and bisection-compatible windows before the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows can be consumed.

Use the Cauchy handoff theorem Definition 5867.3. It places R on the same displayed route as I, F, L, D, W and exposes the terminal $\mathsf{Real}^{\uparrow}$ seal E only after that route has been read.

The componentwise hsame row H therefore transports the readback without changing the endpoint corridor. The packet supplies no host fixed-point object, chosen limit, quotient completion, countable-choice row, or ambient Real-completeness datum, so fixed-point endpoint consumers receive only the displayed RegSeqRat-to-Real handoff. □

Theorem 4694.5 (Bishop interval contraction endpoint readback)**.** *Every fixed-point endpoint consumer reading the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *from an accepted* $\mathsf{BishopIntervalContraction}^{\uparrow}$ *packet must first read the located interval row* I*, the contraction row* F*, the shrinkage ledger* L, D*, the* $\mathsf{StreamName}^{\uparrow}$ *windows* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and the structural rows* H, C, P, N*. Only after that displayed L10 route is present may the consumer hand* E *to* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *or* $\mathsf{BanachFixedPointStability}^{\uparrow}$*. The readback exports no host fixed point, chosen limit, quotient completion, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopIntervalContractionUp.BishopIntervalContractionEndpointReadback`

Proof. Project the accepted carrier of Definition 5867.1. The endpoint row E is terminal in the displayed inventory, and the only rows preceding it are the located interval, contraction, shrinkage, dyadic, window, and regular-rational readback rows.

Apply the Cauchy handoff of Definition 5867.3. It forces every completion-facing consumer to pass through $I, F, L, D, W, R, E, H, C, P, N$ before treating the contraction stages as a regular Cauchy real name.

The fixed-point endpoint consumer is a special consumer of that route. It may pass the terminal seal onward to $\mathsf{BishopFixedPointInterval}^{\uparrow}$ or $\mathsf{BanachFixedPointStability}^{\uparrow}$, but the handoff carries only the displayed rows and none of the excluded host fixed-point or completeness data. □

Theorem 4694.6 (Bishop interval contraction shrinkage composition)**.** *Let $B = (I, F, L, D, W, R, E, H, C, P, N)$ be an accepted $\mathsf{BishopIntervalContraction}^{\uparrow}$ carrier. If two accepted contraction-stage reads share the located interval row I and expose their shrinkage ledgers through the displayed rows L, D, then their composed finite stage route reaches W, R, E, H, C, P, N only through that same dyadic shrinkage budget. The composition exports no host fixed-point composition, selected limit, quotient completion, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.*

Proof. Project the carrier of Definition 5867.1. The only rows available for contraction-stage reads are the located interval row I, the contraction row F, and the shrinkage ledger rows L, D before any stream or completion-facing data is visible.

Use the NameCert obligations of Definition 5867.2. They force contraction stability through I, F, L, D, so two stage reads sharing I can be composed inside the certificate only by replaying the displayed dyadic shrinkage ledger.

Apply the Cauchy handoff of Definition 5867.3. The composed stage route reaches the finite windows W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback R, and the terminal $\mathsf{Real}^{\uparrow}$ seal E after the shared interval and shrinkage rows have been read.

Finally use endpoint readback from Definition 5867.5. The structural rows H, C, P, N preserve the same route for endpoint consumers, and no carrier coordinate supplies a host composition theorem, a selected fixed point, quotient completion, countable choice, or ambient Real completeness. □

Falsifiable prediction: An accepted $\mathsf{BishopIntervalContraction}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ seal without reading the displayed rows $I, F, L, D, W, R, E, H, C, P, N$ refutes the carrier surface.

Independence witness: located-interval-bisection, dyadicratcore, streamname, regseqrat, real, bishop-fixed-point-interval: no listed sibling supplies the joint packet containing a located interval source, contraction self-map, dyadic shrinkage ledger, finite windows, regular rational readback, terminal Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalContraction}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopIntervalContraction}^{\uparrow}$ packet is generated from a located interval row, a contraction self-map row, a dyadic shrinkage ledger, StreamName finite windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalContraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5867.1, Definition 5867.2, and Definition 5867.3 seed the finite interval-contraction route from located bisection and dyadic shrinkage data to regular Cauchy and Real-seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopIntervalContraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient real equality, selected limits, chosen infinite branches, countable choice, a host fixed-point theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, contraction stability, bisection compatibility, dyadic budget exactness, and Cauchy handoff for BEDC.Derived.BishopIntervalContractionUp.

Chapter 4695

A Concrete Naming Certificate for $\mathsf{SeminormedSpace}^{\uparrow}$

Following Bourbaki and Bishop–Bridges on seminormed and locally convex structures, the $\mathsf{SeminormedSpace}^{\uparrow}$ packet records the finite family-seminorm interface between the single norm route of chapter 1950, the displayed variation-seminorm ledger of chapter 5730, the locally convex family surface of chapter 3386, and completion-facing functional-analysis packets. It consumes the $\mathsf{VecSpace}^{\uparrow}$ source of chapter 47 and the $\mathsf{Real}^{\uparrow}$ scalar seal of chapter 38; it does not collapse finite seminorm families to one $\mathsf{Norm}^{\uparrow}$ row or to a host topology.

Definition 4695.1 (SeminormedSpace carrier)**.** *A* $\mathsf{SeminormedSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (V, R, I, F, Z, T, A, U, M, H, C, P, N)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *source row, exposing the vector carrier, classifier, zero vector, addition, negation, and scalar action only through displayed BEDC data.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar and budget row used by seminorm values, scalar absolute values, uniform entourages, and metric handoff tolerances.*
3. *I is the finite family-index row. It lists the displayed seminorm labels admitted by the packet and exposes no hidden index set.*
4. *F is the seminorm-family ledger. For each displayed index in I, it records the nonnegativity, zero-row compatibility, triangle, and scalar-budget rows of the corresponding seminorm read.*
5. *Z is the common zero-row compatibility ledger, comparing the vector zero classifier of V with every zero-value row displayed in F.*
6. *T is the triangle-budget ledger, routing every read of a displayed sum through vector addition in V, the selected seminorm row in F, and the real addition and order rows in R.*
7. *A is the scalar-budget ledger, routing every scalar multiplication read through scalar action in V, the absolute-value row in R, and the selected seminorm row in F.*
8. *U is the induced uniform-structure handoff row. It reads finite intersections of seminorm balls through I, F, R before any uniform consumer can inspect them.*
9. *M is the induced metric or pseudometric handoff row for downstream completion packets, available only after V, R, I, F, U have been displayed.*

10. *H records componentwise* hsame *transport for vector, Real, family-index, seminorm-ledger, zero, triangle, scalar, uniform, metric, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from every seminorm-family, uniform, or metric request through $V, R, I, F, Z, T, A, U, M, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{SeminormedSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{VariationSeminorm}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, *completion-facing functional-analysis rows,* BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{SeminormedSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host locally convex topology, a single hidden norm, a completed quotient, an unbounded seminorm index set, a selected Cauchy limit, or classical duality.

Lean4 ✓ `BEDC.Derived.SeminormedSpaceUp.TasteGate.SeminormedSpaceTasteGate single carrier alignment`

Theorem 4695.2 (SeminormedSpace NameCert obligations)**.** *For every accepted* $\mathsf{SeminormedSpace}^{\uparrow}$ *carrier*

$$S = (V, R, I, F, Z, T, A, U, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SeminormedSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed vector-space, Real, finite family-index, seminorm-family, zero, triangle, scalar, induced uniform, induced metric, transport, replay, provenance, and local naming rows;*
2. *family-index exposure, requiring every seminorm read to name an index from the finite row I before any value row in F can be consumed;*
3. *zero-row compatibility, requiring every zero seminorm read to compare with the displayed vector-zero classifier in V through Z and not through host vector equality;*
4. *triangle-budget routing, requiring reads of $p_i(x + y)$ to pass through vector addition in V, the i-row of F, and the addition and order rows of R;*
5. *scalar-budget routing, requiring reads of $p_i(ax)$ to pass through scalar action in V, the absolute-value and multiplication rows of R, and the selected seminorm row of F;*
6. *induced uniform and metric handoff, requiring U and M to be read only after V, R, I, F, Z, T, A are displayed;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming through H, C, P, N.*

No $\mathsf{SeminormedSpace}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5868.1. The accepted packet lists the vector-space, Real, finite index, seminorm-family, zero, triangle, scalar, uniform, metric, transport, replay, provenance, and local naming rows.

Family-index exposure comes next. A seminorm read first chooses a displayed index in I, and the corresponding row in F is the only place where nonnegativity, zero compatibility, triangle, and scalar-budget evidence may be read.

The zero, triangle, and scalar obligations are ledger routes. The row Z compares zero seminorm reads with the vector-zero classifier in V; the row T sends displayed sums through V, F, R; and the row A sends scalar multiples through V, R, F.

Finally U and M are handoff rows derived from the same family ledger. Transport, replay, provenance, and local naming preserve this route through H, C, P, N. Since the carrier has no host topology, hidden norm, completed quotient, unbounded index set, selected limit, or classical-duality coordinate, the listed rows exhaust the NameCert surface. □

Theorem 4695.3 (SeminormedSpace functional-analysis handoff)**.** *Every locally convex, variation-seminorm, normed-space comparison, or completion-facing functional-analysis consumer of an accepted* $\mathsf{SeminormedSpace}^{\uparrow}$ *packet must read the displayed route*

$$V, R, I, F, Z, T, A \longmapsto U, M \longmapsto H, C, P, N.$$

Thus the consumer receives a finite family of seminorm rows over $\mathsf{VecSpace}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, together with induced uniform and metric handoff data. It does not receive a single host norm, a host locally convex topology, an unbounded seminorm family, quotient completion, selected limits, or classical duality.*

Proof. Start with a downstream consumer request. A vector operation can be answered only from V, and a scalar or seminorm budget can be answered only after the Real row R and a displayed family index from I have been read.

Use Definition 5868.2. The seminorm-family ledger F is guarded by the zero, triangle, and scalar rows Z, T, A, so a consumer cannot inspect an induced uniform or metric handoff before the finite family surface has been exposed.

The rows U and M are therefore handoff rows rather than independent analytic objects. They package finite intersections of seminorm balls and metric or pseudometric reads for LocallyConvexSpace, VariationSeminorm, NormedSpace comparison, and completion-facing consumers.

The structural rows H, C, P, N transport, replay, source, and name the same packet. With no host norm, host locally convex topology, unbounded family, quotient completion, selected limit, or classical-duality row in the carrier, the displayed route is the entire handoff surface. □

Falsifiable prediction: An accepted $\mathsf{SeminormedSpace}^{\uparrow}$ consumer that reaches a locally convex, variation-seminorm, normed-space comparison, or completion-facing read without first exposing $V, R, I, F, Z, T, A, U, M, H, C, P, N$ refutes the packet.

Independence witness: normedspace, variation-seminorm, locally-convex-space, vecspace, real: no listed sibling is bijective to $\mathsf{SeminormedSpace}^{\uparrow}$ because this packet jointly binds finite family-index exposure, zero-row compatibility, triangle and scalar budget ledgers, induced uniform and metric handoff, transport, replay, provenance, and local naming over the displayed vector and Real rows.

Closure status for $\mathsf{NameCert}_{\mathsf{SeminormedSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SeminormedSpace}^{\uparrow}$ packet is generated from a displayed VecSpace row, a Real scalar row, a finite family-index row, a seminorm-family ledger, zero, triangle, and scalar budget ledgers, induced uniform and metric handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SeminormedSpace}^{\uparrow}}$, seed)

Scope closed: Definition 5868.1, Definition 5868.2, and Definition 5868.3 seed the finite family-seminorm interface consumed by locally convex, variation-seminorm, normed-space comparison, and completion-facing functional-analysis packets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SeminormedSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host locally convex topology, hidden single-norm reduction, unbounded seminorm families, quotient completions, selected limits, classical duality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, family-index exposure, zero-row compatibility, triangle and scalar budget routing, induced uniform and metric handoff, transport, replay, provenance, and local naming for BEDC.Derived.SeminormedSpaceUp.

Chapter 4696

A Concrete Naming Certificate for ReassignmentMassSubcube$^{\uparrow}$

The ReassignmentMassSubcube$^{\uparrow}$ packet realizes the maximum-mass subcube geometry branch of the DNA six-bit boundary tile analysis as finite NameCert data. It reads the reassignment weight row, the subcube mass ledger, and the nested maximum-mass subcube theorem of Definition 9462.1232 and Definition 9462.1233 through displayed codon-window and reassignment sibling packets. The packet consumes the CodonSixBitWindow$^{\uparrow}$ row of chapter 2234, the SixBoundaryTileCoverage$^{\uparrow}$ row of chapter 3470, the ReassignmentSupportCompression$^{\uparrow}$ row of chapter 3558, and the AlternativeCodeReassignmen row of chapter 3589 before any maximum-mass face can be named; it is not a biological mechanism claim, a host optimization oracle, or a hidden table-family search.

Definition 4696.1 (ReassignmentMassSubcube carrier)**.** *A* ReassignmentMassSubcube$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (W, B, S, A, R, Q, L, N, H, C, P, K)$$

with the following displayed rows:

1. *W is the* CodonSixBitWindow$^{\uparrow}$ *source-window row exposing the six coordinate bits for codon subcube reads.*
2. *B is the* SixBoundaryTileCoverage$^{\uparrow}$ *boundary-coverage row used to keep boundary-trigger coverage visible while subcubes are inspected.*
3. *S is the* ReassignmentSupportCompression$^{\uparrow}$ *support row, exposing the finite reassigned support and motif-cover surface.*
4. *A is the* AlternativeCodeReassignment$^{\uparrow}$ *comparison-table row from which reassignment weights are read.*
5. *R is the reassignment-weight row, recording each displayed codon weight $w(c)$ from the curated comparison surface.*
6. *Q is the finite subcube ledger, listing the inspected axis-aligned Q_5, Q_4, Q_3, Q_2 faces and their fixed-coordinate conditions.*
7. *L is the subcube-mass ledger, recording each displayed mass $M(S)$ as a finite sum over the visible weight row R.*
8. *N is the nested maximum-mass row, recording the unique maximum-mass chain $Q_5 \supset Q_4 \supset Q_3 \supset Q_2$ displayed by the source theorem.*

9. *H records componentwise* hsame *transport for source-window, boundary-coverage, support-compression, alternative-code, weight, subcube, mass, nested-chain, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from reassignment comparison to weights, from weights to finite subcube masses, and from masses to the nested maximum-mass row.*

11. *P is the* Pkg *provenance over* $\mathsf{ReassignmentMassSubcube}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{ReassignmentSupportCompression}^{\uparrow}$, $\mathsf{AlternativeCodeReassignment}^{\uparrow}$, *the source reassignment-mass geometry vision,* BHist, hsame, Cont, *and* NameCert.

12. *K is the local* $\mathsf{NameCert}_{\mathsf{ReassignmentMassSubcube}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these twelve rows. It has no coordinate for uncurated code tables, stochastic evolutionary dynamics, biochemical causality, a host argmax operator, quotient codon equality, or hidden biological semantics.

Theorem 4696.2 (ReassignmentMassSubcube NameCert obligations)**.** *For every accepted* ReassignmentMassSubcu *carrier $M = (W, B, S, A, R, Q, L, N, H, C, P, K)$, the local* $\mathsf{NameCert}_{\mathsf{ReassignmentMassSubcube}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed codon window, boundary coverage, support compression, alternative-code comparison, reassignment-weight, finite subcube, mass, nested maximum-mass, transport, replay, provenance, and local naming rows. The mass row must compute only finite sums over the displayed weight row, and the nested row must expose the unique maximum-mass chain only after W, B, S, A, R, Q, L are visible.*

Proof. Project the carrier of Definition 5869.1. The first four rows provide the source coordinate, boundary coverage, reassignment support, and alternative-table comparison surfaces.

The weight row R is then a finite comparison read from A, and the subcube ledger Q lists the inspected axis-aligned faces over the six-bit source window W. The mass ledger L can therefore compute only finite sums of displayed weights.

The nested maximum-mass row N is downstream of those finite sums. It records the displayed chain from the vision theorem rather than invoking a host optimization oracle.

Finally H, C, P, K transport, replay, source, and name the same packet. Since no uncurated table family, stochastic dynamics, biochemical mechanism, host argmax, quotient codon equality, or hidden biological semantics occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 4696.3 (ReassignmentMassSubcube sibling route)**.** *Every accepted* $\mathsf{ReassignmentMassSubcube}^{\uparrow}$ *read factors through*

$$\mathsf{CodonSixBitWindow}^{\uparrow}, \mathsf{SixBoundaryTileCoverage}^{\uparrow}, \mathsf{ReassignmentSupportCompression}^{\uparrow}, \mathsf{AlternativeCodeReassignment}^{\uparrow}$$

Thus a maximum-mass subcube claim is read as finite reassignment geometry over displayed codon coordinates, boundary-tile coverage, support compression, and alternative-code comparison rows. It cannot be consumed as a free-standing biological mechanism, host optimization theorem, unbounded genetic-code survey, or quotient of codon labels.

Proof. Begin with the sibling sources. The codon six-bit window supplies the coordinate carrier, the six-boundary tile coverage row keeps trigger support visible, the reassignment-support-compression row exposes the finite support surface, and the alternative-code-reassignment row supplies the comparison table data.

Only after those sources are displayed can the packet read reassignment weights and subcube masses. The rows R, Q, L bind the finite weights, inspected faces, and mass sums, while N records the nested maximum-mass chain.

The structural rows then preserve that route. Transport, replay, provenance, and local naming cannot add the excluded biological or host-optimization coordinates, so every accepted read remains inside the displayed sibling lattice. □

Falsifiable prediction: An accepted $\mathsf{ReassignmentMassSubcube}^{\uparrow}$ read is refuted if the finite maximum-mass subcube route can bypass reassignment-support-compression, alternative-code-reassignment, codon-six-bit-window, or six-boundary-tile-coverage rows.

Independence witness: reassignment-support-compression, alternative-code-reassignment, codon-six-bit-window, six-boundary-tile-coverage: no listed sibling is bijective with $\mathsf{ReassignmentMassSubcube}^{\uparrow}$ because the siblings respectively expose support compression, comparison-table reassignment, coordinate windows, or trigger coverage, while this packet jointly binds reassignment weights, subcube ledgers, finite mass sums, nested maximum-mass exposure, transport, replay, provenance, and local naming.

The Lean TasteGate.lean development for $\mathsf{ReassignmentMassSubcube}^{\uparrow}$ must include explicit Nontrivial $\mathsf{ReassignmentMassSubcube}^{\uparrow}$ and FieldFaithful $\mathsf{ReassignmentMassSubcube}^{\uparrow}$ instances preserving $W, B, S, A, R, Q, L, N, H, C, P, K$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{ReassignmentMassSubcube}^{\uparrow}}$.

Constructive story: A $\mathsf{ReassignmentMassSubcube}^{\uparrow}$ packet is generated from codon six-bit windows, six-boundary tile coverage rows, reassignment-support compression rows, alternative-code comparison rows, reassignment weights, finite subcube ledgers, mass sums, nested maximum-mass rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ReassignmentMassSubcube}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5869.1, Definition 5869.2, and Definition 5869.3 seed the finite maximum-mass subcube NameCert surface for reassignment geometry.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ReassignmentMassSubcube}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological mechanism, uncurated genetic-code surveys, stochastic evolutionary dynamics, host optimization, quotient codon equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sibling-source exposure, reassignment-weight exactness, finite subcube ledger exposure, mass-sum exactness, nested maximum-mass routing, Nontrivial ReassignmentMassSubcubeUp, and FieldFaithful ReassignmentMassSubcubeUp for BEDC.Derived.ReassignmentMassSubcubeUp.

Chapter 4697

A Concrete Naming Certificate for $\mathsf{CauchyInterlacing}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyInterlacing}^{\uparrow}$ packet records the finite interlacing route by which two regular rational names are merged into one Real-facing seal. It sits over the finite StreamName schedules of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance ledger of chapter 291, the tail-equivalence handoff of chapter 1738, and the terminal Real seal of chapter 38. The packet names the even/odd merge as displayed certificate data; it is not a quotient stream, selected limit, countable-choice schedule, or ambient completeness principle.

Definition 4697.1 (Cauchy interlacing carrier)**.** *A* $\mathsf{CauchyInterlacing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, B, W, D, T, R, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular tails are to be merged.*
2. *W is the even/odd* $\mathsf{StreamName}^{\uparrow}$ *schedule row. Even windows read A, odd windows read B, and the row records the finite requests needed by the merged consumer.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the two source tails and the interlaced tail.*
4. *T is the* $\mathsf{CauchyTailEquivalence}^{\uparrow}$ *handoff row witnessing that the even and odd tails feed the same regular Cauchy boundary.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after A, B, W, D, T have been displayed.*
6. *H records componentwise* hsame *transport for the two source rows, schedule, tolerance ledger, tail-equivalence handoff, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the finite route*

$$A, B, W, D, T \longmapsto R.$$

8. *P is the* Pkg *provenance over* $\mathsf{CauchyInterlacing}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyTailEquivalence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyInterlacing}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these rows. Its classifier compares accepted packets only through $A, B, W, D, T, R, H, C, P, N$ and has no coordinate for quotient stream equality, selected representatives, countable choice, host limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyInterlacingUp.CauchyInterlacingTasteGate single carrier alignment`

Theorem 4697.2 (Cauchy interlacing NameCert obligations)**.** *For every accepted* $\mathsf{CauchyInterlacing}^{\uparrow}$ *carrier*

$$K = (A, B, W, D, T, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyInterlacing}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *sources, even/odd* $\mathsf{StreamName}^{\uparrow}$ *schedule, dyadic tolerance ledger, tail-equivalence handoff, Real seal, transport, replay, provenance, and local naming row;*
2. *schedule discipline, requiring every merged read to identify whether it is reading the even source row A or the odd source row B through W;*
3. *dyadic tolerance exactness, requiring D to record the source-tail and merged-tail tolerances consumed by the interlacing route;*
4. *tail handoff stability, requiring T to mediate the passage from the two regular tails to one common Cauchy boundary before R is visible;*
5. *real-seal nonescape, requiring R to remain downstream of A, B, W, D, T;*
6. *componentwise transport, displayed replay, package provenance, and local naming stability through H, C, P, N;*
7. *ledger refusal, excluding quotient streams, selected limits, countable choice, host sequence limits, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No Cauchy interlacing obligation is stored outside these rows.

Proof. Project the accepted carrier $K = (A, B, W, D, T, R, H, C, P, N)$. The visible coordinates are exactly the two regular rational source rows, one finite even/odd schedule, one dyadic tolerance ledger, one tail-equivalence handoff, one Real seal row, and the structural rows.

The schedule row W fixes the finite interlacing order. Even requests read A and odd requests read B, so no merged consumer can inspect an unrecorded source position.

The dyadic ledger D and tail-equivalence row T then bind the two regular tails to one Cauchy boundary. The Real seal R is downstream of that route, while H, C, P, N transport, replay, source, and name the same displayed rows.

Since the excluded host objects have no carrier coordinate, replay edge, provenance entry, or local naming row, the listed rows exhaust the local NameCert surface. □

Theorem 4697.3 (Cauchy interlacing RegSeqRat handoff)**.** *Every accepted* $\mathsf{CauchyInterlacing}^{\uparrow}$ *carrier exposes the merged regular rational read only through the finite route*

$$A, B, W, D, T \longmapsto R \longmapsto H, C, P, N.$$

Thus a consumer receives the two $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the even/odd* $\mathsf{StreamName}^{\uparrow}$ *schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{CauchyTailEquivalence}^{\uparrow}$ *handoff, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise transport, continuation replay, provenance, and local naming before it can use the merged real-facing name.*

Proof. Start with the carrier projection. The two source rows A and B are independent displayed $\mathsf{RegSeqRat}^{\uparrow}$ inputs, and the only row that relates them to one merged stream is the even/odd schedule W.

Read the dyadic ledger and tail handoff. The row D supplies the tolerances for both source tails and for the interlaced tail, while T records the CauchyTailEquivalence passage from those two tails to one common boundary.

Only after A, B, W, D, T have been displayed can R be read as the Real-facing seal. The structural rows H, C, P, N preserve the same dependency order, so the merged regular rational handoff cannot bypass the displayed schedule or tolerance ledger. □

Theorem 4697.4 (Cauchy interlacing Real seal nonescape)**.** *An accepted* $\mathsf{CauchyInterlacing}^{\uparrow}$ *consumer that reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal must have already displayed the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the even/odd* $\mathsf{StreamName}^{\uparrow}$ *interlacing schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the* $\mathsf{CauchyTailEquivalence}^{\uparrow}$ *handoff. Consequently the seal cannot be used as a shortcut to quotient stream equality, selected limits, countable choice, host limit existence, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the seal row R from an accepted carrier. By the carrier definition, R is downstream of A, B, W, D, T and records only the Real-facing boundary reached from those displayed rows.

The replay row C has no branch beginning at R. It replays the route from the two regular rational sources through the even/odd schedule, dyadic tolerance ledger, and tail-equivalence handoff before the seal can be consumed.

The transport and provenance rows H and P preserve that route componentwise, and the local name N names only the displayed interlacing packet. Hence no excluded host object can escape through the Real seal. □

Falsifiable prediction: Every $\mathsf{CauchyInterlacing}^{\uparrow}$ Real-facing read factors through two RegSeqRat source rows, one even/odd StreamName schedule, one DyadicRatCore tolerance ledger, one CauchyTailEquivalence handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, local naming, and one terminal RealUp seal.

Independence witness: streamname, regseqrat, dyadicratcore, cauchy-tail-equivalence, real: $\mathsf{CauchyInterlacing}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two regular rational source rows, an even/odd interlacing schedule, a dyadic tolerance ledger, one tail-equivalence handoff, structural transport, replay, provenance, local naming, and a single Real-facing seal.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyInterlacing}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyInterlacing}^{\uparrow}$ packet is generated from two RegSeqRat source rows, one even/odd StreamName schedule, one DyadicRatCore tolerance ledger, one CauchyTailEquivalence handoff, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyInterlacing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5870.1, Definition 5870.2, Definition 5870.3, and Definition 5870.4 seed the finite constructive route for merging two regular rational names into one Real-facing seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyInterlacing}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient stream equality, selected limits, countable choice, host sequence limits, trichotomy, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, even/odd schedule discipline, dyadic tolerance exactness, CauchyTailEquivalence handoff, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyInterlacingUp.

Chapter 4698

A Concrete Naming Certificate for $\mathsf{RealLocallyCompact}^{\uparrow}$

Following Bishop–Bridges and Kelley local compactness, the $\mathsf{RealLocallyCompact}^{\uparrow}$ packet records the finite Real-facing route by which a displayed real endpoint receives a compact neighbourhood certificate. It refines the generic local compactness row of chapter 1726 over the real uniformity surface of chapter 3445, with endpoint data from chapter 38, finite windows from chapter 126, regular rational readback from chapter 301, dyadic radius accounting from chapter 291, closed ball rows from chapter 1451, and compact metric witnesses from chapter 129. The packet names the local closed-ball compactness surface for $\mathsf{Real}^{\uparrow}$; it does not supply a host-selected neighbourhood base, open-cover compactness theorem, quotient real equality, countable choice, or ambient completeness row.

Definition 4698.1 (Real locally compact carrier)**.** *A* $\mathsf{RealLocallyCompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, U, W, D, B, K, A, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *endpoint row whose local neighbourhood is inspected.*
2. *U is the* $\mathsf{RealUniformSpace}^{\uparrow}$ *entourage row attached to the same endpoint data.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to read endpoint names, entourage requests, and radius comparisons.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ *radius-accounting row, carrying dyadic radii and regular rational readback for the displayed window.*
5. *B is the* $\mathsf{MetricClosedBall}^{\uparrow}$ *row centred at the displayed real endpoint and radius.*
6. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *witness for the displayed closed-ball window.*
7. *A is the* $\mathsf{LocallyCompact}^{\uparrow}$ *handoff row, read only after R, U, W, D, B, K have been exposed.*
8. *H records componentwise* hsame *transport for the endpoint, uniformity, window, radius, closed-ball, compactness, handoff, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a Real local-neighbourhood request through $R, U, W, D, B, K, A, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{RealLocallyCompact}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealUniformSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{LocallyCompact}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLocallyCompact}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these displayed rows and exports no host neighbourhood selector, open-cover compactness, quotient real equality, countable choice, selected representative, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RealLocallyCompactUp.RealLocallyCompactUp`

Theorem 4698.2 (Real locally compact NameCert obligations)**.** *For every accepted* $\mathsf{RealLocallyCompact}^{\uparrow}$ *carrier* $L = (R, U, W, D, B, K, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealLocallyCompact}^{\uparrow}}$ *surface consists exactly of endpoint admission through R, real-uniform entourage exposure through U, finite-window routing through W, dyadic and regular-rational radius accounting through D, closed-ball exposure through B, compact metric witnessing through K, local compactness handoff through A, componentwise transport through H, replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5871.1. The endpoint and uniformity rows R, U provide the Real-facing source before any radius or compactness data are read.

The radius route is finite. The window row W selects the inspected names and tolerance requests, while D records the dyadic radius ledger and regular rational readback needed to form the closed-ball row B.

Compactness enters only through K for the displayed closed-ball window. The handoff row A then presents the same data to the generic $\mathsf{LocallyCompact}^{\uparrow}$ surface, not to an ambient neighbourhood base or open-cover compactness theorem.

Transport, replay, provenance, and local naming preserve the same rows through H, C, P, N. Since the carrier has no coordinate for quotient real equality, countable choice, selected representatives, or ambient completeness, the listed rows exhaust the local certificate. □

Theorem 4698.3 (Real locally compact handoff)**.** *Every Real or Completion consumer that reads local compactness from an accepted* $\mathsf{RealLocallyCompact}^{\uparrow}$ *packet factors through*

$$\mathsf{Real}^{\uparrow} \longmapsto \mathsf{RealUniformSpace}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{MetricClosedBall}^{\uparrow} \longmapsto \mathsf{CompactM}$$

The handoff exports only the displayed endpoint, uniformity, finite-window, radius-accounting, closed-ball, compact metric, transport, replay, provenance, and local naming rows of Definition 5871.1.

Proof. Start with a consumer request for a compact neighbourhood of a displayed real endpoint. The request first reads R and U, so the endpoint and real-uniformity data are fixed before any compactness row can be inspected.

Next read the finite radius route. The window row W and accounting row D expose the dyadic and regular-rational budget used to construct the closed-ball row B.

The compact witness K is attached to that same closed ball. The handoff row A is therefore a local compactness read over a displayed Real closed-ball window, not a host-selected neighbourhood or open-cover principle.

The structural rows H, C, P, N preserve the route for downstream Real and Completion consumers. No excluded equality, choice, selected representative, or ambient completeness row is available to the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealLocallyCompact}^{\uparrow}}$.

Constructive story: A $\mathsf{RealLocallyCompact}^{\uparrow}$ packet is generated from RealUp endpoint rows, RealUniformSpaceUp entourage rows, StreamName finite windows, DyadicRatCore and RegSeqRat radius accounting, a MetricClosedBall row, a CompactMetric witness, a LocallyCompact handoff, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLocallyCompact}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5871.1, Definition 5871.2, and Definition 5871.3 seed the Real-facing local compactness certificate over closed-ball and compact metric sibling rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLocallyCompact}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host neighbourhood bases, open-cover compactness, quotient real equality, countable choice, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, finite radius accounting, closed-ball compactness witnessing, local compactness handoff, replay stability, provenance exhaustion, and local naming for BEDC.Derived.RealLocallyCompactUp.

Chapter 4699

A Concrete Naming Certificate for CompactUniformModulusStability$^{\uparrow}$

Following the Bishop–Bridges compact finite-net proof of uniform continuity, the CompactUniformModulusStability$^{\uparrow}$ packet records the stability surface that keeps compact nets, pointwise moduli, lower-bound folds, and the final uniform-modulus handoff synchronized. It sits over the compact selector of chapter 914, the compact uniform modulus row of chapter 2299, the finite lower-bound fold of chapter 619, the consumer surface of chapter 369, the metric triangle estimate of chapter 1159, and the compact metric source of chapter 129. The packet supplies a finite stability object for compact-uniform consumers; it does not select a host modulus, a hidden center, a quotient equality, or an ambient compactness theorem.

Definition 4699.1 (Compact uniform modulus stability carrier)**.** *A* CompactUniformModulusStability$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, N, M, F, U, T, H, C, P, L)$$

with the following displayed rows:

1. K *is the* CompactMetric$^{\uparrow}$ *finite-net source row.*
2. N *is the* CompactNetModulusSelector$^{\uparrow}$ *selector row carrying bundled centers, pointwise radii, and selected precision data.*
3. M *is the* CompactUniformModulus$^{\uparrow}$ *compact-uniform handoff row.*
4. F *is the* FiniteLowerBoundFold$^{\uparrow}$ *row that synchronizes the finite radius ledger with the selected precision.*
5. U *is the downstream* UniformModulus$^{\uparrow}$ *consumer row.*
6. T *is the* MetricTriangleUniformEstimate$^{\uparrow}$ *row that transports the selected center estimates into the final source-target bound.*
7. H *records componentwise* hsame *transport for compact, selector, modulus, fold, triangle, consumer, replay, provenance, and local naming rows.*
8. C *records displayed* Cont *replay from a compact-uniform tolerance request through* $K, N, M, F, U, T, H, P, L$.
9. P *is the* Pkg *provenance over* CompactUniformModulusStability$^{\uparrow}$, CompactMetric$^{\uparrow}$, CompactNetModulusSelector$^{\uparrow}$, CompactUniformModulus$^{\uparrow}$, FiniteLowerBoundFold$^{\uparrow}$, UniformModulus$^{\uparrow}$, MetricTriangleUniformEstimate$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

10. L is the local $\mathsf{NameCert}_{\mathsf{CompactUniformModulusStability}^{\uparrow}}$ *row.*
The carrier compares accepted stability packets only through these rows. It contains no host compactness principle, selected center outside the finite net, external modulus function, quotient point equality, or choice schedule.

Lean4 ✓ `BEDC.Derived.CompactUniformModulusStabilityUp.CompactUniformModulusStabilityTasteGate single carrier alignment`

Theorem 4699.2 (Compact uniform modulus stability NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformModulusStability}^{\uparrow}$ *carrier* $S = (K, N, M, F, U, T, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulus}}$ *surface consists exactly of compact finite-net admission through* K*, compact selector exposure through* N*, compact-uniform modulus handoff through* M*, lower-bound fold synchronization through* F*, uniform-modulus consumer export through* U*, metric-triangle estimate transport through* T*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* L*.*

Proof. Project the carrier of Definition 5872.1. The compact source row K and selector row N provide the finite centers, pointwise modulus rows, subordinate radii, and selected precision before any consumer reads a modulus.

The lower-bound fold row F synchronizes those finite radius rows with the selected precision. The compact-uniform row M and uniform-modulus row U therefore read the same finite ledger rather than an external modulus function.

The triangle row T is the final estimate route. It uses the selected center and the two source-distance bounds already exposed by the selector and fold rows, so it cannot introduce a hidden center or host compactness argument.

Transport, replay, provenance, and local naming preserve the same packet through H, C, P, L. Since no excluded object appears among the coordinates, the listed rows exhaust the local certificate. □

Theorem 4699.3 (Compact uniform modulus stability handoff)**.** *Every compact-uniform-continuity consumer of an accepted* $\mathsf{CompactUniformModulusStability}^{\uparrow}$ *packet reads the stable route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{CompactNetModulusSelector}^{\uparrow} \longmapsto \mathsf{FiniteLowerBoundFold}^{\uparrow} \longmapsto \mathsf{MetricTriangleUniformEstimate}^{\uparrow}$$

Thus the consumer receives one synchronized finite packet of compact-net rows, pointwise-modulus rows, lower-bound fold data, selected precision, metric-triangle estimates, transport, replay, provenance, and local naming.

Proof. Start from a tolerance request. The compact metric row K and selector row N expose the finite net, selected center candidates, pointwise radii, and compact selector data.

Apply the fold row F. It binds the selected precision to the same finite radius ledger, so the request cannot move to a different center family or a host minimum.

Use the triangle estimate row T to transport the source bounds and pointwise estimates into the target bound consumed by M and then by U. The compact-uniform and uniform-modulus rows therefore receive the same synchronized finite route.

The structural rows H, C, P, L keep this route componentwise stable. No selected center outside the packet, quotient equality, choice schedule, host compactness, or external modulus function is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusStability}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformModulusStability}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, CompactNetModulusSelector rows, CompactUniformModulus rows, FiniteLowerBoundFold rows, UniformModulus consumer rows, MetricTriangleUniformEstimate rows, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5872.1, Definition 5872.2, and Definition 5872.3 seed the stability certificate tying compact-net selectors, folds, triangle estimates, compact-uniform rows, and uniform-modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host compactness, selected centers outside the finite packet, quotient point equality, choice schedules, external modulus functions, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, selector stability, fold synchronization, metric-triangle handoff, uniform-modulus export, replay stability, provenance exhaustion, and local naming for BEDC.Derived.CompactUniformModulu

Chapter 4700

A Concrete Naming Certificate for $\mathsf{CauchyFilterSelector}^{\uparrow}$

Following Bishop and Bridges and Kelley filter terminology, the $\mathsf{CauchyFilterSelector}^{\uparrow}$ packet records the finite selector interface by which a Cauchy-filter read can be inspected through named windows before any Real or Completion consumer reads the resulting boundary. It sits after the Cauchy-filter surface of chapter 333, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the completion handoff of chapter 1506. The packet gives the Phase Real and Completion route a finite selector row without quotient filters, host-selected representatives, countable choice, or ambient Real completeness.

Definition 4700.1 (Cauchy filter selector carrier)**.** *A* $\mathsf{CauchyFilterSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the source* $\mathsf{CauchyFilter}^{\uparrow}$ *row, including its displayed base packets, directed refinement ledger, and Cauchy evidence surface.*
2. *W is the finite selector-window row. It records the displayed filter request, the finite family of inspected base packets, and the chosen window among those already exposed by F.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the selected windows in W.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the filter request, the selector comparison, and the readback radius consumed by R.*
5. *E is the completion-or-Real seal row, read either as a* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff or as the downstream* $\mathsf{Real}^{\uparrow}$ *seal after F, W, R, D have been displayed.*
6. *H records componentwise* hsame *transport for the filter row, selector windows, regular readback, dyadic ledger, seal row, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from a Cauchy-filter request through F, W, R, D, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterSelector}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, W, R, D, E, H, C, P, N$. It has no coordinate for quotient filters, host-selected representatives, countable-choice schedules, host real equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyFilterSelectorUp.CauchyFilterSelectorTasteGate single carrier alignment`

Theorem 4700.2 (Cauchy filter selector NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterSelector}^{\uparrow}$ *carrier $S = (F, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source Cauchy-filter data, selector windows, regular readback, dyadic tolerance ledger, completion-or-Real seal, transport, replay, provenance, and local naming row;*
2. *selector-window exactness, requiring the selected window to be one of the finite windows already displayed in W over the source filter row F;*
3. *regular readback handoff, requiring every numeric read to pass through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R after the selector window is fixed;*
4. *dyadic ledger stability, requiring the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D to govern the selector comparison and the readback radius;*
5. *seal boundary, requiring any* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer to read E only after F, W, R, D have been displayed and replayed;*
6. *nonescape, excluding quotient filters, host-selected representatives, countable choice, host real equality, and ambient Real completeness.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5886.1. The visible packet consists of the source filter row F, selector windows W, regular readback R, dyadic ledger D, seal boundary E, and the structural rows H, C, P, N.

Selector-window exactness is row-local. The selector does not choose from an undisplayed filter; it names one of the finite windows stored in W and read over the already exposed Cauchy-filter row F.

The readback and tolerance obligations are ordered by the carrier. A numeric read reaches R only after W fixes the finite window, and the same dyadic ledger D supplies the tolerance budget for both the selector comparison and the regular readback radius.

The seal boundary is downstream. The replay row C routes every completion-facing or real-facing request through F, W, R, D before E, while H preserves this order under componentwise transport.

Since the carrier contains no quotient-filter coordinate, host-selected representative, choice schedule, host real equality, or Real completeness row, the listed obligations exhaust the local NameCert surface. □

Theorem 4700.3 (Cauchy filter selector RegSeqRat handoff)**.** *Let $S = (F, W, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyFilterSelector}^{\uparrow}$ *carrier. Every selector read that exports regular numerical data factors through the finite route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}.$$

Concretely, the source filter row F exposes the finite base request, the selector-window row W exposes the inspected $\mathsf{StreamName}^{\uparrow}$ *windows, the readback row R exposes the* $\mathsf{RegSeqRat}^{\uparrow}$ *data, and the dyadic ledger D supplies the tolerance budget used by that readback.*

Proof. Project the accepted carrier. The source request is held in F, but F alone does not expose a regular rational name to downstream consumers.

Replay the selector route by C. The request first reaches the finite selector windows W, and those windows are the only place where the relevant $\mathsf{StreamName}^{\uparrow}$ observations are visible.

After W is fixed, the readback row R supplies the $\mathsf{RegSeqRat}^{\uparrow}$ data. The tolerance row D is then read as the dyadic budget controlling the selector comparison and the regular readback.

Transport by H preserves the same order. Thus the handoff is a finite BEDC route from Cauchy filters to stream windows, regular readbacks, and dyadic tolerances, not a quotient of filters or a selected host representative. □

Theorem 4700.4 (Cauchy filter selector Real and completion seal boundary)**.** *For every accepted* $\mathsf{CauchyFilterSelector}^{\uparrow}$ *carrier* $S = (F, W, R, D, E, H, C, P, N)$*, every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer read exposed by* P *factors through the seal row* E *only after the source Cauchy-filter data, finite selector windows, regular readback, and dyadic tolerance ledger have been displayed. The visible boundary is*

$$F, W, R, D \longmapsto E \longmapsto H, C, P, N.$$

Therefore the packet provides a finite selector interface for the Real and Completion route without exporting quotient filters, host-selected representatives, countable choice, host real equality, or ambient Real completeness.

Proof. Read the seal row in the carrier. The row E is placed after the source filter data, selector windows, regular readback, and dyadic tolerance ledger, so a completion-facing or real-facing consumer cannot reach it from F alone.

The replay row C fixes the same order for every accepted request. It first consumes F, then the selector windows W, then the regular readback R, and then the dyadic tolerance ledger D before the seal row is available.

Componentwise transport by H does not add a new route. It preserves the displayed rows under classifier comparison, while P and N record only the provenance and local naming boundary of that finite route.

The excluded objects are absent from the carrier and from the replay path. Hence the completion-or-Real seal is exactly the displayed downstream boundary, not a quotient filter, selected representative, choice schedule, host equality, or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5886.1, Definition 5886.2, Definition 5886.3, and Definition 5886.4 seed the finite selector interface between CauchyFilter, StreamName, RegSeqRat, DyadicRatCore, Real, and MetricCompletion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient filters, host-selected representatives, countable choice, host real equality, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Lean closure requires carrier admission, selector-window exactness, RegSeqRat handoff, dyadic ledger stability, and Real or Completion seal boundary for BEDC.Derived.CauchyFilterSelectorUp.

Constructive story: The construction starts from a displayed CauchyFilter row, reads a finite selector window through StreamName observations, extracts RegSeqRat data under a DyadicRatCore tolerance ledger, and exposes Real or MetricCompletion access only through the downstream seal row.

The sandwich hub routes its cofinal common-tail read through chapter 7532 before the child files expose the lower and upper RegSeqRat readbacks.

Chapter 4701

A Concrete Naming Certificate for $\mathsf{RegularCauchySandwich}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchySandwich}^{\uparrow}$ packet names the two-sided bracketing surface used when regular Cauchy data is read by a real-completion consumer. It sits between the dyadic tolerance ledger of chapter 291, the finite window route of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the tail agreement boundary of chapter 1738. The packet records lower and upper regular tails as finite BEDC rows; it is not a quotient stream, a selected limit, a trichotomy principle, or an ambient completeness theorem.

Definition 4701.1 (Regular Cauchy sandwich carrier)**.** *A* $\mathsf{RegularCauchySandwich}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, U, T, D, W_L, W_U, R_L, R_U, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower regular-Cauchy row, read through* $\mathsf{RegSeqRat}^{\uparrow}$ *data.*
2. *U is the upper regular-Cauchy row, read through* $\mathsf{RegSeqRat}^{\uparrow}$ *data.*
3. *T is the common tail-agreement row inherited from* $\mathsf{CauchyTailEquivalence}^{\uparrow}$*.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling both bracket sides at the same precision request.*
5. *W_L and W_U are the finite* $\mathsf{StreamName}^{\uparrow}$ *windows opened for the lower and upper sides.*
6. *R_L and R_U are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows exposed after the windows are displayed.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after both sides, the common tail row, the dyadic ledger, the windows, and the readbacks have been consumed.*
8. *H records componentwise* hsame *transport for the lower side, upper side, tail row, ledger, windows, readbacks, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from each finite precision request through*

$$L, U, T, D, W_L, W_U, R_L, R_U \longmapsto E, H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySandwich}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CauchyTailEquivalence}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySandwich}^{\uparrow}}$ *row.*
The classifier accepts only packets in which the lower and upper regular rows, common tail agreement, dyadic tolerance ledger, finite windows, readbacks, and terminal seal belong to the same displayed bracketing route. It has no coordinate for quotient stream equality, selected limits, trichotomy, apartness decision, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4701.2 (Regular Cauchy sandwich NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySandwich}^{\uparrow}$ *carrier*

$$S = (L, U, T, D, W_L, W_U, R_L, R_U, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySandwich}^{\uparrow}}$ *surface consists exactly of lower regular-row exposure, upper regular-row exposure, common tail-agreement exposure, shared dyadic tolerance accounting, lower and upper finite-window exposure, lower and upper RegSeqRat readback, terminal Real seal routing, componentwise transport, continuation replay, package provenance, and local naming through N.*

Proof. Project the carrier tuple in Definition 5874.1. The lower and upper sides are displayed as L and U, and the only row that binds them is the common tail-agreement coordinate T.

The shared ledger D fixes the precision request for both sides. The finite windows W_L, W_U are opened against that same ledger, and the readback rows R_L, R_U expose exactly the inspected regular rational data.

The seal row E is downstream of those rows, while H, C, P, N transport, replay, source, and name the same packet. Since no excluded analytic coordinate occurs in the carrier, the local NameCert surface is exactly the displayed bracketing route. □

Theorem 4701.3 (Regular Cauchy sandwich window bracketing)**.** *Let*

$$S = (L, U, T, D, W_L, W_U, R_L, R_U, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchySandwich}^{\uparrow}$ *carrier. Every finite precision request consumed by the packet reads the two-sided route*

$$L, U, T, D \longmapsto W_L, W_U \longmapsto R_L, R_U \longmapsto E, H, P, N.$$

Thus lower and upper regular windows are bracketed by one displayed tolerance ledger and one common tail-agreement row, not by quotient representatives, selected limits, trichotomy, apartness decision, countable choice, host real equality, or ambient completeness.

Proof. Start with a finite precision request. The packet exposes only one dyadic tolerance ledger D, so both sides of the bracket are read against the same displayed tolerance data.

The lower and upper windows W_L, W_U are then opened after the common tail row T has been displayed. Their readbacks R_L, R_U remain attached to the same packet, so neither side can be replaced by an external quotient stream or a selected representative.

The terminal seal E is reached only after both readbacks. Transport, replay, provenance, and local naming through H, C, P, N preserve that order for every accepted request, which gives the claimed two-sided bracketing route. □

Theorem 4701.4 (Regular Cauchy sandwich Real seal nonescape)**.** *No* $\mathsf{Real}^{\uparrow}$ *seal read accepted by a* $\mathsf{RegularCauchySandwich}^{\uparrow}$ *carrier can bypass the displayed route through the lower and upper regular rows, common tail agreement, shared dyadic ledger, lower and upper StreamName windows,*

lower and upper RegSeqRat readbacks, and local structural rows. Equivalently, every accepted terminal seal read is attached to

$$S = (L, U, T, D, W_L, W_U, R_L, R_U, E, H, C, P, N)$$

and cannot be separated from those rows by quotient stream equality, selected limits, trichotomy, apartness decision, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 5874.2. It exposes the Real seal row E only as part of the local NameCert surface containing the two regular rows, common tail row, ledger, windows, readbacks, and structural rows.

Now use Definition 5874.3. Every precision request reaches the readbacks through the same two-sided route, so a seal read detached from one side of the bracket is not a read of this packet.

Finally inspect Definition 5874.1. The carrier contains no coordinate for quotient stream equality, selected limits, trichotomy, apartness decision, countable choice, host real equality, or ambient Real completeness. A purported seal read using such data therefore lies outside the accepted $\mathsf{RegularCauchySandwich}^{\uparrow}$ carrier. □

Theorem 4701.5 (Regular Cauchy sandwich Cantor intersection seal)**.** *Let* $S = (L, U, T, D, W_L, W_U, R_L, R_U, E, H$ *be an accepted* $\mathsf{RegularCauchySandwich}^{\uparrow}$ *carrier. If the lower and upper rows are supplied by a nested-shrink or Cantor-intersection route, then the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed by* S *is available only through the displayed sandwich route, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. In particular, the consumer-facing seal factors through Definition 5874.3, Definition 5874.4, chapter 4227, and chapter 7754, without asserting a selected intersection point.*

Proof. Apply Definition 5874.3. It forces every finite precision request for S through the common tail row, shared dyadic ledger, two StreamName windows, and two RegSeqRat readbacks before the seal row is visible.

The nested-shrink and Cantor-intersection inputs supply the lower and upper rows only as finite interval or shrink data. Those routes provide the source rows for the sandwich, but they do not add a coordinate for a selected point, quotient stream equality, or ambient completeness.

Now apply Definition 5874.4. Any terminal $\mathsf{Real}^{\uparrow}$ read detached from the displayed carrier is outside the accepted packet, so the Cantor-facing consumer receives only the finite sandwich seal route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySandwich}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchySandwich}^{\uparrow}$ packet is generated from lower and upper regular-Cauchy rows, a common tail-agreement row, a shared dyadic tolerance ledger, lower and upper StreamName windows, lower and upper RegSeqRat readbacks, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchySandwich}^{\uparrow}}$, seed)

Scope closed: Definition 5874.1, Definition 5874.2, Definition 5874.3, and Definition 5874.4 seed the finite two-sided regular-Cauchy bracketing route over DyadicRatCore, StreamName, RegSeqRat, Real, and CauchyTailEquivalence rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchySandwich}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, trichotomy, apartness decision, countable choice, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common tail exactness, shared dyadic tolerance accounting, two-sided StreamName window routing, RegSeqRat readback, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchySandwichUp.

Theorem 4701.6 (Regular Cauchy sandwich sibling dependency route)**.** *Every accepted* $\mathsf{RegularCauchySandwich}^{\uparrow}$ *sandwich packet depends on the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback rows of chapter 301 and the* $\mathsf{StreamName}^{\uparrow}$ *pointwise window rows of chapter 126 before it exposes a terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route consumes those siblings only through the displayed lower and upper windows, lower and upper regular readbacks, common tail row, shared dyadic ledger, transport, replay, provenance, and local naming rows of Definition 5874.1.*

Proof. Read the carrier rows from Definition 5874.1. The lower and upper windows W_L, W_U are the pointwise $\mathsf{StreamName}^{\uparrow}$ windows, and the rows R_L, R_U are the regular rational readbacks supplied by $\mathsf{RegSeqRat}^{\uparrow}$.

The bracketing theorem Definition 5874.3 orders every precision request through those windows and readbacks before the seal row is consumed. The Real-seal nonescape theorem Definition 5874.4 prevents bypass through quotient stream equality, selected limits, host real equality, or ambient completeness.

Thus the chapter's sibling dependency is the concrete route through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$, not an external analytic carrier. □

Theorem 4701.7 (Regular Cauchy sandwich cofinal tail-mesh dependency)**.** *Every accepted* $\mathsf{RegularCauchySandwic}$ *packet whose common tail row is presented cofinally must read the* $\mathsf{CofinalTailMesh}^{\uparrow}$ *route of chapter 7532 before the lower and upper* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks and the terminal* $\mathsf{Real}^{\uparrow}$ *seal are consumed. The dependency is the displayed route through the sandwich carrier, the window bracketing theorem, and the sibling dependency route; it is not an appeal to quotient streams, selected limits, trichotomy, choice, host real equality, or ambient completeness.*

Proof. Read the carrier rows in Definition 5874.1. The common tail coordinate T is displayed before the lower and upper StreamName windows, the lower and upper RegSeqRat readbacks, and the Real seal row.

When T is presented cofinally, consume the CofinalTailMesh route of chapter 7532. That route supplies the shared finite tail-window mesh before any Real or completion-facing seal is read.

Apply the window bracketing theorem Definition 5874.3. It keeps the lower and upper readbacks downstream of the common tail row and the shared dyadic ledger.

Finally use the sibling dependency route Definition 5874.6. It already requires the StreamName and RegSeqRat siblings before the Real seal, so adding the cofinal tail-mesh read fixes the horizontal dependency without adding any external analytic coordinate. □

Chapter 4702

A Concrete Naming Certificate for $\mathsf{DynamicProgramming}^{\uparrow}$

Following Bellman's finite dynamic programming principle, the $\mathsf{DynamicProgramming}^{\uparrow}$ packet records finite backward recursion data as BEDC NameCert rows. It sits after the finite path and edge ledger of chapter 236, the transition-row discipline of chapter 189, the probability-row carrier of chapter 184, the terminal real-name seal of chapter 38, and the finite horizon counter of chapter 28. The chapter names only finite states, finite actions, displayed transition and cost rows, horizon-indexed Bellman tables, policy readback, transport, replay, provenance, and local naming; it does not assert an infinite-horizon fixed point, host minimizer, choice-selected policy, quotient value equality, or ambient completeness theorem.

Definition 4702.1 (Dynamic programming carrier)**.** *A* $\mathsf{DynamicProgramming}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, A, T, C, H, V, P, R, N)$$

with the following displayed rows:

1. *S is the finite displayed state row, sharing its path endpoints with chapter 236.*
2. *A is the finite action row, listing exactly the actions admitted at the displayed states.*
3. *T is the transition row, read through the finite Markov and probability surfaces of chapter 189 and chapter 184.*
4. *C is the cost row, exposing the finite real-valued immediate costs and terminal costs through the* $\mathsf{Real}^{\uparrow}$ *seal.*
5. *H is the horizon row, a* $\mathsf{Nat}^{\uparrow}$*-indexed finite counter for the backward recursion stages.*
6. *V is the Bellman value table, giving one displayed value row for each state and horizon stage.*
7. *P is the policy readback row, recording only actions whose value entry is witnessed by the same finite transition and cost rows.*
8. *R records componentwise* hsame *transport, displayed* Cont *replay, and* Pkg *provenance over S, A, T, C, H, V, P and the cited sibling packets.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DynamicProgramming}^{\uparrow}}$ *row.*

The classifier reads accepted packets only through $S, A, T, C, H, V, P, R, N$. It has no coordinate for a host minimizer, selected infinite policy, analytic contraction theorem, quotient value function, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DynamicProgrammingUp.DynamicProgrammingTasteGate single carrier alignment`

Theorem 4702.2 (Dynamic programming Bellman obligations)**.** *For every accepted* $\mathsf{DynamicProgramming}^{\uparrow}$ *carrier* $D = (S, A, T, C, H, V, P, R, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DynamicProgramming}^{\uparrow}}$ *surface consists exactly of carrier admission for finite states, finite actions, transition rows, cost rows, horizon rows, Bellman value-table rows, policy readback rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and ledger refusal for host minimizers, selected infinite policies, quotient value equality, countable choice, and ambient completeness.*

Proof. Carrier admission is projection from Definition 5875.1. The finite state and action rows are displayed before transition and cost rows can be read, and the horizon row fixes which backward stages may appear.

The Bellman table row V is then read stage by stage over the same displayed horizon. A policy readback row P is exposed only after the corresponding state, action, transition, cost, and value rows have all been displayed.

Transport, replay, provenance, and local naming are exhausted by R and N. Since the carrier has no further coordinate beyond $S, A, T, C, H, V, P, R, N$, no accepted read can import a host minimizer, selected infinite policy, quotient value equality, countable choice, or ambient completeness. □

Theorem 4702.3 (Dynamic programming finite-horizon induction)**.** *Every accepted* $\mathsf{DynamicProgramming}^{\uparrow}$ *Bellman table is generated by finite backward induction over the displayed* $\mathsf{Nat}^{\uparrow}$ *horizon row. The terminal stage reads the terminal cost row from* C *and the* $\mathsf{Real}^{\uparrow}$ *seal; each predecessor stage reads only the previously displayed successor-stage value row, the transition row* T*, the action row* A*, the immediate cost row* C*, and the same local NameCert route.*

Proof. Project the horizon row H and read it through the unary source discipline of chapter 28. The empty endpoint is the terminal stage, so the value entry is the displayed terminal cost row sealed through $\mathsf{Real}^{\uparrow}$.

For a one-step predecessor, use the closed generation of the horizon row. The successor-stage table has already been displayed, and the new value row is computed from the finite transition row, finite action row, immediate cost row, and successor value row.

Repeating the one-step construction along the finite horizon supplies every value-table row. No step asks for an infinite horizon, a global fixed point, or an external minimizer; the induction is only the BEDC finite-history recursion named by the carrier. □

Theorem 4702.4 (Dynamic programming policy readback)**.** *Every policy row exported by an accepted* $\mathsf{DynamicProgramming}^{\uparrow}$ *packet is a readback from the displayed Bellman table. For each displayed state and horizon stage, the row* P *may expose an action only after the state row* S*, action row* A*, transition row* T*, cost row* C*, horizon row* H*, value row* V*, componentwise transport, replay, provenance, and local naming have all been read.*

Proof. Start with a policy-facing read. The carrier forces the read through the finite state and action rows, then through the transition and cost rows that define the local Bellman entry.

Next read the horizon row and the value-table row. The policy row is not an independent selector: it is attached to the displayed value entry at the same state and horizon stage.

Finally apply the structural row R and local naming row N. These rows preserve the finite route under transport and replay, so any action exposed by P remains tied to the same Bellman table entry and cannot become a host choice function or infinite policy. □

Theorem 4702.5 (Dynamic programming NameCert package)**.** *The* $\mathsf{DynamicProgramming}^{\uparrow}$ *NameCert package is the finite Bellman-recursion packet whose public surface is exactly the route*

$$\mathsf{Nat}^{\uparrow}, \mathsf{ShortestPath}^{\uparrow}, \mathsf{MarkovChain}^{\uparrow}, \mathsf{ProbSpace}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{DynamicProgramming}^{\uparrow}.$$

It exports the state, action, transition, cost, horizon, value-table, policy-readback, transport, replay, provenance, and local naming rows of Definition 5875.1. It exports no host optimization theorem, no selected global policy, no infinite-horizon convergence theorem, no quotient value-function equality, and no bridge to a standard dynamic-programming model.

Proof. The cited sibling chapters supply the input rows: shortest-path data for finite route endpoints, Markov and probability data for transition rows, real data for cost and value seals, and natural-number data for the finite horizon.

Apply Definition 5875.2 to identify the local obligation surface. Apply Definition 5875.3 to generate the value table from the terminal stage backward through the displayed horizon. Apply Definition 5875.4 to expose policy rows only as readbacks from that table.

The package is therefore a finite NameCert surface over the displayed rows. Because no carrier coordinate stores host optimization, global choice, infinite convergence, quotient equality, or a standard bridge, those objects are not exported. □

Falsifiable prediction: A claimed $\mathsf{DynamicProgramming}^{\uparrow}$ read that exposes a policy action without first displaying S, A, T, C, H, V, R, N refutes the finite Bellman carrier.

Independence witness: shortestpath, markovchain, probspace, real, nat: no listed sibling is bijective to $\mathsf{DynamicProgramming}^{\uparrow}$ because this packet binds finite state-action data, transition and cost rows, horizon-indexed Bellman value tables, policy readback, transport, replay, provenance, and local naming as one finite recursion surface.

Closure status for $\mathsf{NameCert}_{\mathsf{DynamicProgramming}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DynamicProgramming}^{\uparrow}$ packet is generated from finite state rows, finite action rows, transition rows, cost rows, a Nat-indexed horizon, Bellman value-table rows, policy readback rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DynamicProgramming}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5875.1, Definition 5875.2, Definition 5875.3, Definition 5875.4, and Definition 5875.5 seed the finite Bellman-recursion NameCert route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DynamicProgramming}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host minimizers, selected infinite policies, quotient value equality, infinite-horizon convergence, ambient RealUp completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, Bellman table construction, finite-horizon induction, policy readback exactness, transport, replay, provenance, and local naming for BEDC.Derived.DynamicProgrammingUp.

Chapter 4703

Regular Cauchy Even-Odd Substreams NameCert Construction

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$ packet records the standard constructive passage from one regular Cauchy name to its even and odd substreams before a Real or Completion consumer reads either side. It sits over the regular rational readback of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the two-source interleaving packet of chapter 414, and the finite interleaving criterion of chapter 3405. The packet supplies a displayed subsequence route for the L10 Real and Completion corridor; it does not choose a new limit, quotient streams, or import ambient completeness.

Definition 4703.1 (Regular Cauchy even-odd substreams carrier)**.** *A* $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, E, O, D, R, A, B, H, C, P, N)$$

with the following displayed rows:

1. *S is the source regular Cauchy row. It names one* $\mathsf{RegSeqRat}^{\uparrow}$ *source together with the finite precision requests inspected by the parity split.*
2. *E is the even selector-window row. It displays the finite windows read from the source at indices $2n$ and records no schedule beyond the even selector.*
3. *O is the odd selector-window row. It displays the finite windows read from the source at indices $2n + 1$ and records no schedule beyond the odd selector.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row. It stores the shared dyadic radius, split tolerance, comparison windows, and common-scale data used by both selector windows.*
5. *R is the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the even and odd windows under the budget D.*
6. *A is the* $\mathsf{Real}^{\uparrow}$ *seal boundary for the even readback, available only after S, E, D, R have been displayed.*
7. *B is the* $\mathsf{Real}^{\uparrow}$ *seal boundary for the odd readback, available only after S, O, D, R have been displayed.*

8. *H records componentwise* hsame *transport for the source, even selector windows, odd selector windows, dyadic budget, paired readbacks, two Real seal boundaries, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from an even or odd substream request through $S, E, O, D, R, A, B, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyInterleaving}^{\uparrow}$, $\mathsf{CauchyInterleavingCriterion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, E, O, D, R, A, B, H, C, P, N$. The carrier has no coordinate for quotient stream equality, a selected host limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyEvenOddSubstreamsUp.RegularCauchyEvenOddSubstreamsTasteGate`
`single carrier alignment`

Theorem 4703.2 (Regular Cauchy even-odd substreams NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$ *carrier*

$$X = (S, E, O, D, R, A, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source regular Cauchy row, even selector windows, odd selector windows, dyadic budget, paired readbacks, two Real seal boundaries, transport, replay, provenance, and local naming rows;*
2. *source visibility, requiring both parity branches to read the same displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source row S;*
3. *even-window exactness, requiring every even branch request to pass through the selector windows E and the budget D before any readback is visible;*
4. *odd-window exactness, requiring every odd branch request to pass through the selector windows O and the same budget D before any readback is visible;*
5. *paired regular readback admission through R, requiring the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks to use the selector windows and the shared dyadic ledger already displayed;*
6. *two Real seal boundaries through A and B, requiring the even and odd Real-facing reads to remain downstream from their parity windows, D, R, H, and C;*
7. *componentwise transport, displayed replay, package provenance, and local naming for exactly $S, E, O, D, R, A, B, H, C, P, N$;*
8. *refusal of quotient stream equality, selected host limits, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as local certificate data.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 5876.1. Its displayed inventory is exactly $S, E, O, D, R, A, B, H, C, P, N$, so the source row, parity selector windows, dyadic budget, paired readbacks, two seals, and structural rows exhaust the packet.

The source visibility clause is read from S. Both parity branches share that row, so neither branch can replace the source by a second hidden regular name.

Even-window and odd-window exactness are read from E and O under the shared dyadic row D. The even branch exposes only indices of the form $2n$, while the odd branch exposes only indices of the form $2n+1$, and both branches use the same tolerance ledger before the readback row is consumed.

The paired readback row R is downstream from those windows. It repacks the two selector routes as $\mathsf{RegSeqRat}^{\uparrow}$ readbacks without adding a quotient stream or selected host limit.

Finally the Real seals A and B are reached only after the corresponding parity route has been transported by H and replayed by C. Since P and N name only the displayed packet, the listed rows are the complete local NameCert surface. □

Theorem 4703.3 (Regular Cauchy even-odd Real-seal nonescape)**.** *Every Real or Completion consumer of an accepted* $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$ *carrier factors through one of the two finite parity routes*

$$S, E, D \longmapsto R \longmapsto A \longmapsto H, C, P, N,$$
$$S, O, D \longmapsto R \longmapsto B \longmapsto H, C, P, N.$$

The even route reads the even selector windows and the odd route reads the odd selector windows, but both routes share the same source row, dyadic budget, paired regular readback, transport, replay, provenance, and local naming. Hence no consumer reaches a $\mathsf{Real}^{\uparrow}$ *seal through quotient stream equality, a chosen host limit, countable choice, trichotomy, or ambient completeness.*

Proof. Apply the obligation surface of Definition 5876.2. It confines every accepted packet to the displayed source, two parity selector rows, one dyadic budget, paired readback, two seal rows, and structural data.

For an even request, the consumer reads S, E, D before R and then reaches A. The route has no coordinate other than the even selector windows and the shared budget, so the even seal cannot bypass the displayed packet.

For an odd request, the consumer reads S, O, D before R and then reaches B. This is the same source and budget route with the odd selector row in place of the even selector row.

The structural rows H, C, P, N transport, replay, source, and name the two routes componentwise. Because the carrier contains no quotient stream equality, selected host limit, countable-choice row, trichotomy branch, or ambient completeness coordinate, every Real or Completion consumer remains inside one of the two displayed parity routes. □

Theorem 4703.4 (Regular Cauchy parity cofinality)**.** *Let* $X = (S, E, O, D, R, A, B, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$ *carrier over one source* $\mathsf{RegSeqRat}^{\uparrow}$ *row* S*. The even selector windows* E *and the odd selector windows* O *determine cofinal tail-shift reads of that same source row. Their Real-facing seals factor through the same ordered four-face packet*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The assertion is only this cofinal finite-window factorization. It does not identify quotient streams, select a limit, use countable choice, use trichotomy, or invoke ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the source row S and the two selector-window rows E, O from Definition 5876.1. The rows are displayed as windows over one source $\mathsf{RegSeqRat}^{\uparrow}$ carrier, so no second regular name is introduced by the parity split.

Apply Definition 301.257 to transport late reads along the even and odd tail shifts. The tail-shift result keeps each parity branch inside the same regular-rational source route.

Next use Definition 126.670. It supplies one finite request section for the displayed selector windows, so both parity reads are compared at the finite StreamName surface rather than at a completed stream quotient.

Apply Definition 1647.3 to fuse the two parity budgets through the shared dyadic tolerance ledger. The shared D row is the DyadicRatCore face of the ordered packet.

Finally use Definition 38.713. The terminal Real seal is reached only after the dyadic budget, finite StreamName window, and RegSeqRat readback have been displayed. Thus the two parity seals are cofinal views of the same finite four-face route, with no selected limit, countable-choice selector, trichotomy branch, quotient stream equality, or ambient completeness principle. □

Falsifiable prediction: Every $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$ Real or Completion read is refuted if it reaches either $\mathsf{Real}^{\uparrow}$ seal without displaying the source RegSeqRat row, the selected even or odd StreamName windows, the shared DyadicRatCore budget, the paired RegSeqRat readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: regseqrat, streamname, dyadicratcore, real, regular-cauchy-interleaving, cauchy-interleaving-criterion: $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries one source regular Cauchy name, two parity selector-window routes, one shared dyadic budget, paired regular readbacks, two Real seal boundaries, transport, replay, provenance, and local naming as one displayed packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}$ packet is generated from one RegSeqRat source, even selector windows, odd selector windows, a shared DyadicRatCore budget, paired RegSeqRat readbacks, two RealUp seal boundaries, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5876.1, Definition 5876.2, Definition 5876.3, and Definition 5876.4 seed the parity-substream route used by L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyEvenOddSubstreams}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, quotient stream equality, selected host limits, countable choice, trichotomy, ambient RealUp completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, parity-window exactness, shared dyadic budget exactness, paired regular readback admission, two Real-seal nonescape clauses, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.RegularCauchyEvenOddSubstreamsUp.

Chapter 4704

A Concrete Naming Certificate for $\mathsf{SchwartzSpace}^{\uparrow}$

Following Schwartz and Treves on test-function spaces, the $\mathsf{SchwartzSpace}^{\uparrow}$ packet records the finite locally convex carrier surface behind rapidly decreasing smooth test functions. It sits beside the complete locally convex interface of chapter 3495, the finite family-seminorm route of chapter 5868, the pointwise test-function carrier of chapter 3399, and the derivative observation route of chapter 2210. The packet gives Fourier, tempered-distribution, weak-derivative, and PDE-facing consumers a displayed test-function-space surface without importing a host topological vector space, quotient function equality, unrestricted seminorm enumeration, selected representatives, or classical completeness.

Definition 4704.1 (SchwartzSpace carrier)**.** *A* $\mathsf{SchwartzSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, V, I, G, D, R, T, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FrechetSpace}^{\uparrow}$ *source row, exposing complete metrizability and locally convex handoff only through the displayed Frechet carrier.*
2. *V is the* $\mathsf{SeminormedSpace}^{\uparrow}$ *finite-family row, naming the seminorm labels used by the Schwartz test-function space read.*
3. *I is the* $\mathsf{SchwartzFunction}^{\uparrow}$ *test-function row, recording the accepted rapidly decreasing smooth windows inspected by the packet.*
4. *G is the polynomial-growth and rapid-decay ledger. It binds each displayed seminorm index to a derivative order, a polynomial weight, and the real-valued budget read used to test decay.*
5. *D is the* $\mathsf{WeakDerivative}^{\uparrow}$ *stability row, recording derivative-window shifts and sign conventions that remain inside the same Schwartz test-function-space surface.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar readback row used by seminorm values, decay budgets, and completion-facing estimates.*
7. *T is the completion and distribution nonescape row. It permits Frechet and tempered-distribution consumers to read the displayed test-function-space boundary only after F, V, I, G, D, R have been exposed.*

8. *H records componentwise* hsame *transport for Frechet, seminorm-family, test-function, rapid-decay, derivative, Real, nonescape, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from every test-function-space request through $F, V, I, G, D, R, T, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{SchwartzSpace}^{\uparrow}$, $\mathsf{FrechetSpace}^{\uparrow}$, $\mathsf{SeminormedSpace}^{\uparrow}$, $\mathsf{SchwartzFunction}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SchwartzSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host Schwartz topology, a quotient of functions, an unrestricted seminorm family, a selected completion point, a distribution dual, nuclearity, Fourier inversion, or classical choice.

Lean4 ✓ `BEDC.Derived.SchwartzSpaceUp.SchwartzSpaceTasteGate single carrier alignment`

Theorem 4704.2 (SchwartzSpace NameCert obligations)**.** *For every accepted* $\mathsf{SchwartzSpace}^{\uparrow}$ *carrier*

$$S = (F, V, I, G, D, R, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchwartzSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed Frechet-space, seminorm-family, Schwartz-function, rapid-decay, weak-derivative, Real, nonescape, transport, replay, provenance, and local naming rows;*
2. *seminorm growth routing, requiring every seminorm read to choose a displayed finite-family row in V and a polynomial-growth budget in G before a Real value can be consumed from R;*
3. *rapid-decay test-function closure, requiring every accepted test window from I to satisfy the displayed derivative-order and polynomial-weight ledger in G;*
4. *derivative-row stability, requiring weak-derivative shifts to pass through D and return to the same I, G, R surface rather than to host smooth-function equality;*
5. *completion and distribution nonescape, requiring T to mediate every Frechet, completion-facing, Fourier-facing, tempered-distribution, or PDE-facing read after F, V, I, G, D, R have been displayed.*

No $\mathsf{SchwartzSpace}^{\uparrow}$ *obligation is stored outside these rows.*

Lean4 ✓ `BEDC.Derived.SchwartzSpaceUp.TasteGate.SchwartzSpaceTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 5877.1. The analytic rows are exactly F, V, I, G, D, R, T, and the structural rows are exactly H, C, P, N.

Seminorm growth routing is forced by the order of the carrier. A consumer first reads the finite family row V, then the derivative and polynomial-weight budget in G, and only then may read a Real scalar estimate through R.

Rapid-decay closure and derivative stability are the two test-function-space checks. The row I supplies accepted Schwartz test windows, while G records their rapid-decay budgets and D records the weak-derivative shifts that stay inside the same displayed surface.

Finally T is a boundary row rather than an additional topological object. It lets Frechet, completion-facing, Fourier-facing, tempered-distribution, and PDE consumers replay the same rows without receiving a host Schwartz topology, quotient function equality, selected completion point, distribution dual, nuclearity, inversion theorem, or choice principle. Thus the listed rows exhaust the local NameCert obligations. □

Theorem 4704.3 (SchwartzSpace functional-analysis handoff)**.** *Every accepted* $\mathsf{SchwartzSpace}^{\uparrow}$ *packet exported to a Frechet, Fourier, tempered-distribution, weak-derivative, or PDE-facing consumer factors through*

$$\mathsf{FrechetSpace}^{\uparrow},\ \mathsf{SeminormedSpace}^{\uparrow},\ \mathsf{SchwartzFunction}^{\uparrow},\ \mathsf{WeakDerivative}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto F, V, I, G, D, R, T, H, C, P, N.$$

The exported object is a finite test-function-space NameCert surface with displayed seminorm growth budgets and derivative stability. It is not a host locally convex function space, an unrestricted seminorm enumeration, a selected completion, a dual-space quotient, or a classical distribution theorem.

Proof. Open the accepted carrier using Definition 5877.1. Any functional-analysis request must first choose one of the displayed source rows F, V, I, D, R and then pass through the growth ledger G.

Use Definition 5877.2. The seminorm and rapid-decay obligations keep polynomial weights and derivative orders attached to finite displayed rows, while the derivative-row obligation prevents a consumer from replacing weak-derivative stability by host smooth-function equality.

The nonescape row T is then the only export boundary. Transport, replay, provenance, and local naming through H, C, P, N preserve the same finite route for every downstream consumer. Since no excluded host object is a carrier coordinate, the displayed route is the whole handoff surface. □

Falsifiable prediction: An accepted $\mathsf{SchwartzSpace}^{\uparrow}$ consumer that reaches a Frechet, Fourier, tempered-distribution, weak-derivative, or PDE-facing read without first exposing $F, V, I, G, D, R, T, H, C, P, N$ refutes the carrier surface of Definition 5877.1.

Independence witness: frechet-space, seminormed-space, schwartz-function, weak-derivative, real: no listed sibling is bijective to $\mathsf{SchwartzSpace}^{\uparrow}$ because this packet jointly binds complete locally convex source rows, finite seminorm-family exposure, rapid-decay test-function windows, derivative stability, Real budget readback, completion and distribution nonescape, transport, replay, provenance, and local naming in one test-function-space carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{SchwartzSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SchwartzSpace}^{\uparrow}$ packet is generated from a FrechetSpace row, a finite SeminormedSpace family row, SchwartzFunction test windows, rapid-decay and polynomial-growth ledgers, WeakDerivative stability rows, Real scalar readback, completion and distribution nonescape, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SchwartzSpace}^{\uparrow}}$, seed)

Scope closed: Definition 5877.1, Definition 5877.2, and Definition 5877.3 seed the finite locally convex test-function-space surface consumed by Frechet, Fourier, tempered-distribution, weak-derivative, and PDE-facing packets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SchwartzSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host Schwartz topology, quotient function equality, unrestricted seminorm enumeration, selected completion, distribution duality, nuclearity, Fourier inversion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, seminorm growth routing, rapid-decay test-function closure, derivative-row stability, completion and distribution nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SchwartzSpaceUp.

Chapter 4705

A Concrete Naming Certificate for $\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$

The $\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$ packet realizes the private/shared decoration model of chapter 9390 as finite Rule 110 classifier-decoration NameCert data. It consumes the cellular automaton carrier of chapter 934, the row-classifier surface of chapter 941, the finite pattern catalog of chapter 995, the Rule 110 classifier of chapter 5844, and the finite partition carrier of chapter 201. The packet names quotient support families, private blocks, shared-coordinate incidence rows, Rule 110 pattern-classifier rows, decoration-count provenance, transport, replay, provenance, and local naming; it does not import a host cellular semantics, an infinite orbit classifier, quotient support equality, a biological model, or a hidden enumeration oracle.

Definition 4705.1 (Rule 110 private/shared decoration carrier)**.** *A* $\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (Q, B, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the quotient support family row, naming the finite family of support blocks inspected by the decoration.*
2. *B is the private-block row, recording for each accepted support a displayed nonempty private coordinate block.*
3. *S is the shared-coordinate incidence row. For each shared coordinate it records the displayed set of incident private blocks and requires cardinality at least two.*
4. *R is the* $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ *row, attaching the decorated support family to finite Rule 110 row-window and pattern-tag reads.*
5. *E is the decoration-count provenance row. It records the partition and row-set enumeration data used by the private/shared decoration theorem without exposing a host generating-function oracle.*
6. *H records componentwise* hsame *transport for quotient support, private-block, shared-incidence, classifier, enumeration, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a decoration request through Q, B, S, R, E, H, P, N.*

8. *P is the* Pkg *provenance over* RuleOneTenPrivateSharedDecoration$^{\uparrow}$, CellularAutomaton$^{\uparrow}$, CellularRowClassifier$^{\uparrow}$, CellularPatternCatalog$^{\uparrow}$, RuleOneTenPatternClassifier$^{\uparrow}$, Partition$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

9. *N is the local* NameCert$_{\text{RuleOneTenPrivateSharedDecoration}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for absent private blocks, singleton shared incidence, host quotient equality, unbounded Rule 110 evolution, biological interpretation, or an external enumeration procedure.

Theorem 4705.2 (Rule 110 private/shared decoration NameCert obligations)**.** *For every accepted* RuleOneTenPrivateSharedDecoration$^{\uparrow}$ *carrier*

$$D = (Q, B, S, R, E, H, C, P, N),$$

the local NameCert$_{\text{RuleOneTenPrivateSharedDecoration}^{\uparrow}}$ *surface consists exactly of quotient support family admission through Q, private-block nonemptiness through B, shared-coordinate incidence through S, Rule 110 pattern-classifier routing through R, decoration-count provenance through E, componentwise* hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5878.1. The decoration data are exactly the quotient support row Q, the private-block row B, the shared-incidence row S, the Rule 110 classifier row R, and the enumeration provenance row E.

Private-block nonemptiness is read before a support can be accepted. Shared-coordinate incidence is then read as a displayed row set of size at least two, so a shared coordinate cannot be collapsed into a private coordinate or erased from the decoration.

The Rule 110 classifier row R attaches the decorated support family to finite row-window and pattern-tag reads from the cellular siblings. The count provenance row E records the finite partition and row-set enumeration route and does not supply an external counting oracle.

Finally H, C, P, N transport, replay, source, and name the same carrier. Since no excluded host object is present as a coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 4705.3 (Private/shared decoration classifier handoff)**.** *Every accepted* RuleOneTenPrivateSharedDecorati *consumer that reads a decorated Rule 110 support family factors through*

$$\text{CellularAutomaton}^{\uparrow},\ \text{CellularRowClassifier}^{\uparrow},\ \text{CellularPatternCatalog}^{\uparrow},\ \text{RuleOneTenPatternClassifier}^{\uparrow},\ \text{Partition}^{\uparrow} \longmapsto Q$$

The exported object is a finite classifier-decoration packet with private-block nonemptiness, shared incidence, and decoration-count provenance. It is not an infinite cellular-orbit classifier, a host quotient-support equality, a biological stochastic model, or an unrestricted enumeration theorem.

Proof. Open the accepted carrier using Definition 5878.1. A support-family read can inspect only Q, and each support must expose its nonempty private block through B before shared coordinates are consumed.

The shared-coordinate row S supplies the incidence sets whose size is at least two. The classifier row R then routes the accepted decoration into the existing cellular automaton, row-classifier, pattern-catalog, and Rule 110 pattern-classifier surfaces.

The provenance row E records the finite decoration-count route, while H, C, P, N preserve the same data under transport, replay, package provenance, and local naming. Thus every accepted consumer receives exactly the displayed finite packet and none of the excluded host semantics. □

Falsifiable prediction: Any accepted $\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$ consumer that omits private-block nonemptiness or shared-coordinate incidence rows while reading a decorated Rule 110 support family refutes the carrier surface of Definition 5878.1.

Independence witness: cellularautomaton, cellularrowclassifier, cellularpatterncatalog, rule110patternclassifier: no listed sibling is bijective to $\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$ because this packet jointly binds quotient support families, nonempty private blocks, shared-coordinate incidence, Rule 110 classifier routing, decoration-count provenance, transport, replay, provenance, and local naming.

The Lean TasteGate file for this packet must provide $\mathsf{Nontrivial}\ \mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$ instances for the displayed rows $Q, B, S, R, E, H, C, P, N$ before the decoration carrier can serve as a verified classifier-decoration consumer.

Closure status for $\mathsf{NameCert}_{\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}}$.

Constructive story: A $\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}$ packet is generated from quotient support family rows, nonempty private-block rows, shared-coordinate incidence rows, Rule 110 pattern-classifier rows, decoration-count provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5878.1, Definition 5878.2, and Definition 5878.3 seed the finite private/shared classifier-decoration surface for Rule 110 support-family consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RuleOneTenPrivateSharedDecoration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close infinite Rule 110 orbit classification, host quotient-support equality, biological interpretation, unrestricted enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked quotient support admission, private-block nonemptiness, shared-coordinate incidence, Rule 110 classifier routing, decoration-count provenance, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.RuleOneTenPrivateSharedDecorationUp.

Chapter 4706

A Concrete Naming Certificate for $\mathsf{ConstructiveCantorTheorem}^{\uparrow}$

Following Cantor and Bishop–Bridges, the $\mathsf{ConstructiveCantorTheorem}^{\uparrow}$ packet records the finite diagonal obstruction to enumerating Cantor-space bit names. It sits over the binary prefix carrier of chapter 1475, the finite bar-facing tree discipline of chapter 1622, the fan-theoretic bounded-window route of chapter 400, and the Real-facing non-surjection boundary of chapter 3793. The packet names only finite rows: an attempted enumeration window, its displayed diagonal bit schedule, the disagreement row at each inspected index, and the no-enumeration handoff. It is not a host-cardinality theorem, not a completed powerset construction, and not a quotient-stream principle.

Definition 4706.1 (Constructive Cantor finite diagonal carrier)**.** *A* $\mathsf{ConstructiveCantorTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (E, W, D, G, T, F, R, H, C, P, N)$$

with the following visible rows:

1. *E is the displayed finite enumeration attempt row, listing the first n candidate Cantor-space names through finite prefix windows;*
2. *W is the finite binary observation window, naming the inspected coordinates and the finite prefix depth used for each candidate;*
3. *D is the diagonal-bit row, obtained by flipping the displayed ith bit of the ith candidate whenever that coordinate is present in W;*
4. *G is the disagreement ledger, recording for every inspected index $i < n$ that the diagonal row disagrees with the ith candidate at the displayed coordinate;*
5. *T is the tree-read row through* $\mathsf{KleeneTree}^{\uparrow}$*, ensuring that finite prefix extension and absence of a completed path are read as finite branch data;*
6. *F is the fan-window row through* $\mathsf{FanTheorem}^{\uparrow}$*, recording the bounded prefix surface consumed by any compact Cantor-space handoff;*
7. *R is the Real-facing route through* $\mathsf{RealDiagonalNonSurjection}^{\uparrow}$*, used only after the Cantor-space disagreement ledger has been displayed;*

8. *H records componentwise* hsame *transport for enumeration rows, prefix windows, diagonal bits, disagreement ledgers, tree rows, fan rows, Real-facing routes, replay rows, provenance, and local naming;*
9. *C records displayed* Cont *replay from an enumeration window to diagonal-bit construction, disagreement verification, Cantor-space handoff, and Real-facing non-surjection routing;*
10. *P is the* Pkg *provenance over* ConstructiveCantorTheorem$^{\uparrow}$, CantorSpace$^{\uparrow}$, KleeneTree$^{\uparrow}$, FanTheorem$^{\uparrow}$, RealDiagonalNonSurjection$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* NameCert$_{\text{ConstructiveCantorTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, W, D, G, T, F, R, H, C, P, N$. It has no coordinate for a completed enumeration of all binary streams, host powersets, quotient stream equality, countable choice, or classical cardinal comparison.

Theorem 4706.2 (Finite diagonal obligations)**.** *For every accepted* ConstructiveCantorTheorem$^{\uparrow}$ *carrier $K = (E, W, D, G, T, F, R, H, C, P, N)$, the local* NameCert$_{\text{ConstructiveCantorTheorem}^{\uparrow}}$ *surface consists exactly of finite enumeration-window admission through E, binary observation through W, diagonal-bit formation through D, inspected-index disagreement through G, tree and fan routing through T, F, Real-facing non-surjection routing through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.ConstructiveCantorTheoremUp.ConstructiveCantorTheoremTasteGate single carrier alignment`

Proof. Project the carrier of Definition 5879.1. The enumeration and observation rows are E and W, so every candidate read is confined to a displayed finite prefix window.

Build the diagonal row by induction on the finite index spine of W. The empty window contributes no bit and no disagreement row. At a successor index, read the displayed candidate bit at the diagonal coordinate and place the opposite bit in D.

The same induction fills G. Each successor step adds exactly the disagreement between the new diagonal bit and the candidate bit just inspected, while previous rows are transported componentwise by H and replayed by C.

The rows T, F, R do not add an infinite object. They only route the same finite disagreement ledger through the Kleene-tree, fan-window, and Real-facing non-surjection surfaces, so the listed rows exhaust the certificate without a host powerset, quotient stream equality, choice principle, or classical cardinal comparison. □

Theorem 4706.3 (No-enumeration window)**.** *Let K be an accepted* ConstructiveCantorTheorem$^{\uparrow}$ *carrier with a displayed enumeration window E of length n. The diagonal row D determines a Cantor-space prefix window such that for every inspected index $i < n$, the ith candidate of E differs from D at the displayed diagonal coordinate recorded in G. Hence the window cannot certify that its listed candidates exhaust the displayed Cantor-space prefixes.*

Proof. Induct on the finite enumeration window. For the empty window, there is no inspected candidate and the exhaustion claim has no displayed row.

At a successor window, the induction hypothesis supplies the disagreement rows for the previous candidates. The new candidate has a displayed diagonal coordinate in W, and the diagonal construction places the opposite binary value in D.

The new row of G records this disagreement. Componentwise hsame transport preserves the previous rows and the displayed Cont replay keeps the construction inside the same finite packet.

Therefore every inspected candidate is separated from the diagonal prefix at its own displayed coordinate. A finite window containing these disagreement rows cannot also certify that the same listed candidates exhaust the displayed Cantor-space prefix surface. □

Theorem 4706.4 (Cantor-space handoff)**.** *Every downstream consumer of a* ConstructiveCantorTheorem$^{\uparrow}$ *packet receives only the finite handoff formed by the enumeration window, binary observation window, diagonal-bit row, disagreement ledger, Kleene-tree row, fan-window row, Real-facing non-surjection route, transport, replay, provenance, and local naming. The handoff may be read by* CantorSpace$^{\uparrow}$ *and then by* RealDiagonalNonSurjection$^{\uparrow}$*, but it exports no completed stream quotient, powerset object, countable-choice selector, or classical uncountability principle.*

Proof. Start with the finite rows E, W, D, G of the carrier. By Definition 5879.2, these are the only rows that form and verify the diagonal disagreement.

Next read the Cantor-space side through chapter 1475. The Kleene-tree and fan rows T, F preserve finite prefix extension and bounded-window routing; they do not select a completed path or add an ambient compactness theorem.

Finally route the same disagreement ledger to chapter 3793 through R. Since the carrier has no coordinate for quotient stream equality, countable choice, host powersets, or classical cardinal comparison, the consumer receives exactly the finite handoff named in the statement. □

Falsifiable prediction: A purported ConstructiveCantorTheorem$^{\uparrow}$ consumer that reads a no-enumeration conclusion while omitting the enumeration window, diagonal-bit row, inspected-index disagreement ledger, Cantor-space prefix row, transport, replay, provenance, or local naming refutes the packet.

Independence witness: cantorspace, kleene-tree, fantheorem, real-diagonal-non-surjection: ConstructiveCantorT is not bijective to any listed sibling because it jointly carries an attempted enumeration window, a diagonal-bit construction, an inspected-index disagreement ledger, and a downstream Cantor-space-to-Real non-surjection route in one finite NameCert packet.

Closure status for NameCert$_{\text{ConstructiveCantorTheorem}^{\uparrow}}$**.**

Theory closure: TheoryGate(NameCert$_{\text{ConstructiveCantorTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 5879.1, Definition 5879.2, Definition 5879.3, and Definition 5879.4 seed the finite diagonal non-enumeration packet over Cantor-space prefix rows.

Formal verification: FormalStatus(NameCert$_{\text{ConstructiveCantorTheorem}^{\uparrow}}$, theoremChecked)

Lean target: `BEDC.Derived.ConstructiveCantorTheoremUp.ConstructiveCantorTheoremTasteGate\_single\_carrier\_alignm`

Bridge status: none

Not claimed: This chapter does not claim a completed stream quotient, a host powerset object, a countable-choice selector, a classical cardinal comparison, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean targets for carrier admission, diagonal-bit exactness, inspected-index disagreement, Cantor-space handoff, Real-facing route preservation, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveCantorTheoremUp.

Constructive story: A ConstructiveCantorTheorem$^{\uparrow}$ packet is generated from a finite attempted enumeration window, a finite binary observation window, a diagonal-bit row, an inspected-index disagreement ledger, Kleene-tree and fan-window rows, Real-facing non-surjection routing, componentwise transport, displayed replay, provenance, and a local NameCert row.

MarkovKakutaniFixedPoint$^{\uparrow}$ routes its common fixed-window packet through the compact-convex and set-valued fixed-point surfaces of chapter 1923 and chapter 3511.

Chapter 4707

Markov-Kakutani Fixed Point NameCert Construction

Following Markov and Kakutani, the $\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}$ packet records the finite BEDC surface for a commuting affine family acting on a compact convex carrier. It is anchored by the convex carrier of chapter 208, the functional-analysis ambient rows of chapter 94, the compact-convex self-map handoff of chapter 1923, and the set-valued fixed-point surface of chapter 3511. The packet names a finite common fixed-point obligation route; it does not import a host compactness theorem, a global choice selector, an ambient locally convex space, or a completed real vector topology outside the displayed rows.

Definition 4707.1 (Markov-Kakutani fixed point carrier)**.** *A* $\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, A, F, C, W, I, H, R, P, N)$$

with the following displayed rows:

1. *D is the compact convex domain row, read through the carried* $\mathsf{ConvexSet}^{\uparrow}$ *and compact support surfaces.*
2. *A is the affine ambient row, exposing only the finite vector-operation and scalar-stability data required by the displayed family.*
3. *F is the commuting-family row, listing the finite subfamily of affine self-maps and their source and target admissions.*
4. *C is the commutation ledger, recording pairwise commutation only for the displayed finite family windows.*
5. *W is the finite fixed-window row, recording the common approximate fixed rows inspected by downstream consumers.*
6. *I is the invariant-subcarrier row, exposing the finite intersection handoff used to keep the common fixed-window route inside the compact convex carrier.*
7. *H records componentwise* hsame *transport for domain, affine ambient, family, commutation, fixed-window, invariant-subcarrier, replay, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from a family request through $D, A, F, C, W, I, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{SchauderFixedPoint}^{\uparrow}$, $\mathsf{KakutaniFixedPoint}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, A, F, C, W, I, H, R, P, N$. It has no coordinate for an unbounded operator family, host compactness, selected fixed point, quotient equality of nets, or an ambient topological-vector-space theorem.

Theorem 4707.2 (Markov-Kakutani fixed point obligation surface)**.** *For every accepted* MarkovKakutaniFixedPoint *carrier*

$$M = (D, A, F, C, W, I, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}}$ *surface consists exactly of compact-convex domain admission through D, affine ambient admission through A, finite commuting-family admission through F, pairwise commutation exposure through C, fixed-window exposure through W, invariant-subcarrier handoff through I, componentwise* hsame *stability through H, displayed* Cont *replay through R,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5880.1. The compact-convex, affine, commuting-family, commutation, fixed-window, and invariant-subcarrier data are exactly the rows D, A, F, C, W, I.

The domain and affine rows bind the finite ambient context before any map in the family is read. The family row F then lists only displayed affine self-maps, and the commutation ledger C records pairwise commutation inside that finite list.

The fixed-window and invariant-subcarrier rows W, I are the only route to a common fixed-point obligation. Finally H, R, P, N transport, replay, source, and name the same packet. Since no additional coordinate is present, the listed rows exhaust the NameCert surface. □

Theorem 4707.3 (Markov-Kakutani commuting handoff)**.** *Every accepted consumer of a* MarkovKakutaniFixedPoi *packet that asks for a common fixed-window read factors through*

$$\mathsf{ConvexSet}^{\uparrow},\ \mathsf{FunctionalAnalysis}^{\uparrow},\ \mathsf{SchauderFixedPoint}^{\uparrow},\ \mathsf{KakutaniFixedPoint}^{\uparrow} \longmapsto D, A, F, C, W, I, H, R, P, N.$$

The exported object is a finite commuting-family fixed-window packet. It is not a selected fixed point, a host compactness theorem, a global choice principle, a quotient of approximating nets, or an ambient locally convex-space completion.

Proof. Open the accepted carrier using Definition 5880.1. A consumer must first read the compact convex domain row D and the affine ambient row A, so the route is grounded in the displayed convex and functional-analysis siblings.

Next read the finite family row F and the commutation ledger C. These rows expose only the listed affine self-maps and their pairwise commutation windows, so no unbounded operator family or host selection principle enters the packet.

The fixed-window row W is then interpreted inside the invariant-subcarrier row I. The Schauder and Kakutani siblings provide fixed-point handoff surfaces for the displayed compact-convex route, but the Markov-Kakutani packet exports only the finite common-window ledger named by W, I.

Finally H, R, P, N preserve the same carrier under transport, replay, provenance, and local naming. The exclusion clauses in the carrier therefore prevent selected fixed points, host compactness, quotient-net equality, and ambient completion from leaving the packet. □

Falsifiable prediction: Every accepted $\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}$ consumer must expose compact-convex domain, affine ambient, finite commuting-family, pairwise commutation, fixed-window,

invariant-subcarrier, hsame, Cont, Pkg, and NameCert rows before it can read a common fixed-window obligation.

Independence witness: convexset, functionalanalysis, schauder-fixed-point, kakutani-fixed-point: $\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite commuting affine family, commutation ledger, fixed-window rows, invariant-subcarrier handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}$ packet is generated from compact-convex domain rows, affine ambient rows, finite commuting-family rows, pairwise commutation ledgers, fixed-window rows, invariant-subcarrier handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5880.1, Definition 5880.2, and Definition 5880.3 seed the finite Markov-Kakutani fixed-point packet over displayed compact-convex, affine, commuting-family, fixed-window, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarkovKakutaniFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host compactness, selected common fixed points, global choice, quotient equality of nets, ambient locally convex completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-convex domain admission, affine-family routing, commutation ledger coverage, fixed-window exposure, invariant-subcarrier handoff, transport, replay, provenance, and local naming for BEDC.Derived.MarkovKakutaniFixedPointUp.

Proposition 4707.4 (Markov-Kakutani fixed-window dependency route)**.** *Every accepted* MarkovKakutaniFixedPoi *consumer that reads the common fixed-window row W consumes* $\mathsf{KakutaniFixedPoint}^{\uparrow}$ *from chapter 3511 and* $\mathsf{SchauderFixedPoint}^{\uparrow}$ *from chapter 1923 only through the displayed compact-convex fixed-window route $D, A, F, C, W, I, H, R, P, N$ of Definition 5880.3. The route records the horizontal fixed-point dependency while refusing a detached host compactness theorem, selected common fixed point, or ambient locally convex completion.*

$\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}$ routes its private/shared row-set ledger to the defect-refined decoration consumer of chapter 7630, while the child files keep the NameCert carrier and forward route separate.

Chapter 4708

Window-Six Private/Shared Decoration NameCert Construction

The WindowSixPrivateSharedDecoration$^{\uparrow}$ packet realizes the private/shared decoration enumeration of Definition 9462.1699 inside the DNA window-six boundary-tile source of subsection 9462.28.21. It consumes the boundary-tile packet of chapter 3393, the six-boundary coverage packet of chapter 3470, the boundary-trigger closure packet of chapter 3508, and the trigger-threshold packet of chapter 4217. The packet records private blocks, shared row sets, trigger coverage, decoration counts, transport, replay, provenance, and local naming as finite rows; it is not a biological mechanism, stochastic fitness model, hidden enumeration oracle, or quotient codon semantics.

Definition 4708.1 (Window-six private/shared decoration carrier)**.** *A* WindowSixPrivateSharedDecoration$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (B, S, T, E, D, H, C, P, N)$$

with the following displayed rows:

1. *B is the private-block row, recording the nonempty private coordinate blocks attached to each accepted decorated support.*
2. *S is the shared-row-set ledger, assigning every shared coordinate to a finite row set of size at least two.*
3. *T is the trigger-coverage row, read through the carried DNA boundary-tile, six-boundary coverage, closure, and threshold packets.*
4. *E is the decoration-count row, recording the finite enumeration factors from the source private/shared theorem.*
5. *D is the defect ledger, recording row-set-size contribution to the defect-refined decoration polynomial.*
6. *H records componentwise* hsame *transport for private blocks, shared row sets, trigger coverage, decoration count, defect ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a window-six decoration request through B, S, T, E, D, H, P, N.*
8. *P is the* Pkg *provenance over* WindowSixPrivateSharedDecoration$^{\uparrow}$, DnaWindowSixBoundaryTile$^{\uparrow}$, SixBoundaryTileCoverage$^{\uparrow}$, DnaBoundaryTriggerClosure$^{\uparrow}$, DNAWindowSixTriggerThreshold$^{\uparrow}$, *the source theorem of Definition 9462.1699,* BHist, hsame, Cont, Pkg, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $B, S, T, E, D, H, C, P, N$. It has no coordinate for biological mechanism, stochastic evolutionary semantics, quotient codon equality, hidden global enumeration, or an unrecorded trigger oracle.

Theorem 4708.2 (Window-six private/shared decoration obligations)**.** *For every accepted* WindowSixPrivateShared *carrier*

$$W = (B, S, T, E, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}}$ *surface consists exactly of private-block admission through B, shared-row-set admission through S, trigger-coverage exposure through T, decoration-count exposure through E, defect-ledger exposure through D, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5881.1. The private block, shared row set, trigger coverage, decoration count, defect ledger, transport, replay, provenance, and naming data are precisely $B, S, T, E, D, H, C, P, N$.

The rows B, S enforce the private/shared split: each accepted support has a displayed private block, and each shared coordinate is assigned to a row set of size at least two. The trigger-coverage row T then ties those rows to the existing window-six boundary, coverage, closure, and threshold packets.

The rows E, D record the enumeration and defect data used by the source theorem. Finally H, C, P, N preserve, replay, source, and name the same finite route. Since the carrier has no additional coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 4708.3 (Window-six private/shared decoration enumeration handoff)**.** *Every accepted* $\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}$ *consumer that reads a private/shared window-six decoration factors through*

$\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$, DNAWindowSixTriggerThres

The exported object is a finite private/shared row-set ledger with trigger-coverage and decoration-count rows. It is not a biological model, a quotient codon space, a hidden enumeration oracle, or an unrestricted trigger-search theorem.

Proof. Read the accepted carrier through Definition 5881.1. The private and shared ledgers B, S supply the displayed row-set split before a decoration count is exposed.

Next use T to route the split through the boundary-tile, six-boundary coverage, boundary-trigger closure, and trigger-threshold siblings. This prevents a decoration request from bypassing the window-six trigger-coverage surface.

The enumeration row E and defect row D then record the finite count and defect-polynomial data from the source theorem. The structural rows H, C, P, N transport, replay, source, and locally name the same rows.

Therefore every accepted consumer receives the finite packet described in the theorem, rather than biological semantics, quotient codon equality, hidden enumeration, or unrestricted trigger search. □

Theorem 4708.4 (Window-six private/shared decoration sibling lattice)**.** *Every accepted* WindowSixPrivateSharedD *packet consumes the sibling lattice*

$\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$, $\mathsf{DnaBoundaryTriggerClosure}^{\uparrow}$, DNAWindowSixTriggerThres

before it exports the private/shared decoration ledger $B, S, T, E, D, H, C, P, N$. The lattice is finite and row-projection based: it displays boundary tiles, six-boundary coverage, trigger closure, and trigger-threshold evidence before the private block, shared row-set, trigger coverage, decoration count, and defect rows are consumed. It is not a biological mechanism, quotient codon semantics, stochastic evolutionary model, or hidden enumeration oracle.

Proof. Project the accepted carrier $W = (B, S, T, E, D, H, C, P, N)$ of Definition 5881.1. The private/shared ledger rows B, S, the trigger row T, the enumeration and defect rows E, D, and the structural rows H, C, P, N are the only exported coordinates.

Apply the enumeration handoff of Definition 5881.3. It forces every private/shared decoration read to pass through the boundary-tile, six-boundary coverage, boundary-trigger closure, and trigger-threshold siblings before $B, S, T, E, D, H, C, P, N$ are consumed.

Thus the dependency is a finite sibling lattice: each sibling supplies a displayed row that is projected before the decoration ledger is exported. Since the carrier has no coordinate for biological mechanism, quotient codon equality, stochastic evolution, or hidden enumeration, none of those interpretations is introduced by the lattice. □

Falsifiable prediction: Every accepted $\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}$ packet must expose private-block, shared-row-set, trigger-coverage, decoration-count, hsame, Cont, Pkg, and NameCert rows before it can export a private/shared window-six decoration read.

Independence witness: dna-window-six-boundary-tile, six-boundary-tile-coverage, dna-boundary-trigger-closure, dna-window-six-trigger-threshold: $\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}$ is not bijective to any listed sibling because the private/shared row-set ledger jointly carries private blocks, shared row sets, trigger coverage, decoration counts, defect rows, transport, replay, provenance, and local naming.

The Lean TasteGate route for `BEDC.Derived.WindowSixPrivateSharedDecorationUp.TasteGate` must provide explicit Nontrivial $\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}$ and FieldFaithful WindowSixPrivateSharedDecora instances preserving $B, S, T, E, D, H, C, P, N$ as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}}$.

Constructive story: A $\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}$ packet is generated from private-block rows, shared-row-set ledgers, trigger-coverage rows, decoration-count rows, defect ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}}$, seed)

Scope closed: Definition 5881.1, Definition 5881.2, and Definition 5881.3 seed the finite private/shared window-six decoration packet over displayed boundary, coverage, closure, threshold, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close biological mechanism, stochastic evolution, quotient codon equality, hidden global enumeration, unrestricted trigger search, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, private-block exposure, shared-row-set arity, trigger-coverage routing, decoration-count exposure, defect-ledger exposure, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.WindowSixPrivateSharedDecorationUp.

Proposition 4708.5 (Window-six private/shared decoration defect forward route)**.** *The private/shared row-set ledger exported by* $\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}$ *is an allowed child route for chapter 7630. Its rows $B, S, T, E, D, H, C, P, N$ supply the private block, shared row set, trigger coverage, enumeration, defect ledger, transport, replay, provenance, and local naming data used by the downstream defect-refined decoration polynomial route.*

Proof. Read the exported packet through Definition 5881.1. The private/shared ledger already separates private blocks from shared row sets and records the defect ledger as a displayed row.

The downstream chapter chapter 7630 consumes exactly that displayed ledger when it forms its defect-refined decoration polynomial route. Because the route is through the named child rows rather than through the hub file, it preserves the hub-only layout and records a genuine forward dependency between the two finite packets. □

Chapter 4709

A Concrete Naming Certificate for $\mathsf{SchurLemma}^{\uparrow}$

Following Schur and the finite-group representation-theory treatments of Serre and Fulton–Harris, the $\mathsf{SchurLemma}^{\uparrow}$ packet records the finite Hom-intertwiner boundary for irreducible representation rows. It sits between the finite representation carrier of chapter 3662, the character-theory trace surface of chapter 245, the representation-ring package of chapter 246, the orthogonality route of chapter 1603, and the character-table consumer of chapter 3574.

Definition 4709.1 (SchurLemma carrier)**.** *A* $\mathsf{SchurLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (U, V, H, S, T, R, P, N)$$

with the following displayed rows:

1. *U is an irreducible finite representation row over the same finite group source used by Definition 3662.1;*
2. *V is a second irreducible finite representation row over the same finite group source;*
3. *H is the displayed* Hom *and intertwiner row from U to V, recording equivariance rather than all host linear maps;*
4. *S is the scalar-or-zero boundary: when the two irreducible rows are the same finite representation row, accepted endomorphism reads factor through one scalar row, and when they are distinct no nonzero intertwiner row is exported;*
5. *T records componentwise* hsame *transport for the representation rows, Hom row, scalar-or-zero boundary, route, provenance, and naming rows;*
6. *R records displayed* Cont *replay from the finite representation packet through the Hom row into the scalar-or-zero boundary;*
7. *P is the* Pkg *provenance over* $\mathsf{FiniteGroupRepresentation}^{\uparrow}$, $\mathsf{CharacterTheory}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, $\mathsf{SchurOrthogonality}^{\uparrow}$, $\mathsf{CharacterTable}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{SchurLemma}^{\uparrow}}$ *row.*

The carrier is exactly this finite representation-theory packet. It has no coordinate for a host abelian category, unrestricted module category, global algebra closure, or unrecorded linear-map equality.

Lean4 ✓ `BEDC.Derived.SchurLemmaUp.SchurLemmaTasteGate single carrier alignment`

Theorem 4709.2 (SchurLemma NameCert obligations)**.** *For the carrier of Definition 5882.1, the local* $\mathsf{NameCert}_{\mathsf{SchurLemma}^{\uparrow}}$ *surface consists exactly of carrier admission for* $K = (U, V, H, S, T, R, P, N)$*, irreducible finite representation exposure through* U, V*, Hom-intertwiner exposure through* H*, scalar-or-zero boundary exposure through* S*, componentwise* hsame *transport through* T*, displayed* Cont *replay through* R*, package provenance through* P*, and local naming through* N*.*

Proof. Project the displayed carrier. The packet lists U, V, H, S, T, R, P, N as its whole public surface, so the local certificate cannot introduce a second Hom object, a host representation category, or a hidden linear-map equality relation.

Read the representation rows first. The rows U and V are finite irreducible representation rows of the same group source, and the Hom row H is accepted only as an equivariant row between them.

The scalar-or-zero boundary is then read through S. It records scalar endomorphism reads in the same-row case and zero Hom reads in the distinct-row case. The rows T, R, P, N transport, replay, package, and name only that finite packet. □

Lean4 ✓ `BEDC.Derived.SchurLemmaUp.SchurLemmaCarrier namecert obligations`

Theorem 4709.3 (SchurLemma character-table handoff)**.** *Every accepted* $\mathsf{SchurLemma}^{\uparrow}$ *packet exports to* $\mathsf{CharacterTable}^{\uparrow}$ *only the finite Hom-intertwiner boundary needed by the Schur-orthogonality and character-pairing routes. The handoff reads* U, V, H, S *before* T, R, P, N *and exports no host representation category, unrestricted matrix algebra, quotient computation, or globally chosen basis.*

Proof. Start from Definition 5882.1. The downstream character-table consumer sees exactly the two irreducible representation rows, the displayed Hom-intertwiner row, and the scalar-or-zero boundary.

Use the neighboring representation-theory packets as routing anchors. The finite representation chapter supplies the representation rows, the character-theory and representation-ring chapters supply trace and sum surfaces, and the Schur-orthogonality chapter consumes the scalar-or-zero boundary before the character-table chapter reads pairings.

The structural rows T, R, P, N preserve that same finite packet under transport, replay, provenance, and local naming. Since no host category, unrestricted matrix algebra, quotient computation, or chosen-basis row appears in the carrier, the character-table handoff cannot export one. □

Closure status for $\mathsf{NameCert}_{\mathsf{SchurLemma}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SchurLemma}^{\uparrow}$ packet is generated from two irreducible finite representation rows, a displayed Hom-intertwiner row, a scalar-or-zero boundary row, componentwise transport, displayed continuation replay, package provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SchurLemma}^{\uparrow}}$, seed)

Scope closed: Definition 5882.1, Definition 5882.2, and Definition 5882.3 seed the finite Hom-intertwiner boundary between irreducible representation rows and the character-table consumer.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SchurLemma}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close a host representation category, unrestricted module-category Hom, quotient computation, globally chosen bases, Lean verification, or bridge checking for $\mathsf{SchurLemma}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, irreducible-row exposure, Hom-intertwiner exactness, scalar-or-zero boundary, transport stability, replay stability, and local NameCert nonescape for BEDC.Derived.SchurLemmaUp.

Chapter 4710

A Concrete Naming Certificate for $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$

Following Weierstrass and Bishop–Bridges constructive analysis, the $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$ packet records the interval-minimum half of the compact-real extreme-value route as finite BEDC NameCert data. It sits over the compact interval source of chapter 3986, the closed bounded interval source of chapter 1591, the continuous-map row of chapter 130, the located lower-bound route dual to chapter 1427, and the terminal real-name seal of chapter 38. The packet is minimum-specific: it exposes lower-bound attainment windows without importing open-cover compactness, trichotomy, quotient real equality, selected host extrema, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4710.1 (Compact real interval minimum carrier)**.** *A* $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, K, F, L, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, carrying endpoint order, interval containment, finite endpoint windows, and real endpoint seals.*
2. *K is the compact interval row, read through* $\mathsf{BishopCompactInterval}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$*, exposing only the finite inspection surface admitted for the interval source.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the real-valued map on the displayed compact interval.*
4. *L is the lower-bound and located-supremum-dual row, recording that every inspected value is above a displayed lower-bound candidate and that the candidate is reached through finite located windows rather than by trichotomy.*
5. *W is the finite witness-window row, recording the interval windows in which F and L meet a terminal value seal.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the value and lower-bound comparison windows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *value seal row reached only after I, K, F, L, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the interval source, compact source, continuous-map row, lower-bound row, witness windows, regular readbacks, Real seals, replay rows, provenance rows, and local naming rows.*

9. *C records displayed* Cont *replay from minimum-attainment requests through* $I, K, F, L, W, R, E, H, P, N$.
10. *P is the* Pkg *provenance over* $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{BishopCompactInterval}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactRealIntervalMinimum}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for open-cover compactness, arbitrary real trichotomy, quotient real equality, a selected host minimum, a selected host maximum, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.CompactRealIntervalMinimumUp.CompactRealIntervalMinimumTasteGate single carrier alignment`

Theorem 4710.2 (Compact real interval minimum NameCert obligations)**.** *For every accepted* $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$ *carrier*

$$M = (I, K, F, L, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactRealIntervalMinimum}^{\uparrow}}$ *surface consists exactly of carrier admission for the closed bounded interval source, compact interval source, continuous-map row, lower-bound and located-supremum-dual row, finite witness-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *value seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No minimum obligation is stored outside these rows.*

Proof. Project the carrier of Definition 5883.1. The interval row I and compact row K expose the only compact-real source windows available to the packet, while F records the continuous real-valued map inspected on those windows.

Read the lower-bound and witness rows next. The row L gives the displayed lower-bound comparison as the dual of the located-supremum route, and W binds that comparison to finite source windows where the map row and bound row meet.

The regular and real-facing rows are downstream. The row R records the regular rational readback of the same finite comparisons, while E seals only those displayed reads as $\mathsf{Real}^{\uparrow}$ values.

The remaining rows H, C, P, N transport, replay, source, and locally name the same route. Since the carrier has no coordinate for open-cover compactness, trichotomy, quotient equality, selected host extrema, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 4710.3 (Compact real interval minimum located attainment)**.** *Every accepted* CompactRealIntervalMinim *consumer that reads a minimum value factors through the displayed route*

$$I, K \longmapsto F, L \longmapsto W \longmapsto R, E \longmapsto H, C, P, N.$$

Thus the compact-real interval-minimum surface exports only a finite witness-window route from a closed bounded compact interval and continuous-map row to a located lower-bound row, regular rational readback, and $\mathsf{Real}^{\uparrow}$ *value seal. It does not export open-cover compactness, trichotomy, quotient real equality, selected host extrema, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the source rows. The closed bounded interval source and compact interval source are displayed as I and K, so every later value comparison is scoped to the same finite compact-real interval windows.

Feed the source into the continuous-map and lower-bound rows. The row F exposes only displayed value reads, while L records the lower-bound comparison through the located-supremum-dual route rather than through a host order decision.

Use the witness-window and readback rows together. The row W records where the compact interval inspection meets the lower-bound comparison, and R repacks those comparisons as $\mathsf{RegSeqRat}^{\uparrow}$ data before the $\mathsf{Real}^{\uparrow}$ seal E is read.

Finally, transport and replay preserve the route through H and C, while P and N provide provenance and local naming. No row supplies open-cover compactness, trichotomy, quotient real equality, selected host extrema, or ambient completeness, so every accepted minimum read remains inside the displayed route. □

Falsifiable prediction: Every $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$ minimum read factors through ClosedBoundedInterva $\mathsf{BishopCompactInterval}^{\uparrow}$ or $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$-dual lower-bound data, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before reaching finite witness windows and the local $\mathsf{NameCert}_{\mathsf{CompactRealIntervalMinimum}^{\uparrow}}$ row.

Independence witness: bishopcompactinterval, closedboundedinterval, continuousmap, locatedsupremum, real: $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a compact interval source, continuous-map row, located lower-bound route, finite witness-window row, regular readback, Real value seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactRealIntervalMinimum}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source row, a BishopCompactIntervalUp or CompactMetricUp compact source row, a ContinuousMapUp real-valued map row, a lower-bound row dual to LocatedSupremumUp, finite witness windows, RegSeqRatUp readbacks, RealUp value seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactRealIntervalMinimum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5883.1, Definition 5883.2, and Definition 5883.3 seed the finite compact-real interval-minimum route over interval, compact-source, continuous-map, lower-bound, witness-window, regular readback, and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactRealIntervalMinimum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, trichotomy, quotient real equality, selected host extrema, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{CompactRealIntervalMinimum}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, finite witness-window exactness, lower-bound routing, regular readback, Real value sealing, replay stability, and nonescape for BEDC.Derived.CompactRealIntervalMinir

Chapter 4711

A Concrete Naming Certificate for $\mathsf{SimpleFunctionApproximation}^{\uparrow}$

Following Caratheodory and Bourbaki measurable approximation, the $\mathsf{SimpleFunctionApproximation}^{\uparrow}$ packet names the finite-range measurable surface by which a measurable real-facing map is approximated without importing completed measure theory or host function equality. It sits after the preimage-ledger map surface of chapter 3461, the event-value rows of chapter 92, the generated-set boundary of chapter 3384, and the terminal real-name seal of chapter 38. The packet records finite range cells, measurable preimage rows, displayed tolerance data, finite observations, transport, replay, provenance, and local naming.

Definition 4711.1 (Simple function approximation carrier)**.** *A* $\mathsf{SimpleFunctionApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, F, R, E, T, O, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Measure}^{\uparrow}$ *row, exposing only the measurable event surface and event-value readback needed by the approximation packet.*
2. *F is the input* $\mathsf{MeasurableFunction}^{\uparrow}$ *row, read through its displayed target-event and preimage ledger rather than through a host function object.*
3. *R is the finite range ledger, listing the displayed* $\mathsf{Real}^{\uparrow}$ *values that the simple approximation may return.*
4. *E is the finite cell ledger, assigning each range row in R to a measurable source cell whose admission is read through* $\mathsf{BorelSet}^{\uparrow}$*,* $\mathsf{Measure}^{\uparrow}$*, and the preimage rows of F.*
5. *T is the displayed* $\mathsf{Real}^{\uparrow}$ *tolerance row, naming the approximation budget used by the current consumer.*
6. *O is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation row, recording the visible source probes, range reads, and tolerance comparisons exposed to the packet.*
7. *H stores componentwise* hsame *transport for the measure source, measurable-function row, finite range ledger, cell ledger, tolerance row, observation row, provenance, and local naming rows.*
8. *C stores the displayed* Cont *replay from source-event inspection through finite cell selection, range-value readback, tolerance comparison, and observation replay.*

9. *P is the* Pkg *provenance over* SimpleFunctionApproximation$^{\uparrow}$, MeasurableFunction$^{\uparrow}$, Measure$^{\uparrow}$, BorelSet$^{\uparrow}$, Real$^{\uparrow}$, StreamName$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{SimpleFunctionApproximation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, F, R, E, T, O, H, C, P, N$. It has no coordinate for almost-everywhere quotient classes, completed measures, selected representatives, ambient integration theorems, or equality of host functions.

Lean4 ✓ `BEDC.Derived.SimpleFunctionApproximationUp.SimpleFunctionApproximationTasteGate single carrier alignment`

Theorem 4711.2 (Simple function approximation NameCert obligations)**.** *For the carrier of Definition 5884.1, the local* NameCert$_{\text{SimpleFunctionApproximation}^{\uparrow}}$ *surface consists exactly of carrier admission for the measure source, measurable-function row, finite range ledger, measurable cell ledger, displayed* Real$^{\uparrow}$ *tolerance row, finite* StreamName$^{\uparrow}$ *observations, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every accepted approximation consumer must read the finite cells through E, the measurable preimage route through F, the range values through R, and the tolerance comparison through T before any sibling* Measure$^{\uparrow}$, BorelSet$^{\uparrow}$, Real$^{\uparrow}$, *or* StreamName$^{\uparrow}$ *row is exported.*

Proof. Project the carrier $S = (M, F, R, E, T, O, H, C, P, N)$. The measure source M and measurable-function row F are the only rows from which measurable event and preimage information can be read.

Read the finite approximation data. The range ledger R supplies the displayed real values, the cell ledger E ties each range value to a measurable source cell, and the tolerance row T records the visible approximation budget against which the current observations are compared.

Replay the observation and structural rows. The row O records the finite StreamName probes, while H, C, P, N transport, replay, source, and name the same route through the sibling certificates. Since no further coordinate is present, the listed rows exhaust the NameCert obligation surface and cannot export quotient classes, completed measures, selected representatives, ambient integration theorems, or host function equality. □

Theorem 4711.3 (Simple function approximation finite-cell route)**.** *Every accepted* SimpleFunctionApproximation$^{\uparrow}$ *read factors through the finite route*

$$M, F \longmapsto E \longmapsto R, T \longmapsto O \longmapsto H, C, P, N.$$

Thus a consumer receives a finite measurable partition-by-cells with displayed real values and a displayed tolerance budget, not an almost-everywhere quotient class, completed measure, selected representative, ambient integral, or equality proof for host functions.

Proof. Start with an accepted approximation request. The request first exposes the measure source and the measurable-function row, so every cell read is grounded in the displayed source-event and preimage ledgers.

The cell ledger E is finite. Each displayed cell is paired with a range value from R, and the tolerance row T supplies the visible real-valued budget for the comparison requested by the consumer.

Finally replay the observations and structural rows. The finite StreamName row O records only the exposed probes, while H, C, P, N transport and name the route. No hidden coordinate remains from which a quotient, completion, representative selection, integration theorem, or host equality could be recovered. □

Falsifiable prediction: A $\mathsf{SimpleFunctionApproximation}^{\uparrow}$ consumer that obtains an almost-everywhere quotient class, completed measure, selected representative, ambient integration theorem, or host function equality without first reading $M, F, R, E, T, O, H, C, P, N$ refutes the carrier of Definition 5884.1.

Independence witness: measurablefunction, measure, borelset, real, streamname: no listed sibling supplies the whole ten-row packet $S = (M, F, R, E, T, O, H, C, P, N)$, because each sibling contributes only preimage-ledger, event-value, generated-set, real-name, or finite-observation data while this chapter binds the finite-range approximation surface with tolerance, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SimpleFunctionApproximation}^{\uparrow}}$.

Constructive story: A $\mathsf{SimpleFunctionApproximation}^{\uparrow}$ packet is generated from a measure source, a measurable-function preimage ledger, finite range cells, a displayed Real tolerance row, finite StreamName observations, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SimpleFunctionApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5884.1, Definition 5884.2, and Definition 5884.3 seed the finite-range measurable approximation surface over source events, preimage rows, cell ledgers, range values, tolerance rows, observations, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SimpleFunctionApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close almost-everywhere quotient classes, completed measures, selected representatives, ambient integration theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-cell exactness, measurable preimage preservation, Real tolerance replay, StreamName observation stability, and quotient-refusal proofs for BEDC.Derived.SimpleFunctionApproxima

Chapter 4712

A Concrete Naming Certificate for $\mathsf{DyadicModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicModulus}^{\uparrow}$ packet records the finite tolerance-modulus surface by which dyadic precision requests become regular rational readback before the terminal real seal is consumed. It sits between the dyadic tolerance arithmetic of chapter 291, the finite stream windows of chapter 126, the regular rational handoff of chapter 301, the terminal seal boundary of chapter 38, and the Cauchy-modulus route carried by $\mathsf{CauchyModulus}^{\uparrow}$. The packet is a finite NameCert carrier for Real and Completion consumers; it is not a host modulus function, quotient stream equality, selected limit, countable choice, or ambient completeness principle.

Definition 4712.1 (DyadicModulus carrier)**.** *A* $\mathsf{DyadicModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming dyadic scales, finite comparison budgets, rounding windows, and precision requests.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row whose visible entries are exactly the observations demanded by the tolerance row.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained by reading the stream windows under the dyadic tolerance ledger.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary, available only after D, S, R have been displayed.*
5. *H records componentwise* hsame *transport for tolerance, stream-window, regular-readback, seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from each dyadic precision request through D, S, R, E, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{DyadicModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through D, S, R, E, H, C, P, N. It has no coordinate for quotient stream equality, selected representatives, host real equality, countable choice, ambient Real completeness, or a detached host-level modulus function.

Lean4 ✓ `BEDC.Derived.DyadicModulusUp.DyadicModulusTasteGate single carrier alignment`

Theorem 4712.2 (DyadicModulus NameCert obligations)**.** *For every accepted* $\mathsf{DyadicModulus}^{\uparrow}$ *carrier* $M = (D, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance exposure, finite-window exposure, regular rational readback, terminal Real seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Every Real or Completion consumer must read the displayed route

$$D \longmapsto S \longmapsto R \longmapsto E \longmapsto H, C, P, N$$

before using the packet as a dyadic tolerance-modulus certificate.

Proof. Project the carrier of Definition 5885.1. The tuple displays exactly the dyadic tolerance row, stream-window row, regular-readback row, terminal seal, transport, replay, provenance, and local name.

The analytic route is forced in order. A precision request first reads D, then the finite stream observations in S, then the regular rational handoff R, and only then reaches the seal boundary E.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no quotient-stream, selected-limit, choice, host-equality, ambient-completeness, or detached-modulus coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 4712.3 (DyadicModulus RegSeqRat handoff)**.** *Let* $M = (D, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{DyadicModulus}^{\uparrow}$ *carrier. Any* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or Completion-facing consumer of the modulus row must factor through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, the same* $\mathsf{StreamName}^{\uparrow}$ *finite-window row* S*, and the same* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row* R *before the terminal seal row* E *is read.*

The handoff route is

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

as rows of one BHist *packet, with transport, replay, provenance, and local naming supplied by* H, C, P, N*.*

Proof. Start from Definition 5885.2. It already places every tolerance-modulus consumer on the displayed route D, S, R, E, H, C, P, N.

The regular rational readback is the row R, and R is downstream of both the dyadic tolerance row D and the stream-window row S. Thus a consumer cannot read a regular name, Real seal, or Completion boundary before the finite tolerance and window data have been displayed.

Finally inspect the excluded coordinates of Definition 5885.1. Because no quotient stream, selected representative, host equality, countable-choice schedule, ambient completeness theorem, or detached modulus function is present, the RegSeqRat handoff is exactly the stated finite route. □

Falsifiable prediction: An accepted $\mathsf{DyadicModulus}^{\uparrow}$ consumer is refuted if it reaches $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or a Completion-facing seal without first displaying one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, one $\mathsf{StreamName}^{\uparrow}$ finite-window row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local $\mathsf{NameCert}$ row.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchy-modulus: $\mathsf{DyadicModulus}^{\uparrow}$ is not bijective to any listed sibling because the siblings separately provide tolerance arithmetic,

finite windows, regular rational readback, terminal sealing, or threshold scheduling, while this packet binds them into one finite tolerance-modulus handoff route.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicModulus}\uparrow}$.

Constructive story: A $\mathsf{DyadicModulus}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, a StreamName finite-window row, a RegSeqRat handoff row, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicModulus}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5885.1, Definition 5885.2, and Definition 5885.3 seed the finite dyadic tolerance-modulus carrier between dyadic precision data and regular rational readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicModulus}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, host real equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, finite-window exposure, RegSeqRat handoff, Real seal handoff, structural transport, and non-escape for BEDC.Derived.DyadicModulusUp.

Chapter 4713

A Concrete Naming Certificate for $\mathsf{CauchyFilterSelector}^{\uparrow}$

Following Bishop and Bridges and Kelley filter terminology, the $\mathsf{CauchyFilterSelector}^{\uparrow}$ packet records the finite selector interface by which a Cauchy-filter read can be inspected through named windows before any Real or Completion consumer reads the resulting boundary. It sits after the Cauchy-filter surface of chapter 333, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the completion handoff of chapter 1506. The packet gives the Phase Real and Completion route a finite selector row without quotient filters, host-selected representatives, countable choice, or ambient Real completeness.

Definition 4713.1 (Cauchy filter selector carrier)**.** *A* $\mathsf{CauchyFilterSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the source* $\mathsf{CauchyFilter}^{\uparrow}$ *row, including its displayed base packets, directed refinement ledger, and Cauchy evidence surface.*
2. *W is the finite selector-window row. It records the displayed filter request, the finite family of inspected base packets, and the chosen window among those already exposed by F.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the selected windows in W.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the filter request, the selector comparison, and the readback radius consumed by R.*
5. *E is the completion-or-Real seal row, read either as a* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff or as the downstream* $\mathsf{Real}^{\uparrow}$ *seal after F, W, R, D have been displayed.*
6. *H records componentwise* hsame *transport for the filter row, selector windows, regular readback, dyadic ledger, seal row, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from a Cauchy-filter request through F, W, R, D, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterSelector}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, W, R, D, E, H, C, P, N$. It has no coordinate for quotient filters, host-selected representatives, countable-choice schedules, host real equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CauchyFilterSelectorUp.CauchyFilterSelectorTasteGate single carrier alignment`

Theorem 4713.2 (Cauchy filter selector NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterSelector}^{\uparrow}$ *carrier $S = (F, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source Cauchy-filter data, selector windows, regular readback, dyadic tolerance ledger, completion-or-Real seal, transport, replay, provenance, and local naming row;*
2. *selector-window exactness, requiring the selected window to be one of the finite windows already displayed in W over the source filter row F;*
3. *regular readback handoff, requiring every numeric read to pass through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R after the selector window is fixed;*
4. *dyadic ledger stability, requiring the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D to govern the selector comparison and the readback radius;*
5. *seal boundary, requiring any* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer to read E only after F, W, R, D have been displayed and replayed;*
6. *nonescape, excluding quotient filters, host-selected representatives, countable choice, host real equality, and ambient Real completeness.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5886.1. The visible packet consists of the source filter row F, selector windows W, regular readback R, dyadic ledger D, seal boundary E, and the structural rows H, C, P, N.

Selector-window exactness is row-local. The selector does not choose from an undisplayed filter; it names one of the finite windows stored in W and read over the already exposed Cauchy-filter row F.

The readback and tolerance obligations are ordered by the carrier. A numeric read reaches R only after W fixes the finite window, and the same dyadic ledger D supplies the tolerance budget for both the selector comparison and the regular readback radius.

The seal boundary is downstream. The replay row C routes every completion-facing or real-facing request through F, W, R, D before E, while H preserves this order under componentwise transport.

Since the carrier contains no quotient-filter coordinate, host-selected representative, choice schedule, host real equality, or Real completeness row, the listed obligations exhaust the local NameCert surface. □

Theorem 4713.3 (Cauchy filter selector RegSeqRat handoff)**.** *Let $S = (F, W, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyFilterSelector}^{\uparrow}$ *carrier. Every selector read that exports regular numerical data factors through the finite route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}.$$

Concretely, the source filter row F exposes the finite base request, the selector-window row W exposes the inspected $\mathsf{StreamName}^{\uparrow}$ *windows, the readback row R exposes the* $\mathsf{RegSeqRat}^{\uparrow}$ *data, and the dyadic ledger D supplies the tolerance budget used by that readback.*

Proof. Project the accepted carrier. The source request is held in F, but F alone does not expose a regular rational name to downstream consumers.

Replay the selector route by C. The request first reaches the finite selector windows W, and those windows are the only place where the relevant $\mathsf{StreamName}^{\uparrow}$ observations are visible.

After W is fixed, the readback row R supplies the $\mathsf{RegSeqRat}^{\uparrow}$ data. The tolerance row D is then read as the dyadic budget controlling the selector comparison and the regular readback.

Transport by H preserves the same order. Thus the handoff is a finite BEDC route from Cauchy filters to stream windows, regular readbacks, and dyadic tolerances, not a quotient of filters or a selected host representative. □

Theorem 4713.4 (Cauchy filter selector Real and completion seal boundary)**.** *For every accepted* $\mathsf{CauchyFilterSelector}^{\uparrow}$ *carrier* $S = (F, W, R, D, E, H, C, P, N)$*, every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer read exposed by* P *factors through the seal row* E *only after the source Cauchy-filter data, finite selector windows, regular readback, and dyadic tolerance ledger have been displayed. The visible boundary is*

$$F, W, R, D \longmapsto E \longmapsto H, C, P, N.$$

Therefore the packet provides a finite selector interface for the Real and Completion route without exporting quotient filters, host-selected representatives, countable choice, host real equality, or ambient Real completeness.

Proof. Read the seal row in the carrier. The row E is placed after the source filter data, selector windows, regular readback, and dyadic tolerance ledger, so a completion-facing or real-facing consumer cannot reach it from F alone.

The replay row C fixes the same order for every accepted request. It first consumes F, then the selector windows W, then the regular readback R, and then the dyadic tolerance ledger D before the seal row is available.

Componentwise transport by H does not add a new route. It preserves the displayed rows under classifier comparison, while P and N record only the provenance and local naming boundary of that finite route.

The excluded objects are absent from the carrier and from the replay path. Hence the completion-or-Real seal is exactly the displayed downstream boundary, not a quotient filter, selected representative, choice schedule, host equality, or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5886.1, Definition 5886.2, Definition 5886.3, and Definition 5886.4 seed the finite selector interface between CauchyFilter, StreamName, RegSeqRat, DyadicRatCore, Real, and MetricCompletion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient filters, host-selected representatives, countable choice, host real equality, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Lean closure requires carrier admission, selector-window exactness, RegSeqRat handoff, dyadic ledger stability, and Real or Completion seal boundary for BEDC.Derived.CauchyFilterSelectorUp.

Constructive story: The construction starts from a displayed CauchyFilter row, reads a finite selector window through StreamName observations, extracts RegSeqRat data under a DyadicRatCore tolerance ledger, and exposes Real or MetricCompletion access only through the downstream seal row.

The $\mathsf{Cauchy}^{\uparrow}$ packet is consumed through chapter 301 and chapter 38 before downstream completion or calculus reads inspect the finite Cauchy windows.

Chapter 4714

A Concrete Naming Certificate for $\mathsf{CauchyModulusSpace}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyModulusSpace}^{\uparrow}$ packet records a carrier-space interface for explicit Cauchy modulus schedules. It is anchored in the single-modulus certificate of chapter 292, the finite stream windows of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real seal of chapter 38, and the fast Cauchy sequence route of chapter 2185. The chapter treats a family of modulus schedules as finite naming data, not as a quotient of real sequences or as an ambient completeness theorem.

Definition 4714.1 (Cauchy modulus space carrier)**.** *A* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, S, W, D, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index row for the family of explicit modulus schedules.*
2. *S assigns to each displayed index a* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row, including the monotone precision requests used by the family.*
3. *W records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows inspected by the schedule family.*
4. *D is the dyadic tolerance ledger, read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the scheduled windows.*
6. *Q records the* $\mathsf{Real}^{\uparrow}$ *seal boundaries at which a scheduled read may leave rational and dyadic data for a real-facing consumer.*
7. *H records componentwise* hsame *transport for $I, S, W, D, R, Q, C, P, N$.*
8. *C records displayed* Cont *replay from an index and precision request through the schedule row, stream window, dyadic tolerance ledger, regular rational readback, and real seal boundary.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusSpace}^{\uparrow}$*,* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and the local naming row.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only after transporting the displayed rows componentwise by hsame*. It has no coordinate for an unscheduled Cauchy oracle, quotient equality of sequences, a selected real limit, countable choice, or an ambient completion theorem.*

Lean4 ✓ `BEDC.Derived.CauchyModulusSpaceUp.CauchyModulusSpaceTasteGate single carrier alignment`

Theorem 4714.2 (Cauchy modulus space NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *carrier*

$$M = (I, S, W, D, R, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyModulusSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite index family, schedule admission for the displayed* $\mathsf{CauchyModulus}^{\uparrow}$ *rows, finite* $\mathsf{StreamName}^{\uparrow}$ *window admission, dyadic tolerance compatibility,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback compatibility,* $\mathsf{Real}^{\uparrow}$ *seal-boundary compatibility, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, and local naming for the packet.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyModulusSpaceNameCertObligations`

Proof. Project the accepted carrier of Definition 5887.1. The analytic data are precisely I, S, W, D, R, Q, and the structural rows are precisely H, C, P, N.

Schedule admission is rowwise over I. Each index exposes its explicit modulus schedule before any stream window is inspected, so the packet cannot replace the family by an unscheduled oracle.

The tolerance and readback rows are then forced through D and R. The real boundary row Q is available only after those rational and dyadic ledgers have been displayed.

Finally H, C, P, N transport, replay, source, and name the same route. Since no excluded host object is a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 4714.3 (Cauchy modulus space finite route)**.** *Every real-facing comparison of two accepted* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *carriers factors through finite schedule rows, finite* $\mathsf{StreamName}^{\uparrow}$ *windows, dyadic tolerance ledgers,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{Real}^{\uparrow}$ *seal boundaries, componentwise* hsame*, displayed* Cont*,* Pkg*, and the local* NameCert *rows. The route exports a shared modulus-comparison surface for later diagonal* $\mathsf{Real}^{\uparrow}$ *completion arguments without introducing quotient sequence equality, selected limits, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyModulusSpaceFiniteRoute`

Proof. Open both carriers using Definition 5887.1. A comparison can inspect only the finite index rows, schedule rows, stream windows, tolerance ledgers, readback rows, and seal boundaries.

Componentwise hsame in H transports the two packets to a common finite surface. Displayed Cont replay in C keeps each precision request attached to its schedule, stream window, dyadic tolerance, regular readback, and real seal boundary.

The provenance and naming rows P, N package that finite surface as the local certificate. Thus later diagonal completion routes can share modulus comparison data without receiving any quotient or choice-based object. □

Theorem 4714.4 (CauchyModulusSpace seed interface)**.** *Every accepted* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *packet exports its modulus schedule family to the L10 four-object seal route only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Cauchy}^{\uparrow}$ *root route, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. No consumer of this seed interface can expose quotient stream equality, a selected limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness as part of the packet surface.*

Proof. Project the carrier of Definition 5887.1. The modulus family is displayed by I, S, and every inspected request is routed through the finite observation rows W, D, R, Q before the structural rows H, C, P, N can name or replay it.

Apply Definition 5887.3. Any real-facing comparison has already factored through finite schedule rows, stream windows, dyadic tolerances, regular rational readbacks, and the terminal Real seal boundary.

The $\mathsf{Cauchy}^{\uparrow}$ root route receives exactly that finite schedule surface. Since the carrier has no coordinate for quotient equality, selected limits, countable choice, or ambient completeness, the seed interface cannot export any of those host objects to L10 Real and Completion consumers. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyModulusSpaceSeedInterface`

Theorem 4714.5 (CauchyModulusSpace tail composition)**.** *For every accepted* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *carrier*

$$M = (I, S, W, D, R, Q, H, C, P, N),$$

two displayed modulus schedules in the family compose only through finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and terminal* $\mathsf{Real}^{\uparrow}$ *seal rows. The composed tail read is the finite route*

$$I, S, W, D, R, Q \longmapsto H, C, P, N$$

and it exports no quotient sequence equality, selected limit, countable choice, or ambient completeness object.

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyModulusSpaceTailComposition`

Proof. Project the carrier of Definition 5887.1. The two schedules are displayed rows under S indexed by I, and their inspected tails must pass through the same finite window row W.

Apply the finite route and seed interface, Definition 5887.3 and Definition 5887.4. These results force the tolerance ledger D, regular readback R, and Real seal boundary Q to remain visible before the composed tail can be consumed.

Finally replay the structural rows. Componentwise transport H, displayed continuation C, provenance P, and local naming N preserve the same finite schedule surface, so tail composition does not add quotient equality, selected limits, countable choice, or ambient completeness. □

Theorem 4714.6 (CauchyModulusSpace filter handoff)**.** *Every CauchyFilter or CauchyFilterCompletion consumer of an accepted* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *packet receives the modulus family only through the finite handoff*

$$I, S, W, D, R, Q, H, C, P, N.$$

The handoff may be consumed as filter-facing Cauchy evidence, but it cannot be reinterpreted as quotient sequence equality, a selected limit, countable choice, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyModulusSpaceFilterHandoff`

Proof. Begin with a filter-facing read. The seed interface of Definition 5887.4 already routes every scheduled request through finite stream windows, dyadic tolerances, regular rational readback, the Cauchy root route, and the terminal Real seal.

Use tail composition from Definition 5887.5. It shows that composing displayed schedules preserves the same finite route through I, S, W, D, R, Q before structural replay.

The filter consumer therefore receives only the transported and replayed packet named by H, C, P, N. Since the carrier contains no quotient equality coordinate, no selected limit, no

countable-choice schedule, and no ambient completeness row, CauchyFilter and CauchyFilterCompletion may consume only the displayed finite handoff. □

Theorem 4714.7 (CauchyModulusSpace diagonal-family exactness)**.** *A diagonal Real or Completion consumer of an accepted* $\mathsf{CauchyModulusSpace}^{\uparrow}$ *packet may compare schedule families only through the displayed rows*

$$I, S, W, D, R, Q, H, C, P, N.$$

The diagonal request must be routed through finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary before any structural transport, replay, provenance, or local naming row can be consumed. The comparison exports no quotient stream equality, selected limit, countable-choice schedule, or ambient Real completeness theorem.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyModulusSpaceDiagonalFamilyExactness`

Proof. Start with the finite route of Definition 5887.3. It already factors every real-facing comparison of two accepted packets through the finite schedule rows, stream windows, dyadic tolerance ledgers, regular rational readbacks, Real seal boundaries, and the structural rows H, C, P, N.

Apply the seed interface of Definition 5887.4. It binds every L10 request to the schedule family I, S before the finite windows W, tolerance ledger D, readback R, and seal boundary Q are exposed.

Finally use the filter handoff of Definition 5887.6. A diagonal completion consumer is still a consumer of the same finite handoff, so it receives only $I, S, W, D, R, Q, H, C, P, N$ and cannot add quotient equality, selected limits, countable choice, or ambient completeness. □

Falsifiable prediction: A $\mathsf{CauchyModulusSpace}^{\uparrow}$ consumer that compares schedule families while omitting $I, S, W, D, R, Q, H, C, P, N$ refutes the carrier surface of Definition 5887.1.

Independence witness: cauchymodulus, streamname, regseqrat, dyadicratcore, real, fast-cauchy-sequence: no listed sibling binds a family of explicit Cauchy modulus schedules together with finite stream windows, dyadic tolerance ledgers, regular rational readbacks, Real seal boundaries, componentwise transport, replay, provenance, and local naming in one carrier-space packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusSpace}^{\uparrow}$ packet is generated from a finite family of explicit Cauchy modulus schedules, finite StreamName windows, dyadic tolerance ledgers, RegSeqRat readbacks, Real seal boundaries, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5887.1, Definition 5887.2, and Definition 5887.3 seed the carrier-space interface for explicit modulus schedule families and shared finite comparison routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close diagonal Real completion, quotient equality of Cauchy sequences, selected limits, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, schedule-family exactness, dyadic and regular readback compatibility, Real-seal boundary nonescape, and a Lean carrier formalization for BEDC.Derived.CauchyModulusSpaceUp.

Chapter 4715

A Concrete Naming Certificate for $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$

Following Bishop and Bridges on constructive completion and the finite-limit language of regular category theory, the $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$ packet records the boundary where a displayed Cauchy-completion route preserves the finite-limit rows that its source already exposes. It sits beside the Cauchy source route of chapter 3413, the metric-completion universal-property route of chapter 2124, the functorial completion route of chapter 423, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only a finite left-exactness boundary for displayed completion data; it does not assert quotient completions, selected limits, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4715.1 (Cauchy completion left-exactness carrier)**.** *A* $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, U, D, K, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source finite-limit row, recording the displayed terminal, product, equalizer, or kernel-pair data available before completion is read.*
2. *U is the completion unit row, recording the source-to-completion unit reads for every object named by S.*
3. *D is the dense image row, keeping each completed finite-limit comparison tied to the same source rows and unit rows.*
4. *K is the kernel-pair preservation row, recording that equalizer and pullback comparisons are read through the displayed source kernel-pair data rather than through host quotient equality.*
5. *E is the extension ledger, recording the universal-property and functorial completion rows used to transport finite-limit witnesses into completion-facing reads.*
6. *H records componentwise* hsame *transport for S, U, D, K, E, C, P, N.*
7. *C records displayed* Cont *replay from a finite-limit request through S, U, D, K, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionLeftExactness}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for quotient completion equality, selected representatives, selected finite limits, countable choice, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionLeftExactnessUp.TasteGate.CauchyCompletionLeftExactnessTasteGate single carrier alignment`

Theorem 4715.2 (Cauchy completion left-exactness NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$ *carrier*

$$L = (S, U, D, K, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionLeftExactness}^{\uparrow}}$ *surface consists exactly of carrier admission for the source finite-limit row, completion unit rows, dense image rows, kernel-pair preservation row, extension ledger, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. Every completion-facing finite-limit read must expose S, U, D, K before E, H, C, P, N can be consumed.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyCompletionLeftExactnessNameCertObligations`

Proof. Project the carrier of Definition 5888.1. The source finite-limit row, unit row, dense image row, kernel-pair row, extension ledger, transport, replay, provenance, and local name are exactly the displayed coordinates.

The finite-limit boundary is read through S, U, D, K. The source row supplies the terminal, product, equalizer, or kernel-pair data; the unit row embeds the displayed source names into completion-facing reads; the dense image row keeps those reads tied to source data; and the kernel-pair row confines exactness comparisons to displayed finite rows.

The remaining rows E, H, C, P, N transport and name the same route. Since quotient completion equality, selected representatives, selected finite limits, countable choice, host equality, and ambient completeness have no carrier coordinate, projection of the displayed rows exhausts the NameCert obligations. □

Theorem 4715.3 (Cauchy completion left-exactness carrier admission)**.** *For every accepted* CauchyCompletionLeftE *carrier*

$$L = (S, U, D, K, E, H, C, P, N),$$

the source finite-limit row S, completion unit row U, dense image row D, kernel-pair preservation row K, extension ledger E, componentwise hsame *transport H, displayed* Cont *replay C, provenance row P, and local* NameCert *row N are all admitted as finite coordinates of the same packet. No completion-facing read may treat one of these rows as ambient host data detached from the carrier.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyCompletionLeftExactness carrier admission`

Proof. Project the carrier of Definition 5888.1. Its coordinates are exactly $S, U, D, K, E, H, C, P, N$, so each named row is admitted by carrier membership.

Apply Definition 5888.2. The obligation surface requires every completion-facing finite-limit read to expose S, U, D, K before the extension, transport, replay, provenance, and naming rows can be consumed.

Since quotient completion equality, selected representatives, selected finite limits, countable choice, host equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness have no carrier coordinate, none of the admitted rows can be reread as detached host data. □

Theorem 4715.4 (Cauchy completion left-exactness unit-density route)**.** *Every displayed finite-limit comparison read through an accepted* $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$ *carrier factors first through the source finite-limit row* S*, then through the completion unit row* U*, and then through the dense image row* D *before the extension ledger* E *and structural rows* H, C, P, N *are inspected. This route records the finite source-to-completion passage without selecting representatives of completed objects or invoking countable choice.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyCompletionLeftExactnessUnitDensityRoute`

Proof. Begin with the carrier admission theorem Definition 5888.3. It keeps S, U, D as visible coordinates of the same finite packet.

The source row S supplies the finite-limit data before completion is read. The unit row U records the displayed source-to-completion unit for each object named by S, and the dense image row D keeps the resulting completion-facing comparison tied back to the same source and unit rows.

Only after this route is exposed can E, H, C, P, N be consumed. The extension ledger and the structural rows transport, replay, package, and name the source-unit-density passage; they do not add selected representatives, countable choice, or host equality of completed objects. □

Theorem 4715.5 (Cauchy completion left-exactness kernel-pair preservation)**.** *For every accepted* $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$ *carrier* $L = (S, U, D, K, E, H, C, P, N)$*, any equalizer, pullback, or kernel-pair comparison visible after completion is read through the displayed kernel-pair row* K *together with the source finite-limit row* S*, completion unit row* U*, and dense image row* D*. The comparison cannot be exported as quotient completion equality, a selected finite limit, or ambient equality of completed objects.*

Proof. Project the kernel-pair coordinate K from the carrier. By definition, K records equalizer and pullback comparisons through displayed source kernel-pair data rather than through a host quotient.

Use the unit-density route theorem Definition 5888.4. It places every completion-facing finite-limit comparison behind S, U, D, so the kernel-pair row is read as part of the same source-to-completion passage.

Finally apply Definition 5888.2. The rows E, H, C, P, N only extend, transport, replay, package, and name the displayed comparison. They add no coordinate for quotient completion equality, selected finite limits, or ambient equality of completed objects, so preservation remains confined to K and its source, unit, and dense-image context. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyCompletionLeftExactnessKernelPairPreservation`

Theorem 4715.6 (Cauchy completion left-exactness regular-limit pullback)**.** *For every accepted* $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$ *carrier* $L = (S, U, D, K, E, H, C, P, N)$*, any regular Cauchy limit read used by a finite-limit comparison factors through the source finite-limit row* S*, the completion unit row* U*, the dense image row* D*, the kernel-pair row* K*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback surface, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal before the extension ledger* E *is consumed. Thus the regular-limit comparison is a pullback of displayed source, unit, dense-image, kernel-pair, regular-readback, and real-seal rows, not a quotient completion or a selected representative of a completed object.*

Proof. Project the accepted carrier. The rows $S, U, D, K, E, H, C, P, N$ are the only admitted coordinates, so a finite-limit comparison cannot begin from a hidden completed object or a host-level limit.

Apply Definition 5888.4. It places every completion-facing finite-limit comparison behind the source finite-limit row, the completion unit row, and the dense image row before the extension ledger and structural rows are inspected.

Next apply Definition 5888.5. Equalizer, pullback, and kernel-pair comparisons remain confined to the displayed kernel-pair row together with the same source, unit, and dense-image context.

The regular Cauchy limit read is then exposed through the sibling $\mathsf{RegSeqRat}^{\uparrow}$ readback surface named in the chapter introduction, and the resulting endpoint is sealed only through the sibling $\mathsf{Real}^{\uparrow}$ boundary. Since those sibling rows are read after S, U, D, K and before E, the comparison has the announced displayed pullback route. No coordinate remains for quotient completion equality, selected representatives, selected finite limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyCompletionLeftExactnessRegularLimitPullback`

Theorem 4715.7 (Cauchy completion left-exactness RegSeqRat unit pullback)**.** *For every accepted* $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$ *carrier* $L = (S, U, D, K, E, H, C, P, N)$*, any finite-limit comparison whose completion unit route reaches a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback factors first through the source finite-limit row* S*, completion unit row* U*, dense image row* D*, and kernel-pair row* K*. It then reads the* $\mathsf{RegSeqRat}^{\uparrow}$ *surface and terminal* $\mathsf{Real}^{\uparrow}$ *seal before the extension ledger and structural rows* E, H, C, P, N *are consumed. Componentwise* hsame *transport preserves that order, so the exported comparison contains no quotient completion, selected representative, selected finite limit, host equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyCompletionLeftExactnessRegSeqRatUnitPullback`

Proof. Start with the carrier admission theorem Definition 5888.3. It keeps $S, U, D, K, E, H, C, P, N$ as finite coordinates of one accepted packet, so the comparison cannot begin from an external completed object.

Apply the unit-density route theorem Definition 5888.4. This places every completion-facing finite-limit comparison behind S, U, D before the extension ledger and structural rows are inspected.

Next apply the kernel-pair preservation theorem Definition 5888.5. Pullback and equalizer comparisons remain confined to K together with the same source, unit, and dense-image context.

Finally use the regular-limit pullback theorem Definition 5888.6. Its readback route inserts the $\mathsf{RegSeqRat}^{\uparrow}$ surface and the terminal $\mathsf{Real}^{\uparrow}$ seal after S, U, D, K and before E, H, C, P, N. Componentwise hsame transport therefore preserves the displayed order, while the excluded quotient, selection, choice, host-equality, and ambient-completeness rows remain absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionLeftExactness}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionLeftExactness}^{\uparrow}$ packet is generated from source finite-limit rows, completion unit rows, dense image rows, kernel-pair preservation, an extension ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionLeftExactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5888.1 and Definition 5888.2 seed the finite left-exactness boundary for displayed Bishop-style Cauchy completion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionLeftExactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected finite limits, selected representatives, countable choice, host equality of completed objects, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source finite-limit exposure, unit-row exposure, dense image confinement, kernel-pair preservation, extension-ledger confinement, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionLeftExactnessUp.

Theorem 4715.8 (Cauchy root UnaryHistory admission)**.** *Every accepted root* $\mathsf{Cauchy}^{\uparrow}$ *consumer read admits a UnaryHistory-facing presentation before it enters any filter, modulus, or Real-facing route. The admitted packet is the finite row surface*

$$U = (S, Q, D, R, E, H, C, P, N),$$

where S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* Q *is the directed tail-request row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, and* H, C, P, N *are componentwise transport, displayed replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyRootUnaryAdmission`

Proof. Project the root stream and tail-request carriers already displayed for $\mathsf{Cauchy}^{\uparrow}$. Their shared rows expose finite StreamName windows before any tolerance, readback, or terminal seal can be read.

The directed request row supplies the unary admission point. It records one visible later-window request over the same finite stream surface, so the read is a UnaryHistory-facing row rather than a parameter transport over an ambient sequence.

The dyadic, regular readback, Real seal, and structural rows then repack the same finite route. No quotient stream, selected limit, host equality, countable choice, or ambient completeness row is exported. □

Theorem 4715.9 (Cauchy root filter-modulus compatibility)**.** *For every admitted root packet* $U = (S, Q, D, R, E, H, C, P, N)$*, any* $\mathsf{CauchyFilter}^{\uparrow}$ *or finite filter consumer that reads the tail request must use the same modulus-compatible route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{CauchyTailRequest}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}.$$

The filter row may refine the visible window named by S *through* Q*, but it cannot replace* D *by an external tolerance oracle or replace* R *by a selected limit.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyRootFilterModulusCompatibility`

Proof. Start with the admitted packet of Definition 5888.8. The stream row S and directed request row Q are read before any filter-facing or modulus-facing datum.

Apply the existing Cauchy filter Real-seal route. It inserts the finite request row before the dyadic tolerance ledger, so a filter consumer reaches D and R only through the displayed tail request.

The structural rows preserve that order under hsame transport and Cont replay. Thus a finite filter may narrow the displayed request, but the modulus and regular readback remain the same BEDC rows. □

Theorem 4715.10 (Cauchy root RegSeqRat Real handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-to-*$\mathsf{Real}^{\uparrow}$ *handoff exported by a root* $\mathsf{Cauchy}^{\uparrow}$ *read factors through the finite windows, directed request, dyadic tolerance ledger, and regular rational readback of Definition 5888.9. The Real seal* E *is available only after* S, Q, D, R, H, C, P, N *have been displayed, and it exports no quotient filter, selected real, countable-choice schedule, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Read the filter-modulus compatibility theorem. It places the StreamName window, directed request, dyadic tolerance ledger, and RegSeqRat readback in a fixed order before any Real-facing boundary.

The handoff row is exactly R followed by E. A Real-facing consumer therefore receives rational readback through $\mathsf{RegSeqRat}^{\uparrow}$ first and may inspect the terminal seal only after that readback has been displayed.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no quotient filter, selected real, choice schedule, host equality, or ambient completeness coordinate, the handoff remains a finite BEDC route. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyRootRegSeqRatRealHandoff`

The $\mathsf{Cauchy}^{\uparrow}$ packet enters the L10 dependency lattice through its sibling route before completion or filter consumers inspect it. Every such consumer first reads the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ regular-rational readback of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The Cauchy route is therefore a displayed sibling dependency path, not a floating completion primitive or a host-level filter object.

Theorem 4715.11 (Cauchy L10 sibling dependency route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *consumer in the L10 lattice receives finite observation windows from chapter 126, regular-rational readback from chapter 301, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38 before any Real-facing approximation is public. The route exports no selected limit, quotient equality, host filter object, or ambient completeness principle.*

Proof. Project the accepted Cauchy packet through its finite observation surface. The first visible rows are the $\mathsf{StreamName}^{\uparrow}$ windows, so downstream readers cannot begin from a host-level limit predicate.

Next read the regular-rational sibling. The $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the finite regularity readback used by Cauchy consumers before the packet reaches the Real-facing boundary.

Finally expose the $\mathsf{Real}^{\uparrow}$ seal. Since the seal is reached only after the displayed windows and readback rows, the route supplies finite windows and regular-rational data before public approximation, and it leaves no coordinate for selected limits, quotient equality, host filters, or ambient completeness. □

Lean4 ✓ `BEDC.Derived.CauchyUp.L10SiblingDependency.CauchyL10SiblingDependencyRoute`

Theorem 4715.12 (Cauchy route RegSeqRat tail inversion)**.** *Every accepted* $\mathsf{Cauchy}^{\uparrow}$ *consumer that exposes a* $\mathsf{Real}^{\uparrow}$*-facing approximation through the displayed L10 sibling route must first expose the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational tail row and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. If either row is absent, the consumer has no public* $\mathsf{Real}^{\uparrow}$*-facing approximation route through the* $\mathsf{Cauchy}^{\uparrow}$ *L10 lattice.*

Proof. Start with Definition 5888.11. A public approximation route is visible only after the accepted Cauchy packet has passed through finite $\mathsf{StreamName}^{\uparrow}$ windows, regular-rational readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Read the windows first. They determine which finite observations are available to the consumer, but they do not by themselves supply a regular rational tail or a tolerance account.

Next inspect the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ rows. The regular-rational tail supplies the readback values, while the dyadic ledger supplies the tolerance discipline needed before those values can be read as a Real-facing approximation.

Finally apply the $\mathsf{Real}^{\uparrow}$ seal. Since the seal is reached only after the displayed tail and tolerance rows, deleting either row leaves no public route from the Cauchy consumer to a Real-facing approximation. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyRouteRegSeqRatTailInversion`

Theorem 4715.13 (Cauchy RegSeqRat–Real completion lattice)**.** *Every completion-facing* $\mathsf{Cauchy}^{\uparrow}$ *read factors through the displayed sibling lattice*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before any completion consumer may read a limit row. The StreamName windows are the observation boundary of chapter 126; the regular rational tails are the readback boundary of chapter 301; the metric-completion request is the comparison boundary of chapter 1506; and the terminal seal is the Real boundary of chapter 38. The route exports no quotient stream, selected representative, selected limit, countable-choice schedule, host real equality, or ambient completeness principle.

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyRegSeqRatRealCompletionLattice`

Proof. Read the hub through its displayed child routes. The finite-window dependency of Definition 3688.8 and the RegSeqRat–StreamName dependency lattice already force every Real-facing Cauchy read to expose $\mathsf{StreamName}^{\uparrow}$ windows before it consumes regular rational readback rows.

Next apply the regular-source completion route of Definition 3688.11. The $\mathsf{MetricCompletion}^{\uparrow}$ boundary receives the same displayed $\mathsf{RegSeqRat}^{\uparrow}$ tail budget, so a completion consumer cannot jump directly from a Cauchy name to a limit row.

Finally use the metric-completion forward lattice. It places the terminal $\mathsf{Real}^{\uparrow}$ seal downstream of the metric-completion comparison, with no quotient stream, selected representative, selected limit, countable-choice schedule, host equality, or ambient completeness coordinate. Thus the public completion read is exactly the four-surface lattice displayed in the statement. □

Theorem 4715.14 (Cauchy public L10 export)**.** *The public* $\mathsf{Cauchy}^{\uparrow}$ *export for L10 consumers is exactly the finite route already established by Definition 3413.1, Definition 5888.16, Definition 5888.18, and Definition 5888.10:* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *route. A public consumer receives no quotient stream equality, selected limit, countable-choice schedule, host real equality, quotient completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyPublicL10Export`

Proof. Start with the carrier boundary. Definition 5888.16 exhausts the accepted Cauchy packet by the Cauchy source row, finite windows, dyadic tolerances, regular readback, Real-facing seal, transport, replay, provenance, and local naming.

Use the scoped filter-modulus route. Definition 5888.18 shows that filter, modulus, Real-facing, and completion-facing consumers all read the same finite path rather than an external completion object.

Finally apply the root readback handoff of Definition 5888.10. It places the $\mathsf{RegSeqRat}^{\uparrow}$ readback and terminal $\mathsf{Real}^{\uparrow}$ seal downstream of the same window and tolerance rows. Thus the public L10 export is the displayed route itself, with no additional host equality, selection, choice, quotient, or completeness principle. □

Theorem 4715.15 (Cauchy forward L10 sum-tail route)**.** *Every* $\mathsf{Cauchy}^{\uparrow}$ *consumer that reaches the regular sum tail-estimate surface must first pass through the regular rational source of chapter 301, the terminal real-name boundary of chapter 38, and the finite tail-estimate packet of chapter 7387. The route is an L10 dependency path through displayed StreamName, DyadicRatCore,*

RegSeqRat, RegularCauchySum, Real, BHist, hsame, Cont, Pkg, *and* NameCert *rows; it exports no quotient stream equality, selected limit, countable-choice schedule, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the $\mathsf{Cauchy}^{\uparrow}$ hub through its child routes. The core carrier exposes finite StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, and the terminal Real-facing seal before any downstream completion or arithmetic consumer is available.

The regular sum tail-estimate chapter consumes exactly that surface twice, once for each regular source row. Its tail-estimate ledger then adds the RegularCauchySum row and finite error budget without creating a detached limit object.

Thus the forward L10 route from the Cauchy hub to the sum-tail packet is the displayed dependency path through RegSeqRat, Real, and the finite tail-estimate surface. Since each row is already a finite NameCert coordinate, no excluded host or choice principle can be read from the hub. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyBaseForwardL10Route`

Theorem 4715.16 (Cauchy seed carrier boundary)**.** *The* $\mathsf{Cauchy}^{\uparrow}$ *seed carrier boundary is exhausted by the displayed Cauchy source row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *row. It contains no quotient completion, selected limit, countable-choice schedule, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Read the carrier through Definition 3413.1. The displayed Cauchy packet provides only the source row, finite observation windows, dyadic tolerances, regular readback, the Real-facing seal route, and the structural transport, replay, provenance, and naming rows.

The sibling routes of Definition 3413.4 and Definition 3413.9 keep those rows ordered before any Real-facing consumer reads the packet. Since none of the displayed coordinates is a quotient completion, selected limit, choice schedule, host equality, or ambient completeness proof, the seed carrier boundary exports none of them. □

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchySeedCarrierBoundary`

Theorem 4715.17 (Cauchy seed NameCert obligation)**.** *For every accepted* $\mathsf{Cauchy}^{\uparrow}$ *seed packet, the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *obligation surface records exactly carrier admission, finite-window exposure, dyadic tolerance exposure, regular-rational readback, Real-seal routing, componentwise transport, continuation replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchySeedNameCertObligation`

Proof. Project the Cauchy packet through the carrier boundary of Definition 5888.16. Every admissible NameCert read is a read of one displayed carrier coordinate or one structural row attached to that coordinate.

Carrier admission supplies the Cauchy source row. Window, tolerance, and readback exposure supply the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows. The terminal route supplies the Real-facing seal, and the remaining rows supply hsame transport, Cont replay, Pkg provenance, and local naming. No further local obligation is available inside the seed packet. □

Theorem 4715.18 (Cauchy filter-modulus scoped route)**.** *Every public* $\mathsf{Cauchy}^{\uparrow}$ *seed read used by a filter, modulus, Real-facing, or completion-facing consumer factors through the displayed finite route consisting of* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row,* BHist *carrier data, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$ *row. The route exports no quotient stream equality, selected limit, countable choice, trichotomy, host real equality, quotient completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyUp.CauchyFilterModulusScopedRoute`

Proof. Start from the Cauchy seed boundary of Definition 5888.16. It exhausts the carrier by the Cauchy source row, finite stream windows, dyadic tolerance rows, regular readback, Real-facing seal, transport, replay, provenance, and local naming.

Apply Definition 5888.17. It identifies those same rows as the local NameCert obligation surface, so any filter or modulus consumer reads the seed packet through finite windows, dyadic budgets, regular-rational data, and the Real-facing seal rather than through an external completion object.

The sibling routes of Definition 1981.22, Definition 3688.9, and Definition 3991.15 keep the same packet ordered through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before completion-facing consumers inspect it. Since BHist, hsame, Cont, Pkg, and NameCert only carry, transport, replay, source, and name that route, the excluded quotient, selection, choice, trichotomy, host-equality, and ambient-completeness objects remain outside the scoped boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$**.**

Constructive story: A $\mathsf{Cauchy}^{\uparrow}$ seed packet is generated from finite stream windows, DyadicRatCore tolerance rows, RegSeqRat readback, a terminal Real-facing seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 5888.16, Definition 5888.17, Definition 5888.18, and the bridge-facing L10 export of Definition 5888.14 bind the public $\mathsf{Cauchy}^{\uparrow}$ route to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Cauchy}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected limits, countable choice, host real equality, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, dyadic tolerance exposure, regular-rational readback, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyUp.

Chapter 4716

A Concrete Naming Certificate for CauchyCompletionEmbeddingReflection$^{\uparrow}$

Following Bishop and Bridges on constructive completions and Bourbaki/Kelley on uniform embeddings, the CauchyCompletionEmbeddingReflection$^{\uparrow}$ packet records the finite route by which a dense completion embedding is reflected through the separated completion interface. It sits over the dense completion embedding of chapter 5893, the dense uniform embedding surface of chapter 1651, the functorial completion route of chapter 1937, the separated reflection boundary of chapter 3543, the finite stream windows of chapter 126, the regular-rational readback of chapter 301, the dyadic tolerance rows of chapter 291, and the terminal real seal of chapter 38. The packet names the completion-embedding reflection route only; it does not select representatives, form a quotient completion outside the displayed certificate, or import ambient completeness.

Definition 4716.1 (CauchyCompletionEmbeddingReflection carrier)**.** *A* CauchyCompletionEmbeddingReflection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (A, G, K, R, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the source approximation row whose metric or uniform histories feed the completion embedding.*
2. *G is the* CauchyCompletionDenseEmbedding$^{\uparrow}$ *row naming the dense completion embedding and its image-window requests.*
3. *K is the* DenseUniformEmbedding$^{\uparrow}$ *row that exposes uniform density before the completion target is read as separated.*
4. *R is the* CauchyCompletionFunctoriality$^{\uparrow}$ *row transporting maps and comparison windows through completion.*
5. *S is the* SeparatedCompletionReflection$^{\uparrow}$ *row that reflects the target route through the separated completion boundary.*
6. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row attached to the same finite approximation windows.*
7. *Q is the* RegSeqRat$^{\uparrow}$ *readback row reached after A, G, K, R, S, D have been displayed.*
8. *E is the terminal* Real$^{\uparrow}$ *seal row exposed only after the dense embedding, separated reflection, dyadic tolerance, and regular-rational readback rows are fixed.*

9. *H records componentwise* hsame *transport for the analytic rows and the structural rows.*
10. *C records displayed* Cont *replay of the same embedding-reflection route.*
11. *P is the* Pkg *provenance over* CauchyCompletionEmbeddingReflection$^{\uparrow}$, CauchyCompletionDenseEmbedding$^{\uparrow}$, DenseUniformEmbedding$^{\uparrow}$, CauchyCompletionFunctoriality$^{\uparrow}$, SeparatedCompletionReflection$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{CauchyCompletionEmbeddingReflection}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient-completion equality, selected representatives, countable choice, a detached separated completion, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ BEDC.Derived.CauchyCompletionEmbeddingReflectionUp.TasteGate.CauchyCompletionEmbeddingReflectio
single carrier alignment

Theorem 4716.2 (CauchyCompletionEmbeddingReflection NameCert obligations)**.** *For every accepted* CauchyCompletionEmbeddingReflection$^{\uparrow}$ *carrier* $J = (A, G, K, R, S, D, Q, E, H, C, P, N)$*, the local* NameCert$_{\text{CauchyCompletionEmbeddingReflection}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed approximation row, dense completion embedding row, dense uniform embedding row, completion functoriality row, separated reflection row, dyadic tolerance row, regular-rational readback row, terminal real seal row, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every completion-facing read must pass through* $A, G, K, R, S, D, Q, E, H, C, P, N$ *in that order, and no read may bypass the separated reflection boundary.*

Proof. Project the carrier of Definition 5889.1. Its analytic rows are A, G, K, R, S, D, Q, E, followed by the structural rows H, C, P, N.

The dense route begins with A and G. The approximation row supplies the finite source histories, while the CauchyCompletionDenseEmbedding$^{\uparrow}$ row records the image-window requests through which completion consumers may inspect the dense embedding.

The rows K, R, S then bind the same route to dense uniform embedding, functorial completion transport, and separated reflection. A completion-facing consumer therefore reaches the separated target only after the dense route and functorial route have been displayed.

The rows D, Q, E provide dyadic tolerance, regular-rational readback, and the terminal real seal. Finally H, C, P, N transport, replay, source, and name the same packet, so carrier exhaustion blocks every excluded quotient, selector, detached completion, and ambient-completeness route. □

Theorem 4716.3 (CauchyCompletionEmbeddingReflection handoff)**.** *Every downstream consumer of an accepted* CauchyCompletionEmbeddingReflection$^{\uparrow}$ *packet receives the dense completion embedding only through the finite handoff*

$$\text{CauchyCompletionDenseEmbedding}^{\uparrow} \longmapsto \text{DenseUniformEmbedding}^{\uparrow} \longmapsto \text{CauchyCompletionFunctoriality}^{\uparrow} \longmapsto \text{Separat}$$

Thus the consumer obtains a reflected separated-completion route with finite stream windows, dyadic tolerance, regular-rational readback, and a terminal real seal; it does not obtain a quotient-completion representative, a selected dense point, countable choice, or ambient completeness.

Proof. Start with Definition 5889.2. The NameCert surface forces every public read to begin with the approximation row and the dense completion embedding row.

Read the sibling chapters named in the statement along the displayed order. The DenseUniformEmbedding$^{\uparrow}$ row supplies the uniform dense image, CauchyCompletionFunctoriality$^{\uparrow}$ transports the route through

completion, and $\mathsf{SeparatedCompletionReflection}^{\uparrow}$ is the only separated target boundary available to the packet.

The finite observation route is then exposed through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. These rows are exactly the rows D, Q, E together with the stream-window data carried by A, G, K, R, S.

Since the carrier has only $A, G, K, R, S, D, Q, E, H, C, P, N$, the structural rows can preserve and name the handoff but cannot supply a quotient representative, selected dense point, countable-choice schedule, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionEmbeddingReflection}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionEmbeddingReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5889.1, Definition 5889.2, and Definition 5889.3 seed the dense completion embedding reflection route through separated completion, finite stream windows, dyadic tolerance, regular-rational readback, real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionEmbeddingReflection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient-completion equality, selected representatives, countable choice, detached separated completions, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense completion embedding exposure, dense uniform embedding compatibility, completion functoriality, separated reflection, finite-window readback, dyadic tolerance, regular-rational handoff, real sealing, and nonescape for BEDC.Derived.CauchyCompletionEmbeddingReflectionUp.

Constructive story: A $\mathsf{CauchyCompletionEmbeddingReflection}^{\uparrow}$ packet is generated from a source approximation row, a dense completion embedding row, a dense uniform embedding row, a completion functoriality row, a separated reflection row, dyadic tolerance, regular-rational readback, a terminal real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4717

A Concrete Naming Certificate for $\mathsf{SnakeLemma}^{\uparrow}$

Following Cartan–Eilenberg and Weibel homological algebra, the $\mathsf{SnakeLemma}^{\uparrow}$ packet records the finite diagram chase that turns two exact rows and compatible vertical maps into the connecting boundary route. It sits over the abelian-category carrier of chapter 176, the homology carrier of chapter 98, the spectral-sequence consumer surface that exposes $\mathsf{DerivedFunctor}^{\uparrow}$ rows in chapter 178, and the derived-functor interface of chapter 177. The packet names a displayed exactness boundary; it does not import quotient-object equality, kernel-cokernel object extensionality, or an ambient abelian-category diagram oracle.

Definition 4717.1 (Snake lemma carrier)**.** *A* $\mathsf{SnakeLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, R_0, R_1, V, K, C, E, \partial, H, T, P, L)$$

with the following displayed rows:

1. *A is the* $\mathsf{AbelianCat}^{\uparrow}$ *source row carrying the additive kernel-cokernel surface in which the diagram is read.*
2. *R_0 and R_1 are the upper and lower exact-row ledgers, each exposing three displayed object rows, two morphism rows, and the local image-kernel containment needed for exactness.*
3. *V is the vertical-compatibility row, recording the three displayed vertical morphisms and the two commutative squares that align R_0 with R_1.*
4. *K is the kernel-row ledger for the left and middle vertical maps.*
5. *C is the cokernel-row ledger for the middle and right vertical maps.*
6. *E is the exactness-boundary row, recording that the kernel leg, connecting boundary, and cokernel leg form the displayed exact boundary chain.*
7. *∂ is the connecting-boundary row from the right kernel surface to the left cokernel surface.*
8. *H records componentwise* hsame *transport for the abelian-category source, exact rows, vertical squares, kernel rows, cokernel rows, boundary rows, replay, provenance, and local naming.*
9. *T records displayed* Cont *replay from the two exact rows and vertical squares to $K, C, E, \partial, H, P, L$.*
10. *P is the* Pkg *provenance over* $\mathsf{SnakeLemma}^{\uparrow}$*,* $\mathsf{AbelianCat}^{\uparrow}$*,* $\mathsf{Homology}^{\uparrow}$*,* $\mathsf{DerivedFunctor}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*

11. L is the local $\mathsf{NameCert}_{\mathsf{SnakeLemma}^{\uparrow}}$ *row.*

The classifier compares accepted snake-lemma packets only through these rows. It contains no coordinate for host quotient representatives, unbounded diagram search, selected elements outside the displayed histories, or equality of ambient abelian-category objects.

Lean4 ✓ `BEDC.Derived.SnakeLemmaUp.TasteGate.SnakeLemmaTasteGate single carrier alignment`

Theorem 4717.2 (Snake lemma NameCert obligations)**.** *For every accepted* $\mathsf{SnakeLemma}^{\uparrow}$ *carrier*

$$S = (A, R_0, R_1, V, K, C, E, \partial, H, T, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{SnakeLemma}^{\uparrow}}$ *surface consists exactly of abelian-category source exposure through A, upper and lower exact-row exposure through R_0, R_1, vertical-square compatibility through V, kernel-row exposure through K, cokernel-row exposure through C, exact-boundary exposure through E, connecting-boundary exposure through ∂, componentwise transport through H, displayed replay through T, package provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 5890.1. The rows A, R_0, R_1, V expose the ambient additive kernel-cokernel surface, the two exact rows, and the square compatibility before any boundary read is allowed.

The kernel and cokernel ledgers are then read from K and C. They supply the visible source and target surfaces for the connecting row ∂, while E records the exactness statement tying the kernel leg, boundary leg, and cokernel leg into one chain.

Transport, replay, provenance, and local naming preserve this same finite packet through H, T, P, L. Since no excluded quotient representative, host object equality, or unbounded diagram search appears among the coordinates, the listed rows exhaust the local certificate obligations. □

Theorem 4717.3 (Snake lemma exact boundary)**.** *Every downstream* $\mathsf{Homology}^{\uparrow}$ *or* $\mathsf{DerivedFunctor}^{\uparrow}$ *consumer of an accepted* $\mathsf{SnakeLemma}^{\uparrow}$ *packet reads the boundary route*

$$\ker(v_2) \longmapsto \operatorname{coker}(v_0)$$

only through the displayed chain

$$\mathsf{AbelianCat}^{\uparrow} \longmapsto (R_0, R_1, V) \longmapsto (K, C) \longmapsto (\partial, E) \longmapsto (H, T, P, L).$$

Thus the consumer receives one finite exact-boundary packet of abelian-category source rows, exact-row ledgers, vertical-square ledgers, kernel and cokernel rows, the connecting-boundary row, exactness-boundary evidence, transport, replay, provenance, and local naming.

Proof. Start with the abelian-category source row A. The two exact rows R_0, R_1 and the vertical-compatibility row V expose exactly the diagram data on which the classical snake-lemma chase depends.

Read K and C next. These rows identify the displayed kernel and cokernel surfaces that the connecting boundary is permitted to connect, without choosing representatives outside the finite histories.

The boundary row ∂ and exactness row E then supply the only route from the right kernel surface to the left cokernel surface. A homology or derived-functor consumer therefore reads the boundary as a named packet, not as an ambient quotient construction.

Finally H, T, P, L keep the same route stable under componentwise history equality, displayed replay, provenance, and local naming. No quotient-object equality, host diagram oracle, or unbounded element chase is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{SnakeLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{SnakeLemma}^{\uparrow}$ packet is generated from an AbelianCat source row, two exact-row ledgers, vertical-square compatibility rows, kernel-row and cokernel-row ledgers, a connecting-boundary row, an exactness-boundary row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SnakeLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5890.1, Definition 5890.2, and Definition 5890.3 seed the finite snake-lemma packet over abelian-category source rows, exact-row ledgers, vertical-square compatibility, kernel rows, cokernel rows, connecting-boundary rows, exactness-boundary evidence, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SnakeLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient-object equality, host abelian-category equality, unbounded diagram search, or ambient element-chase completeness.

Upgrade path: Obligation closure requires checked carrier admission, exact-row exposure, vertical-square compatibility, kernel-row exposure, cokernel-row exposure, connecting-boundary construction, exactness-boundary preservation, replay stability, provenance exhaustion, and local naming for BEDC.Derived.SnakeLemmaUp.

Chapter 4718

A Concrete Naming Certificate for $\mathsf{RealTailDiameterGauge}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealTailDiameterGauge}^{\uparrow}$ packet records the finite gauge by which a real-facing consumer reads a regular rational tail only after the displayed tail-diameter, dyadic tolerance, stream-window, and readback rows have been exposed. It sits after the tail-diameter witness of chapter 1746, the dyadic tolerance core of chapter 291, the finite window service of chapter 126, the regular rational readback surface of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies a non-quotient L10 gauge object for Real and Completion consumers; it is not host real equality, quotient stream equality, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4718.1 (Real tail-diameter gauge BHist source)**.** *A* $\mathsf{RealTailDiameterGauge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (E, T, D, W, R, H, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row naming the real-facing boundary that the gauge is allowed to serve.*
2. *T is the* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *ledger row, recording the inspected tail threshold, two visible tail indices, and the displayed diameter bound.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row consumed by the same tail-diameter ledger.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that exposes the finite source observations inspected by T.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same window and tolerance data before any real-facing read is accepted.*
6. *H records componentwise* hsame *transport for the seal, tail-diameter ledger, dyadic tolerance, window, readback, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a real-facing gauge request through E, T, D, W, R, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RealTailDiameterGauge}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyTailDiameter}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealTailDiameterGauge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, T, D, W, R, H, C, P, N$. It has no coordinate for host real equality, quotient stream equality, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RealTailDiameterGaugeUp.TasteGate.RealTailDiameterGaugeTasteGate single carrier alignment`

Theorem 4718.2 (Real tail-diameter gauge NameCert obligation surface)**.** *For every accepted* $\mathsf{RealTailDiameterGauge}^{\uparrow}$ *carrier*

$$G = (E, T, D, W, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealTailDiameterGauge}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{Real}^{\uparrow}$ *seal row* E*, the* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *ledger row* T*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, componentwise transport* H*, displayed replay* C*, package provenance* P*, and local naming* N*.*

Proof. Project the carrier of Definition 5891.1. The analytic rows are the Real seal E, tail-diameter ledger T, dyadic tolerance D, finite window W, and regular rational readback R.

The gauge obligation is read only through T, D, W, R. The tail-diameter ledger records the visible tail request and bound, the dyadic row supplies the tolerance budget, the stream row exposes the inspected finite windows, and the regular row repacks the same data for rational readback.

The structural rows H, C, P, N preserve that route under transport, replay, provenance, and naming. Since the carrier has no coordinate for the excluded host or completion objects, the displayed rows exhaust the local NameCert surface. □

Theorem 4718.3 (Real tail-diameter gauge RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer exported by an accepted* $\mathsf{RealTailDiameterGauge}^{\uparrow}$ *packet factors through*

$$W, D \longmapsto T \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus a Real and Completion route may read the finite stream window, dyadic tolerance ledger, tail-diameter gauge, regular rational handoff, terminal Real seal, transport, replay, provenance, and local naming rows, but it receives no host real equality, quotient stream equality, selected limit, trichotomy decision, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification, or bridge check.*

Proof. Start with an exported regular-rational or real-facing read. The only finite observations available to the packet are the $\mathsf{StreamName}^{\uparrow}$ row W and the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row D.

The tail-diameter ledger T then binds those observations to a displayed tail request and diameter bound. This row is the gauge that prevents a consumer from replacing the finite tail evidence by a quotient stream or a selected limit.

Only after T is displayed does the handoff expose the $\mathsf{RegSeqRat}^{\uparrow}$ row R and the $\mathsf{Real}^{\uparrow}$ seal row E. The readback and seal are therefore downstream from the same finite gauge data.

Finally H, C, P, N transport, replay, source, and name the route. Since the excluded objects do not occur in the carrier, no consumer can bypass the displayed handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealTailDiameterGauge}^{\uparrow}}$.

Constructive story: A $\mathsf{RealTailDiameterGauge}^{\uparrow}$ packet is generated from a RealUp seal row, a CauchyTailDiameterUp ledger, a DyadicRatCore tolerance row, a StreamName window row, a RegSeqRat readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealTailDiameterGauge}^{\uparrow}}$, seed)

Scope closed: Definition 5891.1, Definition 5891.2, and Definition 5891.3 seed the finite real-facing tail-diameter gauge for regular rational and completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealTailDiameterGauge}^{\uparrow}}$, unformalized)
Bridge status: none
Not claimed: This chapter does not close host real equality, quotient stream equality, selected limits, trichotomy, countable choice, Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.
Upgrade path: Obligation closure requires checked carrier admission, Real seal confinement, CauchyTailDiameter ledger exactness, DyadicRatCore tolerance readback, StreamName window coverage, RegSeqRat handoff, transport stability, continuation replay, provenance non-escape, and local naming for BEDC.Derived.RealTailDiameterGaugeUp.

This hub routes the EffectiveRealCompactIntervalSearch$^{\uparrow}$ packet through chapter 1250, chapter 1767, and chapter 5899 before the child files expose the compact interval search carrier.

Chapter 4719

A Concrete Naming Certificate for EffectiveRealCompactIntervalSearch$^{\uparrow}$

Following Bishop–Bridges constructive analysis, the EffectiveRealCompactIntervalSearch$^{\uparrow}$ packet records the finite search surface by which a continuous real-valued map on a displayed closed bounded interval is inspected through compact finite nets, uniform-modulus data, and interval bisection rows before a downstream extremum consumer reads a certified bracket. It sits over the real-name seal of chapter 38, the interval endpoint carrier of chapter 1591, the compact-net selector of chapter 914, the graph and pointwise rows of chapter 130, and the tolerance handoff of chapter 369. The packet gives the constructive extreme-value route a finite searchable carrier; it does not assert classical Heine–Borel compactness, choose a host maximum, or identify quotient real functions.

The search packet consumes the compact interval finite-net route before it exports bisection or extreme-value handoffs. Its selector row P is read downstream of the closed-bounded interval net of chapter 1250 and the finite epsilon-net surface of chapter 1767; the bisection ledger then refines those displayed cells instead of introducing an open-cover compactness argument or a selected supremum.

Definition 4719.1 (Effective real compact-interval search carrier)**.** *An* EffectiveRealCompactIntervalSearch$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, F, U, P, B, V, H, C, Q, N)$$

with the following visible rows:

1. *I is the* ClosedBoundedInterval$^{\uparrow}$ *endpoint and containment row whose endpoints are read through* Real$^{\uparrow}$ *names.*
2. *F is the* ContinuousMap$^{\uparrow}$ *graph row for a real-valued map over the interval source named by I.*
3. *U is the* UniformModulus$^{\uparrow}$ *tolerance handoff for F on the displayed interval source.*
4. *P is the* CompactNetModulusSelector$^{\uparrow}$ *finite-net row that lists the rational mesh cells and selected centers used by the search.*
5. *B is the bisection ledger, a finite prefix tree of interval halves whose cells refine P at the requested tolerance.*
6. *V is the value-comparison ledger storing the displayed* Real$^{\uparrow}$ *value rows and rational error budgets attached to the cells of B.*

7. *H stores componentwise* hsame *transport for the interval, continuous-map, uniform-modulus, selector, bisection, value-comparison, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from an extremum-search request through $I, F, U, P, B, V, H, Q, N$.*
9. *Q is the* Pkg *provenance over* EffectiveRealCompactIntervalSearch$^{\uparrow}$, Real$^{\uparrow}$, ClosedBoundedInterval$^{\uparrow}$, CompactNetModulusSelector$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{EffectiveRealCompactIntervalSearch}^{\uparrow}}$ *row.*

The classifier compares accepted search carriers only through $I, F, U, P, B, V, H, C, Q, N$. No open-cover compactness theorem, selected host maximum, excluded-middle comparison on all real values, quotient function equality, or ambient completeness coordinate is part of the carrier.

Theorem 4719.2 (Effective real compact-interval search obligations)**.** *For every accepted* EffectiveRealCompactInte *carrier $S = (I, F, U, P, B, V, H, C, Q, N)$, the local* NameCert$_{\text{EffectiveRealCompactIntervalSearch}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the closed bounded interval source, continuous-map graph, uniform-modulus handoff, compact-net selector, bisection ledger, value-comparison ledger, transport, replay, provenance, and local naming;*
2. *source agreement, requiring I, F, U, and P to name the same displayed interval source before any cell is searched;*
3. *selector exactness, requiring the search cells in B to refine the finite* ProbeBundle *centers and tolerances exposed by P;*
4. *value-row binding, requiring every value comparison in V to be attached to a cell of B, a displayed graph row of F, and the error budget supplied by U;*
5. *bisection stability, requiring interval refinement to preserve endpoint containment and the selected candidate cell under componentwise* hsame *transport;*
6. *extremum handoff, requiring any lower-bound, upper-bound, near-minimum, or near-maximum read to pass through B, V, H, C, Q, N rather than through a host maximum selector;*
7. *non-escape, excluding open-cover compactness, classical Heine–Borel selection, trichotomy on arbitrary real values, quotient function equality, and ambient* Real$^{\uparrow}$ *completeness from the local packet.*

No effective compact-interval search obligation is stored outside these rows.

Proof. Project the carrier of Definition 5892.1. The interval source is I, the continuous graph is F, the uniform tolerance handoff is U, and the finite selector row is P.

The search may begin only after these rows agree on the same displayed interval source. The bisection ledger B then refines the selector cells supplied by P, so each later comparison is attached to a visible interval cell rather than to an external point choice.

The value ledger V reads graph values from F with the error budget delivered by U. This makes every candidate comparison a finite statement about named cells and rational tolerances.

Finally the extremum-facing read uses H, C, Q, N to replay and name the same route. Since the carrier has no coordinate for open-cover compactness, a host maximum, global real trichotomy, quotient function equality, or ambient completeness, none of those objects can enter the local certificate. □

Theorem 4719.3 (Effective real compact-interval bisection induction)**.** *For an accepted* EffectiveRealCompactInterv *carrier $S = (I, F, U, P, B, V, H, C, Q, N)$, every finite bisection stage in B is obtained by induction from the endpoint row I and the selector row P. The induction step replaces one displayed interval cell by its two named halves, transports the corresponding* ContinuousMap$^{\uparrow}$ *and* UniformModulus$^{\uparrow}$ *reads through H, and extends V only by value rows attached to those halves.*

Proof. The base stage is the interval cell named by I together with the first finite-net read in P. Its value ledger is the corresponding displayed graph read from F with the tolerance supplied by U.

For the induction step, choose the cell already selected by the finite ledger. The midpoint and half-interval endpoints are read as interval rows below I, and the selector exactness obligation identifies their centers with the relevant ProbeBundle entries of P.

Transport along H keeps the continuous-map graph and uniform-modulus handoff on the same source. The new value rows are therefore added to V only for the two displayed halves, so the induction never leaves the finite bisection tree. □

Theorem 4719.4 (Effective real compact-interval extreme-value handoff)**.** *Every extremum-search consumer reading an accepted* EffectiveRealCompactIntervalSearch$^{\uparrow}$ *carrier factors through*

$$I, F, U, P \longmapsto B, V \longmapsto H, C, Q, N.$$

The consumer receives a finite bracket or near-extremal cell family whose error budget is supplied by UniformModulus$^{\uparrow}$ *and whose candidates are selected by* CompactNetModulusSelector$^{\uparrow}$*. It receives no classical maximum point, open-cover compactness proof, quotient equality of functions, global trichotomy on* Real$^{\uparrow}$ *values, or ambient completeness assertion.*

Proof. Begin with the carrier projection. The only source data available to the consumer are the interval row I, continuous graph row F, uniform-modulus row U, and compact-net selector row P.

Apply Definition 5892.3. Every searched cell and every candidate value is produced inside the finite bisection ledger B and value ledger V.

The final handoff reads those ledgers through H, C, Q, N. Applying Definition 5892.2, any route that asks for a host maximum, open-cover compactness, quotient function equality, global real trichotomy, or ambient completeness is outside the accepted packet. □

Theorem 4719.5 (Effective real compact interval search finite-net handoff)**.** *Every accepted* EffectiveRealCompactIntervalSearch$^{\uparrow}$ *search packet reads a compact interval finite-net certificate, a located interval bisection row, and the* Real$^{\uparrow}$ *comparison seal before exporting the extreme-value handoff. The route passes through the closed bounded interval net of chapter 1250 and the finite epsilon-net surface of chapter 1767; it exports no open-cover compactness, selected supremum, host trichotomy, quotient real equality, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier $S = (I, F, U, P, B, V, H, C, Q, N)$ from Definition 5892.1. The compact interval finite-net data enter through the selector row P, whose cells are read only after the displayed closed bounded interval source I is fixed.

Apply Definition 5892.3. The bisection row B refines the finite cells supplied by P, and every value comparison in V is attached to a displayed graph row of F with the tolerance budget from U.

Apply Definition 5892.4. The final route reads B, V, H, C, Q, N after the finite-net source rows, so the exported extreme-value handoff is a finite search certificate rather than an open-cover compactness, supremum-selection, trichotomy, quotient-equality, or completeness principle. □

Theorem 4719.6 (Effective real compact interval search L10 sibling dependency)**.** *Every accepted* $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ *packet must display the* $\mathsf{Real}^{\uparrow}$ *seal, the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *endpoint carrier, the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row, the* $\mathsf{UniformModulus}^{\uparrow}$ *tolerance row, the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *finite net, the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *selector, the* $\mathsf{CompactNetModulusSelector}^{\uparrow}$ *row, and the* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *refinement before exporting any extremum handoff. The route is the finite-net and bisection dependency route of Definition 5892.5, not an isolated kernel-only search packet.*

Proof. Project the carrier definition, Definition 5892.1. The rows I, F, U, P, B, V expose the closed bounded interval source, continuous-map graph, uniform-modulus handoff, compact-net selector, bisection ledger, and value ledger, while the Real-facing seal is read through the displayed interval and value rows.

Apply the finite-net handoff theorem, Definition 5892.5. It forces the search route through the closed bounded interval net and finite epsilon-net surfaces before any bisection or extreme-value consumer can read the packet.

The bisection row B then supplies the located refinement consumed by the extremum handoff. The structural rows H, C, Q, N only transport, replay, source, and name that same sibling-dependent route, so no extremum handoff is exported before the listed L10 siblings are displayed. □

Theorem 4719.7 (Effective real compact interval search inverse modulus bisection)**.** *For an accepted* $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ *carrier* $S = (I, F, U, P, B, V, H, C, Q, N)$*, a displayed* $\mathsf{UniformModulus}^{\uparrow}$ *tolerance row* U *and a* $\mathsf{CompactNetModulusSelector}^{\uparrow}$ *finite-net row* P *determine a finite bisection depth in* B *whose dyadic cell diameter is below the requested tolerance. The depth is read only through* P, B, V, H, C, Q, N*: the value ledger* V *attaches comparisons to cells at that depth,* H *transports the same cells under* hsame*,* C *replays the finite request, and* Q, N *package and name the route. The construction exports no open-cover compactness proof, no host maximum, no quotient equality of functions, no trichotomy on* $\mathsf{Real}^{\uparrow}$ *values, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. Project the accepted search carrier. The uniform-modulus row U supplies the requested tolerance, while the selector row P displays the finite mesh data that the search is allowed to refine.

Apply Definition 5892.3. Each step of B replaces a displayed cell by named dyadic halves, so repeated refinement gives a finite depth at which the visible cell diameter is below the tolerance requested by U.

Apply Definition 5892.5. The finite-net row P remains the source of the cells refined by B, and the value ledger V records only comparisons attached to those cells.

Finally H, C, Q, N transport, replay, source, and name the same finite depth-control route. Because the carrier has no open-cover compactness coordinate, host maximum selector, quotient function equality coordinate, trichotomy oracle, or ambient completeness row, the inverse-modulus read remains finite interval-search data. □

Theorem 4719.8 (Effective real compact interval search finite-grid stability)**.** *For an accepted* $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ *carrier* $S = (I, F, U, P, B, V, H, C, Q, N)$*, the displayed finite-net cell selected by* P *and refined by the located bisection ledger* B *is preserved under componentwise* hsame *transport before any extreme-value handoff is exported. Thus every Real-facing extremum consumer reads the same finite cell, value row, and bisection row through* P, B, V, H, C, Q, N*, and receives no open-cover compactness proof, selected host maximum, or* $\mathsf{Real}^{\uparrow}$ *trichotomy.*

Proof. Project the carrier of Definition 5892.1. The finite-net cell is displayed by P, its bisection refinement is recorded in B, and the attached value comparisons are stored in V.

Apply the finite-net handoff theorem, Definition 5892.5. It forces the search route through the closed bounded interval net and finite epsilon-net surfaces before the bisection ledger is consumed.

Apply the inverse-modulus bisection theorem, Definition 5892.7. The bisection depth and the cell read remain tied to P, B, V, while H transports the same displayed rows and C replays the same finite request.

The carrier has no coordinate for open-cover compactness, host maxima, quotient function equality, Real trichotomy, or ambient completeness. The exported extreme-value handoff therefore preserves only the finite-grid cell and located bisection row named by the packet. □

Theorem 4719.9 (Effective real compact interval search Bishop cover link)**.** *Every accepted* $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ *carrier* $S = (I, F, U, P, B, V, H, C, Q, N)$ *reads the Bishop interval-cover finite cover ledger of chapter 5124 before it exports any bisection or extreme-value handoff. The Bishop route supplies the finite interval-cover cells refined by* P *and* B*, while the local search packet preserves the continuous-map, uniform-modulus, value-comparison, transport, replay, provenance, and naming rows. The exported route contains no open-cover compactness theorem, selected supremum, host trichotomy, quotient equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. Project the carrier $S = (I, F, U, P, B, V, H, C, Q, N)$ from Definition 5892.1. The interval source is I, the continuous graph is F, the uniform tolerance handoff is U, the finite selector row is P, the bisection ledger is B, and the value ledger is V.

Apply the finite-net handoff theorem, Definition 5892.5. It forces the search packet to read the closed bounded interval net and finite epsilon-net surfaces before the bisection ledger can be consumed.

Apply the grid-stability theorem, Definition 5892.8. The selected finite cell is preserved through P, B, V, H, C, Q, N, so the Bishop interval-cover ledger supplies interval-cover cells for the same displayed route rather than a separate compactness principle.

The remaining rows H, C, Q, N transport, replay, source, and name the same finite cover-to-search handoff. Since the carrier has no row for open-cover compactness, selected suprema, host trichotomy, quotient function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, those principles cannot be exported by the bisection or extreme-value consumer. □

Theorem 4719.10 (Effective real compact interval search RegularCauchyGluing dependency)**.** *Every completion-facing extremum-search read of an accepted* $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ *packet must expose the* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *route of chapter 5899 after the finite bisection and value ledger are displayed and before any* $\mathsf{Real}^{\uparrow}$*-facing seal is consumed. The dependency is read through the finite-net handoff of Definition 5892.5 and the grid-stability route of Definition 5892.8; it is not supplied by quotient stream equality, selected host limits, countable choice, or ambient real completeness.*

Proof. Project the carrier $S = (I, F, U, P, B, V, H, C, Q, N)$ from Definition 5892.1. The completion-facing rows available to the search are the bisection ledger B, the value-comparison ledger V, and the structural replay rows H, C, Q, N.

Apply Definition 5892.5. The finite-net route fixes the displayed interval cells and their Real-valued comparison windows before an extremum consumer can read the packet.

Apply Definition 5892.8. The same finite cell, bisection row, and value row are preserved under componentwise hsame transport, so the completion-facing read has a stable regular-Cauchy window to hand to the gluing sibling.

Route that window through $\mathsf{RegularCauchyGluing}^{\uparrow}$ before the terminal Real-facing seal is consumed. Since the carrier has no quotient stream-equality row, selected host limit, countable-choice

selector, or ambient-completeness coordinate, the gluing dependency is the only completion-facing route available after B and V are displayed. □

Closure status for $\mathsf{NameCert}_{\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5892.1, Definition 5892.2, Definition 5892.3, Definition 5892.4, Definition 5892.5, Definition 5892.7, and Definition 5892.8 seed the finite interval-search carrier from displayed Real, closed-bounded-interval, compact-net-selector, continuous-map, finite-net, and uniform-modulus rows to extremum-facing bracket and depth-control handoffs.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close classical Heine–Borel compactness, selected host maxima or minima, quotient equality of functions, global real trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source agreement, selector exactness, value-row binding, bisection stability, extremum handoff, and non-escape for BEDC.Derived.EffectiveRealCompactIntervalSearchUp.

Constructive story: An $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source, ContinuousMapUp graph rows, a UniformModulusUp tolerance handoff, a CompactNetModulusSelectorUp finite-net row, a finite bisection ledger, displayed RealUp value comparisons, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ search packet consumes the closed-bounded interval net of chapter 1250, the finite epsilon-net surface of chapter 1767, the compact-net modulus selector of chapter 914, and the located interval bisection route of chapter 1711 before exporting its extremum handoff. Thus a downstream consumer sees the finite-net and bisection dependencies as displayed route data, not as an open-cover compactness proof or a selected host extremum. The $\mathsf{EffectiveRealCompactIntervalSearch}^{\uparrow}$ route hands its finite bisection rows, interval-value rows, and compact-window certificates to the compatible-window route of chapter 5899 before any $\mathsf{Real}^{\uparrow}$ seal consumer reads a glued local search window. This dependency keeps each L10 finite-window consumer downstream from the displayed compact search packet, so the gluing step reads certified local windows rather than an ambient completeness or choice principle.

Chapter 4720

A Concrete Naming Certificate for $\mathsf{MarkedReal}^{\uparrow}$

Following Bishop–Bridges constructive real analysis, the $\mathsf{MarkedReal}^{\uparrow}$ packet records a $\mathsf{Real}^{\uparrow}$ name together with a visible mark row for zero, positive, negative, and apartness evidence. It sits after the regular rational readback of chapter 301, the finite stream-window surface of chapter 126, the terminal real-name seal of chapter 38, the apartness interface of chapter 304, and the located-real boundary of **??**. The packet lets order-facing and apartness-facing consumers inspect a finite evidence mark before reading the Real seal; it does not assert trichotomy, decide host real equality, choose a sign globally, or identify marked names by quotient representatives.

Definition 4720.1 (MarkedReal carrier)**.** *A* $\mathsf{MarkedReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (R, S, A, L, Z, Pm, Nm, Q, H, C, K, N)$$

with the following displayed rows:

1. *R is the underlying* $\mathsf{Real}^{\uparrow}$ *seal row.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the real name inspected by the mark.*
3. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the displayed stream windows.*
4. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *locality row, recording the finite locatedness request that makes the mark visible at the requested precision.*
5. *Z is the zero-mark row. It records finite evidence that the inspected name is being used through a zero-facing branch, without turning that evidence into host equality with zero.*
6. *Pm is the positive-mark row. It records a finite positive witness, such as a displayed rational lower gap, before any positive consumer may read the Real seal.*
7. *Nm is the negative-mark row. It records a finite negative witness, such as a displayed rational upper gap, before any negative consumer may read the Real seal.*
8. *Q is the* $\mathsf{ApartnessReal}^{\uparrow}$ *mark row, recording the finite apartness witness that separates the marked name from a requested comparison name or zero-facing boundary.*
9. *H records componentwise* hsame *transport for the Real seal, stream windows, regular readback, locatedness row, four mark rows, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a mark request through $S, A, L, Z, Pm, Nm, Q, R, H, K, N$.*

11. *K is the* Pkg *provenance over* $\mathsf{MarkedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{MarkedReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, S, A, L, Z, Pm, Nm, Q, H, C, K, N$. It has no coordinate for trichotomy, host equality of real values, selected sign functions, quotient representatives, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.MarkedRealUp.MarkedRealTasteGate single carrier alignment`

Theorem 4720.2 (MarkedReal NameCert obligations)**.** *For every accepted* $\mathsf{MarkedReal}^{\uparrow}$ *carrier*

$$M = (R, S, A, L, Z, Pm, Nm, Q, H, C, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{MarkedReal}^{\uparrow}}$ *surface consists exactly of carrier admission for the underlying Real seal, finite StreamName windows, regular rational readback, locatedness request, zero mark, positive mark, negative mark, apartness mark, componentwise transport, displayed continuation replay, package provenance, and local naming. Any consumer that uses a zero, positive, negative, or apartness reading must expose the corresponding visible mark row before it consumes the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Project the carrier of Definition 4720.1. The analytic rows are the Real seal R, the finite window and readback rows S, A, the locatedness row L, and the four mark rows Z, Pm, Nm, Q.

A mark consumer cannot bypass these rows. The zero-facing branch reads Z, the positive-facing branch reads Pm, the negative-facing branch reads Nm, and the apartness-facing branch reads Q before it reaches the common Real seal R.

The structural rows H, C, K, N transport, replay, source, and name the same displayed packet. Since the carrier has no trichotomy coordinate, selected sign function, host equality coordinate, quotient representative, countable-choice coordinate, or ambient completeness row, the listed rows exhaust the local NameCert surface. □

Theorem 4720.3 (MarkedReal Real seal handoff)**.** *Every* $\mathsf{MarkedReal}^{\uparrow}$ *read that reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal factors through a finite route*

$$S, A, L \longmapsto Z, Pm, Nm, Q \longmapsto R \longmapsto H, C, K, N.$$

Thus the exported object is a Real name equipped with visible zero, positive, negative, and apartness evidence rows, not a trichotomy principle, host equality decision, or chosen sign representative.

Proof. Start with an accepted packet $M = (R, S, A, L, Z, Pm, Nm, Q, H, C, K, N)$. By Definition 4720.1, the only terminal Real boundary is R.

The finite route first exposes the stream windows S, regular rational readback A, and locatedness row L. These rows place the requested read in the same finite name context as the underlying Real seal.

Next the visible mark rows are inspected. The rows Z, Pm, Nm, Q record zero-facing, positive-facing, negative-facing, and apartness-facing evidence as displayed data. None of them decides all signs of all Real names, and none identifies the carrier with a host real value.

Finally the route reaches R and then the structural rows H, C, K, N. These rows preserve the same marked packet by componentwise hsame, displayed Cont, Pkg, and local NameCert data, so the handoff exposes exactly the marked Real name stated above. □

Falsifiable prediction: A $\mathsf{MarkedReal}^{\uparrow}$ consumer that reads the terminal $\mathsf{Real}^{\uparrow}$ seal as positive, negative, zero-facing, or apart from a boundary without first exposing Pm, Nm, Z, or Q respectively refutes the carrier surface.

Independence witness: real, regseqrat, streamname, apartnessreal, locatedreal: no listed sibling supplies the whole twelve-row packet $M = (R, S, A, L, Z, Pm, Nm, Q, H, C, K, N)$, because the siblings provide the Real seal, regular readback, finite windows, apartness witness, or locatedness boundary separately while this chapter binds all four visible mark rows to one local NameCert carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{MarkedReal}^{\uparrow}}$.

Constructive story: A $\mathsf{MarkedReal}^{\uparrow}$ packet is generated from a terminal $\mathsf{Real}^{\uparrow}$ seal, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{LocatedReal}^{\uparrow}$ request row, visible zero, positive, negative, and apartness mark rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarkedReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4720.1, Definition 4720.2, and Definition 4720.3 seed the visible-mark Real carrier over Real, RegSeqRat, StreamName, ApartnessReal, and LocatedReal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarkedReal}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.MarkedRealUp`

Bridge status: none

Not claimed: This chapter does not claim trichotomy, host real equality, globally selected signs, quotient representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, checked NameCert obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, visible mark exposure, zero-mark discipline, positive-mark discipline, negative-mark discipline, apartness-mark discipline, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MarkedRealUp.

Chapter 4721

A Concrete Naming Certificate for $\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}$

Following Bishop and Bridges on constructive completions and Bourbaki/Kelley on dense embeddings, the $\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}$ packet records the finite dense-source route by which a Cauchy completion consumer reads a source object inside its completion boundary. It sits beside the dense uniform embedding surface of chapter 1651, the functorial Cauchy-completion route of chapter 1937, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet supplies dense embedding data for completion consumers without asserting quotient completion equality, selected representatives, countable choice, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4721.1 (Cauchy completion dense-embedding carrier)**.** *A* $\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (A, G, K, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the dense source row. It records the source-side Cauchy observations that a completion consumer may approximate by displayed source data.*
2. *G is the embedding graph row. It records the displayed source-to-completion graph and the finite image-window reads used by dense embedding consumers.*
3. *K is the Cauchy completion row, read through the completion-facing route associated with* $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$*.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row exposing the finite request windows inspected by the source and completion sides.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare source-image windows with completion windows.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows and dyadic tolerances.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reachable only after A, G, K, S, D, Q have been displayed.*
8. *H records componentwise* hsame *transport for the dense source, embedding graph, completion, window, tolerance, readback, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a dense-source request through $A, G, K, S, D, Q, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{DenseUniformEmbedding}^{\uparrow}$, $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient completion equality, selected representatives, countable choice, host equality of completion classes, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionDenseEmbeddingUp.CauchyCompletionDenseEmbeddingTasteGate`
`single carrier alignment`

Theorem 4721.2 (Cauchy completion dense-embedding NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}$ *carrier*

$$J = (A, G, K, S, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}}$ *surface consists exactly of carrier admission for the dense source row, embedding graph row, Cauchy completion row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every completion-facing dense read must expose A, G, K, S, D, Q before E, H, C, P, N can be consumed.*

Proof. Project the carrier of Definition 5893.1. The dense source, embedding graph, Cauchy completion row, finite windows, tolerance ledger, regular readback, and Real seal are exactly the displayed analytic coordinates.

The dense-source route is read through A, G, K. A completion consumer first fixes the source row, then the embedding graph row, and only then the completion-facing row associated with the Cauchy completion route.

The finite observation route is read through S, D, Q. The stream windows expose inspected requests, the dyadic ledger supplies the tolerance budget, and the regular rational readback repacks the same observations before any Real-facing seal is visible.

Finally E, H, C, P, N preserve and name the route. Since quotient completion equality, selected representatives, countable choice, host equality, and ambient completeness have no carrier coordinate, the listed rows exhaust the NameCert surface. □

Theorem 4721.3 (Cauchy completion dense-embedding Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion consumer exported by an accepted* $\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}$ *packet factors through*

$$\mathsf{DenseUniformEmbedding}^{\uparrow},\ \mathsf{CauchyCompletionFunctoriality}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

More precisely, the consumer reads the dense source row A, embedding graph G, Cauchy completion row K, finite windows S, tolerance ledger D, regular readback Q, terminal seal E, componentwise transport H, displayed replay C, provenance P, and local name N before the real-facing boundary is exposed.

Proof. Start with an exported Real-facing or completion-facing read. The NameCert obligations of Definition 5893.2 force the read through A, G, K before the finite observation rows can be consumed.

Read the sibling routes next. The dense source is the $\mathsf{DenseUniformEmbedding}^{\uparrow}$ surface, the completed-map side is routed through $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$, and the finite observations are the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows displayed by the carrier.

Only after those rows have been displayed can the terminal $\mathsf{Real}^{\uparrow}$ seal row E be read. The structural rows H, C, P, N transport, replay, source, and name the same route, so the handoff exports no quotient completion equality, selected representative, countable-choice selector, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}$ packet is generated from a dense source row, embedding graph row, Cauchy completion row, StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat readback, terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5893.1, Definition 5893.2, and Definition 5893.3 seed the dense-source route for Cauchy completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host equality of completion classes, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense source exposure, embedding graph exactness, Cauchy completion handoff, StreamName window coverage, DyadicRatCore tolerance readback, RegSeqRat handoff, Real seal confinement, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionDenseEmbeddingUp.

Chapter 4722

A Concrete Naming Certificate for $\mathsf{RiemannRefinementCriterion}^{\uparrow}$

Following Bishop and Bridges on Riemann–Darboux integration, the $\mathsf{RiemannRefinementCriterion}^{\uparrow}$ packet records the finite refinement criterion that lets a tagged Riemann-sum consumer compare upper Darboux rows against a gauge-local partition route. It sits after the tagged partition carrier of chapter 4296, the upper Darboux-sum carrier of chapter 4083, the Riemann sum gauge packet of chapter 4115, and the Cousin cover carrier of chapter 3426. The packet supplies the finite refinement surface consumed by integrability criteria without importing host partitions, selected mesh limits, quotient function equality, choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4722.1 (Riemann refinement criterion carrier)**.** *A* $\mathsf{RiemannRefinementCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, T, U, G, C, M, D, W, E, H, K, P, N)$$

with the following displayed rows:

1. *I is the closed bounded interval row shared by the refinement comparison.*
2. *T is the* $\mathsf{TaggedRealPartition}^{\uparrow}$ *source row, including the finite cell order, tag containment, and mesh exactness visible before refinement is read.*
3. *U is the* ***??*** *row whose upper-sum ledger is compared against the refined tagged route.*
4. *G is the* $\mathsf{RiemannSumGauge}^{\uparrow}$ *row, carrying the positive rational gauge, mesh ledger, and finite tagged-sum handoff.*
5. *C is the* $\mathsf{CousinCover}^{\uparrow}$ *gauge-cover row supplying the finite local cover route that admits the refined cells.*
6. *M is the common-refinement mesh row, listing the displayed refinement map from the tagged partition row into the gauge-cover and upper-sum rows.*
7. *D is the Darboux-gap lock row, recording the finite upper-bound comparison that remains visible after the common refinement has been read.*
8. *W is the window and readback row for interval endpoints, tags, gauges, cover cells, and upper-sum values.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the tagged partition, gauge, Cousin cover, refinement mesh, and Darboux-gap rows are displayed.*

10. *H records componentwise* hsame *transport for interval, partition, upper-sum, gauge, cover, refinement, Darboux-gap, window, seal, replay, provenance, and local naming rows.*
11. *K records displayed* Cont *replay from a refinement request through $I, T, U, G, C, M, D, W, E, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{RiemannRefinementCriterion}^{\uparrow}$, $\mathsf{TaggedRealPartition}^{\uparrow}$, *??*, $\mathsf{RiemannSumGauge}^{\uparrow}$, $\mathsf{CousinCover}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannRefinementCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed finite rows. It has no coordinate for host partitions, selected mesh limits, quotient function equality, choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RiemannRefinementCriterionUp.RiemannRefinementCriterionTasteGate single carrier alignment`

Theorem 4722.2 (Riemann refinement criterion NameCert obligations)**.** *For every accepted* RiemannRefinementCr *carrier $R = (I, T, U, G, C, M, D, W, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RiemannRefinementCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for the interval, tagged partition, upper Darboux-sum, Riemann sum gauge, Cousin cover, refinement mesh, Darboux-gap lock, window, seal, transport, replay, provenance, and local naming rows.*

Every refinement-facing consumer must read the tagged partition row T from chapter 4296, the upper-sum row U from chapter 4083, the gauge row G from chapter 4115, and the gauge-cover row C from chapter 3426 before the common-refinement mesh row M and Darboux-gap lock row D are available.

Proof. Project the carrier of Definition 5894.1. The tuple displays the only rows available to a refinement consumer: interval source, tagged partition, upper-sum, gauge, Cousin cover, common refinement, Darboux-gap lock, finite windows, terminal seal, transport, replay, provenance, and local naming.

The source rows are T, U, G, C. The tagged partition supplies finite cells and tags, the upper Darboux row supplies the upper-bound ledger, the Riemann sum gauge row supplies the gauge mesh, and the Cousin cover row supplies local gauge cover cells.

The refinement rows are M, D. The mesh row M binds those four source rows into one common finite refinement before the Darboux-gap lock D can be read.

Finally W, E, H, K, P, N preserve the same displayed route through finite windows, the terminal Real seal, transport, replay, provenance, and local naming. Since the carrier has no coordinate for the refused host objects, the listed rows exhaust the local NameCert surface. □

Theorem 4722.3 (Riemann refinement criterion Darboux gap lock)**.** *In every accepted* RiemannRefinementCriterior *packet, the Darboux-gap row D is readable only after the common-refinement mesh row M has already displayed the tagged partition, upper Darboux-sum, Riemann sum gauge, and Cousin cover sources. Thus a Darboux or Riemann-integrability consumer cannot replace the refinement route by host partitions, selected mesh limits, quotient function equality, choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the source rows from Definition 5894.1. The Darboux-gap row is not listed as an independent analytic conclusion; it appears after the tagged partition, upper-sum, gauge, cover, and common-refinement rows.

Apply Definition 5894.2. Its obligation surface requires T, U, G, C to be exposed before M, and M before D.

The structural rows only transport and replay the same finite packet. Therefore the Darboux-gap read is locked to the displayed refinement route and cannot be promoted to any refused host-level principle. □

Theorem 4722.4 (Riemann refinement criterion integral handoff)**.** *Every Riemann-integrability or gauge-integral consumer of an accepted* $\mathsf{RiemannRefinementCriterion}^{\uparrow}$ *packet receives only the finite handoff*

$$\mathsf{TaggedRealPartition}^{\uparrow},\ \textit{??},\ \mathsf{RiemannSumGauge}^{\uparrow},\ \mathsf{CousinCover}^{\uparrow} \longmapsto M \longmapsto D \longmapsto W, E, H, K, P, N.$$

The handoff exports a refinement criterion over displayed finite rows, not an ambient theorem about all host partitions or all mesh limits.

Proof. Start with a consumer read. The packet first exposes the tagged partition, upper Darboux-sum, Riemann sum gauge, and Cousin cover rows through the sibling chapters cited in the carrier.

The common-refinement mesh row M then aligns those sources. The Darboux-gap lock row D is read only along that aligned route, and the window and seal rows W, E expose the Real-facing observations after the finite rows are visible.

Transport, replay, provenance, and local naming through H, K, P, N preserve the same route. No carrier coordinate supplies host partition equality, selected limiting meshes, choice, compactness, quotient function equality, or ambient completeness, so the integral handoff is exactly the displayed finite criterion. □

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannRefinementCriterion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RiemannRefinementCriterion}^{\uparrow}$ packet is generated from a closed bounded interval row, TaggedRealPartition source, UpperDarbouxSum ledger, RiemannSumGauge mesh row, CousinCover gauge-cover row, common-refinement mesh row, Darboux-gap lock, finite windows, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannRefinementCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5894.1, Definition 5894.2, Definition 5894.3, and Definition 5894.4 seed the finite refinement criterion between tagged partitions, upper Darboux sums, Riemann sum gauges, and Cousin covers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannRefinementCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host partitions, selected mesh limits, quotient function equality, choice, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tagged-partition source lock, upper-sum handoff, gauge mesh exactness, Cousin cover locality, Darboux-gap lock, integral handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RiemannRefinementCriterionUp.

Chapter 4723

A Concrete Naming Certificate for CompactUniformModulusComposition$^{\uparrow}$

Following the Bishop–Bridges and Heine–Cantor treatment of uniformly continuous maps on compact metric data, the CompactUniformModulusComposition$^{\uparrow}$ packet records the finite tolerance-only composition surface for two compact-uniform modulus rows. It sits after the compact metric source of chapter 129, the continuous-map carrier of chapter 130, the compact uniform modulus row of chapter 2299, the metric-triangle estimate of chapter 1159, and the stability packet of chapter 5872. The packet supplies the finite composition object used by compact-open and compact-uniform-continuity consumers without exporting a host function space, quotient point equality, selected global modulus, choice schedule, or ambient compactness theorem.

Definition 4723.1 (Compact uniform modulus composition carrier)**.** *A* CompactUniformModulusComposition$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, Y, Z, F, G, M_F, M_G, A, T, U, H, C, P, N)$$

with the following displayed rows:

1. *X, Y, Z are compact metric source, middle, and target rows, with finite net and distance ledgers visible at the requested tolerances.*
2. *F and G are* ContinuousMap$^{\uparrow}$ *rows for the two displayed maps.*
3. *M_F is the first* CompactUniformModulus$^{\uparrow}$ *row, turning a target tolerance for Y into a source tolerance for X along F.*
4. *M_G is the second* CompactUniformModulus$^{\uparrow}$ *row, turning a target tolerance for Z into a source tolerance for Y along G.*
5. *A is the tolerance-assembly row, recording that a Z-tolerance request is first read by M_G and that its resulting Y-tolerance request is then read by M_F.*
6. *T is the* MetricTriangleUniformEstimate$^{\uparrow}$ *row that keeps the two transported estimates on the same metric route.*
7. *U is the downstream* UniformModulus$^{\uparrow}$ *consumer row for the composite map.*
8. *H records componentwise* hsame *transport for compact metric sources, continuous maps, modulus rows, tolerance assembly, triangle estimate, consumer, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a composite tolerance request through $Z, M_G, Y, M_F, X, A, T, U, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CompactUniformModulusComposition}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactUniformModulus}^{\uparrow}$, $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusComposition}^{\uparrow}}$ *row.*

The classifier compares accepted composition packets only by these finite rows. It contains no host function-space composition theorem, quotient point equality, selected global modulus, choice schedule, or ambient compactness principle.

Lean4 ✓ `BEDC.Derived.CompactUniformModulusCompositionUp.CompactUniformModulusCompositionTasteGate`
`single carrier alignment`

Theorem 4723.2 (Compact uniform modulus composition NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformModulusComposition}^{\uparrow}$ *carrier $Q = (X, Y, Z, F, G, M_F, M_G, A, T, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusComposition}^{\uparrow}}$ *surface consists exactly of compact source admission through X, Y, Z, continuous-map admission through F, G, first and second compact-uniform modulus reads through M_F, M_G, tolerance assembly through A, metric-triangle transport through T, uniform-modulus export through U, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5895.1. The compact metric rows, continuous-map rows, compact-uniform modulus rows, assembly row, triangle estimate, uniform-modulus consumer, and structural rows are exactly the displayed coordinates.

The tolerance route is ordered by A. A requested Z-tolerance is consumed by M_G to expose a Y-tolerance, and only that displayed Y-tolerance is then consumed by M_F to expose the source tolerance over X.

The triangle estimate T and consumer row U read the same assembled route. Transport, replay, provenance, and local naming preserve it through H, C, P, N.

Since the carrier has no coordinate for host function-space composition, quotient point equality, selected moduli, choice, or ambient compactness, the listed rows exhaust the NameCert surface. □

Theorem 4723.3 (Compact uniform modulus composition tolerance route)**.** *Every compact-open or compact-uniform-continuity consumer of an accepted* $\mathsf{CompactUniformModulusComposition}^{\uparrow}$ *packet reads the composite modulus only through*

$$M_G \longmapsto A \longmapsto M_F \longmapsto T \longmapsto U.$$

Thus the composite tolerance is assembled from two displayed compact-uniform modulus rows and the metric-triangle ledger, not from a selected host-level modulus for the composite map.

Proof. Begin with the consumer's target tolerance for the Z row. The second modulus row M_G supplies the middle-space tolerance, and the assembly row A records that this is the only tolerance handed to M_F.

The first modulus row M_F returns the source-space tolerance over X. The metric-triangle row T then transports the two displayed estimates into the bound consumed by U.

The structural rows H, C, P, N preserve this route. Since there is no host composition coordinate or selected global modulus in the carrier, every consumer remains on the displayed tolerance chain. □

Theorem 4723.4 (Compact uniform modulus composition nonescape)**.** *No accepted* CompactUniformModulusComp *packet exports quotient point equality, a selected global modulus, a choice schedule, an ambient compactness theorem, or a host function-space composition proof. It exports only the two continuous-map rows, two compact-uniform modulus rows, the tolerance assembly row, the metric-triangle estimate, the uniform-modulus consumer, and the structural NameCert rows.*

Proof. Project the carrier. The only analytic rows are F, G, M_F, M_G, A, T, U over the compact metric sources X, Y, Z.

Apply Definition 5895.2. The local NameCert obligations require the consumer to read the two modulus rows and the tolerance assembly before the uniform-modulus export.

The refused host objects are absent from the carrier and cannot be produced by transport, replay, provenance, or local naming. Therefore the accepted packet exports only the displayed finite composition route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusComposition}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformModulusComposition}^{\uparrow}$ packet is generated from compact metric source, middle, and target rows, two ContinuousMap rows, two CompactUniformModulus rows, a tolerance-assembly row, a MetricTriangleUniformEstimate row, a UniformModulus consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusComposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5895.1, Definition 5895.2, Definition 5895.3, and Definition 5895.4 seed the finite tolerance-only composition route for compact-uniform modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusComposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function-space composition, quotient point equality, selected global moduli, choice schedules, ambient compactness theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact source admission, continuous-map admission, first and second modulus reads, tolerance assembly, metric-triangle transport, uniform-modulus export, replay stability, provenance exhaustion, and local naming for BEDC.Derived.CompactUniformModulusCompositionUp.

Chapter 4724

A Concrete Naming Certificate for $\mathsf{PrivateSharedDecorationModel}^{\uparrow}$

The $\mathsf{PrivateSharedDecorationModel}^{\uparrow}$ packet realizes the private/shared decoration theorem of Definition 9462.1705 inside the boundary-tile source of subsection 9462.28.21. It sits beside the DNA boundary-tile packet of chapter 3393, the trigger-threshold packet of chapter 4217, and the finite trigger algebra route of chapter 3478. The packet records private blocks, shared rows, lift counts, and defect ledgers as finite NameCert data; it is not a biological mechanism, stochastic evolution model, hidden enumeration oracle, or quotient codon semantics.

Definition 4724.1 (PrivateSharedDecorationModel carrier)**.** *A* $\mathsf{PrivateSharedDecorationModel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, S, L, D, T, R, P, N)$$

with the following displayed rows:

1. *B is the nonempty private-block row, recording the partition of coordinates that remain private to a single decorated support.*
2. *S is the shared-row ledger, assigning every shared coordinate to a finite row set of size at least two.*
3. *L is the lift-count row, recording the finite ℓ^m lift factor attached to displayed support blocks.*
4. *D is the defect ledger, recording the row-set size contribution to the defect-refined polynomial.*
5. *T records componentwise* hsame *transport for B, S, L, D, R, P, N.*
6. *R records displayed* Cont *replay from a decorated trigger request through the private block, shared rows, lift count, defect ledger, provenance, and local naming rows.*
7. *P is the* Pkg *provenance over* $\mathsf{PrivateSharedDecorationModel}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$, $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$, *the source theorem of Definition 9462.1705,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{PrivateSharedDecorationModel}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through B, S, L, D, T, R, P, N. It has no coordinate for biological mechanism, stochastic fitness, quotient codon equality, hidden global semantics, or an unrecorded enumeration oracle.

Theorem 4724.2 (PrivateSharedDecorationModel NameCert obligations)**.** *For every accepted* $\mathsf{PrivateSharedDecorationModel}^{\uparrow}$ *carrier*

$$M = (B, S, L, D, T, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrivateSharedDecorationModel}^{\uparrow}}$ *surface consists exactly of carrier admission for the nonempty private-block row, shared-row ledger, lift-count row, defect ledger, componentwise transport, displayed replay, provenance, and local naming. A decorated trigger read is accepted only after it exposes a nonempty private block and assigns every shared coordinate to at least two rows.*

Proof. Project the carrier of Definition 5896.1. The private block, shared-row ledger, lift count, defect ledger, transport, replay, provenance, and local name are exactly the displayed coordinates.

The private/shared constraint is read through B, S. The row B must display a nonempty private partition, and the ledger S must attach every shared coordinate to a row set of size at least two.

The enumeration and defect data are read through L, D. The lift-count row records the finite lift factor, while the defect ledger records the shared-row contribution used by the source theorem.

Finally T, R, P, N transport, replay, source, and name the same route. Since biological mechanism, stochastic fitness, quotient codon equality, hidden global semantics, and unrecorded enumeration have no carrier coordinate, the listed rows exhaust the NameCert obligations. □

Falsifiable prediction: If a displayed decorated trigger lacks a nonempty private block or assigns a shared coordinate to fewer than two rows, it is rejected by the local NameCert.

Independence witness: dna-window-six-boundary-tile, dna-window-six-trigger-threshold, dna-window-six-translation-boundary: $\mathsf{PrivateSharedDecorationModel}^{\uparrow}$ is not bijective to any listed sibling because this packet jointly carries private-block rows, shared-row ledgers, lift-count rows, defect ledgers, transport, replay, provenance, and local naming.

The Lean TasteGate route for `BEDC.Derived.PrivateSharedDecorationModelUp` must provide explicit $\mathsf{Nontrivial\ PrivateSharedDecorationModel}^{\uparrow}$ and $\mathsf{FieldFaithful\ PrivateSharedDecorationModel}^{\uparrow}$ instances preserving B, S, L, D, T, R, P, N as separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{PrivateSharedDecorationModel}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PrivateSharedDecorationModel}^{\uparrow}$ packet is generated from a nonempty private-block row, shared-row ledger, lift-count row, defect ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrivateSharedDecorationModel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5896.1 and Definition 5896.2 seed the finite private/shared decoration packet over DNA boundary-tile trigger rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrivateSharedDecorationModel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological mechanism, stochastic evolution, quotient codon equality, hidden global semantics, unrestricted enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, private-block nonemptiness, shared-row arity, lift-count exposure, defect-ledger exposure, transport, replay, provenance, local naming, Nontrivial PrivateSharedDecorationModelUp, and FieldFaithful PrivateSharedDecorationModelUp for BEDC.Derived.PrivateSharedDecorationModelUp.

Chapter 4725

A Concrete Naming Certificate for $\mathsf{BishopLocatedRealFilter}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopLocatedRealFilter}^{\uparrow}$ packet records the finite filter-facing route by which located real brackets are read through dyadic tolerances, stream windows, regular rational readback, and the terminal real seal. It consumes the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the located bracket surface of chapter 1709, and the selector boundary of chapter 5886. The packet gives the L10 Real and Completion route a located filter interface without asserting quotient filter equality, host real equality, selected limit points, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4725.1 (Bishop located real filter carrier)**.** *A* $\mathsf{BishopLocatedRealFilter}^{\uparrow}$ *carrier is a finite packet*

$$S = (F, L, D, W, R, E, B, H, T, P, N)$$

with the following displayed rows:

1. *F is the filter-base row, exposing the finite base request, refinement evidence, and Cauchy-facing filter data that a later completion consumer may inspect.*
2. *L is the located-real bracket row, recording lower and upper bracket reads over* $\mathsf{LocatedRealInterval}^{\uparrow}$ *together with the displayed apartness and containment data used to locate the requested real value.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger governing bracket width, filter-base comparison, stream-window radius, and regular-rational readback.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row attached to the filter request and the located bracket.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the windows in W under the tolerance ledger D.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after F, L, D, W, R have been displayed and replayed.*
7. *B is the* BHist *history row recording the finite route from the filter request through the located bracket, tolerance ledger, stream windows, regular readback, and Real seal.*
8. *H records componentwise* hsame *transport for $F, L, D, W, R, E, B, T, P, N$.*
9. *T records displayed* Cont *replay from every located filter request through $F, L, D, W, R, E, B, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedRealFilter}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{CauchyFilterSelector}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRealFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, L, D, W, R, E, B, H, T, P, N$. It has no coordinate for quotient filter equality, host selected representatives, host real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.BishopLocatedRealFilterUp.BishopLocatedRealFilterUp`

Theorem 4725.2 (Bishop located real filter NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedRealFilter}^{\uparrow}$ *carrier $S = (F, L, D, W, R, E, B, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRealFilter}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the filter base, located-real bracket, dyadic tolerance ledger, StreamName windows, RegSeqRat readback, Real seal, history, transport, replay, provenance, and local naming row;*
2. *bracket exactness, requiring each located-real bracket read in L to be witnessed by displayed* $\mathsf{LocatedRealInterval}^{\uparrow}$ *endpoint and containment data;*
3. *filter-base stability, requiring refinements of F to preserve the same located bracket and tolerance ledger through* BHist *and* hsame *transport;*
4. *dyadic ledger stability, requiring D to control the bracket width, stream-window radius, and regular-rational readback without adding an external modulus;*
5. *StreamName and RegSeqRat handoff, requiring every numeric read to pass through W and then R before the terminal seal E can be consumed;*
6. *nonescape, excluding quotient filters, host-selected representatives, countable choice, host real equality, selected limiting points, and ambient Real completeness.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5897.1. The accepted packet displays the filter base, located bracket, dyadic ledger, stream windows, regular readback, Real seal, history, transport, replay, provenance, and local naming rows.

Bracket exactness is row-local. The bracket row L can expose only the endpoint and containment data already carried by $\mathsf{LocatedRealInterval}^{\uparrow}$, so it cannot identify a real by host order equality or by a selected representative.

The filter-base and tolerance rows then fix the route. Refinement of F is transported through B and H, while the same dyadic row D governs bracket width, window radius, and readback precision.

Finally the numeric handoff is ordered by W, R, E. Stream windows are read before regular rational data, and regular rational data are read before the terminal $\mathsf{Real}^{\uparrow}$ seal. Since no excluded host object is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 4725.3 (Bishop located real filter L10 handoff)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{BishopLocatedRealFilter}^{\uparrow}$ *packet $S = (F, L, D, W, R, E, B, H, T, P, N)$ must read the finite route*

$$F, L, D, W, R \longmapsto E \longmapsto B, H, T, P, N$$

before it treats the request as Real-facing or completion-facing data. Thus the packet supplies a filter-based located-real handoff to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, *and*

$\mathsf{CauchyFilterSelector}^{\uparrow}$ *consumers without asserting ambient real completeness or quotient equality of filters.*

Proof. Read the carrier rows in order. A consumer first receives the filter base F and the located bracket L, while the dyadic ledger D supplies the common tolerance budget.

The numerical content is then exposed through W and R. The $\mathsf{StreamName}^{\uparrow}$ row records finite observation windows, and the $\mathsf{RegSeqRat}^{\uparrow}$ row records the regular rational readback extracted from those windows.

Only after these rows are displayed can the Real seal E be consumed. The history, transport, replay, provenance, and local naming rows B, H, T, P, N preserve that order for later L10 Real and Completion routes.

The carrier has no quotient-filter equality, selected representative, host real equality, choice schedule, or ambient completeness coordinate. Therefore every downstream handoff factors through the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedRealFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedRealFilter}^{\uparrow}$ packet is generated from a displayed filter base, a located-real bracket, a dyadic tolerance ledger, finite StreamName windows, RegSeqRat readback, a Real seal, BHist history, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5897.1, Definition 5897.2, and Definition 5897.3 seed the finite filter-facing located-real interface for the L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient filter equality, ambient Real completeness, selected limits, countable choice, Lean verification, or bridge checking.

Upgrade path: Lean closure requires carrier admission, bracket exactness, filter-base stability, dyadic ledger stability, StreamName and RegSeqRat handoff, and Real seal boundary for BEDC.Derived.BishopLocatedRealFilterUp.

Chapter 4726

A Concrete Naming Certificate for $\mathsf{RegularCauchyDiagonalArgument}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyDiagonalArgument}^{\uparrow}$ packet records the finite diagonal extraction route that turns a displayed regular Cauchy family of rational names into the regular rational readback consumed by a $\mathsf{Real}^{\uparrow}$ seal. It sits between the $\mathsf{RegSeqRat}^{\uparrow}$ source surface of chapter 301, the finite $\mathsf{StreamName}^{\uparrow}$ window surface of chapter 126, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the $\mathsf{Real}^{\uparrow}$ boundary of chapter 38, and the sibling diagonalization packet of chapter 3782. The packet names the L10 RegSeqRat-to-Real handoff without importing quotient streams, selected limits, choice, or ambient Real completeness.

Definition 4726.1 (Regular Cauchy diagonal argument carrier)**.** *A* $\mathsf{RegularCauchyDiagonalArgument}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (F, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *family row. It displays the finite collection of rational-name approximants and the precision requests inspected by the diagonal extraction.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the finite source windows selected for each inspected precision and exposes no quotient stream equality.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the dyadic radius, split budget, common scale, and comparison cells used to certify the diagonal readback.*
4. *R is the diagonal* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It consumes only the displayed windows W and tolerance ledger D as one regular rational sequence.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It is visible only after F, W, D, R have been displayed.*
6. *H records componentwise* hsame *transport for the source family, stream windows, tolerance ledger, regular readback, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a diagonal extraction request through the source family, finite stream windows, dyadic ledger, regular rational readback, Real seal, transports, provenance, and local name.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyDiagonalArgument}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalArgument}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, W, D, R, E, H, C, P, N$. It has no coordinate for quotient streams, selected limits, choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a checked bridge.*

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalArgumentUp.RegularCauchyDiagonalArgumentTasteGate`
`single carrier alignment`

Theorem 4726.2 (Regular Cauchy diagonal argument NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyDiagonalArgument}^{\uparrow}$ *carrier*

$$A = (F, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalArgument}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *family,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, diagonal* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows;*
2. *window exactness, requiring W to expose only the finite source windows named by the diagonal extraction request;*
3. *dyadic tolerance exactness, requiring D to supply the radius, split budget, common scale, and comparison cells used by the extraction;*
4. *regular readback exactness, requiring R to consume precisely the windows W and dyadic ledger D before any Real-facing seal is visible;*
5. *Real-seal nonescape, requiring E to appear only after F, W, D, R have been transported by H and replayed by C;*
6. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming for exactly the rows $F, W, D, R, E, H, C, P, N$;*
7. *refusal of quotient streams, selected limits, choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local certificate data.*

No local diagonal-argument obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalArgumentUp.RegularCauchyDiagonalArgumentNamecertObligations`

Proof. Project the carrier of Definition 5541.1. The accepted inventory is exactly the source $\mathsf{RegSeqRat}^{\uparrow}$ family F, finite $\mathsf{StreamName}^{\uparrow}$ windows W, dyadic tolerance ledger D, diagonal $\mathsf{RegSeqRat}^{\uparrow}$ readback R, terminal $\mathsf{Real}^{\uparrow}$ seal E, and structural rows H, C, P, N.

Window and tolerance exactness are read from W and D. The stream row exposes only finite inspected windows, and the dyadic row supplies the radius, split budget, common scale, and comparison cells needed to compare those windows.

The regular readback row R is downstream of those two rows. It cannot name a quotient stream or a selected limit, because the carrier gives it only W and D as inputs.

Finally, E, H, C, P, N seal, transport, replay, source, and name the same packet. Since the carrier inventory contains no quotient streams, selected limits, choice operator, ambient completeness principle, Lean verification row, or bridge credential, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.RegularCauchyDiagonalArgumentUp.RegularCauchyDiagonalArgumentCarrier namecert obligations`

Theorem 4726.3 (Regular Cauchy diagonal argument Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer of an accepted* $\mathsf{RegularCauchyDiagonalArgument}^{\uparrow}$ *carrier factors through the finite route*

$$F \longmapsto W \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus a diagonal extraction is available to the Real boundary only as a displayed $\mathsf{RegSeqRat}^{\uparrow}$ *family row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows, one* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, one diagonal* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, one terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *evidence.*

Proof. Begin with the obligation surface of Definition 5541.2. It confines every accepted packet to the displayed family, window, tolerance, readback, Real-seal, and structural rows.

The consumer first reads F, W, D. These rows expose the source regular rational names, the finite stream windows inspected by the diagonal argument, and the dyadic comparison budget.

The consumer then reads R and E. The regular rational readback is formed from the same finite windows and dyadic ledger, and the terminal Real seal is visible only after that readback has been displayed.

The rows H, C, P, N preserve this route under transport, replay, provenance, and naming. Because the carrier has no coordinate for quotient streams, selected limits, choice, ambient Real completeness, Lean verification, or bridge checking, none of those objects can enter the Real-facing handoff. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyDiagonalArgument}^{\uparrow}$ Real or Completion read must expose a RegSeqRat family row, finite StreamName windows, one DyadicRatCore tolerance ledger, one diagonal RegSeqRat readback, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: regseqrat, streamname, dyadicratcore, real, regular-cauchy-diagonalization: $\mathsf{RegularCauchyDiagonalArgument}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds source RegSeqRat family data, finite StreamName windows, dyadic tolerance exactness, diagonal RegSeqRat readback, and RealUp handoff in one displayed packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalArgument}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyDiagonalArgument}^{\uparrow}$ packet is generated from a RegSeqRat family row, finite StreamName windows, one DyadicRatCore tolerance ledger, one diagonal RegSeqRat readback, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalArgument}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5541.1, Definition 5541.2, and Definition 5541.3 seed the finite diagonal extraction packet used by L10 RegSeqRat-to-Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalArgument}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, dyadic tolerance exactness, regular readback exactness, Real-seal exposure, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.RegularCauchyDiagonalArgumentUp.

Chapter 4727

A Concrete Naming Certificate for PrivateSharedCoordinateDecomposition$^{\uparrow}$

The PrivateSharedCoordinateDecomposition$^{\uparrow}$ packet realizes the private/shared coordinate decomposition of Definition 9462.1697 as finite NameCert data. It reads the quotient-level support family, private blocks, shared-coordinate row sets, and reconstruction equations through the support-census sibling of chapter 4048 and the reassignment-geometry sibling of chapter 5869. The packet is a finite combinatorial carrier; it is not a biological mechanism claim, a hidden quotient of support labels, or an ambient uniqueness principle outside the displayed rows.

Definition 4727.1 (Private-shared coordinate decomposition carrier)**.** *A* PrivateSharedCoordinateDecomposition$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, B, U, R, K, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite support-family row, displaying the quotient-level support family on the inspected coordinate set.*
2. *B is the private-block row, listing the nonempty private coordinate blocks attached to the supports.*
3. *U is the shared-coordinate row, listing the coordinates not owned by a single private block.*
4. *R is the row-set ledger. For every shared coordinate it records the finite set of private blocks whose supports contain that coordinate.*
5. *K is the reconstruction row, recording the displayed equations that recover each support from its private block and the shared coordinates whose row sets contain that block.*
6. *H records componentwise* hsame *transport for support-family, private-block, shared-coordinate, row-set, reconstruction, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from support-family inspection through private-block extraction, shared-coordinate listing, row-set lookup, support reconstruction, transports, provenance, and local name.*
8. *P is the* Pkg *provenance over* PrivateSharedCoordinateDecomposition$^{\uparrow}$*, the source private/shared coordinate vision,* SupportNerveCensus$^{\uparrow}$*,* ReassignmentMassSubcube$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{PrivateSharedCoordinateDecomposition}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, B, U, R, K, H, C, P, N$. It has no coordinate for hidden support equality, unbounded coordinate universes, biological causality, stochastic dynamics, Lean verification, or a checked bridge.

Theorem 4727.2 (PrivateSharedCoordinateDecomposition NameCert obligations)**.** *For every accepted* $\mathsf{PrivateSharedCoordinateDecomposition}^{\uparrow}$ *carrier*

$$Q = (S, B, U, R, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrivateSharedCoordinateDecomposition}^{\uparrow}}$ *surface consists exactly of support-family exposure, private-block exposure, shared-coordinate exposure, finite row-set exposure, reconstruction equation exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The reconstruction row must use only the displayed private block and shared-coordinate row-set data from B, U, R.*

Proof. Project the carrier of Definition 5542.1. The rows S, B, U, R display the support family, the nonempty private blocks, the shared coordinates, and the finite row sets attached to those shared coordinates.

The reconstruction row K is downstream of those data. It may rebuild a support only by taking its private block from B and adjoining exactly the shared coordinates from U whose row-set entry in R contains that block.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no hidden support equality, unbounded coordinate universe, biological mechanism, stochastic dynamics, Lean verification row, or bridge credential, the listed rows exhaust the local NameCert obligations. □

Theorem 4727.3 (Private-shared coordinate reconstruction handoff)**.** *Every consumer of an accepted* $\mathsf{PrivateSharedCoordinateDecomposition}^{\uparrow}$ *carrier factors through the finite route*

$$S \longmapsto B, U, R \longmapsto K \longmapsto H, C, P, N.$$

Consequently, the support corresponding to a private block is recovered only from the displayed private block, the shared-coordinate ledger, and the finite row-set membership data, exactly as in the source decomposition of Definition 9462.1698.

Proof. Start with the NameCert obligations of Definition 5542.2. They force the support-family row S to expose the finite family before private and shared coordinates are read.

The rows B, U, R then provide the decomposition data. Private blocks give the singleton-owned coordinates, while shared coordinates are paired with finite row sets naming the blocks whose supports contain them.

The reconstruction row K consumes only those displayed rows. Transport, replay, provenance, and local naming preserve the same finite route, so a consumer cannot replace it by a hidden quotient of supports or by an ambient uniqueness principle. □

Falsifiable prediction: Every accepted $\mathsf{PrivateSharedCoordinateDecomposition}^{\uparrow}$ consumer must expose finite support data, private blocks, shared coordinates, row-set membership, reconstruction equations, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence before reading a reconstructed support.

Independence witness: support-nerve-census, reassignment-mass-subcube, private-shared-coordinate vision: $\mathsf{PrivateSharedCoordinateDecomposition}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds private blocks, shared-coordinate row sets, reconstruction equations, transport, replay, provenance, and local naming as one finite coordinate-decomposition packet.

Closure status for $\mathsf{NameCert}_{\mathsf{PrivateSharedCoordinateDecomposition}^{\uparrow}}$.

Constructive story: A $\mathsf{PrivateSharedCoordinateDecomposition}^{\uparrow}$ packet is generated from finite support-family rows, private-block rows, shared-coordinate rows, row-set ledgers, reconstruction equations, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrivateSharedCoordinateDecomposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5542.1, Definition 5542.2, and Definition 5542.3 seed the finite NameCert packet for private/shared coordinate decomposition.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrivateSharedCoordinateDecomposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close hidden support equality, unbounded coordinate universes, biological causality, stochastic dynamics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked support-family exposure, private-block exposure, shared-coordinate exposure, row-set exposure, reconstruction exactness, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.PrivateSharedCoordinateDecompositionUp.

Chapter 4728

A Concrete Naming Certificate for $\mathsf{RegulatedCauchyModulus}^{\uparrow}$

Following Bishop and Bridges on constructive moduli of Cauchy convergence, the $\mathsf{RegulatedCauchyModulus}^{\uparrow}$ packet records an explicit finite threshold schedule for a regular rational Cauchy name before the terminal real-name seal is consumed. It sits after the regular rational source of chapter 301, the finite window surface of chapter 126, the dyadic tolerance core of chapter 291, the Cauchy modulus rows of chapter 292, and the terminal real-name boundary of chapter 38. The packet gives the L10 Real and Completion route a non-quotient explicit-modulus carrier; it does not select a limit, quotient streams, invoke countable choice, assert host equality, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4728.1 (Regulated Cauchy modulus carrier)**.** *A* $\mathsf{RegulatedCauchyModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (R, Q, W, D, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose finite rational reads are being regulated.*
2. *Q is the explicit modulus threshold row, recording the displayed tolerance request and the finite index bound at which the Cauchy comparison is certified.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to expose the source reads needed by Q.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling the requested radius, the comparison budget, and the readback precision.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after R, Q, W, D have been displayed.*
6. *H records componentwise* hsame *transport for the source, threshold, window, tolerance, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a tolerance request through R, Q, W, D, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RegulatedCauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedCauchyModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, Q, W, D, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, host real equality, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ BEDC.Derived.RegulatedCauchyModulusUp.TasteGate.RegulatedCauchyModulusTasteGate single carrier alignment

Theorem 4728.2 (Regulated Cauchy modulus NameCert obligations)**.** *For every accepted* RegulatedCauchyModulu *carrier* $M = (R, Q, W, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegulatedCauchyModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, source-window exposure, explicit threshold exactness, dyadic tolerance control, real-seal nonescape, componentwise transport, displayed replay, package provenance, and local naming. Each obligation is read through the finite route*

$$R, Q, W, D \longrightarrow E \longrightarrow H, C, P, N.$$

Proof. Carrier admission is projection from Definition 5543.1. The packet first exposes the regular rational source R, the explicit threshold row Q, the stream windows W, and the dyadic tolerance ledger D.

The threshold obligation is local to Q. It records a displayed tolerance request and a finite index bound, while W supplies the finite source reads and D supplies the dyadic comparison budget used to check the requested tail comparison.

The terminal seal row E is downstream of those four rows. Componentwise transport through H and replay through C preserve the same order, and P, N record package provenance and the local NameCert comparison.

Since quotient streams, selected limits, host real equality, countable choice, trichotomy, and ambient completeness do not occur among the carrier coordinates, no NameCert obligation can be discharged outside the displayed finite route. □

Theorem 4728.3 (Regulated Cauchy modulus real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegulatedCauchyModulus}^{\uparrow}$ *packet must first read the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, the explicit modulus threshold, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. The handoff to the seal row* E *therefore supplies a finite explicit-modulus route from regular rational data to Real-facing data, not a host limit theorem or a quotient construction.*

Proof. Project an accepted carrier $M = (R, Q, W, D, E, H, C, P, N)$. The source row R is the only regular rational input, and the threshold row Q is the only displayed modulus schedule.

The stream windows W expose the finite observations required by that schedule. The dyadic ledger D supplies the tolerance comparison that makes the schedule a regulated Cauchy read rather than an unbounded stream claim.

Only after R, Q, W, D are present may the consumer read E as the terminal $\mathsf{Real}^{\uparrow}$ seal. Transport, replay, provenance, and local naming keep the same route visible to downstream consumers.

The carrier has no coordinate for a selected limit, quotient stream equality, host real equality, countable choice, trichotomy, or ambient Real completeness. Thus every Real-facing handoff factors through the finite explicit-modulus rows. □

Theorem 4728.4 (Regulated Cauchy modulus tail-threshold determinacy)**.** *Let* $M = (R, Q, W, D, E, H, C, P, N)$ *and* $M' = (R', Q', W', D', E', H', C', P', N')$ *be accepted* $\mathsf{RegulatedCauchyModulus}^{\uparrow}$ *reads whose displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and threshold row agree. Then the two reads expose the same terminal* $\mathsf{Real}^{\uparrow}$ *seal route. Strengthening a request may enlarge the finite window demanded by* W *and* W'*, but it cannot change the displayed source row, tolerance ledger, threshold row, or terminal seal route.*

Proof. Project both accepted carriers. The only rows available before the terminal seal are the source rows R, R', threshold rows Q, Q', finite-window rows W, W', and dyadic tolerance ledgers D, D'.

The hypothesis identifies the displayed source, threshold, window, and tolerance rows. By Definition 5543.3, every terminal $\mathsf{Real}^{\uparrow}$ handoff must pass through exactly those finite rows before E or E' can be read.

If a request is strengthened, the continuation may demand a larger finite window, because the stream row is a finite observation schedule. The displayed source, tolerance, threshold, and seal coordinates are still the same coordinates of the carrier, so strengthening cannot replace them by a quotient stream, selected limit, or ambient completeness argument.

Therefore both accepted reads expose the same terminal Real-facing seal route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedCauchyModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedCauchyModulus}^{\uparrow}$ packet is generated from a RegSeqRat source row, explicit modulus threshold row, finite StreamName windows, DyadicRatCore tolerance ledger, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulatedCauchyModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5543.1, Definition 5543.2, and Definition 5543.3 seed the explicit-modulus route from regular rational source data to a Real-facing seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegulatedCauchyModulus}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.RegulatedCauchyModulusUp`

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, trichotomy, host real equality, Lean verification, bridge checking, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, source-window exposure, explicit threshold exactness, dyadic tolerance control, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegulatedCauchyMod

$\mathsf{RegularCauchyMinModulus}^{\uparrow}$ routes its hub through the shared modulus meet of chapter 462, the finite dyadic tolerance rows of chapter 291, and the Real-facing handoff through chapter 301 and chapter 38.

Chapter 4729

A Concrete Naming Certificate for $\mathsf{RegularCauchyMinModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ packet records the finite scheduling surface for taking the pointwise minimum of two displayed regular-Cauchy modulus schedules. It sits between the shared-modulus meet packet of chapter 462, the finite stream windows of chapter 126, the regular rational readback boundary of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The downstream selector of chapter 7949 reads the minimum row only after the shared $\mathsf{CauchyModulusMeet}^{\uparrow}$ surface and the $\mathsf{DyadicRatCore}^{\uparrow}$ comparison ledger have displayed the common tolerance budget. The packet is a finite L10 Real-and-Completion route: it names the displayed minimum-modulus schedule, not a selected quotient stream, an ambient completeness theorem, or a choice principle over all precision requests.

The minimum-modulus read also depends on the finite-window induction budget of chapter 8091 and the locatedness tolerance budget of chapter 1627. A Real-facing consumer must therefore see the $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$ schedule and the $\mathsf{LocatednessModulus}^{\uparrow}$ request row before treating m as a stable minimum for $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ handoffs.

Definition 4729.1 (Regular Cauchy minimum-modulus carrier)**.** *A* $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S_0, S_1, M, m, W, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S_0 and S_1 are the two regular-Cauchy schedules whose finite precision requests are to be synchronized.*
2. *M is the* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *row that displays the common meet surface inherited from the two source schedules.*
3. *m is the finite minimum row, recording the requestwise smaller admitted threshold after the two source schedules and the meet row have been read.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger naming exactly which source windows are inspected by the minimum schedule.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows and the same displayed thresholds.*

6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger storing denominator budgets, dyadic radii, slack comparisons, and the finite inequalities used by M and m.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after S_0, S_1, M, m, W, Q, D have been displayed.*
8. *H stores componentwise* hsame *transport for the two schedules, the meet row, the minimum row, the stream windows, the regular-rational readback, the dyadic ledger, the real seal, the provenance row, and the local name.*
9. *C stores displayed* Cont *replay from a finite precision request through $S_0, S_1, M, m, W, Q, D, E, H$.*
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyMinModulus}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMinModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient stream equality, a selected limit, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4729.2 (Regular Cauchy minimum-modulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ *carrier*

$$R = (S_0, S_1, M, m, W, Q, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyMinModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two displayed regular-Cauchy schedules, the* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *row, the finite minimum row, stream windows, regular rational readback, dyadic tolerance ledger, terminal real seal, transport, replay, provenance, and local naming rows;*
2. *meet compatibility, requiring M to be read through the sibling shared-modulus surface of chapter 462 before the minimum row m is consumed;*
3. *finite minimum exactness, requiring each request in m to name the smaller displayed threshold among the two transported source schedules after the dyadic comparisons in D have been read;*
4. *readback stability, requiring the same* $\mathsf{StreamName}^{\uparrow}$ *windows W and* $\mathsf{RegSeqRat}^{\uparrow}$ *row Q to be replayed under componentwise* hsame *transport;*
5. *ledger rows for* Cont *replay,* Pkg *provenance, the* $\mathsf{Real}^{\uparrow}$ *seal handoff, and the local naming certificate.*

No accepted obligation row is stored outside $S_0, S_1, M, m, W, Q, D, E, H, C, P, N$.

Proof. Carrier admission is projection from Definition 5544.1. The accepted packet displays the two schedules, the meet row, the minimum row, finite windows, regular readback, dyadic ledger, Real seal, transport, replay, provenance, and local name.

The meet compatibility row is read before the minimum row because m is meaningful only after the common surface M has synchronized the two source schedules. The sibling packet chapter 462 supplies exactly this shared-modulus boundary.

The finite minimum exactness row is then a dyadic comparison inside D. It chooses no infinite stream representative and invokes no ambient completeness theorem; it records only the displayed smaller threshold for each finite request.

Finally W, Q, E, H, C, P, N replay the same route for stream, regular-rational, and Real-facing consumers. Since none of the carrier coordinates stores quotient stream equality, selected limits,

host real equality, countable choice, or ambient completeness, the listed rows exhaust the local certificate surface. □

Theorem 4729.3 (Regular Cauchy minimum-modulus L10 route)**.** *Let $R = (S_0, S_1, M, m, W, Q, D, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ *carrier. Every L10 Real-and-Completion consumer of the minimum schedule factors through the finite route*

$$S_0, S_1 \longmapsto M \longmapsto m, D \longmapsto W, Q \longmapsto E \longmapsto H, C, P, N.$$

The route first reads the two regular-Cauchy schedules, then the shared $\mathsf{CauchyModulusMeet}^{\uparrow}$ *surface, then the finite minimum row with its* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, then the* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and only then reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It exports no quotient stream equality, selected limit, hidden completion object, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the accepted carrier and the obligation theorem above. They force every consumer request to retain $S_0, S_1, M, m, W, Q, D, E, H, C, P, N$ as one finite packet.

The shared-modulus step reads M before any minimum schedule is used. Thus the consumer is not comparing unrelated streams; it is reading the two source schedules through the same displayed meet surface and the same transported tolerance boundary.

The minimum step reads m together with D. The row D carries the dyadic comparisons and tolerance budgets, while m records only the finite threshold selected by those displayed comparisons.

The stream and regular-rational handoff is then mediated by W and Q, and the terminal seal by E. The structural rows H, C, P, N transport, replay, source, and name the same route. Hence every L10 consumer factors through the displayed sequence, with no quotient stream, selected limit, hidden completion object, countable choice, or ambient completeness coordinate available. □

Theorem 4729.4 (Regular Cauchy minimum-modulus positive gap)**.** *Let $R = (S_0, S_1, M, m, W, Q, D, E, H, C, P, N$ be an accepted* $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ *carrier. Whenever the two source modulus schedules display positive dyadic requests through* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$*, the minimum row m preserves a positive displayed request for the downstream* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *handoff. The route also names the* $\mathsf{LocatednessModulus}^{\uparrow}$ *request row and the* $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$ *finite-window budget before any Real-facing consumer reads E.*

Proof. Project the carrier of Definition 5544.1. The two source schedules are read as S_0, S_1, their common meet is M, and the dyadic comparison ledger is D.

Apply the NameCert obligation theorem, Definition 5544.2. Its meet-compatibility and finite-minimum exactness rows require the row m to be read only after M and the displayed dyadic comparisons in D have synchronized the two source requests.

Apply the L10 route theorem, Definition 5544.3. The positive request stored in m is then handed to W, Q, E through the finite sequence $S_0, S_1, M, m, D, W, Q, E, H, C, P, N$, with the sibling $\mathsf{LocatednessModulus}^{\uparrow}$ row and $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$ schedule providing the locatedness and finite-window context.

Because the carrier contains no quotient stream, selected limit, hidden completion object, countable-choice selector, or ambient completeness coordinate, the preserved positive gap is only the displayed dyadic request exported by the finite packet. □

Theorem 4729.5 (Regular Cauchy minimum-modulus finite-window induction)**.** *Let*

$$R = (S_0, S_1, M, m, W, Q, D, E, H, C, P, N)$$

be an accepted RegularCauchyMinModulus$^{\uparrow}$ *carrier. Extending both source schedules by one displayed finite* StreamName$^{\uparrow}$ *and* RegSeqRat$^{\uparrow}$ *window preserves the same minimum-modulus row exactly when the* CauchyModulusMeet$^{\uparrow}$ *row and the* DyadicRatCore$^{\uparrow}$ *tolerance ledger replay through* hsame *and* Cont. *The base read is the carrier route for* S_0, S_1, M, m, W, Q, D, *and the step read uses the meet-compatibility and finite-minimum exactness rows of Definition 5544.2.*

Proof. Proceed by induction on the displayed finite window extension. In the base case, no new window has been appended, so Definition 5544.1 supplies the existing rows $S_0, S_1, M, m, W, Q, D, E, H, C, P, N$ and the minimum row is the admitted row of the carrier.

For the induction step, append one source window to each schedule and read it through the displayed StreamName$^{\uparrow}$ and RegSeqRat$^{\uparrow}$ rows W, Q. The meet-compatibility row of Definition 5544.2 forces the appended requests to pass through the same CauchyModulusMeet$^{\uparrow}$ row M before m is consumed.

The finite-minimum exactness row then uses the DyadicRatCore$^{\uparrow}$ ledger D to compare the transported thresholds. Transport through H and replay through C preserve the same displayed comparison data, so the appended window keeps the minimum-modulus row precisely when M and D replay through hsame and Cont.

Applying the induction hypothesis to the earlier windows and the step argument to the appended window yields preservation for the whole finite extension, with no quotient stream equality, countable choice, selected limit, or ambient completeness coordinate. □

Theorem 4729.6 (Regular Cauchy minimum-modulus scoped primitive route)**.** *Let*

$$R = (S_0, S_1, M, m, W, Q, D, E, H, C, P, N)$$

be an accepted RegularCauchyMinModulus$^{\uparrow}$ *carrier. Every minimum-modulus consumer factors through* $S_0, S_1, M, m, W, Q, D, E, H, C, P, N$ *together with the* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readback,* DyadicRatCore$^{\uparrow}$ *tolerance rows,* RegularCauchyWindowInduction$^{\uparrow}$ *finite-window schedule,* LocatednessModulus$^{\uparrow}$ *request row, terminal* Real$^{\uparrow}$ *seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. The route exports no quotient stream equality, selected limit, hidden completion object, countable-choice selector, host real equality, or ambient* Real$^{\uparrow}$ *completeness principle.*

Proof. Begin with the obligation theorem, Definition 5544.2. It fixes carrier admission, meet compatibility, finite minimum exactness, readback stability, replay, provenance, and local naming as rows of the single finite packet.

Apply the L10 route theorem, Definition 5544.3. Every Real-and-Completion consumer reads the two source schedules, the meet row, the minimum row with dyadic tolerance data, the stream and regular-rational handoff, the real seal, and the structural rows in that order.

Use the positive-gap theorem, Definition 5544.4, to bind the locatedness request row and the finite-window budget to the displayed dyadic request. Then apply the finite-window induction theorem, Definition 5544.5, so extensions of the inspected windows remain within the same M, D, H, C replay surface.

Thus every consumer route is scoped by the named BEDC primitives and sibling packets, and the excluded completion, choice, quotient, and host-equality claims remain outside the accepted RegularCauchyMinModulus$^{\uparrow}$ carrier. □

Falsifiable prediction: An accepted RegularCauchyMinModulus$^{\uparrow}$ consumer that reaches a RegSeqRat$^{\uparrow}$ readback or Real$^{\uparrow}$ seal without reading $S_0, S_1, M, m, W, Q, D, E, H, C, P, N$ refutes the carrier surface.

Independence witness: cauchymodulusmeet, streamname, regseqrat, dyadicratcore, real: no listed sibling supplies the joint packet containing two regular-Cauchy schedules, a shared meet row, a finite minimum row, stream windows, regular rational readback, dyadic tolerance ledger, terminal Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMinModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ packet is generated from two regular-Cauchy schedules, a CauchyModulusMeet row, a finite minimum row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyMinModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5544.1, Definition 5544.2, Definition 5544.3, Definition 5544.4, Definition 5544.5, and Definition 5544.6 seed the finite minimum-modulus route from two regular-Cauchy schedules through a shared meet surface to stream, regular-rational, and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyMinModulus}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, quotient stream equality, selected limits, hidden completion objects, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, meet compatibility, finite minimum exactness, readback stability, and the L10 Real-and-Completion route for BEDC.Derived.RegularCauchyMinModulusUp.

Theorem 4729.7 (Regular Cauchy minimum-modulus CauchyModulus dependency)**.** *Every* RegularCauchyMinMo *consumer reads the request-normalization rows of chapter 292 before it may normalize a source tail request into the minimum-modulus row. The same route reads the regular-sequence handoff of chapter 301 before any* $\mathsf{Real}^{\uparrow}$ *completion-facing seal is consumed.*

Thus the minimum-modulus row depends on $\mathsf{CauchyModulus}^{\uparrow}$ *for source request normalization and on* $\mathsf{RegSeqRat}^{\uparrow}$ *for regular readback, while it supplies no quotient stream equality, selected limit, hidden completion object, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the minimum-modulus request. A consumer cannot form the minimum row until the modulus comparison schedule has displayed how source tail requests are normalized, so the $\mathsf{CauchyModulus}^{\uparrow}$ request-normalization rows are read first.

Next read the regular-sequence handoff. The $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the regular readback used by the completion-facing route, and this readback occurs only after the modulus schedule has already fixed the request shape.

Finally inspect the $\mathsf{Real}^{\uparrow}$ seal. Since the seal is downstream of the displayed request schedule and regular readback, it cannot introduce quotient stream equality, a selected limit, a hidden completion object, countable choice, or ambient completeness. □

Theorem 4729.8 (Regular Cauchy minimum-modulus downstream sibling route)**.** *Any* CauchyTailThresholdNorma *consumer reading a normalized shared threshold through chapter 1299 must preserve the* $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ *row as the finite lower-bound and modulus witness before any* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal read. In particular, the downstream route factors through the same source schedules, meet row, minimum row, finite windows, regular-rational readback, dyadic tolerance ledger, transport, replay, provenance, and local naming rows exposed by Definition 5544.9, Definition 5544.10, and Definition 5544.11.*

Proof. Project the carrier of Definition 5544.1. The displayed packet carries $S_0, S_1, M, m, W, Q, D, E, H, C, P, N$, so the minimum row m is read together with the meet, window, regular-rational, dyadic, seal, transport, replay, provenance, and naming rows.

Apply the forward and hub routes. They force downstream consumers to keep the minimum-modulus row downstream of the $\mathsf{CauchyModulusMeet}^{\uparrow}$ row and upstream of the Real-facing readback surface, rather than reading m as an isolated scalar.

Now read the threshold normalizer. Its normalized shared threshold is a Real-facing consumer route, so it must expose the RegularCauchyMinModulus row before passing to the $\mathsf{RealTailAgreementSeal}^{\uparrow}$ handoff or the terminal $\mathsf{Real}^{\uparrow}$ seal.

Finally use the Real dependency route. It already excludes quotient stream equality, selected limits, countable-choice schedules, and ambient Real completeness, so the downstream sibling relation is exactly the finite lower-bound and modulus witness carried by the accepted packet. □

Theorem 4729.9 (Regular Cauchy minimum-modulus forward sibling route)**.** *Every downstream read of* $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ *by the selector of chapter 7949 must first expose the* $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows already fixed by this chapter. In carrier notation, the selector may consume the minimum row only after the route*

$$S_0, S_1, M, m, W, Q, D, E, H, C, P, N$$

has displayed M as the meet surface, D as the dyadic tolerance ledger, W as the finite stream-window service, Q as the regular-rational readback row, and E as the Real-facing seal.

Proof. Start with the carrier of Definition 5544.1. It displays $S_0, S_1, M, m, W, Q, D, E, H, C, P, N$ as one finite packet, so the downstream selector cannot read m apart from the meet, window, readback, dyadic, seal, transport, replay, provenance, and naming rows.

Apply the NameCert obligations of Definition 5544.2. They force meet compatibility through M, finite minimum exactness through m and D, and readback stability through W and Q before any consumer treats the minimum schedule as accepted data.

Apply the L10 route of Definition 5544.3 and the positive-gap theorem of Definition 5544.4. These results place the displayed minimum before the $\mathsf{Real}^{\uparrow}$ seal while keeping the $\mathsf{LocatednessModulus}^{\uparrow}$ and $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$ context visible.

Hence a downstream Cauchy-subsequence selector receives only the already named finite route. It receives no quotient stream equality, selected limit, hidden completion object, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle. □

Theorem 4729.10 (Regular Cauchy minimum-modulus hub dependency route)**.** *Every accepted* $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ *packet consumes the* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *meet row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the* $\mathsf{Real}^{\uparrow}$ *seal before exporting the minimum-modulus row to any downstream consumer. In carrier notation, the route exposes*

$$S_0, S_1, M, m, W, Q, D, E, H, C, P, N$$

with M read as the meet surface, D read as the dyadic comparison ledger, W read as the finite window service, Q read as the regular-rational readback, and E read as the Real-facing seal.

Proof. Project the carrier of Definition 5544.1. The minimum-modulus row m is not an isolated output; it is displayed inside the finite packet $S_0, S_1, M, m, W, Q, D, E, H, C, P, N$.

Read the sibling route already present in the chapter. The $\mathsf{CauchyModulusMeet}^{\uparrow}$ row M synchronizes the two source schedules before m can be consumed, and the $\mathsf{DyadicRatCore}^{\uparrow}$ row D supplies the comparison ledger that makes the displayed minimum meaningful.

Now read the Real-and-Completion handoff. The $\mathsf{StreamName}^{\uparrow}$ windows W and $\mathsf{RegSeqRat}^{\uparrow}$ row Q provide the finite readback surface, while E seals the same route for $\mathsf{Real}^{\uparrow}$ consumers. Transport, replay, provenance, and local naming remain attached through H, C, P, N, so the hub dependency route exports only the displayed minimum-modulus packet and no private completion or choice coordinate. □

The Real-facing route for $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ is a finite dependency route through the $\mathsf{RegSeqRat}^{\uparrow}$ readbacks of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows of chapter 291, the $\mathsf{StreamName}^{\uparrow}$ finite windows of chapter 126, and the terminal $\mathsf{Real}^{\uparrow}$ sealing surface of chapter 38. A consumer may read the minimum-modulus row only after those displayed rows are present in the same BHist, hsame, Cont, Pkg, and local NameCert route; it receives no quotient stream equality, selected limit, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate.

Theorem 4729.11 (Regular Cauchy minimum-modulus sibling route)**.** *Every* $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ *read factors through the* $\mathsf{CauchyModulus}^{\uparrow}$ *carrier of chapter 292 and the* $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ *normalizer of chapter 778 before exposing the minimum modulus row. The route first displays the source modulus request, then normalizes the regular-Cauchy threshold schedule, and only then reads the finite minimum row together with its* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *support.*

Proof. Start with the carrier of Definition 5544.1. The accepted packet displays source schedules, the meet row, the minimum row, stream windows, regular-rational readback, dyadic tolerance data, the Real seal, transport, replay, provenance, and local naming.

Read the $\mathsf{CauchyModulus}^{\uparrow}$ sibling first. It supplies the carrier-level modulus request whose finite thresholds are visible before the minimum row can be inspected.

Next read the $\mathsf{RegularCauchyModulusNormalizer}^{\uparrow}$ sibling. Its normalizer keeps the regular-Cauchy threshold schedule on the same displayed carrier route, so the minimum row is not a detached host-level comparison.

The exposed minimum modulus row is therefore downstream of both sibling packets. Since the route remains inside the displayed BHist, hsame, Cont, Pkg, and local NameCert rows, it exports no quotient completion, selected limit, countable-choice selector, or ambient Real completeness principle. □

Chapter 4730

A Concrete Naming Certificate for $\mathsf{TaylorTheorem}^{\uparrow}$

Following Taylor and the validated-numerics treatment of finite Taylor models, the $\mathsf{TaylorTheorem}^{\uparrow}$ packet records the finite theorem-facing route from displayed derivative data to a polynomial jet and a checked remainder envelope. It sits after the Taylor-model enclosure surface of chapter 442, the derivative observation row of chapter 122, the polynomial carrier of chapter 50, the dyadic rational arithmetic core of chapter 291, the regular-rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite Taylor theorem certificate for one displayed center, order, domain window, derivative ledger, polynomial jet, and remainder bound; it does not import analytic convergence, quotient real equality, selected limits, or a host Taylor series.

Definition 4730.1 (Taylor theorem carrier)**.** *A* $\mathsf{TaylorTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, J, P, R, E, Q, H, C, G, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{Derivative}^{\uparrow}$ *row naming the center, finite order, domain window, and derivative observations inspected by the packet.*
2. *J is the finite jet ledger. Each coefficient is read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic and the same derivative window named by D.*
3. *P is the* $\mathsf{Poly}^{\uparrow}$ *row assembled from the displayed finite jet ledger.*
4. *R is the finite remainder-envelope row. It records the derivative-order budget, dyadic interval or ball enclosure, and endpoint window used to bound the residual after P is read.*
5. *E is the* $\mathsf{TaylorModel}^{\uparrow}$ *enclosure row that packages the displayed polynomial part and remainder envelope as a validated finite jet.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback route for polynomial values, derivative observations, and the remainder bound.*
7. *H records componentwise* hsame *transport for derivative, jet, polynomial, remainder, Taylor-model, readback, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from every Taylor-theorem read through $D, J, P, R, E, Q, H, G, N$.*

9. *G is the* Pkg *provenance over* $\mathsf{TaylorTheorem}^{\uparrow}$, $\mathsf{TaylorModel}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{TaylorTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, J, P, R, E, Q, H, C, G, N$. It has no coordinate for an infinite Taylor series, analytic convergence, quotient equality of real names, selected limiting values, or an ambient smooth-function theorem.

Theorem 4730.2 (Taylor theorem NameCert obligations)**.** *For every accepted* $\mathsf{TaylorTheorem}^{\uparrow}$ *carrier*

$$T = (D, J, P, R, E, Q, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{TaylorTheorem}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed derivative row, finite jet ledger, polynomial row, remainder envelope, Taylor-model enclosure, readback route, transport, replay, provenance, and local naming rows;*
2. *derivative-to-jet routing, requiring every coefficient in J to be read from the finite* $\mathsf{Derivative}^{\uparrow}$ *observations in D and through* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic;*
3. *polynomial assembly, requiring P to use exactly the displayed finite coefficient rows in J;*
4. *remainder-envelope exposure, requiring R to bind the next derivative-order budget, the domain window, and the dyadic enclosure before any error bound is exported;*
5. *Taylor-model handoff, requiring E to package only the displayed P and R rows;*
6. *regular and real readback, requiring Q to pass through* $\mathsf{RegSeqRat}^{\uparrow}$ *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is visible;*
7. *non-escape from analytic convergence, quotient real equality, selected limits, and host Taylor series semantics.*

No $\mathsf{TaylorTheorem}^{\uparrow}$ *obligation is stored outside these rows.*

Lean4 ✓ `BEDC.Derived.TaylorTheoremUp.TasteGate.TaylorTheoremTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 5898.1. The theorem-facing data are exactly D, J, P, R, E, Q, and the structural rows are exactly H, C, G, N.

The derivative-to-jet route is finite. Each coefficient read is a displayed entry of J, and the definition of J attaches that entry to the derivative row D and to dyadic rational arithmetic through $\mathsf{DyadicRatCore}^{\uparrow}$.

Polynomial assembly and remainder exposure are then separate rows. The polynomial row P consumes only the coefficients in J, while the remainder row R consumes the derivative-order budget and domain window before any bound is exported.

Finally the Taylor-model and readback rows seal the route. The row E packages the polynomial and remainder as a finite Taylor-model enclosure, and Q sends the same displayed data through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. Since no carrier coordinate names a host Taylor series or a selected limit, the listed rows exhaust the local NameCert surface. □

Theorem 4730.3 (Taylor theorem finite remainder envelope)**.** *Every accepted* $\mathsf{TaylorTheorem}^{\uparrow}$ *carrier exports a remainder claim only through the displayed route*

$$\mathsf{Derivative}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Poly}^{\uparrow} \longmapsto \mathsf{TaylorModel}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

More precisely, a consumer must first read the derivative row D, finite jet ledger J, polynomial row P, remainder-envelope row R, Taylor-model enclosure E, and regular-rational and real readback row Q before it may cite an error bound for the displayed polynomial approximation. The exported envelope is not an analytic convergence theorem, a quotient equality of real functions, a selected limit, or an ambient Taylor-series object.

Proof. Start with an accepted carrier $T = (D, J, P, R, E, Q, H, C, G, N)$. The only source of derivative information is D, and the only coefficient ledger is the finite row J read through $\mathsf{DyadicRatCore}^{\uparrow}$.

Next assemble the approximation. The polynomial row P is built from J, and the remainder row R binds the derivative-order budget, domain window, and dyadic enclosure that measure the residual after that polynomial row has been fixed.

Then pass through the enclosure and readback rows. The Taylor-model row E packages the polynomial and remainder as one finite validated jet, while Q routes the resulting value and bound through $\mathsf{RegSeqRat}^{\uparrow}$ and the terminal $\mathsf{Real}^{\uparrow}$ seal.

The transport, replay, provenance, and local naming rows preserve exactly this route. Because the carrier contains no coordinate for analytic convergence, quotient function equality, selected limits, or host Taylor series semantics, every exported remainder envelope is exhausted by the displayed finite rows. □

Falsifiable prediction: Every accepted $\mathsf{TaylorTheorem}^{\uparrow}$ remainder-envelope read factors through a DerivativeUp row, a DyadicRatCore coefficient ledger, a PolynomialUp row, a TaylorModelUp enclosure, a RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: taylormodel, derivative, polynomial, dyadicratcore, regseqrat, real: $\mathsf{TaylorTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds finite derivative observations, coefficient arithmetic, polynomial assembly, a theorem-facing remainder envelope, Taylor-model enclosure, regular-rational readback, real sealing, transport, replay, provenance, and local naming in one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{TaylorTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{TaylorTheorem}^{\uparrow}$ packet is generated from a DerivativeUp row, a finite DyadicRatCore coefficient ledger, a PolynomialUp row, a finite remainder envelope, a TaylorModelUp enclosure, RegSeqRatUp and RealUp readback, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TaylorTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5898.1, Definition 5898.2, and Definition 5898.3 seed the finite Taylor theorem route from derivative observations through polynomial jets to displayed remainder envelopes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TaylorTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close analytic convergence, quotient equality of real names, selected limits, host Taylor series semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-to-jet routing, polynomial assembly, finite remainder-envelope exposure, Taylor-model handoff, regular and real readback, and non-escape for BEDC.Derived.TaylorTheoremUp.

Chapter 4731

A Concrete Naming Certificate for $\mathsf{LagrangeInversion}^{\uparrow}$

Following Lagrange and the classical finite coefficient form of the inversion theorem, the $\mathsf{LagrangeInversion}^{\uparrow}$ packet records the coefficient-reversion route that extracts finitely many inverse-series coefficients from one displayed Taylor jet with a nonzero linear coefficient. It sits after the finite Taylor theorem route of chapter 5898, the derivative observation surface of chapter 122, the polynomial carrier of chapter 50, the dyadic rational arithmetic core of chapter 291, the regular-rational readback rows of chapter 301, and the terminal real-name seals of chapter 38. The packet names a finite inverse-series coefficient extraction certificate; it does not import analytic inverse-function reasoning, a convergent inverse power series, quotient real equality, selected roots, or ambient real completeness.

Definition 4731.1 (Lagrange inversion carrier)**.** *A* $\mathsf{LagrangeInversion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (c, J, a_1, R, B, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *c is the displayed center row, read as a named* $\mathsf{Real}^{\uparrow}$ *endpoint seal together with the finite local window in which the Taylor jet is interpreted.*
2. *J is the finite* $\mathsf{TaylorTheorem}^{\uparrow}$ *jet row. It lists the Taylor coefficients used by the inverse-coefficient extraction and records the associated* $\mathsf{Derivative}^{\uparrow}$ *and* $\mathsf{Poly}^{\uparrow}$ *provenance.*
3. *a_1 is the nonzero linear coefficient witness, represented as a displayed apartness or inverse row over* $\mathsf{DyadicRatCore}^{\uparrow}$ *and sealed by the same* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback route as J.*
4. *R is the finite coefficient-reversion ledger. Each inverse coefficient requested by the packet is obtained by a displayed recurrence using only earlier rows of R, the finite jet J, and the linear witness a_1.*
5. *B records dyadic rational coefficient bounds for the finite coefficient-reversion ledger and the polynomial truncations consumed by the packet.*
6. *Q lists the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows for the displayed coefficients, the linear witness, the recurrence denominators, and the finite polynomial values.*
7. *E records the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seals for the center, coefficient reads, and finite inverse-polynomial handoff.*

8. *H records componentwise* hsame *transport for the center, Taylor jet, nonzero linear witness, reversion ledger, coefficient bounds, readback rows, endpoint seals, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from every inverse-coefficient read through $c, J, a_1, R, B, Q, E, H, P, N$.*
10. *P is the* Pkg *provenance over* LagrangeInversion$^\uparrow$, TaylorTheorem$^\uparrow$, Derivative$^\uparrow$, Poly$^\uparrow$, DyadicRatCore$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* NameCert$_{\text{LagrangeInversion}^\uparrow}$ *row.*

The classifier compares accepted packets only through the displayed rows $c, J, a_1, R, B, Q, E, H, C, P, N$. It has no coordinate for an infinite inverse series, analytic convergence, selected inverse branches, quotient equality of real names, countable choice, or an ambient inverse-function theorem.

Lean4 ✓ `BEDC.Derived.LagrangeInversionUp.LagrangeInversionTasteGate single carrier alignment`

Theorem 4731.2 (Lagrange inversion NameCert obligations)**.** *For every accepted* LagrangeInversion$^\uparrow$ *carrier*

$$L = (c, J, a_1, R, B, Q, E, H, C, P, N),$$

the local NameCert$_{\text{LagrangeInversion}^\uparrow}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed center, finite Taylor jet, nonzero linear coefficient witness, coefficient-reversion ledger, coefficient bounds, readback rows, endpoint seals, transport, replay, provenance, and local naming rows;*
2. *Taylor-jet routing, requiring every source coefficient read to pass through J and the finite* TaylorTheorem$^\uparrow$, Derivative$^\uparrow$, *and* Poly$^\uparrow$ *rows it names;*
3. *linear-coefficient apartness, requiring every division used by the reversion recurrence to cite the displayed nonzero witness a_1 over* DyadicRatCore$^\uparrow$*;*
4. *finite reversion exactness, requiring every row of R to be computed from earlier displayed rows, the finite jet J, and the witness a_1;*
5. *coefficient-bound readback, requiring B and Q to expose dyadic rational bounds and* RegSeqRat$^\uparrow$ *reads before any terminal* Real$^\uparrow$ *seal in E is consumed;*
6. *structural stability, requiring H, C, P, N to transport, replay, source, and name only the rows already listed.*

No LagrangeInversion$^\uparrow$ *obligation is stored outside these rows.*

Proof. Project the carrier of Definition 4731.1. The theorem-facing rows are exactly c, J, a_1, R, B, Q, E, and the structural rows are exactly H, C, P, N.

The source data are finite. The row J is a TaylorTheorem$^\uparrow$ jet and therefore already factors through derivative observations, polynomial assembly, dyadic coefficient arithmetic, regular rational readback, and real endpoint sealing. The row a_1 is displayed separately, so every recurrence division cites a named nonzero linear coefficient witness.

The coefficient extraction is the finite ledger R. Each row of R reads only earlier inverse-coefficient rows, the listed source coefficients in J, and the dyadic arithmetic attached to a_1; hence no analytic inverse branch or infinite series coordinate is introduced.

Finally B, Q, E bind the numeric output to finite readback. Dyadic coefficient bounds are displayed before regular rational reads, and the terminal Real$^\uparrow$ seals are reached only after those rows are visible. The transport, replay, provenance, and local naming rows preserve this same packet, so the listed obligations exhaust the local NameCert surface. □

Theorem 4731.3 (Lagrange inversion Taylor-polynomial handoff)**.** *Every accepted* $\mathsf{LagrangeInversion}^{\uparrow}$ *carrier exports an inverse-polynomial coefficient read only through the finite route*

$$\mathsf{TaylorTheorem}^{\uparrow} \longmapsto \mathsf{Derivative}^{\uparrow}, \mathsf{Poly}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto R, B \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

More precisely, a consumer must first read the displayed center c, finite Taylor jet J, nonzero linear coefficient witness a_1, coefficient-reversion ledger R, dyadic coefficient bounds B, regular rational readbacks Q, endpoint seals E, componentwise hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and local* NameCert *row N before it may consume a finite inverse-polynomial coefficient. The handoff exports coefficient extraction only for the displayed finite truncation, not analytic convergence, selected inverse branches, quotient real equality, countable choice, or ambient real completeness.*

Proof. Start with an accepted carrier $L = (c, J, a_1, R, B, Q, E, H, C, P, N)$. The finite Taylor input is J, whose source dependencies are the Taylor theorem, derivative, polynomial, dyadic rational, regular rational, and real-name rows cited in the carrier.

Next read the nonzero linear coefficient witness a_1. This row is the only source for the divisions in the reversion recurrence, so the consumer cannot replace it by a selected local inverse or by a host inverse-function theorem.

Then consume the finite reversion ledger R and coefficient bounds B. The ledger is finite because it contains only the inverse coefficients requested by the packet, and each displayed row cites earlier ledger entries and the finite source jet. The bounds in B keep the dyadic rational output visible before readback.

Finally pass through Q, E, H, C, P, N. Regular rational readback precedes the terminal real endpoint seals, while transport, replay, provenance, and local naming preserve exactly the displayed route. Since the carrier has no coordinate for analytic convergence, quotient real equality, selected inverse branches, countable choice, or ambient real completeness, every inverse-polynomial coefficient read is exhausted by the finite handoff above. □

Falsifiable prediction: Every accepted $\mathsf{LagrangeInversion}^{\uparrow}$ inverse-coefficient read factors through a displayed center, finite TaylorTheorem jet, Derivative and Polynomial provenance, a nonzero linear coefficient witness, a finite coefficient-reversion ledger, DyadicRatCore coefficient bounds, RegSeqRat readbacks, Real endpoint seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: taylor-theorem, derivative, polynomial, dyadicratcore, regseqrat, real: $\mathsf{LagrangeInversion}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds one center, one finite Taylor jet, a nonzero linear coefficient witness, coefficient-reversion recurrence rows, dyadic coefficient bounds, readback rows, endpoint seals, transport, replay, provenance, and local naming in one inverse-coefficient certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{LagrangeInversion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LagrangeInversion}^{\uparrow}$ packet is generated from a displayed center, a finite TaylorTheoremUp jet with DerivativeUp and PolynomialUp provenance, a nonzero linear coefficient witness, a finite coefficient-reversion ledger, DyadicRatCore coefficient bounds, RegSeqRat readbacks, Real endpoint seals, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LagrangeInversion}^{\uparrow}}$, seed)

Scope closed: Definition 4731.1, Definition 4731.2, and Definition 4731.3 seed the finite inverse-series coefficient extraction route from a displayed Taylor jet to inverse-polynomial coefficient reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LagrangeInversion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close analytic inverse-function reasoning, convergence of an inverse series, selected inverse branches, quotient real equality, countable choice, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Taylor-jet routing, nonzero linear coefficient apartness, finite reversion exactness, coefficient-bound readback, Real endpoint sealing, transport and replay stability, and nonescape for BEDC.Derived.LagrangeInversionUp.

Chapter 4732

A Concrete Naming Certificate for $\mathsf{TaylorRemainder}^{\uparrow}$

Following Taylor's theorem and Bishop–Bridges constructive analysis, the $\mathsf{TaylorRemainder}^{\uparrow}$ packet isolates the finite remainder-envelope data used by chapter 5898 and chapter 442. It sits after the derivative observation row of chapter 122, the polynomial carrier of chapter 50, the regular-rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names only displayed finite derivative windows, polynomial residual rows, dyadic or regular-rational error budgets, readback, transport, replay, provenance, and local naming; it does not import analytic convergence, quotient equality of functions, selected limits, or a host smooth-function theorem.

Definition 4732.1 (Taylor remainder carrier)**.** *A* $\mathsf{TaylorRemainder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, P, W, E, Q, S, H, C, G, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{Derivative}^{\uparrow}$ *observation row naming the center, order, domain window, and derivative budget inspected by the remainder read.*
2. *P is the* $\mathsf{Poly}^{\uparrow}$ *row for the finite Taylor polynomial whose residual is being bounded.*
3. *W is the finite remainder-window row. It records the endpoint or interval window, the next derivative-order budget, and the comparison side on which the residual is read.*
4. *E is the error-envelope row, storing the displayed dyadic or regular-rational bound for the residual after P has been fixed.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row through which the bound and polynomial value are exposed as regular rational names.*
6. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after the derivative, polynomial, window, envelope, and regular-rational rows have been displayed.*
7. *H records componentwise* hsame *transport for derivative, polynomial, window, envelope, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from every remainder-envelope request through $D, P, W, E, Q, S, H, G, N$.*
9. *G is the* Pkg *provenance over* $\mathsf{TaylorRemainder}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{TaylorRemainder}^\uparrow}$ *row.*
The classifier compares accepted packets only through $D, P, W, E, Q, S, H, C, G, N$. It has no coordinate for an infinite Taylor series, analytic convergence, quotient equality of real functions, selected limiting values, or an ambient differentiability theorem.

Lean4 (definition) `BEDC.Derived.TaylorRemainderUp.TaylorRemainderCarrier`

Theorem 4732.2 (Taylor remainder NameCert obligations)**.** *For every accepted* $\mathsf{TaylorRemainder}^\uparrow$ *carrier*

$$R = (D, P, W, E, Q, S, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{TaylorRemainder}^\uparrow}$ *surface consists exactly of carrier admission for R, derivative-window exposure through D, polynomial-source exposure through P, finite remainder-window visibility through W, error-envelope accountability through E, regular-rational readback through Q, terminal real sealing through S, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through G, and local naming through N.*

Proof. Project the carrier of Definition 4732.1. The analytic-facing rows are D, P, W, E: a derivative observation, a finite polynomial source, a displayed remainder window, and a residual envelope.

The readback rows are ordered. The envelope row E is read only after the derivative and polynomial rows have fixed the residual being bounded, then Q exposes the regular-rational readback and S supplies the terminal $\mathsf{Real}^\uparrow$ seal.

The structural rows H, C, G, N transport, replay, source, and name exactly those displayed coordinates. Since no carrier coordinate stores an infinite Taylor series, analytic convergence theorem, quotient function equality, selected limit, or host differentiability principle, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.TaylorRemainderUp.TaylorRemainderCarrier namecert obligations`

Theorem 4732.3 (Taylor remainder Real seal handoff)**.** *Every accepted* $\mathsf{TaylorRemainder}^\uparrow$ *remainder-envelope read factors through the finite route*

$$\mathsf{Derivative}^\uparrow \longmapsto \mathsf{Poly}^\uparrow \longmapsto \mathsf{RegSeqRat}^\uparrow \longmapsto \mathsf{Real}^\uparrow$$

as instantiated by D, P, W, E, Q, S. A $\mathsf{TaylorTheorem}^\uparrow$ *or* $\mathsf{TaylorModel}^\uparrow$ *consumer may read the displayed residual bound only after the derivative observation, polynomial source, finite remainder window, error envelope, regular-rational readback, terminal real seal, componentwise transport, continuation replay, provenance, and local certificate rows are present.*

Proof. Start with an accepted carrier $R = (D, P, W, E, Q, S, H, C, G, N)$. The derivative row D fixes the observed order and domain window, while P fixes the polynomial whose residual is being bounded.

The finite remainder window W and envelope E then bind the residual read. They record the endpoint or interval window, the derivative-order budget, and the displayed dyadic or regular-rational error bound before any consumer can cite a theorem-facing error estimate.

Finally Q and S route the same displayed data through regular-rational readback and the terminal Real seal. The transport, replay, provenance, and local naming rows preserve this order, so Taylor-theorem and Taylor-model consumers receive a finite remainder packet rather than analytic convergence, quotient equality, a selected limit, or an ambient smooth-function theorem. □

Falsifiable prediction: Every accepted $\mathsf{TaylorRemainder}^{\uparrow}$ remainder-envelope read factors through one DerivativeUp row, one PolynomialUp row, one finite remainder-window row, one error-envelope row, one RegSeqRatUp readback row, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: taylor-theorem, taylormodel, derivative, polynomial, regseqrat, real: $\mathsf{TaylorRemainder}^{\uparrow}$ is not bijective to any listed sibling because it isolates the theorem-facing residual window, error-envelope row, regular-rational readback, Real seal, transport, replay, provenance, and local naming as one finite certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{TaylorRemainder}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TaylorRemainder}^{\uparrow}$ packet is generated from a DerivativeUp observation row, a PolynomialUp source row, a finite remainder window, a displayed error envelope, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TaylorRemainder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4732.1, Definition 4732.2, and Definition 4732.3 seed the finite Taylor residual route from derivative observations and polynomial sources to regular-rational readback and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TaylorRemainder}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close analytic convergence, quotient equality of real functions, selected limits, ambient differentiability, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-window exposure, polynomial-source exposure, finite remainder-window visibility, error-envelope accountability, regular and real readback, transport, replay, provenance, and local naming for BEDC.Derived.TaylorRemainderUp.

The $\mathsf{ApproximationTower}^{\uparrow}$ hub routes finite level ledgers through chapter 126, chapter 301, chapter 291, and chapter 38 before the child files unpack carrier and obligation rows.

Chapter 4733

A Concrete Naming Certificate for $\mathsf{ApproximationTower}^{\uparrow}$

The $\mathsf{ApproximationTower}^{\uparrow}$ packet realizes the finite level-and-window tower of chapter 9414 as BEDC NameCert data. It sits beside the finite stream observations of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance carrier of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. Those siblings provide windows, readback, tolerance, and sealing rows; this packet binds them into one finite approximation tower without adding a hidden limit selector, quotient stream, ambient completeness theorem, or physical-adequacy row.

Definition 4733.1 (ApproximationTower carrier)**.** *An* $\mathsf{ApproximationTower}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (L, W, D, R, E, H, C, P, N)$$

with the following visible rows:

1. *L is the finite level ledger naming the approximation stages consumed by the tower.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row recording the finite observations available at each level.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row assigning displayed dyadic error bounds to the levels.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that compares successive level observations through regular rational data.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite windows, dyadic tolerances, and regular readback rows have been displayed.*
6. *H records componentwise* hsame *transport for L, W, D, R, E and the structural rows.*
7. *C records displayed* Cont *replay of the level ledger, finite windows, dyadic tolerances, regular readback, and real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{ApproximationTower}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ApproximationTower}^{\uparrow}}$ *row.*

The carrier has no coordinate for a hidden source, quotient stream equality, selected limit point, ambient completeness theorem, or physical-adequacy classifier.

Lean4 (statement) `BEDC.Derived.ApproximationTowerUp`

Theorem 4733.2 (ApproximationTower finite NameCert surface)**.** *For every accepted* $\mathsf{ApproximationTower}^{\uparrow}$ *carrier* $A = (L, W, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ApproximationTower}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite level ledger, finite window exposure through* W*, dyadic tolerance exposure through* D*, regular rational readback through* R*, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

No accepted read exports a hidden limit selector, quotient stream, unbounded level family, ambient real-completeness row, or physical-adequacy classifier.

Proof. Project the carrier of Definition 4733.1. Its analytic rows are L, W, D, R, E, and its structural rows are H, C, P, N.

The level ledger L fixes the finite tower shape before any observation is read. The window row W then exposes the finite stream observations at those levels, and the dyadic row D supplies the displayed tolerance bounds attached to the same levels.

The regular readback row R compares the displayed windows through rational data, after which the real seal E may be consumed. Transport, replay, provenance, and local naming preserve only this route through H, C, P, N.

Since the carrier has no coordinate for a hidden source, quotient stream, selected limit, ambient real completeness, or physical-adequacy classifier, the listed rows exhaust the local NameCert surface. □

Theorem 4733.3 (ApproximationTower L10 sibling route)**.** *Every accepted* $\mathsf{ApproximationTower}^{\uparrow}$ *read factors through the concrete L10 sibling rows* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *before any tower level can be consumed. For a carrier* $A = (L, W, D, R, E, H, C, P, N)$*, the level ledger* L *is readable only with the finite window row* W*, dyadic tolerance row* D*, regular rational readback row* R*, terminal real seal* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*, package provenance* P*, and local* $\mathsf{NameCert}_{\mathsf{ApproximationTower}^{\uparrow}}$ *row* N*.*

The vision reference motivates the packet, but it is not a substitute for these concrete-instance dependencies. No accepted read may bypass the StreamName, RegSeqRat, DyadicRatCore, and Real rows by appealing to a hidden limit selector, quotient stream, unbounded level family, ambient completeness theorem, or physical-adequacy classifier.

Proof. Project the carrier of Definition 4733.1. The rows $L, W, D, R, E, H, C, P, N$ are the complete displayed packet, with no hidden coordinate outside the finite level, window, tolerance, readback, seal, transport, replay, provenance, and naming surface.

The finite NameCert surface of Definition 4733.2 identifies W as the $\mathsf{StreamName}^{\uparrow}$ route, D as the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance route, R as the $\mathsf{RegSeqRat}^{\uparrow}$ readback route, and E as the terminal $\mathsf{Real}^{\uparrow}$ seal. A tower level is therefore visible only after those sibling rows have been read.

Finally the structural rows H, C, P, N preserve that same route for downstream consumers. The source vision supplies orientation for the packet, but it does not replace the concrete sibling rows; hence any read that skips $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ leaves the accepted $\mathsf{ApproximationTower}^{\uparrow}$ surface. □

Theorem 4733.4 (ApproximationTower obligation closure)**.** *For every accepted* $\mathsf{ApproximationTower}^{\uparrow}$ *carrier* $A = (L, W, D, R, E, H, C, P, N)$*, the packet supplies the five required NameCert obligation rows for the tower route: carrier admission for finite levels, window exposure through* $\mathsf{StreamName}^{\uparrow}$*, dyadic tolerance exactness through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal handoff, and structural transport, replay, provenance, and naming nonescape through* H, C, P, N*.*

The obligations are exactly the visible rows of the carrier. They do not add a hidden source, quotient stream equality, selected limit point, ambient completeness theorem, physical-adequacy classifier, or external approximation oracle.

Proof. Project the carrier of Definition 4733.1. The finite level ledger L supplies carrier admission for displayed stages, and the window row W exposes only the finite $\mathsf{StreamName}^{\uparrow}$ observations available at those stages.

The dyadic row D supplies tolerance exactness, while R supplies the regular rational readback attached to the same displayed windows. The real seal E is downstream from those rows by Definition 4733.3.

The structural rows H, C, P, N then transport, replay, source, and name the same finite surface. By Definition 4733.2, the carrier has no additional coordinate, so the listed obligations exhaust the accepted $\mathsf{ApproximationTower}^{\uparrow}$ packet. □

Falsifiable prediction: Every accepted $\mathsf{ApproximationTower}^{\uparrow}$ read exposes finite level admission, StreamNameUp windows, DyadicRatCoreUp tolerances, RegSeqRatUp readback, RealUp sealing, transport, replay, provenance, and local NameCert before any tower level is consumed.

Independence witness: streamname, regseqrat, dyadicratcore, real, approximationtowerresidue: $\mathsf{ApproximationTower}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite level admission, windows, tolerances, readback, Real sealing, transport, replay, provenance, and local naming as one tower packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ApproximationTower}^{\uparrow}}$.

Constructive story: An $\mathsf{ApproximationTower}^{\uparrow}$ packet is generated from a finite level ledger, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ApproximationTower}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4733.1 and Definition 4733.2 seed the finite approximation tower over level, window, dyadic tolerance, regular readback, real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ApproximationTower}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not provide checked Lean obligations, hidden-source recovery, quotient stream equality, ambient completeness, physical adequacy, or a selected limit for $\mathsf{ApproximationTower}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, dyadic tolerance exactness, regular readback, real sealing, transport, replay, provenance, and local naming for BEDC.Derived.ApproximationTowerUp.

Theorem 4733.5 (ApproximationTower Real consumer route)**.** *Every accepted* $\mathsf{ApproximationTower}^{\uparrow}$ *consumer that reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal must first display the finite level ledger, the* $\mathsf{StreamName}^{\uparrow}$ *window rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{ApproximationTower}^{\uparrow}}$ *row. The route is the concrete L10 completion path through chapter 126, chapter 291, chapter 301, and chapter 38.*

Proof. Project the accepted carrier $A = (L, W, D, R, E, H, C, P, N)$ of Definition 4733.1. The row L is the only finite level ledger, W is the only displayed stream-window source, D is the only dyadic tolerance surface, R is the only regular rational readback row, and E is the only terminal real seal.

Apply the finite NameCert surface of Definition 4733.2. It forces the analytic rows to be read with the structural rows H, C, P, N, so a Real-facing consumer receives transport, replay, provenance, and local naming before it can consume E.

Finally use the L10 sibling route of Definition 4733.3. The route anchors the window, tolerance, readback, and seal rows in the StreamName, DyadicRatCore, RegSeqRat, and Real chapters named above. Thus the accepted Real consumer cannot bypass the finite tower route through a hidden source, quotient stream equality, selected limit point, ambient completeness theorem, physical-adequacy classifier, or external approximation oracle. □

The sibling route makes the Real-facing use of $\mathsf{ApproximationTower}^{\uparrow}$ explicit: the tower seal is never read as a kernel-only artifact, but through the same L10 rows named by the carrier and consumed by the Real route.

Theorem 4733.6 (ApproximationTower sibling dependency route)**.** *Every* $\mathsf{ApproximationTower}^{\uparrow}$ *Real-facing consumer first reads the* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *sibling route already named by Definition 4733.1 before it reads the tower seal. In particular, the carrier rows* D, W, R, E *are exposed as dyadic tolerance, stream window, regular rational readback, and terminal real seal data before the structural rows* H, C, P, N *package the tower for downstream use.*

Proof. Project the accepted carrier $A = (L, W, D, R, E, H, C, P, N)$ of Definition 4733.1. The rows D, W, R, E are named there as the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, $\mathsf{StreamName}^{\uparrow}$ window row, $\mathsf{RegSeqRat}^{\uparrow}$ readback row, and $\mathsf{Real}^{\uparrow}$ seal row.

Apply Definition 4733.5. A Real-facing consumer reaches the terminal seal only after the finite level ledger, the four sibling rows, and the structural rows have been displayed.

Thus the tower seal is downstream from the dyadic tolerance, stream window, regular readback, and Real seal route already carried by A. The rows H, C, P, N preserve and name that route; they do not introduce a separate kernel-only consumption path. □

Chapter 4734

A Concrete Naming Certificate for $\mathsf{ArchimedeanOrderedCauchyCompletion}^{\uparrow}$

Following Bishop–Bridges constructive completion, the $\mathsf{ArchimedeanOrderedCauchyCompletion}^{\uparrow}$ packet records the finite NameCert surface for an Archimedean ordered Cauchy completion built from displayed dyadic rational data. It sits as an L10 real-completion neighbour of the dyadic carrier of chapter 291, the finite stream-name interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the constructive order handoff of section 38.3. The packet binds density, Archimedean order, regular-Cauchy sealing, and RealUp readback in one finite carrier; it does not import quotient completion, selected limits, trichotomy, countable choice, host real equality, or ambient completeness.

Definition 4734.1 (ArchimedeanOrderedCauchyCompletion carrier)**.** *An* $\mathsf{ArchimedeanOrderedCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, S, Q, R, O, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row carrying dyadic rational observations, signed arithmetic, tolerance comparison, and density requests.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row exposing finite observation windows for completion names.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row reading regular Cauchy rational sequences through the same dyadic tolerances.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, Q have been displayed.*
5. *O is the* $\mathsf{RealAlgOrder}^{\uparrow}$ *order-and-apartness handoff row for the sealed real names.*
6. *L is the Archimedean density ledger: every displayed positive tolerance request is answered by a dyadic row of D before the corresponding stream window and regular-readback row are consumed.*
7. *H records componentwise* hsame *transport for D, S, Q, R, O, L.*
8. *C records displayed* Cont *replay of the same completion route.*
9. *P is the* Pkg *provenance over* $\mathsf{ArchimedeanOrderedCauchyCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanOrderedCauchyCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for a quotient set of Cauchy sequences, a selected representative, a global order decision, countable choice, or a separate completeness oracle.

Lean4 ✓ BEDC.Derived.ArchimedeanOrderedCauchyCompletionUp.ArchimedeanOrderedCauchyCompletionTasteGate single carrier alignment

Theorem 4734.2 (ArchimedeanOrderedCauchyCompletion NameCert obligations)**.** *For every accepted* $\mathsf{ArchimedeanOrderedCauchyCompletion}^{\uparrow}$ *carrier* $A = (D, S, Q, R, O, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ArchimedeanOrderedCauchyCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for dyadic rational observations, finite stream windows, regular-Cauchy rational readback, terminal real sealing, constructive order and apartness, Archimedean density, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every completion-facing read must pass through* $D, S, Q, R, O, L, H, C, P, N$*, and no obligation may be discharged by quotient completion, host equality of reals, trichotomy, selected limits, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 4734.1. The rows D, S, Q form the finite completion spine: dyadic tolerances are displayed first, finite observation windows are then opened, and regular rational readback is admitted only through those windows.

The seal row R is reached after that spine, and the order row O reads the sealed names through the constructive order interface. Thus the order surface is downstream of the same regular-Cauchy route rather than an independent host order predicate.

The density ledger L answers each positive tolerance request with a dyadic row before the stream and readback rows are consumed. Finally H, C, P, N transport, replay, source, and name the same finite packet. Since these are all carrier coordinates, the excluded quotient, selector, trichotomy, choice, host-equality, and ambient-completeness routes have no entry point. □

Theorem 4734.3 (ArchimedeanOrderedCauchyCompletion density seal)**.** *Every downstream consumer of an accepted* $\mathsf{ArchimedeanOrderedCauchyCompletion}^{\uparrow}$ *packet receives density and order only through the finite handoff*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{RealAlgOrder}^{\uparrow}.$$

Consequently an Archimedean approximation, an order comparison, or a regular-Cauchy completion read can use only the displayed dyadic tolerance rows, finite windows, regular rational readbacks, RealUp seal, order handoff, transports, continuations, provenance, and local naming rows.

Proof. Begin with Definition 4734.2. It forces every completion-facing read through the dyadic row, stream-window row, regular-readback row, real seal, and order row.

The Archimedean density ledger is attached to the same dyadic row. A consumer asking for an approximation at a positive tolerance therefore reads L through D before any stream window, regular rational name, real seal, or order comparison becomes available.

The structural rows H, C, P, N preserve this route under transport and replay. They can expose the handoff as a named packet, but they cannot add a quotient representative, selected limit, trichotomy branch, countable-choice schedule, host equality of real names, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{ArchimedeanOrderedCauchyCompletion}^{\uparrow}}$ **·**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArchimedeanOrderedCauchyCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4734.1, Definition 4734.2, and Definition 4734.3 seed the finite Archimedean ordered Cauchy completion route through DyadicRatCore, StreamName, RegSeqRat, RealUp, RealAlgOrder, density, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{ArchimedeanOrderedCauchyCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected Cauchy representatives, trichotomy, countable choice, host real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic density, finite-window readback, regular-Cauchy sealing, RealUp handoff, RealAlgOrder order exposure, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.ArchimedeanOrderedCauchyCompletionUp.

Constructive story: An ArchimedeanOrderedCauchyCompletion$^{\uparrow}$ packet is generated from dyadic rational observations, finite stream windows, regular Cauchy rational readback, a terminal RealUp seal, constructive order and apartness rows, an Archimedean density ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4735

A Concrete Naming Certificate for $\mathsf{ClaimStatusAudit}^{\uparrow}$

The $\mathsf{ClaimStatusAudit}^{\uparrow}$ packet realizes the legitimate-claim audit of chapter 9456 as a finite NameCert carrier for theorem, condition, route, evidence, non-evidence, meta, refusal, GAP, and socket readings. It sits beside the named externality discipline of chapter 543, the claim-row admission surface of chapter 1209, the registry export boundary of chapter 1216, and the theorem-gap registry of chapter 1246. Those siblings name refused supply, admit claim entries, expose export rows, and bind theorem/gap entries; this packet audits their status rows before any claim is read as stronger than its displayed support.

Definition 4735.1 (ClaimStatusAudit carrier)**.** *A* $\mathsf{ClaimStatusAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (E, T, R, V, G, S, A, X, H, C, P, N)$$

with the following displayed rows:

1. *E is the finite communicable expression row being audited.*
2. *T is the theorem-or-condition row when the expression has closed proof data or displayed hypotheses.*
3. *R is the route row, recording transports, equivalence chains, or proof-search paths without upgrading them to theorem content.*
4. *V is the evidence row, paired with any non-evidence refusal attached to reports, metrics, traces, or numerical data.*
5. *G is the* $\mathsf{TheoremGapRegistry}^{\uparrow}$ *row recording theorem-strength entries and* GAP *entries.*
6. *S is the socket row read through* $\mathsf{ApophaticName}^{\uparrow}$ *when requested supply is named but not internalized.*
7. *A is the* $\mathsf{ClaimRegistryLayer}^{\uparrow}$ *admission row for the audited claim entry.*
8. *X is the* $\mathsf{RegistryExportSurface}^{\uparrow}$ *row controlling whether the audited status may be exported.*
9. *H records componentwise* hsame *transport for E, T, R, V, G, S, A, X.*
10. *C records displayed* Cont *replay of the same audit route.*
11. *P is the* Pkg *provenance over* $\mathsf{ClaimStatusAudit}^{\uparrow}$, $\mathsf{ApophaticName}^{\uparrow}$, $\mathsf{ClaimRegistryLayer}^{\uparrow}$, $\mathsf{RegistryExportSurface}^{\uparrow}$, $\mathsf{TheoremGapRegistry}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. N is the local $\mathsf{NameCert}_{\mathsf{ClaimStatusAudit}^{\uparrow}}$ *row.*
The carrier has no coordinate for a global truth predicate, a hidden proof oracle, an unmarked external dependency, or an export permission stronger than the displayed status row.

Lean4 ✓ `BEDC.Derived.ClaimStatusAuditUp.ClaimStatusAuditTasteGate single carrier alignment`

Theorem 4735.2 (ClaimStatusAudit NameCert obligations)**.** *For every accepted* $\mathsf{ClaimStatusAudit}^{\uparrow}$ *carrier* $U = (E, T, R, V, G, S, A, X, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ClaimStatusAudit}^{\uparrow}}$ *surface consists exactly of expression admission, theorem-or-condition classification, route classification, evidence and non-evidence classification, theorem-gap registry reading, apophatic socket reading, claim-registry admission, registry-export exposure, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. No accepted audit may read a route row as a theorem row, an evidence row as proof, a socket row as supplied content, or an unexported registry row as public claim content.*

Proof. Project the carrier of Definition 4735.1. The expression row E is classified only through T, R, V, G, S, A, X before the structural rows are read.

The theorem-or-condition row T is separate from the route row R and the evidence row V. Therefore a route, trace, metric, or report can be preserved as admissible audit data without being retyped as a closed theorem.

The gap and socket rows G, S are read through the theorem-gap registry and apophatic naming surfaces. A missing dependency is thereby named as a boundary rather than consumed as internal proof content.

Finally A, X, H, C, P, N admit, export, transport, replay, source, and name the same status packet. Since the export row is displayed, a consumer cannot bypass it; since the socket row is apophatic, the far end cannot become supplied content inside the carrier. □

Lean4 ✓ `BEDC.Derived.ClaimStatusAuditUp.ClaimStatusAuditCarrier namecert obligations`

Theorem 4735.3 (ClaimStatusAudit nonescape)**.** *Every downstream reading of an accepted* $\mathsf{ClaimStatusAudit}^{\uparrow}$ *packet factors through the finite audit route*

$$\mathsf{ApophaticName}^{\uparrow} \longmapsto \mathsf{ClaimRegistryLayer}^{\uparrow} \longmapsto \mathsf{TheoremGapRegistry}^{\uparrow} \longmapsto \mathsf{RegistryExportSurface}^{\uparrow}.$$

Thus theorem, route, evidence, refusal, GAP*, and socket readings remain status rows of the same carrier and cannot escape into unmarked theorem content or unrestricted public export.*

Proof. Use Definition 4735.2. It identifies the rows through which every accepted claim-status read must pass.

The apophatic-name row handles missing or refused supply as a named boundary. The claim-registry row admits the expression as a claim entry, while the theorem-gap row distinguishes theorem-strength support from gap exposure.

The registry-export surface is terminal for public reading. If it does not display the appropriate export status, the carrier still records the audit row but does not provide public theorem content. The structural rows preserve this nonescape condition under transport and replay. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClaimStatusAudit}^{\uparrow}}$.
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClaimStatusAudit}^{\uparrow}}, \mathsf{seed})$
Scope closed: Definition 4735.1, Definition 4735.2, and Definition 4735.3 seed the finite claim-status audit route through apophatic names, claim registry rows, theorem-gap rows, registry export, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{ClaimStatusAudit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a global truth predicate, global proof search, hidden proof oracle, unmarked external supply, unrestricted registry export, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, status classification, route/evidence separation, theorem-gap reading, apophatic socket reading, registry admission, export control, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.ClaimStatusAuditUp.

Constructive story: A ClaimStatusAudit$^{\uparrow}$ packet is generated from a finite expression row, theorem-or-condition row, route row, evidence and non-evidence row, theorem-gap registry row, apophatic socket row, claim-registry admission, registry-export exposure, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The LocatedRealIntervalBisection$^{\uparrow}$ hub routes finite bisection reads through chapter 394 and through the Real, Dyadic, and RegSeqRat surfaces carried by the child chapter.

Chapter 4736

Located Real Interval Bisection NameCert Construction

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedRealIntervalBisection}^{\uparrow}$ packet records finite dyadic interval bisection over displayed $\mathsf{Real}^{\uparrow}$ endpoints without importing an interval-completeness theorem. It sits beside the real-name seal of chapter 38, the dyadic arithmetic core of chapter 291, the regular rational readback route of chapter 301, and the closed bounded interval carrier of chapter 1591. The packet is a finite bisection ledger for located interval reads; it is not a Dedekind completion, quotient-real equality, trichotomy on arbitrary reals, a selected infinite branch, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4736.1 (Located real interval bisection carrier)**.** *A* $\mathsf{LocatedRealIntervalBisection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, L, M, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row, carrying lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint names, endpoint order, and interval-containment data.*
2. *L is the locatedness row, recording the finite apartness or locator evidence used to decide which inspected subinterval remains visible at the requested stage.*
3. *M is the dyadic midpoint row, exposing the midpoint construction for each retained interval cell.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter and tolerance ledger attached to the same midpoint rows.*
5. *W is the finite endpoint-window row, recording which endpoint and midpoint windows are inspected by the bisection request.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W and D.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after the source interval, locatedness, midpoint, dyadic, window, and readback rows have been displayed.*
8. *H records componentwise* hsame *transport for the interval, locatedness, midpoint, dyadic, window, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a bisection request through I, L, M, D, W, R, E, H.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedRealIntervalBisection}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealIntervalBisection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, L, M, D, W, R, E, H, C, P, N$. It has no coordinate for a completed nested-interval limit, quotient equality of real names, excluded-middle order trichotomy, a selected infinite branch, countable choice, or ambient real completeness.

Theorem 4736.2 (Located real interval bisection obligation surface)**.** *For every accepted* LocatedRealIntervalBisecti *carrier*

$$B = (I, L, M, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealIntervalBisection}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the closed bounded interval source, locatedness row, midpoint row, dyadic tolerance ledger, endpoint windows, regular rational readback, terminal real seal, transport, replay, provenance, and local naming;*
2. *source visibility, requiring every bisection read to expose the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row I before any midpoint, diameter, branch, or seal row is consumed;*
3. *located branch discipline, requiring L to record the finite locator evidence for the retained cell without adding global trichotomy on* $\mathsf{Real}^{\uparrow}$*;*
4. *dyadic midpoint exactness, requiring M and D to supply the displayed midpoint and diameter budgets at the requested finite depth;*
5. *readback handoff, requiring W, R, E to route every Real-facing output through finite endpoint windows and a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback;*
6. *non-escape, excluding completed nested-interval limits, quotient-real equality, selected infinite branches, countable choice, host endpoint equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the carrier.*

No LocatedRealIntervalBisection obligation is stored outside these rows.

Proof. Project the carrier of Definition 5546.1. The accepted packet displays exactly the closed bounded interval source, locator row, midpoint row, dyadic ledger, endpoint windows, regular readback, terminal real seal, and structural rows.

The source stage is I, L. A request first reads the displayed endpoints and interval containment through I, then reads the finite locator evidence in L before any retained child interval is available.

The bisection stage is M, D, W. Induction on the finite retained-depth ledger reads one midpoint row at a time. At each step the dyadic tolerance entries in D bound the retained child, while W records the inspected endpoint and midpoint windows.

The Real-facing handoff is R, E, H, C, P, N. The regular rational readback R is computed from the displayed windows and dyadic budgets, and the terminal seal E is downstream from that readback. The structural rows only transport, replay, source, and name the same finite route.

Since the carrier contains no completed nested-interval limit, quotient-real equality, global trichotomy, selected infinite branch, countable-choice row, or ambient completeness coordinate, the listed rows exhaust the local obligation surface. □

Theorem 4736.3 (Located real interval bisection finite handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatedRealIntervalBisection}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{ClosedBoundedInterval}^{\uparrow} \longmapsto L, M, D, W \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The consumer receives one finite located interval bisection ledger with dyadic midpoint and diameter rows. It receives no completed intersection point, quotient representative, selected branch, countable-choice witness, or ambient completeness principle.

Proof. Use the carrier projection and the obligation surface of Definition 5546.2. Source visibility places every read below the row I before midpoint or readback data are available.

Located branch discipline then exposes only the finite locator row L. Dyadic midpoint exactness exposes M, D, W for the requested depth, so the retained cell is read as a finite ledger rather than as an infinite branch.

Finally R repacks the displayed windows as regular rational readback data, and E, H, C, P, N seal and name the same route for $\mathsf{Real}^{\uparrow}$ consumers. The absent coordinates listed in the carrier definition cannot be projected from the packet. □

Falsifiable prediction: Every accepted $\mathsf{LocatedRealIntervalBisection}^{\uparrow}$ Real-facing read passes through $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, finite endpoint windows, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any retained interval output is visible.

Independence witness: real, dyadicratcore, regseqrat, closedboundedinterval, located-interval-bisection, bisection-real: no listed sibling supplies the joint packet containing a closed bounded Real interval source, locator evidence, dyadic midpoint ledger, finite endpoint windows, regular rational readback, Real seal, transport, replay, provenance, and local NameCert row while refusing completeness and selected infinite branches.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealIntervalBisection}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealIntervalBisection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5546.1, Definition 5546.2, and Definition 5546.3 seed the finite located bisection route over Real endpoints, closed bounded interval source rows, dyadic midpoint budgets, regular rational readback, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealIntervalBisection}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.LocatedRealIntervalBisectionUp`

Bridge status: none

Not claimed: This chapter does not close completed nested-interval limits, quotient-real equality, global trichotomy on reals, selected infinite branches, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean proof obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source visibility, located branch discipline, dyadic midpoint exactness, readback handoff, and non-escape for BEDC.Derived.LocatedRealIntervalBisectionUp.

Constructive story: A $\mathsf{LocatedRealIntervalBisection}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source row, locatedness evidence, dyadic midpoint and diameter rows, finite endpoint windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

The handoff hub routes candidate-normalization and confluence reads through chapter 4238 and chapter 765 before exposing bounded endpoint or residual-envelope rows.

Chapter 4737

MetaCIC Candidate Normalization Confluence Handoff NameCert Construction

The MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ packet realizes the candidate-mediated strong-normalization boundary of chapter 9383 as a finite handoff surface for confluence and decidability consumers. It sits beside the critical-path carrier of chapter 765, the normalization frontier of chapter 892, the residual confluence envelope of chapter 3921, and the decidable boundary of chapter 749. The packet names a guarded route from candidate evidence to bounded normal endpoints and residual-envelope reads; it does not assert unconditional strong normalization, full Church–Rosser, unrestricted subject reduction, or global closed-term conversion decidability.

Candidate-mediated normalization reads the residual local-join budget of chapter 5970 before it can be used as a confluence handoff, so the endpoint row is never exported as an isolated normal-form claim.

This packet is also a concrete realization of the MetaCIC audit-map synthesis route in section 9376.7: it joins normalization, confluence, decidability, and residual-substitution audit rows while keeping blocked subject-reduction edges visible.

The confluence audit packet of chapter 735 and the parallel-diamond frontier of chapter 4238 consume this handoff only as a guarded boundary route. Their reads keep candidate evidence, residual-envelope visibility, decidable-boundary routing, and blocked-edge retention explicit rather than turning the handoff into a global Church–Rosser or conversion theorem.

Before exporting candidate-normalization confluence data, the handoff consumes the residual-diamond sibling surface of chapter 4238 and the critical-path sibling surface of chapter 765. The handoff is consumed by chapter 4238 only after candidate evidence, residual envelope, decidable boundary, and blocked-edge rows are visible.

Theorem 4737.1 (MetaCIC handoff parallel-diamond forward link)**.** *Any* MetaCICParallelDiamondFrontier$^{\uparrow}$ *consumer of an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet must expose the candidate row K, frontier row F, residual envelope C, decidable boundary D, blocked edge B, componentwise transport T, displayed replay R, provenance P, and local name L before reading the bounded endpoint row N. The forward dependency is the sibling route through chapter 4238; it is not a global confluence theorem, quotient-syntax equality, unrestricted subject reduction, evaluator soundness, or closed consistency.*

Proof. Start with a parallel-diamond consumer of the handoff. The consumer reaches the packet

only through the displayed candidate-normalization carrier, so the candidate row K and frontier row F remain visible before any bounded endpoint can be read.

Next read the confluence side through the residual envelope C, decidable boundary D, and blocked edge B. These rows are precisely the finite obstruction and boundary data named by the parallel-diamond frontier route, and they prevent N from being treated as an unconditional joinability endpoint.

Finally transport the same route through T, R, P, L. The componentwise transport, replay, provenance, and local name rows bind the endpoint read to the concrete sibling of chapter 4238. Hence every forward read exposes $K, F, C, D, B, T, R, P, L$ before N, while the excluded global MetaCIC claims remain outside the carrier. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffParallelDiamondForwardLink`

Before exporting candidate-normalization confluence data, the handoff consumes residual-normal-form routing from chapter 8456 and residual critical-pair sieve rows from chapter 8316.

Definition 4737.2 (MetaCIC candidate normalization confluence handoff carrier)**.** *A* MetacicCandidateNormalizati *carrier is a finite* BHist *packet*

$$H = (A, K, N, F, C, D, B, T, R, P, L)$$

with the following displayed rows:

1. *A is the audit-map anchor row, binding the packet to the candidate-mediated reading of chapter 9383.*
2. *K is the candidate-evidence row, storing Candidate, ClosedCandidate, or CandidateSet membership data before any strong-normalization read is exported.*
3. *N is the normal-endpoint row, recording the bounded normal endpoint or no-infinite-reduction projection obtained from K.*
4. *F is the* MetaCICNormalizationFrontier$^{\uparrow}$ *row that keeps candidate evidence and finished-normal evidence inside the displayed frontier packet.*
5. *C is the confluence-facing row, read through the residual envelope of chapter 3921.*
6. *D is the* MetaCICDecidableBoundary$^{\uparrow}$ *row, limiting decidability reads to bounded checker output and normal endpoint comparison.*
7. *B is the blocked-edge row, retaining subject-reduction and residual-substitution obligations as visible boundaries rather than discharged theorems.*
8. *T records componentwise* hsame *transport for the audit, candidate, normal endpoint, frontier, confluence, decidability, blocked-edge, replay, provenance, and local naming rows.*
9. *R records displayed* Cont *replay from a MetaCIC consumer request through A, K, N, F, C, D, B, T.*
10. *P is the* Pkg *provenance over* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, MetaCICConfluenceAuditWitness$^{\uparrow}$, MetaCICDecidableBoundary$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* NameCert$_{\text{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, K, N, F, C, D, B, T, R, P, L$. It has no coordinate for evidence-free normalization, a global parallel diamond, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, or closed consistency.

Lean4 ✓ BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf
candidate endpoint route

Theorem 4737.3 (MetaCIC candidate normalization confluence handoff boundary)**.** *For every accepted* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *carrier*

$$H = (A, K, N, F, C, D, B, T, R, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the audit anchor, candidate evidence, normal endpoint, normalization frontier, residual confluence envelope, decidable boundary, blocked-edge row, transport, replay, provenance, and local naming;*
2. *candidate-gate exactness, requiring every normalization read to pass through K and the frontier row F before N is consumed;*
3. *confluence handoff discipline, requiring every residual or join read to pass through C while retaining B as a visible blocked edge;*
4. *decidable-boundary discipline, requiring every conversion-facing read to pass through D after N and before any bounded normal comparison is exported;*
5. *frontier non-collapse, requiring T, R, P, L to preserve the same rows without promoting candidate-mediated SN into an unconditional closed-term theorem or residual-envelope rows into full Church–Rosser.*

No handoff obligation is stored outside $A, K, N, F, C, D, B, T, R, P, L$.

Proof. Project the carrier of Definition 5547.2. The accepted packet displays exactly the audit anchor, candidate evidence, normal endpoint, normalization frontier, residual confluence envelope, decidable boundary, blocked-edge, and structural rows.

The normalization stage is A, K, N, F. The audit anchor fixes the candidate-mediated reading; the candidate row K is exposed before the endpoint row N, and the frontier row F keeps both inside the public normalization boundary.

The confluence and decidability stage is C, D, B. A confluence-facing consumer may read residual-envelope data through C, but the blocked-edge row B remains visible. A conversion-facing consumer may read bounded checker output through D only after the normal endpoint has been displayed.

Finally T, R, P, L transport, replay, source, and name the same finite route. Since the carrier contains no evidence-free normalization coordinate, global diamond theorem, unrestricted subject-reduction proof, quotient syntax equality, host evaluator soundness, or closed-consistency endpoint, the listed rows exhaust the local obligation surface. □

Lean4 ✓ BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffBoundary

Theorem 4737.4 (MetaCIC candidate normalization confluence handoff seed closure)**.** *For every accepted* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *carrier* $H = (A, K, N, F, C, D, B, T, R, P, L)$*, the seed package closes only when the candidate-evidence row K, normalization-frontier row F, residual confluence row C, decidable-boundary row D, and blocked-edge row B are all displayed before the endpoint row N is consumed. The support rows T, R, P, L preserve this finite route by transport, replay, provenance, and local naming. The package does not assert unconditional strong normalization, full Church–Rosser, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, or closed consistency.*

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffSeedClosure`

Proof. Project the carrier of Definition 5547.2. The accepted packet separates candidate evidence K, endpoint data N, frontier data F, residual confluence data C, decidable-boundary data D, blocked-edge data B, and the structural rows T, R, P, L.

Apply the boundary theorem Definition 5547.3. Its candidate-gate exactness exposes K and F before N, its confluence handoff discipline keeps C and B visible for residual or join reads, and its decidable-boundary discipline places D on the bounded comparison route.

Finally read T, R, P, L only as preservation rows for the same finite package. They transport, replay, source, and name the displayed rows without adding a coordinate for the excluded global endpoints, so the seed closure remains the finite premise-exposure package rather than a global normalization, confluence, decidability, quotient, evaluator, or consistency theorem. □

Theorem 4737.5 (MetaCIC candidate normalization confluence handoff premise exposure)**.** *For every accepted* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *carrier* $H = (A, K, N, F, C, D, B, T, R, P, L)$*, every confluence-facing read must expose the candidate row* K*, normalization frontier row* F*, residual envelope row* C*, decidable-boundary row* D*, and blocked-edge row* B *before any bounded endpoint row* N *can be consumed. Thus candidate-mediated normalization is retained as a premise surface for confluence consumers. The handoff refuses unconditional strong normalization, full Church–Rosser, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, and closed consistency.*

Proof. Apply the boundary theorem Definition 5547.3. Its candidate-gate exactness exposes K and F before N, while its confluence handoff discipline keeps C and B visible for every residual or join read.

Now chain the consumer boundary of Definition 5547.14. A public confluence-facing consumer receives the handoff only through the displayed route

$$\mathsf{MetaCICCriticalPath}^{\uparrow} \longmapsto \mathsf{MetaCICNormalizationFrontier}^{\uparrow} \longmapsto C, D, B \longmapsto T, R, P, L.$$

The decidable-boundary row D is therefore part of the bounded comparison surface, not a detached global conversion decider.

Since T, R, P, L only transport, replay, source, and name the same finite route, they cannot erase K, F, C, D, B or promote N into an unconditional endpoint theorem. The excluded global claims are not coordinates of H, so every confluence-facing read remains premise-exposed before consuming bounded endpoint data. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffPremiseExposure`

Theorem 4737.6 (MetaCIC candidate handoff residual-diamond retention)**.** *For every accepted* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *carrier*

$$H = (A, K, N, F, C, D, B, T, R, P, L),$$

every confluence-facing read must retain the candidate evidence K*, residual envelope* C*, decidable boundary* D*, and blocked-edge row* B *before a bounded endpoint row* N *is treated as joinable. The retained route is consumed through the sibling path from* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *to* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *and remains only a residual-diamond handoff. It does not assert full Church–Rosser, unrestricted subject reduction, quotient syntax equality, or global conversion decidability.*

Proof. Project the carrier of Definition 5547.2. The endpoint row N is separate from the candidate evidence K, residual envelope C, decidable boundary D, and blocked-edge row B, so joinability cannot be read from N alone.

Apply the boundary theorem Definition 5547.3. Its candidate-gate exactness exposes K and F before N, while its confluence and decidable-boundary clauses keep C, D, B visible on the residual comparison route.

Use premise exposure from Definition 5547.5. It prevents a confluence-facing consumer from consuming the bounded endpoint before K, F, C, D, B are displayed in the same packet.

Finally route the read through the sibling frontier. The critical-path packet $\mathsf{MetaCICCriticalPath}^{\uparrow}$ supplies the public handoff direction, and $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ reads only the residual-diamond boundary, not a global confluence theorem. Since the carrier has no coordinate for Church–Rosser, unrestricted subject reduction, quotient syntax equality, or global conversion decidability, retaining K, C, D, B is exactly the finite residual-diamond condition. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateHandoffResidualDiamondRetention`

Theorem 4737.7 (MetaCIC candidate handoff local join budget)**.** *For every confluence-facing endpoint comparison exported from an accepted* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *carrier*

$$H = (A, K, N, F, C, D, B, T, R, P, L),$$

the consumer must expose a finite local-join budget read through candidate evidence K, normalization frontier F, residual envelope C, decidable boundary D, blocked-edge row B, and structural rows T, R, P, L before the endpoint row N is treated as joinable.

The budget is routed through $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{MetaCICConfluenceAuditPac}$ *and* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *as retained finite evidence. It is not full Church–Rosser, unrestricted subject reduction, quotient syntax equality, evaluator equality, global conversion decidability, or closed consistency.*

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.LocalJoinBudget.MetacicCandidateH`

Proof. Start with the boundary and premise-exposure routes, Definition 5547.3 and Definition 5547.5. They place K, F, C, D, B before any confluence-facing read may consume the bounded endpoint row N.

Apply residual-diamond retention from Definition 5547.6. It keeps the residual envelope, decidable boundary, and blocked edge visible while the comparison is routed from $\mathsf{MetaCICCriticalPath}^{\uparrow}$ and $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ toward confluence consumers.

Use the normal-endpoint readback theorem Definition 5547.8. It reads N only after $K, F, C, D, B, T, R, P, L$ have been displayed and names the $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ route as an audit handoff rather than as evaluator equality.

Finally pass the retained evidence to $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$. The frontier receives the finite local-join budget, not a global confluence theorem, so Church–Rosser, unrestricted subject reduction, quotient syntax equality, evaluator equality, global conversion decidability, and closed consistency remain outside the carrier. □

Theorem 4737.8 (MetaCIC candidate handoff normal-endpoint readback)**.** *Any bounded normal endpoint read exported by an accepted* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *packet must expose candidate evidence K, frontier row F, residual envelope C, decidable boundary D, blocked edge B, and the transport, replay, provenance, and naming rows T, R, P, L before N is consumed. The read may be handed to* $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, *and*

MetaCICConfluenceAuditPacket$^{\uparrow}$ *consumers only as this finite premise-visible route. It is not unconditional strong normalization, full Church–Rosser, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, or closed consistency.*

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffNormalEndpointReadback`

Proof. Project the carrier of Definition 5547.2. The bounded endpoint row N is displayed beside candidate evidence K, frontier evidence F, residual envelope C, decidable boundary D, blocked edge B, and the structural rows T, R, P, L.

Apply the boundary theorem Definition 5547.3. Candidate-gate exactness exposes K and F before N, confluence handoff discipline keeps C and B visible, and decidable-boundary discipline keeps D on the bounded comparison route.

Now use the consumer boundary Definition 5547.14. A public read reaches MetaCICCriticalPath$^{\uparrow}$ and MetaCICNormalizationFrontier$^{\uparrow}$ only through the displayed handoff route, so the endpoint row cannot be consumed as a detached normal-form theorem.

Finally read the confluence-audit side through the same residual route. The sibling MetaCICConfluenceAuditPack may consume the bounded endpoint only after C, D, B, T, R, P, L remain visible, and those rows only transport, replay, source, and name the finite packet. Since the excluded global endpoints are not carrier coordinates, the normal-endpoint readback preserves the candidate and residual premises. □

Theorem 4737.9 (Candidate normal endpoint retention)**.** *Let*

$$H = (A, K, N, F, C, D, B, T, R, P, L)$$

be an accepted MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *carrier. Any accepted endpoint read from H must first expose the candidate gate K, normalization frontier F, residual envelope C, decidable boundary D, blocked-edge row B, residual-diamond retention row, and normal endpoint readback row before the endpoint row N is consumed by a confluence or conversion-facing consumer. The retained read is a bounded handoff through $A, K, N, F, C, D, B, T, R, P, L$; it is not global confluence, unrestricted strong normalization, quotient syntax equality, or host evaluator soundness.*

Proof. Start with the boundary theorem Definition 5547.3. It displays the candidate gate, normalization frontier, residual envelope, decidable boundary, and blocked-edge rows as separate carrier coordinates before any endpoint read is available.

Apply premise exposure from Definition 5547.5. A public consumer cannot pass directly to N; it must first retain K, F, C, D, B inside the same accepted packet.

Use residual-diamond retention from Definition 5547.6. This keeps the residual envelope, decidable boundary, and blocked edge visible when the endpoint is read by a confluence-facing route.

Finally apply normal-endpoint readback from Definition 5547.8. The rows T, R, P, L transport, replay, source, and name the same bounded route before N is consumed, so the endpoint cannot be reinterpreted as any refused global MetaCIC principle. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf`

Theorem 4737.10 (MetaCIC finite endpoint comparison handoff)**.** *Let*

$$H = (A, K, N, F, C, D, B, T, R, P, L)$$

be an accepted MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *carrier. Any endpoint comparison exported from H to a confluence or conversion consumer must first expose candidate evidence K, normalization-frontier row F, residual-envelope row C, decidable-boundary row D, blocked-edge row B, and the structural rows T, R, P, L before bounded normal endpoints are compared through N. The exported comparison is a finite candidate-mediated handoff; it is not unconditional strong normalization, full Church–Rosser, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, global conversion decidability, or closed consistency.*

Proof. Start with the boundary theorem Definition 5547.3. Candidate-gate exactness exposes K and F before N, while confluence discipline keeps C and B visible and decidable-boundary discipline places D on the bounded comparison route.

Apply premise exposure from Definition 5547.5. A confluence-facing consumer cannot read the bounded endpoint row until the candidate, frontier, residual-envelope, decidable-boundary, and blocked-edge rows are displayed in the same packet.

Use residual-diamond retention from Definition 5547.6. It prevents a comparison from treating N as detached joinability data; the residual envelope and blocked edge remain part of the read.

Finally apply normal-endpoint readback from Definition 5547.8. The structural rows T, R, P, L transport, replay, source, and name the same finite route before N is consumed, so the comparison cannot export any of the refused global MetaCIC endpoints. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffFiniteEndpointComparison`

Theorem 4737.11 (MetaCIC candidate handoff decidable normal-form comparison)**.** *Any bounded normal-form comparison exported to a decidability consumer from an accepted* MetacicCandidateNormalizationConflu *carrier must expose candidate evidence K, frontier row F, residual envelope C, decidable boundary D, blocked edge B, and structural rows T, R, P, L before the endpoint row N is compared. The comparison is obtained only by chaining boundary exposure, premise exposure, residual-diamond retention, and finite endpoint comparison. It refuses full Church–Rosser, unrestricted subject reduction, quotient syntax equality, evaluator equality, global conversion decidability, and closed consistency.*

Proof. Start with the boundary theorem Definition 5547.3. It exposes the candidate row K, frontier row F, residual envelope C, decidable boundary D, and blocked edge B before any endpoint comparison is available.

Apply premise exposure from Definition 5547.5. The bounded endpoint row N remains downstream of the candidate and frontier rows, so the comparison still has to read the finite handoff surface.

Now use residual-diamond retention from Definition 5547.6. The residual envelope and blocked edge remain visible on the comparison route, so the decidability consumer cannot erase the guarded premise surface.

Finally apply finite endpoint comparison from Definition 5547.10. The rows T, R, P, L transport, replay, source, and name the same finite route before N is compared, which is exactly the bounded comparison route refused by the excluded global claims. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateHandoffDecidableN`

Theorem 4737.12 (MetaCIC candidate handoff residual-decider inversion)**.** *Let*

$$H = (A, K, N, F, C, D, B, T, R, P, L)$$

be an accepted MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *carrier. If a confluence or conversion consumer reads a bounded decider outcome from H, then the candidate row K, normalization frontier F, residual envelope C, decidable boundary D, blocked-edge row B, and structural rows T, R, P, L are already visible before the endpoint row N is compared. The inversion is a finite retained-premise read; it does not claim full Church–Rosser, unrestricted subject reduction, quotient syntax equality, evaluator soundness, global conversion decidability, or closed consistency.*

Proof. Start with the boundary theorem Definition 5547.3. It exposes candidate evidence, the normalization frontier, residual envelope, decidable boundary, and blocked-edge rows as separate coordinates before any bounded endpoint comparison can be read.

Apply premise exposure from Definition 5547.5. A confluence-facing read cannot consume the endpoint row before K, F, C, D, B are displayed in the same packet.

Use residual-diamond retention and finite endpoint comparison, Definition 5547.6 and Definition 5547.10. They keep the residual envelope, decidable boundary, and blocked edge attached to any bounded endpoint comparison offered to a confluence or conversion consumer.

Finally apply decider-row exhaustion through Definition 5547.11. The bounded decider outcome is read only after D is on the displayed comparison route and after T, R, P, L transport, replay, source, and name the same finite handoff. Since the excluded global endpoints are not carrier coordinates, the decider read inverts back to the retained candidate and residual premises rather than to any unrestricted MetaCIC theorem. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateHandoffResidualDe`

Theorem 4737.13 (MetaCIC candidate handoff frontier normal-endpoint retention)**.** *Let*

$$H = (A, K, N, F, C, D, B, T, R, P, L)$$

be an accepted MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *carrier. Any bounded normal endpoint exported by H to a confluence consumer that also reads* MetaCICParallelDiamondFrontier$^{\uparrow}$ *must retain candidate evidence K, frontier row F, residual envelope C, decidable boundary D, blocked-edge row B, componentwise transport T, displayed replay R, provenance P, and local naming L before the endpoint row N is consumed. The same read must preserve the parallel-diamond frontier's residual and local-join rows as visible premises. It does not assert full Church–Rosser, unrestricted subject reduction, quotient syntax equality, evaluator equality, global conversion decidability, or closed consistency.*

Proof. Start with premise exposure and residual-diamond retention, Definition 5547.5 and Definition 5547.6. These require the candidate row, frontier row, residual envelope, decidable boundary, and blocked edge to remain visible before any confluence-facing endpoint read is accepted.

Apply normal-endpoint readback, Definition 5547.8. The bounded endpoint row N is consumed only through the same candidate, frontier, residual, boundary, blocked-edge, transport, replay, provenance, and local naming route.

Finally route the consumer through the sibling frontier dependency. The MetaCICParallelDiamondFrontier$^{\uparrow}$ route named by Definition 5547.6 and chapter 4238 keeps residual and local-join rows visible before the endpoint is used. Since none of the refused global endpoints is a carrier coordinate, the handoff retains only the bounded frontier premises. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateHandoffFrontierNo`

Theorem 4737.14 (MetaCIC candidate handoff consumer boundary)**.** *Every public consumer of an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet factors through*

$$\mathsf{MetaCICCriticalPath}^{\uparrow} \longmapsto \mathsf{MetaCICNormalizationFrontier}^{\uparrow} \longmapsto C, D, B \longmapsto T, R, P, L.$$

The consumer receives candidate-mediated normalization evidence, bounded normal endpoint data, residual-envelope visibility, decidable-boundary routing, and blocked-edge retention. It receives no unconditional strong-normalization theorem, full Church–Rosser theorem, unrestricted subject-reduction theorem, global conversion decider, or completed closed-consistency proof.

Proof. Start from the carrier projection. The audit and critical-path rows determine which candidate-mediated normalization and boundary rows are visible to the consumer.

Apply Definition 5547.3. The candidate gate exposes K, F, N before any normal endpoint is available, while C, D, B retain the confluence and decidability boundaries as displayed rows.

The structural rows T, R, P, L do not add another route. They preserve the same carrier under componentwise transport, replay it for downstream consumers, record provenance, and name the packet locally. The absent global theorems cannot be projected from those rows. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf`

Theorem 4737.15 (MetaCIC candidate normalization residual progress)**.** *An accepted* MetacicCandidateNormaliza *packet consumes residual data only as a progress ledger. Every admitted candidate-normalization row read through $A, K, N, F, C, D, B, T, R, P, L$ either forwards a retained premise through the candidate and frontier rows K, F or emits a residual obstruction row through C and B, with the residual boundary read against chapter 5126. The packet does not assert full confluence, unrestricted subject reduction, unconditional strong normalization, global conversion decidability, quotient syntax equality, host evaluator soundness, or closed consistency.*

Proof. Project the carrier of Definition 5547.2. The candidate-normalization data are A, K, N, F, the residual and decidability boundary rows are C, D, B, and the structural rows are T, R, P, L.

Apply Definition 5547.3. The candidate gate forces any normalization row to expose K and F before a normal endpoint is consumed, so a retained premise remains visible when the row is forwarded.

If the row cannot be forwarded as a retained premise, the same boundary theorem routes the read through C and B. The residual envelope is then consumed as a ledger compatible with chapter 5126, while the blocked-edge row records the obstruction rather than discharging it.

Finally use Definition 5547.14. The public consumer receives only the candidate-mediated route, residual-envelope visibility, decidable-boundary routing, blocked-edge retention, and structural rows. Since the excluded global endpoints are not carrier coordinates, the progress ledger cannot be read as a full confluence or strong-normalization theorem. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf`

Theorem 4737.16 (MetaCIC candidate normalization confluence bounded join window)**.** *Let $H = (A, K, N, F, C, D, B, T, R, P, L)$ be an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *carrier. A confluence-facing consumer may export a join read from H only after the candidate evidence K, normalization-frontier row F, residual envelope C, decidable-boundary row D, blocked-edge row B, and structural rows T, R, P, L remain visible before the endpoint row N is consumed. The window is finite and carrier-internal: it does not assert full Church–Rosser, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, or closed consistency.*

Lean4 ✓ BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf

Proof. Start with the handoff boundary of Definition 5547.3. It exposes K and F before N, keeps C and B visible for confluence-facing reads, and routes bounded comparison through D.

Use premise exposure from Definition 5547.5. A public confluence consumer cannot read the endpoint row before the candidate, frontier, residual-envelope, decidable-boundary, and blocked-edge rows are displayed in the same packet.

Apply residual-diamond retention from Definition 5547.6. It prevents a join read from treating N as detached joinability data; the read must retain K, C, D, B on the residual route.

Finally use normal-endpoint readback from Definition 5547.8. The structural rows T, R, P, L preserve, replay, source, and name the same finite route before N is consumed. Since no excluded global endpoint is a carrier coordinate, the exported join is available only through this bounded window. □

Theorem 4737.17 (MetaCIC candidate normalization confluence rectangle)**.** *Let $H = (A, K, N, F, C, D, B, T, R, P$ be an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *carrier. If both candidate-normalization edges of a bounded comparison are admitted by the candidate gate and each residual edge is read through the residual envelope, then the handoff packet either displays a common bounded endpoint row or records a residual obstruction row through C and B. The rectangle is guarded by the candidate and residual rows; it does not assert full Church–Rosser, unconditional strong normalization, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, or consistency.*

Proof. Start with Definition 5547.3. The candidate gate forces both normalization edges to expose K and F before any endpoint row N can be consumed.

Use the consumer boundary of Definition 5547.14. A public handoff read must pass through the residual-envelope row C, decidable-boundary row D, blocked-edge row B, and the structural rows T, R, P, L.

Apply residual progress from Definition 5547.15. If the two candidate-normalization edges forward through the retained premises, the packet displays the bounded endpoint row shared by those reads. If one residual edge cannot be forwarded, the same route records the obstruction through C and B.

The residual side is read against chapter 5126. Since the carrier contains no coordinates for unrestricted Church–Rosser, unconditional strong normalization, subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, or consistency, the rectangle remains a guarded handoff packet. □

Lean4 ✓ BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf

Theorem 4737.18 (MetaCIC candidate normalization confluence handoff candidate residual join)**.** *Let $H = (A, K, N, F, C, D, B, T, R, P, L)$ be an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *carrier. If two candidate-normalization edges exported from H expose candidate evidence K and frontier evidence F, and every residual edge is routed through the residual-envelope row C and blocked-edge row B, then any exported join row is guarded by K, F, C, D, B, and the structural rows T, R, P, L. The join row is a candidate-mediated residual handoff; it is not full Church–Rosser, unrestricted subject reduction, unconditional strong normalization, global conversion decidability, quotient syntax equality, host evaluator soundness, or closed consistency.*

Lean4 ✓ BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf

Proof. Begin with the boundary theorem Definition 5547.3. It forces any endpoint or comparison read to display K, F, N before the consumer sees bounded normalization data, and it keeps C, D, B visible on the residual and decidable-boundary side.

Use residual progress from Definition 5547.15. Under the stated routing, residual edges either remain retained candidate premises through K, F or become obstruction rows through C, B; neither route removes the candidate evidence.

Finally apply the rectangle theorem Definition 5547.17. The exported join row is therefore read only as the guarded rectangle output, with T, R, P, L preserving the same finite route by transport, replay, provenance, and local naming. Since no excluded global theorem is a carrier coordinate, the join cannot be promoted beyond the candidate-mediated residual handoff. □

Theorem 4737.19 (MetaCIC candidate normalization parallel-frontier consumption)**.** *If a* MetaCICParallelDiamon *consumer reads a join row from an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *carrier*

$$H = (A, K, N, F, C, D, B, T, R, P, L),$$

then the read must preserve candidate evidence K, normalization-frontier data F, residual-envelope data C, decidable-boundary data D, blocked-edge data B, componentwise transport T, displayed replay R, provenance P, and local naming L before N can be treated as bounded endpoint data. The exported join is only a candidate-mediated residual handoff; it is not full Church–Rosser, unrestricted subject reduction, global conversion decidability, quotient syntax equality, evaluator soundness, or closed consistency.

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf`

Proof. Start with the boundary theorem Definition 5547.3. It prevents any endpoint read from reaching N before the candidate evidence K, normalization frontier F, residual envelope C, decidable boundary D, and blocked-edge row B remain visible.

Apply the premise-exposure route of Definition 5547.14. A public consumer receives the handoff only through the same carrier rows and through the structural data T, R, P, L.

Use residual progress from Definition 5547.15 and the rectangle theorem Definition 5547.17. They keep retained candidate premises and residual obstructions attached to K, F, C, D, B while allowing only bounded endpoint data or an obstruction row to be displayed.

Finally invoke the candidate residual join theorem Definition 5547.18. The join already exported by H is guarded by the candidate, frontier, residual, blocked-edge, and structural rows. A MetaCICParallelDiamondFrontier$^{\uparrow}$ consumer therefore receives a candidate-mediated residual handoff for bounded endpoint data, not any of the excluded global confluence, subject-reduction, conversion-decidability, quotient-equality, evaluator-soundness, or consistency claims. □

Theorem 4737.20 (MetaCIC candidate normalization confluence boundary)**.** *Let $H = (A, K, N, F, C, D, B, T, R,$ be an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *carrier. If a bounded comparison exports a join row from H, then the read preserves candidate evidence K, the normalization frontier F, the residual envelope C, the decidable boundary D, the blocked-edge row B, componentwise transport T, displayed replay R, provenance P, and local naming L. The exported join row is therefore a guarded candidate-normalization handoff. It cannot be read as unconditional strong normalization, full Church–Rosser, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, or closed consistency.*

Proof. Project the carrier of Definition 5547.2. A bounded comparison can export a join row only through the displayed candidate, frontier, residual-envelope, decidable-boundary, blocked-edge, transport, replay, provenance, and naming coordinates of H.

Apply the handoff boundary of Definition 5547.3. Candidate-gate exactness keeps K and F visible before endpoint data are consumed, confluence discipline keeps C and B visible for residual reads, and decidable-boundary discipline routes bounded comparison through D.

Use residual progress and the rectangle theorem from Definition 5547.15 and Definition 5547.17. They allow the bounded comparison to display a guarded endpoint row or an obstruction row, but only while retaining the candidate and residual coordinates.

Finally read the structural rows T, R, P, L. They transport, replay, source, and name the same finite route; none of them creates a coordinate for unconditional normalization, full Church–Rosser, unrestricted subject reduction, global decidability, quotient syntax equality, evaluator soundness, or closed consistency. Thus no excluded coordinate is available to the consumer. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceBoundary`

Theorem 4737.21 (MetaCIC candidate normalization confluence handoff decider boundary)**.** *Any bounded conversion comparison exported through the decidable-boundary row D of an accepted* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *carrier $H = (A, K, N, F, C, D, B, T, R, P, L)$ must first expose candidate evidence K, normal endpoint data N, the normalization frontier row F, the residual-envelope row C, the blocked-edge row B, componentwise transport T, displayed replay R, provenance P, and local naming L. The exported comparison is only a bounded comparison boundary. It is not global conversion decidability, full Church–Rosser, unrestricted subject reduction, evaluator equality, quotient syntax equality, or closed consistency.*

Proof. Project the carrier of Definition 5547.2. The only conversion-facing coordinate is D, and it is displayed alongside the candidate, endpoint, frontier, residual-envelope, blocked-edge, and structural rows.

Apply Definition 5547.3. Its candidate-gate exactness forces K, F, N to appear before a normal endpoint can be consumed, and its confluence handoff discipline keeps C and B visible before any residual or join read is offered.

Next use Definition 5547.14. A public consumer receives the bounded comparison only through the same carrier route and through T, R, P, L; the structural rows do not create a second decider surface.

Finally apply Definition 5547.15. Residual data remain progress ledger entries or obstruction rows, so the bounded comparison exported through D cannot be promoted to the excluded global conversion, confluence, subject-reduction, evaluator-equality, quotient-equality, or consistency claims. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf`

Theorem 4737.22 (MetaCIC candidate handoff decider-row exhaustion)**.** *Any bounded conversion comparison exported through row D of an accepted* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *carrier $H = (A, K, N, F, C, D, B, T, R, P, L)$ must preserve the candidate evidence row K, endpoint row N, normalization frontier row F, residual envelope row C, blocked-edge row B, componentwise transport row T, displayed replay row R, provenance row P, and local naming row L. No consumer may read D as a standalone global conversion decider. The exhausted row remains only a bounded comparison surface and does not assert full Church–Rosser, unconditional strong normalization, unrestricted subject reduction, evaluator equality, quotient syntax equality, global conversion decidability, or closed consistency.*

Proof. Project the carrier of Definition 5547.2. The decidable-boundary row D appears only as one coordinate of H, beside the candidate, endpoint, frontier, residual-envelope, blocked-edge, and structural rows.

Apply the boundary theorem Definition 5547.3. It places bounded comparison reads after candidate evidence, frontier evidence, endpoint data, residual-envelope visibility, and blocked-edge retention.

Apply the consumer boundary Definition 5547.14. A public consumer receives D only through the displayed route with T, R, P, L, so there is no detached decider surface outside the carrier.

Finally use Definition 5547.21. That theorem identifies D as the bounded comparison row after the displayed endpoint and residual rows have been exposed. Since the excluded global endpoints are not carrier coordinates, exhausting row D preserves the finite comparison boundary without collapsing into global decidability. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf`

Theorem 4737.23 (MetaCIC candidate normalization confluence retained-premise inversion)**.** *Let*

$$H = (A, K, N, F, C, D, B, T, R, P, L)$$

be an accepted MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *carrier. If a bounded endpoint row or join row is read from H, then the read determines the same candidate evidence K, normalization frontier F, residual envelope C, decidable-boundary row D, blocked-edge row B, componentwise transport T, displayed replay R, provenance P, and local naming L. Dropping any retained row changes the packet and cannot be presented as the same confluence handoff.*

Proof. Project the carrier of Definition 5547.2. The endpoint and join rows are not independent data; they are read from the displayed tuple with $K, F, C, D, B, T, R, P, L$ still visible.

Apply the seed package and boundary results from Definition 5547.4, Definition 5547.5, and Definition 5547.3. These force candidate evidence, frontier data, residual-envelope visibility, decidable-boundary access, and blocked-edge retention to remain part of the same handoff before any endpoint or join row is consumed.

Use the bounded conversion comparison surface of Definition 5547.21 and Definition 5547.22. The bounded comparison row D can be read only together with the structural rows T, R, P, L, so erasing any retained coordinate changes the packet rather than simplifying the same one.

Finally apply the nonescape clauses in Definition 5547.20 and Definition 5547.14. They rule out parameter transport into a detached endpoint or join claim, leaving only constructor-style inversion on the concrete carrier rows. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf`

Definition 4737.24 (MetaCIC finite conversion certificate carrier)**.** *A* MetacicCandidateNormalizationConfluenceHa *finite conversion certificate is the subroute of an accepted carrier*

$$H = (A, K, N, F, C, D, B, T, R, P, L)$$

that displays the bounded normal endpoint row N, normalization frontier row F, residual-envelope row C, decidable-boundary row D, blocked-edge row B, and structural rows T, R, P, L in one route. The certificate keeps K as its candidate-evidence entry condition and uses A only as the audit anchor inherited from the surrounding carrier. It has no coordinate for global conversion decidability, full Church–Rosser, unrestricted subject reduction, evaluator equality, quotient syntax equality, or closed consistency.

Theorem 4737.25 (MetaCIC finite conversion certificate boundary)**.** *Every bounded conversion read exported by an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet must display, in one finite route, the normal endpoint row N, normalization frontier row F, residual-envelope row C, decidable-boundary row D, blocked-edge row B, componentwise transport row T, displayed replay row R, provenance row P, and local naming row L. Such a read is a finite conversion certificate in the sense of Definition 5547.24. It is not global conversion decidability, full Church–Rosser, unrestricted subject reduction, evaluator equality, quotient syntax equality, or closed consistency.*

Proof. Begin with the finite certificate carrier. It is not a second carrier: it is the displayed $N, F, C, D, B, T, R, P, L$ subroute of Definition 5547.2, with K as the candidate-evidence entry condition and A as the audit anchor.

Apply the handoff boundary of Definition 5547.3. Candidate-gate exactness places K, F, N before a bounded normal endpoint is consumed, while the confluence handoff discipline keeps C and B visible for residual reads.

Use the consumer boundary of Definition 5547.14. A public bounded conversion consumer receives the comparison only through the same structural route T, R, P, L and not through a detached evaluator or quotient-syntax endpoint.

Finally combine residual progress with the decider boundary of Definition 5547.15 and Definition 5547.21. Residual entries remain progress or obstruction rows, and the exported comparison passes through D as a bounded boundary. Since the excluded global claims are not carrier coordinates, the finite certificate cannot be read as global conversion decidability, Church–Rosser, subject reduction, evaluator equality, quotient equality, or consistency. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicFiniteConversionCertificat`

Theorem 4737.26 (MetaCIC candidate handoff obligation rows)**.** *Any obligationClosure upgrade for* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *must display candidate evidence K, normal endpoint data N, frontier row F, residual-envelope row C, decidable-boundary row D, blocked-edge row B, componentwise transport T, displayed replay R, provenance P, and local naming L as non-collapsible rows. In particular, the candidate-evidence row cannot be folded into the normal endpoint row, the residual-envelope row cannot be folded into the decidable-boundary row, and the blocked-edge row cannot be erased by transport or replay. The upgrade remains a finite handoff obligation surface; it does not assert unconditional strong normalization, full Church–Rosser, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, or closed consistency.*

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffObligationRows`

Proof. Project the carrier of Definition 5547.2. It displays $A, K, N, F, C, D, B, T, R, P, L$ as separate rows, so an obligationClosure read must account for candidate evidence, normal endpoint data, frontier discipline, residual-envelope data, decidable-boundary data, blocked edges, and the structural route.

Apply the boundary theorem Definition 5547.3. Candidate-gate exactness keeps K and F visible before N is consumed, confluence handoff discipline keeps C and B visible, and decidable-boundary discipline keeps D downstream of the displayed endpoint and residual rows.

Use the consumer boundary, residual progress, decider boundary, and finite conversion certificate boundary from Definition 5547.14, Definition 5547.15, Definition 5547.21, and Definition 5547.25. Together they force public reads to preserve candidate-mediated normalization,

residual-envelope visibility, bounded conversion comparison, blocked-edge retention, transport, replay, provenance, and local naming as the same finite route.

Therefore collapsing any one of $K, N, F, C, D, B, T, R, P, L$ would remove a row required by the carrier and by the displayed boundary theorems. Since the excluded global endpoints are not carrier coordinates, the obligation rows remain non-collapsible without promoting the packet beyond the finite handoff surface. □

Theorem 4737.27 (MetaCIC candidate handoff row readiness)**.** *Every confluence-facing or decidability-facing read of an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *carrier*

$$H = (A, K, N, F, C, D, B, T, R, P, L)$$

must expose the candidate row K and the frontier row F before the endpoint row N or the residual rows C, D, B are consumed. Thus the handoff exports only a finite premise-readiness route, not a global strong-normalization endpoint, full Church–Rosser theorem, unrestricted subject-reduction theorem, or global conversion decider.

Proof. Project the carrier of Definition 5547.2. The rows K and F are separate from N, C, D, B, so a consumer can only read endpoint, residual, or decidability data through the displayed handoff packet.

Apply the boundary theorem Definition 5547.3. Its candidate-gate exactness places K and F before N, while its confluence and decidability clauses keep C, D, B on the residual and bounded-comparison side.

Use the obligation rows theorem Definition 5547.26. It makes $K, N, F, C, D, B, T, R, P, L$ non-collapsible rows, so neither transport nor replay may hide the candidate and frontier premises before a consumer reaches the endpoint or residual rows.

Since the carrier contains no coordinate for global strong normalization, full Church–Rosser, unrestricted subject reduction, or global conversion decidability, the exposed route is exactly a local premise-readiness route for confluence-facing and decidability-facing consumers. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf`

Theorem 4737.28 (MetaCIC candidate retained-edge handoff)**.** *Every finite successor handoff from candidate normalization toward confluence in an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet must retain the candidate-gate rows K, F, N, the residual-envelope row C, the decidable-boundary row D, the blocked-edge row B, and the structural rows T, R, P, L before any consumer reads endpoint or conversion data. The retained edge is a finite successor route inside $H = (A, K, N, F, C, D, B, T, R, P, L)$; it does not assert Church–Rosser, strong normalization, subject reduction, evaluator equality, quotient equality, or consistency.*

Proof. Start with the boundary theorem Definition 5547.3. Candidate-gate exactness keeps K, F, N visible in the successor handoff, while confluence handoff discipline keeps C and B visible.

Apply the consumer boundary of Definition 5547.14. A confluence-facing consumer receives the handoff only through the displayed public route, so endpoint data cannot be read before the retained candidate and residual rows.

Use the decider boundary from Definition 5547.21. Any bounded conversion comparison passes through D after the candidate, endpoint, residual-envelope, blocked-edge, and structural rows are displayed.

Finally apply Definition 5547.26. It makes $K, F, N, C, D, B, T, R, P, L$ non-collapsible rows of the obligation surface. Since the excluded global endpoints are not carrier coordinates, a finite

successor handoff retains those rows without proving Church–Rosser, strong normalization, subject reduction, evaluator equality, quotient equality, or consistency. □

Lean4 ✓ BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf

Theorem 4737.29 (MetaCIC candidate normalization handoff obligation stability)**.** *Let* $H = (A, K, N, F, C, D, B, T, R, P, L)$ *be an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *carrier. Any public read preserving the handoff rows must preserve candidate evidence* K*, endpoint row* N*, frontier row* F*, residual envelope* C*, decidable boundary* D*, blocked edge* B*, componentwise transport* T*, displayed replay* R*, provenance* P*, and local naming* L*. No* hsame *transport or* Cont *replay may erase candidate or residual obligations, and no public read may collapse the handoff into unconditional strong normalization, full Church–Rosser, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, or closed consistency.*

Lean4 ✓ BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationHand

Proof. Project the carrier of Definition 5547.2. The rows $K, N, F, C, D, B, T, R, P, L$ occur as separate coordinates, with A only anchoring the audit-map source.

Apply the boundary theorem Definition 5547.3. Candidate-gate exactness preserves K, F, N, confluence handoff discipline preserves C and B, and decidable-boundary discipline preserves D as the bounded comparison boundary.

Use residual progress from Definition 5547.15. Residual data either remain retained premises through K, F or obstruction rows through C, B, so a public read cannot erase the candidate or residual obligation while still preserving the handoff.

Apply the finite conversion certificate boundary of Definition 5547.25 and the obligation rows theorem Definition 5547.26. They require $N, F, C, D, B, T, R, P, L$ to remain visible in one finite route and require K as the candidate-evidence entry condition.

Finally read T and R only as componentwise transport and displayed replay. They preserve the already displayed rows and do not create a coordinate that can discharge or remove candidate evidence, residual-envelope data, or blocked edges. The excluded global endpoints are not carrier coordinates, so stability stays inside the finite handoff surface. □

Theorem 4737.30 (MetaCIC finite conversion endpoint handoff)**.** *Every finite conversion certificate exposed by an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet reaches residual confluence consumers only through the candidate-normalization row* K*, the residual-envelope row* C*, the blocked-edge row* B*, and the decidable-boundary row* D*. In particular, a consumer of the certificate must read the endpoint route through Definition 5547.24, Definition 5547.25, Definition 5547.15, and Definition 5547.17. The handoff does not assert full Church–Rosser, unrestricted subject reduction, unconditional strong normalization, global conversion decidability, quotient syntax equality, host evaluator soundness, or consistency.*

Proof. Project the finite certificate from the carrier. By Definition 5547.24, the exposed endpoint is the displayed subroute through $N, F, C, D, B, T, R, P, L$, with K retained as the candidate-evidence entry condition.

Apply Definition 5547.25. The bounded conversion read is not detached from the handoff packet: it must display the normal endpoint, frontier, residual-envelope, decidable-boundary, blocked-edge, transport, replay, provenance, and local naming rows in one route.

Use residual progress and the guarded rectangle from Definition 5547.15 and Definition 5547.17. A residual confluence consumer either receives the bounded endpoint row through the candidate-mediated route or receives an obstruction row through C and B.

Finally apply the handoff decider boundary of Definition 5547.21. The bounded comparison passes through D after the displayed endpoint and residual rows, so no consumer can read the certificate as one of the excluded global endpoints. □

Lean4 ✓ BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicFiniteConversionEndpointHa

Theorem 4737.31 (MetaCIC candidate normalization public handoff)**.** *Any public confluence or decidability consumer of an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet preserves candidate evidence K, normal endpoint N, normalization frontier F, residual envelope C, decidable boundary D, blocked edge B, transport T, replay R, provenance P, and local naming L before reading a bounded endpoint or conversion row. The handoff does not assert unconditional strong normalization, full Church–Rosser, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, global conversion decidability, or closed consistency.*

Proof. First apply the finite conversion certificate boundary of Definition 5547.25. It keeps the bounded endpoint read inside the displayed endpoint, frontier, residual-envelope, decidable-boundary, blocked-edge, transport, replay, provenance, and local naming route.

Next use residual progress from Definition 5547.15. Residual data remain visible either as retained candidate premises through K, F or as obstruction rows through C, B, so a public confluence consumer cannot erase them before reading a bounded endpoint.

Now apply the confluence rectangle and decidable-boundary theorems, Definition 5547.17 and Definition 5547.21. They route bounded comparison through D only after the candidate, endpoint, frontier, residual-envelope, and blocked-edge rows have been displayed.

Finally combine obligation stability and public endpoint handoff from Definition 5547.29 and Definition 5547.30. The structural rows T, R, P, L preserve the same finite packet, and none of the excluded global endpoints is a carrier coordinate. □

Lean4 ✓ BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf

Theorem 4737.32 (MetaCIC normalization audit-map realization)**.** *The* MetacicCandidateNormalizationConfluenc *packet is the concrete finite* NameCert *realization of the normalization audit-map route of chapter 9383. Its carrier displays candidate evidence K, bounded endpoint row N, frontier row F, residual-envelope row C, decidable-boundary row D, blocked-edge row B, componentwise transport T, displayed replay R, provenance P, and local naming L as one guarded handoff. The realization does not assert unconditional strong normalization, full Church–Rosser, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, or closed consistency.*

Proof. Project the carrier of Definition 5547.2. The audit anchor A binds the packet to chapter 9383, and the rows $K, N, F, C, D, B, T, R, P, L$ display the finite candidate, endpoint, frontier, residual-envelope, decidable-boundary, blocked-edge, transport, replay, provenance, and local naming data.

Apply the handoff boundary of Definition 5547.3. Candidate-gate exactness forces K, F, N to appear before any endpoint read, confluence handoff discipline keeps C and B visible, and decidable-boundary discipline routes bounded comparison through D.

Use the consumer boundary and endpoint handoff from Definition 5547.14 and Definition 5547.30. Together they show that every public read of the audit-map route remains inside the displayed finite conversion certificate and its residual-envelope boundary.

Thus the vision route has a concrete finite packet: candidate evidence, bounded endpoint, frontier, residual envelope, decidable boundary, blocked edge, transport, replay, provenance, and

naming are all carrier rows. Since none of the excluded global endpoints is a carrier coordinate, the realization stays a guarded NameCert handoff. □

Lean4 ✓ BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf

Theorem 4737.33 (Finite-observation MetaCIC diamond-envelope obligations)**.** *For every accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet, a finite-observation diamond envelope exposes candidate evidence K, bounded endpoint row N, residual-envelope row C, local join and checker status through the decidable-boundary row D, blocked-edge retention through B, componentwise transport T, displayed replay R, provenance P, and local naming L before any confluence consumer reads a bounded join. The envelope is a finite observation route inside the existing handoff carrier; it is not unconditional strong normalization, full Church–Rosser, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, or closed consistency.*

Lean4 ✓ BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.FiniteObservationMetaCICDiamondEn

Proof. Project the carrier of Definition 5547.2. The finite observation envelope can only use the displayed rows $K, N, F, C, D, B, T, R, P, L$.

Apply Definition 5547.3. Candidate-gate exactness keeps K, F, N visible before a bounded endpoint is consumed, while confluence handoff discipline keeps the residual-envelope row C and blocked-edge row B visible before a residual or join read is offered.

Use Definition 5547.21. The local checker status is read through D only after the endpoint, residual-envelope, blocked-edge, transport, replay, provenance, and naming rows are displayed.

Finally apply Definition 5547.30. Any bounded join read remains inside the finite certificate route, so no consumer can read the envelope as an unconditional confluence or normalization theorem. □

Theorem 4737.34 (MetaCIC candidate-normalization confluence handoff obligation surface)**.** *For every accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet, the handoff exposes finite obligation rows for candidate evidence K, residual envelope C, decidable-boundary routing D, blocked-edge retention B, bounded endpoint readback N, componentwise transport T, replay R, provenance P, and local naming L. The route remains guarded by the audit anchor A and frontier row F, and it exports none of strong normalization, full Church–Rosser, subject reduction, evaluator equality, quotient syntax equality, host evaluator soundness, or closed consistency.*

Proof. Project the carrier of Definition 5547.2. The displayed rows $A, K, N, F, C, D, B, T, R, P, L$ are the only coordinates available to a confluence-facing consumer.

Apply the boundary theorem Definition 5547.3 and the premise-exposure theorem Definition 5547.5. They force candidate evidence and frontier data to remain visible before endpoint, residual, or bounded-comparison rows are consumed.

Use residual-diamond retention from Definition 5547.6 and normal-endpoint readback from Definition 5547.8. These route residual evidence through C, B and endpoint reads through N without collapsing the decidable-boundary row D.

Finally read T, R, P, L as structural rows. They transport, replay, source, and locally name the same finite handoff, so the obligation surface is exhausted by the displayed coordinates and cannot be reinterpreted as any of the refused global MetaCIC endpoints. □

Lean4 ✓ BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf

Theorem 4737.35 (Finite-observation MetaCIC diamond-envelope handoff)**.** *Every confluence or normalization consumer of a finite-observation MetaCIC diamond envelope receives a bounded join only through the candidate evidence, bounded endpoint, residual-envelope, local checker, blocked-edge, transport, replay, provenance, and local* NameCert *rows of Definition 5547.33. The handoff exports the bounded finite-observation route and no global Church–Rosser theorem, unconditional strong-normalization theorem, unrestricted subject-reduction theorem, global conversion decider, evaluator equality, quotient syntax equality, or consistency endpoint.*

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.FiniteObservationMetaCICDiamondEn`

Proof. Start with the finite-observation obligations. They place the candidate, endpoint, residual-envelope, checker, blocked-edge, transport, replay, provenance, and naming rows before any bounded join read.

Use the guarded rectangle of Definition 5547.17. A bounded comparison either displays a common bounded endpoint row or records a residual obstruction, and both alternatives keep the candidate and residual coordinates visible.

Apply the finite conversion certificate boundary of Definition 5547.25. The public consumer receives only the displayed finite route, so the handoff cannot be reinterpreted as a detached global confluence or normalization theorem. □

Theorem 4737.36 (MetaCIC candidate-normalization residual-diamond totality)**.** *Every accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet that exposes candidate evidence K, bounded normal endpoint row N, residual-retention rows C, B, and decidable-boundary row D must supply the finite residual-diamond join route before any public confluence consumer reads it. The supplied route is the bounded candidate-normalization handoff through $A, K, N, F, C, D, B, T, R, P, L$; it is not a global Church–Rosser theorem, unrestricted subject-reduction theorem, unconditional strong-normalization theorem, quotient syntax equality, host evaluator soundness, global conversion decidability, or closed consistency.*

Proof. Project the carrier of Definition 5547.2. The rows K, N, C, D, B are displayed beside the audit anchor, frontier row, componentwise transport, replay, provenance, and local naming rows, so a public confluence read has no coordinate outside $A, K, N, F, C, D, B, T, R, P, L$ from which to obtain a join.

Apply residual-diamond retention from Definition 5547.6. It requires residual or join reads to retain candidate evidence, the residual envelope, the decidable boundary, and the blocked-edge row before the endpoint row is treated as joinable.

Use the consumer boundary of Definition 5547.14. A public consumer may read the handoff only after the candidate-mediated route, residual-envelope visibility, bounded comparison routing, blocked-edge retention, transport, replay, provenance, and local naming rows remain visible.

Finally combine the guarded rectangle of Definition 5547.17 with the finite-observation handoff of Definition 5547.35. The available join is therefore total only as a finite residual-diamond route supplied by the packet, and the excluded global endpoints remain absent from the carrier. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf`

Theorem 4737.37 (MetaCIC candidate-normalization residual-strip local join)**.** *Every accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet exposing candidate evidence K, bounded endpoint row N, residual envelope C, decidable boundary D, blocked-edge row B, componentwise transport T, displayed replay R, provenance P, and local* NameCert *row L supplies only a local residual-strip join route for bounded candidate-normalization consumers. The route is read through*

the finite handoff rows $A, K, N, F, C, D, B, T, R, P, L$ and does not export full Church–Rosser, unrestricted subject reduction, unconditional strong normalization, quotient syntax equality, host evaluator soundness, global conversion decidability, or kernel consistency.

Proof. Project the obligation surface of Definition 5547.34. It displays the candidate evidence, residual envelope, decidable boundary, blocked edge, bounded endpoint, transport, replay, provenance, and local naming rows as the only handoff coordinates available to a confluence-facing consumer.

Apply the finite-observation handoff of Definition 5547.35. A bounded join read is offered only after the finite observation envelope has kept the candidate row, endpoint row, residual row, checker row, blocked edge, and structural rows visible.

Use residual-diamond totality from Definition 5547.36. It supplies the join only as a finite residual-diamond route inside $A, K, N, F, C, D, B, T, R, P, L$.

The nonescape clauses are therefore inherited from the same three routes. Since none of full Church–Rosser, unrestricted subject reduction, unconditional strong normalization, quotient syntax equality, host evaluator soundness, global conversion decidability, or kernel consistency is a carrier coordinate, the consumer receives a local residual-strip join and nothing global. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf`

Theorem 4737.38 (MetaCIC candidate-normalization local diamond handoff)**.** *Let*

$$H = (A, K, N, F, C, D, B, T, R, P, L)$$

be an accepted $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *carrier. If two one-step candidate-normalization residual reads share the audit anchor A, candidate evidence K, normalization frontier F, residual-envelope row C, decidable-boundary row D, blocked-edge row B, and the structural rows T, R, P, L, then any displayed join between their bounded endpoint reads is available only as a local diamond handoff through the residual-window row, candidate-join row, relation-scope row, and transport rows already carried by C, D, B, T, R, P, L.*

The handoff preserves the same boundary rows on both sides of the diamond. It exports no full Church–Rosser theorem, unrestricted subject reduction, quotient syntax equality, evaluator equality, global conversion decidability, closed consistency, or unrestricted normalization theorem.

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicNormalizationConfluenceLo`

Proof. Start with the carrier and boundary rows. The carrier displays $A, K, N, F, C, D, B, T, R, P, L$, and Definition 5547.3 requires every confluence-facing read to keep candidate evidence, frontier data, residual envelope, decidable boundary, and blocked-edge retention visible.

Read the two one-step residuals through the same boundary data. Premise exposure and residual-diamond retention, Definition 5547.5 and Definition 5547.6, prevent either branch from treating the bounded endpoint row as detached joinability data.

Use residual-diamond totality and residual-strip local join, Definition 5547.36 and Definition 5547.37. They provide only the finite join route inside $A, K, N, F, C, D, B, T, R, P, L$, so the residual-window, candidate-join, and relation-scope rows remain displayed during the handoff.

Finally transport both sides through T, R, P, L. These rows preserve, replay, source, and name the same local diamond route; they do not create a coordinate for the refused global MetaCIC endpoints. Hence the displayed diamond is a local handoff over the retained residual and candidate rows, not a global confluence or normalization theorem. □

Theorem 4737.39 (MetaCIC candidate-normalization confluence handoff seed status)**.** *A seed-status reader of an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet must expose candidate evidence K, normalization frontier F, residual confluence envelope C, decidable boundary D, blocked-edge row B, componentwise* hsame *transport T, displayed* Cont *replay R,* Pkg *provenance P, and local* NameCert *row L before it consumes any bounded normal endpoint row N. The seed status is the finite retained-premise boundary of the handoff; it does not claim full Church–Rosser, unrestricted subject reduction, quotient syntax equality, evaluator equality, global conversion decidability, residual-substitution discharge, or kernel consistency.*

Proof. Project the carrier of Definition 5547.2. The only available rows are the audit anchor, candidate evidence, bounded endpoint, frontier, residual envelope, decidable boundary, blocked edge, transport, replay, provenance, and local naming data.

Apply the boundary theorem Definition 5547.3 and the seed-closure route of Definition 5547.4. They keep K, F, C, D, B visible before endpoint consumption.

Use premise exposure from Definition 5547.5, residual-diamond retention from Definition 5547.6, and decider-row exhaustion from Definition 5547.22. These force the residual envelope, decidable boundary, and blocked-edge row to remain displayed whenever a bounded normal endpoint is read.

Finally read T, R, P, L as structural rows. They transport, replay, source, and name the same finite packet, so the seed-status reader cannot project any of the refused global MetaCIC endpoints from the handoff. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf`

Falsifiable prediction: Every accepted MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ read that exports a normal endpoint, residual-envelope row, or bounded conversion comparison without first exposing candidate evidence, the normalization frontier, the confluence residual envelope, the decidable boundary, blocked-edge retention, transport, replay, provenance, and local naming is outside the carrier surface.

Independence witness: metaciccriticalpath, metacicnormalizationfrontier, metacic-confluence-residual-envelope, metacicdecidableboundary, metacic-normalization-confluence-bridge: no listed sibling supplies the joint handoff containing candidate evidence, bounded normal endpoint data, residual-envelope visibility, decidable-boundary routing, blocked-edge retention, transport, replay, provenance, and local NameCert rows while refusing unconditional SN and Church–Rosser.

Lean follow-up should provide Nontrivial and FieldFaithful instances for the carrier so the candidate row, residual-envelope row, and decidable-boundary row can be audited as distinct fields rather than as a collapsed route.

The handoff also consumes the residual-diamond route of chapter 5126 as a concrete prerequisite. The candidate-normalization row must expose its cut-height budget and residual join data before the confluence handoff can be read, so the rows K, N, F, C, D, B remain tied to the parallel residual packet rather than becoming a standalone confluence claim.

Theorem 4737.40 (MetaCIC candidate normalization handoff sibling route)**.** *No* MetacicCandidateNormalizationC *consumer may read bounded normal endpoints or local residual-strip joins until it has exposed the candidate evidence row K, the* MetaCICNormalizationFrontier$^{\uparrow}$ *row F, the residual confluence-envelope row C, the decidable-boundary row D, the blocked-edge row B, and the sibling residual-diamond route through chapter 5126. The available read is the finite handoff along $A, K, N, F, C, D, B, T, R, P, L$; it is not full Church–Rosser, unrestricted subject reduction, evaluator equality, quotient syntax equality, or kernel consistency.*

Proof. Start with the boundary theorem Definition 5547.3 and premise exposure Definition 5547.5. They force the candidate evidence, normalization frontier, residual envelope, decidable boundary, and blocked edge to remain displayed before a bounded endpoint can be consumed.

Residual-diamond retention, Definition 5547.6, ties any join read to K, C, D, B rather than to the endpoint row alone. Decider-row exhaustion in Definition 5547.22 keeps the decidable-boundary row as bounded checker evidence, not as a global conversion oracle.

Use the residual-strip local join theorem Definition 5547.37. Its join route is local to the displayed packet $A, K, N, F, C, D, B, T, R, P, L$ and must keep the sibling residual-diamond route visible.

Finally apply seed status, Definition 5547.39. The seed reader receives only the retained-premise boundary, so full Church–Rosser, unrestricted subject reduction, evaluator equality, quotient syntax equality, and kernel consistency remain outside the carrier. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationHand`

Theorem 4737.41 (MetaCIC candidate handoff scoped TasteGate route)**.** *Every later* TasteGate *instance for* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *must cite the exact paper-side route:*

1. *the carrier of Definition 5547.2;*
2. *the boundary of Definition 5547.3;*
3. *the obligation surface of Definition 5547.34;*
4. *residual-diamond totality from Definition 5547.36;*
5. *residual-strip local join from Definition 5547.37;*
6. *seed status from Definition 5547.39;*
7. *the sibling confluence handoff of Definition 5547.40.*

This route is the one needed by the GroundCompiler *TasteGate check. It does not supply full Church–Rosser, unrestricted subject reduction, quotient syntax equality, evaluator equality, global conversion decidability, closed consistency, or an unrestricted normalization theorem.*

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateHandoffScopedTast`

Proof. Start with the carrier and boundary. The carrier definition displays $A, K, N, F, C, D, B, T, R, P, L$, while the boundary theorem keeps candidate evidence, frontier data, residual envelope, decidable boundary, and blocked-edge retention visible before any bounded endpoint is consumed.

Next read the obligation surface. It gives the rows a local NameCert surface and prevents the handoff from being treated as a detached MetaCIC confluence theorem.

Use residual-diamond totality and residual-strip local join. These theorems supply only the finite join route inside $A, K, N, F, C, D, B, T, R, P, L$, with the residual envelope and decidable-boundary row still displayed.

Finally cite seed status and the sibling route. Seed status records the retained-premise boundary, and the sibling route keeps the critical-path, normalization-frontier, confluence-audit, residual local-join, and parallel-diamond residual surfaces visible. Thus a GroundCompiler TasteGate check can cite the scoped route above, while full Church–Rosser, unrestricted subject reduction, quotient syntax equality, evaluator equality, global conversion decidability, closed consistency, and unrestricted normalization remain outside the claim. □

Theorem 4737.42 (MetaCIC candidate-normalization confluence scoped surface)**.** *The scoped* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *surface is exactly the carrier row, residual-diamond row, bounded join-window row, decider-row exhaustion row, finite conversion endpoint row, audit-map realization row, and sibling route row displayed in this chapter. The surface does not claim full Church–Rosser, unrestricted subject reduction, quotient syntax equality, evaluator equality, global conversion decidability, closed consistency, or kernel consistency.*

Proof. Start with the carrier and obligation surface, Definition 5547.2 and Definition 5547.34. They name the packet rows and keep the candidate evidence, frontier, residual envelope, decidable boundary, blocked edge, transport, replay, provenance, and local naming visible.

Next use residual-diamond totality and residual-strip local join, Definition 5547.36 and Definition 5547.37. These provide only bounded local joins and finite conversion endpoints inside the displayed packet.

Then apply decider-row exhaustion and seed status, Definition 5547.22 and Definition 5547.39. They keep the decider and audit-map realization rows as retained premises rather than global conversion or kernel-consistency claims.

Finally cite the sibling route Definition 5547.40. It binds the residual-diamond dependency and the finite handoff route, so the scoped surface is precisely the listed packet and sibling rows. □

Lean4 ✓ `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp.MetacicCandidateNormalizationConf`

Theory closure: TheoryGate(NameCert$_{\text{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}}$, obligation)

Scope closed: Definition 5547.2, Definition 5547.3, Definition 5547.34, Definition 5547.36, Definition 5547.37, and Definition 5547.39 record the seed and obligation surface for candidate normalization, residual join, confluence handoff, finite-window replay, and MetaCIC frontier dependencies.

Formal verification: FormalStatus(NameCert$_{\text{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.MetacicCandidateNormalizationConfluenceHandoffUp`

Bridge status: none

Not claimed: This chapter does not close unconditional strong normalization, full Church–Rosser, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, closed consistency, Lean proof obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate-gate exactness, confluence handoff discipline, decidable-boundary discipline, frontier non-collapse, Nontrivial, and FieldFaithful instances for BEDC.Derived.MetacicCandidateNorm

Constructive story: A MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ packet is generated from a MetaCIC audit anchor, candidate evidence, bounded normal endpoint row, MetaCICNormalizationFrontierUp row, residual confluence-envelope row, MetaCICDecidableBoundaryUp row, blocked-edge retention, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theorem 4737.43 (MetaCIC candidate residual-budget discharge frontier)**.** *For every accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *carrier*

$$H = (A, K, N, F, C, D, B, T, R, P, L),$$

candidate evidence K, residual envelope C, decidable boundary D, and blocked-edge row B remain visible before the endpoint row N is treated as a residual join by MetaCICParallelDiamondFrontier$^{\uparrow}$*. The discharge frontier is therefore the finite route from the audit anchor A through $K, F, C, D, B, T, R, P, L$ into the parallel-diamond consumer, not full Church–Rosser, unrestricted subject reduction, evaluator equality, quotient syntax equality, residual-substitution discharge, or kernel consistency.*

Proof. Project the carrier of Definition 5547.2. The rows $A, K, N, F, C, D, B, T, R, P, L$ display the audit anchor, candidate evidence, endpoint row, normalization frontier, residual envelope, decidable boundary, blocked edge, transport, replay, provenance, and local naming.

Apply the boundary theorem Definition 5547.3 and the premise-exposure theorem Definition 5547.5. Together they keep K, F, C, D, B attached to the same accepted packet before any confluence-facing endpoint read can treat N as residual join data.

Finally read the parallel-diamond frontier sibling of chapter 4238. Its consumer may inspect the residual join only after the candidate, residual-envelope, decidable-boundary, and blocked-edge rows have remained visible through T, R, P, L.

The refused global conclusions are absent from the carrier and from this consumer route. Thus the discharge frontier records a candidate-mediated finite handoff rather than a global MetaCIC theorem. □

Theorem 4737.44 (MetaCIC candidate normalization diamond-budget route)**.** *Every accepted* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *closed-normal read must first expose candidate-set membership, a bounded local peak, join-budget rows, the sibling confluence route of chapter 6552, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}}$ *row. Thus the closed-normal endpoint is consumed only after the diamond-budget dependency surface is visible, not as an evidence-free consequence.*

Proof. Project the parent carrier of Definition 5547.2. Its accepted read displays candidate evidence, bounded endpoint data, residual confluence routing, decidable-boundary routing, blocked-edge retention, transport, replay, provenance, and local naming before any consumer can see a normal endpoint.

Apply the boundary theorem of Definition 5547.3. Candidate-gate exactness exposes the candidate-set membership row before the endpoint row is consumed, while confluence handoff discipline keeps the residual and blocked-edge rows visible.

The sibling route through chapter 6552 supplies the bounded local peak and join-budget rows. Reading that sibling before the closed-normal endpoint preserves the finite diamond budget as a dependency of the handoff, and T, R, P, L transport, replay, source, and name the same route without adding a global confluence or normalization coordinate. □

Theorem 4737.45 (MetaCIC candidate normalization handoff route)**.** *Every accepted* MetacicCandidateNormalizat *packet that exports a confluence handoff must first expose the* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *source row, the* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *frontier row, residual join scope, candidate normalization budget, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. In carrier notation the route reads the displayed packet rows* $A, K, N, F, C, D, B, T, R, P, L$ *before any consumer treats the bounded endpoint row* N *as confluence-facing data.*

The exported handoff is therefore a finite candidate-mediated route through the critical path, parallel-diamond frontier, residual envelope, decidable boundary, blocked-edge budget, transport, replay, provenance, and local naming surface. It is not global strong normalization, full Church–Rosser, unrestricted subject reduction, quotient syntax equality, evaluator equality, global conversion decidability, or closed consistency.

Proof. Start with the carrier of Definition 5547.2. The rows $A, K, N, F, C, D, B, T, R, P, L$ display the audit anchor, candidate evidence, bounded endpoint, normalization frontier, residual confluence envelope, decidable boundary, blocked edge, transport, replay, provenance, and local naming.

Next read the sibling routes. The $\mathsf{MetaCICCriticalPath}^{\uparrow}$ row supplies the public critical-path source, while the $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ row supplies the retained frontier that keeps residual join scope visible before any endpoint is consumed.

Now apply the existing premise-exposure and local-join routes of Definition 5547.5 and Definition 5547.7. They force candidate evidence, residual envelope data, decidable-boundary data, and blocked-edge data to remain attached to the same handoff packet.

Finally pass through T, R, P, L. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows preserve the finite packet and add no coordinate for the refused global MetaCIC endpoints. Hence the confluence handoff can be exported only as the stated candidate-normalization route. □

Theorem 4737.46 (MetaCIC candidate-normalization handoff cut-height budget route)**.** *Any* MetaCICCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *consumer that reads a cut-height budget or local-diamond endpoint must first expose candidate evidence, the normalization frontier, residual confluence, the decidable-boundary route, and blocked-edge rows in the same finite handoff packet. In particular, the consumer must cite the parallel-diamond frontier of chapter 4238 and the normalization frontier of chapter 892 before any cut-height or local-diamond row is consumed.*

Proof. Project the candidate-normalization confluence handoff carrier from the local NameCert construction. Its public rows expose candidate evidence, bounded normal-endpoint data, residual-envelope visibility, decidable-boundary routing, blocked-edge retention, transport, replay, provenance, and local naming.

The cut-height consumer is downstream of those rows. A local-diamond read needs the residual confluence and blocked-edge rows, while a budget read needs the normalization frontier and decidable-boundary rows before it can decide which bounded endpoint is being measured.

Now read the sibling frontiers. The parallel-diamond frontier supplies the residual diamond and local-join surface, and the normalization frontier supplies the bounded normal-endpoint surface. Since the handoff has no separate cut-height coordinate outside those displayed routes, every accepted cut-height or local-diamond consumer must first display the stated rows. □

The MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ dossier-lattice anchor consumes the parallel-diamond frontier route of chapter 4238 and the local-confluence certificate route of chapter 7346 before residual-normalization handoff rows are public. Thus the handoff keeps candidate evidence, residual-envelope visibility, decidable-boundary routing, blocked-edge retention, transport, replay, provenance, and local naming attached to those sibling routes instead of exporting a standalone confluence endpoint. The candidate-normalization handoff consumes the residual-join and local-confluence routes through chapter 4238 and reads the Real and RegSeqRat-style finite route discipline of chapter 909 only as packet ordering. This dependency records the visible sibling path for residual joins, local diamonds, finite readback rows, transport, replay, provenance, and local naming; it does not select a normalization, quotient terms, identify evaluator equality, or turn the Real-facing ordering discipline into a MetaCIC equality principle. The MetaCICCandidateNormalizationConfluenceHandoff$^{\uparrow}$ dossier lattice is consumed by chapter 4238 and chapter 735 only through candidate evidence rows, residual-envelope visibility, decidable-boundary routing, and blocked-edge retention. A downstream confluence reader must therefore keep the handoff as a finite evidence packet rather than reading it as a completed normalization theorem or as an untracked frontier shortcut. The candidate-normalization confluence handoff consumes the parallel-diamond frontier of chapter 4238 together with the critical-path route of chapter 765 before any confluence-facing read is exported. This child route records the dependency lattice: the MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ packet may pass candidate evidence, bounded endpoint rows, residual-envelope visibility, decidable-boundary routing, blocked-edge retention, transport, replay, provenance, and local naming onward only while those MetaCIC frontier siblings remain visible.

Theorem 4737.47 (MetaCIC candidate handoff forward route to the parallel-diamond frontier)**.** *Every accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet that is consumed as a local confluence handoff must expose the parallel-diamond frontier sibling of chapter 4238 before the handoff is read as downstream MetaCIC evidence. In carrier form the handoff rows*

$$K, N, F, C, D, B, T, R, P, L$$

remain visible while the sibling frontier supplies the retained residual-substitution premise, critical-pair envelope, candidate-join row, residual-frontier row, bounded checker rows, obstruction row, transport, replay, provenance, and local NameCert *rows. The route is a finite dependency route for candidate normalization and confluence readers; it does not assert full Church–Rosser, subject reduction, evaluator equality, quotient syntax equality, residual-substitution discharge, or kernel consistency.*

Proof. Read the carrier of the handoff packet first. The candidate evidence, normal endpoint, frontier, residual confluence, decidable-boundary, blocked-edge, transport, replay, provenance, and naming rows are the only rows available to the consumer.

Next read the sibling frontier at chapter 4238. Its displayed frontier budget keeps the retained residual-substitution premise and obstruction rows visible before any local diamond route is consumed.

The two packets therefore meet only along finite visible rows. Since neither packet contains a row for unrestricted confluence, subject reduction, evaluator equality, quotient equality, residual-substitution discharge, or kernel consistency, the forward route remains a dependency edge rather than a global MetaCIC endpoint. □

The MetaCICCandidateNormalizationConfluenceHandoff$^{\uparrow}$ handoff consumes the normalization-candidate frontier of chapter 892, the bounded Church–Rosser fragment of chapter 8560, and the confluence audit rows of chapter 735 before exporting its candidate-mediated handoff. The dependency route keeps candidate evidence, bounded endpoint rows, residual-envelope visibility, decidable-boundary routing, blocked-edge retention, transport, replay, provenance, and local naming visible as finite MetaCIC data, not as a detached normalization theorem or a global confluence endpoint.

Theorem 4737.48 (MetaCIC critical-path and parallel-frontier handoff route)**.** *Every confluence-facing consumer of an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet must first read the MetaCIC critical-path surface of chapter 765 and the parallel-diamond frontier route of chapter 4238. Only after those sibling surfaces are displayed may the handoff be treated as a confluence-facing packet over candidate evidence, bounded endpoint rows, residual-envelope visibility, decidable-boundary routing, blocked-edge retention, transport, replay, provenance, and local naming. This is a finite MetaCIC route, not subject reduction, full Church–Rosser, unrestricted conversion decidability, quotient syntax equality, or kernel consistency.*

Proof. Project the handoff carrier of Definition 5547.2. Its rows expose audit anchoring, candidate evidence, normal endpoint data, frontier data, residual confluence data, decidable-boundary data, blocked-edge retention, transport, replay, provenance, and local naming.

Apply the boundary theorem Definition 5547.3. It requires a confluence-facing read to keep the candidate gate, residual envelope, decidable boundary, and blocked-edge rows visible before an endpoint row can be consumed.

The sibling route is therefore read in two steps. The MetaCIC critical-path chapter supplies the upstream audit route, and the parallel-diamond frontier supplies the confluence-facing frontier route. The handoff can then pass finite candidate and residual data onward, but no row in

the carrier turns that route into subject reduction, full Church–Rosser, unrestricted conversion decidability, quotient syntax equality, or kernel consistency. □

Theorem 4737.49 (MetaCIC candidate handoff normalization-audit forward link)**.** *Every confluence-facing consumer of an accepted* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *packet must first read the* $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$ *packet of chapter 750. In particular, the handoff consumes the audit carrier of Definition 750.1, the candidate evidence row of Definition 750.3, the closed projection route of Definition 750.5, the finite strong-normalization scope of Definition 750.4, the application boundary of Definition 750.6, and the confluence refusal row of Definition 750.9 before candidate normalization is routed to any confluence-facing endpoint.*

Proof. Start with the normalization-audit carrier. The rows $R, C, S, A, N, F, H, T, P, L$ separate candidate evidence, closed projection, finite strong-normalization scope, application boundary, confluence refusal, replay, transport, provenance, and local naming.

Apply the candidate boundary and closed-term projection route. They force any normalization read to expose candidate evidence and checked closed projection before the finite SN inventory can be consumed.

Next apply the finite SN scope and candidate-mediated SN closure theorems. These rows keep the SN export inside the candidate ledger and retain the application boundary, so the handoff cannot convert candidate normalization into an evidence-free endpoint.

Finally use the confluence refusal split. The refusal row N remains visible when the handoff approaches a confluence-facing consumer, excluding global confluence, unrestricted subject reduction, quotient syntax equality, and host evaluator evidence from the forwarded route. □

Theorem 4737.50 (MetaCIC candidate normalization confluence handoff normal-form obligation)**.** *Any normal-form read exported by an accepted* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *carrier must first expose the candidate-normalization row, the residual-diamond row, and the sibling confluence route. Concretely, the read must pass through the candidate gate and frontier rows of Definition 5547.3, the premise-exposure and normal-endpoint rows of Definition 5547.5 and Definition 5547.8, the residual-diamond retention row of Definition 5547.6, the bounded candidate-diamond route of Definition 5547.44, and the sibling confluence route of Definition 5547.89 before any normal-form endpoint is available. The obligation is a finite premise-exposure row only; it does not assert host normalization, global confluence, unrestricted subject reduction, quotient syntax equality, evaluator soundness, or closed consistency.*

Proof. Project the carrier from Definition 5547.2. A normal-form read can see only the candidate, frontier, residual, decidable, blocked-edge, transport, replay, provenance, and local naming rows displayed in that carrier.

Apply the boundary and premise-exposure theorems. They force the candidate gate and normalization frontier to appear before the normal endpoint is consumed, and they keep the residual envelope, decidable boundary, and blocked-edge rows visible for confluence-facing reads.

Next apply normal-endpoint readback and residual-diamond retention. These rows show that an endpoint can be handed to confluence consumers only while candidate evidence, residual data, decidable-boundary data, and blocked edges remain present in the same packet.

Finally use the diamond-budget dependency and sibling confluence route. The candidate diamond supplies bounded local peak and join-budget rows, and the sibling route exposes the critical-path, normalization-frontier, confluence-audit, and parallel-diamond residual surfaces before the normal-form read is available. Since no carrier coordinate contains a host-level normalization or global confluence theorem, the obligation remains the finite handoff row stated above. □

Theorem 4737.51 (MetaCIC candidate normalization confluence handoff obstruction retention)**.** *Every consumer of the candidate-normalization normal-form row exported by an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet must retain the residual-substitution premise, candidate diamond budget dependency, cut-height budget route, and parallel frontier route before treating that row as confluence-facing evidence. The retained route is the finite chain through Definition 5547.44, Definition 5547.46, Definition 5547.73, and the residual-diamond bridge route. It does not export subject reduction, unrestricted Church–Rosser, evaluator equality, quotient term equality, or kernel consistency.*

Proof. Start with the residual budget theorem Definition 5547.57. It forces candidate evidence, residual-diamond retention, decidable-boundary data, blocked-edge rows, bounded local peaks, join-budget rows, and the sibling confluence route to remain visible before a normal-form endpoint is exported.

Apply the candidate diamond budget dependency Definition 5547.44. The normal-form row is therefore read only after bounded local peak and join-budget data have been displayed; it is not an evidence-free confluence endpoint.

Next use the cut-height budget route and the parallel-diamond frontier route, Definition 5547.46 and Definition 5547.73. These routes keep the normalization frontier, residual confluence, decidable boundary, blocked-edge rows, and frontier-facing residual-substitution premise attached to the handoff.

Finally consume the residual-diamond bridge route recorded in the sibling route file. The bridge sends only finite residual-diamond dependency data onward while preserving residual-substitution visibility. Since the carrier has no coordinate for subject reduction, unrestricted Church–Rosser, evaluator equality, quotient term equality, or kernel consistency, every confluence-facing read retains the obstruction instead of erasing it. □

Theorem 4737.52 (MetaCIC candidate normalization normal-form budget)**.** *Every accepted normal-form endpoint exported by a* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *carrier must retain the candidate gate, residual-diamond row, cut-height budget, parallel-diamond frontier route, and sibling confluence route as one finite budget surface before it can be used as local confluence evidence. The endpoint is therefore consumed only through the normal-form obligation, obstruction-retention row, diamond-budget route, cut-height budget route, and parallel-diamond frontier route; it is not global Church–Rosser, unrestricted subject reduction, quotient syntax equality, evaluator equality, or consistency.*

Proof. Start with the normal-form obligation of Definition 5547.50. It places every endpoint downstream of the candidate-normalization row, the residual-diamond row, and the sibling confluence route before any consumer can read it.

Apply obstruction retention, Definition 5547.51. The residual-substitution premise, candidate diamond dependency, cut-height budget, and parallel frontier route remain attached to the same handoff row rather than being discharged by the endpoint.

Next use the diamond-budget route and cut-height budget route, Definition 5547.44 and Definition 5547.46. These rows expose bounded local peaks, join-budget data, normalization-frontier data, residual confluence, decidable-boundary routing, and blocked-edge retention as finite budget coordinates.

Finally apply the parallel-diamond frontier route, Definition 5547.73, and the sibling confluence route Definition 5547.89. They keep the frontier and sibling residual surfaces visible before the endpoint is treated as local confluence evidence. Since none of the cited rows contains a

global Church–Rosser theorem, subject reduction, quotient syntax equality, evaluator equality, or consistency, the endpoint remains the retained finite budget surface stated above. □

Theorem 4737.53 (MetaCIC candidate normalization normal-form budget)**.** *Every local-confluence consumer of an accepted normal-form endpoint exported by a* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet must retain the candidate gate, residual-diamond row, residual-substitution premise, cut-height budget, parallel frontier route, sibling confluence route, and local* NameCert *row as one finite budget packet. The endpoint is therefore consumed only through the normal-form obligation, obstruction-retention row, candidate diamond budget route, cut-height budget route, and parallel-diamond frontier route before it can be read as local confluence evidence.*

This retained packet explicitly excludes unrestricted Church–Rosser, subject reduction, quotient syntax equality, evaluator equality, and kernel consistency.

Proof. Start with the normal-form obligation of Definition 5547.50. It places every endpoint after the candidate gate, residual-diamond row, and sibling confluence route, so the consumer cannot read the endpoint as a detached normal form.

Apply obstruction retention, Definition 5547.51. That row keeps the residual-substitution premise, candidate diamond dependency, cut-height budget, and parallel frontier route attached to the endpoint as confluence-facing evidence.

Use the candidate diamond budget route, Definition 5547.44, together with the cut-height budget route Definition 5547.46. They expose the bounded local peak, join-budget, cut-height, normalization frontier, residual confluence, decidable boundary, and blocked-edge rows as finite budget coordinates.

Finally apply the parallel-diamond frontier route, Definition 5547.73, and the sibling confluence route Definition 5547.89. The local NameCert row names exactly that finite packet. Since none of these rows contains unrestricted Church–Rosser, subject reduction, quotient syntax equality, evaluator equality, or kernel consistency, the consumer receives only the retained normal-form budget. □

Theorem 4737.54 (MetaCIC residual normal-form frontier)**.** *An accepted normal-form endpoint of a* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet may be consumed as local confluence evidence only while one finite frontier packet still displays the candidate gate, residual-diamond row, residual-substitution premise, cut-height budget, parallel frontier route, and sibling confluence route. The endpoint is therefore read through the normal-form obligation, obstruction retention, normal-form budget, diamond-budget route, cut-height route, and parallel frontier route before any local-confluence consumer sees it.*

The frontier packet preserves obstruction rows. It does not export subject reduction, unrestricted Church–Rosser, evaluator equality, quotient syntax equality, global normalization, or kernel consistency.

Proof. Start with the normal-form obligation, Definition 5547.50. It places the endpoint after the candidate gate, residual-diamond row, and sibling confluence route, so the endpoint is never presented as an isolated normal form.

Apply obstruction retention and the normal-form budget theorem, Definition 5547.51 and Definition 5547.52. These rows keep the residual-substitution premise, residual-diamond row, cut-height budget, parallel frontier route, and sibling confluence route attached to the same finite handoff packet.

Next use the diamond-budget and cut-height routes, Definition 5547.44 and Definition 5547.46. They expose bounded local peak, join-budget, and cut-height data as visible frontier coordinates rather than as hidden global confluence assumptions.

Finally apply the parallel-diamond frontier route, Definition 5547.73. Together with the sibling confluence route, it leaves the residual and frontier rows visible when the endpoint is consumed as local confluence evidence. Since the carrier has no coordinate for subject reduction, unrestricted Church–Rosser, evaluator equality, quotient syntax equality, global normalization, or kernel consistency, the endpoint remains a finite obstruction-preserving frontier read. □

Theorem 4737.55 (MetaCIC candidate normalization normal-form obligation route)**.** *Every normal-form endpoint read exported by a* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *carrier must pass through the candidate gate, residual-diamond retention, cut-height budget, parallel-diamond frontier route, sibling confluence route, and local* NameCert *rows before it can be used as confluence-facing evidence. The route retains the residual and frontier evidence attached to the endpoint; it does not export subject reduction, unrestricted Church–Rosser, evaluator equality, quotient syntax equality, global normalization, or kernel consistency.*

Proof. Start with the normal-form obligation of Definition 5547.50. It places every endpoint downstream of the candidate gate, residual-diamond row, and sibling confluence route before any consumer can read it.

Apply obstruction retention, Definition 5547.51. The retained residual-substitution premise, candidate diamond dependency, cut-height budget, and parallel frontier route remain attached to the endpoint instead of being discharged by the normal-form read.

Finally use the normal-form budget theorem Definition 5547.52. It keeps the cut-height budget, parallel-diamond frontier surface, sibling confluence route, and local naming rows visible before the endpoint is treated as confluence-facing evidence. Since none of the cited rows contains subject reduction, unrestricted Church–Rosser, evaluator equality, quotient syntax equality, global normalization, or kernel consistency, the read exports only the retained finite obligation route. □

Theorem 4737.56 (MetaCIC retained-premise normal-form handoff)**.** *Every strong-normalization-facing consumer of the normal-form endpoint exported by an accepted* MetacicCandidateNormalizationConfluenceHan *packet must retain the candidate gate, the residual-diamond retention row, the decidable-boundary row, and the sibling confluence route. The consumer may read the bounded normal-form endpoint only as a finite handoff through those rows; it does not receive candidate-free normalization, quotient syntax equality, host evaluator soundness, unrestricted subject reduction, global confluence, or closed consistency.*

Proof. Apply the normal-form obligation of Definition 5547.50. It forces a normal-form read through the candidate-normalization row, residual row, and sibling confluence route before the endpoint is available.

Next use residual-diamond retention from Definition 5547.6. That row keeps the residual envelope, decidable boundary, and blocked-edge data visible while the endpoint is treated as a confluence-facing read.

The diamond-budget route of Definition 5547.44 supplies the bounded local peak and join-budget rows. These are the finite rows that a strong-normalization-facing consumer may inspect; they do not discharge the candidate gate or replace it with a global normalization theorem.

Finally apply the sibling confluence route of Definition 5547.89. It keeps the critical-path, normalization-frontier, confluence-audit, and parallel-diamond residual surfaces visible before the handoff reaches a consumer. Hence the endpoint remains a retained-premise normal-form handoff and no candidate-free normalization or quotient syntax equality is exposed. □

Theorem 4737.57 (MetaCIC candidate-normalization residual budget)**.** *Any normal-form endpoint exported by an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet to a strong-normalization-facing consumer must retain, before the endpoint is read, the candidate evidence, residual-diamond retention row, decidable-boundary data, blocked-edge rows, bounded local peak rows, join-budget rows, and the sibling confluence route. The endpoint is therefore a finite residual-budget read, not candidate-free normalization, global confluence, unrestricted subject reduction, quotient syntax equality, evaluator soundness, or closed consistency.*

Proof. Start with the normal-form obligation of Definition 5547.50 and the retained-premise handoff of Definition 5547.56. Together they force candidate evidence and the sibling confluence route to remain visible before a normal-form endpoint is exported.

Use residual-diamond retention from Definition 5547.6. It keeps the residual envelope, decidable-boundary data, and blocked-edge rows attached to the endpoint read rather than allowing a detached normal-form token.

Finally apply the diamond-budget route of Definition 5547.44. Its bounded local peak and join-budget rows are the finite budget a strong-normalization-facing consumer may inspect. Since the cited rows exhaust the exported endpoint surface, none of candidate-free normalization, global confluence, unrestricted subject reduction, quotient syntax equality, evaluator soundness, or closed consistency is supplied. □

Theorem 4737.58 (MetaCIC candidate-normalization residual exhaustion)**.** *Every accepted* MetacicCandidateNorm *handoff row whose candidate set, bounded local peak, join-budget row, residual envelope, decidable-boundary row, blocked-edge row, transport, replay, provenance, and local* NameCert *are displayed has an exhaustive finite endpoint surface. It either forwards a retained premise through the candidate and normalization frontier rows, or emits the blocked residual edge as an obstruction. No consumer may erase that obstruction and read global confluence, unrestricted subject reduction, quotient syntax equality, closed consistency, or a candidate-free normal-form theorem.*

Proof. Project the displayed handoff carrier from the parent chapter. The candidate set, frontier rows, residual envelope, decidable boundary, blocked-edge row, transport, replay, provenance, and local naming data are the only rows available to the consumer.

Apply the residual budget theorem Definition 5547.57. It requires the candidate evidence, residual-diamond retention, decidable-boundary data, blocked-edge rows, bounded local peak rows, join-budget rows, and sibling confluence route to remain visible before any endpoint is exported.

Now read the displayed forward-or-blocked row as finite data. In the forward case the retained premise is carried through the candidate and frontier rows. In the blocked case the residual edge remains an obstruction attached to the endpoint read. The carrier's refused endpoints exclude candidate-free normalization, global confluence, unrestricted subject reduction, quotient syntax equality, closed consistency, and any consumer route that erases the obstruction. □

Theorem 4737.59 (MetaCIC candidate-normalization residual-join choice-free handoff)**.** *When an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet exposes finite residual budget exhaustion and a displayed local-confluence certificate route, the residual-join endpoint is read as a finite handoff row. The endpoint is not a selected global normal form: it remains attached to the candidate evidence, normal-form obligation, residual budget, residual exhaustion surface, local confluence certificate route, transport, replay, provenance, and local* NameCert *rows.*

Proof. Start with the normal-form obligation of Definition 5547.50. It keeps candidate evidence and the sibling confluence route visible before any endpoint is public.

Apply the residual budget theorem, Definition 5547.57. The bounded local peak, join-budget, residual-diamond retention, decidable-boundary, and blocked-edge rows remain finite budget data rather than a choice of global normal form.

Now use residual exhaustion, Definition 5547.58. The forward case carries the retained premise through the candidate and frontier rows, while the blocked case keeps the residual edge as an obstruction attached to the endpoint.

Finally read the local confluence certificate route through the sibling confluence surface already cited by the normal-form and residual-budget rows. Since the endpoint is assembled only from those displayed rows and the structural transport, replay, provenance, and naming data, it is a choice-free residual-join handoff. □

Definition 4737.60 (Normalization-confluence bridge carrier)**.** *A normalization-confluence bridge carrier for* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *is a finite* BHist *packet*

$$B = (A, K, N, J, Q, D, O, H, C, P, L)$$

with the following displayed rows:

1. *A is the MetaCIC audit anchor for the closed typed term boundary.*
2. *K is the candidate-normalization evidence row used to expose candidate-mediated strong normalization data.*
3. *N is the bounded normal endpoint row reached from K.*
4. *J is the residual local-join budget row, recording only the bounded join checks available at the confluence frontier.*
5. *Q is the closed checker row that verifies the finite term and type boundary before any endpoint or join row is consumed.*
6. *D is the obstruction row retaining failed residual edges and blocked comparisons.*
7. *O records componentwise* hsame *transport for the audit anchor, candidate evidence, endpoint, join budget, closed checker, obstruction, replay, provenance, and local naming rows.*
8. *H records displayed* Cont *replay through $A, K, N, J, Q, D, O, P, L$.*
9. *C is the* Pkg *provenance over* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ $\mathsf{MetaCICDecidableBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *P is the local public-route packet row for the bounded bridge budget.*
11. *L is the local* $\mathsf{NameCert}$ *row.*

The carrier has no coordinate for full confluence, unrestricted subject reduction, evaluator equality, quotient syntax equality, global conversion decidability, host evaluator soundness, or kernel consistency.

Theorem 4737.61 (Normalization-confluence bridge obligations)**.** *Every accepted normalization-confluence bridge carrier exposes candidate-mediated strong-normalization evidence and bounded local confluence rows only through*

$$A, K, N, J, Q, D, O, H, C, P, L.$$

The candidate row K may feed the bounded endpoint row N, and the residual local-join budget J may feed the confluence frontier only after the closed checker Q and obstruction row D remain

visible. The bridge does not prove full confluence, unrestricted subject reduction, evaluator equality, quotient syntax equality, global conversion decidability, host evaluator soundness, or kernel consistency.

Proof. Project the bridge carrier. The only normalization-facing rows are the audit anchor A, candidate evidence K, bounded endpoint N, residual local-join budget J, closed checker Q, and obstruction row D.

Use the candidate-normalization handoff boundary of Definition 5547.3. It keeps candidate evidence and frontier data visible before bounded endpoint or residual rows can be consumed.

Apply residual-diamond retention and decider-boundary routing from Definition 5547.6 and Definition 5547.21. These force J, Q, D to remain finite frontier rows rather than global confluence or subject-reduction evidence.

Finally read the structural rows O, H, C, P, L. They transport, replay, package, route, and name the same bounded bridge budget, so a consumer receives candidate-mediated normalization and local confluence frontier data without extracting any refused global MetaCIC endpoint. □

Theorem 4737.62 (MetaCIC candidate typed-diamond route)**.** *Every typed-diamond consumer of a* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *bridge carrier must retain candidate evidence, the closed checker, the residual local-join budget, the decidable boundary, and blocked-edge rows before consuming bounded endpoints. The route may pass through residual-diamond and parallel-diamond sibling frontiers, but it refuses full Church–Rosser, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, and kernel consistency.*

Proof. Project the bridge carrier of Definition 5547.60. Its candidate evidence row K, bounded endpoint row N, residual local-join budget J, closed checker row Q, obstruction row D, and structural rows O, H, C, P, L are separate coordinates.

Invoke the bridge obligations of Definition 5547.61. They force candidate evidence and bounded local confluence rows to remain visible, and they place the closed checker and obstruction row before endpoint or join rows are consumed.

Route the typed-diamond read through residual-diamond retention, Definition 5547.6. This keeps the residual envelope, decidable boundary, and blocked-edge data attached to the endpoint comparison rather than letting N stand alone.

Finally use the parallel-diamond forward link, Definition 5547.1. It sends the consumer through the parallel-diamond frontier as a guarded boundary route. The structural rows then transport, replay, source, and name only this bounded route, so no full Church–Rosser theorem, unrestricted subject-reduction proof, quotient syntax equality, host evaluator soundness, or kernel-consistency endpoint is exported. □

Theorem 4737.63 (MetaCIC candidate handoff downstream route)**.** *Every public read of* MetacicCandidateNormal *is consumed by chapter 735 and chapter 4238 only after candidate evidence, residual-envelope visibility, decidable-boundary routing, and blocked-edge retention have been exposed in the same finite handoff packet. The downstream route also consumes the residual-diamond sibling chapter 5126 and the confluence-audit packet chapter 735 before exporting a bounded endpoint read. The route exports a downstream confluence dependency surface, not an unconditional strong-normalization theorem, full Church–Rosser theorem, unrestricted subject-reduction theorem, global conversion decider, quotient syntax equality, host evaluator soundness, or closed consistency.*

Proof. Start with the boundary theorem Definition 5547.3. It exposes the candidate row K, frontier row F, residual envelope C, decidable-boundary row D, and blocked-edge row B before any bounded endpoint or comparison row is consumed.

Apply premise exposure from Definition 5547.5. It prevents a confluence-facing consumer from reading the handoff unless the candidate evidence and residual boundary remain visible in the same packet.

Use residual-diamond retention, Definition 5547.6, to route the downstream read through the parallel-diamond frontier. The frontier receives only the retained residual-diamond handoff, not a global confluence theorem.

Finally apply normal-endpoint readback, Definition 5547.8. The confluence audit packet may consume the bounded endpoint only after C, D, B, T, R, P, L remain visible. Thus both downstream chapters read the same candidate-mediated handoff route and no excluded global endpoint is exported. □

Theorem 4737.64 (MetaCIC candidate-mediated confluence route)**.** *Any confluence-facing consumer of a* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *packet must first read candidate evidence, residual-envelope visibility, decidable-boundary routing, blocked-edge retention, and normal-endpoint readback. Only after those rows remain visible may the consumer pass the bounded route to chapter 735 or chapter 4238. The route does not claim strong normalization, full Church–Rosser, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, or closed consistency.*

Proof. Start with Definition 5547.63. It already routes candidate evidence, residual-envelope visibility, decidable-boundary routing, and blocked-edge retention to the confluence audit and parallel-diamond frontier consumers.

Apply premise exposure from Definition 5547.5. A confluence-facing consumer cannot read the bounded endpoint before the candidate and residual boundary rows remain displayed in the same packet.

Use residual-diamond retention from Definition 5547.6. It keeps the residual envelope and blocked-edge rows on the route that is handed to the parallel-diamond frontier.

Finally apply normal-endpoint readback from Definition 5547.8. The endpoint is therefore bounded by the visible rows C, D, B, T, R, P, L, so the exported route is a candidate-mediated confluence audit surface rather than any of the refused global MetaCIC endpoints. □

Theorem 4737.65 (MetaCIC candidate residual-obstruction retention)**.** *Every confluence-facing endpoint read of a* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *packet must retain candidate evidence, the residual envelope, the decidable-boundary row, the blocked-edge row, and normal-endpoint readback before any bounded route is exported to MetaCIC confluence consumers. The exported route is therefore a retained obstruction surface through the candidate packet, not an unrestricted Church–Rosser theorem, subject-reduction theorem, quotient syntax equality, evaluator soundness claim, or closed-consistency endpoint.*

Proof. Start with the downstream route of Definition 5547.63. It exposes candidate evidence, residual-envelope visibility, decidable-boundary routing, and blocked-edge retention in the same finite packet before either confluence consumer can read the handoff.

Apply premise exposure from Definition 5547.5. A bounded endpoint is not available to a confluence-facing consumer unless the candidate evidence and residual boundary remain visible.

Use residual-diamond retention from Definition 5547.6. This keeps the residual envelope and blocked-edge row attached to the route that reaches the parallel-diamond frontier.

Finally apply normal-endpoint readback from Definition 5547.8 and then the confluence route of Definition 5547.64. The endpoint readback is exported only with the retained rows, so the consumer receives a bounded obstruction route and none of the excluded global MetaCIC conclusions. □

Theorem 4737.66 (MetaCIC candidate normalization orphan route)**.** *Public reads of* MetacicCandidateNormalizati *pass to chapter 735 and chapter 4238 only after candidate evidence, residual-envelope visibility, decidable-boundary routing, blocked-edge retention, and normal-endpoint readback remain displayed in the same handoff packet. The route is a concrete downstream dependency theorem for the confluence lattice; it does not export a global Church–Rosser theorem, strong-normalization theorem, unrestricted subject-reduction theorem, quotient syntax equality, evaluator soundness claim, or closed-consistency endpoint.*

Proof. First apply the boundary theorem Definition 5547.3. It places the candidate row, frontier row, residual envelope, decidable-boundary row, and blocked-edge row upstream of every bounded endpoint read.

Next use premise exposure from Definition 5547.5. This keeps candidate evidence and residual-envelope visibility displayed before either downstream consumer may read the handoff.

Then apply residual-diamond retention from Definition 5547.6. The retained residual envelope and blocked-edge row are exactly the rows required by the parallel-diamond frontier.

Finally use normal-endpoint readback from Definition 5547.8, together with Definition 5547.65. The confluence audit packet and parallel-diamond frontier therefore receive a displayed candidate-mediated dependency route, not any of the refused global MetaCIC conclusions. □

The candidate-normalization confluence handoff reads the parallel-diamond frontier of chapter 4238 through the local candidate-diamond-budget and residual-frontier siblings before any handoff row is made public. It also consumes chapter 765 as the critical-path source that fixes the typed-window and residual-frontier rows before the parallel-diamond frontier is read. This route keeps candidate evidence, residual-envelope visibility, decidable-boundary rows, and blocked-edge retention visible inside the finite MetaCIC packet.

Theorem 4737.67 (MetaCIC candidate normalization handoff obligations)**.** *Every candidate-normalization confluence handoff read factors through* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$*, the candidate-diamond-budget route, and the residual-frontier route siblings before any confluence handoff row is public. The handoff may then expose candidate evidence, bounded endpoint data, residual-envelope visibility, decidable-boundary routing, blocked-edge retention, transport, replay, provenance, and local naming, but it cannot bypass those frontier siblings.*

Proof. Project the handoff carrier of Definition 5547.2. Its public rows record candidate evidence, bounded endpoint data, residual confluence data, decidable-boundary data, blocked-edge retention, transport, replay, provenance, and local naming.

Use the local candidate-diamond-budget route and residual-frontier route siblings. The former exposes bounded local-peak and join-budget rows before a closed-normal endpoint is consumed, while the latter keeps the parallel-diamond frontier visible before a confluence-facing handoff is exported.

The candidate-normalization side also consumes the normalization audit map of chapter 9383; that map supplies the candidate-mediated SN budget before residual confluence visibility is exposed.

Finally read chapter 4238 as the upstream frontier surface. Since the carrier has no row that makes the handoff public without those sibling routes, every accepted read factors through the displayed frontier dependency before presenting confluence handoff data. □

Theorem 4737.68 (MetaCIC parallel frontier residual-bridge consumption)**.** *Any residual-diamond bridge read of an accepted* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *packet must first expose the candidate diamond budget, cut-height budget,* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *route,* MetaCICParallelDiamondFrontier

dependency, residual frontier reverse dependency, and seed obligation boundary. The bridge may then consume the finite rows $K, F, C, D, B, T, R, P, L$ only while residual-substitution premises remain visible; it cannot be read as subject reduction, evaluator equality, quotient term equality, global normalization, unrestricted confluence, or kernel consistency.

Proof. Begin with the candidate diamond budget route of Definition 5547.44 and the cut-height budget route of Definition 5547.46. These expose bounded local peaks, join-budget rows, normalization-frontier data, residual confluence data, decidable-boundary data, and blocked-edge retention before an endpoint-facing read is available.

Next read the critical-path and frontier routes. The MetaCIC critical-path handoff of Definition 5547.48 fixes the upstream audit direction, while the parallel-diamond frontier route of Definition 5547.73 keeps the residual-substitution premise, candidate-join row, bounded-check row, obstruction row, transport, replay, provenance, and local naming visible.

Use the residual frontier reverse dependency and the seed obligation boundary. The reverse dependency keeps the parallel frontier as dependency data rather than as an isolated conclusion, and Definition 5547.85 exposes $K, F, C, D, B, T, R, P, L$ before bounded endpoint consumption.

Finally consume the residual-diamond bridge route. Since the bridge reads only the displayed residual-diamond dependency surface and the carrier has no coordinate for subject reduction, evaluator equality, quotient term equality, global normalization, unrestricted confluence, or kernel consistency, every accepted bridge read retains the stated premises before any confluence endpoint is consumed. □

Theorem 4737.69 (MetaCIC candidate confluence orphan route)**.** *Every accepted* MetacicCandidateNormalizationC *read that exports the normalization/confluence bridge route first consumes the residual-frontier rows of chapter 4238. The consumed rows are the retained residual-substitution premise, critical-pair row, candidate-join row, residual-frontier row, closed-checker row, closed-normal fragment row, bounded-check row, obstruction row, transport, replay, provenance, and local naming surface; the handoff does not export subject reduction, unrestricted confluence, evaluator equality, quotient term equality, residual-substitution discharge, or kernel consistency.*

Proof. Project the handoff carrier of Definition 5547.2. Its candidate, bounded endpoint, residual confluence, decidable-boundary, blocked-edge, transport, replay, provenance, and local naming rows can be read only as a finite handoff packet.

Next read the upstream frontier through chapter 4238. That chapter displays the retained premise row P, critical-pair row K, candidate-join row J, residual-frontier row R, checker rows S, C, B, obstruction row O, and structural rows H, T, G, N before a confluence-facing consumer can inspect the local-diamond handoff.

Finally combine this frontier read with the existing bridge-budget route of Definition 5547.68. The bridge route consumes exactly the displayed residual-frontier dependency before exporting normalization/confluence data, so the handoff remains inside the finite dependency lattice and none of the refused global endpoints is exposed. □

Parallel-diamond dependency route. The candidate-normalization confluence handoff consumes chapter 4238 for the residual critical-pair windows that remain visible before any confluence handoff row is exposed. The frontier packet supplies the typed local-join boundary and residual-budget ledger, while the handoff packet only routes candidate normalization, normal endpoints, blocked edges, transport, replay, provenance, and local naming through that boundary. Hence the handoff may advertise a confluence-facing row only after the parallel-diamond frontier has fixed

the residual window and excluded full confluence, subject reduction, evaluator equality, quotient syntax equality, and closed consistency.

Theorem 4737.70 (MetaCIC candidate-normalization handoff parallel-diamond dependency)**.** *Every accepted* MetaCICCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *read that consumes the parallel-diamond frontier of chapter 4238 does so only through the displayed critical-pair row, residual-join row, candidate-normalization row, bounded-check row, obstruction row, componentwise transport, replay, provenance, and local* NameCert *rows. The route is a finite sibling dependency on* MetaCICParallelDiamondFrontier$^{\uparrow}$*, not a duplicate confluence theorem, subject-reduction theorem, evaluator equality, quotient syntax equality, residual-substitution discharge, or kernel-consistency claim.*

Proof. Read the handoff carrier through its displayed candidate-normalization and bounded endpoint rows. A confluence-facing consumer cannot inspect the handoff before the critical-pair and residual-join rows supplied by chapter 4238 have fixed the frontier boundary.

Next preserve the bounded-check and obstruction rows. These rows keep failed residual-substitution, blocked-edge, and closedness obligations visible as retained data rather than discharging them into a global parallel-diamond result.

Finally transport the same route through the componentwise hsame data, displayed replay, provenance, and local NameCert row. Since no coordinate exports full confluence, subject reduction, evaluator equality, quotient syntax equality, residual-substitution discharge, or kernel consistency, the dependency is exactly the finite sibling route stated above. □

Theorem 4737.71 (MetaCIC candidate-normalization handoff forward link)**.** *Every* MetaCICCandidateNormalizati *consumer that exports a residual join to MetaCIC normalization consumers must first display the parallel-diamond frontier of chapter 4238 or the residual-frontier route carried by that frontier. Only after the candidate evidence, residual-envelope row, decidable-boundary row, blocked-edge ledger, transport row, replay row, provenance row, and local* NameCert *row have been read through that frontier may the confluence handoff be public.*

Proof. Read the handoff carrier of Definition 5547.2. Its confluence-facing rows are candidate evidence, bounded endpoint data, residual envelope, decidable boundary, blocked-edge retention, and the structural transport, replay, provenance, and naming rows.

Use the residual-diamond retention theorem Definition 5547.6. It keeps candidate evidence, residual envelope, decidable boundary, and blocked-edge rows visible before any bounded endpoint is treated as joinable.

The sibling routes in this hub then point the retained residual data to chapter 4238. That frontier is the public place where the residual-frontier route and local parallel-diamond budget are displayed.

Since the carrier has no coordinate for a public confluence handoff detached from those rows, any consumer exporting a residual join must pass through the frontier route before the handoff is public. □

Every candidate-normalization confluence handoff consumer must read the residual diamond and local-join data through chapter 4238 before exporting a confluence-facing handoff. The MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ packet therefore presents bounded endpoint, residual-envelope, decidable-boundary, blocked-edge, transport, replay, provenance, and local naming rows only after the parallel-diamond frontier has supplied the displayed residual-diamond and local-join surface.

Theorem 4737.72 (Parallel-diamond frontier dependency bridge)**.** *Every accepted* MetaCICCandidateNormalizatio*n carrier reads the residual join route through chapter 4238 before it exports a normalization-confluence budget to a downstream candidate-normalization consumer.*

Proof. The handoff carrier already exposes candidate-normalization, residual-join, and confluence-budget rows through its sibling route files. The parallel-diamond frontier is the only displayed sibling that licenses the residual join as a diamond-facing dependency rather than as an isolated normalization claim.

Thus the confluence budget is exported only after the residual join has passed through the parallel-diamond frontier route. No kernel-only or local-normalization row can stand in for that horizontal dependency. □

Theorem 4737.73 (Candidate normalization handoff parallel-diamond frontier route)**.** *Any* MetaCICCandidateNor*consumer that exports a local diamond budget must first cite chapter 4238. The export preserves the residual-substitution premise, candidate-join row, bounded-check row, obstruction row, transport row, replay row, provenance row, and local* NameCert *row before the handoff may be read as a frontier-facing diamond route.*

Proof. Read the existing parallel-diamond dependency route for the handoff. It places the candidate-normalization budget on the same finite route as the frontier packet rather than on a global confluence theorem.

The cited frontier chapter supplies the public location for that route. A consumer that exports a local diamond budget therefore reaches the frontier only after preserving the residual-substitution premise, candidate join, bounded check, obstruction, transport, replay, provenance, and local naming rows.

Thus the handoff is a displayed dependency through MetaCICParallelDiamondFrontier$^{\uparrow}$. It does not export unrestricted residual substitution, global Church–Rosser, evaluator equality, quotient term equality, or kernel consistency. □

Theorem 4737.74 (MetaCIC candidate normalization parallel-diamond frontier seed dependency)**.** *Before any* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *read may use the parallel frontier of chapter 4238, it must consume the residual-substitution premise, critical-pair row, candidate-join row, bounded-check row, and obstruction row exposed by that sibling. The handoff route then reads its bounded endpoint, residual envelope, decidable-boundary, blocked-edge, transport, replay, provenance, and local naming rows as downstream data rather than as a replacement for the parallel-diamond frontier seed surface.*

Proof. Read the parallel-diamond frontier chapter first. Its seed surface keeps the residual-substitution premise, critical-pair row, candidate-join row, bounded-check row, obstruction row, and structural NameCert rows visible before any local confluence-facing read is available.

Apply the handoff carrier and candidate diamond budget routes in this chapter. They expose bounded endpoint, residual-envelope, decidable-boundary, blocked-edge, transport, replay, provenance, and local naming rows only after the upstream frontier dependency has been displayed.

Finally compare the dependency order. Since the candidate-normalization handoff has no coordinate for discharging residual substitution or replacing the frontier obstruction row, every accepted read that uses chapter 4238 must keep those sibling rows ahead of the handoff read. □

Theorem 4737.75 (MetaCIC candidate-normalization orphan parallel-frontier route)**.** *Any confluence-facing read of* MetaCICCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *reaches the* MetaCICParallelDiamondFrontier$^{\uparrow}$

consumer of chapter 4238 through the candidate evidence row, residual-envelope row, decidable-boundary row, and blocked-edge row before bounded endpoint data is public. The route preserves transport, replay, provenance, and local NameCert *rows, and it exports no global confluence theorem, quotient term equality, evaluator equality, unrestricted residual substitution, or kernel consistency claim.*

Proof. Start with the handoff boundary surface. The carrier of Definition 5547.2 and the residual-diamond retention theorem keep candidate evidence, residual envelope, decidable boundary, and blocked-edge retention visible before any endpoint data is consumed.

Next apply the forward-link route of Definition 5547.71. It sends the retained residual data to the parallel-diamond frontier rather than to a detached confluence oracle.

Finally read the frontier consumer at chapter 4238. The transport, replay, provenance, and local naming rows remain attached to the same finite handoff, so the orphan-facing read is a sibling dependency on MetaCICParallelDiamondFrontier$^{\uparrow}$ and not an export of any excluded host theorem. □

Theorem 4737.76 (Candidate normalization retained frontier route)**.** *Every candidate-normalization confluence handoff that consumes a bounded local diamond must first read the retained-premise frontier of chapter 4238. In carrier notation the consumer reaches the handoff rows $K, F, C, D, B, T, R, P, L$ only after the sibling frontier has exposed the retained premise row, candidate-join row, residual-frontier row, bounded-check row, obstruction row, transport row, replay row, provenance row, and local* NameCert *row.*

The route is a finite candidate-normalization dependency. It does not supply residual-substitution discharge, subject reduction, full Church–Rosser, evaluator equality, quotient term equality, global normalization, or kernel consistency.

Proof. Start with the local handoff carrier of Definition 5547.2. Its rows $K, F, C, D, B, T, R, P, L$ expose candidate evidence, bounded endpoint data, residual-envelope visibility, decidable-boundary routing, blocked-edge retention, transport, replay, provenance, and local naming.

Next read the sibling frontier. The parallel-diamond frontier chapter supplies the retained-premise and candidate-join route consumed by this handoff, so the local diamond budget cannot be inspected until those frontier rows are visible.

Finally apply the existing parallel-diamond frontier route of Definition 5547.73. It keeps the residual-substitution premise, bounded-check row, obstruction row, transport, replay, provenance, and local naming attached to the candidate-normalization handoff. Therefore the new route is a child dependency through MetaCICParallelDiamondFrontier$^{\uparrow}$, not an independent confluence or kernel endpoint. □

Theorem 4737.77 (MetaCIC candidate normalization confluence handoff public export)**.** *The* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet may be exported publicly only as the finite route through* MetaCICCriticalPath$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, MetaCICParallelDiamondFrontier$^{\uparrow}$, *the residual join budget,* MetaCICDecidableBoundary$^{\uparrow}$, *blocked-edge retention, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. For an accepted handoff carrier $H = (A, K, N, F, C, D, B, T, R, P, L)$, any public read must keep candidate evidence, bounded endpoint data, residual-envelope visibility, decidable-boundary routing, blocked-edge data, transport, replay, provenance, and local naming visible before the endpoint row is consumed.*

The exported route is not global strong normalization, full Church–Rosser, unrestricted subject reduction, quotient syntax equality, evaluator equality, global conversion decidability, or closed consistency.

Proof. Project the carrier of Definition 5547.2. Its public rows are $A, K, N, F, C, D, B, T, R, P, L$, so a public export starts from the audit anchor, candidate evidence, bounded endpoint, frontier row, residual confluence row, decidable boundary, blocked edge, transport, replay, provenance, and local name.

Use the boundary and candidate handoff routes. The boundary theorem Definition 5547.3 keeps candidate evidence and normalization-frontier data visible before endpoint consumption, while Definition 5547.45 sends the same packet through $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$, residual join scope, and candidate-normalization budget rows.

Next apply the residual budget and route-factorization surfaces, Definition 5547.57 and Definition 5547.83. They force every residual join or parallel-diamond read to retain the bounded budget, decidable boundary, and blocked-edge rows rather than replacing them by a global confluence theorem.

Finally read T, R, P, L. Componentwise transport, displayed replay, package provenance, and local naming preserve the finite route already displayed by the sibling theorems. Since no carrier coordinate stores global strong normalization, full Church–Rosser, unrestricted subject reduction, quotient syntax equality, evaluator equality, global conversion decidability, or closed consistency, the only public export is the stated finite route. □

The candidate-normalization confluence handoff consumes the parallel-diamond frontier of chapter 4238 through the displayed residual-join, critical-pair, and candidate-diamond rows before any confluence-facing endpoint is read. In carrier terms, the $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ packet may route its candidate evidence, residual envelope, decidable-boundary row, blocked-edge ledger, transport, replay, provenance, and local $\mathsf{NameCert}$ onward only while the sibling frontier still exposes its residual-substitution premise, local critical-pair surface, candidate join, bounded checker rows, and obstruction row. The bridge is therefore a finite residual-diamond dependency route, not subject reduction, unrestricted Church–Rosser, quotient syntax equality, evaluator equality, global conversion decidability, or kernel consistency. The candidate-normalization confluence handoff consumes the residual-frontier and finite candidate-diamond rows before it exposes its local confluence route. In particular, chapter 4238 supplies the parallel frontier surface that the handoff reads as dependency data rather than as an isolated conclusion.

Theorem 4737.78 (MetaCIC candidate-normalization residual-join frontier)**.** *An accepted* $\mathsf{MetacicCandidateNorma}$ *handoff may consume a residual-join frontier only after the candidate set, normalization window, residual-substitution row, join-locality row, and strong-normalization handoff have all been displayed. The frontier read remains a finite route through the candidate-normalization carrier, residual-substitution boundary, local join ledger, bounded normal-form endpoint,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*; it is not global Church–Rosser, unrestricted subject reduction, quotient syntax equality, evaluator soundness, or kernel consistency.*

Proof. Project the carrier of Definition 5547.2. Its candidate evidence, bounded endpoint, residual envelope, decidable-boundary route, blocked-edge row, transport, replay, provenance, and local naming rows are visible before any frontier read is public.

Read the candidate and window rows first. The candidate set supplies the finite normalization candidates, and the normalization window fixes the bounded endpoint at which a residual join can be inspected.

Next consume the residual-substitution and join-locality rows. The residual-substitution boundary keeps substitutions attached to the displayed residual envelope, while the local join ledger keeps the join inside the candidate window rather than a host equality space.

Finally attach the strong-normalization handoff. It makes the bounded normal endpoint available to the confluence-facing consumer without erasing the candidate, window, substitution, and locality rows. Since the carrier has no coordinate for global Church–Rosser, subject reduction, quotient syntax equality, evaluator soundness, or kernel consistency, the frontier read is exactly the finite route stated above. □

Theorem 4737.79 (MetaCIC candidate normalization residual-join scope)**.** *An accepted* MetacicCandidateNormaliz *candidate-normalization handoff may expose residual joins only after it has read the candidate diamond budget, the cut-height budget, the frontier dependency route, and the residual diamond bridge route. The resulting scope is the finite route through MetaCIC candidate rows, residual windows, candidate joins,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*; it is not an unscoped global confluence claim.*

Proof. Project the parent carrier of Definition 5547.2. Its visible rows already separate candidate evidence, bounded endpoint data, residual confluence routing, decidable-boundary routing, blocked-edge retention, transport, replay, provenance, and local naming.

Read the budget rows next. The candidate diamond route of Definition 5547.44 fixes the bounded peak and join-budget surface, while the cut-height route of Definition 5547.46 fixes the height boundary before a residual endpoint can be consumed.

Finally read the frontier and residual-diamond routes. The residual-frontier dependency and the bridge route of chapter 4238 keep residual windows and candidate joins attached to the displayed BHist, hsame, Cont, Pkg, and NameCert rows. Since no carrier coordinate stores global confluence, quotient syntax equality, evaluator equality, or kernel consistency, the handoff exposes only the scoped residual-join route stated above. □

Theorem 4737.80 (MetaCIC residual normal-form endpoint budget)**.** *Every accepted* MetacicCandidateNormalizat *normal-form endpoint read that is used as residual-join evidence must retain the candidate row, bounded endpoint row, candidate diamond budget, cut-height budget, residual diamond bridge route, and parallel-diamond frontier route before local confluence evidence is consumed. The retained surface is a finite route through the candidate-normalization carrier and its sibling frontier packets; it is not global Church–Rosser, unrestricted subject reduction, quotient syntax equality, evaluator soundness, or kernel consistency.*

Proof. Project the residual-join scope of Definition 5547.79. A residual-join consumer enters through the candidate-normalization carrier, so the candidate row and bounded endpoint row remain visible before the endpoint can count as evidence.

Read the budget rows next. The diamond-budget route of Definition 5547.44 supplies the candidate diamond budget, and the cut-height route of Definition 5547.46 supplies the bounded endpoint height discipline.

Now attach the sibling frontier routes. The residual diamond bridge route keeps the residual bridge row in scope, while Definition 5547.73 keeps the parallel-diamond frontier route visible before a local confluence consumer can read the endpoint as join evidence.

Since the named rows are all finite carrier or sibling-route data, consuming local confluence evidence cannot erase them. The handoff has no coordinate for global Church–Rosser, unrestricted subject reduction, quotient syntax equality, evaluator soundness, or kernel consistency, so the endpoint remains a guarded residual normal-form budget rather than an unscoped confluence theorem. □

Theorem 4737.81 (MetaCIC candidate normalization residual-join locality scope)**.** *Any* MetacicCandidateNormali *confluence handoff that exports residual-join data must first display the* MetaCICCriticalPath$^{\uparrow}$ *source*

row, the residual-join locality row, and the MetaCICParallelDiamondFrontier$^{\uparrow}$ *boundary row. A confluence consumer may read the handoff only after these rows have been kept in the finite* BHist, hsame, Cont, Pkg, *and* NameCert *route; it cannot treat candidate-normalization evidence as global Church–Rosser, unrestricted residual-substitution compatibility, subject reduction, quotient syntax equality, evaluator soundness, or kernel consistency.*

Proof. Start from the handoff carrier of Definition 5547.2. Its candidate evidence, bounded endpoint, residual envelope, decidable boundary, blocked edge, transport, replay, provenance, and local naming rows remain visible before a confluence-facing consumer reaches any endpoint.

Read the local sibling routes next. The critical-path and frontier route of Definition 5547.48 exposes MetaCICCriticalPath$^{\uparrow}$, while Definition 5547.79 keeps residual joins scoped by candidate rows, residual windows, transport, replay, provenance, and local naming.

Finally use Definition 5547.73 together with chapter 4238. The parallel-diamond frontier supplies the boundary row that a confluence consumer must see before reading the handoff, so the exported route remains a finite residual-join locality handoff rather than any of the excluded global MetaCIC claims. □

Theorem 4737.82 (MetaCIC candidate normalization residual-matrix forward route)**.** *Every* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *handoff consumed by chapter 8134 must first display candidate evidence, the normalization frontier, the residual envelope, the decidable boundary, the blocked edge, componentwise transport, displayed replay, provenance, and local naming rows. The residual-join matrix therefore reads the handoff only after the finite route through the carrier of Definition 5547.2; it does not receive global Church–Rosser, unrestricted subject reduction, evaluator soundness, quotient syntax equality, or kernel consistency.*

Proof. Project the candidate-normalization handoff carrier. The candidate evidence row, normalization-frontier row, residual-envelope row, decidable-boundary row, and blocked-edge row are visible before any structural row is replayed.

Next route the matrix consumer through the existing residual scope. The residual-join scope and residual budget exactness results keep the candidate, frontier, residual, boundary, and blocked-edge rows attached to the same finite packet.

Finally read transport, replay, provenance, and local naming. These rows preserve the displayed handoff into chapter 8134, so the matrix consumer receives a guarded child dependency route rather than an unscoped confluence theorem. □

Theorem 4737.83 (MetaCIC candidate normalization confluence handoff route factorization)**.** *Every accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet consumed by the* MetaCICParallelDiamondF *route or by the normalization-confluence bridge must first expose the residual-budget factorization row of Definition 5547.92. The factorization keeps the candidate evidence, normal endpoint, frontier row, residual confluence row, decidable boundary, blocked edge, transport, replay, provenance, and local name visible before the handoff reaches chapter 4238 or the residual-substitution boundary of chapter 2181. It does not claim full confluence, subject reduction, evaluator equality, quotient syntax equality, or closed consistency.*

Proof. Project the local residual-budget exactness theorem. It displays candidate evidence, the normal endpoint, frontier row, residual confluence row, decidable boundary, blocked edge, transport, replay, provenance, and local naming before any residual budget is read.

Compose that projection with the parallel-diamond frontier route. The frontier consumer may read the handoff only after the residual-budget factorization row has fixed the bounded endpoint and kept the residual-substitution premise visible.

The same displayed row is the local premise for the normalization-confluence bridge. Since the packet has no coordinate for full confluence, subject reduction, evaluator equality, quotient syntax equality, or closed consistency, route composition exports only the residual-budget factorization boundary. □

Theorem 4737.84 (MetaCIC candidate normalization confluence handoff critical-path consumption)**.** *Any* MetaCICCriticalPath$^{\uparrow}$ *or* MetaCICParallelDiamondFrontier$^{\uparrow}$ *consumer of an accepted* MetacicCandidateNor *packet must first read the residual-budget factorization row of Definition 5547.83. The consumed route keeps candidate evidence, normal endpoint, frontier row, residual confluence row, decidable boundary, blocked edge, transport, replay, provenance, and local name visible before the handoff is used by the critical path or the parallel-diamond frontier. It does not discharge full confluence, subject reduction, evaluator equality, quotient syntax equality, closed consistency, or residual-substitution.*

Proof. Start with the route factorization theorem. It forces the handoff to expose the residual-budget row before any downstream consumer can use the normalization-confluence boundary.

For a MetaCICCriticalPath$^{\uparrow}$ consumer, compose that factorization with the critical-path route. The critical path may retain the candidate evidence, normal endpoint, frontier row, residual confluence row, decidable boundary, blocked edge, transport, replay, provenance, and local name, but it cannot skip the residual-budget boundary.

For a MetaCICParallelDiamondFrontier$^{\uparrow}$ consumer, compose the same factorization with the parallel-diamond frontier route. The frontier read receives the handoff only after the residual-budget row has fixed the bounded endpoint and kept the residual-substitution premise visible.

The packet contains no carrier row for full confluence, subject reduction, evaluator equality, quotient syntax equality, closed consistency, or residual-substitution discharge. Therefore critical-path and frontier consumption preserve exactly the retained-premise boundary supplied by the handoff. □

Theorem 4737.85 (MetaCIC candidate handoff seed obligations)**.** *Every seed-obligation read of an accepted* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet exposes candidate evidence K, normalization frontier F, residual envelope C, decidable boundary D, blocked edge B, componentwise transport T, displayed replay R, provenance P, and local* NameCert *row L before bounded endpoint consumption. The read remains a finite handoff boundary and does not assert unconditional strong normalization, full Church–Rosser, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, or closed consistency.*

Proof. Start with the handoff boundary of Definition 5547.3. It exposes candidate evidence and frontier data before endpoint consumption, keeps the residual and blocked-edge rows visible, and routes bounded comparison through the decidable-boundary row.

Use seed closure and premise exposure from Definition 5547.4 and Definition 5547.5. These theorems force K, F, C, D, B to remain displayed before a confluence-facing or decidability-facing consumer reaches N.

Finally apply decider-row exhaustion from Definition 5547.22. The structural rows T, R, P, L preserve the same finite packet, so the bounded endpoint is consumed only after the seed-obligation rows have been exposed. □

Theorem 4737.86 (MetaCIC candidate handoff induction)**.** *Induction over the displayed row order*

$$K, F, C, D, B, T, R, P, L$$

preserves candidate evidence, residual-envelope visibility, and decidable-boundary exposure before any endpoint row N is consumed. Hence the handoff remains finite-row evidence for the accepted MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *packet and exports no unconditional strong normalization, Church–Rosser theorem, subject reduction theorem, quotient syntax equality, evaluator soundness theorem, or closed consistency principle.*

Proof. Project the accepted carrier through the handoff boundary of Definition 5547.3. The row order starts with candidate evidence K and normalization frontier F, so the induction base already exposes the candidate surface before any residual or endpoint-facing read.

For the residual step, use premise exposure from Definition 5547.5. Adding C, D, B keeps the residual envelope, decidable boundary, and blocked edge as displayed rows rather than hidden assumptions, and decider-row exhaustion from Definition 5547.22 keeps D finite before endpoint consumption.

For the structural step, apply the seed obligations of Definition 5547.85. The rows T, R, P, L only transport, replay, package, and locally name the same displayed packet, so they preserve the candidate evidence and the residual-envelope boundary already exposed by the earlier rows.

Thus every prefix of $K, F, C, D, B, T, R, P, L$ keeps the relevant evidence visible before N. Since the endpoint row is not consumed during the induction, none of the excluded global metatheorems or host evaluator conclusions is exported. □

Theorem 4737.87 (MetaCIC candidate residual handoff scope)**.** *Every accepted* MetacicCandidateNormalizationCo *packet routes residual-envelope data C and blocked-edge data B through candidate evidence K, normalization frontier F, decidable boundary D, componentwise transport T, displayed replay R, provenance P, and local* NameCert *row L before any bounded endpoint consumption. The route remains a residual handoff scope and does not assert full Church–Rosser, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, or closed consistency.*

Proof. Begin with the seed obligations of Definition 5547.85. They expose $K, F, C, D, B, T, R, P, L$ before endpoint consumption, so residual-envelope and blocked-edge data are visible rows rather than hidden premises.

Apply the boundary theorem Definition 5547.3 and the premise-exposure theorem Definition 5547.5. These force the candidate evidence and normalization frontier to precede every confluence-facing or decidability-facing handoff read.

Finally use decider-row exhaustion from Definition 5547.22. The decidable boundary is consumed as a finite row, while T, R, P, L only transport, replay, package, and locally name the same packet. Hence no endpoint consumer can replace the residual handoff by any excluded global metatheorem or host-evaluator claim. □

Theorem 4737.88 (MetaCIC candidate handoff residual frontier scope)**.** *Every accepted* MetacicCandidateNormaliz *packet routes residual-envelope data C and blocked-edge data B through the normalization frontier F and decidable boundary D before any endpoint-facing consumer reads the packet. Hence the handoff is a scoped frontier certificate: it cannot be read as unconditional strong normalization, unrestricted confluence, global conversion decidability, quotient syntax equality, or host evaluator soundness.*

Proof. Start from the seed-obligation exposure of Definition 5547.85. The accepted packet displays K, F, C, D, B and the structural rows before bounded endpoint consumption, so the residual envelope and blocked edge are not hidden premises.

Apply the boundary theorem Definition 5547.3 together with premise exposure from Definition 5547.5. These force candidate evidence to pass through the normalization frontier before a confluence-facing read can consume the endpoint.

Finally use decider-row exhaustion from Definition 5547.22. Since the decidable boundary row is exhausted before endpoint consumption, no consumer can replace the displayed residual frontier by global conversion decidability, quotient syntax equality, unrestricted confluence, unconditional strong normalization, or host evaluator soundness. □

Theorem 4737.89 (MetaCIC candidate normalization sibling confluence route)**.** *Every confluence-facing read of an accepted* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *packet must first expose the sibling route through chapter 765, chapter 892, chapter 735, chapter 5970, and chapter 5126. The residual local-join determinacy packet supplies the finite residual-join ledger consumed before the candidate endpoint can be treated as confluence-facing evidence. The handoff may then export candidate-mediated endpoint, residual-envelope, decidable-boundary, and blocked-edge rows to a confluence consumer, but it cannot present a standalone confluence theorem before those sibling chapters have been displayed.*

Proof. Project the handoff carrier from Definition 5547.2. Its public confluence route stores audit, candidate, frontier, confluence, decidable-boundary, blocked-edge, transport, replay, provenance, and local naming rows rather than a detached confluence theorem.

Apply the boundary and consumer-boundary theorems of this chapter. They keep the candidate evidence, normalization frontier, residual envelope, decidable boundary, and blocked edge visible before any endpoint or join row is consumed.

The sibling chapters named in the statement supply the critical-path, normalization-frontier, confluence-audit, residual local-join, and residual-diamond obstruction surfaces for those rows. The local-join determinacy route contributes the finite join ledger that the candidate endpoint must consume before it is exported as confluence-facing evidence. Residual obstruction rows therefore route through the residual-join and parallel-diamond siblings rather than through a standalone confluence theorem. Since no carrier coordinate bypasses them, every confluence-facing handoff factors through the displayed sibling route. □

Theorem 4737.90 (MetaCIC candidate normalization local-confluence route)**.** *Any local-confluence consumer of an accepted* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *packet must first read the candidate-normalization carrier rows, the candidate diamond-budget dependency of chapter 6552, the residual bridge route inside the handoff packet, and then the local-confluence frontier of chapter 7346. The resulting route is a finite confluence-facing dependency chain; it is not a standalone local-confluence theorem, unrestricted Church–Rosser, subject reduction, quotient syntax equality, evaluator equality, global conversion decidability, or kernel consistency.*

Proof. Project the carrier of Definition 5547.2. A local-confluence read starts from the same audit anchor, candidate evidence, bounded endpoint, normalization frontier, residual envelope, decidable boundary, blocked edge, transport, replay, provenance, and local naming rows as every accepted handoff read.

Apply the candidate diamond-budget dependency route. It forces the consumer to keep the bounded local peak and join-budget rows visible before any endpoint row is treated as confluence-facing evidence.

Next read the residual bridge route inside this hub. The residual envelope, decidable-boundary row, and blocked-edge ledger remain displayed, so the handoff cannot erase residual-substitution or critical-pair obligations on the way to a local-confluence consumer.

Finally pass to the local-confluence frontier of chapter 7346. That sibling may consume the exposed candidate and residual rows as a frontier premise, but it receives no coordinate for global confluence, subject reduction, quotient syntax equality, evaluator equality, conversion decidability, or kernel consistency. □

Theorem 4737.91 (MetaCIC handoff local confluence certificate route)**.** *Every* MetaCICCandidateNormalizationCo *read exported to a normalization or confluence consumer must pass through the local-confluence certificate sibling chapter 7346, the parallel-diamond frontier sibling chapter 4238, the residual-join route chapter 7378, and the candidate-normalization budget rows of chapter 6552 before the handoff is public. The route is therefore*

$$\mathsf{MetaCICCandidateNormalizationConfluenceHandoff}^{\uparrow} \longmapsto (\mathsf{local\ confluence},\ \mathsf{MetaCICParallelDiamondFrontier}^{\uparrow},\ \mathsf{residu}$$

No consumer may read the handoff as a direct ambient confluence theorem, a hidden critical-pair normalizer, or a residual-join certificate with the local confluence and budget rows suppressed.

Proof. Read the local confluence sibling chapter 7346 first. It provides the certificate row that turns candidate overlap data into a local joinability check, so a confluence-facing consumer cannot start from the handoff alone.

Next read the parallel-diamond frontier sibling chapter 4238 and the residual-join route chapter 7378. These siblings keep the frontier and residual rows visible before a join is exported, and they prevent the candidate packet from becoming an unscoped global diamond assertion.

Finally read the candidate-normalization budget rows of chapter 6552. They bound the normalization side of the handoff before the packet is exported, so the public route contains the local confluence certificate, frontier, residual join, budget, replay, transport, provenance, and local naming surfaces together. □

Theorem 4737.92 (MetaCIC candidate normalization confluence handoff residual budget exactness)**.** *The* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *packet exposes residual-budget factorization only after candidate evidence K, normal endpoint N, frontier row F, residual confluence row C, decidable boundary D, blocked edge B, transport T, replay R, provenance P, and local name L have all been displayed. This finite route keeps the bounded residual budget tied to the carrier rows of the handoff packet and to the sibling confluence surfaces of chapter 765, chapter 4238, and chapter 5126. The row asserts the local residual-budget exactness needed by the handoff; it does not claim full Church–Rosser, unrestricted subject reduction, evaluator soundness, quotient syntax equality, or closed consistency.*

Proof. Project the candidate-normalization handoff packet. The finite route already displays candidate evidence, the bounded endpoint, the frontier row, the residual confluence row, the decidable boundary, the blocked edge, the transport row, the replay row, the provenance row, and the local name row before any residual budget is read.

Apply the sibling surfaces named in the statement. The critical-path row supplies the candidate anchor, the parallel-diamond frontier supplies the residual confluence boundary, and the residual-diamond sibling keeps the bounded budget local. Since the packet has no coordinate for full Church–Rosser, unrestricted subject reduction, evaluator soundness, quotient syntax equality, or closed consistency, the theorem records only the exact residual budget surface. □

Theorem 4737.93 (MetaCIC candidate normalization residual budget factorization)**.** *Any accepted* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *residual budget factors through candidate evidence K, normal endpoint N, frontier row F, residual confluence row C, decidable boundary*

D, blocked edge B, transport T, replay R, provenance P, and local name L before any downstream residual join consumes it. The factorization routes through chapter 765, chapter 4238, and chapter 5126; it exports no residual join that bypasses the candidate evidence, normal endpoint, frontier row, decidable boundary, blocked-edge ledger, structural transport, replay, provenance, or local naming.

Proof. Project the displayed handoff packet. Its residual-budget row can be read only after the candidate evidence, normal endpoint, frontier row, residual confluence row, decidable boundary, blocked edge, transport, replay, provenance, and local name have all been exposed.

Use Definition 5547.92 for the exactness surface. The same displayed rows already bind the budget to the carrier rather than to a detached residual-join theorem.

Finally read the sibling routes. $\mathsf{MetaCICCriticalPath}^{\uparrow}$ supplies the candidate-critical anchor, $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ supplies the frontier boundary, and $\mathsf{ParallelDiamondResidual}^{\uparrow}$ supplies the bounded residual-confluence row. Since the packet contains no coordinate outside those rows, every downstream residual join consumes the stated factorization first. □

Theorem 4737.94 (MetaCIC candidate normalization confluence handoff status)**.** *For an accepted* $\mathsf{MetacicCandidateNormalizationConfluenceHandoff}^{\uparrow}$ *packet whose displayed rows include a candidate-normalization row K, a residual-join row C, a finite cut-height budget B, and a dependency row F for the parallel-diamond frontier, every confluence handoff factors through the residual-budget window before it can be consumed by the* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *route. The available handoff surface is exactly the visible route through candidate evidence, bounded normal endpoint, residual join, cut-height budget, blocked-edge ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *naming.*

This status row may cite the candidate-normalization handoff route of chapter 5547, the residual join scope of chapter 5126, the parallel-diamond dependency route of chapter 4238, and the local confluence certificate route of chapter 765. It exports no evidence-free normalization theorem, abstract source-equivalence theorem, classifier-transport theorem, full Church–Rosser theorem, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, or closed consistency claim.

Proof. Project the accepted handoff packet to its displayed rows. The candidate-normalization row K, residual-join row C, finite cut-height budget B, and frontier dependency F are all visible before the confluence-facing consumer can read the bounded endpoint or any residual join.

Apply the residual-budget exactness theorem and the local factorization theorem above. They force the confluence handoff through the same residual-budget window and keep the blocked-edge ledger, transport, replay, provenance, and local name rows attached to the read.

Now route the result to the sibling frontier. The parallel-diamond frontier consumes the handoff only after the candidate-normalization route, residual join scope, and local confluence certificate have displayed the same finite rows. Since the carrier has no coordinate for evidence-free normalization, abstract source equivalence, classifier transport, or global confluence, the handoff cannot bypass the residual-budget window. □

Theorem 4737.95 (MetaCIC handoff parallel-diamond sibling dependency)**.** *Every accepted* $\mathsf{MetacicCandidateNor}$ *carrier that exports candidate-normalization confluence data must consume the finite parallel-diamond frontier rows of chapter 4238 together with the candidate-normalization router surface of chapter 5210. The handoff therefore reads residual-premise retention, local critical-pair routing, candidate evidence, bounded endpoint routing, obstruction retention, transport, replay, provenance, and local naming before any confluence-facing consumer can use it.*

Proof. Project the handoff carrier through Definition 5547.2. Its candidate row, frontier row, residual envelope, decidable boundary, blocked edge, transport, replay, provenance, and local name remain visible before the bounded endpoint row is exported.

Read the parallel-diamond frontier next. The frontier of chapter 4238 supplies the retained residual premise, local critical-pair, local-join, obstruction, and structural rows that any confluence-facing use must preserve.

Finally route candidate evidence through chapter 5210. The router keeps the candidate evidence and normalization readback inside a bounded certificate route, so the handoff cannot be read as premise-free confluence, unrestricted subject reduction, quotient syntax equality, host evaluator soundness, or closed consistency. □

Chapter 4738

A Concrete Naming Certificate for CantorIntersectionModulus$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the CantorIntersectionModulus$^{\uparrow}$ packet records Cantor intersection as explicit finite modulus data rather than as ambient compactness. It sits after the located nested-interval surface of chapter 1713, the bisection route of chapter 1711, the dyadic arithmetic core of chapter 291, the finite request interface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the finite prefix bar of chapter 5863. The chapter names the finite data needed to turn a retained nested branch into a regular Cauchy real name; it does not invoke open-cover compactness or a selected infinite branch.

Definition 4738.1 (Cantor intersection modulus carrier)**.** *A* CantorIntersectionModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathcal{M} = (L, B, D, S, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *L is the located closed interval row, recording the endpoint order, locatedness tests, and retained closed-interval inclusion data.*
2. *B is the retained nested bisection branch ledger, exposing only the finite branch decisions already displayed by* LocatedIntervalBisection$^{\uparrow}$ *and* LocatedRealNestedIntervals$^{\uparrow}$*.*
3. *D is the dyadic diameter schedule from* DyadicRatCore$^{\uparrow}$*, recording the depth-to-radius budget and the finite halving estimates used at each retained stage.*
4. *S is the* StreamName$^{\uparrow}$ *finite-window row, listing the precision requests and interval stages inspected by the downstream real-name consumer.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to the selected finite windows and their dyadic endpoint approximants.*
6. *E is the terminal* Real$^{\uparrow}$ *seal reached only after the interval, bisection, dyadic schedule, stream window, and regular rational readback rows have been displayed.*
7. *F is the finite fan-depth and modulus output row. It records the finite prefix depth at which the diameter schedule answers the requested precision and the bar-window handoff used by* FiniteFanTheorem$^{\uparrow}$*.*
8. *H records componentwise* hsame *transport for the interval, branch, diameter, window, readback, real seal, fan-depth, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from an interval request through L, B, D, S, R, E, F, H and into the local certificate.*

10. *P is the* Pkg *provenance over* $\mathsf{CantorIntersectionModulus}^{\uparrow}$, $\mathsf{LocatedRealNestedIntervals}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$ $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteFanTheorem}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorIntersectionModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, a selected infinite branch, countable choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CantorIntersectionModulusUp.CantorIntersectionModulusTasteGate single carrier alignment`

Theorem 4738.2 (Cantor intersection modulus NameCert obligations)**.** *For every accepted* CantorIntersectionModu *carrier*

$$\mathcal{M} = (L, B, D, S, R, E, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorIntersectionModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the located closed interval row, retained nested bisection branch ledger, dyadic diameter schedule,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, finite fan-depth and modulus output, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every public read of the packet must expose L, B, D before the stream window S, must expose S, R before the real seal E, and must expose the fan-depth row F before exporting a precision modulus.*

Thus a downstream completion or real-name consumer receives a finite modulus route from nested interval data into regular Cauchy real names. The packet exports no open-cover compactness theorem, selected infinite branch, countable-choice principle, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Carrier admission is projection from Definition 5548.1. The accepted packet displays exactly the located closed interval row, retained branch ledger, dyadic diameter schedule, finite stream windows, regular rational readback, terminal real seal, finite fan-depth output, transport, replay, provenance, and local naming rows.

The route order is forced by the displayed carrier. The nested interval consumer first reads L and B as finite interval and branch data, then reads D as the dyadic diameter schedule that bounds the retained interval at each displayed depth.

The real-name handoff is finite. The row S lists the precision windows, R reads back the corresponding regular rational approximants, and E seals the resulting $\mathsf{Real}^{\uparrow}$ row only after those windows and readbacks are already present.

Finally the row F records the finite fan-depth and modulus output used by the handoff to chapter 5863. Since the carrier contains no coordinate for open covers, selected infinite branches, countable choice, quotient real equality, or ambient completeness, H, C, P, N can transport, replay, source, and name only the displayed finite route. □

Theorem 4738.3 (Finite fan interval handoff)**.** *Every* $\mathsf{CantorIntersectionModulus}^{\uparrow}$ *consumer that asks for a finite precision window factors through the interval-to-fan route*

$$L, B, D \longrightarrow S, R, E \longrightarrow F, H, C, P, N.$$

The finite fan-depth row F may use the prefix-bar discipline of chapter 5863 only after the located interval, retained bisection branch, and dyadic diameter rows have fixed the inspected depth. Ordinary regular real readback still passes through the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows; the fan row supplies only the finite window bound.*

Proof. Start with an accepted carrier $\mathcal{M} = (L, B, D, S, R, E, F, H, C, P, N)$. The first three rows determine the displayed nested interval data: L gives the located closed interval, B gives the retained finite bisection branch, and D gives the dyadic diameter schedule.

The stream and real-name rows then read only the windows named by that displayed interval data. The rows S and R expose the requested finite precision windows and regular rational readback, and E records the terminal real seal reached from those rows.

It remains to identify the fan use. The row F is the only carrier coordinate that records a finite fan-depth or modulus output, so any consumer asking for a prefix-bar bound must pass through F after L, B, D, S, R, E. The transport, replay, provenance, and local naming rows H, C, P, N then export the same finite route and cannot introduce open-cover compactness, a selected infinite branch, countable choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every $\mathsf{CantorIntersectionModulus}^{\uparrow}$ precision-window read factors through one located closed interval row, one retained nested bisection branch ledger, one $\mathsf{DyadicRatCore}^{\uparrow}$ diameter schedule, one $\mathsf{StreamName}^{\uparrow}$ finite-window row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one terminal $\mathsf{Real}^{\uparrow}$ seal, one finite $\mathsf{FiniteFanTheorem}^{\uparrow}$ depth row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: located-real-nested-intervals, located-interval-bisection, dyadicratcore, streamname, regseqrat, real, finite-fan-theorem: $\mathsf{CantorIntersectionModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries nested interval data, dyadic diameter scheduling, real-name readback, and finite fan-depth output as one modulus packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorIntersectionModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorIntersectionModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5548.1, Definition 5548.2, and Definition 5548.3 seed the finite Cantor-intersection modulus route through located interval rows, retained bisection ledgers, dyadic diameter schedules, finite stream windows, regular rational readbacks, terminal real seals, and finite fan-depth rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorIntersectionModulus}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.CantorIntersectionModulusUp`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected infinite branches, countable choice, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fan-depth exactness, interval-window coverage, componentwise transport, replay, provenance, local naming, and non-escape for BEDC.Derived.CantorIntersectionModulusUp.

Constructive story: A $\mathsf{CantorIntersectionModulus}^{\uparrow}$ packet is generated from located closed interval rows, retained nested bisection branch ledgers, dyadic diameter schedules, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, terminal $\mathsf{Real}^{\uparrow}$ seals, finite $\mathsf{FiniteFanTheorem}^{\uparrow}$ depth outputs, componentwise transport, displayed replay, provenance, and a local NameCert row.

Chapter 4739

A Concrete Naming Certificate for $\mathsf{CompactUniformContinuityLedger}^{\uparrow}$

Following Bishop and Bridges on compact metric uniform continuity, the $\mathsf{CompactUniformContinuityLedger}^{\uparrow}$ packet records the finite NameCert ledger that assembles compact finite-net data, pointwise continuity rows, metric distance observations, rational lower-bound folds, and the final uniform-modulus output. It sits over the compact carrier of chapter 60, the compact metric source of chapter 129, the continuous and continuous-map rows of chapter 59 and chapter 130, the metric distance surface of chapter 57, the rational ledger of chapter 37, the total-order selector route of chapter 54, the finite-net fold of chapter 619, and the $\mathsf{UniformModulus}^{\uparrow}$ consumer of chapter 369. The packet names the full compactness-implies-uniform-continuity ledger as finite BEDC data; it is not an open-cover theorem, a host minimum, a selected subcover, or an ambient choice principle.

Definition 4739.1 (Compact uniform continuity ledger carrier)**.** *A* $\mathsf{CompactUniformContinuityLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, F, M, R, T, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact finite-net row, including the compact source, the finite* $\mathsf{ProbeBundle}$ *of centers, and the located coverage witnesses read from the compact metric packet.*
2. *F is the pointwise modulus row for the continuous map, carrying the graph reads, centerwise source radii, and target-tolerance certificates over the same compact source.*
3. *M is the metric distance row, recording the source distances from an input point to a displayed center, from a second input point to that center, and the target distances used by the triangle estimate.*
4. *R is the finite* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold row, read through the* $\mathsf{TotalOrder}^{\uparrow}$ *selector route over the bundled positive source radii.*
5. *T is the finite triangle and tolerance ledger tying the lower-bound fold to the source and target metric comparisons.*
6. *U is the output* $\mathsf{UniformModulus}^{\uparrow}$ *row, exposing the tolerance-only precision history obtained from K, F, M, R, T.*

7. *H records componentwise* hsame *transport for compact finite nets, pointwise modulus rows, metric distance observations, rational folds, triangle ledgers, output rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a compact-uniform-continuity tolerance request through $K, F, M, R, T, U, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactUniformContinuityLedger}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{TotalOrder}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformContinuityLedger}^{\uparrow}}$ *row.*

The classifier compares accepted ledgers only through these coordinates. It contains no coordinate for an arbitrary open cover, selected subcover, host minimum over points, quotient function equality, countable choice, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.CompactUniformContinuityLedgerUp.CompactUniformContinuityLedgerTasteGate`
`single carrier alignment`

Theorem 4739.2 (Compact uniform continuity ledger NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformContinuityLedger}^{\uparrow}$ *carrier $L = (K, F, M, R, T, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformContinui}}$ *surface consists exactly of carrier admission for the compact finite-net row, pointwise modulus row, metric distance row, finite rational lower-bound fold, triangle and tolerance ledger, output uniform-modulus row, componentwise transport, displayed continuation replay, package provenance, and local naming; source compatibility between K and F; metric-read compatibility between M and the compact source; fold exactness through R and the* $\mathsf{TotalOrder}^{\uparrow}$ *selector route; triangle exactness through T; uniform-modulus handoff through U; and nonescape from arbitrary open covers, selected subcovers, host minima, quotient function equality, countable choice, and ambient real completeness.*

Proof. Project the accepted carrier of Definition 5549.1. The visible rows are exactly the compact finite-net data, pointwise modulus data, metric distance observations, rational fold, triangle ledger, output row, and structural rows.

The source lock is read before any modulus row is consumed. The compact row K and pointwise row F name the same compact metric source, so the finite centers and local radii cannot move to another carrier.

The rational fold is the row R. It is computed over the displayed bundled radii through the $\mathsf{TotalOrder}^{\uparrow}$ selector route, and the metric row M supplies only the distances later used by the source and target triangle estimates.

The triangle and tolerance row T binds these reads into the output row U. Componentwise transport, continuation replay, package provenance, and local naming then preserve the same ledger, so no excluded open-cover, choice, quotient, host-minimum, or completeness coordinate is available to a consumer. □

Theorem 4739.3 (Compact uniform continuity ledger finite-fold route)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactUniformContinuityLedger}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{ContinuousMap}^{\uparrow}, \quad \mathsf{Met}^{\uparrow}, \quad \mathsf{Rat}^{\uparrow}, \quad \mathsf{TotalOrder}^{\uparrow}, \quad \mathsf{UniformModulus}^{\uparrow}.$$

More explicitly, the consumer must first read compact finite-net centers and pointwise modulus rows, then the metric distance observations, then the finite $\mathsf{Rat}^{\uparrow}$ *lower-bound fold selected by the*

$\mathsf{TotalOrder}^{\uparrow}$ *route, then the triangle and tolerance ledger, and only then the output uniform-modulus row. No compact-uniform-continuity read can bypass this finite fold by using an arbitrary open cover, selected subcover, host minimum, or choice schedule.*

Proof. Start with the compact finite-net row K and the pointwise modulus row F. They expose the bundled centers, local radii, graph reads, and source compatibility required by the compact-uniform-continuity request.

Next read the metric row M and the rational fold row R. The metric row supplies the source and target distances used by the later estimate, while R folds the displayed positive radius family through the $\mathsf{TotalOrder}^{\uparrow}$ selector route. The selected precision is therefore a finite history, not an external minimum.

Finally read T and U. The triangle and tolerance ledger transports the selected lower bound into the two source estimates and the target triangle estimate, and the $\mathsf{UniformModulus}^{\uparrow}$ row receives only that tolerance-only precision history.

The rows H, C, P, N keep the route stable under transport, replay, provenance, and naming. Since the carrier has no open-cover, selected-subcover, host-minimum, or choice coordinate, every compact-uniform-continuity consumer factors through the displayed finite fold. □

Falsifiable prediction: Every accepted $\mathsf{CompactUniformContinuityLedger}^{\uparrow}$ compact-uniform-continuity read must expose a compact finite-net row, pointwise continuous-map modulus rows, metric distance observations, a finite $\mathsf{Rat}^{\uparrow}$ lower-bound fold, a $\mathsf{TotalOrder}^{\uparrow}$ selector route, a triangle and tolerance ledger, a terminal $\mathsf{UniformModulus}^{\uparrow}$ row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: compact, compactmetric, continuous, continuousmap, metric, rat, totalorder, finitenetminimumfold, uniformmodulus: $\mathsf{CompactUniformContinuityLedger}^{\uparrow}$ is not bijective to any listed sibling because it binds the whole compactness-implies-uniform-continuity route from finite compact coverage through pointwise radii, metric observations, rational folding, triangle estimates, and the terminal UniformModulus handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformContinuityLedger}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformContinuityLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5549.1, Definition 5549.2, and Definition 5549.3 seed the finite NameCert ledger for compactness-implies-uniform-continuity over compact finite nets, pointwise modulus rows, metric distance rows, RatUp folds, TotalOrder selector routes, triangle ledgers, UniformModulus handoff, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformContinuityLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, host minima, quotient function equality, countable choice, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source compatibility, metric-read compatibility, rational fold exactness, triangle exactness, uniform-modulus handoff, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.CompactUniformContinuityLedgerUp.

Constructive story: A $\mathsf{CompactUniformContinuityLedger}^{\uparrow}$ packet is generated from compact finite-net rows, ContinuousMap pointwise modulus rows, Metric distance observations, RatUp lower-bound folds, TotalOrder selector routes, triangle and tolerance ledgers, UniformModulus output rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4740

A Concrete Naming Certificate for $\mathsf{FrechetMetricEmbedding}^{\uparrow}$

Following Fréchet and Kuratowski, the $\mathsf{FrechetMetricEmbedding}^{\uparrow}$ packet records a metric space by the finite distance observations that send a point to its displayed distances from a finite probe family. It sits over the metric source of chapter 57, the real-distance rows of chapter 38, the distance-function route of chapter 7569, and the embedding interfaces of chapter 439 and chapter 1652. The packet names only displayed finite reads; it does not import host function extensionality, quotient equality of maps, or an ambient function-space carrier.

Definition 4740.1 (Fréchet metric embedding carrier)**.** *A* $\mathsf{FrechetMetricEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, Q, D, A, H, C, P, N)$$

with the following displayed rows:

1. *X is the point row whose accepted element is the source point being embedded.*
2. *Q is the* $\mathsf{Met}^{\uparrow}$ *source row, carrying the source classifier and source-distance interface.*
3. *D is the family of* $\mathsf{Real}^{\uparrow}$*-valued distance-read rows $d(X, q)$ for displayed probes q.*
4. *A is the finite probe-family and classifier row: two packets agree exactly when the displayed* $\mathsf{Real}^{\uparrow}$ *distance reads agree componentwise on the same probe family.*
5. *H records componentwise* hsame *transport for the point row, metric-source row, distance-read rows, probe-family classifier, replay row, provenance row, and local naming row.*
6. *C records displayed* Cont *replay from source metric reads through the probe-family distance reads and then through the classifier-by-displayed-distance-agreement.*
7. *P is the* Pkg *provenance over* $\mathsf{FrechetMetricEmbedding}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{KuratowskiEmbedding}^{\uparrow}$*,* $\mathsf{IsometricEmbedding}^{\uparrow}$*,* $\mathsf{UniformEmbedding}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FrechetMetricEmbedding}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host function object, quotient equality of distance functions, selected completion representatives, or an ambient real-valued function space.

Lean4 ✓ `BEDC.Derived.FrechetMetricEmbeddingUp.FrechetMetricEmbeddingTasteGate single carrier alignment`

Theorem 4740.2 (Fréchet metric embedding NameCert obligations)**.** *For every accepted* $\mathsf{FrechetMetricEmbedding}^{\uparrow}$ *carrier* $F = (X, Q, D, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FrechetMetricEmbedding}^{\uparrow}}$ *surface consists exactly of the finite rows displayed in Definition 5550.1. Carrier admission reads the point row, metric-source row,* $\mathsf{Real}^{\uparrow}$ *distance-read rows, finite probe family, classifier-by-displayed-distance-agreement,* hsame *transport,* Cont *replay,* Pkg *provenance, and local naming row. Classifier stability compares accepted packets only by the displayed* $\mathsf{Real}^{\uparrow}$ *distance reads over the shared finite probe family, with transport and replay preserving that same route.*

Proof. Project the accepted carrier $F = (X, Q, D, A, H, C, P, N)$. The point row X and metric-source row Q are the only source data exposed before distance reads are requested.

The row D then records the finite $\mathsf{Real}^{\uparrow}$ distance observations against the probe family named by A. Since A classifies by displayed distance agreement, two accepted packets can be compared only by componentwise equality of these finite reads under the same probe family.

Finally read H, C, P, N. Transport, replay, provenance, and local naming preserve the point-to-distance route without adding host function extensionality, quotient equality of maps, selected representatives, or an ambient function-space carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetMetricEmbedding}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FrechetMetricEmbedding}^{\uparrow}}$, seed)

Scope closed: Definition 5550.1 and Definition 5550.2 seed the finite distance-function embedding route over MetricSpaceUp, RealUp, KuratowskiEmbeddingUp, IsometricEmbeddingUp, and UniformEmbeddingUp.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FrechetMetricEmbedding}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function extensionality, quotient equality of maps, selected completion representatives, an ambient function-space carrier, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, displayed-distance classifier stability, hsame transport, Cont replay, provenance, and local NameCert coverage for BEDC.Derived.FrechetMetricEmbeddingUp.

Constructive story: A $\mathsf{FrechetMetricEmbedding}^{\uparrow}$ packet is generated from a point row, a MetricSpaceUp source row, RealUp-valued distance-read rows, a finite probe-family classifier, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4741

A Concrete Naming Certificate for $\mathsf{CaristiFixedPoint}^{\uparrow}$

Following Caristi's fixed point theorem and the Ekeland complete-metric descent route, the $\mathsf{CaristiFixedPoint}^{\uparrow}$ packet records the finite surface by which a self-map satisfying a potential-decrease inequality reaches a seal-facing fixed endpoint. It sits beside the Banach fixed-point packet of chapter 396, the stability handoff of chapter 5856, and the variational descent ledger of chapter 3926. The packet names a complete-metric fixed-point certificate over one displayed potential and one displayed self-map; it is not a host minimizer theorem, a choice-selected descent sequence, quotient equality of points, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4741.1 (Caristi fixed point carrier)**.** *A* $\mathsf{CaristiFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (X, d, \phi, T, E, B, R, H, Q, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompleteMetric}^{\uparrow}$ *domain row, naming the metric carrier and its complete-metric handoff surface.*
2. *d is the distance row used for all comparisons between a point and its image under T.*
3. *ϕ is the lower-semicontinuous potential row, read through* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *and a regular-rational value ledger.*
4. *T is the self-map row whose graph is inspected only through the displayed* Cont *route.*
5. *E is the Caristi descent inequality row, recording the finite comparison $d(x, Tx) \leq \phi(x) - \phi(Tx)$ for every admitted probe row.*
6. *B is the Ekeland handoff row, exposing the variational descent route that turns the potential inequality into a terminal fixedness boundary.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *endpoint seal, used only after the complete-metric descent row has been consumed.*
8. *H records componentwise* hsame *transport for the domain, distance, potential, self-map, descent, Ekeland handoff, endpoint seal, replay, provenance, and local naming rows.*
9. *Q records displayed* Cont *replay from any fixed-point read through $X, d, \phi, T, E, B, R, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{CaristiFixedPoint}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LowerSemicontinuous}^{\uparrow}$, $\mathsf{EkelandVariationalPrinciple}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CaristiFixedPoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, d, \phi, T, E, B, R, H, Q, P, N$. It has no coordinate for a host-selected minimizer, arbitrary choice sequence, quotient point equality, global contraction theorem, or ambient completeness beyond the displayed $\mathsf{CompleteMetric}^{\uparrow}$ *row.*

Lean4 ✓ `BEDC.Derived.CaristiFixedPointUp.CaristiFixedPointTasteGate single carrier alignment`

Theorem 4741.2 (Caristi fixed point NameCert obligations)**.** *For every accepted* $\mathsf{CaristiFixedPoint}^{\uparrow}$ *carrier*

$$C = (X, d, \phi, T, E, B, R, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CaristiFixedPoint}^{\uparrow}}$ *surface consists exactly of carrier admission for the complete-metric row, distance row, lower-semicontinuous potential, self-map row, Caristi descent inequality, Ekeland handoff, endpoint seal, transport, replay, provenance, and local naming. The obligation surface also records the comparison boundary with* $\mathsf{BanachFixedPoint}^{\uparrow}$ *and* $\mathsf{PicardIteration}^{\uparrow}$*: Banach supplies contraction-orbit fixedness, while this packet supplies potential-descent fixedness.*

Proof. Project the carrier of Definition 5551.1. Its analytic rows are exactly X, d, ϕ, T, E, B, R, and its structural rows are exactly H, Q, P, N.

The descent inequality is local to the displayed self-map. The row E reads d, ϕ, and T together, so a consumer cannot detach the distance comparison from the lower-semicontinuous potential ledger.

The fixed-point endpoint is downstream from complete-metric descent. The row B sends the Caristi inequality into the Ekeland variational handoff, and R seals only the resulting regular-rational and real endpoint boundary.

Finally the Banach/Picard comparison is only a boundary row. The provenance records the neighbouring fixed-point route, but the carrier has no contraction constant or Picard-orbit coordinate from which a Banach proof could be read. Hence the displayed rows exhaust the NameCert obligations. □

Theorem 4741.3 (Caristi fixed point Ekeland handoff)**.** *Every accepted* $\mathsf{CaristiFixedPoint}^{\uparrow}$ *packet factors its descent read through the finite route*

$$\mathsf{CompleteMetric}^{\uparrow}, \mathsf{LowerSemicontinuous}^{\uparrow}, \mathsf{EkelandVariationalPrinciple}^{\uparrow} \longmapsto E, B, R, H, Q, P, N.$$

The Ekeland handoff consumes the displayed potential-decrease inequality and returns only a certificate-local endpoint boundary. It does not produce a host minimizer, selected descent sequence, quotient equality of points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $C = (X, d, \phi, T, E, B, R, H, Q, P, N)$. The complete-metric row X and distance row d provide the only metric input available to the descent route.

The lower-semicontinuous row ϕ and inequality row E then form the Caristi descent datum. A consumer must read T through the same route, because E compares a point with its displayed image under T.

Apply the Ekeland handoff row B. It repacks the potential-decrease datum as the finite variational descent ledger named by $\mathsf{EkelandVariationalPrinciple}^{\uparrow}$, and it leaves the endpoint seal to R.

The transport, replay, provenance, and local name preserve this order. Since the carrier has no selector row for a host minimizer or arbitrary descent sequence, the handoff exports only the stated certificate-local endpoint boundary. □

Theorem 4741.4 (Caristi fixed point endpoint fixedness and non-escape)**.** *For an accepted* $\mathsf{CaristiFixedPoint}^{\uparrow}$ *carrier, the endpoint row R is classifier-fixed under the displayed self-map row T after the Caristi descent inequality E and Ekeland handoff B have been consumed. Every endpoint read factors through*

$$X, d, \phi, T, E, B, R, H, Q, P, N,$$

and no consumer may read host fixed-point equality, selected limits, quotient point equality, global contraction soundness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

Proof. Read the endpoint row through the carrier. The row R is introduced only after the complete-metric, potential, self-map, inequality, and Ekeland handoff rows have been displayed.

The fixedness assertion is classifier-internal. Applying T at the endpoint route is allowed only through Q, and the comparison back to R is transported by H inside the same local NameCert surface.

The non-escape boundary follows from the absence of additional coordinates. There is no row for a host equality of points, a selected limiting sequence, quotient equality, a contraction constant, or ambient real-completeness theorem. Thus every endpoint fixedness read remains inside $X, d, \phi, T, E, B, R, H, Q, P, N$. □

Falsifiable prediction: Every accepted $\mathsf{CaristiFixedPoint}^{\uparrow}$ endpoint read factors through a CompleteMetricUp row, a lower-semicontinuous potential row, a displayed Caristi descent inequality, an EkelandVariationalPrincipleUp handoff, a RegSeqRatUp and RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: banachfixedpoint, banach-fixed-point-stability, ekeland-variational-principle, picard-iteration, complete-metric: $\mathsf{CaristiFixedPoint}^{\uparrow}$ is not bijective to any listed sibling because it jointly stores complete-metric descent, lower-semicontinuous potential, self-map graph, Caristi inequality, Ekeland handoff, Banach/Picard comparison boundary, endpoint sealing, transport, replay, provenance, and local naming in one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CaristiFixedPoint}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CaristiFixedPoint}^{\uparrow}$ packet is generated from a complete-metric row, distance row, lower-semicontinuous potential row, self-map row, Caristi descent inequality, Ekeland handoff, Banach/Picard comparison boundary, RegSeqRat and Real endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CaristiFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5551.1, Definition 5551.2, Definition 5551.3, and Definition 5551.4 seed the complete-metric potential-descent fixed-point packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CaristiFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host fixed-point equality, selected minimizers, selected descent sequences, quotient point equality, global contraction soundness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower-semicontinuous potential readback, Caristi inequality exactness, Ekeland handoff, endpoint fixedness, Banach/Picard boundary confinement, transport, replay, provenance, and local naming for BEDC.Derived.CaristiFixedPointUp.

Chapter 4742

A Concrete Naming Certificate for $\mathsf{WeightedDeformationSpine}^{\uparrow}$

The $\mathsf{WeightedDeformationSpine}^{\uparrow}$ packet realizes the weighted deformation spine of subsection 9462.28.21 as finite trigger-weight deformation data. It sits beside the boundary-tile packet of chapter 3393, the reassignment-mass packet of chapter 5869, and the private/shared decoration packet of chapter 5896. The packet records trigger support, weights, deformation route, boundary-tile readback, transport, replay, provenance, and local naming together; it is not a biological mechanism, stochastic model, hidden graph search, quotient codon equality, or unrecorded trigger oracle.

Definition 4742.1 (Weighted deformation operator carrier)**.** *A* $\mathsf{WeightedDeformationSpine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, L, D, B, H, C, P, N)$$

with the following displayed rows:

1. *S is the trigger-support row, naming the finite codon-window vertices admitted by the packet.*
2. *L is the weight ledger, assigning each admitted trigger row its displayed reassignment mass.*
3. *D is the deformation-route row, recording the nested connected supports and their Hamming-adjacent spine.*
4. *B is the boundary-tile readback row, tying the Stop, AGR, AAA, and AUA modules back to the DNA-window six boundary-tile source.*
5. *H records componentwise* hsame *transport for S, L, D, B, C, P, N.*
6. *C records displayed* Cont *replay from any deformation-spine read through trigger support, weights, route, boundary readback, provenance, and local naming.*
7. *P is the* Pkg *provenance over* $\mathsf{WeightedDeformationSpine}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{ReassignmentMassSubcu}$ $\mathsf{PrivateSharedDecorationModel}^{\uparrow}$*, the weighted-spine theorem of Definition 9462.1260,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{WeightedDeformationSpine}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through S, L, D, B, H, C, P, N. It has no coordinate for a biological causal mechanism, stochastic evolution model, quotient codon semantics, hidden global enumeration, or unweighted trigger boundary.

Theorem 4742.2 (Weighted deformation spine NameCert obligations)**.** *For every accepted* WeightedDeformationSp *carrier*

$$W = (S, L, D, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{WeightedDeformationSpine}^{\uparrow}}$ *surface consists exactly of carrier admission for trigger support, weight ledger, deformation route, boundary-tile readback, componentwise transport, displayed replay, provenance, and local naming. The weighted deformation route must preserve the nested connected supports and the spine path*

$$\mathrm{UAG} - \mathrm{UAA} - \mathrm{UGA} - \mathrm{AGA} - \mathrm{AGG}$$

with branch

$$\mathrm{AGA} - \mathrm{AAA} - \mathrm{AUA}.$$

Proof. Project the carrier of Definition 5552.1. The support, weight, route, boundary, transport, replay, provenance, and local name are exactly the displayed coordinates.

The route is weighted, not merely supported. The row L must be read before D, because the nested connected supports are selected by maximum-mass connected candidates from the source theorem.

The boundary readback is also explicit. The row B attaches the Stop, AGR, AAA, and AUA modules to the DNA-window six boundary-tile source, so a consumer cannot reinterpret the spine as an ungrounded graph path.

Finally H, C, P, N preserve and name the same rows. Since biological mechanism, stochastic dynamics, quotient codon equality, hidden enumeration, and unweighted trigger boundaries have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 4742.3 (Weighted deformation spine trigger stability)**.** *For accepted* $\mathsf{WeightedDeformationSpine}^{\uparrow}$ *carriers, componentwise* hsame *transport preserves the trigger support S, weight ledger L, deformation route D, and boundary-tile readback B as one packet. A deformation consumer may vary only through displayed transport and replay rows; it cannot keep the same route while dropping the weight ledger, or keep the same support while replacing the boundary readback by an unrecorded trigger classifier.*

Proof. Start with the accepted carrier $W = (S, L, D, B, H, C, P, N)$. The transport row H is componentwise across support, weights, route, boundary readback, replay, provenance, and local naming.

The weight ledger is tied to the route. If D is preserved, the maximum-mass connected-candidate interpretation still requires the weights stored in L; otherwise the deformation boundary is no longer the weighted spine named by the packet.

The boundary readback is tied to the trigger support. If S is preserved, the Stop, AGR, AAA, and AUA module readback must remain the displayed row B, not a hidden classifier outside the carrier.

Thus every stable trigger read preserves S, L, D, B, H, C, P, N together. The packet cannot be reduced to support alone, route alone, or weights alone. □

Theorem 4742.4 (Weighted deformation spine TasteGate surface)**.** *The future Lean TasteGate file for namespace* BEDC.Derived.WeightedDeformationSpineUp *must provide* Nontrivial $\mathsf{WeightedDeformationSpine}^{\uparrow}$ *and* FieldFaithful $\mathsf{WeightedDeformationSpine}^{\uparrow}$ *instances preserving the same finite carrier rows S, L, D, B, H, C, P, N. Nontriviality is witnessed by the distinction between support-only, weight-only, and route-only reads; field faithfulness preserves the joint trigger-support, weight-ledger, deformation-route, boundary-readback, transport, replay, provenance, and local naming surface.*

Proof. The carrier contains at least three independently readable analytic rows: support S, weights L, and route D. Collapsing the packet to one of them erases the other two and therefore cannot preserve the NameCert obligations.

Boundary readback supplies a further separate row. The row B connects the deformation spine to the DNA-window boundary-tile source, while H, C, P, N transport, replay, source, and name the packet.

A TasteGate consumer must preserve all of these rows as fields of one carrier. That is exactly the paper-side surface for the stated Nontrivial and FieldFaithful instances. □

Falsifiable prediction: Removing the weight ledger changes the accepted deformation boundary while leaving the trigger support readable.

Independence witness: observervtracekernel, finitewindowobserver, observerfilterbudgetselector, codon-window-sibling slugs: explain why none is bijective because only this packet stores trigger support, weights, deformation route, boundary-tile readback, transport, replay, provenance, and local naming together.

Closure status for $\mathsf{NameCert}_{\mathsf{WeightedDeformationSpine}^{\uparrow}}$ **·**

Constructive story: A $\mathsf{WeightedDeformationSpine}^{\uparrow}$ packet is generated from finite trigger-support rows, a weight ledger, a connected deformation route, boundary-tile readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeightedDeformationSpine}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5552.1, Definition 5552.2, Definition 5552.3, and Definition 5552.4 seed the finite trigger-weight deformation packet over the DNA-window spine.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeightedDeformationSpine}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological mechanism, stochastic evolution, quotient codon equality, hidden global enumeration, unweighted trigger classification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, trigger-support exactness, weight-ledger exactness, deformation-route stability, boundary-tile readback, transport, replay, provenance, local naming, Nontrivial WeightedDeformationSpineUp, and FieldFaithful WeightedDeformationSpineUp for BEDC.Derived.WeightedDeformationSpineUp.

$\mathsf{CompactRealInterval}^{\uparrow}$ routes closed interval compactness through chapter 38, chapter 291, chapter 301, and chapter 3471; the child files below keep the carrier, finite-net, diagonal-selection, and Real-interval routes separate.

Chapter 4743

A Concrete Naming Certificate for $\mathsf{CompactRealInterval}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Heine-Borel finite-net reading of closed intervals, the $\mathsf{CompactRealInterval}^{\uparrow}$ packet records a compact closed interval as finite BEDC NameCert data. It sits over the real-name seal of chapter 38, the dyadic scale and tolerance rows of chapter 291, the stream-window interface of chapter 126, the regular rational readback of chapter 301, and the finite-net compactness siblings chapter 129 and chapter 3471. The packet is an interval carrier for later compact-real consumers; it does not import host compactness, selected subcovers, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4743.1 (Compact real interval carrier)**.** *A* $\mathsf{CompactRealInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (A, B, O, D, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two located* $\mathsf{Real}^{\uparrow}$ *endpoint rows, each exposed through finite real-name windows before any interval request is consumed.*
2. *O is the order and apartness ledger, recording the displayed endpoint order, located overlap tests, boundary apartness rows, and refusal of trichotomy outside the inspected interval windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *finite tolerance ledger, recording common-scale comparisons, mesh radii, endpoint slack, and dyadic containment checks.*
4. *W is the finite dyadic net schedule, listing the mesh windows used to inspect the interval between the endpoint rows.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, carrying the finite stream requests that read endpoint and mesh data without opening a quotient stream.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, repacking endpoint, mesh, order, and tolerance checks as regular rational finite windows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the endpoint and inspected mesh values.*
8. *H records componentwise* hsame *transport for endpoints, order/apartness ledgers, dyadic tolerances, finite nets, stream windows, regular readbacks, Real seals, replay rows, provenance rows, and local naming rows.*

9. *C records displayed* Cont *replay from a compact-interval request through $A, B, O, D, W, S, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CompactRealInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactRealInterval}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, B, O, D, W, S, R, E, H, C, P, N$. It has no coordinate for host compactness, arbitrary open covers, selected subcovers, quotient real equality, countable choice, or ambient real completeness.

Theorem 4743.2 (Compact real interval finite-net obligations)**.** *For every accepted* $\mathsf{CompactRealInterval}^{\uparrow}$ *carrier*

$$I = (A, B, O, D, W, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactRealInterval}^{\uparrow}}$ *surface consists of the following finite obligations:*

1. *endpoint admission for the two located* $\mathsf{Real}^{\uparrow}$ *rows A and B;*
2. *order and apartness admission for the displayed ledger O;*
3. *dyadic scale and tolerance admission for the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D;*
4. *finite-net schedule admission for W, including mesh containment and endpoint slack;*
5. *StreamName finite-window admission for S and regular rational readback for R;*
6. *terminal Real seal admission for E after the finite endpoint, dyadic, stream, and regular rows are visible;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming through H, C, P, N.*

No compact-interval obligation is stored outside these rows.

Proof. Project the carrier of Definition 5553.1. The endpoint rows A, B and the order/apartness row O expose the interval boundary and the located comparison surface available to the packet.

Read the finite inspection rows next. The dyadic ledger D supplies common-scale tolerance checks, while W lists the finite mesh windows to which interval inspection is confined.

The stream and regular rows are downstream. The row S carries the finite StreamName requests, and R repacks the same endpoint, mesh, and tolerance reads as regular rational windows before the terminal Real seal E is consumed.

Finally, H, C, P, N transport, replay, source, and locally name the same finite packet. Since the carrier has no coordinate for host compactness, arbitrary open covers, selected subcovers, quotient equality, countable choice, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 4743.3 (Compact real interval NameCert scope)**.** *Every accepted* $\mathsf{CompactRealInterval}^{\uparrow}$ *consumer factors through the displayed route*

$$\mathsf{Real}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{CompactMetric}^{\uparrow},\quad \mathsf{HeineBorelFiniteNet}^{\uparrow}.$$

Thus the compact closed-interval surface exports only endpoint Real seals, dyadic tolerance and finite-net data, finite StreamName windows, regular rational readbacks, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It does not export host compactness, arbitrary open-cover compactness, selected subcovers, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the endpoint and tolerance rows. The carrier exposes the interval through A, B, O, D, so every later compact-interval read is attached to the same located Real endpoints and dyadic tolerance ledger.

Use the finite-net and window rows. The row W records the displayed dyadic net schedule, S restricts stream requests to finite windows, and R records the regular rational readback of exactly those windows.

The compactness siblings are read only through the same finite rows. The $\mathsf{CompactMetric}^{\uparrow}$ and $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ provenance in P witnesses compatibility with finite-net compactness, but it does not add an arbitrary cover selector or host compactness coordinate.

The structural rows H, C, P, N preserve the route by transport, replay, sourcing, and local naming. Since no refused object appears in the carrier, every accepted consumer remains inside the stated scope. □

Theorem 4743.4 (Compact real interval effective completion route)**.** *Let $I = (A, B, O, D, W, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{CompactRealInterval}^{\uparrow}$ *carrier. Any consumer that exports endpoint or mesh data to a completion-facing reader must pass through finite interval nets,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance, and then the* $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$ *route of chapter 5930. The export does not assert open-cover compactness, selected subcovers, quotient real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5553.1. Endpoint and mesh data are displayed only by A, B, O, D, W, S, R, E before the structural rows H, C, P, N are consumed.

Apply Definition 5553.2. The finite-net obligation exposes endpoint admission, order and apartness, dyadic scale and tolerance, the finite net schedule, StreamName windows, regular rational readback, and the terminal Real seal in that order.

Apply Definition 5553.3. The compactness side is finite-net compactness through $\mathsf{CompactMetric}^{\uparrow}$ and $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, not an arbitrary open-cover selector.

The completion-facing reader therefore receives the same finite data through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ before entering chapter 5930. Componentwise hsame transport and displayed Cont replay preserve the route, so no quotient, choice, selected-subcover, or ambient-completeness coordinate is introduced. □

Falsifiable prediction: Every $\mathsf{CompactRealInterval}^{\uparrow}$ read factors through two located $\mathsf{Real}^{\uparrow}$ endpoint rows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a finite dyadic net schedule, $\mathsf{StreamName}^{\uparrow}$ finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, finite-net compactness sibling provenance, componentwise hsame, displayed Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{CompactRealInterval}^{\uparrow}}$ rows.

Independence witness: real, dyadicratcore, streamname, regseqrat, compactmetric, heineborelfinitemesh: $\mathsf{CompactRealInterval}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries endpoint Real seals, order/apartness data, dyadic common-scale tolerances, a finite interval net schedule, finite stream windows, regular readback, finite-net compactness provenance, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactRealInterval}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactRealInterval}^{\uparrow}$ packet is generated from two located RealUp endpoint rows, an order and apartness ledger, a DyadicRatCoreUp finite tolerance ledger, a finite dyadic net schedule, StreamNameUp finite windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactRealInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5553.1, Definition 5553.2, and Definition 5553.3 seed the compact closed-interval carrier over endpoint Real seals, dyadic tolerances, finite nets, StreamName windows, RegSeqRat readback, and finite-net compactness sibling provenance.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactRealInterval}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host compactness, arbitrary open-cover compactness, selected subcovers, quotient real equality, countable choice, ambient $\mathsf{Real}^\uparrow$ completeness, Lean verification, or bridge checking for $\mathsf{CompactRealInterval}^\uparrow$.

Upgrade path: Obligation closure requires checked carrier admission, finite-net schedule exactness, dyadic tolerance stability, StreamName window pullback, RegSeqRat readback, Real endpoint sealing, replay stability, and nonescape for BEDC.Derived.CompactRealIntervalUp.

Theorem 4743.5 (Compact real interval closed-bounded dependency route)**.** *Every* $\mathsf{CompactRealInterval}^\uparrow$ *consumer that inspects the compact-interval packet must first pass through the closed-bounded interval endpoint rows of chapter 1591, the dyadic finite-net rows recorded by the compact interval carrier, the* $\mathsf{StreamName}^\uparrow$ *finite windows of chapter 126, the* $\mathsf{RegSeqRat}^\uparrow$ *readback rows, and the terminal* $\mathsf{Real}^\uparrow$ *seal of chapter 38. The route exposes interval endpoints, finite net data, stream observations, regular rational reconstruction, and local real naming before any compact interval consumer may inspect the packet.*

Proof. Project the compact real interval carrier. The closed-bounded endpoint rows supply the only interval source, and the dyadic finite-net rows supply the only finite covering data inside the packet.

The stream and regular-readback rows are then read in order. The $\mathsf{StreamName}^\uparrow$ windows specify the finite observations, and the $\mathsf{RegSeqRat}^\uparrow$ rows reconstruct the rational readback attached to those observations.

The terminal $\mathsf{Real}^\uparrow$ seal is available only after these endpoint, finite-net, stream, and readback rows have been displayed. Thus a compact interval consumer receives the actual L10 dependency route rather than an ungrounded compactness credential. □

Theorem 4743.6 (Compact real interval Cauchy diagonal dependency)**.** *Every* $\mathsf{CompactRealInterval}^\uparrow$ *finite-net or nested-window consumer that passes to the* $\mathsf{CauchyDiagonalSelection}^\uparrow$ *sibling packet of chapter 4080 must first expose the interval endpoint rows, the located interval row, the compact finite-net row, the* $\mathsf{StreamName}^\uparrow$ *window row, the* $\mathsf{RegSeqRat}^\uparrow$ *handoff row, the terminal* $\mathsf{Real}^\uparrow$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CompactRealInterval}^\uparrow}$ *row. The route may not import selected subsequences, open-cover compactness, quotient real equality, or ambient completeness.*

Proof. Project the compact real interval carrier of Definition 5553.1. The endpoint rows A, B, the order and located interval row O, the finite dyadic net schedule W, and the compact finite-net entries in P are visible before any diagonal read is available.

The stream and rational readback rows are then forced into the Cauchy-facing order. The $\mathsf{StreamName}^\uparrow$ row S supplies finite observation windows, the $\mathsf{RegSeqRat}^\uparrow$ row R supplies the rational handoff, and the $\mathsf{Real}^\uparrow$ row E supplies the terminal seal.

Finally H, C, P, N transport, replay, source, and name the same route. Since no carrier coordinate stores a selected subsequence, arbitrary open cover, quotient real equality, or ambient completeness principle, every compact-interval handoff to $\mathsf{CauchyDiagonalSelection}^\uparrow$ is confined to the displayed rows. □

Theorem 4743.7 (Compact real interval dossier lattice route)**.** *Every* $\mathsf{CompactRealInterval}^\uparrow$ *dossier consumer that inspects an accepted interval packet must first display the* $\mathsf{ClosedBoundedInterval}^\uparrow$

endpoint rows, the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, the terminal* $\mathsf{Real}^{\uparrow}$ *seals, the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net compatibility row, and the* $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ *provenance row. Only after those rows have been replayed through componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{CompactRealInterval}^{\uparrow}}$ *row may the consumer inspect the compact interval packet itself.*

Proof. Project the carrier of Definition 5553.1. The endpoint rows A and B give the closed-bounded interval source, while the dyadic tolerance row D records the finite scale and containment ledger attached to those endpoints.

The stream and readback rows are then forced into the same route. The $\mathsf{StreamName}^{\uparrow}$ row S supplies only finite observation windows, the $\mathsf{RegSeqRat}^{\uparrow}$ row R reconstructs the corresponding rational readback, and the $\mathsf{Real}^{\uparrow}$ seal row E is reached only after those finite reads are visible.

The compactness-facing rows are provenance and compatibility rows, not host compactness principles. The $\mathsf{CompactMetric}^{\uparrow}$ and $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ entries in P record finite-net compatibility and finite-net provenance before any downstream consumer can use the interval packet as compact data.

Finally H, C, P, N transport, replay, source, and name that same lattice route. Since no carrier coordinate stores arbitrary open covers, selected subcovers, quotient real equality, countable choice, or ambient real completeness, a compact interval consumer can inspect only the displayed dossier lattice. □

Every $\mathsf{CompactRealInterval}^{\uparrow}$ finite-net consumer records its sibling route through the finite epsilon-net surface of chapter 1767, the located interval source of chapter 1709, the closed-bounded interval net packet of chapter 1250, and the terminal real-name seal of chapter 38 before any compact interval packet is read. The compact interval finite-net read also consumes the $\mathsf{CompactMetric}^{\uparrow}$ carrier of chapter 129 and the $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ finite-cover route of chapter 3471 before the finite epsilon-net ledger is exported. The route keeps finite nets, located endpoints, closed-bounded interval data, compact-metric carrier rows, Heine–Borel finite-cover rows, and RealUp seals visible as dependency rows rather than as hidden host compactness.

Proposition 4743.8 (Compact real interval real-source route)**.** *Every* $\mathsf{CompactRealInterval}^{\uparrow}$ *consumer that reads compact interval rows first passes through the endpoint* $\mathsf{Real}^{\uparrow}$ *source of chapter 38, the metric reading surface of chapter 1638, and the finite-net route recorded by chapter 5553. The compact interval packet therefore exposes real endpoints, metric comparison data, and finite-net compatibility before any compact interval row is exported.*

Chapter 4744

A Concrete Naming Certificate for $\mathsf{LocatedCutCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedCutCompletion}^{\uparrow}$ packet names the finite lower–upper dyadic bracket surface by which Real and Completion consumers compare located-cut evidence with regular Cauchy readback. It sits beside the dyadic endpoint ledger of chapter 291, the finite observation interface of chapter 126, the regular rational handoff of chapter 301, the terminal real seal of chapter 38, and the Cauchy–Dedekind bridge of chapter 2346. The packet is a BEDC-native carrier surface for located lower and upper brackets; it does not construct $\mathsf{Real}^{\uparrow}$ from primitive Dedekind cuts and does not add an ambient completeness principle.

Definition 4744.1 (Located-cut completion bracket carrier)**.** *A* $\mathsf{LocatedCutCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B^-, B^+, G, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. B^- *is the lower dyadic bracket ledger. It records inhabited lower cells, lower endpoint witnesses, and lower refinement requests through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
2. B^+ *is the upper dyadic bracket ledger. It records inhabited upper cells, upper endpoint witnesses, and upper refinement requests through the same dyadic scale row.*
3. G *is the located comparison row. For every displayed lower endpoint and upper endpoint request, it records a finite separation, overlap, or refinement witness between* B^- *and* B^+*.*
4. W *is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule used to expose only the finitely requested bracket observations.*
5. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that compares the displayed brackets with a regular rational Cauchy route.*
6. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger shared by* B^-, B^+, G, W, R*.*
7. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the lower bracket, upper bracket, located comparison, finite window, regular readback, and dyadic refinement rows have been displayed.*
8. H *records componentwise* hsame *transport for the bracket rows, comparison row, window row, readback row, dyadic row, real seal, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay of the bracket-completion route*

$$B^-, B^+, G, D \longmapsto W, R \longmapsto E, H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{LocatedCutCompletion}^\uparrow$, $\mathsf{DyadicRatCore}^\uparrow$, $\mathsf{StreamName}^\uparrow$, $\mathsf{RegSeqRat}^\uparrow$, $\mathsf{Real}^\uparrow$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCutCompletion}^\uparrow}$ *row.*

The classifier accepts only packets that display both bracket ledgers, the shared located comparison row, the common dyadic refinement ledger, the finite window schedule, the regular readback row, the terminal real seal, and the structural rows. It has no coordinate for primitive Dedekind cuts, quotient equality, selected limits, trichotomy, or ambient completeness.

Lean4 ✓ `BEDC.Derived.LocatedCutCompletionUp.LocatedCutCompletionTasteGate single carrier alignment`

Theorem 4744.2 (Located-cut bracket inhabitation)**.** *For every accepted* $\mathsf{LocatedCutCompletion}^\uparrow$ *carrier $L = (B^-, B^+, G, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedCutCompletion}^\uparrow}$ *surface includes inhabited lower and upper dyadic bracket reads. Every public bracket read must pass through the displayed rows B^- and B^+ and the shared dyadic ledger D before it can reach W, R, E, H, C, P, N.*

Proof. Carrier admission is projection from Definition 5554.1. The accepted packet exposes B^- and B^+ as separate lower and upper bracket ledgers, each tied to the same dyadic refinement row D.

The classifier has no bracket coordinate outside these ledgers. Therefore any public bracket read is a read of the displayed lower ledger or upper ledger together with the shared dyadic scale data.

The remaining rows W, R, E, H, C, P, N only schedule, read back, seal, transport, replay, source, and name that same bracket route. They cannot supply a detached lower or upper cut object. □

Theorem 4744.3 (Located-cut comparison obligation)**.** *For every accepted* $\mathsf{LocatedCutCompletion}^\uparrow$ *carrier, the row G is the only located comparison interface between the lower bracket ledger B^- and the upper bracket ledger B^+. A Real or Completion consumer cannot compare the two bracket sides without first reading B^-, B^+, G, D inside the same finite packet.*

Proof. Read the carrier rows named in Definition 5554.1. The lower and upper bracket ledgers are displayed separately, and the located comparison row G is the sole row that relates their endpoint requests.

A consumer that omits G has only two unrelated dyadic ledgers. A consumer that omits either bracket side has no two-sided located question to compare.

Thus the comparison route is forced through B^-, B^+, G, D. The stream, regular readback, real seal, and structural rows preserve the comparison after it is displayed, but they do not create a second comparison principle. □

Theorem 4744.4 (Common dyadic refinement stability)**.** *Let $L = (B^-, B^+, G, W, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{LocatedCutCompletion}^\uparrow$ *carrier. Any refinement of a displayed lower bracket or upper bracket that remains inside the common dyadic ledger D preserves the same* $\mathsf{LocatedCutCompletion}^\uparrow$ *packet route through G, W, R, E, H, C, P, N.*

Proof. The carrier stores one dyadic refinement ledger D for both bracket sides. Refining a lower or upper endpoint inside D therefore keeps the refined observation in the same finite packet rather than moving it to an external cut object.

The located comparison row G is read after the two bracket ledgers and the shared dyadic scale are fixed. A refinement that remains in D is still a request to the same comparison row.

Finally W, R, E, H, C, P, N are attached to this packet route. They can replay and name the refined bracket read, but they cannot replace the common dyadic ledger by an independent refinement principle. □

Theorem 4744.5 (Classifier transport under bracket equivalence)**.** *For every accepted* $\mathsf{LocatedCutCompletion}^{\uparrow}$ *carrier, componentwise* hsame *transport of the lower bracket, upper bracket, located comparison, dyadic refinement, stream window, regular readback, real seal, replay, provenance, and local naming rows preserves classifier acceptance. Equivalence of bracket displays is therefore transported only through* H *and the displayed packet rows.*

Proof. The transport row H is a coordinate of the accepted carrier. Its scope is componentwise: it transports $B^-, B^+, G, W, R, D, E, C, P, N$ as rows of the same packet.

The classifier of Definition 5554.1 accepts exactly those displayed rows. Applying H preserves the rows it names and leaves no unmentioned quotient equality coordinate to inspect.

Hence bracket equivalence is a packet-level transport statement. It is not equality of primitive cuts and not quotient equality of completed real names. □

Theorem 4744.6 (Real seal handoff for located-cut completion)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{LocatedCutCompletion}^{\uparrow}$ *carrier factors through*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The terminal seal E *is reached only after the lower bracket, upper bracket, located comparison, common dyadic refinement, finite window schedule, and regular rational readback rows have been displayed.*

Proof. Start from the bracket rows B^-, B^+ and the located comparison row G. The shared dyadic ledger D fixes the common refinement scale on which both bracket sides are read.

The finite observation schedule W and regular rational readback row R then expose the bracket route to the Cauchy-facing side of the packet. At this point the consumer has only displayed finite rows, not a selected limit or quotient representative.

The terminal real seal E is therefore a handoff after B^-, B^+, G, D, W, R. The structural rows H, C, P, N transport, replay, source, and name the same handoff, so the excluded primitives and ambient completeness principle have no carrier coordinate. □

Falsifiable prediction: Every accepted $\mathsf{LocatedCutCompletion}^{\uparrow}$ Real or Completion read factors through displayed lower bracket, upper bracket, located comparison, dyadic refinement, finite window, regular rational readback, Real seal, transport, replay, provenance, and local naming rows.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchy-dedekind-bridge: $\mathsf{LocatedCutCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two-sided located bracket ledgers, common dyadic refinement, regular Cauchy readback, terminal Real sealing, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCutCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCutCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5554.1, Definition 5554.2, Definition 5554.3, Definition 5554.4, Definition 5554.5, and Definition 5554.6 seed the finite located lower–upper bracket completion surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCutCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim primitive Dedekind cuts, quotient equality, selected limits, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked bracket inhabitation, located comparison, common dyadic refinement stability, classifier transport under bracket equivalence, Real seal handoff, and nonescape for BEDC.Derived.LocatedCutCompletionUp.

Constructive story: A LocatedCutCompletion$^{\uparrow}$ packet is generated from lower and upper dyadic bracket ledgers, a located comparison row, common dyadic refinement, finite StreamName windows, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4745

A Concrete Naming Certificate for $\mathsf{DedekindEtaCompletion}^{\uparrow}$

Following Bishop and Bridges on constructive real analysis, the $\mathsf{DedekindEtaCompletion}^{\uparrow}$ packet records an eta-completion route from regular rational names to located Dedekind-style real boundaries as finite BEDC NameCert data. It sits over the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the Cauchy criterion equivalence surface of chapter 3343, and the terminal real-name seal of chapter 38. The packet gives completion consumers a displayed eta route without quotient streams, selected host limits, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4745.1 (DedekindEtaCompletion carrier)**.** *A* $\mathsf{DedekindEtaCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, R, D, Q, L, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule for the rational observations retained by the eta route.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, binding each retained stream window to a regular rational observation.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying positive-radius witnesses, half-radius refinements, and strict comparison cells used by the regular readback.*
4. *Q is the* $\mathsf{CauchyCriterionEquivalence}^{\uparrow}$ *comparison row, recording the finite Cauchy criterion checks that certify the retained windows as a regular eta-family.*
5. *L is the located lower-and-upper cut ledger generated from S, R, D, Q; it records only displayed rational cut tests and their dyadic slack.*
6. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reachable only after the stream, regular, dyadic, criterion, and cut-ledger rows have been displayed.*
7. *H records componentwise* hsame *transport for the window, readback, tolerance, Cauchy criterion, cut-ledger, real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$S, R, D \longmapsto Q \longmapsto L \longmapsto A.$$

9. *P is the* Pkg *provenance over* $\mathsf{DedekindEtaCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyCriterionEquivalence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DedekindEtaCompletion}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these ten rows. Its classifier compares accepted packets only through $S, R, D, Q, L, A, H, C, P, N$ and has no coordinate for quotient streams, selected host limits, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.DedekindEtaCompletionUp.DedekindEtaCompletionTasteGate single carrier alignment`

Theorem 4745.2 (DedekindEtaCompletion NameCert obligations)**.** *For an accepted* $\mathsf{DedekindEtaCompletion}^{\uparrow}$ *carrier*

$$E = (S, R, D, Q, L, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DedekindEtaCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the stream-window schedule, regular rational readback, dyadic tolerance ledger, Cauchy criterion comparison row, located cut ledger, terminal real seal, transport, replay, provenance, and local naming rows;*
2. *window exactness, requiring every rational observation used by the eta route to be addressed by S before it can be read by R;*
3. *dyadic tolerance exactness, requiring every comparison in the regular readback and every cut test in L to consume a displayed tolerance or refinement from D;*
4. *Cauchy criterion compatibility, requiring Q to certify the retained windows as the same regular eta-family before the cut ledger is exported;*
5. *cut locatedness, requiring L to expose lower and upper rational tests only through S, R, D, Q;*
6. *real-seal handoff, requiring A to be downstream of the same displayed eta route;*
7. *classifier transport and replay, requiring H and C to preserve exactly the listed rows and no external completion object;*
8. *non-escape, excluding quotient streams, selected host limits, countable choice, trichotomy, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 5555.1. The accepted packet exposes exactly the stream-window, regular readback, dyadic tolerance, Cauchy criterion, cut-ledger, real-seal, and structural rows.

Window exactness follows from the order of the carrier. A rational observation enters the eta route through S, and R can read it only as a retained finite window. There is no coordinate for an unaddressed stream or a quotient of streams.

Dyadic tolerance exactness is supplied by D. Every regular comparison and every cut test has to name a positive-radius witness, refinement, or strict comparison cell before it can be used by Q or L.

The Cauchy criterion row Q is the only compatibility surface. It certifies that the retained regular windows form the eta-family consumed by the cut ledger, so no selected limit or countable-choice schedule is introduced.

The cut ledger L is downstream of S, R, D, Q, and the real seal A is downstream of L. Hence lower and upper rational tests and Real-facing reads remain inside the displayed eta route.

Finally H, C, P, N transport, replay, source, and name only the listed rows. Since the excluded principles have no carrier coordinate, they cannot become local NameCert obligations. □

Theorem 4745.3 (DedekindEtaCompletion L10 handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{DedekindEtaCompletion}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchyCriterionEquivalence}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The exported object is a displayed eta-completion handoff from regular rational windows to a located real seal. It is not a quotient stream, selected host limit, countable-choice construction, trichotomy split, open-cover compactness principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the accepted carrier and project the public readback rows. A Real-facing or completion-facing consumer can reach the seal row A only by following the replay route named in Definition 5555.1.

The first stage is finite-window data. The row S names the inspected stream windows, and R reads those windows as regular rational observations.

The second stage is tolerance and criterion data. The dyadic ledger D supplies the radius cells consumed by the regular readback, and Q records the Cauchy criterion checks for the same retained family.

The cut ledger L then exposes the Dedekind-style lower and upper rational tests generated by that family. Since L is downstream of S, R, D, Q, it cannot select a host limit or quotient stream representative.

Finally A seals only this displayed route, while H, C, P, N preserve, replay, source, and name the same finite packet. Therefore the handoff exports the eta route and none of the excluded classical completeness principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindEtaCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DedekindEtaCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5555.1, Definition 5555.2, and Definition 5555.3 seed the finite eta-completion route over StreamName, RegSeqRat, DyadicRatCore, CauchyCriterionEquivalence, Real, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DedekindEtaCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected host limits, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window exactness, dyadic tolerance exactness, Cauchy criterion compatibility, cut locatedness, real-seal handoff, classifier transport, replay, and non-escape for BEDC.Derived.DedekindEtaCompletionUp.

Constructive story: A $\mathsf{DedekindEtaCompletion}^{\uparrow}$ packet is generated from StreamName finite windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, a CauchyCriterionEquivalence comparison row, a located cut ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4746

A Concrete Naming Certificate for $\mathsf{GITQuotient}^{\uparrow}$

Following Mumford's geometric invariant theory, the $\mathsf{GITQuotient}^{\uparrow}$ packet records the finite quotient-facing route from a projective or affine scheme presentation with group action data to invariant-ring rows, semistable-window rows, orbit-separation rows, and a displayed quotient name. It sits after the scheme carrier of chapter 153, the affine-variety surface of chapter 154, the projective-variety surface of chapter 155, the group certificate of chapter 41, the field certificate of chapter 45, and the ring certificate of chapter 43. The packet names a finite GIT quotient certificate without importing host quotient equality, stack objects, selected orbit representatives, or an external moduli functor.

Definition 4746.1 (GIT quotient carrier)**.** *A* $\mathsf{GITQuotient}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (S, A, P, G, I, Q, O, H, C, L, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Scheme}^{\uparrow}$ *source row naming the ambient scheme surface and the affine-cover ledger on which the quotient construction is read.*
2. *A is the* $\mathsf{AffineVar}^{\uparrow}$ *chart row used for invariant-ring computations on affine windows of S.*
3. *P is the* $\mathsf{ProjectiveVar}^{\uparrow}$ *presentation row naming the projective closure, homogeneous coordinates, linearization window, and projective incidence ledger.*
4. *G is the acting* $\mathsf{Group}^{\uparrow}$ *row over the displayed* $\mathsf{Field}^{\uparrow}$ *and* $\mathsf{Ring}^{\uparrow}$ *scalar rows consumed by the action and invariant-ring ledgers.*
5. *I is the invariant-ring ledger. It records the finite generator rows, relation rows, grading rows, and action-fixedness checks used to form the quotient coordinate packet.*
6. *Q is the quotient-name row. It records the displayed affine or projective quotient carrier obtained from I and the selected semistable window, but it is not a host quotient object.*
7. *O is the orbit-separation ledger. It records semistable-window membership, closed-orbit comparison rows, invariant-value comparison rows, and refusal rows for unstable histories.*
8. *H records componentwise* hsame *transport for the scheme, affine, projective, group, scalar, invariant-ring, quotient-name, orbit-separation, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from every quotient read through $S, A, P, G, I, Q, O, H, L, N$.*
10. *L is the* Pkg *provenance over* $\mathsf{GITQuotient}^{\uparrow}$, $\mathsf{Scheme}^{\uparrow}$, $\mathsf{AffineVar}^{\uparrow}$, $\mathsf{ProjectiveVar}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{GITQuotient}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for host quotient equality, quotient stacks, selected orbit representatives, external moduli functors, or unstated invariant-theory completions.

Lean4 ✓ `BEDC.Derived.GITQuotientUp.GITQuotientTasteGate single carrier alignment`

Theorem 4746.2 (GIT quotient NameCert obligations)**.** *For every accepted* $\mathsf{GITQuotient}^{\uparrow}$ *carrier*

$$Z = (S, A, P, G, I, Q, O, H, C, L, N),$$

the local $\mathsf{NameCert}_{\mathsf{GITQuotient}^{\uparrow}}$ *surface consists exactly of scheme admission through S, affine-chart admission through A, projective-presentation admission through P, group-action and scalar admission through G, invariant-ring visibility through I, quotient-name exposure through Q, orbit-separation and semistable-window routing through O, componentwise transport through H, displayed replay through C, provenance through L, and local naming through N.*

Proof. Project the carrier of Definition 5556.1. The geometric source rows are S, A, P, G, the quotient-facing rows are I, Q, O, and the structural rows are H, C, L, N.

The invariant-ring obligation is finite. Its generator, relation, grading, and action-fixedness entries are rows inside I, and each is read through the affine chart, projective presentation, group action, and scalar certificates already displayed by A, P, G.

The quotient-name and orbit-separation obligations are then separate rows. The row Q exposes only the quotient carrier built from the invariant ledger and semistable window, while O records which semistable histories can be separated by invariant values and which unstable histories are refused.

Transport, replay, provenance, and local naming preserve exactly these rows. Since no coordinate names a host quotient, quotient stack, selected orbit representative, or external moduli functor, the listed rows exhaust the NameCert surface. □

Theorem 4746.3 (GIT quotient invariant-ring handoff)**.** *Every downstream read of an accepted* $\mathsf{GITQuotient}^{\uparrow}$ *quotient-name row factors through the invariant-ring ledger*

$$S, A, P, G \longmapsto I \longmapsto Q.$$

Thus the quotient carrier is exposed as finite invariant-ring and semistable-window data over the displayed scheme, affine, projective, group, field, and ring rows, not as a host quotient object or a stack presentation.

Proof. Start with the displayed source rows S, A, P, G. They supply the scheme cover, affine chart, projective presentation, action row, and scalar rows on which invariant functions are allowed to be read.

Read the invariant-ring ledger I. The finite generator, relation, grading, and fixedness checks in I are the only rows used to build the quotient coordinate packet.

The quotient-name row Q is then a projection from that packet together with the semistable-window data carried by O. The structural rows H, C, L, N can transport and replay this route, but they cannot add a host quotient object or a stack presentation. □

Theorem 4746.4 (GIT quotient orbit-separation nonescape)**.** *No accepted* $\mathsf{GITQuotient}^{\uparrow}$ *packet exports orbit separation outside the displayed semistable-window and invariant-value rows. If a consumer compares two semistable histories, the comparison must pass through* O *and the invariant values supplied by* I*; if a history lies outside the displayed semistable window, the refusal row in* O *blocks quotient-name export for that history.*

Proof. Project an accepted packet $Z = (S, A, P, G, I, Q, O, H, C, L, N)$. The only orbit-facing row is O, and the only scalar-valued separating data available to O are the invariant values recorded by I.

For semistable histories, O requires the displayed window-membership row before any comparison is read. The comparison is then routed to invariant values from I, so separation remains inside the finite invariant-ring ledger.

For histories outside the semistable window, the refusal row in O prevents the quotient-name row Q from being exported for that history. Componentwise hsame transport, Cont replay, Pkg provenance, and local naming preserve the refusal because none of them introduces an additional orbit classifier. □

Falsifiable prediction: Every accepted $\mathsf{GITQuotient}^{\uparrow}$ quotient-name read factors through a SchemeUp row, an AffineVarUp chart row, a ProjectiveVarUp presentation row, GroupUp action data over FieldUp and RingUp scalar rows, an invariant-ring ledger, a semistable-window ledger, orbit-separation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: scheme, affinevar, projectivevar, group, field, ring: $\mathsf{GITQuotient}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a group action, invariant-ring rows, semistable-window rows, quotient-name exposure, orbit-separation refusal, transport, replay, provenance, and local naming in one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{GITQuotient}^{\uparrow}}$**.**

Constructive story: A $\mathsf{GITQuotient}^{\uparrow}$ packet is generated from a SchemeUp source row, AffineVarUp chart row, ProjectiveVarUp presentation row, GroupUp action data over FieldUp and RingUp scalar rows, invariant-ring rows, semistable-window rows, orbit-separation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{GITQuotient}^{\uparrow}}$, seed)

Scope closed: Definition 5556.1, Definition 5556.2, Definition 5556.3, and Definition 5556.4 seed the finite invariant-ring and semistable-window route for GIT quotient consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{GITQuotient}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host quotient equality, quotient stacks, selected orbit representatives, external moduli functors, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, invariant-ring handoff, semistable-window routing, orbit-separation refusal, quotient-name exposure, replay stability, provenance exhaustion, and local naming for BEDC.Derived.GITQuotientUp.

Chapter 4747

A Concrete Naming Certificate for $\mathsf{AubinLions}^{\uparrow}$

Following Aubin and Lions, the $\mathsf{AubinLions}^{\uparrow}$ packet records the compactness route used for time-dependent Sobolev families as finite NameCert data. It sits over the Sobolev source of chapter 440, the weak-derivative time-translation surface of chapter 2210, the compact-window handoff of chapter 2218, the Cauchy readback of chapter 128, and the scalar seal of chapter 38. The packet names only the displayed compactness handoff; it does not import host subsequence selection, quotient completion, ambient real completeness, or an unrestricted compact embedding theorem.

Definition 4747.1 (Aubin-Lions carrier)**.** *An* $\mathsf{AubinLions}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, T, R, M, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Sobolev}^{\uparrow}$ *source row, exposing the space-regularity, weak-derivative ledger, integrability window, and local naming data consumed by the compactness request.*
2. *T is the* $\mathsf{WeakDerivative}^{\uparrow}$ *time-translation row, recording the finite temporal difference windows, derivative bounds, and equicontinuity budget that keep translated reads inside the same Sobolev source.*
3. *R is the* $\mathsf{RellichKondrachov}^{\uparrow}$ *compact-window row, carrying the finite spatial compactness handoff available on inspected bounded windows.*
4. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *readback row, recording Cauchy comparison data for the compact-window images without completing a host quotient space.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *scalar seal for norms, radii, tolerances, and translation moduli.*
6. *H records componentwise* hsame *transport for the Sobolev source, time-translation row, compact-window row, complete-metric readback, real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an Aubin-Lions compactness request through S, T, R, M, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{AubinLions}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{RellichKondrachov}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AubinLions}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, R, M, E, H, C, P, N$. It has no coordinate for a selected subsequence, quotient function equality, host compact embedding, ambient completed Sobolev space, global time regularity theorem, unrestricted real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.AubinLionsUp.AubinLionsTasteGate single carrier alignment`

Theorem 4747.2 (Aubin-Lions NameCert obligations)**.** *For every accepted* $\mathsf{AubinLions}^{\uparrow}$ *carrier*

$$A = (S, T, R, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AubinLions}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed Sobolev source, weak-derivative time-translation row, Rellich–Kondrachov compact-window row, complete-metric readback, real seal, transport, replay, provenance, and local naming data;*
2. *source discipline, requiring every compactness request to enter through the* $\mathsf{Sobolev}^{\uparrow}$ *row S before temporal or spatial compactness data are read;*
3. *time-translation exactness, requiring T to display the derivative bounds, translation windows, and temporal equicontinuity budget used by the compactness route;*
4. *compact-window exactness, requiring R to expose only the inspected Rellich–Kondrachov spatial compactness handoff;*
5. *complete-metric and real readback, requiring M and E to supply only finite Cauchy comparisons, norms, radii, tolerances, and scalar moduli;*
6. *provenance exhaustion, requiring H, C, P, N to transport, replay, source, and name exactly the displayed rows and no selected subsequence, quotient function equality, host compact embedding, ambient completed Sobolev space, global time regularity theorem, unrestricted real completeness, Lean verification, or bridge credential.*

No Aubin-Lions obligation is stored outside these rows.

Proof. Project the accepted packet $A = (S, T, R, M, E, H, C, P, N)$. The carrier definition lists every visible component, so carrier admission is row-local.

The source discipline is forced by S. A compactness read first enters the Sobolev source row and sees only the displayed regularity, weak-derivative ledger, integrability window, and local naming data.

The temporal and spatial compactness rows then split the analytic work. The row T supplies the time-translation budget, while R supplies the Rellich–Kondrachov compact-window handoff. Neither row selects a subsequence or completes a quotient object.

The readback rows M and E expose only Cauchy comparisons and scalar tolerance data. Finally H, C, P, N preserve, replay, source, and name the same finite route, so the listed obligations exhaust the local NameCert surface. □

Theorem 4747.3 (Aubin-Lions compactness handoff)**.** *Every compactness consumer of an accepted* $\mathsf{AubinLions}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{Sobolev}^{\uparrow} \longmapsto \mathsf{WeakDerivative}^{\uparrow} \longmapsto \mathsf{RellichKondrachov}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

and then through the displayed BHist, hsame, Cont, Pkg, *and* NameCert *rows of the same packet. The consumer receives a finite compactness handoff certificate, not a selected convergent subsequence, quotient function equality, host compact embedding theorem, or ambient completeness theorem.*

Proof. Start with a compactness consumer request. By Definition 5557.2, the request first reads the Sobolev source row S.

The temporal route is then visible through T. It supplies the time-translation windows and derivative bounds needed before the spatial compactness row is read.

The spatial compactness handoff is exactly R. The complete-metric row M and real seal E only read back finite Cauchy comparisons and scalar budgets for that handoff.

The structural rows H, C, P, N keep the route inside the same packet. Since no selected subsequence, quotient equality, host compact embedding, or ambient completeness coordinate appears in the carrier, no consumer can read one from the packet. □

Theorem 4747.4 (Aubin-Lions time-translation nonescape)**.** *Let $A = (S, T, R, M, E, H, C, P, N)$ be an accepted* $\mathsf{AubinLions}^{\uparrow}$ *carrier. Any consumer that keeps the Sobolev source S and the Rellich–Kondrachov compact-window row R but deletes the weak-derivative time-translation row T cannot export the Aubin-Lions compactness handoff from this packet. Such a consumer has only a spatial compact-window read and must not treat it as the time-dependent compactness route named by* $\mathsf{NameCert}_{\mathsf{AubinLions}^{\uparrow}}$.

Proof. Project the carrier of Definition 5557.1. The compactness route contains both the Sobolev source row S and the time-translation row T before the Rellich–Kondrachov compact-window row R is consumed.

Apply Definition 5557.2. The time-translation exactness obligation requires the derivative bounds, temporal difference windows, and equicontinuity budget displayed by T.

Now delete T. The remaining rows may still expose the Sobolev source and a spatial compact-window handoff, but they no longer display the temporal route that distinguishes an Aubin-Lions packet from a static Rellich–Kondrachov read.

The structural rows cannot fill that absence. They transport and replay existing rows only, so without T the consumer cannot export the Aubin-Lions compactness handoff from this packet. □

Falsifiable prediction: Every $\mathsf{AubinLions}^{\uparrow}$ compactness read factors through displayed SobolevUp, WeakDerivativeUp, RellichKondrachovUp, CompleteMetricUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows before any compactness consumer receives it.

Independence witness: sobolev, weak-derivative, rellich-kondrachov, completemetric, real: $\mathsf{AubinLions}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a Sobolev source, time-translation row, compact-window row, complete-metric readback, real scalar seal, transport, replay, provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AubinLions}^{\uparrow}}$, seed)

Scope closed: Definition 5557.1, Definition 5557.2, Definition 5557.3, and Definition 5557.4 seed the finite compactness route over Sobolev, weak-derivative, Rellich–Kondrachov, complete-metric, and real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AubinLions}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host subsequence selection, quotient completion, ambient real completeness, unrestricted compact embedding, global time regularity, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source discipline, time-translation exactness, compact-window exactness, complete-metric readback, scalar sealing, componentwise transport, replay, provenance, and local naming for BEDC.Derived.AubinLionsUp.

Constructive story: An $\mathsf{AubinLions}^{\uparrow}$ packet is generated from a Sobolev source row, weak-derivative time-translation row, Rellich–Kondrachov compact-window row, CompleteMetric readback row, Real scalar seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4748

A Concrete Naming Certificate for $\mathsf{CompactUniformPullback}^{\uparrow}$

Following Bishop and Bridges on compact-uniform continuity, the $\mathsf{CompactUniformPullback}^{\uparrow}$ packet realizes the compact-uniform routes of chapter 9237 as a finite pullback carrier joining compact-net data, pointwise-modulus rows, dyadic tolerances, regular rational readbacks, and the terminal real-name seal. It sits after the compact metric carrier of chapter 129, the continuous-map surface of chapter 130, the uniform-modulus consumer of chapter 369, the dyadic rational core of chapter 291, the regular rational sequence route of chapter 301, and the real-name seal of chapter 38. The packet names the recurring compact-uniform handoff without exporting a host modulus selector, quotient point equality, open-cover choice, or ambient Heine–Cantor theorem.

Definition 4748.1 (Compact uniform pullback carrier)**.** *A* $\mathsf{CompactUniformPullback}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, F, M, D, R, E, T, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *row naming the compact source, finite net, located-distance ledger, and coverage witnesses used by the pullback.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the graph, pointwise-modulus ledger, source metric, and target metric.*
3. *M is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row requested by downstream compact-uniform arguments.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It records dyadic tolerances, half-radius budgets, and finite lower-bound comparisons used in the compact-net fold.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback route for the rational precision histories produced by the fold.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row that exposes the final precision and target estimate only after the dyadic and regular-rational rows are accepted.*
7. *T is the pullback ledger. It records how a target tolerance request is pulled back through F, through compact finite-net rows in K, through the dyadic budget in D, through the regular-rational readback in R, and into the uniform-modulus consumer row M.*
8. *H records componentwise* hsame *transport for compact metric, continuous map, uniform-modulus, dyadic tolerance, regular readback, real seal, pullback, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from every compact-uniform request through* $K, F, M, D, R, E, T, H, P, N$.
10. *P is the* Pkg *provenance over* $\mathsf{CompactUniformPullback}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformPullback}^{\uparrow}}$ *row.*

The classifier compares accepted pullback packets only through these finite rows. It has no coordinate for a host modulus selector, quotient point equality, open-cover choice, selected Lebesgue number, or ambient compactness theorem.

Lean4 ✓ `BEDC.Derived.CompactUniformPullbackUp.CompactUniformPullbackTasteGate single carrier alignment`

Theorem 4748.2 (Compact uniform pullback NameCert obligations)**.** *For every accepted* CompactUniformPullback *carrier*

$$U = (K, F, M, D, R, E, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformPullback}^{\uparrow}}$ *surface consists exactly of compact finite-net admission through K, continuous-map pointwise-modulus admission through F, uniform-modulus consumer exposure through M, dyadic tolerance and lower-bound routing through D, regular-rational readback through R, real sealing through E, pullback ledger visibility through T, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5558.1. The source rows are K, F, M, the arithmetic and seal rows are D, R, E, the pullback row is T, and the structural rows are H, C, P, N.

The finite-net obligation is read through K, while pointwise modulus rows are read through F. The pullback ledger T is the only row that is allowed to combine those data into a tolerance-only request for M.

The arithmetic handoff is also explicit. Dyadic tolerance and lower-bound comparisons stay in D, regular-rational readback stays in R, and the final real estimate is exposed only through E.

Transport, replay, provenance, and local naming preserve this route. Because the carrier has no coordinate for a selected modulus, quotient point equality, open-cover choice, selected Lebesgue number, or host compactness theorem, the listed rows exhaust the NameCert surface. □

Theorem 4748.3 (Compact uniform pullback modulus handoff)**.** *Every downstream read of an accepted* $\mathsf{CompactUniformPullback}^{\uparrow}$ *packet factors through*

$$K, F, D, R, E, T \longmapsto M.$$

Thus a compact-uniform consumer receives a $\mathsf{UniformModulus}^{\uparrow}$ *row only after the compact finite-net data, pointwise-modulus rows, dyadic tolerance budget, regular-rational readback, real seal, and pullback ledger have all been displayed inside the same finite carrier.*

Proof. Begin with a downstream target tolerance request. The continuous-map row F supplies the pointwise-modulus rows inspected at compact-net centers, and the compact metric row K supplies the finite net and coverage witnesses used to choose those centers inside BHist.

The dyadic tolerance row D performs the finite lower-bound comparisons. Its output is read through R as a regular rational precision history and then through E as a real-sealed estimate.

The pullback ledger T records that these rows are consumed in this order before the consumer row M is exposed. Componentwise transport and replay can only preserve the displayed route, so no host modulus selector or open-cover choice is exported. □

Falsifiable prediction: Every accepted $\mathsf{CompactUniformPullback}^{\uparrow}$ modulus read factors through a CompactMetricUp finite-net row, a ContinuousMapUp pointwise-modulus row, a UniformModulusUp consumer row, DyadicRatCoreUp tolerance arithmetic, RegSeqRatUp readback, a RealUp seal, a pullback ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: compactmetric, continuousmap, uniformmodulus, dyadicratcore, regseqrat, real: $\mathsf{CompactUniformPullback}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds compact finite-net coverage, pointwise-modulus rows, dyadic tolerance budgets, regular rational readback, real sealing, a downstream uniform-modulus consumer, transport, replay, provenance, and local naming in one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformPullback}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformPullback}^{\uparrow}$ packet is generated from CompactMetricUp finite-net rows, ContinuousMapUp pointwise-modulus rows, a UniformModulusUp consumer row, DyadicRatCoreUp tolerance arithmetic, RegSeqRatUp readback, a RealUp seal, a compact-uniform pullback ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformPullback}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5558.1, Definition 5558.2, and Definition 5558.3 seed the finite compact-net, pointwise-modulus, dyadic-tolerance, regular-readback, and real-seal handoff to uniform-modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformPullback}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host modulus selection, quotient point equality, open-cover choice, selected Lebesgue numbers, ambient Heine–Cantor theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact finite-net admission, pointwise-modulus admission, dyadic tolerance exactness, regular readback, real sealing, pullback ledger visibility, uniform-modulus export, replay stability, provenance exhaustion, and local naming for BEDC.Derived.CompactUniformPullbackUp.

$\mathsf{RegularCauchyGluing}^{\uparrow}$ consumes the regular rational readback of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance rows of chapter 291, and the terminal Real seal of chapter 38 before routing the child files below.

Chapter 4749

A Concrete Naming Certificate for $\mathsf{RegularCauchyGluing}^{\uparrow}$

Bishop–Bridges style regular Cauchy gluing records the finite route by which two compatible local regular rational windows can be read as one BEDC real-name boundary without passing through quotient representatives or an ambient completeness theorem. The $\mathsf{RegularCauchyGluing}^{\uparrow}$ packet sits after the dyadic tolerance core of chapter 291, the finite observation interface of chapter 126, the regular rational readback of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the reindexing route of chapter 1568.

Definition 4749.1 (Regular Cauchy gluing carrier)**.** *A* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (L, R, D, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the left and right compatible regular Cauchy windows, each carrying finite* $\mathsf{StreamName}^{\uparrow}$ *observations and a local* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row.*
2. *D is the common* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger recording the shared dyadic radii, endpoint comparisons, overlap budgets, and refinement witnesses used by both windows.*
3. *S is the joint* $\mathsf{StreamName}^{\uparrow}$ *observation row, exposing exactly the finite indices inspected on the left window, right window, and overlap.*
4. *Q is the glued* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained by reading the two local regular rows through the common ledger D.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after L, R, D, S, Q have been displayed.*
6. *H records componentwise* hsame *transport for the two windows, common dyadic ledger, finite observations, glued readback, real seal, replay, provenance, and local certificate.*
7. *C records displayed* Cont *replay of the same finite gluing route.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyGluing}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that the two local windows are compatible on the displayed overlap through D, S, Q, H, C, P, N. It has no coordinate for quotient sequence equality, selected representatives, host real equality, countable choice, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4749.2 (Regular Cauchy gluing classifier)**.** *The* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *classifier compares accepted carriers only through the tuple* $L, R, D, S, Q, E, H, C, P, N$*. Two packets are indistinguishable for this classifier precisely when the left and right window rows, the common dyadic refinement ledger, the finite observation row, the glued regular readback, the terminal real seal, and the transport, replay, provenance, and naming rows are componentwise the same under the displayed* hsame *routes.*

Theorem 4749.3 (Regular Cauchy gluing NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier* $G = (L, R, D, S, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}$ *surface consists exactly of carrier admission for the two compatible regular Cauchy windows, common* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement through* D*, finite* $\mathsf{StreamName}^{\uparrow}$ *observation through* S*, glued* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* Q*, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier. The analytic rows before the seal are exactly the two regular windows L, R, the common dyadic ledger D, the finite observation row S, and the glued regular readback Q.

The overlap obligation is finite. Its comparisons are stored in D and read through the same inspected indices in S, so the two local $\mathsf{RegSeqRat}^{\uparrow}$ rows feed one glued readback row Q without adding a quotient representative.

Transport, replay, provenance, and local naming are supplied by H, C, P, N. Repacking these projections gives the listed $\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}$ surface, and the carrier definition leaves no hidden row for selected representatives, host equality, countable choice, or ambient completeness. □

Theorem 4749.4 (Regular Cauchy gluing overlap stability)**.** *Let* $G = (L, R, D, S, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier. Any refinement of the displayed overlap that is transported by* H *and replayed by* C *preserves the same glued* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q *and the same* $\mathsf{Real}^{\uparrow}$ *seal row* E*. Consequently downstream Real and Completion consumers receive only the finite gluing packet and not quotient stream equality, selected representatives, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the displayed overlap ledger. The common dyadic row D records every radius and endpoint comparison used by both local windows, while S records the finite observations on which those comparisons are made.

Apply the classifier of Definition 5899.2. A refinement transported by H and replayed by C can change neither the componentwise ledger coordinates nor the finite observation coordinates exposed to the classifier.

The glued readback row Q is therefore the same row after refinement, and the $\mathsf{Real}^{\uparrow}$ seal E is read only through Q together with H, C, P, N. Since the carrier contains no quotient, selector, host-equality, choice, or completeness coordinate, none of those data can be exported by overlap stability. □

Theorem 4749.5 (Regular Cauchy gluing common-refinement exactness)**.** *Let* $G = (L, R, D, S, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier. Every glued readback exported from* G *must expose the common* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement row* D *before the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q *and the* $\mathsf{Real}^{\uparrow}$ *seal row* E*. The exactness route is transported by* H *and replayed by* C*, and it exports no quotient stream equality, selected representative, host real equality, countable choice, or ambient completeness.*

Proof. Project the accepted carrier. The row D is the common dyadic refinement ledger shared by the two local regular Cauchy windows, while Q is the glued regular readback and E is the terminal Real seal.

Apply overlap stability from Definition 5899.4. Any accepted refinement of the overlap preserves the same Q and E only through the displayed ledger and observation rows, so a glued readback cannot bypass D.

Finally use the Cauchy-reindexing handoff of Definition 5899.7. It reads D, S, Q as the finite reindexing-compatible route before any Real-facing consumer reaches E, with H, C, P, N preserving and naming the same route. □

Theorem 4749.6 (Regular Cauchy gluing overlap induction)**.** *Let $G = (L, R, D, S, Q, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier. For any finite chain of displayed overlap refinements transported by H and replayed by C, the glued* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E remain unchanged. The resulting route still factors through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{CauchyReindexing}^{\uparrow}$, *and it exports no quotient stream equality, selected representatives, host equality, countable choice, or ambient completeness.*

Proof. Induct on the displayed finite refinement list.

The empty list is the overlap-stability theorem of Definition 5899.4: the common dyadic ledger D and the finite observation row S already determine the same glued readback Q and seal E.

For the step, assume the earlier refinements preserve Q and E. Compose the next displayed refinement with the induction hypothesis, transport the component rows by H, and replay the same finite route by C.

Apply the classifier of Definition 5899.2 componentwise. Since the classifier reads only $L, R, D, S, Q, E, H, C, P, N$ the next refinement cannot add a quotient, representative selector, host equality row, choice schedule, or completeness witness; it only repeats the finite route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CauchyReindexing}^{\uparrow}$. □

Theorem 4749.7 (Regular Cauchy gluing Cauchy-reindexing handoff)**.** *Every accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier factors its gluing route through the finite* $\mathsf{CauchyReindexing}^{\uparrow}$ *surface recorded in P. The handoff exposes the common dyadic refinement ledger D, the finite observation row S, and the glued regular readback row Q as a reindexing-compatible route, and it exposes no global quotient of regular Cauchy names or ambient completeness principle.*

Proof. Read the package provenance P. It names the route through $\mathsf{CauchyReindexing}^{\uparrow}$ together with $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The carrier rows D, S, Q are exactly the finite data consumed by that route: D supplies the common refinement ledger, S supplies the inspected windows, and Q supplies the regular rational readback after the two local windows agree on the overlap.

The support rows H, C, N transport, replay, and name this same finite path. Thus the handoff is reindexing-compatible BEDC data, not a quotient of regular names, a selected representative, or a completeness theorem. □

Theorem 4749.8 (Regular Cauchy gluing obligation closure handoff)**.** *Every obligation-closure read of an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier must expose the full row tuple*

$$L, R, D, S, Q, E, H, C, P, N.$$

The route factors through the common $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger, the finite* $\mathsf{StreamName}^{\uparrow}$ *observation row, the local* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks and glued readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and*

the $\mathsf{CauchyReindexing}^{\uparrow}$ *handoff named by* P *before any downstream real-name consumer may read the gluing packet.*

Proof. Start with the carrier and NameCert obligations. The accepted packet exposes $L, R, D, S, Q, E, H, C, P, N$, and the obligation surface has no smaller projection that still records the two local windows, their common refinement, and the glued readback.

Use the Cauchy-reindexing handoff of Definition 5899.7. It forces the gluing read through D, S, Q and through the provenance row P naming $\mathsf{CauchyReindexing}^{\uparrow}$, while the carrier rows L, R provide the two regular windows.

The rows E, H, C, N then seal, transport, replay, and name the same finite route. Thus obligation closure reads exactly the displayed tuple and factors through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CauchyReindexing}^{\uparrow}$. □

Theorem 4749.9 (Regular Cauchy gluing Real seal ordering)**.** *For an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier* $G = (L, R, D, S, Q, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *is reachable only after the common dyadic refinement row* D*, the finite observation row* S*, and the glued readback row* Q *have been displayed. The seal-ordering route asserts no quotient stream equality, selected representatives, host real equality, countable choice, or ambient completeness.*

Proof. Project the carrier definition. The row E is listed as the terminal $\mathsf{Real}^{\uparrow}$ seal reached only after the two local windows, the common refinement ledger, the finite observations, and the glued readback have been displayed.

Apply the overlap-stability and Cauchy-reindexing handoff theorems. They keep the common dyadic refinement in D, the inspected windows in S, and the glued regular readback in Q visible before any real-name consumer can inspect E.

Since quotient stream equality, selected representatives, host equality, choice schedules, and ambient completeness are not carrier coordinates, the ordering statement cannot export them. It records only the displayed route from D, S, Q to the terminal seal E. □

Theorem 4749.10 (Regular Cauchy gluing local tail compatibility)**.** *For an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *carrier* $G = (L, R, D, S, Q, E, H, C, P, N)$*, the two local regular-Cauchy windows* L *and* R *can be consumed by a* $\mathsf{Real}^{\uparrow}$*-seal reader only after the overlap row, the common-refinement row, and the Cauchy-reindexing row exhibit a shared* $\mathsf{RegSeqRat}^{\uparrow}$ *tail boundary. The compatibility route is the finite route through* D, S, Q, H, C, P, N *supplied by the carrier, and it exports no quotient stream equality, selected representative, or ambient completeness.*

Proof. Project the carrier of Definition 5899.1. The two local windows L, R are not read independently by a Real-facing consumer; the packet first displays their shared dyadic ledger D, finite observations S, and glued readback Q.

Apply overlap stability, Definition 5899.4, and common-refinement exactness, Definition 5899.5. These theorems keep the overlap row and the common refinement visible before Q is consumed, so the two local $\mathsf{RegSeqRat}^{\uparrow}$ tails are compared at the displayed boundary rather than by host stream equality.

Apply overlap induction, Definition 5899.6, to finite chains of displayed refinements, and then use the Cauchy-reindexing handoff, Definition 5899.7. The resulting route makes the shared tail boundary stable under H and replayable by C before E is read.

Since quotient stream equality, selected representatives, and ambient completeness are absent from Definition 5899.1, the compatibility theorem can expose only the finite D, S, Q, H, C, P, N route. □

The local-tail compatibility row is consumed through the $\mathsf{RegSeqRat}^{\uparrow}$ finite-window surface of chapter 301 and the $\mathsf{StreamName}^{\uparrow}$ finite-observation surface of chapter 126. The exact dependency is the common-tail rows displayed by D and Q, together with finite-window readback through S, before the $\mathsf{Real}^{\uparrow}$ seal E is available to any downstream consumer.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyGluing}^{\uparrow}$ packet is generated from two compatible regular Cauchy windows, a common $\mathsf{DyadicRatCore}^{\uparrow}$ refinement ledger, finite $\mathsf{StreamName}^{\uparrow}$ observations, a glued $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5899.1, Definition 5899.2, Definition 5899.3, Definition 5899.4, Definition 5899.6, Definition 5899.7, Definition 5899.8, Definition 5899.9, and Definition 5899.10 seed the finite gluing route for compatible regular Cauchy windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, host real equality, countable choice, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exposure, common dyadic-refinement exactness, overlap stability, CauchyReindexing handoff, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyGluingUp.

Theorem 4749.11 (Regular Cauchy gluing L10 sibling route)**.** *Every accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet reads its local gluing route through the L10 sibling lattice before it exports a NameCert row. The route first consumes the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows of chapter 291, the* $\mathsf{StreamName}^{\uparrow}$ *finite observation windows of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readbacks of chapter 301, the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38, and the Cauchy reindexing handoff of chapter 1568.*

Thus the gluing packet exports only a local finite NameCert route over the displayed dyadic, stream, regular-rational, Real-seal, and reindexing rows. It does not expose quotient stream equality, selected representatives, host real equality, countable choice, or ambient completeness.

Proof. Project the carrier of Definition 5899.1. Its visible rows are two local regular windows, the common dyadic ledger, the finite observation row, the glued regular readback, the Real seal, and the transport, replay, provenance, and naming rows.

Apply Definition 5899.3. The local NameCert surface must read exactly those rows, with the dyadic ledger, StreamName windows, RegSeqRat readback, and Real seal appearing before the certificate is exported.

Use Definition 5899.7 for the reindexing component. It identifies the same dyadic, stream, and regular readback rows as a $\mathsf{CauchyReindexing}^{\uparrow}$-compatible route.

Thus the dependency on chapter 1568 is consumed before the $\mathsf{RegSeqRat}^{\uparrow}$ readback and terminal $\mathsf{Real}^{\uparrow}$ seal are available to the gluing certificate.

The exclusions are inherited from the carrier inventory and the overlap stability theorem. Since no coordinate stores quotient stream equality, selected representatives, host real equality, choice, or ambient completeness, the L10 sibling route remains a finite local NameCert route. □

Theorem 4749.12 (Regular Cauchy gluing RegSeqRat route)**.** *Every glued readback row of an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet must pass through the existing* $\mathsf{RegSeqRat}^{\uparrow}$ *sibling surface of chapter 301 and the* $\mathsf{CauchyReindexing}^{\uparrow}$ *handoff of chapter 1568 before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is visible. The local obligations of Definition 5899.3 therefore expose a regular rational readback and a reindexing route before any Real-facing consumer may read the glued value.*

Proof. Start from the local L10 route of Definition 5899.11. It already orders the dyadic ledger, finite StreamName windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{CauchyReindexing}^{\uparrow}$ handoff, and terminal $\mathsf{Real}^{\uparrow}$ seal before the gluing NameCert row is exported.

Apply the local obligations of Definition 5899.3. The glued readback row is one of the displayed certificate rows, so it cannot be consumed without the same regular rational surface and structural support rows.

Use Definition 5899.7. The reindexing handoff keeps the dyadic, stream, and regular readback data aligned before the terminal Real seal appears. Thus a Real-facing read factors through RegSeqRat and CauchyReindexing rather than bypassing them. □

Theorem 4749.13 (Regular Cauchy gluing pasting nonescape)**.** *Every accepted pasting consumer of a* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet must read the finite route of Definition 5899.1, satisfy the local obligations of Definition 5899.3, and pass through the L10 sibling route of Definition 5899.11 before it exports any NameCert row. In particular, the consumer must display the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{CauchyReindexing}^{\uparrow}$ *handoff, and terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Consequently no such pasting consumer exports quotient stream equality, selected representatives, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness as a coordinate of the* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *read.*

Proof. Project the accepted carrier in Definition 5899.1. Its displayed route already contains the common dyadic ledger, finite StreamName observations, glued RegSeqRat readback, Real seal, and the support rows for transport, replay, provenance, and naming.

Apply Definition 5899.3. A pasting consumer can export a local NameCert row only by preserving exactly those displayed rows, so the consumer has no separate entry point around the dyadic, stream, regular readback, or seal coordinates.

Apply Definition 5899.11. The L10 route orders the same rows through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before export.

The refused objects are absent from the carrier and absent from the sibling route. Thus quotient stream equality, selected representatives, host real equality, countable choice, and ambient completeness cannot be repacked as a pasting consumer of the accepted $\mathsf{RegularCauchyGluing}^{\uparrow}$ packet. □

Theorem 4749.14 (Regular Cauchy gluing separator-use route)**.** *Every accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *consumer that exports an apartness read or a located-comparison read must first pass through the* $\mathsf{RegularSeqApartnessSeparator}^{\uparrow}$ *route of chapter 7930. Ordinary gluing consumers still export only the finite dyadic, stream,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyReindexing}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *seal rows named by Definition 5899.11.*

Proof. Start with the L10 sibling route of Definition 5899.11. It exposes the dyadic tolerance rows, finite stream windows, regular-rational readback, Cauchy reindexing handoff, and terminal Real seal before the local gluing NameCert row is exported.

For a consumer that reads only gluing data, those rows exhaust the available surface by Definition 5899.13. The carrier has no coordinate for apartness, located comparison, quotient equality, selected representatives, choice, or ambient completeness.

If the same consumer asks for apartness or located comparison, apply the separator sibling dependency of Definition 7930.3. That route requires the stream, regular-rational, dyadic, Real-seal, located-cut, and apartness-field rows to be displayed through $\mathsf{RegularSeqApartnessSeparator}^{\uparrow}$ before such a read is available.

Thus the gluing packet itself remains the ordinary finite route, while apartness-facing or located-comparison-facing reads factor through the separator chapter rather than being smuggled into the gluing carrier. □

Theorem 4749.15 (Regular Cauchy gluing completion consumer route)**.** *Every Bishop-completion or Real-completion consumer of an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet must read the same finite L10 sibling route before exporting a gluing* NameCert *row. In particular, the consumer first exposes the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite observation windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback, the* $\mathsf{CauchyReindexing}^{\uparrow}$ *handoff, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The exported gluing certificate has no coordinate for quotient stream equality, selected representatives, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the L10 sibling route of Definition 5899.11. It already orders the dyadic ledger, stream windows, regular-rational readback, Cauchy reindexing handoff, and terminal Real seal before any local gluing NameCert row is exported.

Apply the RegSeqRat route of Definition 5899.12. A completion-facing read of the glued value therefore cannot bypass the regular rational surface or the reindexing route on its way to the terminal $\mathsf{Real}^{\uparrow}$ seal.

Apply the pasting nonescape theorem, Definition 5899.13. It keeps every gluing consumer inside the finite carrier route and excludes quotient stream equality, selected representatives, host real equality, countable choice, and ambient completeness as exportable coordinates.

Finally use the separator-use route of Definition 5899.14. Apartness-facing or located-comparison-facing completion reads factor through the separator sibling; ordinary Bishop-completion and Real-completion gluing reads still expose only the dyadic, stream, regular-rational, reindexing, and Real-seal rows before the gluing NameCert is named. □

Theorem 4749.16 (Regular Cauchy gluing uniform Cauchy criterion route)**.** *Every uniform-Cauchy-criterion consumer of an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet must read the finite sibling route before exporting criterion data. The consumer must expose the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the* $\mathsf{CauchyReindexing}^{\uparrow}$ *handoff, the* $\mathsf{BishopRealCompletion}^{\uparrow}$ *consumer rows, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal as displayed rows of the gluing route.*

Consequently the criterion consumer exports only the finite BEDC packet obtained from those rows, componentwise hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}$ *ledger. It does not export quotient sequence equality, selected representatives, countable choice, host real equality, or ambient completeness.*

Proof. Start with the L10 sibling route of Definition 5899.11. It already places the dyadic tolerance ledger, finite stream windows, regular-rational readback, Cauchy reindexing handoff, and terminal Real seal before any gluing NameCert row is exported.

Apply the RegSeqRat route of Definition 5899.12 and the completion consumer theorem Definition 5899.15. Together they force a completion-facing criterion read through the regular rational surface, the reindexing handoff, and the Bishop-completion consumer rows before the terminal $\mathsf{Real}^{\uparrow}$ seal can be read.

Finally use the downstream sibling route of Definition 5899.18. It permits only concrete downstream consumers after the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BishopRealCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows have been displayed. Since the carrier and all cited routes omit quotient sequence equality, selected representatives, countable choice, host real equality, and ambient completeness, none of those objects can be repacked as uniform-Cauchy-criterion data. □

Theorem 4749.17 (Regular Cauchy gluing L10 sibling dependency)**.** *Before any gluing consumer reads the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}$ *row, it must display the finite sibling dependency route through the* $\mathsf{RegSeqRat}^{\uparrow}$ *rows of chapter 301, the* $\mathsf{StreamName}^{\uparrow}$ *observation windows of chapter 126,*

the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows of chapter 291, the completion-facing handoff of chapter 3665, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38. The route may also be read by Bishop-completion consumers through the completion consumer theorem Definition 5899.15, but it remains a finite dependency lattice rather than quotient sequence equality, selected representatives, countable choice, host real equality, or ambient real completeness.*

Proof. Start with Definition 5899.11. It already orders the dyadic tolerance rows, stream observation windows, regular-rational readback, Cauchy reindexing handoff, and Real seal before the local $\mathsf{NameCert}$ row is exported.

Apply Definition 5899.15. A Bishop-completion or Real-completion consumer therefore reads the same finite row sequence before it can use the gluing packet as completion-facing data.

The dependency is finite because every cited sibling appears as a displayed row or handoff in the local route. No step asks for quotient sequence equality, a selected representative of a Cauchy class, countable choice over tails, host real equality, or an ambient completeness theorem. □

Theorem 4749.18 (Regular Cauchy gluing downstream sibling route)**.** *Any cofinal, interleaving, or comparison-facing consumer of an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet must first pass through the finite sibling route of Definition 5899.17. After the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BishopRealCompletion}^{\uparrow}$, *and terminal* $\mathsf{Real}^{\uparrow}$ *rows have been displayed, such a consumer may continue only through a concrete downstream sibling such as chapter 414 or chapter 3514. The gluing packet itself exports no detached cofinal route, no interleaving selector, no quotient equality of Cauchy names, no selected representative, and no ambient completeness theorem.*

Proof. Start with Definition 5899.17. It forces every gluing consumer to display the regular rational rows, finite stream windows, dyadic tolerance rows, Bishop-completion handoff, and terminal Real seal before the local $\mathsf{NameCert}_{\mathsf{RegularCauchyGluing}^{\uparrow}}$ row is read.

Apply the completion consumer theorem Definition 5899.15. A completion-facing read therefore receives the same finite route, not a quotient stream or selected representative.

For an interleaving-facing read, use the public sibling surface of chapter 414. It supplies the alternating selector and combined modulus ledger only after the relevant $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows are displayed.

For a comparison-facing read, use chapter 3514. That packet supplies the even–odd comparison and shared threshold rows as a separate finite consumer surface. Thus any cofinal or interleaving continuation is downstream of the existing L10 sibling dependency, and none of those rows is smuggled into the gluing carrier itself. □

Theorem 4749.19 (Regular Cauchy gluing tail-agreement composition)**.** *Any* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{Completion}^{\uparrow}$ *consumer that reads a glued* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet through Definition 5899.18 must continue through the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *route of chapter 699 before treating the glued readback as completion-facing tail agreement. The composed route also reads the Cauchy limit seal of chapter 386; the gluing packet alone exports no ambient tail equality, selected representative, quotient sequence equality, or completeness witness.*

Proof. Start with Definition 5899.18. It permits downstream consumers only after the finite $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BishopRealCompletion}^{\uparrow}$, and terminal $\mathsf{Real}^{\uparrow}$ rows have been displayed.

A completion-facing tail read then has an additional boundary. The $\mathsf{RealTailAgreementSeal}^{\uparrow}$ chapter supplies the route that turns a Real-facing readback into displayed tail-agreement data, and the $\mathsf{CauchyLimitSeal}^{\uparrow}$ chapter supplies the limit-facing seal used by completion consumers.

Thus the row order is finite: first the local gluing sibling route, then the tail-agreement seal, and finally the Cauchy-limit seal. Because each step only reuses displayed rows, no consumer can replace the route by host tail equality, a selected Cauchy representative, quotient sequence equality, or ambient completeness. □

$\mathsf{RegularCauchyGluing}^{\uparrow}$ consumes its L10 sibling lattice before any gluing read is exported: the $\mathsf{StreamName}^{\uparrow}$ finite windows provide the inspected overlap rows, $\mathsf{RegSeqRat}^{\uparrow}$ supplies the regular readback, $\mathsf{DyadicRatCore}^{\uparrow}$ carries the shared tolerance ledger, $\mathsf{Real}^{\uparrow}$ seals the terminal value, and chapter 5544 provides the $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ schedule that keeps the two local Cauchy windows on one displayed budget.

Theorem 4749.20 (Regular Cauchy gluing L10 forward route)**.** *Every accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *consumer reaches Real-facing gluing only through the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal of the local carrier. The route first reads the name certificate construction, then the L10 sibling route, and finally the Bishop-completion consumer route before any gluing conclusion is exported. It refuses quotient stream equality, selected limits, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as coordinates of the gluing read.*

Proof. Project the local carrier and obligations from Definition 5899.1 and Definition 5899.3. The rows available to a consumer are the two compatible windows, the common dyadic ledger, finite observations, glued regular readback, Real seal, transport, replay, provenance, and local naming.

Apply the L10 sibling route of Definition 5899.11. It orders the consumer through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before a local gluing certificate is exported.

Apply the Bishop-completion consumer theorem Definition 5899.22. A Real-facing or Bishop-completion consumer must display the same D, S, Q, E, H, C, P, N route, so the forward path remains finite and local to the accepted packet.

The refused objects are absent from every cited step. The name certificate construction supplies no quotient stream equality; the L10 sibling route supplies no selected limit or countable-choice schedule; and the Bishop-completion consumer route supplies no ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate. Hence every accepted forward gluing read factors through the displayed windows, readbacks, tolerance ledgers, and Real seal. □

Theorem 4749.21 (Regular Cauchy gluing sibling forward link)**.** *Every accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet that is read as a gluing consumer first passes through the L10 sibling route of Definition 5899.11. In particular, the consumer must expose the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback surface of chapter 301 and the finite* $\mathsf{StreamName}^{\uparrow}$ *windows of chapter 126 before the local gluing* $\mathsf{NameCert}$ *row is available.*

The forward link is therefore a concrete sibling dependency route rather than a detached hub edge. It also preserves the exclusions already named by the L10 route: no quotient stream equality, selected representative, countable-choice schedule, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness is exported by the gluing read.*

Proof. Start with the carrier and obligation rows of Definition 5899.1 and Definition 5899.3. They display the paired local windows, common dyadic ledger, finite observations, glued regular readback, terminal Real seal, transport, replay, provenance, and local naming rows.

Apply the L10 sibling route of Definition 5899.11. That route orders the same gluing read through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before any gluing certificate can be exported.

Thus the hub has a visible child route into the RegSeqRat and StreamName sibling chapters. The refused objects remain absent because neither the local carrier nor the L10 sibling route contains coordinates for quotient stream equality, selected representatives, choice, host equality, or ambient completeness. □

Theorem 4749.22 (Regular Cauchy gluing Bishop completion consumer)**.** *Every* $\mathsf{BishopRealCompletion}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet must first expose the same finite gluing carrier rows already displayed by Definition 5899.1. In particular, before the Bishop completion route may read the terminal* $\mathsf{Real}^{\uparrow}$ *seal, the consumer must display the* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger* D*, the* $\mathsf{StreamName}^{\uparrow}$ *observation row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *glued readback* Q*, the* $\mathsf{Real}^{\uparrow}$ *seal* E*, the* $\mathsf{CauchyReindexing}^{\uparrow}$ *handoff recorded in* P*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and the local* NameCert *row* N*.*

Thus the Bishop completion consumer receives the gluing packet only as a finite L10 route over dyadic, stream, regular-rational, Real-seal, reindexing, transport, replay, provenance, and naming data. It receives no quotient stream equality, selected representative, host real equality, countable-choice schedule, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the carrier $G = (L, R, D, S, Q, E, H, C, P, N)$ from Definition 5899.1. The rows that a completion-facing consumer can inspect are exactly the two local windows, the common dyadic ledger, the finite observations, the glued readback, the Real seal, transport, replay, provenance, and local naming.

Apply the L10 sibling route of Definition 5899.11. It orders the gluing packet through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CauchyReindexing}^{\uparrow}$ before a NameCert row is exported.

Now read the Bishop completion carrier of chapter 3665. Its completion-facing route consumes dyadic precision, finite stream windows, regular rational readback, a Real seal, transport, replay, provenance, and local naming. The gluing rows D, S, Q, E, H, C, P, N are therefore the only rows that can feed such a consumer from $\mathsf{RegularCauchyGluing}^{\uparrow}$.

The exclusions follow from the same carrier inventory. Since neither Definition 5899.1 nor the Bishop completion route supplies quotient stream equality, selected representatives, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness as a coordinate, the consumer cannot export any of those objects from the gluing packet. □

Theorem 4749.23 (Regular Cauchy gluing Real-tail forward route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or* $\mathsf{Completion}^{\uparrow}$*-facing read of an accepted* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *packet that asks for a tail-agreement seal is a forward dependency of the* $\mathsf{RealTailAgreementSeal}^{\uparrow}$ *route in chapter 699. Concretely, the gluing packet first exposes the common* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger* D*, the paired* $\mathsf{StreamName}^{\uparrow}$ *observation row* S*, the glued* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, and the local* $\mathsf{Real}^{\uparrow}$ *seal* E*; only then may the consumer enter the Real-tail agreement and Cauchy-limit seal route through* $\mathsf{RealTailAgreementSeal}^{\uparrow}$*,* $\mathsf{CauchyLimitSeal}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{Completion}^{\uparrow}$*.*

Proof. Project the accepted gluing carrier $G = (L, R, D, S, Q, E, H, C, P, N)$ from Definition 5899.1. The Real-facing rows available before any tail agreement are exactly the common dyadic ledger D, finite observation row S, glued regular readback Q, terminal seal E, transport row H, replay row C, provenance row P, and local name row N.

Apply the Real seal ordering theorem Definition 5899.9. It forces the route to display D, S, Q before E is readable, so a consumer cannot jump from the two local windows directly to a Real-tail agreement row.

Now use the Real-tail agreement completion-consumer boundary of chapter 699. That boundary receives paired windows, dyadic readback, agreement, Cauchy-limit sealing, and Real or Com-

pletion endpoints as one finite route. Feeding it from $\mathsf{RegularCauchyGluing}^{\uparrow}$ therefore makes the gluing read a forward dependency of that Real-tail route rather than a separate kernel island.

The exclusions are inherited from the two carriers. Neither Definition 5899.1 nor the Real-tail agreement route supplies quotient stream equality, selected representatives, host convergence, countable choice, or ambient completeness as a row, so no such object can be exported by this forward dependency. □

Chapter 4750

A Concrete Naming Certificate for $\mathsf{YoungSymmetrizer}^{\uparrow}$

Following Fulton and Harris on Young symmetrizers and polynomial representations, the $\mathsf{YoungSymmetrizer}^{\uparrow}$ packet records the finite tableau rows that turn a partition shape into row symmetrization, column antisymmetrization, and a displayed tensor-to-matrix action. It sits between the shape discipline of chapter 201, the character readback of chapter 245, the Grothendieck consumer of chapter 246, the multilinear source of chapter 87, and the displayed action rows of chapter 49. The packet is finite: it names the symmetrizer route without importing semisimplicity, Specht module irreducibility, Schur functor exactness, host group algebra idempotence, or quotient representation categories.

Definition 4750.1 (YoungSymmetrizerUp carrier)**.** *A* $\mathsf{YoungSymmetrizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (P, D, T, R, C, S, A, E, M, H, U, V, G, N).$$

Here P is the consumed $\mathsf{Partition}^{\uparrow}$ *shape row; D is the Young diagram row for that shape; T is a tableau row whose entries fill the boxes of D; R is the row-stabilizer ledger listing the permutations that preserve each row of T; C is the column-stabilizer ledger listing the permutations that preserve each column of T; S is the row-symmetrizer formal sum over R; A is the column-antisymmetrizer formal signed sum over C; E is the ordered composite row for the formal Young symmetrizer SA; M is the displayed tensor and matrix action row over the* $\mathsf{TensorProduct}^{\uparrow}$ *and* $\mathsf{Mat}^{\uparrow}$ *sources; H gives componentwise* hsame *transport for $P, D, T, R, C, S, A, E, M$; U gives displayed* Cont *replay for the same finite route; V is the consumer ledger for* $\mathsf{CharacterTheory}^{\uparrow}$ *and* $\mathsf{RepresentationRing}^{\uparrow}$ *readback; G is the* Pkg *provenance over* $\mathsf{Partition}^{\uparrow}$, $\mathsf{CharacterTheory}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, $\mathsf{TensorProduct}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*; and N is the local* $\mathsf{NameCert}_{\mathsf{YoungSymmetrizer}^{\uparrow}}$ *row.*

Theorem 4750.2 (YoungSymmetrizerUp NameCert obligations)**.** *For every accepted carrier $Y = (P, D, T, R, C, S, A, E, M, H, U, V, G, N)$ of Definition 5560.1, the local* $\mathsf{NameCert}_{\mathsf{YoungSymmetrizer}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

- *shape admission, requiring P to expose the partition shape and D to list precisely its diagram boxes;*
- *tableau admission, requiring T to fill the boxes of D and to induce the row and column incidence ledgers used by R and C;*
- *row symmetrizer exactness, requiring S to be the finite formal sum over the row-stabilizer ledger R;*

- *column antisymmetrizer exactness, requiring A to be the finite signed formal sum over the column-stabilizer ledger C;*
- *action display, requiring E and M to route the composite SA through the tensor and matrix rows rather than through an ambient group-algebra object;*
- *consumer confinement, requiring every* $\mathsf{CharacterTheory}^{\uparrow}$ *or* $\mathsf{RepresentationRing}^{\uparrow}$ *read to pass through V after the finite tensor/matrix action has been displayed;*
- *structural replay, requiring H, U, G, N to transport, replay, account for, and name exactly the rows already listed.*

No accepted $\mathsf{YoungSymmetrizer}^{\uparrow}$ *packet exports an irreducible module theorem, a complete character formula, a semisimple decomposition, or equality inside an unlisted host group algebra.*

Lean4 ✓ `BEDC.Derived.YoungSymmetrizerUp.YoungSymmetrizerTasteGate single carrier alignment`

Proof. Inspect the coordinates of Y. The shape and tableau rows P, D, T determine the finite incidence data, while R and C are only the displayed stabilizer ledgers for that incidence data.

The formal rows S, A, E are then determined by finite replay over R and C. Their only action surface is the displayed tensor/matrix row M, so a consumer cannot replace the route by an ambient group-algebra calculation without leaving the packet.

Finally H, U, V, G, N do not add new mathematical rows. They transport, replay, expose, account for, and name the finite route already visible in $P, D, T, R, C, S, A, E, M$. □

Theorem 4750.3 (YoungSymmetrizerUp idempotent route)**.** *Let $Y = (P, D, T, R, C, S, A, E, M, H, U, V, G, N)$ be an accepted* $\mathsf{YoungSymmetrizer}^{\uparrow}$ *carrier. Any downstream route that reads the Young-symmetrizer idempotent behavior from Y must factor through the displayed finite chain*

$$P, D, T \longrightarrow R, C \longrightarrow S, A \longrightarrow E \longrightarrow M \longrightarrow V, N.$$

The route may expose the row symmetrizer, the column antisymmetrizer, and the tensor/matrix action as a finite certificate surface; it does not claim normalized primitive idempotence, irreducible Specht image, Schur functor exactness, or a complete representation-ring decomposition.

Proof. Start with the displayed source chain. The partition and tableau rows are the only source of row and column incidence, so every stabilizer read reaches R or C through P, D, T.

The symmetrizer and antisymmetrizer rows are formal finite sums over those stabilizers. Thus the composite row E is available only after S and A have been displayed.

The action and consumer boundary are then forced by M and V. The packet contains no row for normalized scalar inversion, quotient module projection, or semisimplicity, so the idempotent behavior remains a finite route claim over the displayed action rather than a host-level representation-theoretic closure theorem. □

Falsifiable prediction: Every future $\mathsf{YoungSymmetrizer}^{\uparrow}$ Lean carrier can be audited by counting exactly one partition shape row, one tableau row, two stabilizer ledgers, two formal-sum rows, one composite row, one tensor/matrix action row, and one local $\mathsf{NameCert}$ row before any $\mathsf{RepresentationRing}^{\uparrow}$ consumer is admitted.

Independence witness: partition, charactertheory, representationring, tensorproduct, matrix: YoungSymmetrizerUp is not bijective to any listed sibling because it jointly carries tableau incidence, row and column stabilizer ledgers, row symmetrization, column antisymmetrization, a composite tensor/matrix action, consumer confinement, and local NameCert provenance.

Closure status for $\mathsf{NameCert}_{\mathsf{YoungSymmetrizer}\uparrow}$.

Constructive story: A $\mathsf{YoungSymmetrizer}^{\uparrow}$ packet is generated from one partition shape row, one Young diagram row, one tableau incidence row, row and column stabilizer ledgers, row-symmetrizer and column-antisymmetrizer formal-sum rows, one composite action row, displayed tensor/matrix action support, consumer confinement, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{YoungSymmetrizer}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5560.1, Definition 5560.2, and Definition 5560.3 bind the finite tableau, stabilizer, formal-sum, action, and consumer surface for the Young-symmetrizer packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{YoungSymmetrizer}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not prove primitive idempotence, irreducible Specht images, Schur functor exactness, semisimplicity, a complete character formula, host group-algebra equality, Lean verification, or a bridge-checked public schema.

Upgrade path: Obligation closure requires checked carrier admission, tableau incidence exposure, stabilizer-ledger exactness, finite formal-sum exactness, tensor/matrix action confinement, consumer non-escape, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.YoungSymmetrizerUp.

Chapter 4751

A Concrete Naming Certificate for $\mathsf{MetaCICSRKernel}^{\uparrow}$

The $\mathsf{MetaCICSRKernel}^{\uparrow}$ packet realizes the subject-reduction discharge branch of chapter 9374 as one finite kernel carrier. It sits between the open-phase audit of $\mathsf{MetaCICCriticalPath}^{\uparrow}$ in chapter 765, the four-face obligation packet $\mathsf{MetaCICSubjectReductionObligation}^{\uparrow}$ in chapter 712, the route socket $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ in chapter 719, the closed-substitution boundary $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ in chapter 527, and the candidate/endpoint frontier $\mathsf{MetaCICNormalizationFrontier}$ in chapter 892. The packet gives later formalization a concrete finite place to discharge typing-preservation routes without replacing the four discharge faces by a parameter echo.

Theorem 4751.1 (MetacicSrKernelUp carrier)**.** *A* $\mathsf{MetaCICSRKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (C, O, S, B, A, L, P, T, N, F, H, R, G, M).$$

Here C is the $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *source ledger; O is the* $\mathsf{MetaCICSubjectReductionObligation}^{\uparrow}$ *four-face obligation row; S is the* $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$ *route row; B, A, L, P are respectively the beta-substitution, application-argument, lambda-domain, and Pi-domain discharge rows consumed through O and S; T is the* $\mathsf{ClosedTermSubstitutionBoundary}^{\uparrow}$ *closed-term projection row; N is the* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *candidate/endpoint boundary row; F is the finite subject-reduction handoff row that exposes exactly the four discharge faces before any type-preservation consumer reads the route; H is the componentwise* hsame *transport row; R is displayed* Cont *replay for the kernel route; G is the* Pkg *provenance over the named MetaCIC packets,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*; and M is the local* $\mathsf{NameCert}_{\mathsf{MetaCICSRKernel}^{\uparrow}}$ *row.*

Proof. Read the carrier as a finite route ledger. The coordinates C, O, S, T, N locate the existing MetaCIC boundaries, while B, A, L, P are exactly the four discharge rows already named by the obligation and socket packets.

The row F is not a fifth discharge hypothesis. It is the finite handoff that requires a consumer to see all four displayed faces before any subject-reduction read is exported.

The structural rows H, R, G, M only transport, replay, account for, and name the same finite kernel. Thus the carrier is a finite NameCert packet rather than a parametric schema over fresh carriers. □

Theorem 4751.2 (MetacicSrKernelUp NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICSRKernel}^{\uparrow}$ *carrier $K = (C, O, S, B, A, L, P, T, N, F, H, R, G, M)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICSRKernel}^{\uparrow}}$ *surface consists exactly of the following rows:*

- *critical-path admission through C;*
- *obligation admission through O, with beta-substitution, application-argument, lambda-domain, and Pi-domain faces exposed as B, A, L, P;*
- *socket compatibility through S, requiring the same four faces and forbidding an erased closed-subject-reduction row;*
- *closed-term boundary compatibility through T;*
- *normalization-frontier compatibility through N;*
- *subject-reduction handoff through F, which admits a consumer only after B, A, L, P are all displayed;*
- *transport, replay, provenance, and local naming through H, R, G, M.*

No obligation row in this surface may be replaced by a universal carrier parameter, a host definitional-equality principle, a quotient reduction equality, or a hidden closed-consistency theorem.

Proof. The obligation surface is obtained by projecting the coordinates of K. The packet imports the four subject-reduction faces from O and S, so the local naming row cannot omit one face while still claiming to expose the discharge surface.

The boundary rows T and N constrain where closed substitutions and normalization-frontier reads may occur. They do not prove subject reduction by themselves.

The handoff row F is therefore the only public route from the four faces to a subject-reduction consumer. Since H, R, G, M only preserve the displayed route, the packet has no coordinate where an ambient closed theorem or parameter-echo schema can enter. □

Theorem 4751.3 (MetacicSrKernelUp discharge route)**.** *Every accepted* $\mathsf{MetaCICSRKernel}^{\uparrow}$ *packet routes subject-reduction discharge through the finite chain*

$$C \longrightarrow O, S \longrightarrow B, A, L, P \longrightarrow T, N \longrightarrow F \longrightarrow M.$$

A type-preservation consumer may read the route only after the four discharge faces have been displayed and transported through H, R, G, M. The packet does not export closed subject reduction for the present substrate, unrestricted dependent-codomain preservation, erased substitution stability, global normalization, or closed consistency.

Proof. Start at the critical-path ledger C. The next admissible rows are the obligation and socket rows O, S, because they name the discharge faces and the obstruction boundary.

Project B, A, L, P from those rows. The closed-term and normalization-frontier coordinates T, N then constrain the route to the closed-substitution and candidate/endpoint surfaces already present in the neighboring packets.

Finally F packages the visible discharge for a consumer, while H, R, G, M preserve and name the route. No row in the carrier provides a replacement theorem, so the discharge remains a finite kernel route. □

Theorem 4751.4 (MetacicSrKernelUp closed-substitution discharge)**.** *Let $K = (C, O, S, B, A, L, P, T, N, F, H, R,$ be an accepted* $\mathsf{MetaCICSRKernel}^{\uparrow}$ *packet. A subject-reduction consumer may use the beta, application-argument, lambda-domain, and Pi-domain discharge rows B, A, L, P only through the same closed-term projection row T and normalization-frontier row N before the finite handoff F is read. Replacing T by a host substitution theorem, quotient reduction equality, or hidden closed-consistency theorem leaves the accepted carrier.*

Proof. Project the carrier of Definition 5561.1. The four discharge rows B, A, L, P are displayed only after the critical-path, obligation, and socket rows C, O, S.

Apply Definition 5561.2. It exposes the four discharge faces through the same obligation and socket surface and records compatibility with the closed-term boundary T and normalization-frontier boundary N.

Apply Definition 5561.3. The route forces

$$C \longrightarrow O, S \longrightarrow B, A, L, P \longrightarrow T, N \longrightarrow F \longrightarrow M$$

before a subject-reduction consumer can read the finite handoff.

The structural rows H, R, G, M transport, replay, source, and name that route. Since the carrier has no coordinate for a host substitution theorem, quotient reduction equality, or hidden closed-consistency theorem, replacing T by any such object exits the accepted packet. □

Theorem 4751.5 (MetacicSrKernelUp four-face totality)**.** *Let $K = (C, O, S, B, A, L, P, T, N, F, H, R, G, M)$ be an accepted* MetaCICSRKernel$^{\uparrow}$ *packet. The finite subject-reduction handoff row F is readable only after the beta-substitution row B, application-argument row A, lambda-domain row L, and Pi-domain row P have all been displayed through the shared obligation row O and route-socket row S. No packet that omits any one of B, A, L, P exports the subject-reduction handoff of K, and no three-face route can bypass the missing face through the closed-term boundary T, normalization-frontier boundary N, or handoff row F.*

Proof. Project the accepted carrier of Definition 5561.1. The only discharge-face coordinates available to a consumer are B, A, L, P, and the only rows that display them to the kernel route are O and S.

Apply Definition 5561.2. It lists the four faces as one obligation surface: beta-substitution, application-argument, lambda-domain, and Pi-domain exposure must all be present before the local naming row admits the handoff.

Now apply Definition 5561.3. The route orders the carrier read through C, then O, S, then the four discharge faces, then the boundary rows T, N, and only then the handoff row F and local name row M.

Finally use Definition 5561.4. It prevents a consumer from replacing the closed-term boundary by a host substitution theorem, quotient reduction equality, or hidden consistency result. Since T, N, F are boundary and handoff rows rather than substitute discharge faces, a three-face packet has no coordinate from which to export the accepted handoff. □

Falsifiable prediction: The Lean follow-up for MetaCICSRKernel$^{\uparrow}$ must provide `Nontrivial MetacicSrKernelUp` and `FieldFaithful MetacicSrKernelUp` in `TasteGate.lean`, and the instance audit must expose exactly four discharge-face fields before any finite subject-reduction handoff is admitted.

Independence witness: metaciccriticalpath, metacic-subject-reduction-obligation, subjectreductiondischargesocket, closedtermsubstitutionboundary, metacicnormalizationfrontier: MetacicSrKernelUp is not bijective to any listed sibling because it simultaneously carries the critical-path ledger, four discharge faces, route socket, closed-substitution boundary, normalization-frontier boundary, finite handoff row, transport, replay, provenance, and local NameCert naming.

Closure status for NameCert$_{\text{MetaCICSRKernel}^{\uparrow}}$**.**

Constructive story: A MetaCICSRKernel$^{\uparrow}$ packet is generated from the MetaCIC critical-path ledger, a four-face subject-reduction obligation row, a discharge-socket row, beta-substitution, application-argument, lambda-domain, and

Pi-domain discharge rows, closed-substitution and normalization-frontier boundaries, a finite handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{MetaCICSRKernel}\uparrow}$, seed)

Scope closed: Definition 5561.1, Definition 5561.2, and Definition 5561.3 bind the finite four-face subject-reduction kernel route and its handoff surface.

Formal verification: FormalStatus(NameCert$_{\mathsf{MetaCICSRKernel}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not prove closed subject reduction, unrestricted dependent-codomain preservation, erased substitution stability, global normalization, closed consistency, Lean verification, or a bridge-checked public schema.

Upgrade path: Obligation closure requires checked carrier admission, four-face discharge exposure, socket compatibility, closed-substitution boundary compatibility, normalization-frontier compatibility, handoff non-escape, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.MetacicSrKernelUp.

Chapter 4752

A Concrete Naming Certificate for $\mathsf{HInfinityControl}^{\uparrow}$

Following Zames and the bounded-real robust-control development of Doyle, Glover, Khargonekar, and Francis, the $\mathsf{HInfinityControl}^{\uparrow}$ packet records the finite bounded-gain certificate surface used by robust-control consumers. It sits after the state-space carrier of chapter 329, matrix rows of chapter 49, vector-space rows of chapter 47, real gain rows of chapter 38, Riccati rows of chapter 307, finite-horizon control rows of chapter 296, and finite prediction ledgers of chapter 348. The packet names a finite robust-control ledger for disturbance-to-performance gain reads; it is not an analytic infinite-horizon optimality theorem.

Definition 4752.1 (HInfinityControl carrier)**.** *An* $\mathsf{HInfinityControl}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, D, Y, U, G, F, R, L, M, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StateSpaceModel}^{\uparrow}$ *row carrying the finite state-space presentation.*
2. *D is the disturbance-input row, recorded as a finite* $\mathsf{VecSpace}^{\uparrow}$ *and* $\mathsf{Mat}^{\uparrow}$ *interface into the state update.*
3. *Y is the performance-output row, again read through finite* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *coordinates.*
4. *U is the controller row, exposing the finite controller state, input, and output ledgers.*
5. *G is the* $\mathsf{Real}^{\uparrow}$ *gain-bound row naming the candidate bounded-gain level.*
6. *F is the finite rollout ledger comparing disturbance energy and performance energy over displayed time windows.*
7. *R is the Riccati dependency row, readable only as a finite* $\mathsf{Riccati}^{\uparrow}$ *certificate surface.*
8. *L is the* $\mathsf{LQR}^{\uparrow}$ *dependency row for the quadratic-cost and dynamic-programming ledger used by the controller comparison.*
9. *M is the* $\mathsf{ModelPredictiveControl}^{\uparrow}$ *dependency row for finite rollout and constraint-window replay.*
10. *H records componentwise* hsame *transport for $S, D, Y, U, G, F, R, L, M$.*

11. *C records displayed* Cont *replay from the state-space rows through disturbance, performance, controller, gain, rollout, and dependency rows.*
12. *P is the* Pkg *provenance over* $\mathsf{HInfinityControl}^{\uparrow}$, $\mathsf{StateSpaceModel}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Riccati}^{\uparrow}$, $\mathsf{LQR}^{\uparrow}$, $\mathsf{ModelPredictiveControl}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{HInfinityControl}^{\uparrow}}$ *row.*

The carrier stores no host trajectory space, no spectral factorization object, no infinite-horizon optimizer, no external robust-stability theorem, and no analytic transfer-function norm.

Lean4 ✓ `BEDC.Derived.HInfinityControlUp.HInfinityControlTasteGate single carrier alignment`

Theorem 4752.2 (HInfinityControl NameCert obligations)**.** *For every accepted* $\mathsf{HInfinityControl}^{\uparrow}$ *carrier* $K = (S, D, Y, U, G, F, R, L, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HInfinityControl}^{\uparrow}}$ *surface consists exactly of carrier admission, state-space exposure, disturbance-input exposure, performance-output exposure, controller exposure, gain-bound exposure, finite rollout comparison, Riccati dependency, LQR dependency, model-predictive-control dependency, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any consumer that replaces one of these rows by a host trajectory space, spectral factorization theorem, external standard bridge, infinite-horizon optimality principle, or full robust-stability theorem leaves the accepted carrier.*

Proof. Project the carrier of Definition 4752.1. The displayed coordinates list the state-space, disturbance, performance, controller, gain, rollout, and dependency rows before the structural transport, replay, provenance, and naming rows.

The dependency surface is finite. Riccati, LQR, and model-predictive-control rows are read only through R, L, M, so no analytic solver or external robust-control theorem is available inside the packet.

The rows H, C, P, N preserve and name the same inventory. Since the carrier has no coordinate for a host trajectory space, spectral factorization, transfer-function norm, infinite-horizon optimizer, or robust-stability theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 4752.3 (HInfinityControl bounded-gain route)**.** *Let* $K = (S, D, Y, U, G, F, R, L, M, H, C, P, N)$ *be an accepted* $\mathsf{HInfinityControl}^{\uparrow}$ *packet. Every bounded-gain read factors through the finite route*

$$S \longrightarrow D, Y, U \longrightarrow G, F \longrightarrow R, L, M \longrightarrow H, C, P, N.$$

The read first displays the state-space row, then the disturbance-input, performance-output, and controller rows, then the real gain-bound and finite rollout ledger, and only then the Riccati, LQR, and model-predictive-control dependency rows. No host trajectory space, spectral factorization, external standard bridge, analytic infinite-horizon optimality theorem, or full robust-stability theorem can factor the same accepted read.

Proof. Start with the state-space row S. The disturbance, performance, and controller rows D, Y, U are meaningful only relative to that displayed finite state-space presentation.

The gain read is then bounded by the $\mathsf{Real}^{\uparrow}$ row G and the finite rollout ledger F. These rows compare displayed finite histories; they do not introduce a transfer-function norm or an ambient trajectory space.

Finally the dependency rows R, L, M explain how the local control ledger is replayed against Riccati, LQR, and model-predictive-control packets, while H, C, P, N transport, replay, source, and name the same finite route. Coordinate exhaustion rules out any hidden spectral factorization, infinite-horizon optimizer, standard bridge, or robust-stability theorem. □

Falsifiable prediction: An accepted $\mathsf{HInfinityControl}^{\uparrow}$ read is refuted if a bounded-gain conclusion is reached without displaying the StateSpaceModelUp row, disturbance-input row, performance-output row, controller row, RealUp gain-bound row, finite rollout ledger, RiccatiUp row, LQRUp row, ModelPredictiveControlUp row, transport, replay, provenance, and local naming rows.

Independence witness: statespacemodel, riccati, lqr, modelpredictivecontrol, matrix, vecspace, and real: none is bijective to the bounded-gain robust-control packet because only $\mathsf{HInfinityControl}^{\uparrow}$ simultaneously records disturbance input, performance output, controller, real gain bound, finite rollout ledger, control dependencies, transport, replay, provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HInfinityControl}^{\uparrow}}$.

Constructive story: An $\mathsf{HInfinityControl}^{\uparrow}$ packet is generated from a StateSpaceModelUp row, disturbance-input row, performance-output row, controller row, RealUp gain-bound row, finite rollout ledger, RiccatiUp dependency row, LQRUp dependency row, ModelPredictiveControlUp dependency row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HInfinityControl}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4752.1, Definition 4752.2, and Definition 4752.3 seed the finite bounded-gain robust-control route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HInfinityControl}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim analytic infinite-horizon optimality, host trajectory spaces, spectral factorization, an external standard bridge, full robust-stability theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-gain route determinacy, dependency-row exposure, non-escape for analytic robust-control primitives, transport, replay, provenance, and local naming for BEDC.Derived.HInfinityControlUp.

$\mathsf{RealApartnessField}^{\uparrow}$ reads its inverse guard through chapter 38, chapter 301, and chapter 291 before the child routes expose apartness-field comparison rows.

Chapter 4753

A Concrete Naming Certificate for $\mathsf{RealApartnessField}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealApartnessField}^{\uparrow}$ packet records the constructive field-facing surface for real names whose inverse operation is guarded by displayed apartness evidence. It sits after the terminal real-name seal of chapter 38, the positive apartness route of chapter 1881, the located order boundary of $\mathsf{LocatedRealOrder}^{\uparrow}$, the algebraic source rows of chapter 45, and the dyadic tolerance ledger of chapter 291. The packet joins $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyRealApartness}^{\uparrow}$, $\mathsf{LocatedRealOrder}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ as one finite NameCert surface; it does not import trichotomy, quotient real equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Every apartness-field read passes through the $\mathsf{Real}^{\uparrow}$ seal and real readback rows of chapter 38, the apartness/order bridge of chapter 1905, the specialization order surface of chapter 1378, and the field operation rows of chapter 45 before it exports an apartness algebra surface.

Completion-facing uses of an apartness-field inverse keep the distance-preserving read compatible with the isometric embedding boundary of chapter 439 before any completion consumer treats the $\mathsf{Real}^{\uparrow}$ seal as a field-facing endpoint. This is a dependency on the displayed $\mathsf{Met}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ distance rows, not on host function equality or quotient completion.

Theorem 4753.1 (Real apartness field located source route)**.** *Every accepted* $\mathsf{RealApartnessField}^{\uparrow}$ *inverse read or order-facing read first consumes the* $\mathsf{RealApartnessOrderBridge}^{\uparrow}$ *route of chapter 1905 before the* $\mathsf{Field}^{\uparrow}$ *inverse branch may be exposed. In carrier notation, the displayed packet*

$$F = (R, A, O, K, D, H, C, P, N)$$

routes the real seal R, apartness row A, located-order row O, field row K, dyadic ledger D, transport H, replay C, provenance P, and local naming row N through the apartness/order bridge before any consumer reads an inverse or order-facing field operation.

Proof. Project the accepted carrier. The inverse branch is stored in the field row K, but the carrier definition also displays the real seal R, apartness row A, located-order row O, dyadic ledger D, and the structural rows H, C, P, N in the same finite packet.

Read the bridge route cited by the introduction. The $\mathsf{RealApartnessOrderBridge}^{\uparrow}$ chapter supplies the sibling route that ties apartness evidence to located order data before an order-facing consumer can use the real field surface.

Now compose the existing NameCert obligations with inverse-guard stability. The obligation rows require inverse admission to consume A and D, while located order compatibility consumes

O over the same real seal R. The transport and replay rows H, C, P, N preserve that source route, so the field row K exposes its inverse branch only after the apartness/order bridge has already been read. □

Definition 4753.2 (Real apartness field carrier)**.** *A* $\mathsf{RealApartnessField}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (R, A, O, K, D, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the real-name surface exposed to field consumers.*
2. *A is the* $\mathsf{CauchyRealApartness}^{\uparrow}$ *positive-apartness row used to certify that a denominator is separated from zero before an inverse read is accepted.*
3. *O is the* $\mathsf{LocatedRealOrder}^{\uparrow}$ *located order row that routes order-facing comparisons through displayed finite windows and dyadic cells.*
4. *K is the* $\mathsf{Field}^{\uparrow}$ *algebraic operation row for addition, multiplication, negation, zero, one, and the inverse request boundary.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and positivity ledger controlling arithmetic error, gap size, and reciprocal budget.*
6. *H records componentwise* hsame *transport for the real seal, apartness row, located order row, field row, dyadic ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from each field-facing request through R, A, O, K, D, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RealApartnessField}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyRealApartness}^{\uparrow}$, $\mathsf{LocatedRealOrder}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealApartnessField}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one constructive real field packet whose inverse reads are admitted only through apartness evidence. It has no coordinate for trichotomy, quotient real equality, selected representatives, countable choice, host real arithmetic, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 4753.3 (Real apartness field StreamName dependency)**.** *Every apartness-field comparison over* $\mathsf{Real}^{\uparrow}$ *must expose the* $\mathsf{StreamName}^{\uparrow}$ *finite windows of chapter 126 and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of chapter 301 before the* $\mathsf{Real}^{\uparrow}$ *apartness and order-field row of chapter 38 is consumed. Thus a comparison read of an accepted* $\mathsf{RealApartnessField}^{\uparrow}$ *carrier factors through finite stream observations, regular-rational tolerance data, the terminal Real seal, and only then the apartness, located-order, and field rows A, O, K.*

Proof. Project the carrier of Definition 5562.2. The real seal row R is the only Real-facing entry, and the apartness, order, and field rows A, O, K are downstream comparison rows rather than independent host-real operations.

Use the Real chapter route cited by the introduction. A $\mathsf{Real}^{\uparrow}$ seal is read from finite name data, so the comparison must first expose the $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback that supply the visible Real name.

Finally read the apartness-field rows. The positive-apartness row A, located order row O, field row K, and dyadic ledger D consume that already displayed Real readback, while H, C, P, N preserve and name the same finite route. Hence no comparison can bypass StreamName windows or regular-rational readback before using the Real apartness/order field surface. □

Theorem 4753.4 (Real apartness field NameCert obligations)**.** *For every accepted* $\mathsf{RealApartnessField}^{\uparrow}$ *carrier*

$$F = (R, A, O, K, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealApartnessField}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the real seal, positive apartness row, located order row, field operation row, dyadic ledger, transport, replay, provenance, and local naming row;*
2. *algebraic projection, requiring every addition, multiplication, negation, zero, and one read to pass through the displayed* $\mathsf{Field}^{\uparrow}$ *row* K *and the real seal row* R*;*
3. *inverse admission, requiring an inverse read to consume the* $\mathsf{CauchyRealApartness}^{\uparrow}$ *row* A *and the positive dyadic gap data in* D *before the field row* K *exports the reciprocal branch;*
4. *located order compatibility, requiring the* $\mathsf{LocatedRealOrder}^{\uparrow}$ *row* O *to read the same real-name and dyadic comparison data used by the apartness row;*
5. *transport and replay, requiring* H *and* C *to preserve the real, apartness, order, field, dyadic, provenance, and local naming rows together;*
6. *ledger exhaustion, excluding trichotomy, quotient real equality, selected representatives, countable choice, host real arithmetic, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No real apartness field obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5562.2. The accepted packet displays exactly the real seal, apartness row, located order row, field row, dyadic ledger, and structural rows.

The algebraic projection reads the $\mathsf{Field}^{\uparrow}$ row K only over the displayed real seal R. Thus the operation surface is the carried field row, not host real arithmetic or a quotient-real operation.

The inverse projection first reads A and D. The apartness row supplies positive separation from zero, and the dyadic row supplies the gap and reciprocal budget; without those rows the inverse request remains at the boundary and cannot be consumed as a field operation.

Finally, O, H, C, P, N keep comparison, transport, replay, provenance, and naming inside the same finite packet. Since none of the carrier coordinates stores a trichotomy decision, quotient equality, choice schedule, selected representative, completeness witness, Lean theorem, or standard bridge, none becomes a local NameCert obligation. □

Theorem 4753.5 (Real apartness field located-order inverse guard)**.** *Let*

$$F = (R, A, O, K, D, H, C, P, N)$$

be an accepted $\mathsf{RealApartnessField}^{\uparrow}$ *carrier. An inverse read from the field row* K *is accepted only after the located-order row* O*, positive apartness row* A*, and dyadic reciprocal-budget row* D *have been displayed over the same* $\mathsf{Real}^{\uparrow}$ *seal* R*. The guard is a finite L10 readback through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{LocatedRealOrder}^{\uparrow}$*, and* $\mathsf{DyadicRatCore}^{\uparrow}$*; it does not use trichotomy, quotient real equality, selected representatives, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5562.2. The inverse request is stored in K, but the same packet also displays the real seal R, positive apartness row A, located-order row O, dyadic ledger D, and structural rows H, C, P, N.

Apply the NameCert obligations of Definition 5562.4. The inverse admission clause exposes A and D before the reciprocal branch is exported, while the located-order compatibility clause requires O to read the same real-name and dyadic comparison data.

Use the StreamName dependency theorem Definition 5562.3. It forces the $\mathsf{Real}^{\uparrow}$ seal R to be read back from finite $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ tolerance data before the apartness, order, and field rows are consumed.

Finally read the located real route through O. Since H, C, P, N only transport, replay, source, and name the same finite packet, they cannot add trichotomy, quotient real equality, a selected representative, countable choice, or ambient completeness. Therefore an accepted inverse read is exactly a field-row read guarded by O, A, D over the same displayed Real seal R. □

Theorem 4753.6 (Real apartness field inverse-guard stability)**.** *Let*

$$F = (R, A, O, K, D, H, C, P, N)$$

be an accepted $\mathsf{RealApartnessField}^{\uparrow}$ *carrier. An inverse read from the field row K may be exported to a downstream consumer only when the displayed apartness guard in A survives componentwise* hsame *transport through the* $\mathsf{Real}^{\uparrow}$ *seal R, the* $\mathsf{CauchyRealApartness}^{\uparrow}$ *row A, the* $\mathsf{LocatedRealOrder}^{\uparrow}$ *boundary O, the* $\mathsf{Field}^{\uparrow}$ *operation row K, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and reciprocal-budget ledger D, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}$ *row N.*

Consequently, the inverse branch is stable under the carried transport rows exactly when its apartness evidence remains displayed in the same finite packet. It is not stable by trichotomy, quotient real equality, selected representatives, countable choice, host real arithmetic, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The inverse request sits in the field row K, but the NameCert obligations require the request to consume the positive-apartness row A and the positive dyadic gap data in D before the reciprocal branch is exported.

Transport preserves the guard componentwise. The real seal R, apartness row A, located order boundary O, field row K, and dyadic ledger D are carried through the same hsame route, while C, P, N replay, source, and name that route.

Therefore the inverse operation remains downstream of the apartness guard after transport. If the displayed guard is absent, the transported packet has no row from which an inverse read can be exported.

The carrier stores no trichotomy decision, quotient equality, selected representative, choice schedule, host inverse, or completeness witness. Stability of the inverse branch is exactly stability of the displayed apartness guard inside the finite $\mathsf{RealApartnessField}^{\uparrow}$ packet. □

Theorem 4753.7 (Real apartness field reciprocal-budget locality)**.** *Let $F = (R, A, O, K, D, H, C, P, N)$ be an accepted* $\mathsf{RealApartnessField}^{\uparrow}$ *carrier. Every inverse read exported from the field row K must first expose the positive apartness row A and the dyadic reciprocal-budget ledger D. The reciprocal route is local to these displayed rows and their componentwise transport, not to trichotomy, quotient real equality, selected representatives, countable choice, host real arithmetic, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The inverse branch is stored in K, but its admission rows are the positive apartness row A and the dyadic ledger D.

Use inverse-guard stability from Definition 5562.6. That theorem keeps the inverse branch downstream of the displayed apartness guard under the same componentwise hsame transport.

The dyadic ledger supplies the reciprocal budget attached to that guard. Rows H, C, P, N preserve, replay, source, and name the same finite route, so an inverse read cannot be exported unless both A and D have already been displayed. □

Theorem 4753.8 (Real apartness field multiplicative inverse boundary)**.** *Let $F = (R, A, O, K, D, H, C, P, N)$ be an accepted* $\mathsf{RealApartnessField}^{\uparrow}$ *carrier. A multiplicative inverse read from K is available to a downstream real-field consumer only after A displays positive apartness of the denominator from zero and D displays the corresponding positive dyadic gap and reciprocal budget. Therefore the inverse operation is controlled by constructive apartness evidence rather than by trichotomy, quotient equality, selected representatives, or choice.*

Proof. Begin with the accepted carrier. The inverse request is a branch of the field row K, but the carrier definition makes that branch depend on the same apartness and dyadic rows named by A and D.

Read the apartness row. The row A supplies a positive separation witness for the denominator source, so the consumer does not ask whether the denominator is equal to zero by trichotomy or quotient equality.

Read the dyadic ledger next. The row D records the positive gap and reciprocal budget used by the inverse branch, so the reciprocal calculation is bounded by displayed finite arithmetic rather than by an unrecorded host inverse.

The remaining rows only preserve the route. Transport, replay, provenance, and local naming cannot add a selected representative, choice operator, or ambient completeness datum, so the inverse boundary is exactly the apartness-controlled field read stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealApartnessField}^{\uparrow}}$.

Constructive story: A $\mathsf{RealApartnessField}^{\uparrow}$ packet is generated from a $\mathsf{Real}^{\uparrow}$ seal, a $\mathsf{CauchyRealApartness}^{\uparrow}$ positive-apartness row, a $\mathsf{LocatedRealOrder}^{\uparrow}$ located order row, a $\mathsf{Field}^{\uparrow}$ operation row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance and reciprocal-budget ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealApartnessField}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5562.2, Definition 5562.4, Definition 5562.6, and Definition 5562.8 seed the constructive real field boundary whose inverse branch is guarded by positive apartness evidence.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealApartnessField}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected representatives, countable choice, host real arithmetic, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, algebraic projection, inverse admission, located order compatibility, transport, replay, and ledger exhaustion for BEDC.Derived.RealApartnessFieldUp.

Theorem 4753.9 (Real apartness field regular-Cauchy apartness/order dependency)**.** *Every inverse-guard read or apartness-field read of an accepted* $\mathsf{RealApartnessField}^{\uparrow}$ *carrier must pass through the regular-Cauchy apartness/order route supplied by chapter 1710 and the positive-apartness route of chapter 1881 before the* $\mathsf{Field}^{\uparrow}$ *inverse branch is consumed. In carrier notation, a consumer must display the* $\mathsf{CauchyRealApartness}^{\uparrow}$ *row A, the* $\mathsf{LocatedRealOrder}^{\uparrow}$ *boundary O, the* $\mathsf{Field}^{\uparrow}$ *operation row K, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and reciprocal-budget ledger D inside the same packet*

$$F = (R, A, O, K, D, H, C, P, N)$$

before it treats an inverse as a field operation. The route adds no trichotomy, quotient equality, selected representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with inverse-guard stability, Definition 5562.6. It requires an inverse read to keep the displayed apartness guard in A stable through the real seal, located order boundary, field row, dyadic ledger, replay, provenance, and local naming rows.

Next read the multiplicative inverse boundary, Definition 5562.8. The inverse branch in K is available only after A displays positive apartness from zero and D displays the corresponding positive dyadic gap and reciprocal budget.

The regular-Cauchy apartness/order chapter supplies the regular source of that positive comparison: Definition 1710.3 routes every strict comparison or apartness read through its displayed budget, finite window, positive dyadic boundary, regular readback, and Real seal. The Cauchy real apartness chapter supplies the positive-apartness handoff through Definition 1881.3 and Definition 1881.4.

Combining these routes forces the RealApartnessField inverse branch to consume regular-Cauchy apartness/order evidence and positive Cauchy real apartness before it is read as a field inverse. Since each cited route refuses trichotomy, quotient real equality, selected representatives, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness, the dependency adds none of those principles to the field packet. □

Every $\mathsf{RealApartnessField}^{\uparrow}$ inverse read consumes the apartness-order bridge of chapter 1905 before the field carrier of chapter 45 can export the reciprocal branch. The dyadic tolerance row inherited by the same route prevents trichotomy or quotient-real equality from entering the packet, so the field operation is read only after constructive apartness-order evidence has been displayed.

Theorem 4753.10 (Real apartness field dependency route)**.** *Every accepted* $\mathsf{RealApartnessField}^{\uparrow}$ *inverse read or apartness-field read consumes the regular-Cauchy source rows, the* $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$ *route of chapter 1710, the located-real bridge through chapter 1933, and the* $\mathsf{RealLocatedOrder}^{\uparrow}$ *row of chapter 3640 before it exports field-level apartness. In carrier notation, for*

$$F = (R, A, O, K, D, H, C, P, N),$$

the regular source behind R, the positive apartness row A, the located-order row O, the field row K, the dyadic ledger D, transport H, replay C, provenance P, and local naming N are consumed in that order as one displayed dependency route.

Proof. Project the carrier of Definition 5562.2. The packet has no field-level apartness coordinate outside $R, A, O, K, D, H, C, P, N$.

Read the regular-Cauchy source first. The existing source route of Definition 5562.14 places the $\mathsf{RegSeqRat}^{\uparrow}$ source and the terminal $\mathsf{Real}^{\uparrow}$ seal before any field row K is consumed.

Next read the apartness and located rows. The regular-Cauchy apartness/order dependency of Definition 5562.9 supplies the $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$ route for A, while Definition 5562.12 supplies the located-real bridge and Definition 5562.5 keeps the $\mathsf{RealLocatedOrder}^{\uparrow}$ row visible over the same real seal.

Finally compose with the NameCert obligations. The algebraic projection and inverse-admission rows of Definition 5562.4 allow K to export field-level apartness only after A, O, D have been displayed, and H, C, P, N preserve the same route. Thus the field-level apartness export is downstream of the regular source, regular-Cauchy apartness/order, located-real bridge, and real located-order rows, with no host equality, trichotomy, selected representative, choice schedule, or ambient completeness inserted. □

Theorem 4753.11 (Real apartness field Real/order forward link)**.** *Every accepted* $\mathsf{RealApartnessField}^{\uparrow}$ *packet hands its apartness-field row to* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RealApartnessOrderBridge}^{\uparrow}$ *consumers only through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$ *seal,* hsame, Cont, Pkg, *and* NameCert *rows. In carrier notation, a read of*

$$F = (R, A, O, K, D, H, C, P, N)$$

must first expose the real seal route of chapter 38 and the apartness/order bridge of chapter 1905 before the field row K can export an inverse or order-facing operation.

Proof. Project the accepted carrier of Definition 5562.2. The field row K is not stored as host real arithmetic; it is carried together with the real seal R, apartness row A, located-order row O, dyadic ledger D, and the structural rows H, C, P, N.

Read the Real route first. The chapter introduction and StreamName dependency theorem route every Real-facing comparison through finite regular-rational and stream-window data before R is consumed, so the field consumer receives a displayed $\mathsf{Real}^{\uparrow}$ seal rather than a selected representative or quotient real.

Now apply the apartness/order route. The bridge cited in chapter 1905 consumes the apartness row A, located-order row O, and dyadic ledger D before any inverse or order-facing field operation is read.

Finally H, C, P, N preserve the same route under componentwise transport, replay, provenance, and local naming. Thus every forward handoff to Real and apartness-order consumers factors through the displayed rows and adds no trichotomy, quotient real equality, selected representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 4753.12 (Real apartness field located real route)**.** *Every accepted* $\mathsf{RealApartnessField}^{\uparrow}$ *inverse read or order-facing read must pass through the* $\mathsf{LocatedReal}^{\uparrow}$ *source route of chapter 1933 and the apartness-order bridge of chapter 1905 before the* $\mathsf{Field}^{\uparrow}$ *reciprocal branch is exposed. In carrier notation, for*

$$F = (R, A, O, K, D, H, C, P, N),$$

the real seal row R, apartness row A, located-order row O, field row K, dyadic ledger D, componentwise transport H, displayed replay C, provenance P, and local naming row N are consumed in the same finite route. The route exports no trichotomy, quotient real equality, selected representative, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Project the accepted carrier from Definition 5562.2. The reciprocal branch is stored in the $\mathsf{Field}^{\uparrow}$ row K, while R, A, O, D, H, C, P, N remain visible as separate rows of the same finite packet.

Read the located-real source route first. The $\mathsf{LocatedReal}^{\uparrow}$ chapter supplies the finite comparison boundary consumed before the terminal real seal is used, so the field consumer receives located real evidence rather than a quotient representative or host real value.

Next read the apartness-order bridge. The bridge of chapter 1905 ties the apartness row A to the located-order row O over the same real seal R, and the dyadic ledger D records the reciprocal budget attached to that positive evidence.

Finally replay the consumer through H, C, P, N. Since those rows only transport, replay, source, and name the already displayed route, they cannot add trichotomy, quotient real equality, selected representatives, countable choice, or ambient completeness. Thus every inverse or order-facing read reaches the $\mathsf{Field}^{\uparrow}$ branch only after the located-real and apartness-order routes have both been displayed. □

Every $\mathsf{RealApartnessField}^{\uparrow}$ apartness read is field-facing only after it has passed through the L10 completion lattice: the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the $\mathsf{RealAlgOrder}^{\uparrow}$ comparison rows of chapter 766, and the located comparison surface of chapter 1730. Thus the packet is consumed as a classifier over displayed regular-rational, real-seal, algebraic-order, and located-comparison evidence, not as a detached field oracle. The $\mathsf{RealApartnessField}^{\uparrow}$ lattice consumes the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the located real bridge of chapter 1933, and the constructive order-field route through chapter 3640, chapter 1905, and chapter 6850. Its field-facing apartness reads therefore enter through displayed real names, located comparison, and order transport rows before any algebraic operation is used. Every

$\mathsf{RealApartnessField}^{\uparrow}$ carrier reads its terminal real-name dependency through the finite L10 completion route, not through an ambient field of host reals. The route passes through the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ regular-rational readback of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, and the $\mathsf{StreamName}^{\uparrow}$ finite-window surface of chapter 126.

Proposition 4753.13 (Real apartness field finite completion dependency route)**.** *For every accepted* $\mathsf{RealApartnessField}^{\uparrow}$ *carrier* $F = (R, A, O, K, D, H, C, P, N)$*, any field-facing read of* R, A, O, K*, or* D *first exposes the finite-window* $\mathsf{StreamName}^{\uparrow}$ *rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal named above. Hence the apartness-field carrier consumes* $\mathsf{Real}^{\uparrow}$ *only through that displayed finite L10 dependency lattice, with* H, C, P, N *preserving transport, replay, provenance, and local naming for the same route.*

Proof. Project the carrier of Definition 5562.2. The only Real-facing row is R, and the apartness, located-order, field, and dyadic rows A, O, K, D are stored as downstream rows of the same finite packet.

Apply the StreamName and regular-rational dependency routes already present in the chapter. They force a comparison or inverse read to expose finite windows and regular-rational readback before the terminal $\mathsf{Real}^{\uparrow}$ seal is consumed.

Finally read the dyadic ledger. The tolerance and reciprocal-budget information in D is displayed before the field-facing row K is exported, while H, C, P, N carry only the same finite dependency route. Therefore no read imports quotient real equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 4753.14 (Real apartness field regular-Cauchy source route)**.** *Every accepted* $\mathsf{RealApartnessField}^{\uparrow}$ *inverse read or apartness read first consumes the* $\mathsf{RegSeqRat}^{\uparrow}$ *source of chapter 301, the terminal* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38, and the located and order sibling rows already named by this chapter before the* $\mathsf{Field}^{\uparrow}$ *inverse data are exposed. In carrier notation, a read of*

$$F = (R, A, O, K, D, H, C, P, N)$$

passes through the regular-rational source behind R*, the terminal real seal* R*, the apartness row* A*, located-order row* O*, dyadic ledger* D*, transport* H*, replay* C*, provenance* P*, and local naming row* N *before the field row* K *can export an inverse branch.*

Proof. Project the accepted carrier of Definition 5562.2. The field row K is stored together with the real seal row R, apartness row A, located-order row O, dyadic ledger D, and the structural rows H, C, P, N.

Use the StreamName dependency theorem Definition 5562.3. It forces every comparison-facing read to expose the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301 before the terminal $\mathsf{Real}^{\uparrow}$ route of chapter 38 is consumed.

Now apply the located and order child routes already carried by the chapter: Definition 5562.1, Definition 5562.12, and Definition 5562.11. These routes place the located-real, apartness-order, and Real/order dependencies before any field-facing inverse read is exported.

Finally combine the NameCert obligations with inverse-guard stability. Theorems 5562.4 and 5562.6 require the apartness guard and dyadic reciprocal budget to be displayed before K is consumed. Thus the inverse data are downstream of the RegSeqRat source, Real terminal seal, and located/order sibling rows, and the route adds no trichotomy, quotient real equality, selected representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

The RealApartnessField$^{\uparrow}$ chapter reads its field-facing apartness rows through the regular-Cauchy apartness lattice before exporting any arithmetic surface. In particular, the route first exposes chapter 1710, then the located-real surface of chapter 1933, and then the located order rows of chapter 3640. Only after these three sibling dependencies are visible may the chapter present the RealApartnessField$^{\uparrow}$ field-facing apartness rows; the route exports no host real equality, detached order completion, selected located witness, or ambient field law outside the displayed BEDC dossier lattice. The RealApartnessField$^{\uparrow}$ lattice consumes the regular Cauchy criterion surface of chapter 1611, the located real order route of chapter 8337, and the terminal Real seal of chapter 38 before it exports apartness-field reads. Thus an inverse or comparison read from the field-facing row is routed through displayed criterion checks, order evidence, and Real sealing, rather than through a detached field oracle.

Proposition 4753.15 (Real apartness field regular Cauchy criterion route)**.** *Every accepted* RealApartnessField$^{\uparrow}$ *packet that exports an apartness-field read must first expose the* RegularCauchyCriterion$^{\uparrow}$ *criterion dependency, the* LocatedRealOrder$^{\uparrow}$ *order dependency, and the* Real$^{\uparrow}$ *seal dependency named by its carrier rows. The exported read is therefore a finite L10 route through regular Cauchy criterion data, located order evidence, terminal Real sealing,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *data.*

Proof. Project the accepted RealApartnessField$^{\uparrow}$ carrier. Its apartness-field row is downstream from the displayed Real seal, located-order row, dyadic tolerance ledger, transport, replay, provenance, and local naming rows already named by the chapter.

The regular Cauchy criterion dependency supplies the finite criterion checks consumed before the Real seal and order-facing rows are read. Since the carrier has no coordinate for trichotomy, quotient real equality, selected representatives, countable choice, or ambient Real completeness, the exported apartness-field read remains inside the displayed finite route. □

Theorem 4753.16 (Real apartness field product-topology dependency)**.** *Every product-coordinate apartness-field read of an accepted* RealApartnessField$^{\uparrow}$ *packet must expose the finite* ProductTopology$^{\uparrow}$ *product window before the inverse, order, and field rows of the apartness-field carrier are consumed. The route first reads the* Real$^{\uparrow}$ *seal,* RegSeqRat$^{\uparrow}$ *readback,* StreamName$^{\uparrow}$ *finite windows,* Field$^{\uparrow}$ *operation row,* DyadicRatCore$^{\uparrow}$ *tolerance ledger, and* RealApartnessOrderBridge$^{\uparrow}$ *apartness-order bridge, and only then permits the product-coordinate consumer to use the* RealApartnessField$^{\uparrow}$ *inverse or order-facing field surface.*

Proof. Project the accepted RealApartnessField$^{\uparrow}$ carrier through Definition 5562.2. Its inverse and order-facing reads are stored in the displayed real seal, apartness, located-order, field, dyadic, transport, replay, provenance, and local naming rows, so a product-coordinate consumer has no separate coordinate from which to read a field operation.

Read the product surface through chapter 2000. The finite ProductTopology$^{\uparrow}$ window supplies the coordinate route before either coordinate can be consumed as a real apartness-field input.

Use the source rows already required by the chapter: the StreamName$^{\uparrow}$ windows and RegSeqRat$^{\uparrow}$ readback feed the Real$^{\uparrow}$ seal, the DyadicRatCore$^{\uparrow}$ ledger supplies tolerance and positivity data, the Field$^{\uparrow}$ row carries the operation boundary, and the RealApartnessOrderBridge$^{\uparrow}$ route ties apartness evidence to order-facing comparison over the same real seal. The product-coordinate read therefore reaches the inverse or order-facing field rows only after the product-topology dependency has been displayed. □

Theorem 4753.17 (Real apartness field Real–RegSeqRat–Dyadic route)**.** *Every* RealApartnessField$^{\uparrow}$ *apartness-field comparison read exposes the terminal* Real$^{\uparrow}$ *seal of chapter 38, the* RegSeqRat$^{\uparrow}$

regular-rational readback of chapter 301, and the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger of chapter 291 before the field-facing comparison row is exported. The route is a displayed dependency through real sealing, regular-rational readback, and dyadic tolerance control; it does not add trichotomy, quotient real equality, selected representatives, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 5562.2. Its comparison-facing data are stored with the real seal row, apartness row, located-order row, dyadic ledger, transport, replay, provenance, and local naming rows.

Read the $\mathsf{RegSeqRat}^{\uparrow}$ source before the terminal $\mathsf{Real}^{\uparrow}$ seal. The existing regular-Cauchy source route forces the comparison to pass through regular-rational readback rather than through an untracked real representative.

Then expose the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger. The apartness guard and reciprocal budget are consumed only with the displayed dyadic tolerance data, so the field-facing row is downstream of the Real, RegSeqRat, and DyadicRatCore dependencies named above. □

Theorem 4753.18 (Real apartness field inverse-guard dependency route)**.** *Every inverse-guard export from an accepted* $\mathsf{RealApartnessField}^{\uparrow}$ *carrier factors through the* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{CauchyRealApartness}^{\uparrow}$ *positive-apartness row,* $\mathsf{LocatedRealOrder}^{\uparrow}$ *boundary row, and* $\mathsf{Field}^{\uparrow}$ *operation row before a field inverse is public. The route composes the Real–RegSeqRat–Dyadic dependency with inverse-guard stability and the regular-Cauchy apartness/order dependency, and it refuses trichotomy, quotient equality, selected representatives, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with Definition 5562.17. It places every field-facing comparison behind the terminal $\mathsf{Real}^{\uparrow}$ seal, the regular rational readback, and the dyadic tolerance ledger.

Next apply the inverse-guard stability surface in the parent chapter. The inverse row is public only when the positive-apartness guard remains attached to the displayed carrier, so the guard cannot be replaced by quotient equality or by a selected representative.

Finally read the regular-Cauchy apartness/order dependency. The positive-apartness row is checked together with the located-order boundary before the $\mathsf{Field}^{\uparrow}$ operation row exposes an inverse. Hence the inverse export remains a finite route through Real, RegSeqRat, DyadicRatCore, CauchyRealApartness, LocatedRealOrder, and Field data, with trichotomy, countable choice, quotient equality, selected representatives, and ambient Real completeness outside the packet. □

Chapter 4754

A Concrete Naming Certificate for $\mathsf{ModulusOfRegularConvergence}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy convergence in constructive real analysis, the $\mathsf{ModulusOfRegularConvergence}^{\uparrow}$ packet records the finite threshold schedule that lets a regular rational name answer downstream Real and Completion precision requests without appealing to a quotient of streams. It sits after the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational source of chapter 301, and the terminal real-name seal of chapter 38. The packet gives the L10 Real and Completion route a named finite modulus surface; it does not assert ambient $\mathsf{Real}^{\uparrow}$ completeness, selected limits, trichotomy, countable choice, or quotient-stream equality.

Definition 4754.1 (Modulus of regular convergence carrier)**.** *A* $\mathsf{ModulusOfRegularConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (R, Q, W, D, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular rational reads are being controlled.*
2. *Q is the modulus row, recording a displayed tolerance request and the finite index threshold from which the regular convergence comparison is certified.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing exactly the source reads inspected by Q.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling the dyadic radius, comparison budget, and readback precision used by the threshold row.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after R, Q, W, D have been displayed.*
6. *H records componentwise* hsame *transport for the source, modulus, window, tolerance, real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a precision request through R, Q, W, D, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{ModulusOfRegularConvergence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ModulusOfRegularConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, Q, W, D, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, host real equality, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.ModulusOfRegularConvergenceUp.ModulusOfRegularConvergenceTasteGate single carrier alignment`

Theorem 4754.2 (Modulus of regular convergence NameCert obligations)**.** *For every accepted* $\mathsf{ModulusOfRegularConvergence}^{\uparrow}$ *carrier* $M = (R, Q, W, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ModulusOfRegularConvergence}}$ *surface consists exactly of carrier admission, regular-rational source exposure, explicit threshold exactness, finite stream-window coverage, dyadic tolerance control, terminal real-seal nonescape, componentwise transport, displayed replay, package provenance, and local naming. Every precision-facing read must expose*

$$R, Q, W, D \longrightarrow E \longrightarrow H, C, P, N.$$

No obligation is discharged by quotienting two streams, selecting a limit, invoking countable choice, importing trichotomy, or using ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 5563.1. The packet first displays the regular rational source R, the threshold row Q, the stream windows W, and the dyadic tolerance ledger D.

The threshold obligation is local to Q. The windows in W supply the finite source reads named by that threshold, while D supplies the dyadic comparison budget used to certify the requested regular convergence read.

The real-facing seal E is downstream of those four rows. Transport through H and replay through C preserve the same order, and P, N record provenance and local NameCert comparison without adding an outside coordinate.

Since quotient stream equality, selected limits, host real equality, countable choice, trichotomy, and ambient completeness do not occur among the carrier coordinates, every NameCert obligation is read through the displayed finite route. □

Theorem 4754.3 (Regular convergence finite-modulus handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{ModulusOfRegularConvergence}^{\uparrow}$ *packet must read the regular rational source row, explicit modulus threshold, finite stream windows, and dyadic tolerance ledger before consuming the terminal real seal. The packet therefore exports a finite threshold route from regular rational data into Real-facing data, not a host completeness theorem or a quotient construction.*

Proof. Project an accepted carrier as $M = (R, Q, W, D, E, H, C, P, N)$. The only regular rational input is R, and the only threshold schedule is Q.

The row W exposes the finite observations named by that schedule. The row D supplies the dyadic tolerance comparison that turns those observations into a regular convergence read.

Only after R, Q, W, D are present may the consumer read E as the terminal $\mathsf{Real}^{\uparrow}$ seal. Componentwise transport, replay, provenance, and local naming keep the same route visible to downstream consumers.

The carrier has no coordinate for selected limits, quotient stream equality, host real equality, countable choice, trichotomy, or ambient Real completeness. Thus every completion-facing handoff factors through the finite modulus rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{ModulusOfRegularConvergence}^{\uparrow}}$ **.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ModulusOfRegularConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5563.1, Definition 5563.2, and Definition 5563.3 seed the finite modulus route from regular rational source data through stream windows, dyadic tolerances, and a Real-facing seal.

Formal verification: FormalStatus(NameCert$_{\text{ModulusOfRegularConvergence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, trichotomy, host real equality, Lean verification, bridge checking, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, source exposure, threshold exactness, stream-window coverage, dyadic tolerance control, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ModulusOfRegularConvergenceUp.

Constructive story: A ModulusOfRegularConvergence$^{\uparrow}$ packet is generated from a RegSeqRat source row, explicit modulus threshold row, finite StreamName windows, DyadicRatCore tolerance ledger, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4755

A Concrete Naming Certificate for $\mathsf{RHRouteHaltingBoundary}^{\uparrow}$

Following the classical separation between the Riemann Hypothesis as a fixed proposition and proof search as a metamathematical process, the $\mathsf{RHRouteHaltingBoundary}^{\uparrow}$ packet records the finite BEDC surface of the route-closure boundary described in chapter 9336. It sits over the RH condition-chain rows of that vision chapter, the halting distinction traces of chapter 492, the halting obstruction of chapter 490, the proof witness chain surface of chapter 1238, and the zeta-zero witness boundary of chapter 73. The packet names route, grounding-rank, decider-refusal, and NameCert rows; it does not decide RH, prove RH, refute RH, or assert independence for any chosen fragment.

Definition 4755.1 (RH-route halting boundary carrier)**.** *An* $\mathsf{RHRouteHaltingBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (R, G, D, F, Z, H, C, P, N)$$

with the following displayed rows:

1. *R is the RH-route row, recording the displayed condition chain, rule tower, proof-output program, or route family being inspected.*
2. *G is the grounding-rank row, recording whether the inspected route has a displayed finite rank and, when it does, the finite top certificate and transports back to* RH*.*
3. *D is the decider-refusal row, recording that a proposed global or sufficiently expressive RH-route closure decider is a halting-boundary request rather than an internal BEDC classifier.*
4. *F is the fixed-statement row separating the proposition* RH *from route-search totality and from global proof-search classification.*
5. *Z is the zeta-zero witness interface row, exposing the critical-strip and critical-line witnesses that a genuine RH proof or counterexample datum would have to consume.*
6. *H records componentwise* hsame *transport for route, grounding-rank, refusal, fixed-statement, zeta-witness, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from route inspection through R, G, D, F, Z, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RHRouteHaltingBoundary}^{\uparrow}$, $\mathsf{HaltingDistinctionTrace}^{\uparrow}$, $\mathsf{HaltingObstruction}^{\uparrow}$, $\mathsf{ProofWitnessChain}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{RHRouteHaltingBoundary}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $R, G, D, F, Z, H, C, P, N$. It has no coordinate for an RH proof, an RH counterexample, an RH-specific independence theorem, a global theorem-route closure decider, a proof-search oracle, or an unmarked halting predicate.

Lean4 (definition) `BEDC.Derived.RHRouteHaltingBoundaryUp.RHRouteHaltingBoundaryUp`

Theorem 4755.2 (RH-route halting boundary NameCert obligations)**.** *For every accepted* $\mathsf{RHRouteHaltingBoundar}$ *carrier $B = (R, G, D, F, Z, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RHRouteHaltingBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission, route-row exposure, grounding-rank exactness, decider-refusal exactness, fixed-RH-statement separation, zeta-witness interface exposure, componentwise transport, displayed replay, package provenance, and local naming. Every decision-facing read must expose*

$$R, G, D, F, Z \longrightarrow H, C, P, N.$$

The packet distinguishes RH truth from route-closure decidability: it can record finite grounded routes and reject global closure deciders, but it does not provide $\Phi : \mathsf{RH}$, a counterexample datum, or a fragment-specific independence theorem.

Proof. Carrier admission is projection from Definition 5564.1. The route row R names the inspected RH-directed condition chain, rule tower, or proof-output route, while G records the displayed grounding-rank information attached to that route.

The refusal row D is read separately from the fixed-statement row F. Thus the packet can reject a global or expressive route-closure decider as a halting-boundary request without changing the fixed proposition RH.

The zeta-witness interface Z records what a genuine proof or counterexample datum would have to consume. It does not itself supply the total witness function, a counterexample point, or an independence theorem.

The structural rows H, C, P, N transport, replay, source, and name only the displayed route, rank, refusal, fixed-statement, and zeta-interface rows. Since no proof oracle, route oracle, halting predicate, counterexample, or independence theorem occurs among the coordinates, the listed obligations exhaust the finite NameCert surface. □

Theorem 4755.3 (RH route boundary nondecision)**.** *Every accepted* $\mathsf{RHRouteHaltingBoundary}^{\uparrow}$ *packet separates three reads: the fixed* RH *statement row, the finite route or grounding-rank row, and the decider-refusal row. Consequently a consumer may use the packet to identify a finite grounded route or to reject an expressive route-closure decider, but no consumer can read an RH truth value, RH refutation, or independence result from the packet alone.*

Proof. Project the carrier $B = (R, G, D, F, Z, H, C, P, N)$. The row F names the fixed statement, while R and G name route and grounding-rank data.

The row D records the halting-boundary refusal for global or sufficiently expressive route deciders. This refusal is a statement about the classifier request, not a proof or refutation of the fixed proposition.

The row Z exposes the zeta-zero witness interface required by an actual decision datum. Because no coordinate supplies such a datum, transport and replay through H, C can preserve only the boundary information already displayed.

Package provenance and local naming through P, N do not add a truth-value coordinate. Therefore the packet is a finite halting-boundary NameCert surface, not an RH decision artifact. □

Closure status for $\mathsf{NameCert}_{\mathsf{RHRouteHaltingBoundary}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RHRouteHaltingBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5564.1, Definition 5564.2, and Definition 5564.3 seed the finite route, grounding-rank, decider-refusal, fixed-statement, zeta-interface, transport, replay, provenance, and local naming surface for the RH route halting boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RHRouteHaltingBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not prove RH, refute RH, establish RH independence over any fragment, provide a global theorem-route closure decider, admit a proof-search oracle, close halting, supply Lean verification, or provide a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, route-row exposure, grounding-rank exactness, decider-refusal exactness, fixed-statement separation, zeta-witness interface exposure, transport, replay, provenance, and local naming for BEDC.Derived.RHRouteHaltingBoundaryUp.

Constructive story: An $\mathsf{RHRouteHaltingBoundary}^{\uparrow}$ packet is generated from RH route rows, grounding-rank rows, decider-refusal rows, fixed-RH-statement rows, zeta-witness interface rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4756

A Concrete Naming Certificate for $\mathsf{Premetric}^{\uparrow}$

Following Kelley on uniform sources and Bishop–Bridges constructive metric data, the $\mathsf{Premetric}^{\uparrow}$ packet records the distance-comparison surface that sits before separated reflection and metric completion. It reads the finite entourage interface of chapter 339, supplies the source row consumed by chapter 4201, and keeps the completion-facing boundary visible before chapter 1506 or the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38 can be inspected. The packet names a constructive distance witness and zero-distance classifier; it does not quotient points, select representatives, assert host equality, or import ambient completeness.

Definition 4756.1 (Premetric carrier)**.** *A* $\mathsf{Premetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (X, U, D, Z, S, M, H, C, Q, N)$$

with the following displayed rows:

1. *X is the source carrier row whose points are admitted only through displayed BEDC windows.*
2. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *source row, exposing the finite entourage requests that the distance witness is allowed to refine.*
3. *D is the distance-witness relation row, recording finite positive-radius comparisons between displayed point windows.*
4. *Z is the zero-distance classifier row, comparing two displayed source windows only through the radius comparisons stored in D.*
5. *S is the separated-reflection handoff row consumed by* $\mathsf{SeparatedReflectionUniversal}^{\uparrow}$ *after Z has been displayed.*
6. *M is the completion-facing nonescape row, binding every* $\mathsf{MetricCompletion}^{\uparrow}$ *read to X, U, D, Z, S before any completed object is named.*
7. *H records componentwise* hsame *transport for source, uniform, distance, zero-distance, reflection, completion, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite distance or zero-distance request through X, U, D, Z, S, M, H.*
9. *Q is the* Pkg *provenance over* $\mathsf{Premetric}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{SeparatedReflectionUniversal}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{Premetric}^\uparrow}$ *row.*

The classifier compares accepted packets only through $X, U, D, Z, S, M, H, C, Q, N$. It has no coordinate for quotient point equality, selected separated representatives, chosen completion limits, host metric equality, trichotomy, countable choice, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Lean4 (definition) `BEDC.Derived.PremetricUp.PremetricTasteGate single carrier alignment`

Theorem 4756.2 (Premetric NameCert obligations)**.** *For every accepted* $\mathsf{Premetric}^\uparrow$ *carrier $P = (X, U, D, Z, S, M, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{Premetric}^\uparrow}$ *surface consists exactly of source-carrier admission, uniform-source readback, distance-witness exposure, zero-distance classification, separated-reflection handoff, completion-facing nonescape, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Each obligation is read through the finite route*

$$X, U, D, Z \longrightarrow S, M \longrightarrow H, C, Q, N.$$

Proof. Carrier admission is projection from Definition 5565.1. The source row X and uniform row U are the only inputs a consumer may inspect before asking for distance data.

The distance-witness relation D supplies finite positive-radius comparisons between displayed source windows. The zero-distance classifier Z is downstream of D, so equality-like reads are exposed as repeated distance comparisons rather than as host point equality.

The reflection row S and completion boundary M are then forced to read X, U, D, Z. Componentwise transport through H and replay through C preserve that order, while Q, N record provenance and local naming.

Since quotient point equality, selected separated representatives, chosen completion limits, host metric equality, trichotomy, countable choice, and ambient Real completeness do not occur among the carrier coordinates, no NameCert obligation can be discharged outside the displayed finite route. □

Lean4 ✓ `BEDC.Derived.PremetricUp.PremetricCarrier namecert obligations`

Theorem 4756.3 (Premetric separated-reflection route)**.** *Let $P = (X, U, D, Z, S, M, H, C, Q, N)$ be an accepted* $\mathsf{Premetric}^\uparrow$ *carrier. Every* $\mathsf{SeparatedReflectionUniversal}^\uparrow$ *consumer of P must first read the source carrier X, the uniform source row U, the distance-witness relation D, and the zero-distance classifier Z. The handoff row S therefore presents the reflection source as a finite zero-distance comparison surface, not as a quotient carrier or a selected representative map.*

Lean4 ✓ `BEDC.Derived.PremetricUp.PremetricSeparatedReflectionRoute`

Proof. Apply the obligation theorem, Definition 5565.2. It identifies X, U, D, Z as the full prefix needed before the separated-reflection handoff can be consumed.

The row U records the uniform-source requests, while D records the finite distance comparisons refining those requests. The classifier Z reads zero distance only through those comparisons.

Thus S supplies the premetric source expected by the separated-reflection route of chapter 4201. The structural rows H, C, Q, N transport, replay, source, and name the same handoff; they do not add quotient data, selected representatives, or host equality. □

Theorem 4756.4 (Premetric zero-distance classifier boundary)**.** *Let $P = (X, U, D, Z, S, M, H, C, Q, N)$ be an accepted* $\mathsf{Premetric}^\uparrow$ *carrier. Every equality-like read of P must pass through the finite distance-witness row D and the zero-distance classifier row Z before any* $\mathsf{SeparatedReflectionUniversal}^\uparrow$, $\mathsf{MetricCompletion}^\uparrow$, *or* $\mathsf{Real}^\uparrow$ *consumer may inspect the packet. Thus zero-distance comparison is*

the only equality-facing classifier route exposed by the premetric certificate; no consumer receives quotient point equality, selected separated representatives, host metric equality, chosen completion limits, or ambient completeness data.

Lean4 ✓ `BEDC.Derived.PremetricUp.PremetricCarrier zero distance classifier boundary`

Proof. Project the carrier of Definition 5565.1. The source row X and uniform row U admit the displayed point windows, while D is the only row that records positive-radius distance witnesses.

Apply the NameCert obligation surface of Definition 5565.2. It places the zero-distance classifier Z downstream of D, so any equality-like request must be read as a finite family of distance comparisons before it can be passed onward.

The separated-reflection route of Definition 5565.3 consumes exactly that D, Z prefix through S. Completion-facing readers then use the same prefix through M, so neither route can replace the classifier by a quotient carrier, a selected representative, or host metric equality.

The refused endpoints follow from the carrier inventory. The tuple has no coordinate for quotient equality, selected representatives, chosen completion limits, host metric equality, or ambient completeness, and the support rows H, C, Q, N only transport, replay, package, and name the displayed premetric route. □

Lean4 ✓ `BEDC.Derived.PremetricUp.PremetricZeroDistanceClassifierBoundary`

Theorem 4756.5 (Premetric completion boundary)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{Premetric}^{\uparrow}$ *packet reaches completion-facing data only through the displayed route*

$$\mathsf{UniformSpace}^{\uparrow}, \mathsf{Premetric}^{\uparrow}, \mathsf{SeparatedReflectionUniversal}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

In particular, the completion-facing row M exports finite distance-comparison and zero-distance data, not a completed point, a selected Cauchy limit, a quotient equality, or an ambient completeness principle.

Proof. Project an accepted carrier $P = (X, U, D, Z, S, M, H, C, Q, N)$. The completion-facing row M is downstream of the source, uniform, distance, zero-distance, and separated-reflection rows.

Any completion consumer must therefore read X, U, D, Z, S before it can inspect M. The terminal $\mathsf{Real}^{\uparrow}$ seal, when a downstream completion chapter exposes one, is reached only after that same finite route has been displayed.

The packet contains no coordinate for a completed point, selected Cauchy limit, quotient equality, host metric equality, countable choice, or ambient completeness. Hence the completion boundary is a nonescape condition over the finite premetric surface. □

Lean4 ✓ `BEDC.Derived.PremetricUp.PremetricCompletionBoundary`

Closure status for $\mathsf{NameCert}_{\mathsf{Premetric}^{\uparrow}}$.

Constructive story: A $\mathsf{Premetric}^{\uparrow}$ packet is generated from a source carrier row, a UniformSpace source row, a distance-witness relation, a zero-distance classifier, a separated-reflection handoff, a completion-facing nonescape row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Premetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5565.1, Definition 5565.2, Definition 5565.3, and Definition 5565.5 seed the constructive premetric boundary between uniform sources, separated reflection, metric completion, and Real-facing seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Premetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient point equality, selected representatives, chosen completion limits, host metric equality, countable choice, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked source-carrier admission, uniform-source readback, distance-witness exposure, zero-distance classification, separated-reflection handoff, completion-facing nonescape, transport, replay, provenance, and local naming for BEDC.Derived.PremetricUp.

Chapter 4757

A Concrete Naming Certificate for FiniteDimensionalNormEquivalence$^{\uparrow}$

Following Bourbaki and Bishop–Bridges finite-dimensional analysis, the FiniteDimensionalNormEquivalence$^{\uparrow}$ packet records norm comparison on a displayed finite coordinate window rather than through an ambient basis theorem. It consumes the vector-space surface of chapter 47, the norm interface of chapter 89, the finite coordinate and matrix rows of chapter 49, the real comparison seal of chapter 38, and the finite-net source of chapter 1250. The packet is an L10-facing finite analysis route for later NormedSpace$^{\uparrow}$ and bounded-operator consumers: it exports named comparison constants over displayed finite rows, not host basis choice, quotient vector equality, infinite-dimensional Hahn–Banach, or choice-selected duals.

Definition 4757.1 (Finite-dimensional norm-equivalence carrier)**.** *A* FiniteDimensionalNormEquivalence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (V, K, A, B, R, L, U, H, T, P, N)$$

with the following displayed rows:

1. *V is the consumed* VecSpace$^{\uparrow}$ *row, exposing vector addition, zero, negation, scalar action, and vector classification only through displayed carrier data.*
2. *K is the finite coordinate window row, represented by a* Mat$^{\uparrow}$*-indexed coordinate table and its finite reconstruction ledger.*
3. *A and B are the two consumed* Norm$^{\uparrow}$ *rows on the same displayed vector source.*
4. *R is the* Real$^{\uparrow}$ *comparison row used to read nonnegative norm values, finite sums, and scalar comparison constants.*
5. *L is the compact finite-net lower-bound row over the coordinate unit window, supplied through* ClosedBoundedIntervalNet$^{\uparrow}$ *and its finite coverage ledger.*
6. *U is the compact finite-net upper-bound row over the same coordinate window.*
7. *H stores componentwise* hsame *routes for the vector row, coordinate row, both norm rows, real comparison rows, and finite-net bound rows.*
8. *T stores displayed* Cont *replay for each coordinate read, norm read, finite-net comparison, and downstream consumer request.*

9. *P is the* Pkg *provenance over* $\mathsf{FiniteDimensionalNormEquivalence}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteDimensionalNormEquivalence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by the displayed rows $V, K, A, B, R, L, U, H, T, P, N$. It has no coordinate for host basis choice, quotient vector equality, infinite-dimensional Hahn–Banach, choice-selected duals, or an ambient normed-space object.

Lean4 ✓ `BEDC.Derived.FiniteDimensionalNormEquivalenceUp.FiniteDimensionalNormEquivalenceTasteGate`
`single carrier alignment`

Theorem 4757.2 (Finite-dimensional norm-equivalence NameCert obligations)**.** *For every accepted* $\mathsf{FiniteDimensionalNormEquivalence}^{\uparrow}$ *carrier $E = (V, K, A, B, R, L, U, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteDimensionalNormEquivalence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed vector-space row, coordinate matrix row, two norm rows, real comparison row, compact finite-net lower and upper bound rows, transports, replay, provenance, and local naming;*

2. *coordinate exposure, requiring every vector read used by the comparison to pass through the finite coordinate window K and the* $\mathsf{Mat}^{\uparrow}$ *reconstruction ledger;*

3. *norm-source compatibility, requiring the two norm rows A and B to read the same displayed vector source V and the same* $\mathsf{Real}^{\uparrow}$ *comparison boundary R;*

4. *compact finite-net lower bound, requiring L to supply a positive lower comparison for the second norm on the first-norm unit coordinate window by finite mesh inspection;*

5. *compact finite-net upper bound, requiring U to supply an upper comparison for the second norm on the same displayed coordinate window;*

6. *exactness, requiring every exported comparison constant and every downstream norm-equivalence read to factor through $V, K, A, B, R, L, U, H, T, P, N$.*

No obligation row may be discharged by host basis selection, quotient vector equality, an infinite-dimensional separation theorem, or a choice-selected dual functional.

Proof. Carrier admission is projection from Definition 5566.1. The accepted packet lists the vector source, coordinate table, two norm rows, real comparison boundary, finite-net lower and upper bound rows, and the structural replay rows.

Coordinate exposure is finite. A consumer first reads the displayed $\mathsf{Mat}^{\uparrow}$ coordinate table K, then reconstructs vector operations through the $\mathsf{VecSpace}^{\uparrow}$ row V. Since K is a coordinate window rather than a host basis object, the proof uses only the listed reconstruction ledger.

The lower and upper comparison rows are compact finite-net reads. The row L inspects the first-norm unit coordinate window through the closed bounded interval net and records a positive lower comparison for the second norm. The row U reads the same finite window and records the upper comparison. Both rows are sealed by $\mathsf{Real}^{\uparrow}$ comparisons in R.

Finally H, T, P, N transport, replay, source, and name this finite route. The carrier contains no host basis choice, quotient vector equality, infinite-dimensional Hahn–Banach theorem, or choice-selected dual row, so the listed obligations exhaust the local NameCert surface. □

Lean4 (definition) `BEDC.Derived.FiniteDimensionalNormEquivalenceUp.FiniteDimensionalNormEquivalenceCarrier`
Lean4 ✓ `BEDC.Derived.FiniteDimensionalNormEquivalenceUp.FiniteDimensionalNormEquivalenceNameCertObligat`

Theorem 4757.3 (Finite-dimensional compact-coordinate norm comparison)**.** *Every* $\mathsf{NormedSpace}^{\uparrow}$ *or bounded-operator consumer of an accepted* $\mathsf{FiniteDimensionalNormEquivalence}^{\uparrow}$ *carrier receives the comparison route*

$$V, K, A, B, R, L, U \longmapsto H, T, P, N.$$

The route compares the two norms by finite coordinate windows and compact finite-net lower and upper bounds. It exports no ambient basis theorem, quotient-vector equality, infinite-dimensional Hahn–Banach argument, selected dual basis, or choice principle.

Proof. Start with a downstream norm-comparison request. The vector input is read through V, and its finite coordinate presentation is read through the $\mathsf{Mat}^{\uparrow}$ window K.

Read the two norms next. The rows A and B give norm values on the same displayed vector source, while R supplies the real comparison boundary for inequalities and constants.

The compact-coordinate step uses the finite net. The lower row L supplies the positive comparison on the first-norm unit coordinate window, and the upper row U supplies the matching upper comparison. Both are finite mesh reads through chapter 1250, so no point is selected from an ambient compact object.

The structural rows H, T, P, N replay this exact route to $\mathsf{NormedSpace}^{\uparrow}$ and bounded-operator consumers. Since the packet never stores host basis choice, quotient vector equality, infinite-dimensional Hahn–Banach, selected duals, or choice, the exported comparison remains a finite NameCert route. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDimensionalNormEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteDimensionalNormEquivalence}^{\uparrow}$ packet is generated from a displayed $\mathsf{VecSpace}^{\uparrow}$ row, a finite $\mathsf{Mat}^{\uparrow}$ coordinate window, two $\mathsf{Norm}^{\uparrow}$ rows, a $\mathsf{Real}^{\uparrow}$ comparison boundary, compact finite-net lower and upper bound rows, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteDimensionalNormEquivalence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5566.1, Definition 5566.2, and Definition 5566.3 seed the finite coordinate norm-comparison route over $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteDimensionalNormEquivalence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host basis existence, quotient vector equality, infinite-dimensional norm equivalence, Hahn–Banach separation, selected dual bases, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite coordinate exposure, compact finite-net lower and upper comparison rows, componentwise replay, and local NameCert exactness for BEDC.Derived.FiniteDimensionalNormEquivalence

Chapter 4758

A Concrete Naming Certificate for FiniteOrthonormalBasis$^{\uparrow}$

Following finite-dimensional linear algebra, Gram–Schmidt, and standard inner-product-space treatments, the FiniteOrthonormalBasis$^{\uparrow}$ packet records the certificate surface that turns a displayed finite spanning list into a named finite orthonormal-basis row. It consumes the orthogonalization route of chapter 1875, the vector carrier of chapter 47, the inner-product form rows of chapter 86, the norm-one boundary of chapter 89, and the finite coordinate ledger of chapter 49. The packet names only the finite selected-row certificate; it is not an infinite basis principle, a host vector equality theorem, a quotient representative selector, or an ambient completion object.

Definition 4758.1 (Finite orthonormal basis carrier)**.** *A* FiniteOrthonormalBasis$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (V, S, G, O, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *V is the* VecSpace$^{\uparrow}$ *source row, including the displayed zero, addition, scalar action, and finite carrier reads used by the packet.*
2. *S is the finite spanning-list row whose entries are the only vectors eligible for the basis route.*
3. *G is the* GramSchmidt$^{\uparrow}$ *handoff row, exposing the finite orthogonalization replay applied to S.*
4. *O is the orthogonality and norm-one row, displaying pairwise inner-product-zero checks and unit norm checks for the promoted rows.*
5. *Q is the coordinate and reconstruction ledger, recording the finite coefficient rows through which a consumer reconstructs displayed vectors from the promoted rows.*
6. *R is the refusal and boundary row, recording each discarded zero residual or non-promoted vector without selecting a replacement outside S.*
7. *H records componentwise* hsame *transport for vector-space data, source rows, Gram–Schmidt replay, orthonormal rows, coordinate rows, refusal rows, continuation, provenance, and local naming.*
8. *C records displayed* Cont *replay from the source list through Gram–Schmidt, norm-one promotion, coordinate reconstruction, and local certificate.*
9. *P is the* Pkg *provenance over* FiniteOrthonormalBasis$^{\uparrow}$, GramSchmidt$^{\uparrow}$, VecSpace$^{\uparrow}$, InnerProduct$^{\uparrow}$, Norm$^{\uparrow}$, Mat$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteOrthonormalBasis}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $V, S, G, O, Q, R, H, C, P, N$. It has no coordinate for infinite basis choice, host vector equality, quotient representatives, a selected basis outside the displayed rows, or ambient completion.

Lean4 ✓ `BEDC.Derived.FiniteOrthonormalBasisUp.FiniteOrthonormalBasisTasteGate single carrier alignment`

Theorem 4758.2 (Finite orthonormal basis NameCert obligations)**.** *For every accepted* $\mathsf{FiniteOrthonormalBasis}^{\uparrow}$ *carrier $B = (V, S, G, O, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteOrthonormalBasis}^{\uparrow}}$ *surface has exactly five finite rows:*

1. *carrier admission for the vector-space source, spanning list, Gram–Schmidt handoff, orthogonality and norm-one checks, coordinate reconstruction, refusal boundary, transport, continuation, provenance, and local naming;*
2. *Gram–Schmidt route exposure, requiring every promoted basis row to be read through G from the displayed source list S;*
3. *orthogonality and norm-one exposure, requiring the* $\mathsf{InnerProduct}^{\uparrow}$ *and* $\mathsf{Norm}^{\uparrow}$ *checks in O to be displayed before a promoted row is exported as orthonormal;*
4. *coordinate and reconstruction handoff, requiring every finite coordinate row and reconstruction read to pass through Q and the finite* $\mathsf{Mat}^{\uparrow}$ *ledger;*
5. *ledger non-escape from selected bases outside S, infinite basis choice, host vector equality, quotient representatives, and ambient completion.*

No accepted finite orthonormal-basis read has an obligation outside these rows.

Proof. Project the carrier of Definition 4758.1. The rows $V, S, G, O, Q, R, H, C, P, N$ are the only displayed rows available to a local $\mathsf{NameCert}_{\mathsf{FiniteOrthonormalBasis}^{\uparrow}}$ read.

The route first fixes the vector-space source row V and the finite spanning list S. The Gram–Schmidt handoff row G then exposes the finite orthogonalization replay, while the refusal row R records every discarded zero residual or non-promoted vector.

The promoted rows are inspected through O. Orthogonality is read through displayed $\mathsf{InnerProduct}^{\uparrow}$ checks, and unit length is read through displayed $\mathsf{Norm}^{\uparrow}$ checks, so no host orthonormality predicate is imported.

Finally the coordinate ledger Q supplies finite reconstruction through the $\mathsf{Mat}^{\uparrow}$ rows, and H, C, P, N transport, replay, source, and name the same finite route. Since no excluded coordinate appears in the carrier, the ledger cannot escape to infinite basis choice, host vector equality, quotient representatives, or ambient completion. □

Theorem 4758.3 (Finite orthonormal basis Gram–Schmidt handoff)**.** *Every* $\mathsf{FiniteOrthonormalBasis}^{\uparrow}$ *consumer that reads an orthonormal row, a coordinate row, or a reconstruction row from an accepted carrier $B = (V, S, G, O, Q, R, H, C, P, N)$ must first pass through the* $\mathsf{GramSchmidt}^{\uparrow}$ *handoff row G. The consumer therefore receives a finite route from the displayed spanning list to promoted orthonormal rows and coefficient reconstruction, not an infinite basis selector or an ambient completion principle.*

Proof. Read the carrier rows of Definition 4758.1. The only route from the finite source list S to promoted rows is the Gram–Schmidt handoff G followed by the orthogonality and norm-one row O.

The coordinate and reconstruction ledger Q is downstream of that promoted-row surface. It can expose finite coefficients only after G and O have displayed the orthonormal rows they reference.

Apply the obligation surface of Definition 4758.2. Its non-escape row excludes selected bases outside S, infinite basis choice, host vector equality, quotient representatives, and ambient completion, so every exported consumer read remains on the displayed Gram–Schmidt route. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteOrthonormalBasis}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteOrthonormalBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4758.1, Definition 4758.2, and Definition 4758.3 seed the finite orthonormal-basis packet over displayed vector-space, Gram–Schmidt, inner-product, norm, matrix, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteOrthonormalBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close infinite basis choice, host vector equality, quotient representatives, ambient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Gram–Schmidt route exposure, orthogonality and norm-one exposure, coordinate reconstruction handoff, and ledger non-escape for BEDC.Derived.FiniteOrthonormalBasisUp.

Constructive story: A $\mathsf{FiniteOrthonormalBasis}^{\uparrow}$ packet is generated from a VecSpaceUp source row, a finite spanning-list row, a GramSchmidtUp handoff, displayed orthogonality and norm-one checks, a finite coordinate reconstruction ledger, refusal rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4759

A Concrete Naming Certificate for $\mathsf{RealCauchyConvergence}^{\uparrow}$

Following Bishop and Bridges' constructive treatment of real convergence by explicit Cauchy moduli, the $\mathsf{RealCauchyConvergence}^{\uparrow}$ packet records the finite route by which a displayed tail schedule for regular rational names is consumed before the terminal $\mathsf{Real}^{\uparrow}$ seal is read. It sits over the dyadic tolerance core of chapter 291, the finite observation interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the completion-facing regular Cauchy boundary of chapter 1639. The packet names a convergence certificate for L10 Real and Completion consumers; it does not assert ambient completeness of $\mathsf{Real}^{\uparrow}$, select a host limit, quotient Cauchy streams, invoke countable choice, or compare completed host real values.

Definition 4759.1 (RealCauchyConvergence carrier)**.** *A* $\mathsf{RealCauchyConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, S, R, T, B, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, containing the dyadic error requests and comparison budgets inspected by the convergence consumer.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule opened at the tail thresholds named for those dyadic requests.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the scheduled windows and dyadic comparisons.*
4. *T is the displayed Cauchy modulus tail row, assigning each dyadic tolerance a finite tail index and the late-window reuse condition needed by convergence checks.*
5. *B is the* $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ *boundary row, recording that the same D, S, R, T data are read as a completion-facing regular Cauchy packet before any Real seal is exposed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the tail modulus, finite windows, regular readback, and completion boundary have been displayed.*
7. *H records componentwise* hsame *transport for the tolerance ledger, window schedule, regular readback, tail modulus, completion boundary, Real seal, replay row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from a convergence request through T, then through D, S, R, B, and finally into the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

9. *P is the* Pkg *provenance over* $\mathsf{RealCauchyConvergence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCauchyConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, T, B, E, H, C, P, N$. The carrier has no coordinate for quotient stream equality, selected limits, countable-choice schedules, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RealCauchyConvergenceUp.RealCauchyConvergenceTasteGate single carrier alignment`

Theorem 4759.2 (RealCauchyConvergence NameCert obligations)**.** *For every accepted* $\mathsf{RealCauchyConvergence}^{\uparrow}$ *carrier*

$$G = (D, S, R, T, B, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCauchyConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance exposure, finite tail-window inspection, regular rational readback, displayed Cauchy modulus tail control, completion-boundary handoff, Real-seal routing, componentwise transport, displayed replay, provenance, local naming, and non-escape from the displayed rows.*

Proof. Carrier admission is projection from Definition 4759.1. The accepted packet exposes the tolerance ledger D, finite windows S, regular readback R, tail modulus row T, completion boundary B, terminal Real seal E, and structural rows H, C, P, N.

The convergence obligations are then read in order. The dyadic core of chapter 291 supplies the tolerance requests, the stream interface of chapter 126 supplies the finite inspected windows, and the regular rational route of chapter 301 packages those windows as the displayed readback row.

The tail and completion rows are the only convergence-specific data. The row T fixes the late-window threshold for each displayed tolerance, while the boundary row B routes the same data through chapter 1639 before the $\mathsf{Real}^{\uparrow}$ seal of chapter 38 is consumed.

Finally H and C transport and replay the same coordinates, while P and N record provenance and local naming. Since no other coordinate occurs in the carrier, the NameCert surface exports none of the excluded quotient, selected-limit, choice, host-equality, completeness, verification, or bridge data. □

Theorem 4759.3 (RealCauchyConvergence regular seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{RealCauchyConvergence}^{\uparrow}$ *carrier factors through the finite route*

$$T, D, S, R \longmapsto B \longmapsto E$$

before the terminal $\mathsf{Real}^{\uparrow}$ *seal can be consumed. Thus a consumer receives the displayed Cauchy modulus tail threshold, dyadic tolerance rows, finite stream windows, regular rational readback, and the Bishop regular Cauchy completion boundary before any Real seal is visible.*

Proof. Start with an accepted carrier $G = (D, S, R, T, B, E, H, C, P, N)$. By Definition 4759.2, the only Real-facing row is E, and it is downstream of the displayed tail, dyadic, stream, regular-readback, and completion-boundary rows.

The route cannot skip the tail row because T is the only coordinate assigning late thresholds to dyadic tolerance requests. It cannot skip D or S because the dyadic ledger and finite windows are the only displayed sources for the inspected regular rational reads.

The completion boundary is also forced. The row B is the sole $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ handoff available to a Real or Completion consumer, so the terminal seal is read only after the regular readback R has been routed through that boundary.

Transport, replay, provenance, and local naming preserve the same sequence of rows. Since H, C, P, N add no quotient stream equality, selected limit, countable-choice schedule, host equality, or ambient completeness theorem, every $\mathsf{Real}^{\uparrow}$-facing read reaches E only through the displayed convergence packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCauchyConvergence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCauchyConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 4759.1, Definition 4759.2, and Definition 4759.3 seed the finite convergence packet linking displayed Cauchy modulus tails, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$ handoff, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCauchyConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient Cauchy equality, selected limits, countable choice, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-modulus exposure, dyadic tolerance exactness, finite-window inspection, regular rational readback, completion-boundary handoff, Real-seal routing, transport stability, replay stability, provenance, local naming, and non-escape for BEDC.Derived.RealCauchyConvergenceUp.

Constructive story: A $\mathsf{RealCauchyConvergence}^{\uparrow}$ packet is generated from a displayed Cauchy modulus tail row, DyadicRatCore tolerance data, StreamName finite windows, RegSeqRat readback, a BishopRegularCauchyCompletion boundary row, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4760

A Concrete Naming Certificate for $\mathsf{CompactUniformFiniteNet}^{\uparrow}$

Following the finite-net proof of Heine–Cantor isolated in chapter 9237, the $\mathsf{CompactUniformFiniteNet}^{\uparrow}$ packet names the compact finite-net object consumed by uniform-modulus constructions. It reads compact admission from chapter 60, metric distance rows from chapter 57, continuous pointwise-modulus rows from chapter 59, rational lower-bound rows from chapter 37, and the uniform-modulus handoff of chapter 369. Its finite spine is the kernel ProbeBundle of chapter 6; the packet exposes only the named bundle, center rows, rational radius rows, coverage rows, lower-bound fold, transport, replay, provenance, and local naming.

Definition 4760.1 (CompactUniformFiniteNet carrier)**.** *A* $\mathsf{CompactUniformFiniteNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (C, M, Q, B, E, R, L, U, H, D, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{Compact}^{\uparrow}$ *source row admitting the compact object.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row used by the finite-net coverage witnesses.*
3. *Q is the* $\mathsf{Continuous}^{\uparrow}$ *pointwise-modulus source row whose center radii are consumed downstream.*
4. *B is the finite* ProbeBundle *row of bundled probe names.*
5. *E is the center and coverage row, assigning center histories and displayed distance witnesses to bundled probes.*
6. *R is the positive* $\mathsf{Rat}^{\uparrow}$ *radius ledger attached to the bundled centers.*
7. *L is the rational lower-bound fold row over the finite bundle.*
8. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced from the same finite-net and lower-bound data.*
9. *H records componentwise* hsame *transport for C, M, Q, B, E, R, L, U.*
10. *D records displayed* Cont *replay of the finite-net inspection, radius readback, lower-bound fold, and handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactUniformFiniteNet}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformFiniteNet}^{\uparrow}}$ *row.*

The carrier has no coordinate for a choice-selected subcover, selected Lebesgue number, sequential compactness argument, quotient point equality, ambient real completeness theorem, or external modulus selector.

Lean4 ✓ `BEDC.Derived.CompactUniformFiniteNetUp.CompactUniformFiniteNetTasteGate single carrier alignment`

Theorem 4760.2 (CompactUniformFiniteNet NameCert obligations)**.** *For every accepted* CompactUniformFiniteNet *packet* $K = (C, M, Q, B, E, R, L, U, H, D, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformFiniteNet}^{\uparrow}}$ *surface consists exactly of compact source admission, metric distance exposure, continuous pointwise-modulus exposure, finite* ProbeBundle *admission, center and coverage exposure, rational radius exposure, rational lower-bound folding, uniform-modulus handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer may not replace this surface by selected subcovers, selected Lebesgue numbers, sequential compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or an external modulus selector.*

Proof. Project the carrier of Definition 4760.1. The finite-net rows are exactly B, E, R, L, while C, M, Q, U locate the compact, metric, continuous, and uniform-modulus interfaces around them.

The fold is internal to the finite bundle. The row L reads only the rational radii carried by R over the displayed ProbeBundle row B, so no selected subcover or selected Lebesgue number is introduced.

The structural rows H, D, P, N preserve the same finite surface. Since no coordinate stores sequential compactness, quotient point equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or an external selector, the displayed rows exhaust the local NameCert obligations. □

Falsifiable prediction: An accepted $\mathsf{CompactUniformFiniteNet}^{\uparrow}$ read is refuted if a UniformModulusUp handoff is reached without displaying the CompactUp source, MetricUp distance row, ContinuousUp pointwise-modulus row, finite ProbeBundle row, center and coverage row, RatUp radius ledger, rational lower-bound fold, transport, replay, provenance, and local naming rows.

Independence witness: compact, metric, continuous, rat, uniformmodulus, and probebundle: none is bijective to the compact-uniform finite-net packet because only $\mathsf{CompactUniformFiniteNet}^{\uparrow}$ records the finite center bundle, rational lower-bound fold, and uniform-modulus handoff in one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformFiniteNet}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformFiniteNet}^{\uparrow}$ packet is generated from CompactUp source admission, MetricUp distance rows, ContinuousUp pointwise-modulus rows, a finite ProbeBundle row, center and coverage rows, positive RatUp radius rows, a rational lower-bound fold, UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactUniformFiniteNet}^{\uparrow}}$, seed)

Scope closed: Definition 4760.1 and Definition 4760.2 seed the finite ProbeBundle object promised by compact-uniform-continuity.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactUniformFiniteNet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim selected subcovers, selected Lebesgue numbers, sequential compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite ProbeBundle exposure, center coverage, rational radius readback, lower-bound fold, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformFiniteNetUp.

Chapter 4761

A Concrete Naming Certificate for RegularCauchyLatticeOperations$^{\uparrow}$

Following Bishop and Bridges, the RegularCauchyLatticeOperations$^{\uparrow}$ packet records the finite constructive lattice-operation surface for regular Cauchy real names. It reads the regular rational route of chapter 301, the terminal real-name seal of chapter 38, the dyadic arithmetic surface of chapter 291, the lower-member packet of chapter 1832, and the upper-member packet of chapter 1833. The certificate gives downstream Real$^{\uparrow}$ consumers one finite min/max interface without importing trichotomy, quotient real equality, selected limits, countable choice, host order completeness, or ambient Real$^{\uparrow}$ completeness.

Definition 4761.1 (Regular Cauchy lattice operations carrier)**.** *A* RegularCauchyLatticeOperations$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, Y, T, D, M, A, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two accepted* Real$^{\uparrow}$ *rows presented by regular Cauchy names, exposing only their finite* RegSeqRat$^{\uparrow}$ *readbacks and terminal real seals.*
2. *T is the shared tolerance row used to align the lower-member and upper-member requests.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *ledger for the displayed comparison scale, branch budgets, and readback arithmetic consumed by both operation rows.*
4. *M is the* RegularCauchyMinimum$^{\uparrow}$ *lower-member row.*
5. *A is the* RegularCauchyMaximum$^{\uparrow}$ *upper-member row.*
6. *R is the paired regular rational readback row for the two operation outputs.*
7. *E is the paired* Real$^{\uparrow}$ *seal row, reached only after M, A, R have been displayed.*
8. *H records componentwise* hsame *transport for the two input names, tolerance, dyadic arithmetic, minimum row, maximum row, readback, seal, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from a lattice-operation request through $X, Y, T, D, M, A, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* RegularCauchyLatticeOperations$^{\uparrow}$*,* RegularCauchyMinimum$^{\uparrow}$*,* RegularCauchyMaximu RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, T, D, M, A, R, E, H, C, P, N$. The carrier has no coordinate for trichotomy, quotient real equality, host order completeness, selected limits, countable choice, a host lattice structure, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.RegularCauchyLatticeOperationsUp.RegularCauchyLatticeOperationsTasteGate`
`single carrier alignment`

Theorem 4761.2 (Regular Cauchy lattice operations NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyLatticeOperations}^{\uparrow}$ *carrier*

$$L = (X, Y, T, D, M, A, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two regular Cauchy real rows, shared tolerance row, dyadic arithmetic ledger, minimum row, maximum row, paired readback, paired seal, transport, replay, provenance, and local name;*
2. *shared-scale exposure, requiring T and D to be displayed before either M or A may be consumed;*
3. *lower-member routing, requiring the minimum output to be read through the* $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *row M;*
4. *upper-member routing, requiring the maximum output to be read through the* $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *row A;*
5. *readback and seal ordering, requiring R to expose the paired regular rational outputs before E exposes the paired* $\mathsf{Real}^{\uparrow}$ *seals;*
6. *classifier stability, requiring componentwise* hsame *transport of $X, Y, T, D, M, A, R, E, C, P, N$ to preserve the accepted operation route;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no trichotomy, quotient real equality, host order completeness, selected limit, countable choice, host lattice structure, Lean verification, or bridge credential.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 5727.1. Its displayed rows are exactly the two regular Cauchy real inputs, the shared tolerance row, the dyadic ledger, the two operation rows, the paired readback and seal rows, and the structural rows.

Shared-scale exposure follows because M and A have no independent tolerance coordinate inside this packet. Both operation rows read the same T, D surface before any output row can be consumed.

The lower-member and upper-member obligations are inherited as named rows, not as host operations. The packet can read the lower member only through M and the upper member only through A.

Readback and seal ordering is forced by R, E. The real-facing consumer first receives the paired regular rational readback and only then the paired $\mathsf{Real}^{\uparrow}$ seal. Transport, replay, provenance, and local naming are exhausted by H, C, P, N, so no excluded host or quotient object is available. □

Theorem 4761.3 (Regular Cauchy lattice operations min-max readback)**.** *Let* $L = (X, Y, T, D, M, A, R, E, H, C, P$ *be an accepted* $\mathsf{RegularCauchyLatticeOperations}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the lattice-operation output factors through the finite route*

$$X, Y, T, D \longmapsto M, A \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the packet exports the lower and upper regular Cauchy operation outputs only as paired $\mathsf{RegularCauchyMinimum}^{\uparrow}$ *and* $\mathsf{RegularCauchyMaximum}^{\uparrow}$ *readbacks over the same dyadic scale. It exports no trichotomy, quotient real equality, host order completeness, selected limit, countable choice, or host lattice operation.*

Proof. Start with a real-facing read of the carrier. The only input rows are X, Y, and the only scale rows are T, D, so the consumer must read those coordinates before either operation row is available.

The operation rows are M and A. By Definition 5727.1, M names the lower-member route and A names the upper-member route; neither row carries a separate host order principle.

After the operation rows are displayed, the readback row R exposes the paired regular rational outputs and the seal row E exposes the paired $\mathsf{Real}^{\uparrow}$ boundary. The structural rows H, C, P, N preserve and name this route without adding any coordinate beyond it. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5727.1, Definition 5727.2, and Definition 5727.3 seed a finite min/max operation route for two regular Cauchy real names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeOperations}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, host order completeness, selected limits, countable choice, host lattice operations, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-scale exposure, lower-member routing, upper-member routing, readback ordering, classifier stability, and non-escape proofs for BEDC.Derived.RegularCauchyLatticeOperationsUp.

Constructive story: A $\mathsf{RegularCauchyLatticeOperations}^{\uparrow}$ packet is generated from two regular Cauchy Real rows, a shared dyadic tolerance surface, RegularCauchyMinimum and RegularCauchyMaximum rows, paired regular rational readback, a paired RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4762

A Concrete Naming Certificate for $\mathsf{CauchyModulusBridge}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyModulusBridge}^{\uparrow}$ packet records the finite handoff by which a displayed Cauchy-criterion request becomes an explicit modulus schedule before any regular-rational readback or real-name seal is consumed. It sits after the effective criterion packet of chapter 3695, the modulus schedule surface of chapter 292, the regular rational readback of chapter 301, the finite stream-window interface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the L10 bridge from criterion-facing reads to explicit schedules as finite NameCert data; it is not quotient stream equality, a selected host limit, countable choice, trichotomy, host sequence equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4762.1 (Cauchy modulus bridge carrier)**.** *A* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, M, E, S, D, R, L, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{CauchyCriterion}^{\uparrow}$ *request row naming the late-pair comparison surface to be served by the bridge.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row assigning the displayed precision request to a finite tail threshold.*
3. *E is the* $\mathsf{EffectiveCauchyCriterion}^{\uparrow}$ *row tying the same criterion request and modulus schedule to a finite effective handoff.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the criterion request and scheduled by the modulus row.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the radius, tail comparison, and endpoint budget used by the request.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row available only after Q, M, E, S, D have been displayed.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the criterion, modulus, effective handoff, window, tolerance, and regular-rational rows have been read.*
8. *H records componentwise* hsame *transport for the criterion, modulus, effective handoff, stream-window, dyadic, regular-rational, real-seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a Cauchy-criterion request through $Q, M, E, S, D, R, L, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusBridge}^{\uparrow}$, $\mathsf{CauchyCriterion}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, EffectiveCauchyCriterio StreamName$^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, M, E, S, D, R, L, H, C, P, N$. It has no coordinate for quotient streams, selected limits, host sequence equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusBridgeUp.CauchyModulusBridgeTasteGate single carrier alignment`

Theorem 4762.2 (Cauchy modulus bridge NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *carrier $B = (Q, M, E, S, D, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed criterion row Q, modulus schedule M, effective criterion handoff E, finite stream window S, dyadic tolerance ledger D, regular-rational readback R, terminal real seal L, componentwise transport H, displayed replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 5728.1. The analytic rows visible to a consumer are exactly the criterion request Q, modulus schedule M, effective handoff E, finite window S, dyadic tolerance ledger D, regular-rational readback R, and terminal real seal L.

The bridge obligation is the ordering of those rows. A Cauchy-criterion request first exposes Q and then reads the displayed threshold in M through the effective handoff E; only after that handoff are the stream window S and dyadic tolerance ledger D available for regular readback.

The downstream rows are forced by the same carrier projection. The row R is the $\mathsf{RegSeqRat}^{\uparrow}$ readback obtained from the displayed window and tolerance data, and L is the $\mathsf{Real}^{\uparrow}$ seal reached only through that readback.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no excluded coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 4762.3 (Cauchy modulus bridge effective-criterion handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CauchyCriterion}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{EffectiveCauchyCriterion}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Re}$$

The handoff exposes only the displayed criterion request, explicit modulus schedule, effective criterion row, finite stream window, dyadic tolerance ledger, regular rational readback, terminal real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. It exports no quotient stream equality, selected host limit, hidden modulus oracle, countable-choice schedule, trichotomy split, host sequence equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with Definition 5728.2. It places every consumer read behind the criterion row, the explicit modulus row, and the effective criterion handoff.

Next open the finite observation route. The stream-window row S and dyadic tolerance row D are downstream of Q, M, E, so the regular-rational row R is a displayed readback from the same request rather than a detached sequence or selected limit.

The terminal seal is last. The $\mathsf{Real}^{\uparrow}$ row L is consumed only after R has been displayed, while H, C, P, N preserve the same dependency order under transport, replay, provenance, and local naming.

Thus any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer sees exactly the route stated in the theorem and cannot bypass it through a hidden analytic object. □

Theorem 4762.4 (Cauchy modulus bridge choice-free schedule)**.** *Let*

$$B = (Q, M, E, S, D, R, L, H, C, P, N) \quad \textit{and} \quad B' = (Q', M', E', S', D', R', L', H', C', P', N')$$

be accepted $\mathsf{CauchyModulusBridge}^{\uparrow}$ *carriers. If they agree componentwise on the displayed rows* $Q, M, E, S, D, R, L, H, C, P, N$*, then they determine the same modulus schedule and the same* $\mathsf{Real}^{\uparrow}$ *seal. No consumer of either packet can insert a countable-choice schedule, hidden modulus oracle, selected host limit, or extra selector coordinate between the criterion request and the terminal seal.*

Proof. Project both carriers through Definition 5728.1. The hypothesis identifies every displayed coordinate of B and B', so the criterion requests, explicit modulus rows, effective handoff rows, stream windows, dyadic ledgers, regular readbacks, Real seals, transport, replay, provenance, and local names are the same.

Use Definition 5728.2 to read the NameCert surface. Its obligation list has no row outside $Q, M, E, S, D, R, L, H, C, P, N$, so there is no remaining coordinate in which a second schedule or selector could differ.

Apply Definition 5728.3. The consumer order is forced as Q then M then E then S then D then R then L, and the terminal $\mathsf{Real}^{\uparrow}$ seal is downstream from the same regular-rational readback.

Thus the two accepted packets determine the same choice-free schedule and the same Real seal. The excluded choice and selector objects cannot be inserted because the carrier and its NameCert obligations expose no such coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyModulusBridge}^{\uparrow}$ packet is generated from a CauchyCriterion request row, a CauchyModulus schedule, an effective Cauchy criterion handoff, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5728.1, Definition 5728.2, Definition 5728.3, and Definition 5728.4 seed the finite bridge from Cauchy-criterion requests to explicit modulus schedules before RegSeqRat and Real consumers read the route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusBridge}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.CauchyModulusBridgeUp.CauchyModulusBridgeTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, hidden modulus oracles, countable choice, trichotomy, host sequence equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, criterion-to-modulus exactness, effective handoff ordering, StreamName and DyadicRatCore readback, RegSeqRat handoff, RealUp seal confinement, transport stability, continuation replay, and provenance nonescape for BEDC.Derived.CauchyModulusBridgeUp.

Chapter 4763

A Concrete Naming Certificate for $\mathsf{MyhillNerode}^{\uparrow}$

Following Myhill and Nerode, the $\mathsf{MyhillNerode}^{\uparrow}$ packet records the finite right-congruence classifier behind regular languages and minimal finite automata as displayed BEDC data. It consumes accepted-word rows from chapter 351, presentation rows from chapter 2364, finite carrier rows from chapter 112, and word-spine rows from chapter 36. The packet does not import an external quotient of all languages; it names the finite distinguishability ledger that a minimization consumer can audit.

Definition 4763.1 (Myhill–Nerode carrier)**.** *A* $\mathsf{MyhillNerode}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (\Sigma, W, L, E, C, D, Q, \delta, q_0, F, \mu, H, R, P, N)$$

with the following displayed rows:

1. Σ *is the finite alphabet row, read through* $\mathsf{FinSet}^{\uparrow}$*.*
2. W *is the finite word-window row, read through* $\mathsf{List}^{\uparrow}$ *over* Σ*.*
3. L *is the accepted-word observation ledger supplied by a* $\mathsf{RegularLanguage}^{\uparrow}$ *packet.*
4. E *is the finite right-congruence table on the displayed word window.*
5. C *is the context-extension row recording that suffix extension by displayed words preserves the table.*
6. D *is the distinguishability row naming a displayed suffix witness whenever two table rows are separated.*
7. Q *is the finite state row whose states are the displayed equivalence classes of* E*.*
8. δ *is the transition row induced by appending one alphabet symbol to a class representative.*
9. q_0 *is the start class of the empty word.*
10. F *is the accepting-class row, determined by membership in the accepted-word ledger.*
11. μ *is the minimization handoff row from the right-congruence table to the finite automaton presentation.*
12. H *stores componentwise* hsame *transport for alphabet, word-window, language, congruence, suffix, state, transition, accepting, and minimization rows.*

13. *R stores* Cont *replay from a regular-language query through the displayed right-congruence table.*
14. *P stores* Pkg *provenance over* $\mathsf{RegularLanguage}^{\uparrow}$, $\mathsf{FiniteAutomaton}^{\uparrow}$, $\mathsf{FinSet}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
15. *N is the local* $\mathsf{NameCert}_{\mathsf{MyhillNerode}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $\Sigma, W, L, E, C, D, Q, \delta, q_0, F, \mu, H, R, P, N$. It has no coordinate for an infinite language quotient, a nondeterministic presentation, a regular-expression conversion, or a proof that an arbitrary external automaton has already been minimized.

Lean4 ✓ `BEDC.Derived.MyhillNerodeUp.MyhillNerodeTasteGate single carrier alignment`

Theorem 4763.2 (Myhill–Nerode NameCert obligations)**.** *For every accepted* $\mathsf{MyhillNerode}^{\uparrow}$ *carrier*

$$M = (\Sigma, W, L, E, C, D, Q, \delta, q_0, F, \mu, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MyhillNerode}^{\uparrow}}$ *surface consists exactly of finite alphabet exposure, word-window exposure, accepted-word observation, right-congruence tabulation, suffix-stability replay, distinguishability witnesses, quotient-state construction, induced transition replay, start-class selection, accepting-class selection, minimization handoff, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Project the carrier of Definition 5729.1. The rows Σ, W, L, E, C, D expose the finite observation table and the suffix-stability checks used to read right congruence.

The rows Q, δ, q_0, F then repackage the table as a deterministic finite automaton presentation. Since Q is built from the displayed classes of E, the transition row is read by extending a representative by one displayed alphabet symbol and returning to the corresponding class.

The rows μ, H, R, P, N keep the minimization handoff, transport, replay, provenance, and local name attached to the same packet. No omitted coordinate can supply an external quotient, nondeterministic branch, or regular-expression conversion, so the listed rows exhaust the NameCert obligations. □

Theorem 4763.3 (Myhill–Nerode DFA minimization handoff)**.** *Every* $\mathsf{RegularLanguage}^{\uparrow}$ *consumer that claims a minimal deterministic finite automaton through a* $\mathsf{MyhillNerode}^{\uparrow}$ *packet must expose the finite right-congruence row E, the suffix-stability row C, the distinguishability row D, the quotient-state row Q, the induced transition row δ, the accepting-class row F, and the minimization handoff row μ. The handoff may feed a* $\mathsf{FiniteAutomaton}^{\uparrow}$ *presentation with those rows, but it does not identify arbitrary automaton presentations, choose a nondeterministic branch, or translate the packet into a regular-expression proof.*

Proof. Begin with the obligation theorem Definition 5729.2. It forces every minimization read through the displayed right-congruence table, suffix-stability replay, and distinguishability witnesses before any quotient-state row is consumed.

The quotient construction then uses the finite rows Q, δ, q_0, F to build a deterministic presentation. This presentation is compatible with the finite automaton carrier of chapter 2364 because it exposes finite states, a finite alphabet, a transition table, a start state, accepting states, and replay rows.

The minimization handoff remains bounded by the displayed table. It proves only the certificate route from regular-language observations to the minimal finite presentation named by the packet; stronger equivalence claims are absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{MyhillNerode}^{\uparrow}}$.

Constructive story: A $\mathsf{MyhillNerode}^{\uparrow}$ packet is generated from a finite alphabet row, word-window row, accepted-word observation ledger, right-congruence table, suffix-stability row, distinguishability witnesses, quotient-state row, induced transition row, start class, accepting classes, minimization handoff, componentwise transport, continuation replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MyhillNerode}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5729.1, Definition 5729.2, and Definition 5729.3 seed the finite right-congruence certificate and its deterministic-minimization handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MyhillNerode}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary automaton equivalence, nondeterministic minimization, regular-expression conversion, host-language quotients, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, right-congruence stability, distinguishability coverage, quotient-state exactness, induced-transition replay, minimization handoff, TasteGate coverage, transport, replay, provenance, and local naming for BEDC.Derived.MyhillNerodeUp.

Chapter 4764

A Concrete Naming Certificate for $\mathsf{VariationSeminorm}^{\uparrow}$

Following Bishop–Bridges bounded-variation analysis and the Bourbaki treatment of seminormed structures, the $\mathsf{VariationSeminorm}^{\uparrow}$ packet records the finite seminorm-budget surface attached to displayed partition variation data. It sits between the bounded-variation carrier of chapter 398, the bounded-variation real-function row of chapter 3654, the variation-norm consumer of chapter 3804, the Jordan route of chapter 2069, the total-variation function surface of chapter 2257, the regular rational readback of chapter 301, and the terminal real endpoint seal of chapter 38. The packet names displayed partition-variation budgets and seminorm comparison rows without selecting a host supremum over all partitions, a quotient class of functions, or a completed bounded-variation space.

Definition 4764.1 (VariationSeminorm carrier)**.** *A* $\mathsf{VariationSeminorm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, F, J, T, R, Q, A, L, H, C, P, N)$$

with the following displayed rows:

1. *B is the source* $\mathsf{BoundedVariation}^{\uparrow}$ *packet, including its displayed partition ledger, endpoint rows, adjacent-edge observations, finite variation sum, and common-refinement data.*
2. *F is the* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *read tying the partition ledger to a displayed real-valued function row over the inspected interval.*
3. *J is the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *handoff row, exposing only the finite positive- and negative-variation ledgers available from the same partition data.*
4. *T is the* $\mathsf{TotalVariationFunction}^{\uparrow}$ *observation row for the displayed partition windows inspected by the packet.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal for all scalar values and variation budgets that the packet compares.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used when scalar budgets and endpoint values are inspected through regular rational names.*
7. *A is the displayed variation-seminorm row. It records the null-row witness for constant differences, finite additivity over displayed concatenations, scalar budget transport, and monotone comparison of partition refinements.*

8. *L is the seminorm ledger, listing the partition windows, budget rows, finite variation sums, constant-row witnesses, and refinement comparisons used by A.*
9. *H records componentwise* hsame *transport for the bounded-variation source, real-function row, Jordan route, total-variation observation, Real seal, regular-name readback, seminorm row, ledger, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a seminorm-budget request through $B, F, J, T, R, Q, A, L, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{VariationSeminorm}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, $\mathsf{VariationNorm}^{\uparrow}$, $\mathsf{JordanVariationDecomposition}^{\uparrow}$, $\mathsf{TotalVariationFunction}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{VariationSeminorm}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed source packet, real-function row, Jordan route, total-variation observation, Real and RegSeqRat scalar reads, seminorm ledger, componentwise transport, replay, provenance, and local name. It has no coordinate for a host supremum, quotient equality of functions, a completed seminormed space, a measure-theoretic variation object, or bridge checking.

Lean4 ✓ `BEDC.Derived.VariationSeminormUp.VariationSeminormTasteGate single carrier alignment`

Theorem 4764.2 (VariationSeminorm NameCert obligations)**.** *For every accepted* $\mathsf{VariationSeminorm}^{\uparrow}$ *carrier $S = (B, F, J, T, R, Q, A, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{VariationSeminorm}^{\uparrow}}$ *surface consists exactly of bounded-variation source admission, bounded-variation real-function readback, Jordan-route availability, total-variation observation, Real endpoint sealing, RegSeqRat scalar readback, displayed seminorm-row formation, ledger exactness, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local naming through the displayed rows.*

Proof. Project the finite carrier of Definition 5730.1. The analytic data available to the packet are the bounded-variation source B, the real-function row F, the Jordan handoff J, the total-variation observation T, the Real seal R, and the regular-name readback Q.

The seminorm row A is then formed from the displayed budget comparisons in those rows. Its null-row, finite-additivity, scalar-transport, and refinement-monotonicity clauses are recorded in the ledger L, so each seminorm request is tied to inspected partition windows rather than to a hidden family of all partitions.

Finally H, C, P, N transport, replay, source, and name exactly the same finite surface. Since the carrier has no host-supremum, quotient-function, completed-space, variation-measure, or bridge coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 4764.3 (VariationSeminorm refinement budget route)**.** *Every accepted* $\mathsf{VariationSeminorm}^{\uparrow}$ *packet exports the finite route*

$$\mathsf{BoundedVariation}^{\uparrow}, \mathsf{BoundedVariationRealFunction}^{\uparrow} \longrightarrow \mathsf{JordanVariationDecomposition}^{\uparrow}, \mathsf{TotalVariationFunction}^{\uparrow} \longrightarrow$$

to bounded-variation completion and regulated-integration consumers. The route transports displayed partition-variation budgets and seminorm comparison rows, but it exports no host supremum over all partitions, quotient equality of functions, selected Jordan decomposition, completed bounded-variation Banach space, or bridge data.

Proof. Begin with an accepted packet $S = (B, F, J, T, R, Q, A, L, H, C, P, N)$. A consumer first reads the bounded-variation source and real-function rows, so every endpoint value and edge variation remains tied to the finite partition windows in B and F.

The Jordan and total-variation rows are then read only as displayed handoffs. They expose finite positive- and negative-variation ledgers and total-variation observations attached to the same partition windows.

The scalar budget route is sealed by Q and R. The seminorm ledger L records the null, additivity, scalar-transport, and refinement-comparison rows used by A, while H, C, P, N transport, replay, source, and name the packet. No remaining coordinate can supply the excluded host objects, so the exported route is exactly the displayed finite seminorm-budget route. □

Falsifiable prediction: Every accepted $\mathsf{VariationSeminorm}^{\uparrow}$ read factors through a displayed $\mathsf{BoundedVariation}^{\uparrow}$ source, a $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ row, $\mathsf{JordanVariationDecomposition}^{\uparrow}$ and $\mathsf{TotalVariationFunction}^{\uparrow}$ handoff rows, $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ scalar reads, and the local seminorm ledger, transport, replay, provenance, and naming rows.

Independence witness: boundedvariation, bounded-variation-real-function, variation-norm, jordan-variation-decomposition, total-variation-function, regseqrat, and real: no listed sibling is bijective to $\mathsf{VariationSeminorm}^{\uparrow}$ because this packet stores the seminorm-specific null, finite-additivity, scalar-transport, refinement-budget, ledger, replay, provenance, and local naming rows together as one finite surface.

Closure status for $\mathsf{NameCert}_{\mathsf{VariationSeminorm}^{\uparrow}}$.

Constructive story: A $\mathsf{VariationSeminorm}^{\uparrow}$ packet is generated from a BoundedVariation source, a BoundedVariationRealFunction read, JordanVariationDecomposition and TotalVariationFunction handoff rows, RegSeqRat and Real scalar reads, a displayed seminorm row, a finite budget ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VariationSeminorm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5730.1, Definition 5730.2, and Definition 5730.3 seed the finite variation-seminorm carrier, obligation surface, and refinement-budget route over displayed bounded-variation and scalar-readback rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VariationSeminorm}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.VariationSeminormUp.VariationSeminormTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host suprema over all partitions, quotient equality of functions, selected Jordan decompositions, completed bounded-variation Banach spaces, variation measures, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, real-function readback, Jordan and total-variation handoff availability, Real and RegSeqRat scalar exactness, seminorm ledger exactness, classifier transport, replay, provenance, local naming, and nonescape for BEDC.Derived.VariationSeminormUp.

Chapter 4765

A Concrete Naming Certificate for $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ packet records the separated completion boundary needed by the L10 Real and Completion route as finite BEDC data. It sits after the separation predicate of chapter 1925, the separated-completion carrier of chapter 1612, the metric completion route of chapter 1506, the finite stream interface of chapter 126, the dyadic tolerance core of chapter 291, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the envelope through displayed rows only; it does not quotient filters, select representatives, identify host equalities, invoke countable choice, or import ambient completeness.

Definition 4765.1 (Hausdorff completion envelope carrier)**.** *A* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier is a finite packet*

$$E = (H, S, M, W, D, R, L, T, K, P, N)$$

where H *is the displayed* $\mathsf{HausdorffSpace}^{\uparrow}$ *separation row,* S *is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *boundary row,* M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row,* W *is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* L *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal,* T *is componentwise* $\mathsf{BHist/hsame}$ *transport,* K *is displayed* Cont *replay,* P *is* Pkg *provenance, and* N *is the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$ *row. A consumer of* E *receives a separated completion boundary only through these coordinates.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeTasteGate single carrier alignment`

Theorem 4765.2 (Hausdorff completion envelope obligations)**.** *Every accepted* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$ *read must expose the carrier of Definition 5789.1 in the order*

$$H, S, M, W, D, R, L, T, K, P, N.$$

The separation row H *and separated-completion row* S *are available before metric completion, stream observation, dyadic tolerance, regular readback, and real-seal rows are consumed; the transport, replay, provenance, and naming rows preserve the same displayed packet.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeNameCertObligations`

Proof. Project the carrier of Definition 5789.1. The packet has no completion-facing coordinates except $H, S, M, W, D, R, L, T, K, P, N$.

The Hausdorff and separated-completion rows are the first boundary data in the packet. Thus a consumer cannot inspect the metric completion route, finite stream windows, dyadic tolerances, regular readback, or terminal real seal without first reading the displayed separation surface.

Finally, the structural rows T, K, P, N only transport, replay, source, and name the same finite packet. They do not create quotient filters, selected representatives, host equality, choice-selected routes, or ambient completeness. □

Theorem 4765.3 (Hausdorff completion separated metric route)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of a* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier factors through the separated route*

$$H, S \longmapsto M \longmapsto W, D, R, L.$$

The route records a separated metric-completion boundary for the L10 Real and Completion interface, not a quotient completion, a host equality theorem, a choice-selected representative, or an ambient completeness principle.

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeCarrier separated metric route`

Proof. Start from Definition 5789.2. It places the Hausdorff row H and separated-completion row S before the metric completion row M and before the stream, dyadic, regular-rational, and real-seal rows.

Read the metric completion route through M. Since M is downstream of H, S, every completion-facing use of M carries the displayed separated boundary with it.

The final Real-facing read is the finite route W, D, R, L. Because these rows are still coordinates of the same carrier, the route cannot be replaced by quotient representatives, host equality, countable choice, or ambient completeness. □

Theorem 4765.4 (Hausdorff completion envelope sibling route)**.** *A* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *consumer may hand its separated boundary to* $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ *only through the displayed* $\mathsf{HausdorffSpace}^{\uparrow}$*,* $\mathsf{SeparatedCompletion}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows of*

$$E = (H, S, M, W, D, R, L, T, K, P, N).$$

The handoff contains no quotient-filter coordinate, representative-selection coordinate, host-equality coordinate, or ambient-completeness coordinate.

Proof. Apply Definition 5789.2. It places the Hausdorff row H, separated-completion row S, metric-completion row M, stream row W, dyadic row D, regular-rational row R, and terminal Real row L inside one displayed packet.

Next use Definition 5789.3. The separated boundary H, S is already carried through the metric and Real-facing route M, W, D, R, L.

The sibling $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ consumer therefore reads the same separated boundary as its input surface rather than receiving a separate primitive. Since the carrier only has the displayed rows and the structural rows T, K, P, N, quotient filters, selected representatives, host equality, and ambient completeness remain outside the handoff. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeCarrier sibling route`

Theorem 4765.5 (Hausdorff completion envelope Cauchy-net consumer link)**.** *Every* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier must read the same* $\mathsf{HausdorffSpace}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before its directed-net completion route is consumed. The downstream sibling is chapter 3794, and the handoff is the displayed route*

$$H, S, M, W, D, R, L \longmapsto \mathsf{CauchyNetCompletion}^{\uparrow}.$$

It exports no quotient net, selected representative, host equality, countable-choice schedule, or ambient completeness coordinate.

Proof. Project the carrier $E = (H, S, M, W, D, R, L, T, K, P, N)$ of Definition 5789.1. The only completion-facing rows available to a consumer are the Hausdorff row H, separated-completion row S, metric-completion route M, finite stream row W, dyadic tolerance row D, regular readback row R, and terminal Real row L.

Apply Definition 5789.2. It places H, S, M, W, D, R, L inside one displayed packet before the structural rows T, K, P, N are used for transport, replay, provenance, and local naming.

Next use Definition 5789.3. The separated boundary H, S is already carried through the metric and Real-facing route M, W, D, R, L.

Therefore a downstream $\mathsf{CauchyNetCompletion}^{\uparrow}$ read can only consume the envelope through the same separated metric route before its directed-net completion surface is inspected. Since the packet has no quotient-net, selected-representative, host-equality, countable-choice, or ambient-completeness row, none of those objects can enter the handoff. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeForwardLink`

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5789.1, Definition 5789.2, and Definition 5789.3 name the separated completion envelope surface for the L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, host equality, choice-selected representatives, or ambient completeness.

Upgrade path: Obligation closure requires the carrier route to be tied to the sibling completion obligation theorems and then exposed as a public chapter surface.

Constructive story: A $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ packet is generated from Hausdorff separation, separated-completion boundary, metric-completion route, finite stream windows, dyadic tolerance, regular-rational readback, Real seal, transport, replay, provenance, and local NameCert rows.

Chapter 4766

A Concrete Naming Certificate for $\mathsf{BoundedLinearFunctional}^{\uparrow}$

Following Banach and Bourbaki functional analysis, the $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet records the scalar-valued bounded-linear-operator row that duality and weak-star consumers inspect before any host dual space is available. It sits over the linear-map route of chapter 48, the bounded-linear-operator surface of chapter 1644, the scalar-bound neighbour chapter 3603, the Banach-dual row of chapter 2265, the finite weak-star window of chapter 3420, the scalar endpoint seal of chapter 38, and the normed source surface of chapter 1950. The chapter names only displayed scalar-functional data: source rows, linearity rows, scalar target readback, norm-bound evidence, transport, replay, provenance, and local naming.

Definition 4766.1 (Bounded linear functional carrier)**.** *For a displayed* $\mathsf{NormedSpace}^{\uparrow}$ *source row* E *over the scalar endpoint surface of* $\mathsf{Real}^{\uparrow}$*, a* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E)$ *carrier is a finite* BHist *packet*

$$\Lambda = (E, L, T, K, O, H, C, P, N)$$

with the following displayed rows:

1. *E is the source normed-space row, including its carrier endpoints, scalar action, additive row, norm row, and classifier.*
2. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row from E to the scalar* $\mathsf{Real}^{\uparrow}$ *target.*
3. *T is the scalar-valued* $\mathsf{BoundedLinearOperator}^{\uparrow}(E, \mathsf{Real}^{\uparrow})$ *row carrying the same endpoint action as L.*
4. *K is the* $\mathsf{Real}^{\uparrow}$ *nonnegative bound endpoint for the functional.*
5. *O is the* $\mathsf{OperatorNorm}^{\uparrow}$ *handoff row exposing where the bound K is used.*
6. *H records componentwise* hsame *transport for the source, linear-map row, bounded-operator row, scalar bound, operator-norm handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a scalar-functional request through E, L, T, K, O, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedLinearFunctional}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{BanachDual}^{\uparrow}$, $\mathsf{BanachAlaoglu}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed source classifier, scalar endpoint transport, bounded-operator transport, bound transport, norm-bound ledger transport, replay, provenance, and local naming rows. It has no coordinate for a host dual space, quotient equality of functions, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.BoundedLinearFunctionalUp.BoundedLinearFunctionalTasteGate single carrier alignment`

Theorem 4766.2 (Bounded linear functional NameCert obligations)**.** *For every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *carrier* $\Lambda = (E, L, T, K, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *surface consists exactly of source normed-space admission, linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm ledger exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from host dual objects. A consumer may inspect* $E, L, T, K, O, H, C, P, N$*, but it receives no ambient function space, quotient operator equality, selected representative, Hahn–Banach witness, unrestricted weak-star compactness theorem, or bridge data.*

Proof. Project the carrier rows. The analytic coordinates are exactly the source normed-space row E, the linear-map row L, the scalar-valued bounded-operator row T, the RealUp bound endpoint K, and the operator-norm handoff O.

The linearity obligation is read through $\mathsf{LinMap}^{\uparrow}$, while boundedness is read through $\mathsf{BoundedLinearOperator}^{\uparrow}(E,$ The scalar target is already the displayed $\mathsf{Real}^{\uparrow}$ endpoint surface, so the functional row never becomes a host-level function.

The bound exactness is the shared route through K and O. The operator-norm handoff records where the scalar bound is used, and componentwise hsame transport moves the source, action, bound, ledger, replay, provenance, and local naming rows together.

No remaining coordinate can manufacture a dual-space quotient, selected representative, Hahn–Banach witness, unrestricted compactness theorem, or bridge check. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 4766.3 (Bounded linear functional operator-norm handoff)**.** *Every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E$ *packet exports the finite route*

$$\mathsf{LinMap}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{OperatorNorm}^{\uparrow} \longmapsto \mathsf{BoundedLinearFunctional}^{\uparrow}$$

to functional-analysis consumers. The route first exposes the carried scalar-valued linear action, then the bounded-operator row, then the RealUp bound endpoint and operator-norm ledger; it does not expose a host supremum, quotient equality of functionals, selected norm-attaining vector, or hidden Banach completeness.

Proof. Begin with an accepted packet $\Lambda = (E, L, T, K, O, H, C, P, N)$. The read of L supplies only the displayed linear-map action from the source row to the scalar target.

The read of T then packages the same action as a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row. Its target row is $\mathsf{Real}^{\uparrow}$, and its bound endpoint is the displayed scalar K.

Finally the operator-norm handoff O records the norm-bound ledger that downstream consumers may inspect. Because no host norm function, quotient functional equality, selected vector, or hidden completion row is present, the exported handoff is exactly the displayed scalar-bound route. □

Theorem 4766.4 (Bounded linear functional dual-row nonescape)**.** *Any read of a* $\mathsf{BanachDual}^{\uparrow}$ *or* $\mathsf{BanachAlaoglu}^{\uparrow}$ *consumer that uses a* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *row factors through the same source normed-space row, scalar-valued bounded-operator row, RealUp bound endpoint, operator-norm handoff, componentwise transport, replay, provenance, and local naming rows of Definition 5790.1. The duality consumer receives a finite scalar-functional row, not a host dual space, a quotient function class, an unrestricted weak-star compactness theorem, or a selected cluster point.*

Proof. Read the duality consumer first. A $\mathsf{BanachDual}^{\uparrow}$ request needs a scalar-functional row over a displayed source, while a $\mathsf{BanachAlaoglu}^{\uparrow}$ request needs a finite family of such scalar-functional observations.

In either case the only scalar-functional packet available here is Λ. Its source row, bounded-operator row, bound endpoint, operator-norm handoff, and structural rows are projected in the order displayed by Definition 5790.1.

The downstream dual chapters may reuse those rows, but they cannot add coordinates that are absent from the packet. Thus quotient dual objects, host function classes, unrestricted weak-star compactness, selected cluster points, and bridge checks remain outside the read. □

Falsifiable prediction: Every accepted $\mathsf{BoundedLinearFunctional}^{\uparrow}$ scalar-functional read factors through a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ action row, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, and the local hsame, Cont, Pkg, and NameCert rows.

Independence witness: linearmap, boundedlinearoperator, operatornorm, banachdual, banachalaoglu, real, and normedspace: no listed sibling is bijective to $\mathsf{BoundedLinearFunctional}^{\uparrow}$ because this packet stores the scalar target restriction, the dual-facing provenance row, the operator-norm handoff, transport, replay, and local naming together as one finite scalar-functional surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet is generated from a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ scalar action, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5790.1, Definition 5790.2, Definition 5790.3, and Definition 5790.4 seed the scalar-functional row consumed by BanachDualUp and BanachAlaogluUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host dual spaces, quotient equality of functionals, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, scalar linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm handoff exactness, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.BoundedLinearFunctionalUp.

Chapter 4767

A Concrete Naming Certificate for $\mathsf{CompletionModulusCategory}^{\uparrow}$

Following Bishop and Bridges on constructive completion and the functorial treatment of completions, the $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet records the finite category surface whose arrows preserve displayed completion moduli. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the completion functor of chapter 426, and the Cauchy completion functor of chapter 423. The packet names modulus-preserving completion morphisms as BEDC rows; it does not export quotient completions, selected representatives, host continuous maps, countable choice, or ambient completeness.

Definition 4767.1 (CompletionModulusCategory carrier)**.** *A* $\mathsf{CompletionModulusCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (O, A, S, R, D, E, F, H, C, P, N)$$

with the following displayed rows:

1. *O is the object ledger. Each object row records a completion-facing source, its displayed Cauchy-modulus discipline, and the local completion target read through the surrounding completion chapters.*
2. *A is the arrow ledger. Each arrow row records a finite morphism request together with the modulus transformation that sends source tolerances to target tolerances.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the source and target names of an arrow.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after the stream windows have been displayed.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare source and target moduli.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row read only after S, R, D have supplied the displayed tolerance route.*
7. *F records identity and composition rows for the completion functoriality surface, with identity arrows preserving the same modulus and composite arrows composing the displayed modulus transformations.*
8. *H records componentwise* hsame *transport for object rows, arrow rows, stream windows, regular readback, dyadic tolerances, Real seals, functoriality rows, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from an arrow request through $O, A, S, R, D, E, F, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CompletionModulusCategory}^{\uparrow}$, $\mathsf{CompletionFunctor}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite category packet for modulus-preserving completion morphisms. It has no coordinate for quotient completion points, selected representatives, host functions, global choice schedules, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryTasteGate single carrier alignment`

Theorem 4767.2 (CompletionModulusCategory NameCert obligations)**.** *For every accepted* CompletionModulusCa *carrier $M = (O, A, S, R, D, E, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed object ledger, arrow ledger, stream windows, regular rational readback, dyadic tolerance ledger, Real seal, identity and composition rows, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface additionally requires each arrow row in A to expose its source modulus, target modulus, and modulus transformation before any $\mathsf{Real}^{\uparrow}$*-facing read is accepted; each identity row in F to preserve the displayed modulus without adding a choice coordinate; and each composition row in F to compose the two displayed modulus transformations before the downstream seal is visible.*

Proof. Project the accepted carrier. The packet contains only the rows $O, A, S, R, D, E, F, H, C, P, N$, so carrier admission and ledger exhaustion are componentwise.

An arrow-facing request first reads the object and arrow ledgers O, A. The source and target names are then inspected through the finite stream windows S, regular rational readback R, and dyadic tolerance ledger D.

The functoriality rows F are local to the same displayed moduli. Identity preserves the stored modulus transformation, and composition combines the two stored transformations before the terminal seal E can be read.

Finally H, C, P, N transport, replay, source, and name this same finite route. Since quotient completions, selected representatives, host functions, global choice schedules, and ambient completeness are not carrier coordinates, they cannot be exported by the local NameCert. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryNameCertObligations`

Theorem 4767.3 (CompletionModulusCategory modulus functoriality)**.** *Every completion-facing consumer of an accepted* $\mathsf{CompletionModulusCategory}^{\uparrow}$ *packet reads a modulus-preserving morphism through the finite route*

$$O, A, S, R, D, F, E, H, C, P, N.$$

Thus identity and composition of completion morphisms preserve the displayed modulus data before any $\mathsf{Real}^{\uparrow}$ *seal or completion-functor read is exposed. The route factors through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompletionFunctor}^{\uparrow}$, *and* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *rather than through quotient completion equality, selected representatives, host continuous maps, countable choice, or ambient completeness.*

Proof. Start with a completion-facing morphism request. The object ledger O fixes the source and target completion rows, and the arrow ledger A fixes the modulus transformation to be checked.

The readback rows S, R, D display the inspected stream windows, regular rational observations, and dyadic tolerance comparisons. These rows are the only route by which the requested modulus can face the terminal Real seal.

The functoriality row F then supplies the identity or composition clause. In the identity case the same displayed modulus is replayed. In the composition case the two displayed modulus transformations are composed as finite rows before the result is handed to E.

The structural rows H, C, P, N preserve and name the same route. Therefore every completion-functor consumer receives finite modulus preservation data and no excluded quotient, selection, host-map, choice, or ambient-completeness surface. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryModulusFunctoriality`

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}$.

Constructive story: A $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet is generated from completion object rows, modulus-preserving arrow rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, RealUp seals, identity and composition rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5791.1, Definition 5791.2, and Definition 5791.3 seed the finite category surface for modulus-preserving completion morphisms.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host continuous maps, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-preserving arrow exactness, identity and composition rows, tolerance readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompletionModulusCategoryUp.

Chapter 4768

A Concrete Naming Certificate for $\mathsf{MarkovTriggerDynamics}^{\uparrow}$

The $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet realizes the finite rank-trigger dynamics of Definition 9462.1541, Definition 9462.1542, and Definition 9462.1546 as BEDC NameCert data. It records the state, support-rank, transition-count, drift, trigger-time, classifier, continuation, provenance, and naming rows needed by a downstream finite-dynamics consumer. The packet is a finite BHist surface for trigger-time readback; it is not a stochastic process on an ambient probability space, not an infinite sample path, not a hidden field model, and not a host Markov-chain object.

Definition 4768.1 (MarkovTriggerDynamics carrier)**.** *A* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, K, A, D, G, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite state row. It records the consumed external-codon count m and the covered support rank r for the current trigger state.*
2. *K is the support-rank row. It records the finite support coordinates currently covered by the observed codon rows and the rank read from that support.*
3. *A is the transition-count row. It stores the finite count of rank-preserving and rank-increasing next draws available from the current state.*
4. *D is the drift row. It records the displayed one-step rank drift computed from the same transition counts.*
5. *G is the trigger-time row. It records the finite recursion for the time to reach full rank and the deterministic threshold row consumed by trigger-time readers.*
6. *H records componentwise* hsame *transport for state, support-rank, transition-count, drift, trigger-time, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a state read through S, K, A, D, G, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$, BHist, hsame, Cont, *finite rank-trigger rows, finite transition-count rows, finite trigger-time rows, and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient probability space, hidden generator field, infinite sample path, external random oracle, host Markov-chain semantics, or unstated independence assumption.

Lean4 ✓ `BEDC.Derived.MarkovTriggerDynamicsUp.MarkovTriggerDynamicsTasteGate single carrier alignment`

Theorem 4768.2 (MarkovTriggerDynamics NameCert obligations)**.** *For every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier* $T = (S, K, A, D, G, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed state row, support-rank row, transition-count row, drift row, trigger-time row, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface requires the transition-count row A *to be computed from the finite support-rank row* K*, the drift row* D *to read only the transition counts in* A*, and the trigger-time row* G *to replay the finite recursion from the displayed state row* S *without adding an external probability carrier.*

Proof. Project the accepted carrier. The packet exposes only $S, K, A, D, G, H, C, P, N$, so every NameCert obligation is a componentwise obligation on those rows.

The state and support rows S, K determine the finite rank-trigger situation. The transition-count row A counts rank-preserving and rank-increasing next draws from that finite support surface.

The drift row D is downstream of A, and the trigger-time row G is downstream of the same state and transition-count data. Thus the trigger-time read is a finite recursion over displayed rows, not an imported Markov-chain object.

Transport, replay, provenance, and local naming preserve the same coordinates. Since the excluded ambient and hidden objects are not coordinates of T, no consumer can read them from the packet. □

Theorem 4768.3 (MarkovTriggerDynamics finite trigger readback)**.** *Every trigger-time consumer of an accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *packet reads the finite route*

$$S, K, A, D, G, H, C, P, N.$$

Consequently the transition law, drift, and trigger-time rows are all determined by finite BHist transition-count data. No trigger-time read exports an infinite sample path, host Markov process, hidden field, or unstated independence source.

Proof. Start with the state row S and support-rank row K. They display the finite input state and the rank information that determines which next-draw counts are available.

The transition-count row A is the only row from which the drift row D may be read. The trigger-time row G then replays the finite recursion from those same transition counts.

Finally H, C, P, N transport, replay, source, and name the finite trigger route. Because no other row exists in the carrier, the stated nonescape clauses follow. □

Falsifiable prediction: Every $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ trigger-time read factors through finite state, support-rank, transition-count, drift, trigger-time, hsame, Cont, Pkg, and NameCert rows.

Independence witness: dna-boundary-tile, rank-trigger, finite-markov-transition: $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries state rows, support-rank rows, transition-count rows, drift rows, trigger-time rows, componentwise hsame transport, displayed Cont replay, provenance, and local naming.

Theorem 4768.4 (MarkovTriggerDynamics sibling dependency route)**.** *Every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *trigger-time read routes its finite state and transition-count rows through chapter 189 or chapter 4074 when the carrier is read as a Markov surface, through chapter 195 when it is read as finite transition evolution, and through chapter 3508 for the DNA boundary-trigger consumer.*

Proof. Project the existing carrier rows $S, K, A, D, G, H, C, P, N$. The state row S, support-rank row K, and transition-count row A provide exactly the finite Markov read, so a Markov-surface consumer reaches this packet through the Markov-chain or finite Markov-partition certificates.

The same rows, together with drift row D and trigger-time row G, form the finite transition-evolution route consumed by the dynamical-system certificate. The structural rows H, C, P, N then transport, replay, source, and name that route for the DNA boundary-trigger consumer.

This is a dependency route only. It does not add an ambient probability space, infinite sample path, unstated independence source, or host Markov-chain object to the carrier. □

Nontrivial TasteGate and FieldFaithful instances remain required before this finite trigger surface can be read as a checked biological field-faithfulness claim.

Closure status for $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet is generated from finite state rows, support-rank rows, transition-count rows, drift rows, trigger-time recursion rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5792.1, Definition 5792.2, and Definition 5792.3 seed the finite rank-trigger Markov readback surface for DNA boundary-tile dynamics.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient probability spaces, infinite sample paths, hidden field models, host Markov-chain semantics, biological field-faithfulness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-count exactness, drift readback, trigger-time recursion, nontrivial TasteGate coverage, FieldFaithful evidence, transport, replay, provenance, and local naming for BEDC.Derived.MarkovTriggerDynamicsUp.

Chapter 4769

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet records the finite constructive route from regular Cauchy rational names to located completion data and then to the terminal $\mathsf{Real}^{\uparrow}$ seal. It reads the dyadic arithmetic surface of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the completion service exposed by chapter 128, and the real-name boundary of chapter 38. The packet supplies a located completion neighbour for the regular-Cauchy real route without asserting quotient completion equality, selected representatives, host order completeness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4769.1 (Regular Cauchy located completion carrier)**.** *A* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, Q, K, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the Cauchy name is inspected at requested precision scales.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic ledger for tolerance comparison, shrinkage, and rational distance estimates.*
4. *Q is the located completion row, recording the displayed located-distance and approximation data extracted from S, R, D.*
5. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row used only as a finite completion handoff for the displayed located data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular readback and located completion rows have been displayed.*
7. *H records componentwise* hsame *transport for stream windows, regular rational readbacks, dyadic arithmetic, located completion data, completion service, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a located-completion request through $S, R, D, Q, K, E, H, P, N$.*

9. *P is the* Pkg *provenance over* RegularCauchyLocatedCompletion$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CompleteMetric$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{RegularCauchyLocatedCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, Q, K, E, H, C, P, N$. The carrier has no coordinate for quotient completion equality, selected representatives, countable choice, host order completeness, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedCompletionUp.RegularCauchyLocatedCompletionTasteGate`
`single carrier alignment`

Theorem 4769.2 (Regular Cauchy located completion obligations)**.** *For every accepted* RegularCauchyLocatedCom *carrier*

$$L = (S, R, D, Q, K, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyLocatedCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the stream-window row, regular rational readback row, dyadic arithmetic ledger, located completion row, complete-metric handoff, real seal, transport, replay, provenance, and local name;*
2. *window-readback coherence, requiring S to expose the finite inspection windows before R may be consumed as a regular rational name;*
3. *dyadic locatedness, requiring D to supply the tolerance comparisons and distance estimates used by the located completion row Q;*
4. *completion handoff ordering, requiring Q to be displayed before the* CompleteMetric$^{\uparrow}$ *row K is exposed;*
5. *real-seal ordering, requiring E to be read only after S, R, D, Q, K have been displayed;*
6. *classifier stability, requiring componentwise* hsame *transport and displayed* Cont *replay to preserve all visible rows;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no quotient completion equality, selected representative, countable choice, host order completeness, ambient* Real$^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 5793.1. Its rows list the finite stream windows, regular rational readback, dyadic arithmetic ledger, located completion data, complete-metric handoff, real seal, and the structural rows.

Window-readback coherence follows because R has no independent observation coordinate in this packet. The regular rational read must pass through S, and the tolerance computations used by that read are then checked against the dyadic row D.

The located completion row Q is the only row that records located-distance data. The completion handoff K consumes that displayed row, and the real seal E is exposed only after the handoff has been displayed.

Transport, replay, provenance, and local naming are exhausted by H, C, P, N. Since quotient completion equality, selected representatives, countable choice, host order completeness, and ambient Real$^{\uparrow}$ completeness are absent from the carrier, no NameCert obligation can export them. □

Theorem 4769.3 (Regular Cauchy located completion Real seal route)**.** *Let* $L = (S, R, D, Q, K, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the located completion read factors through the finite route*

$$S, R, D \longmapsto Q \longmapsto K \longmapsto E \longmapsto H, C, P, N.$$

Thus the packet reaches the real-name boundary only through displayed $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance arithmetic, located completion data, and the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff. It does not export quotient completion equality, selected representatives, countable choice, host order completeness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing read of the packet. The only observable name data are the stream windows S and the regular rational readback R, so any request for a real seal must first inspect those rows.

The dyadic row D supplies the tolerance and distance comparisons used by the located completion data Q. The complete-metric handoff K is then read as a service row for that displayed located data, not as an ambient completeness theorem.

Finally the seal row E exposes the $\mathsf{Real}^{\uparrow}$ boundary, and H, C, P, N transport, replay, source, and name the same displayed route. No remaining carrier coordinate can provide quotient completion equality, selected representatives, choice data, host order completeness, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5793.1, Definition 5793.2, and Definition 5793.3 seed a finite route from regular Cauchy names through located completion data to the $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host order completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window-readback coherence, dyadic locatedness, completion handoff ordering, real-seal ordering, classifier stability, and non-escape proofs for BEDC.Derived.RegularCauchyLocatedCompletionU

Constructive story: A $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore arithmetic, located completion data, a CompleteMetric handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4770

A Concrete Naming Certificate for $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$

Following Banach, Picard, and Bishop–Bridges constructive analysis, the $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet records the finite handoff from an explicit contraction estimate to the Cauchy threshold consumed by the regular-rational and real endpoint routes. It sits between the Banach fixed-point modulus packet of chapter 4188, the Picard iteration and error-estimate packets of chapter 2359 and chapter 2233, and the regular Cauchy completion boundary of chapter 5793. The packet gives the endpoint route a single displayed Cauchy-threshold surface without selecting a fixed point, quotienting completion names, or importing ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4770.1 (Picard threshold Cauchy handoff carrier)**.** *A* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, I, E, M, R, K, S, T, C, P, N)$$

with the following visible rows:

1. *B is the* $\mathsf{BanachFixedPointModulus}^{\uparrow}$ *source row whose contraction-rate route has already exposed the rational Lipschitz and finite Picard ledgers.*
2. *I is the* $\mathsf{PicardIteration}^{\uparrow}$ *ledger of adjacent iterate windows and replay order.*
3. *E is the* $\mathsf{PicardErrorEstimate}^{\uparrow}$ *row, carrying the residual-and-ratio estimate used to bound the Picard tail.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row produced from B, I, E for each requested dyadic or rational tolerance.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row made available only after the threshold row M has been displayed.*
6. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row consumed at the handoff boundary, not an ambient completeness theorem.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, R, K have been read.*
8. *T stores componentwise* hsame *transports for the Banach-modulus, Picard-iteration, error-estimate, Cauchy-threshold, regular-rational, complete-metric, real-seal, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from the contraction-rate request through $B, I, E, M, R, K, S, T, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$, $\mathsf{BanachFixedPointModulus}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{PicardErrorEstimate}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, I, E, M, R, K, S, T, C, P, N$. It has no coordinate for a selected fixed point, host fixed-point equality, quotient completion equality, detached Cauchy selector, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.PicardThresholdCauchyHandoffUp.PicardThresholdCauchyHandoffTasteGate`
`single carrier alignment`

Theorem 4770.2 (Picard threshold Cauchy handoff NameCert obligations)**.** *For every accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier $H = (B, I, E, M, R, K, S, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyH}}$ *surface consists exactly of carrier admission for the displayed rows; Banach-modulus source visibility through B; Picard-iteration visibility through I; error-estimate visibility through E; Cauchy-threshold construction through M; regular-rational readback through R; complete-metric service access through K; real seal access through S; classifier stability through T and C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 5794.1. The accepted packet exposes exactly the Banach-modulus source row, the Picard-iteration ledger, the error-estimate row, the Cauchy-threshold row, the regular-rational readback, the complete-metric service, the real seal, and the structural rows.

The threshold rows are ordered. The rows B, I, E must be displayed before M can answer a tolerance request, since M is the only coordinate that records the finite Cauchy threshold.

The endpoint rows are downstream. The row R reads the threshold as regular rational data, K is the visible complete-metric service row, and S is exposed only after those rows have been displayed. Transport, replay, provenance, and local naming are exhausted by T, C, P, N, so no further NameCert obligation is present. □

Theorem 4770.3 (Picard threshold Cauchy handoff Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing endpoint read of an accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{BanachFixedPointModulus}^{\uparrow},\ \mathsf{PicardIteration}^{\uparrow},\ \mathsf{PicardErrorEstimate}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Complete}$$

Thus the real seal is reached only after the explicit Picard threshold has been displayed as a $\mathsf{CauchyModulus}^{\uparrow}$ *row and repacked through the regular-rational and complete-metric handoff rows. The route exports no selected fixed point, quotient completion equality, detached Cauchy selector, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing endpoint request. The only contraction-rate source row is B, and its Picard data are refined in the visible rows I and E, so the request first reads those rows.

The threshold stage is forced by M. Apply the Banach fixed-point modulus route of Definition 4188.3 together with the Picard iteration surface of chapter 2359 and the error-estimate surface of chapter 2233. These sources supply the displayed threshold row without adding a selected endpoint.

After M is fixed, the readback and completion rows R and K expose the regular-rational and complete-metric boundary used by chapter 301 and chapter 128. The seal row S is then the only $\mathsf{Real}^{\uparrow}$ coordinate, and the structural rows T, C, P, N preserve the same route. □

Closure status for $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5794.1, Definition 5794.2, and Definition 5794.3 seed the finite Picard-threshold handoff from BanachFixedPointModulus, PicardIteration, and PicardErrorEstimate rows to CauchyModulus, RegSeqRat, CompleteMetric, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected fixed points, host fixed-point equality, quotient completion equality, detached Cauchy selectors, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Picard-threshold construction, regular-rational readback, complete-metric service access, real-seal ordering, classifier stability, provenance, and local naming for BEDC.Derived.PicardThreshol

Constructive story: A $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet is generated from a BanachFixedPointModulus source row, PicardIteration ledger, PicardErrorEstimate row, CauchyModulus threshold, RegSeqRat readback, CompleteMetric service row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4771

A Concrete Naming Certificate for $\mathsf{DiniUniformLimitModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the classical Dini theorem, the $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ packet extracts the finite uniform-modulus ledger visible in compact-metric monotone convergence data. It sits over chapter 2196, chapter 1436, chapter 129, chapter 130, chapter 463, chapter 369, chapter 301, and chapter 38. The packet names the finite net, rational tolerance budget, and extracted modulus route; it does not import open-cover compactness, chosen limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4771.1 (Dini uniform-limit modulus carrier)**.** *A* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row naming the compact-metric finite-source observations consumed by the extraction.*
2. *F is the monotone* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, recording the displayed continuous approximants and their pointwise monotone order.*
3. *W is the pointwise window row supplied by the Dini-continuity and Dini-uniform-convergence routes.*
4. *E is the finite net row over K, naming the finite mesh on which pointwise windows are inspected.*
5. *Q is the rational tolerance-budget row, storing the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerances assigned to the finite net and to the later readback.*
6. *U is the extracted* $\mathsf{UniformModulus}^{\uparrow}$ *row, obtained from E, Q, W and the monotone continuous family row F.*
7. *L is the* $\mathsf{UniformLimit}^{\uparrow}$ *handoff row, exposing only the modulus-controlled limit route supplied by U.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational tolerance transport.*
9. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row, naming the real-valued read without adding ambient real completeness.*
10. *H records componentwise* hsame *transport for compact-metric source, monotone family, pointwise window, finite net, rational tolerance, extracted modulus, uniform-limit handoff, rational readback, real seal, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from the compact-metric source and monotone family through the finite net, tolerance budget, extracted modulus, and uniform-limit handoff.*
12. *P is the* Pkg *provenance over* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$, $\mathsf{DiniContinuity}^{\uparrow}$, $\mathsf{DiniUniformConvergence}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, W, E, Q, U, L, R, S, H, C, P, N$. It has no coordinate for open-cover compactness, selected limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DiniUniformLimitModulusUp.TasteGate.DiniUniformLimitModulusTasteGate`
`single carrier alignment`

Theorem 4771.2 (Dini uniform-limit modulus NameCert obligations)**.** *For every accepted* DiniUniformLimitModulu *carrier*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed compact-metric source, monotone continuous family, pointwise window, finite net, rational tolerance budget, extracted uniform modulus, UniformLimit handoff, RegSeqRat readback, Real seal, componentwise transport, replay, provenance, and local naming rows.*

The obligation surface requires monotone-window visibility through F and W, finite-net extraction through E and Q, modulus handoff through U and L, Real-seal nonescape through S, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses open-cover compactness, selected limiting values, quotient function equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The only computational rows are the compact-metric source K, monotone family F, pointwise windows W, finite net E, rational budget Q, extracted modulus U, uniform-limit handoff L, rational readback R, and real seal S.

The monotone-window step is local to F and W. The finite-net step is local to E and Q, so the modulus row U is extracted from displayed finite data rather than from an open cover or a choice of limiting values.

The handoff to $\mathsf{UniformLimit}^{\uparrow}$ passes only through U and L. The rational and real readback rows R and S name the downstream values without adding quotient function equality or ambient completeness.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded objects are not coordinates of D, no NameCert consumer can read them from this carrier. □

Falsifiable prediction: Every accepted $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ read must expose compact-metric source rows, monotone continuous-family rows, pointwise window rows, a finite net, a rational tolerance budget, an extracted uniform modulus, a UniformLimit handoff, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dini-continuity, diniuniformconvergence, compactmetric, continuousmap, uniformlimit, uniformmodulus, regseqrat, real: $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ is not bijective to any

listed sibling because it binds the finite net and rational tolerance budget to an extracted uniform-modulus handoff before UniformLimit and Real consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5795.1 and Definition 5795.2 seed the finite uniform-modulus ledger extracted from compact-metric monotone convergence data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected limiting values, quotient function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone-window visibility, finite-net extraction, modulus handoff, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.DiniUniformLimitModulusUp.

Constructive story: A $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ packet is generated from compact-metric source rows, monotone continuous-family rows, pointwise windows, finite net rows, rational tolerance-budget rows, extracted uniform-modulus rows, UniformLimit handoff rows, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 4772

A Concrete Naming Certificate for $\mathsf{SummationByParts}^{\uparrow}$

Following Abel and Dirichlet, the $\mathsf{SummationByParts}^{\uparrow}$ packet records the finite identity surface by which displayed partial sums, coefficient windows, adjacent differences, and endpoint terms are bound into one NameCert row. It sits beside the Abel-summation route of chapter 1763, the Abel-test consumer of chapter 1496, and the Dirichlet-test consumer of chapter 1497. Its source rows use the finite series carrier of chapter 121; its regular readback, dyadic tolerance, and endpoint seal use chapter 301, chapter 291, and chapter 38. The packet names a finite algebraic identity for downstream convergence tests; it does not import infinite sums, quotient series equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4772.1 (Summation by parts carrier)**.** *A* $\mathsf{SummationByParts}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Series}^{\uparrow}$ *source row, exposing only the inspected finite term window and its displayed partial sums.*
2. *A is the coefficient-window row, naming the coefficient entries read over the same finite interval.*
3. *Δ is the adjacent-difference row, recording the displayed values $a_k - a_{k+1}$ used by the identity.*
4. *P is the partial-sum-window row, naming the cumulative sums paired with A and Δ.*
5. *B is the boundary-term row, displaying the endpoint products and the finite interior products determined by S, A, Δ, P.*
6. *T is the convergence-test handoff row consumed by* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$.
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed finite identity data.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the finite additions, subtractions, products, and endpoint comparisons used by B.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after $S, A, \Delta, P, B, T, R, D$ have been displayed.*
10. *H records componentwise* hsame *transport for the source, coefficient, difference, partial-sum, boundary, handoff, readback, dyadic, endpoint, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay of the route*

$$S, A, \Delta, P, B, T, R, D \longmapsto E.$$

12. *Q is the* Pkg *provenance over* $\mathsf{SummationByParts}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, A, \Delta, P, B, T, R, D, E, H, C, Q, N$. It has no coordinate for an infinite sum, quotient series equality, selected convergence witness, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SummationByPartsUp.SummationByPartsTasteGate single carrier alignment`

Theorem 4772.2 (Summation by parts NameCert obligations)**.** *For every accepted* $\mathsf{SummationByParts}^{\uparrow}$ *carrier*

$$K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite packet; source and partial-sum exposure through S and P; coefficient-window and adjacent-difference exposure through A and Δ; boundary-term exactness through B; convergence-test handoff through T; regular readback, dyadic accounting, and endpoint sealing through R, D, E; and transport, replay, provenance, and local naming through H, C, Q, N.*

Proof. Project the accepted carrier. The projection exposes exactly the rows $S, A, \Delta, P, B, T, R, D, E, H, C, Q, N$, so every naming obligation must be read from one of those displayed coordinates.

The identity rows are finite. The source row S and partial-sum row P display the inspected cumulative sums, the coefficient row A displays the paired coefficients, and Δ displays the adjacent differences used by the interior terms. The boundary row B records only the endpoint products and interior products determined by those rows.

The consumer handoff is downstream of the identity. A convergence-test consumer first reads T, and the regular and real-facing route then passes through R, D, E. These rows can transport the displayed finite calculation, but they do not introduce an independent summation principle.

Finally H, C, Q, N preserve, replay, source, and name the same route. Because the carrier has no coordinate for infinite sums, quotient series equality, selected convergence witnesses, countable choice, trichotomy, or ambient real completeness, the stated rows exhaust the local NameCert surface. □

Theorem 4772.3 (Summation by parts Cauchy-series handoff)**.** *Every accepted* $\mathsf{SummationByParts}^{\uparrow}$ *packet that is consumed by an* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$ *route hands off only the finite identity chain*

$$\mathsf{Series}^{\uparrow} \longmapsto S, A, \Delta, P, B, T \longmapsto R, D, E, H, C, Q, N.$$

Thus a Cauchy-series or real-seal consumer may read the summation-by-parts row only after the series window, coefficient window, adjacent-difference ledger, partial-sum window, boundary ledger, and test handoff have been displayed. The handoff supplies no infinite sum, quotient series equality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a convergence-test read. Carrier admission exposes the source row S and the finite identity rows A, Δ, P, B before the handoff row T is available.

The downstream chapters may add their own test-specific rows. The $\mathsf{AbelSummation}^{\uparrow}$ consumer reads the displayed finite identity as its transform row, the $\mathsf{AbelTest}^{\uparrow}$ consumer combines it with a monotone null coefficient ledger, and the $\mathsf{DirichletTest}^{\uparrow}$ consumer combines it with bounded partial sums and a null-tail schedule. In each case the summation-by-parts contribution remains the same displayed finite packet.

The Cauchy-facing route is therefore forced through R and D before E can seal the endpoint. Transport, replay, provenance, and local naming preserve that same route, so no excluded summation or completeness datum can be read from the packet. □

Falsifiable prediction: An accepted $\mathsf{SummationByParts}^{\uparrow}$ consumer that reaches an $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ row without reading the displayed source, coefficient, adjacent-difference, partial-sum, boundary-term, and handoff rows refutes the carrier surface.

Independence witness: abel-summation, abel-test, dirichlet-test, series, regseqrat, dyadicratcore, real: no listed sibling supplies the whole thirteen-row packet $K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N)$, because each sibling contributes only a transform consumer, convergence-test consumer, source series, regular readback, dyadic ledger, or endpoint seal while this chapter binds the finite identity itself.

Closure status for $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$.

Constructive story: A $\mathsf{SummationByParts}^{\uparrow}$ packet is generated from a SeriesUp finite source row, coefficient windows, adjacent-difference rows, partial-sum windows, boundary-term ledgers, AbelSummation/AbelTest/DirichletTest handoff rows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$, seed)

Scope closed: Definition 5796.1, Definition 5796.2, and Definition 5796.3 seed the finite summation-by-parts identity packet over $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close infinite summation, quotient series equality, selected convergence witnesses, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite identity exactness, convergence-test handoff, Cauchy-series readback, dyadic accounting, endpoint sealing, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.SummationByPartsUp.

Chapter 4773

A Concrete Naming Certificate for $\mathsf{RealLineOrder}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealLineOrder}^{\uparrow}$ packet records the constructive real-line order and apartness boundary visible to finite BEDC NameCert consumers. It sits over the dyadic tolerance ledger of chapter 291, the stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, the rational Cauchy completion route of chapter 3670, and the Bishop regular Cauchy limit seal of chapter 1821. The packet gives L10 consumers a located comparison interface before any real-order algebra can read it; it does not import trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4773.1 (Real line order carrier)**.** *A* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (D, S, R, L, A, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the positive dyadic radius used by every finite comparison request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing only the finite stream observations inspected at that tolerance.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the inspected stream windows into regular rational comparison data.*
4. *L is the located comparison row, recording the finite verdict surface for $x < y$ as a witnessed positive gap at the displayed tolerance, an unresolved window requiring a smaller displayed tolerance, or a symmetric failure of the current request.*
5. *A is the apartness row, recording positive-gap readback for $x \# y$ only through D, S, R, L.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the same displayed stream and regular-rational data, not from host real equality.*
7. *H records componentwise* hsame *transport for dyadic tolerance, stream windows, regular-rational readback, located comparison, apartness, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite order request through $D, S, R, L, A, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RealLineOrder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, R, L, A, E, H, C, P, N$. It has no coordinate for trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RealLineOrderUp.RealLineOrderTasteGate single carrier alignment`

Theorem 4773.2 (Real line order NameCert obligations)**.** *For every accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier*

$$O = (D, S, R, L, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance row, stream-window row, regular-rational readback row, located comparison row, apartness row,* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise transport row, replay row, provenance row, and local naming row.*

The obligation surface requires finite tolerance visibility through D, window visibility through S, regular-rational comparison readback through R, located order exposure through L, apartness exposure through A, real-seal nonescape through E, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the accepted carrier of Definition 5797.1. The only analytic rows are the dyadic tolerance D, the finite stream windows S, the regular-rational readback R, the located comparison row L, the apartness row A, and the terminal real seal E.

The comparison step is located rather than trichotomic. A finite request may display a positive gap, request a smaller displayed tolerance, or fail symmetrically at the current window; none of these outcomes supplies a global three-way case split.

The equality-sensitive routes are absent. The readback row R is regular-rational data over the displayed windows, and the seal row E is reached only after D, S, R, L, A have been inspected. Thus the packet refuses quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded principles are not coordinates of O, no local NameCert obligation can demand them. □

Lean4 ✓ `BEDC.Derived.RealLineOrderUp.RealLineOrderNameCertObligations`

Theorem 4773.3 (Real line order apartness readback)**.** *Every apartness read exported by an accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RealLineOrder}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The apartness row A may expose only a positive-gap witness already visible through D, S, R, L. It exports no trichotomy datum, quotient equality, selected representative, host real equality, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Proof. Start with an apartness request. The request must first choose a displayed positive dyadic tolerance in D and inspect the finite windows in S.

The regular-rational readback R is then the only comparison source. The located comparison row L reads this finite data and either displays a positive gap at the requested tolerance or leaves the request unresolved for a smaller displayed tolerance.

The apartness row A can cite only the positive-gap branch already exposed by L. It refuses trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$ because those objects are not carrier rows.

The terminal seal E preserves the same finite route into $\mathsf{Real}^{\uparrow}$. Transport and replay through H and C keep the route stable, while P and N only record provenance and local naming. □

Theorem 4773.4 (Real line order L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier must read the dyadic tolerance, stream-window, regular-rational readback, located comparison, apartness, and* $\mathsf{Real}^{\uparrow}$ *seal rows in the order*

$$D, S, R, L, A, E.$$

Consequently the handoff supplies a finite non-quotient comparison boundary for later real algebra and order packets, while refusing trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. An L10 order request begins with finite tolerance data. The row D fixes the displayed dyadic radius, and S opens only the stream windows inspected at that radius.

The row R repacks those windows as regular-rational readback. The located comparison row L can then answer only with the finite comparison surface generated from D, S, R.

Apartness is downstream of located comparison. The row A may expose a positive gap only when L has already displayed one, and E seals the same finite route as a $\mathsf{Real}^{\uparrow}$-facing endpoint.

Because no earlier or later row stores trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$, the L10 handoff cannot export those principles to later consumers. □

Falsifiable prediction: Every accepted $\mathsf{RealLineOrder}^{\uparrow}$ read must expose dyadic tolerance, StreamName windows, RegSeqRat readback, located comparison, apartness, RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before an L10 order consumer can read a comparison boundary.

Independence witness: dyadicratcore, streamname, regseqrat, real, rational-cauchy-completion, bishop-regular-cauchy-limit-seal: $\mathsf{RealLineOrder}^{\uparrow}$ is not bijective to any listed sibling because it binds located comparison and apartness rows to the finite readback route before the RealUp seal is available.

Closure status for $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5797.1, Definition 5797.2, Definition 5797.3, and Definition 5797.4 seed the finite non-quotient order and apartness boundary for displayed RealUp names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient equality, selected representatives, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite tolerance visibility, stream-window visibility, regular-rational readback, located comparison, apartness readback, RealUp seal handoff, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.RealLineOrderUp.

Constructive story: A $\mathsf{RealLineOrder}^{\uparrow}$ packet is generated from a DyadicRatCoreUp tolerance row, StreamName finite windows, RegSeqRat readback, located comparison, apartness, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4774

A Concrete Naming Certificate for $\mathsf{SchwartzKernel}^{\uparrow}$

Following Schwartz and Gelfand–Shilov, the $\mathsf{SchwartzKernel}^{\uparrow}$ packet records the finite NameCert route by which a distribution kernel is read as a bilinear action between Schwartz test probes and tempered-distribution endpoints. It sits over the Schwartz-function carrier of chapter 3399, the tempered-distribution endpoint of chapter 2310, the nuclear factorization row of chapter 215, the projective tensor norm route of chapter 4088, the tensor-product source of chapter 87, and the real seal of chapter 38. The chapter exposes the kernel theorem as finite action, tensor, nuclearity, bound, transport, replay, provenance, and local naming rows; it does not import a host distribution space, quotient test-function equality, selected representatives, or an unrestricted topological-vector-space oracle.

Definition 4774.1 (Schwartz kernel carrier)**.** *A* $\mathsf{SchwartzKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, U, J, B, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SchwartzFunction}^{\uparrow}$ *test-probe row naming the finite seminorm windows inspected on the source side.*
2. *T is the* $\mathsf{TemperedDistribution}^{\uparrow}$ *endpoint row naming the distributional action read after the test windows are displayed.*
3. *U is the* $\mathsf{TensorProduct}^{\uparrow}$ *row naming the finite tensor source on which the two test-probe sides are paired.*
4. *J is the* ***??*** *row recording the projective-tensor bound used to compare the paired test windows.*
5. *B is the* $\mathsf{Nuclear}^{\uparrow}$ *factorization row, exposing the finite nuclear decomposition route by which the kernel action is read.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed scalar bounds and kernel-action readbacks.*
7. *H records componentwise* hsame *transport for test probes, tempered endpoint, tensor source, projective bound, nuclear factorization, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite kernel request through $S, T, U, J, B, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{SchwartzKernel}^{\uparrow}$, $\mathsf{SchwartzFunction}^{\uparrow}$, $\mathsf{TemperedDistribution}^{\uparrow}$, $\mathsf{Nuclear}^{\uparrow}$, ***??***, $\mathsf{TensorProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^\uparrow}$ *row.*

The classifier compares accepted carriers only through $S, T, U, J, B, R, H, C, P, N$. It has no coordinate for a host distribution space, quotient equality of test functions, selected representatives, ambient bornological completeness, or a topological-vector-space theorem outside the displayed rows.

Lean4 ✓ `BEDC.Derived.SchwartzKernelUp.SchwartzKernelTasteGate single carrier alignment`

Theorem 4774.2 (Schwartz kernel NameCert obligations)**.** *For every accepted* $\mathsf{SchwartzKernel}^\uparrow$ *carrier*

$$K = (S, T, U, J, B, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^\uparrow}$ *surface consists exactly of Schwartz test-probe admission through S, tempered-distribution endpoint admission through T, tensor-source admission through U, projective-bound exposure through J, nuclear-factorization exposure through B, scalar RealUp sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every kernel consumer must read the distributional action through these ten rows. No consumer may replace them by an ambient kernel theorem, quotient test-function equality, selected representative, hidden topological vector space, or host nuclear-space completion.

Proof. Project the accepted carrier of Definition 5798.1. The analytic rows are the Schwartz test row S, the tempered-distribution endpoint T, the tensor source U, the projective bound J, the nuclear factorization B, and the RealUp seal R.

The action route is finite. The tensor row U supplies the paired test-probe source, J records the displayed projective bound, and B records the nuclear factorization by which the kernel action becomes readable by a finite consumer.

Transport and replay do not create new analytic structure. The rows H and C preserve the displayed packet componentwise and replay only the same kernel request. The provenance and naming rows P, N package the route without adding host quotient equality or a hidden completion theorem.

Thus the listed rows are exactly the local NameCert obligations for $\mathsf{SchwartzKernel}^\uparrow$. □

Theorem 4774.3 (Schwartz kernel nuclear factorization boundary)**.** *Every accepted* $\mathsf{SchwartzKernel}^\uparrow$ *read factors through the finite route*

$$\mathsf{SchwartzFunction}^\uparrow,\ \mathsf{TensorProduct}^\uparrow,\ ??,\ \mathsf{Nuclear}^\uparrow \longmapsto \mathsf{TemperedDistribution}^\uparrow \longmapsto \mathsf{Real}^\uparrow.$$

The nuclear row may expose only the displayed factorization and bound data already routed through S, U, J. It exports no host theorem identifying all kernels with all continuous bilinear forms, no quotient equality of test probes, no selected representative of a distribution, and no ambient completeness claim for the surrounding function spaces.

Proof. Start with a kernel read. The request first displays the finite Schwartz windows in S and the tensor source U on which the two test-probe sides are paired.

The projective tensor bound J is the only bound row available to the consumer. The nuclear factorization row B can cite only this displayed tensor-bound route, so its readback is a finite factorization certificate rather than an ambient nuclear-space theorem.

The tempered-distribution endpoint T then reads the resulting action, and R seals the scalar outputs as RealUp data. Transport through H and replay through C keep the same row order, while P and N record source and local naming.

Since no carrier coordinate stores host quotient equality, selected representatives, or ambient completeness, those principles cannot be exported by the factorization boundary. □

Falsifiable prediction: Every accepted $\mathsf{SchwartzKernel}^{\uparrow}$ packet must expose SchwartzFunctionUp test probes, TensorProductUp source data, ProjectiveTensorNormUp bounds, NuclearUp factorization, TemperedDistributionUp endpoint action, RealUp scalar sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before a kernel consumer can read the action.

Independence witness: schwartz-function, tempered-distribution, nuclear, projective-tensor-norm, tensorproduct, real: $\mathsf{SchwartzKernel}^{\uparrow}$ is not bijective to any listed sibling because it binds the test-probe tensor route, nuclear factorization boundary, distribution endpoint, and scalar seal as one finite kernel-action packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{SchwartzKernel}^{\uparrow}$ packet is generated from SchwartzFunctionUp test probes, a TemperedDistributionUp endpoint, TensorProductUp source data, ProjectiveTensorNormUp bounds, NuclearUp factorization, RealUp scalar seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5798.1, Definition 5798.2, Definition 5798.3, the falsifiable prediction, and the independence witness seed the finite kernel-action route over Schwartz, tempered-distribution, tensor, nuclear, bound, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host distribution-space semantics, quotient equality of test functions, selected distribution representatives, ambient nuclear-space completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, test-probe visibility, tensor-source admission, projective-bound exactness, nuclear-factorization exposure, tempered-endpoint action, RealUp scalar sealing, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.SchwartzKernelUp.

Chapter 4775

A Concrete Naming Certificate for $\mathsf{SynonymousTransition}^{\uparrow}$

The $\mathsf{SynonymousTransition}^{\uparrow}$ packet realizes the finite synonymous-transition geometry of Definition 9462.1186 as BEDC NameCert data. It sits beside the six-bit codon-window carrier of chapter 2234, the codon transition matrix of chapter 2245, the DNA boundary-tile packet of chapter 3393, the window-coverage trigger algebra of chapter 3478, and the DNA-window trigger threshold of chapter 4217. The packet names finite codon-window, class-adjacency, boundary-spectrum, threshold, transport, replay, provenance, and local naming rows; it is not a biological mechanism, stochastic fitness model, quotient codon semantics, or unrecorded enumeration oracle.

Definition 4775.1 (Synonymous transition carrier)**.** *A* $\mathsf{SynonymousTransition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (W, M, A, B, T, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *row naming the finite Q_6 codon-window surface.*
2. *M is the* $\mathsf{CodonTransitionMatrix}^{\uparrow}$ *row naming one-bit codon transitions inspected by the packet.*
3. *A is the class-adjacency row recording the displayed synonymous and cross-class adjacency counts, including the largest weights of Definition 9462.1186.*
4. *B is the boundary-spectrum row recording internal edge counts, external boundary degrees, and the control-pair corner-contact data.*
5. *T is the* $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$ *row naming the finite threshold at which an adjacency or boundary-spectrum read may trigger a downstream tile consumer.*
6. *H records componentwise* hsame *transport for codon windows, transition matrix, class adjacency, boundary spectrum, trigger threshold, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite synonymous-transition request through W, M, A, B, T, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{SynonymousTransition}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{CodonTransitionMatrix}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$, $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $W, M, A, B, T, H, C, P, N$. It has no coordinate for biological mechanism, stochastic fitness, quotient codon equality, hidden enumeration, or an ambient graph-theory oracle outside the displayed finite rows.

Theorem 4775.2 (Synonymous transition NameCert obligations)**.** *For every accepted* $\mathsf{SynonymousTransition}^{\uparrow}$ *carrier*

$$G = (W, M, A, B, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$ *surface consists exactly of codon-window admission through W, transition-matrix admission through M, class-adjacency exposure through A, boundary-spectrum exposure through B, trigger-threshold exposure through T, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every downstream synonymous-transition consumer must read the graph through these nine rows. It cannot replace them by biological causation, stochastic selection, quotient codon semantics, an unrecorded enumeration, or a hidden graph oracle.

Proof. Project the accepted carrier of Definition 5799.1. The finite codon surface is W, the one-bit transition source is M, and the named graph data are the class-adjacency row A and boundary-spectrum row B.

The trigger row T records when the displayed adjacency or boundary-spectrum data may be read by a downstream tile or trigger consumer. It does not add a biological mechanism or a stochastic model; it only names the finite threshold over the same graph rows.

Transport and replay are componentwise. The rows H and C preserve and replay W, M, A, B, T with the same finite endpoints, while P and N record provenance and local naming.

Since the carrier has no coordinate for quotient codon equality, hidden enumeration, biological causation, or ambient graph semantics, the listed rows exhaust the local NameCert obligations. □

Theorem 4775.3 (Synonymous transition boundary-spectrum handoff)**.** *Every accepted* $\mathsf{SynonymousTransition}^{\uparrow}$ *read factors through the finite route*

$$\mathsf{CodonSixBitWindow}^{\uparrow},\ \mathsf{CodonTransitionMatrix}^{\uparrow} \longmapsto \mathsf{SynonymousTransition}^{\uparrow} \longmapsto \mathsf{DnaWindowSixBoundaryTile}^{\uparrow},\ \mathsf{Wind}$$

The handoff exposes class-adjacency weights, internal-edge counts, external boundary degrees, and control-pair corner contacts only as finite packet rows. It exports no biological mechanism, stochastic fitness model, quotient codon semantics, or unrecorded enumeration oracle.

Proof. Start with the codon-window row W and the one-bit transition matrix row M. These rows supply the finite Q_6 source and the adjacency relation inspected by the packet.

The class-adjacency row A records the largest displayed weights, and B records the boundary-spectrum data. The downstream boundary-tile and trigger-algebra consumers therefore receive a finite graph packet rather than a biological or stochastic explanation.

The threshold row T names when the finite rows can be consumed by the trigger route. Transport through H and replay through C keep the same graph rows visible, while P and N only package their provenance and local name.

Thus every public read of the synonymous-transition geometry remains inside the finite codon-window, transition, adjacency, boundary-spectrum, threshold, transport, replay, provenance, and naming surface. □

Falsifiable prediction: Every accepted $\mathsf{SynonymousTransition}^{\uparrow}$ packet must expose CodonSixBitWindowUp, CodonTransitionMatrixUp, class-adjacency, boundary-spectrum, DNAWindowSixTriggerThresholdUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before a downstream tile or trigger consumer can read the synonymous-transition graph.

Independence witness: codon-six-bit-window, codon-transition-matrix, dna-window-six-boundary-tile, window-coverage-trigger-algebra, dna-window-six-trigger-threshold: $\mathsf{SynonymousTransition}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries class-adjacency weights, boundary-spectrum rows, and trigger-threshold handoff over the finite codon-window graph.

Closure status for $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$.

Constructive story: A $\mathsf{SynonymousTransition}^{\uparrow}$ packet is generated from a CodonSixBitWindowUp source, a CodonTransitionMatrixUp one-bit transition row, class-adjacency counts, boundary-spectrum data, DNAWindowSixTriggerThresholdUp rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5799.1, Definition 5799.2, Definition 5799.3, the falsifiable prediction, and the independence witness seed the finite synonymous-transition packet over codon-window, transition, adjacency, boundary-spectrum, threshold, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological mechanism, stochastic fitness, quotient codon semantics, hidden enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, codon-window visibility, transition-matrix exactness, class-adjacency exposure, boundary-spectrum exposure, trigger-threshold handoff, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.SynonymousTransitionUp.

Chapter 4776

A Concrete Naming Certificate for $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$

Following Feller and Billingsley on finite-sum normal approximation, the $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ packet records the finite BEDC surface by which an iid random-variable window is centered, scaled, read as a distribution row, and handed to a real-normal comparison seal. It sits after the probability source of chapter 184, the measurable random-variable rows of chapter 185, the law readback of chapter 186, the regular rational window of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite central-limit-facing certificate; it is not an asymptotic central limit theorem, a characteristic-function convergence theorem, a host probability-limit operator, countable choice, quotient distribution equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4776.1 (Central-limit finite-window carrier)**.** *A* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(P, V, S, K, D, R, E, H, C, Q, N).$$

Here P is the source $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the event classifier and total-mass normalization. The row V is the displayed iid* $\mathsf{RandomVar}^{\uparrow}$ *window over P, including the finite index range and the shared law token read by the window. The row S is the finite partial-sum ledger naming the displayed sum, the sample count, and the centered numerator. The row K is the centering and scaling row, recording the finite mean token, variance or spread token, positive scale request, and normalized finite-sum expression. The row D is the* $\mathsf{Distribution}^{\uparrow}$ *readback for the normalized finite sum and its comparison request. The row R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *window that presents rational test intervals, tolerances, and finite comparison samples for the distribution read. The row E is the* $\mathsf{Real}^{\uparrow}$ *normal-window seal naming the terminal real comparison against the displayed normal row at the requested finite window. The row H records componentwise* hsame *transport for the probability source, iid window, partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat window, Real normal-window seal, continuation, provenance, and local naming rows. The row C records* Cont *replay from a normal-facing read through P, V, S, K, D, R, E and then through the structural rows. The row Q is the* Pkg *provenance over* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert. *The row N is the local* $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$ *row. The classifier compares accepted carriers only through these eleven rows.*

Lean4 ✓ `BEDC.Derived.CentralLimitFiniteWindowUp.TasteGate.CentralLimitFiniteWindowTasteGate`
`single carrier alignment`

Theorem 4776.2 (Central-limit finite-window NameCert obligations)**.** *For every accepted* CentralLimitFiniteWindo *carrier* $(P, V, S, K, D, R, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$ *surface consists exactly of the finite rows in Definition 5800.1. Carrier admission displays the probability source, iid random-variable window, finite partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat comparison window, RealUp normal-window seal, transport, replay, provenance, and local naming row. The certificate imports no host asymptotic central limit theorem, characteristic-function limit, Lindeberg replacement principle, countable-choice schedule, quotient distribution equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Project the carrier rows in order. The probability source P and iid random-variable window V are the only stochastic data exposed to the certificate, and the partial-sum ledger S fixes the finite sum before any normal-facing read is visible.

The centering and scaling row K then determines the normalized finite expression. The distribution row D and RegSeqRat window R provide the only comparison surface through which a finite law read can reach the terminal $\mathsf{Real}^{\uparrow}$ normal-window seal E.

Finally H, C, Q, N transport, replay, source, and name the same displayed route. Since the carrier has no coordinate for an asymptotic theorem, characteristic-function limit, quotient law equality, countable choice, or ambient completeness, the listed rows exhaust the local finite NameCert surface. □

Theorem 4776.3 (Central-limit finite-window normal handoff)**.** *Every normal-facing read of an accepted* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ *carrier factors through the finite route*

$$P \longmapsto V \longmapsto S \longmapsto K \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, Q, N$$

before any consumer receives a normal-window comparison. Thus the read is the displayed iid finite-sum, normalization, distribution, RegSeqRat, and RealUp handoff itself; it exports no host asymptotic CLT, countable choice, quotient distribution equality, characteristic-function convergence principle, or ambient real completeness.

Proof. Begin with a normal-facing request. The only probability data available are the source row P and the finite iid window V, so the request must first read the displayed sample range and shared law token.

The partial-sum row S and normalization row K are then forced. They provide the finite sum, centering token, scaling token, and normalized expression that the downstream distribution read consumes.

The request can reach a normal-window comparison only through D, R, E. The distribution row D names the finite law read, the RegSeqRat row R exposes rational windows and tolerances, and the RealUp row E seals the displayed normal comparison. The structural rows H, C, Q, N preserve that route without adding analytic content.

Therefore every accepted read factors through the finite iid-sum, normalization, distribution, RegSeqRat, and RealUp rows. The excluded asymptotic, choice, quotient, characteristic-function, and completeness principles cannot be inserted into the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ packet is generated from a probability source row, iid random-variable window, finite partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat comparison window, RealUp normal-window seal, componentwise hsame transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5800.1, Definition 5800.2, and Definition 5800.3 seed the finite central-limit-facing handoff through ProbSpace, RandomVar, Distribution, RegSeqRat, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CentralLimitFiniteWindow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close the asymptotic central limit theorem, characteristic-function convergence, Lindeberg replacement, countable-choice schedules, quotient distribution equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, iid-window routing, partial-sum ledger exactness, normalization stability, distribution-to-RegSeqRat handoff, RealUp normal-window nonescape, transport, replay, provenance, and local naming for future BEDC.Derived.CentralLimitFiniteWindowUp.

Chapter 4777

A Concrete Naming Certificate for $\mathsf{LipschitzRealMap}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LipschitzRealMap}^{\uparrow}$ packet records a constructive real-map certificate whose continuity is controlled by a displayed dyadic Lipschitz constant and finite regular-rational windows. It sits after the dyadic tolerance ledger of chapter 291, the countable-name window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the located order and apartness neighbour of chapter 5797. The packet names the finite L10 route by which later continuous-map and metric-uniform-continuity consumers may read a real-valued map without importing host function extensionality, quotient representatives, selected limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4777.1 (Lipschitz real-map carrier)**.** *A* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, K, W, R, M, H, C, P, N)$$

with the following rows:

1. *S is the source* $\mathsf{Real}^{\uparrow}$ *seal row naming the accepted real input surface through displayed* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *data.*
2. *T is the target* $\mathsf{Real}^{\uparrow}$ *seal row naming the accepted real output surface through the same kind of finite readback.*
3. *K is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *Lipschitz constant row, including the positive dyadic bound and the displayed tolerance ledger used by every modulus request.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row for the source and target names inspected by the request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the displayed source and target windows into rational comparison data.*
6. *M is the modulus-inequality row, recording that every accepted finite pair of source reads with displayed apartness or distance bound is sent to a target read whose displayed difference is bounded by the dyadic constant in K times the source bound, up to the requested displayed tolerance.*
7. *H records componentwise* hsame *transport for source seal, target seal, dyadic constant, finite windows, regular-rational readback, modulus inequality, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a finite map request through $S, T, K, W, R, M, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{LipschitzRealMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealLineOrder}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, T, K, W, R, M, H, C, P, N$. It has no coordinate for host function equality, quotient equality of real presentations, selected Cauchy representatives, global uniform continuity, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LipschitzRealMapUp.LipschitzRealMapTasteGate single carrier alignment`

Theorem 4777.2 (Lipschitz real-map NameCert obligations)**.** *For every accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier*

$$F = (S, T, K, W, R, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$ *surface consists exactly of carrier admission for the source* $\mathsf{Real}^{\uparrow}$ *seal, target* $\mathsf{Real}^{\uparrow}$ *seal, dyadic Lipschitz constant, finite StreamName windows, RegSeqRat readback, modulus inequality, componentwise transport, replay, provenance, and local naming rows.*

The obligation surface requires finite source and target visibility through S and T, dyadic bound visibility through K, finite window visibility through W, rational readback through R, modulus-inequality exposure through M, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses host function extensionality, quotient equality of real presentations, selected representatives, global uniform-continuity principles, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5801.1. The source and target real seals are the only real-name endpoints, and both are read through finite StreamName and RegSeqRat windows rather than through host real equality.

The Lipschitz datum is the dyadic row K. A map request can inspect only the finite windows W and their rational readback R before the modulus row M exposes the displayed inequality for the requested tolerance.

The structural rows do not add analytic content. The transport row H preserves the already displayed source, target, constant, window, readback, and modulus rows componentwise, while C replays the same route and P, N record provenance and local naming.

Since no carrier coordinate stores host function equality, quotient real equality, selected representatives, global uniform continuity, or ambient completeness, no local NameCert obligation can require those objects. □

Theorem 4777.3 (Lipschitz real-map modulus stability)**.** *Let F_0 and F_1 be accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carriers whose source seals, target seals, dyadic Lipschitz constant rows, finite StreamName windows, and RegSeqRat readback rows are componentwise* hsame*-transported. Then every displayed modulus-inequality read exported by F_0 transports to the corresponding displayed modulus-inequality read exported by F_1.*

The stability claim is confined to the finite rows $S, T, K, W, R, M, H, C, P, N$. It does not identify host functions, quotient real presentations, selected Cauchy names, or ambient complete metric structures.

Proof. Start with a displayed modulus request for F_0. Its source and target real seals are read only through the finite StreamName windows and RegSeqRat readback rows named by S, T, W, R.

Use the componentwise hsame hypotheses. They transport the dyadic constant row K and the finite window/readback rows into the corresponding rows of F_1, so the same displayed source tolerance and target tolerance are available after transport.

The modulus row M is a row of the carrier rather than a host theorem about all representatives. Therefore the transported request reads the F_1 modulus row with the same displayed dyadic bound and the transported finite readback data.

Finally C, P, N replay, source, and name the transported route. No quotient equality, host function equality, selected representative, or ambient completeness principle is introduced by this transport. □

Theorem 4777.4 (Lipschitz real-map L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier must read the route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RealLineOrder}^{\uparrow} \longmapsto \mathsf{LipschitzRealMap}^{\uparrow}$$

through the finite source seal, target seal, dyadic constant, finite windows, regular-rational readback, modulus inequality, transport, replay, provenance, and local NameCert rows. The handoff supplies a finite Lipschitz-control surface for later continuous-map and metric-uniform-continuity packets, while refusing host function extensionality, quotient equality, selected representatives, global uniform-continuity principles, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. An L10 map request begins with source and target real-name seals. By the carrier definition, these seals are visible only through the finite StreamName windows and RegSeqRat readback rows used by S, T, W, R.

The request then reads the dyadic constant row K and the located comparison surface supplied by the real-line order neighbour. These rows provide the displayed source difference and target tolerance against which the modulus inequality is checked.

The modulus row M is the only analytic output of the packet. It hands a consumer a finite inequality route, not a host-level function theorem.

The rows H, C, P, N transport, replay, source, and name the same route. Thus later continuous-map and metric-uniform-continuity packets can consume the finite Lipschitz surface without receiving quotient equality, selected representatives, host function extensionality, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$.

Constructive story: A $\mathsf{LipschitzRealMap}^{\uparrow}$ packet is generated from source and target RealUp seal rows, a DyadicRatCore Lipschitz constant, finite StreamName windows, RegSeqRat readback, a displayed modulus-inequality row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$, seed)

Scope closed: Definition 5801.1, Definition 5801.2, Definition 5801.3, and Definition 5801.4 seed the finite Lipschitz real-map surface over the current L10 real and completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function extensionality, quotient equality of real presentations, selected Cauchy representatives, global uniform continuity, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source and target RealUp sealing, dyadic constant visibility, finite window readback, modulus-inequality stability, transport, replay, provenance, and local naming for future BEDC.Derived.LipschitzRealMapUp.

Chapter 4778

A Concrete Naming Certificate for HyperbolicQuasiGeodesicShadow$^{\uparrow}$

The HyperbolicQuasiGeodesicShadow$^{\uparrow}$ packet realizes the observer-expansion shadow route of section 9463.4 as finite quasi-geodesic, boundary, visual-metric, Busemann, and lamination-compatible rows. It sits after disk readout through chapter 377, the metric surface of chapter 3474, the visual-metric packet of chapter 3866, the Busemann cocycle route of chapter 4134, the geodesic-lamination packet of chapter 4203, and the observer-expansion packet of chapter 4167. The packet names a finite shadow tied to a displayed quasi-geodesic route; it does not complete the boundary, choose a global geodesic representative, identify quotient ideal points, or import host hyperbolic geometry.

Definition 4778.1 (Hyperbolic quasi-geodesic shadow carrier)**.** *A* HyperbolicQuasiGeodesicShadow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, G, E, V, B, L, H, C, P, A, N)$$

with the following rows:

1. *D is the disk readout row, exposing only displayed* UnitDisk$^{\uparrow}$ *coordinates and the associated* HyperbolicMetric$^{\uparrow}$ *metric-read data.*
2. *G is the quasi-geodesic route row, recording the finite path samples, distortion budget, endpoint-facing direction, and local route ledger inspected by the shadow request.*
3. *E is the boundary endpoint row named by the displayed route, not by a completed ideal-boundary quotient.*
4. *V is the visual-metric shadow row, recording the finite shadow window read through* HyperbolicVisualMetric$^{\uparrow}$ *and the boundary endpoint E.*
5. *B is the Busemann cocycle tolerance row, recording the displayed additive tolerance used to compare the route and the shadow window.*
6. *L is the geodesic-lamination compatibility row, recording whether the displayed route is compatible with the finite noncrossing leaf data consumed by* HyperbolicGeodesicLamination$^{\uparrow}$.
7. *H records componentwise* hsame *transport for disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow, Busemann tolerance, lamination compatibility, replay, provenance, refusal, and local naming rows.*
8. *C records displayed* Cont *replay from an observer-expansion shadow request through $D, G, E, V, B, L, H, P, A, N$.*

9. *P is the* Pkg *provenance over* HyperbolicQuasiGeodesicShadow$^{\uparrow}$, UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicVisualMetric$^{\uparrow}$, HyperbolicBusemannCocycle$^{\uparrow}$, HyperbolicGeodesicLamination$^{\uparrow}$, HyperbolicObserverExpar BHist, hsame, Cont, *and* NameCert.
10. *A is the refusal row excluding completed boundary quotients, selected global geodesics, ambient hyperbolic compactification, physical observer trajectories, and host curvature semantics.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, G, E, V, B, L, H, C, P, A, N$.

Theorem 4778.2 (Hyperbolic quasi-geodesic shadow NameCert obligations)**.** *For every accepted* HyperbolicQuasiGeodesicShadow$^{\uparrow}$ *carrier*

$$Q = (D, G, E, V, B, L, H, C, P, A, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$ *surface consists exactly of disk-readout visibility, quasi-geodesic route visibility, boundary endpoint exposure, visual-metric shadow-window exposure, Busemann cocycle tolerance, geodesic-lamination compatibility, componentwise transport, replay, provenance, refusal, and local naming rows.*

The packet exports no completed ideal boundary, quotient boundary equality, selected global geodesic, ambient hyperbolic compactification, physical observer trajectory, host curvature theorem, or global field semantics.

Proof. Project the carrier rows in order. The disk readout D supplies the only coordinate and metric source, while G supplies the displayed route samples and distortion budget inspected by the request.

The endpoint and shadow rows are downstream of that route. The endpoint row E names only the boundary read visible from G, and the visual row V records the finite shadow window tied to that endpoint.

The comparison rows B and L keep the shadow route finite. The Busemann tolerance is a displayed cocycle budget, and lamination compatibility is a finite noncrossing-leaf check, not a global geodesic-foliation theorem.

Finally H, C, P, A, N transport, replay, source, refuse, and name the same packet. Since the excluded host objects are not carrier rows, they cannot appear as NameCert obligations. □

Theorem 4778.3 (Hyperbolic quasi-geodesic shadow stability)**.** *Let Q_0 and Q_1 be accepted* HyperbolicQuasiGeodesi *carriers whose disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow window, Busemann tolerance, lamination compatibility, refusal, provenance, and local naming rows are componentwise* hsame*-transported. Then every observer-expansion consumer reads the same finite shadow surface through Q_0 and Q_1.*

The stability claim is confined to the finite rows $D, G, E, V, B, L, H, C, P, A, N$. It does not identify completed boundaries, quotient ideal points, selected geodesics, ambient compactifications, physical observer trajectories, host curvature data, or global fields.

Proof. Start with an observer-expansion shadow request for Q_0. The request must read disk coordinates and metric data through D and then the finite route samples and distortion budget through G.

Use the componentwise hsame transport. It carries the endpoint E, visual shadow window V, Busemann tolerance B, and lamination compatibility row L to the corresponding rows of Q_1.

The refusal row is transported with the same packet. Therefore the transported consumer sees the same excluded host objects and cannot insert completed boundary quotients, selected global geodesics, ambient compactifications, physical trajectories, curvature theorems, or global fields.

The replay row C and the provenance and naming rows P, N then present the transported shadow as the same finite observer-expansion surface. □

Theorem 4778.4 (Hyperbolic quasi-geodesic shadow vision handoff)**.** *Every observer-expansion consumer of an accepted* $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ *carrier must read the route*

$\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HyperbolicGeodesicLaminatio}$

through disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow, Busemann tolerance, lamination compatibility, transport, replay, provenance, refusal, and local NameCert rows. The handoff realizes the vision-level shadow route as finite NameCert data without turning observer expansion into physical cosmology or a host hyperbolic-boundary theorem.

Proof. The vision handoff begins with disk and metric data. Rows D and G ensure that the consumer reads only displayed disk observations, metric readouts, finite route samples, and a distortion budget.

The endpoint and shadow window are then forced. Rows E and V bind the boundary endpoint and visual-metric shadow to the same route, while B records the Busemann tolerance needed to compare route and shadow.

Lamination compatibility is read through L. This makes the packet consumable by geodesic-lamination and observer-expansion rows without selecting a global geodesic representative or completing the boundary.

The rows H, C, P, A, N transport, replay, source, refuse, and name the handoff. Thus the vision-level quasi-geodesic shadow is realized as finite NameCert data and not as ambient hyperbolic geometry. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ read must expose a boundary endpoint, visual-metric shadow window, Busemann cocycle tolerance, quasi-geodesic route, transport row, provenance row, refusal row, and local NameCert before any observer-expansion consumer may read the shadow.

Independence witness: hyperbolic-visual-metric, hyperbolic-busemann-cocycle, hyperbolic-geodesic-lamination, hyperbolic-observer-expansion: $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ is not bijective to these siblings because it binds the quasi-geodesic route and shadow window together before the observer-expansion packet may consume the boundary read.

The Lean TasteGate for this packet must later provide Nontrivial $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ and FieldFaithful $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ in `lean4/BEDC/Derived/HyperbolicQuasiGeodesicShadowUp/` Those instances must keep $D, G, E, V, B, L, H, C, P, A, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ packet is generated from disk readout rows, a quasi-geodesic route, a boundary endpoint, a visual-metric shadow window, Busemann cocycle tolerance, geodesic-lamination compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, refusal, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5802.1, Definition 5802.2, Definition 5802.3, and Definition 5802.4 seed the finite quasi-geodesic shadow route for observer-expansion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed boundary quotients, selected global geodesics, ambient hyperbolic compactification, physical observer trajectories, host curvature semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk readout, quasi-geodesic route admission, endpoint exposure, visual-metric shadow windows, Busemann tolerance, lamination compatibility, TasteGate nontriviality, field faithfulness, refusal exactness, transport, replay, provenance, and local naming for future BEDC.Derived.HyperbolicQuasiGeodesicShadowUp.

Chapter 4779

A Concrete Naming Certificate for $\mathsf{Dendrite}^{\uparrow}$

Following Nadler and Kuratowski on continuum theory, the $\mathsf{Dendrite}^{\uparrow}$ packet records the finite BEDC surface for a locally connected compact metric continuum whose tree-like form is read through unique arcs and cutpoint separation. It sits over the compact metric carrier of chapter 129, the locally connected surface of chapter 5809, the Peano continuum boundary of chapter 2160, and the tree certificate of chapter 119. The packet names displayed endpoint, unique-arc, and cutpoint-separation rows; it does not import host continua, arbitrary path spaces, open-cover compactness, or quotient equality of arcs.

Definition 4779.1 (Dendrite carrier)**.** *A* $\mathsf{Dendrite}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, L, P, T, E, A, C, H, R, G, Q, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the metric distance rows, finite ProbeBundle-net rows, complete-limit witness rows, and rational tolerance comparisons already certified by the compact-metric chapter.*
2. *L is the* $\mathsf{LocallyConnected}^{\uparrow}$ *row, recording the displayed connected neighbourhood refinements through which local arc and cutpoint requests are inspected.*
3. *P is the* $\mathsf{PeanoContinuum}^{\uparrow}$ *row, binding the compact metric and locally connected continuum surfaces before any dendrite consumer reads an arc boundary.*
4. *T is the* $\mathsf{Tree}^{\uparrow}$ *row, recording the finite tree-like separation surface used to rule out cycle-shaped routes.*
5. *E is the endpoint ledger, listing endpoint rows and their neighbourhood-read witnesses.*
6. *A is the unique-arc ledger, recording for every displayed endpoint or carried point pair the finite arc row, its endpoint membership rows, and its non-branching comparison rows.*
7. *C is the cutpoint-separation ledger, recording the displayed separation rows used when removing a carried point disconnects the relevant finite tree-like boundary.*
8. *H records componentwise* hsame *transport for compact metric data, local connectedness data, Peano-continuum data, tree data, endpoint rows, unique-arc rows, cutpoint-separation rows, replay, provenance, and local naming.*

9. *R records displayed* Cont *replay from a dendrite request through $K, L, P, T, E, A, C, H, G, Q, N$.*
10. *G is the* Pkg *provenance over* $\mathsf{Dendrite}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{PeanoContinuum}^{\uparrow}$, $\mathsf{Tree}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *Q records the local source and consumer provenance for endpoint, unique-arc, and cutpoint-separation reads.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{Dendrite}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host continuum, arbitrary path selection, open-cover compactness, cycle elimination by excluded middle, or quotient equality of arcs.

Lean4 ✓ `BEDC.Derived.DendriteUp.DendriteTasteGate single carrier alignment`

Theorem 4779.2 (Dendrite NameCert obligations)**.** *For every accepted* $\mathsf{Dendrite}^{\uparrow}$ *carrier*

$$D = (K, L, P, T, E, A, C, H, R, G, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{Dendrite}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact metric source, locally connected row, Peano-continuum row, tree row, endpoint ledger, unique-arc ledger, cutpoint-separation ledger, transport, replay, provenance, source provenance, and local naming;*
2. *compact-continuum visibility, requiring every dendrite consumer to read compact metric and local connectedness data through K, L, P before reading endpoint or arc rows;*
3. *tree-like exactness, requiring the non-cycle and separation information to pass through T and the cutpoint-separation ledger C;*
4. *unique-arc exactness, requiring every arc-facing read to use the displayed ledger A with its endpoint membership and non-branching comparison rows;*
5. *endpoint exactness, requiring endpoint reads to use only the displayed endpoint ledger E and not a host boundary predicate;*
6. hsame, Cont, *and* Pkg *stability, requiring componentwise transport, displayed replay, and provenance to preserve precisely the listed rows;*
7. *non-escape, excluding host continua, arbitrary path spaces, open-cover compactness, selected arc representatives, and quotient equality of arcs.*

No dendrite obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5803.1. The accepted tuple displays exactly the compact metric source, local connectedness, Peano-continuum row, tree row, endpoint ledger, unique-arc ledger, cutpoint-separation ledger, transport, replay, provenance, source provenance, and local naming.

The compact-continuum route is K, L, P. The compact metric source supplies distance, finite-net, complete-limit, and tolerance-comparison rows; the locally connected row supplies connected neighbourhood refinements; and the Peano-continuum row binds those surfaces before endpoint or arc data are exposed.

The tree-like route is T, E, A, C. The tree row supplies the finite non-cycle surface, the endpoint ledger records boundary reads, the unique-arc ledger records the displayed arc row between

carried point pairs, and the cutpoint-separation ledger records the separation witnesses used by downstream consumers.

Finally, H, R, G, Q, N transport, replay, source, and name the same finite packet. Since the carrier has no row for a host continuum, arbitrary path space, open-cover compactness principle, selected arc representative, or quotient equality of arcs, the listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$ surface. □

Theorem 4779.3 (Dendrite unique-arc handoff)**.** *Every unique-arc or cutpoint-facing consumer of an accepted* $\mathsf{Dendrite}^\uparrow$ *carrier must read the finite route*

$$\mathsf{CompactMetric}^\uparrow,\ \mathsf{LocallyConnected}^\uparrow,\ \mathsf{PeanoContinuum}^\uparrow,\ \mathsf{Tree}^\uparrow \longmapsto E, A, C, H, R, G, Q, N.$$

The handoff exposes endpoint rows, unique-arc rows, cutpoint-separation rows, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It does not expose arbitrary host paths, open-cover compactness, selected arc representatives, quotient equality of arcs, or a continuum object outside the displayed packet.*

Proof. Start with the compact-continuum source. The rows K, L, P force a consumer to read the compact metric, locally connected, and Peano-continuum surfaces before any arc-facing data can be inspected.

Next read the tree row T. This is the only row carrying the tree-like non-cycle surface, so a later cutpoint or arc argument cannot replace it by a host graph or a classical continuum theorem.

The endpoint and arc data are then E, A, C. Endpoint reads pass through E, unique-arc reads pass through A, and cutpoint-separation reads pass through C; the three ledgers remain tied to the same compact-continuum and tree source rows.

The structural rows H, R, G, Q, N preserve this route under transport, replay, provenance, and local naming. Because no excluded host-side row appears in the carrier, the consumer receives exactly the displayed unique-arc handoff and nothing stronger. □

Falsifiable prediction: Every accepted $\mathsf{Dendrite}^\uparrow$ read must expose CompactMetric, LocallyConnected, PeanoContinuum, Tree, endpoint, unique-arc, cutpoint-separation, componentwise hsame, displayed Cont, Pkg, source provenance, and local NameCert rows before a continuum or arc consumer can inspect the dendrite boundary.

Independence witness: compactmetric, locally-connected, peano-continuum, tree: $\mathsf{Dendrite}^\uparrow$ is not bijective to any listed sibling because it binds endpoint, unique-arc, and cutpoint-separation ledgers over their common compact-continuum and tree-like source.

Closure status for $\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$**.**

Constructive story: A $\mathsf{Dendrite}^\uparrow$ packet is generated from CompactMetricUp, LocallyConnectedUp, PeanoContinuumUp, TreeUp, endpoint rows, unique-arc rows, cutpoint-separation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, source provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$, seed)

Scope closed: Definition 5803.1, Definition 5803.2, and Definition 5803.3 seed the finite dendrite certificate over compact metric, locally connected, Peano-continuum, tree, endpoint, unique-arc, cutpoint-separation, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host continua, arbitrary path spaces, open-cover compactness, selected arc representatives, quotient equality of arcs, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-continuum visibility, tree-like exactness, endpoint exactness, unique-arc exactness, cutpoint-separation exactness, transport, replay, provenance, and local naming for BEDC.Derived.DendriteUp.

Chapter 4780

A Concrete Naming Certificate for $\mathsf{YoungIntegration}^{\uparrow}$

Following Young's integration theorem and Bishop–Bridges constructive analysis, the $\mathsf{YoungIntegration}^{\uparrow}$ packet records the finite dyadic route for integrating one Holder-controlled path against another. It sits beside the Holder-continuity surface of chapter 1766, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the tagged-mesh Riemann integral boundary of chapter 1526. The chapter names only a finite partition-and-error certificate; it does not import host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4780.1 (Young integration finite partition carrier)**.** *A* $\mathsf{YoungIntegration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (F, G, A, B, W, V, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the integrand path row, read through a* $\mathsf{HolderContinuity}^{\uparrow}$ *packet with its source interval observations, target Real estimates, rational exponent, and displayed Holder constant.*
2. *G is the integrator path row, read through a second* $\mathsf{HolderContinuity}^{\uparrow}$ *packet with its own source interval observations, target Real estimates, rational exponent, and displayed Holder constant.*
3. *A and B are the two Holder exponent ledgers. They include the finite comparison row witnessing that the displayed exponents have a Young margin for the dyadic partition family.*
4. *W is the dyadic partition-window row. It lists the inspected endpoints, dyadic mesh refinements, cell order, adjacent-cell handoffs, and the finite cells on which the integration read is allowed to form sums.*
5. *V is the cross-variation tolerance ledger. It records the cellwise oscillation products, Holder-bound products, Young-margin comparisons, and finite sum-difference tolerances consumed by the route.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger for endpoint radii, mesh widths, exponent-comparison margins, oscillation products, and final error bounds.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational trace of dyadic Young sums.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the integral value, reached only after the two Holder rows, dyadic windows, cross-variation ledger, dyadic tolerances, and regular readback have been displayed.*
9. *H records componentwise* hsame *transport for the two Holder paths, exponent ledgers, partition windows, cross-variation ledger, dyadic ledger, readback, Real seal, replay, provenance, and local name.*
10. *C records displayed* Cont *replay from a Young-integration request through Holder admission, dyadic partition windows, cross-variation tolerances, regular rational readback, and the Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{YoungIntegration}^{\uparrow}$, $\mathsf{HolderContinuity}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, G, A, B, W, V, D, R, E, H, C, P, N$. It has no coordinate for an ambient path space, quotient equality of functions, a selected sequence of partitions, a hidden limiting argument, countable choice, measure completion, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.YoungIntegrationUp.YoungIntegrationTasteGate single carrier alignment`

Theorem 4780.2 (Young integration NameCert obligations)**.** *For every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *carrier $Y = (F, G, A, B, W, V, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$ *surface is exhausted by admission of two* $\mathsf{HolderContinuity}^{\uparrow}$ *path rows, exponent-margin comparison, dyadic partition-window formation, cross-variation tolerance accounting,* $\mathsf{DyadicRatCore}^{\uparrow}$ *exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No accepted consumer may replace these rows by host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, or ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5804.1. The rows F and G expose the two Holder-controlled paths, and A, B expose only the finite exponent and Young-margin comparisons attached to those rows.

The partition and tolerance data are then forced. The row W lists the dyadic windows available to the route, while V records the cross-variation products and sum-difference tolerances over exactly those windows.

The terminal read is D, R, E. Dyadic exactness is read through D, the regular rational trace through R, and the Real integral seal through E only after the preceding rows have been consumed.

Finally H, C, P, N transport, replay, source, and name the same displayed route. Since the excluded objects have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 4780.3 (Young integration dyadic error budget)**.** *Every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *read that reaches the* $\mathsf{Real}^{\uparrow}$ *seal factors through the finite dyadic budget*

$$\mathsf{HolderContinuity}^{\uparrow}, \mathsf{HolderContinuity}^{\uparrow} \longmapsto \mathsf{DyadicPartition}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The row V must display the cross-variation tolerance consumed between the partition windows and the rational readback. Therefore the exported integral value is a finite dyadic Young-sum seal, not a Riemann-integral replacement, a measure-completion integral, a quotient path equality, a selected limiting partition, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the two Holder rows. Their displayed exponents and constants are read through F, G, A, B, so the route has only the finite power-law data needed to bound oscillations on dyadic cells.

Next read the dyadic partition windows. The row W fixes the cells, endpoints, mesh refinements, and adjacent-cell handoffs before any sum-difference comparison is requested.

The error budget is the pair V, D. The cross-variation ledger V records the oscillation products and Young-margin comparisons, and the dyadic ledger D records the exact rational tolerances used to compare any two displayed sums.

The readback and seal are downstream. The regular sequence row R is the only rational trace exported from the finite budgets, and E is the only Real seal. Thus the consumer cannot obtain any of the excluded host-level or choice-level objects from the packet. □

Theorem 4780.4 (Young integration Riemann boundary)**.** *Every* $\mathsf{RiemannIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *packet reads it only as a finite tagged-mesh boundary: two Holder path rows, a dyadic partition-window row, a cross-variation tolerance ledger, dyadic exactness, regular rational readback, Real sealing, transport, replay, provenance, and local naming. The consumer receives no independent Riemann-integral certificate, no Darboux gap claim, no quotient equality of integrands, no measure-completion object, and no selected mesh-limit principle.*

Proof. The only Riemann-facing data in the carrier are the displayed dyadic windows and finite sum budgets. The two Holder path rows provide values to be sampled, while W supplies the finite tagged-mesh boundary.

The cross-variation ledger is not a Darboux or measure-theoretic claim. It records only the tolerance comparisons needed for the Young-sum route before the regular rational readback is sealed as a Real value.

The provenance row may name $\mathsf{RiemannIntegral}^{\uparrow}$ as a consumer boundary, but the local certificate remains $F, G, A, B, W, V, D, R, E, H, C, P, N$. Therefore a Riemann-integral consumer receives a finite boundary row rather than any independent integral theorem or hidden limiting principle. □

Theorem 4780.5 (Young integration Cauchy-modulus consumer)**.** *Every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *packet whose cross-variation ledger* V *requests a tail precision must consume the* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *route before* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *sealing. The route remains finite: it exports the displayed Young partition windows, dyadic error budget, explicit Cauchy-modulus handoff, regular rational readback, and terminal Real seal, but it exports no selected limiting partition, countable-choice schedule, hidden modulus oracle, or ambient completion theorem.*

Proof. Project the carrier of Definition 5804.1. The rows W, V, D, R, E expose the partition windows, cross-variation tolerance ledger, dyadic error budget, regular rational readback, and terminal Real seal.

Use Definition 5804.3. The row V is the place where sum-difference tolerances and tail precision demands are recorded, and D is the dyadic ledger that makes those demands finite.

When such a tail precision is requested, apply the effective handoff of Definition 5728.3 and the schedule determinacy of Definition 5728.4. They force the precision request through an explicit $\mathsf{CauchyModulusBridge}^{\uparrow}$ schedule before R can be read and before E can seal the result.

The remaining rows H, C, P, N transport, replay, source, and name the same finite route. Since neither the Young carrier nor the bridge carrier contains a selected limiting partition, countable-choice schedule, hidden oracle, or ambient completion coordinate, no such object is exported. □

Falsifiable prediction: An accepted $\mathsf{YoungIntegration}^{\uparrow}$ packet is refuted if a consumer reaches the $\mathsf{Real}^{\uparrow}$ seal while omitting either $\mathsf{HolderContinuity}^{\uparrow}$ path row, the dyadic partition-window row W, the cross-variation ledger V, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D, or the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Independence witness: HolderContinuity, DyadicPartition, DyadicRatCore, RegSeqRat, Real, RiemannIntegral: none is bijective with $\mathsf{YoungIntegration}^{\uparrow}$ because the packet jointly carries two Holder paths, Young-margin exponent rows, dyadic partition windows, cross-variation tolerances, dyadic exactness, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$.

Constructive story: A $\mathsf{YoungIntegration}^{\uparrow}$ packet is generated from two HolderContinuityUp path rows, exponent-margin ledgers, dyadic partition windows, cross-variation tolerance accounting, DyadicRatCore exactness, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5804.1, Definition 5804.2, Definition 5804.3, Definition 5804.4, and Definition 5804.5 seed the finite dyadic Young-integration route over HolderContinuityUp, DyadicPartitionUp, DyadicRatCoreUp, CauchyModulusBridgeUp, RegSeqRatUp, RealUp, and RiemannIntegralUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked two-path admission, exponent-margin comparison, dyadic partition-window formation, cross-variation tolerance accounting, dyadic exactness, regular rational readback, Real-seal nonescape, and structural transport for BEDC.Derived.YoungIntegrationUp.

Chapter 4781

A Concrete Naming Certificate for $\mathsf{VariationDiminishing}^{\uparrow}$

Following Schoenberg and Karlin, the $\mathsf{VariationDiminishing}^{\uparrow}$ packet records a finite analysis row for transformations that do not increase displayed sign variation. It consumes the total-variation function surface of chapter 2257, the bounded-variation real-function carrier of chapter 3654, the regulated-function source of chapter 1554, and the tagged integration boundary of chapter 1526. The packet names the finite comparison by which a kernel or transformation row is read as variation-diminishing without importing a host operator algebra, total-positivity theorem, selected partitions, quotient functions, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4781.1 (Variation-diminishing carrier)**.** *A* $\mathsf{VariationDiminishing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (B, T, R, I, K, M, H, C, P, N)$$

with the following rows:

1. *B is the* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *source row naming the accepted bounded-variation input surface.*
2. *T is the* $\mathsf{TotalVariationFunction}^{\uparrow}$ *row naming the displayed total-variation ledger used to count variation before and after the transformation.*
3. *R is the* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *row naming the regulated readback through which input and output functions are compared by finite step windows.*
4. *I is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *row naming the finite tagged-mesh integration boundary used when the transformation is read by kernel action or integral averaging.*
5. *K is the kernel or transformation row, including its displayed positivity-order or sign-regularity window.*
6. *M is the variation comparison row recording that each accepted finite sign-change ledger for the output is routed to a no-larger sign-change ledger for the input.*
7. *H records componentwise* hsame *transport for bounded-variation source, total-variation ledger, regulated readback, integral boundary, kernel row, comparison row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite transformation request through $B, T, R, I, K, M, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{VariationDiminishing}^{\uparrow}$, $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, $\mathsf{TotalVariationFunction}^{\uparrow}$, $\mathsf{RegulatedRealFunction}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and sibling* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, T, R, I, K, M, H, C, P, N$. It has no coordinate for host function equality, quotient representatives, selected limiting partitions, a global total-positivity theorem, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.VariationDiminishingUp.VariationDiminishingTasteGate single carrier alignment`

Theorem 4781.2 (Variation-diminishing NameCert obligations)**.** *For every accepted* $\mathsf{VariationDiminishing}^{\uparrow}$ *carrier*

$$V = (B, T, R, I, K, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded-variation source row B, total-variation ledger T, regulated-function readback R, Riemann-integral boundary I, kernel or transformation row K, variation comparison row M, componentwise transport H, displayed replay C, provenance P, and local naming N.*

The obligation surface requires every output variation read to pass through the displayed comparison row M after B, T, R, I, K have been projected. It refuses host operator equality, quotient equality of functions, selected partitions, unrestricted total positivity, measure-theoretic kernels, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5805.1. The source row B supplies the bounded-variation input, while T supplies the total-variation ledger on which finite sign-change comparisons can be read.

The rows R and I keep the analytic route finite. Regulated readback gives step-window access to input and output functions, and the Riemann-integral boundary records only the tagged-mesh action needed by a kernel or averaging read.

The row K names the transformation window, and M is the only row that compares variation before and after the transformation. Thus the NameCert consumer obtains a variation-diminishing assertion only through the displayed comparison row, not through a host theorem about all kernels.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate stores quotient functions, selected limiting partitions, unrestricted total positivity, measure completion, or ambient real completeness, no local obligation can require them. □

Theorem 4781.3 (Variation-diminishing total-variation route)**.** *Every accepted* $\mathsf{VariationDiminishing}^{\uparrow}$ *consumer read factors through the route*

$$\mathsf{BoundedVariationRealFunction}^{\uparrow},\ \mathsf{TotalVariationFunction}^{\uparrow},\ \mathsf{RegulatedRealFunction}^{\uparrow},\ \mathsf{RiemannIntegral}^{\uparrow} \longmapsto \mathsf{VariationD}$$

The output variation ledger is accepted only after the bounded-variation input, cumulative total-variation ledger, regulated readback, tagged integration boundary, kernel row, and comparison row have been displayed. The route exports no selected limit, quotient function equality, global total-positivity principle, measure-completion object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. A variation-diminishing request first projects B and T. These rows bind the input function to the bounded-variation and total-variation sibling surfaces, so the requested comparison starts from finite variation data rather than from a host function space.

Next project R and I. The regulated row supplies finite step-window readback, while the integral boundary supplies the tagged-mesh route through which a kernel or averaging transformation can be inspected.

The transformation row K and comparison row M then give the only accepted variation comparison. They state that the displayed output sign-change ledger routes to a no-larger input ledger in the same finite packet.

Finally H, C, P, N preserve the route under transport, replay, provenance, and local naming. Hence every public read of $\mathsf{VariationDiminishing}^{\uparrow}$ passes through the four cited sibling anchors and does not acquire the excluded host-level principles. □

Falsifiable prediction: A $\mathsf{VariationDiminishing}^{\uparrow}$ packet whose output variation read bypasses the displayed total-variation ledger or the regulated readback row is not accepted by the local NameCert.

Independence witness: total-variation-function, bounded-variation-real-function, regulatedrealfunction, riemannintegral: $\mathsf{VariationDiminishing}^{\uparrow}$ is not bijective to any listed sibling because it binds the source variation ledger, regulated readback, tagged integration boundary, transformation row, and no-increase comparison as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$.

Constructive story: A $\mathsf{VariationDiminishing}^{\uparrow}$ packet is generated from bounded-variation source data, a total-variation ledger, regulated readback, Riemann tagged-mesh boundary, a kernel or transformation row, a variation comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5805.1, Definition 5805.2, Definition 5805.3, the falsifiable prediction, and the independence witness seed the finite variation-diminishing route over the current analysis rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host operator equality, quotient equality of functions, selected limiting partitions, unrestricted total positivity, measure completion, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, bounded-variation source visibility, total-variation ledger exactness, regulated readback, tagged integration boundary, transformation-row exposure, comparison-row stability, transport, replay, provenance, and local naming for future BEDC.Derived.VariationDiminishingUp.

$\mathsf{FrobeniusReciprocity}^{\uparrow}$ routes induction–restriction comparison through chapter 247, chapter 246, and chapter 245 before the child file states the local certificate.

Chapter 4782

A Concrete Naming Certificate for $\mathsf{FrobeniusReciprocity}^{\uparrow}$

Following Frobenius on induced characters, Serre's finite-group representation theory, and the induction–restriction formulation used by Fulton–Harris, the $\mathsf{FrobeniusReciprocity}^{\uparrow}$ packet records the finite comparison row between induction from a subgroup and restriction to that subgroup. It consumes the action rows of chapter 3662, the subgroup source of chapter 80, the representation-ring ledger of chapter 246, the induction–restriction packet of chapter 247, and the character-pairing surface of chapter 245. The packet names only finite source rows, adjunction ledgers, character-pairing boundaries, transport, replay, provenance, and downstream handoff rows; it does not assert a host category of representations, a functor equality, semisimplicity, Schur orthogonality, or a completed character table.

Theorem 4782.1 (FrobeniusReciprocityUp source obligations)**.** *For every accepted* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet, the source surface is the displayed finite tuple*

$$\mathcal{F} = (G, H, R, I, Q, \Phi, \eta, \epsilon, \chi, \lambda, C, P, N),$$

where G is the consumed $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ *action row, H is the consumed* $\mathsf{Subgroup}^{\uparrow}$ *row, R is the consumed* $\mathsf{RepresentationRing}^{\uparrow}$ *ledger, I is the consumed* $\mathsf{InducedRep}^{\uparrow}$ *induction–restriction row, Q is the consumed* $\mathsf{CharacterTheory}^{\uparrow}$ *pairing row, Φ is the Frobenius comparison row, η, ϵ are the displayed unit and counit rows, χ is the character-pairing boundary, λ is the finite ledger of visible source and endpoint reads, C is componentwise* Cont *replay, P is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *row. No source obligation is imported from a host representation category, quotient carrier, functor category, or external adjunction object.*

Proof. Project the accepted packet. The source rows are precisely G, H, R, I, Q together with the local comparison rows $\Phi, \eta, \epsilon, \chi, \lambda, C, P, N$.

The consumed rows are already finite BEDC certificates. The finite-group representation row supplies the action display, the subgroup row supplies the inclusion boundary, the representation-ring row supplies the Grothendieck ledger, the induced-representation row supplies the induction–restriction endpoints, and the character-theory row supplies the pairing surface.

Since the tuple has no coordinate for a host representation category, quotient carrier, functor category, or external adjunction object, the listed rows exhaust the source obligations. □

Theorem 4782.2 (FrobeniusReciprocityUp adjunction ledger)**.** *The adjunction data of an accepted* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet are exactly the finite rows $\Phi, \eta, \epsilon, \lambda$ over the consumed sources*

H, R, I. The row Φ compares the displayed induction endpoint with the displayed restriction endpoint, η and ϵ record the unit and counit witnesses as BHist *rows, and λ records the visible continuations among source, endpoint, and Frobenius reads. The ledger exports no host naturality square, functor equality, adjunction object, or semisimple decomposition.*

Proof. Begin with the induction–restriction source. The packet consumes the $\mathsf{InducedRep}^{\uparrow}$ row I, so the available endpoints are the displayed induction and restriction rows already carried by that certificate.

The Frobenius comparison is read through Φ. The unit and counit witnesses are read through η and ϵ, and every visible path among source and endpoint reads is recorded by the finite ledger λ.

Exactness is projection from the tuple. Any row outside $\Phi, \eta, \epsilon, \lambda$ is not part of the adjunction ledger, and no host naturality square or functor equality can be recovered from a coordinate that the packet does not carry. □

Theorem 4782.3 (FrobeniusReciprocityUp character-pairing boundary)**.** *Every character-pairing read of a* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet factors through the consumed* $\mathsf{CharacterTheory}^{\uparrow}$ *row Q, the representation-ring source R, the induction–restriction source I, and the displayed pairing boundary χ before it can inspect Φ, η, ϵ or λ. The boundary supplies only the finite character-pairing comparison needed for reciprocity and does not export Schur orthogonality, irreducible decomposition, character-table computation, or a completed class-function algebra.*

Proof. Read the character side first. The only character-theory coordinate is Q, and the only representation-ring coordinate feeding it is R.

The induction and restriction endpoints enter through I. The displayed pairing boundary χ then names the finite comparison used by the Frobenius row before the ledger reads $\Phi, \eta, \epsilon, \lambda$.

Because the tuple has no coordinate for Schur orthogonality, irreducible decomposition, character-table computation, or a completed class-function algebra, every character-pairing read remains inside the stated finite boundary. □

Theorem 4782.4 (FrobeniusReciprocityUp NameCert surface)**.** *The* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *obligation surface is the conjunction of the source obligations of Definition 5806.1, the adjunction ledger of Definition 5806.2, the character-pairing boundary of Definition 5806.3, componentwise* hsame *transport on all displayed source and ledger rows, finite* Cont *replay through C, and* Pkg *provenance through P. The surface exports no obligation outside the displayed tuple $\mathcal{F}$.*

Proof. First combine the source obligations with the adjunction ledger. The source theorem identifies the consumed BEDC certificates, and the ledger theorem identifies the only Frobenius comparison, unit, counit, and continuation rows.

Next add the character-pairing boundary. It places every character read behind Q, R, I, χ before the Frobenius ledger can be inspected.

Finally apply componentwise transport and replay. The rows C and P preserve exactly the displayed tuple, and the local row N names the resulting certificate. Since no obligation outside $\mathcal{F}$ is available, these clauses give the stated NameCert surface. □

Theorem 4782.5 (FrobeniusReciprocityUp consumer handoff)**.** *A downstream consumer of* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *may read exactly the consumed finite-group action row G, subgroup row H, representation-ring row R, induced-representation row I, character-theory row Q, Frobenius rows Φ, η, ϵ, character-pairing boundary χ, visible ledger λ, replay row C, provenance row P, and local name row N. Any consumer handoff to* $\mathsf{InducedRep}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, *or* $\mathsf{CharacterTheory}^{\uparrow}$ *factors through those*

rows and cannot bypass them through a host category, functor equality, semisimplicity theorem, or character-table computation.

Proof. Start with a downstream read. The only visible source coordinates are G, H, R, I, Q, and the only local Frobenius coordinates are $\Phi, \eta, \epsilon, \chi, \lambda, C, P, N$.

For an $\mathsf{InducedRep}^{\uparrow}$ consumer, the handoff is through I together with the Frobenius rows. For a $\mathsf{RepresentationRing}^{\uparrow}$ consumer, the handoff is through R and the source ledger. For a $\mathsf{CharacterTheory}^{\uparrow}$ consumer, the handoff is through Q and the pairing boundary χ.

The replay and provenance rows preserve the same finite route. Thus a consumer cannot bypass the displayed packet through a host category, functor equality, semisimplicity theorem, or character-table computation. □

Theorem 4782.6 (FrobeniusReciprocityUp sibling lattice)**.** *The* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet is a finite comparison consumer of the sibling carriers in chapter 3662, chapter 80, chapter 246, chapter 247, and chapter 245. Its local rows compare induction and restriction after those carriers are visible; they do not form an isolated kernel row and do not replace the representation, subgroup, ring, induced-representation, or character-theory certificates.*

Proof. Read the source tuple of Definition 5806.1. The rows G, H, R, I, Q are precisely the five sibling certificates named in the statement.

The consumer handoff of Definition 5806.5 permits downstream reads only through those rows together with the Frobenius comparison, unit, counit, pairing boundary, ledger, replay, provenance, and local name rows.

Therefore the packet sits inside the displayed representation-theory lattice. It is a comparison consumer over the sibling carriers, not a standalone kernel surface from which the sibling certificates can be reconstructed. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5806.1, Definition 5806.2, Definition 5806.3, Definition 5806.4, Definition 5806.5, and Definition 5806.6 seed the finite Frobenius reciprocity certificate over displayed finite-group representation, subgroup, representation-ring, induced-representation, and character-theory rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, semisimplicity, Schur orthogonality, irreducible decomposition, character-table computation, functor-category equality, or a host adjunction theorem.

Upgrade path: Obligation closure requires checked carrier admission, adjunction-ledger exactness, character-pairing boundary, NameCert surface, and downstream handoff for the same finite packet.

Constructive story: A $\mathsf{FrobeniusReciprocity}^{\uparrow}$ packet is generated from consumed finite-group representation, subgroup, representation-ring, induced-representation, and character-theory rows, then records a finite Frobenius comparison, unit and counit rows, character-pairing boundary, visible continuation ledger, package provenance, and local NameCert evidence.

Chapter 4783

A Concrete Naming Certificate for $\mathsf{NormalOperator}^{\uparrow}$

Following Reed and Simon, the $\mathsf{NormalOperator}^{\uparrow}$ packet records the standard normal-operator surface as finite NameCert data over displayed Hilbert and inner-product candidates. It consumes the inner-product carrier of chapter 86, the Hilbert carrier of chapter 91, the linear-map rows of chapter 48, the operator-norm boundary of chapter 3603, and the downstream spectral-theorem consumer of chapter 214. The packet exposes only a bounded linear operator, its displayed adjoint-action row, the norm ledger, and the normality commutator row; it does not claim spectral measure existence, functional calculus, diagonalization, projection-valued measures, or a host operator algebra.

Definition 4783.1 (NormalOperator carrier)**.** *For a displayed* $\mathsf{Hilbert}^{\uparrow}$ *candidate* H *with* $\mathsf{InnerProduct}^{\uparrow}$ *row* I*, a* $\mathsf{NormalOperator}^{\uparrow}(H)$ *carrier is a finite* BHist *packet*

$$\mathcal{N} = (H, I, T, T^*, A, K, Q, L, H_T, C, P, N)$$

with the following ten displayed fields:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *carrier row and I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row over the same point-history carrier.*
2. *T is a bounded* $\mathsf{LinMap}^{\uparrow}$ *endpoint action on the carried Hilbert endpoints.*
3. *T^* is the displayed adjoint-action row, certified by the finite inner-product comparison*

   $$\langle Tx, y\rangle_I \ \mathsf{hsame}\ \langle x, T^*y\rangle_I$$

   for the vector histories inspected by the packet.
4. *A is the adjoint-domain ledger, recording that the adjoint row is read over the same Hilbert, inner-product, linear-map, and boundedness surfaces as T.*
5. *K is the* $\mathsf{OperatorNorm}^{\uparrow}$ *bound row for T and for the displayed adjoint action T^*.*
6. *Q is the normality commutator row*

   $$T^*T \ \mathsf{hsame}\ TT^*$$

   read only on certified vector histories.
7. *L is the operator graph ledger: it stores inspected input histories, output histories, linearity rows, adjoint rows, norm-bound rows, and the commutator row.*

8. *H_T records componentwise* hsame *transport for the Hilbert source, inner-product row, endpoint actions, adjoint row, norm row, commutator row, and ledger.*
9. *C records displayed* Cont *replay for endpoint action requests, adjoint-action requests, norm-bound requests, and commutator inspections.*
10. *P, N are the* Pkg *provenance and local* $\mathsf{NameCert}_{\mathsf{NormalOperator}^\uparrow}$ *naming rows.*

The classifier compares accepted carriers by action agreement on certified vector histories, adjoint-action agreement on the same inspected histories, transport of the operator-norm row, and transport of the graph, adjoint, normality, continuation, provenance, and local-name ledgers. It has no coordinate for host operator equality, quotient completion, spectral measures, eigenvector bases, or external functional calculus.

Lean4 ✓ `BEDC.Derived.NormalOperatorUp.NormalOperatorTasteGate single carrier alignment`

Theorem 4783.2 (NormalOperator NameCert obligations)**.** *For every accepted* $\mathsf{NormalOperator}^\uparrow$ *carrier*

$$\mathcal{N} = (H, I, T, T^*, A, K, Q, L, H_T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NormalOperator}^\uparrow}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the common* $\mathsf{Hilbert}^\uparrow$ *and* $\mathsf{InnerProduct}^\uparrow$ *rows;*
2. *bounded* $\mathsf{LinMap}^\uparrow$ *action for T on certified vector histories;*
3. *adjoint-action agreement for T^* against the displayed inner product;*
4. $\mathsf{OperatorNorm}^\uparrow$ *bound rows for the operator action and adjoint action;*
5. *normality commutator exactness through the displayed row Q;*
6. *graph-ledger exactness for input histories, output histories, linearity rows, adjoint rows, norm rows, and commutator rows;*
7. *classifier transport by action agreement, adjoint-action agreement, norm-row agreement, and componentwise ledger transport;*
8. Cont *replay,* Pkg *provenance, and local naming for exactly the displayed packet;*
9. *refusal of spectral measure existence, diagonalization, projection-valued measures, host operator quotients, and unrecorded functional calculus.*

Proof. Project the carrier of Definition 5807.1. The Hilbert and inner-product source rows, endpoint action, adjoint-action row, adjoint-domain ledger, norm row, commutator row, graph ledger, transport row, continuation row, provenance row, and local name are the full displayed inventory.

The adjoint and boundedness obligations are read before any spectral consumer appears. The adjoint row is the finite inner-product comparison for certified vector histories, and the norm row is the displayed $\mathsf{OperatorNorm}^\uparrow$ bound attached to both endpoint actions.

Normality is exactly the commutator row Q. Because Q compares T^*T and TT^* only through inspected vector histories and their graph ledger, the packet does not appeal to host equality of operators.

Finally H_T, C, P, N transport, replay, source, and name those rows. Since the carrier has no spectral-measure, diagonalization, projection-valued-measure, quotient, or functional-calculus coordinate, the listed rows exhaust the local normal-operator NameCert obligations. □

Theorem 4783.3 (NormalOperator InnerProduct spectral anchor)**.** *Every downstream spectral read of an accepted* $\mathsf{NormalOperator}^{\uparrow}$ *packet factors through the common Hilbert and inner-product rows, the bounded linear action, the displayed adjoint-action row, the operator-norm bound, and the normality commutator ledger before it can be consumed by the* $\mathsf{SpectralTheorem}^{\uparrow}$ *surface. The route is*

$$(H, I) \longmapsto (T, T^*, A, K, Q, L) \longmapsto (H_T, C, P, N),$$

and it exports no spectral projection, spectral measure, eigenbasis, Borel functional calculus, or host operator-algebra equality.

Proof. Expose the accepted packet by Definition 5807.1. The only analytic source rows are the Hilbert carrier, inner-product comparison row, endpoint action, displayed adjoint action, norm bound, and normality commutator.

Apply Definition 5807.2. The graph ledger forces the operator action, adjoint action, boundedness evidence, and commutator evidence to be read from one finite packet, and classifier transport keeps the operator and adjoint rows over the same certified vector histories.

It remains to hand the packet to spectral consumers. The $\mathsf{SpectralTheorem}^{\uparrow}$ chapter may consume the normality anchor only through the displayed rows already named here. Because no spectral projection, spectral measure, eigenbasis, Borel functional calculus, or host operator-algebra equality is a field of the carrier, the anchor supplies a pre-spectral normal-operator surface rather than a spectral theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5807.1, Definition 5807.2, and Definition 5807.3 seed the normal-operator surface over Hilbert, inner-product, bounded linear-map, adjoint-action, operator-norm, and commutator rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim spectral measures, spectral projections, diagonalization, eigenbasis construction, Borel functional calculus, host operator quotients, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, adjoint-action agreement, norm-bound stability, normality commutator exactness, classifier transport, graph-ledger exactness, spectral-consumer nonescape, and bridge data for BEDC.Derived.NormalOperatorUp.

Constructive story: A $\mathsf{NormalOperator}^{\uparrow}$ packet is generated from a Hilbert source, an inner-product row, a bounded linear endpoint action, a displayed adjoint action, operator-norm bounds, a normality commutator row, graph and transport ledgers, continuation replay, provenance, and a local NameCert row.

Chapter 4784

A Concrete Naming Certificate for $\mathsf{HausdorffMeasure}^{\uparrow}$

Following Hausdorff and Federer's metric measure theory, the $\mathsf{HausdorffMeasure}^{\uparrow}$ packet records the finite dyadic-cover surface through which Hausdorff content and scale-stable measure reads become visible inside BEDC. It sits over the metric carrier of chapter 57, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the cover-valued outer-measure boundary of chapter 3385, and the finite scale-cover comparison surface of chapter 3877. The packet names only displayed dyadic cover packets, diameter budgets, weighted cover sums, scale comparison, transport, replay, provenance, and local naming; it is not a quotient cover family, not a selected infimum, not countable choice over covers, and not an ambient measure primitive.

Definition 4784.1 (Hausdorff measure dyadic-cover carrier)**.** *A* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (M, D, R, O, B, C, S, T, E, K, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the finite point classifier and distance comparisons used to bound cover diameters.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row, naming the dyadic radius budget and dyadic exponent used by the cover packet.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *value-seal row for diameter powers and finite cover sums.*
4. *O is the* $\mathsf{OuterMeasure}^{\uparrow}$ *handoff row, read only as a finite cover-valued boundary and not as a completed measure primitive.*
5. *B is the* $\mathsf{BoxDimension}^{\uparrow}$ *comparison row, exposing finite scale-cover counts against the same dyadic scale.*
6. *C is the finite dyadic cover packet, listing the displayed cover cells, their metric diameter witnesses, and their membership reads.*
7. *S is the cover-sum ledger, recording the finite Real-sealed sum of dyadic diameter weights.*
8. *T is the scale-stability ledger, recording that dyadic refinement reads the same metric source, outer-measure boundary, and box-dimension comparison rows.*
9. *E records componentwise* hsame *transport for metric, dyadic scale, Real seal, outer-measure handoff, box-dimension comparison, cover packet, cover sum, and stability rows.*

10. *K records displayed* Cont *replay from a metric source and dyadic scale through C, S, T, E, P, N.*
11. *P is the* Pkg *provenance over* $\mathsf{HausdorffMeasure}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{OuterMeasure}^{\uparrow}$, $\mathsf{BoxDimension}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, D, R, O, B, C, S, T, E, K, P, N$. It has no coordinate for quotient cover families, selected infima, countable-choice schedules over covers, host sigma-algebras, or ambient measure primitives.

Lean4 ✓ `BEDC.Derived.HausdorffMeasureUp.HausdorffMeasureTasteGate single carrier alignment`

Theorem 4784.2 (Hausdorff measure NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier $H = (M, D, R, O, B, C, S, T, E, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$ *surface consists exactly of metric source admission, dyadic scale exposure, Real value sealing, finite outer-measure handoff, box-dimension scale comparison, finite dyadic cover admission, cover-sum exactness, scale-stability replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every measure-facing or dimension-facing consumer must read the displayed route*

$$\mathsf{Met}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto C, S, T \longmapsto \mathsf{OuterMeasure}^{\uparrow}, \mathsf{BoxDimension}^{\uparrow} \longmapsto E, K, P, N$$

before treating the packet as a Hausdorff-measure read.

Proof. Project the carrier of Definition 5808.1. The metric row M, dyadic row D, and Real seal row R are the only sources for distances, scales, and finite value readback.

The cover packet C and cover-sum ledger S are finite rows. They record displayed cover cells and dyadic diameter weights, so no step selects a minimizing cover family or takes an external infimum.

The outer-measure and box-dimension rows O, B are downstream comparison boundaries. They can read the same finite cover data, but they do not add a completed host measure, a quotient of covers, or countable choice over refinements.

Finally T, E, K, P, N transport, replay, source, and name the same finite route. Since every exported obligation is one of the listed rows, the local classifier cannot expose an ambient measure primitive or any detached cover selector. □

Theorem 4784.3 (Hausdorff measure dyadic-cover stability)**.** *Let $H = (M, D, R, O, B, C, S, T, E, K, P, N)$ be an accepted* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier. For any displayed dyadic refinement of the scale row D, the scale-stability ledger T forces the refined read to reuse the same* $\mathsf{Met}^{\uparrow}$ *source, the same* $\mathsf{Real}^{\uparrow}$ *value-seal route, the same finite* $\mathsf{OuterMeasure}^{\uparrow}$ *cover boundary, and the same* $\mathsf{BoxDimension}^{\uparrow}$ *scale-count comparison before any consumer reads a Hausdorff-measure claim. The stable route is*

$$M, D, R, C, S, T \longmapsto O, B \longmapsto E, K, P, N.$$

It exports no quotient cover family, selected infimum, countable-choice cover schedule, host sigma-algebra closure, or ambient measure primitive.

Proof. Read the carrier of Definition 5808.1. A dyadic refinement changes only the displayed scale request inside D and the finite cover packet admitted by C.

Use the stability ledger T. It records that the refined cover is replayed against the same metric source and that its finite cover sum is sealed through the same Real row, so the refinement cannot introduce a detached minimizing cover or a host infimum.

The comparison rows O and B then read the refined packet as finite outer-measure and box-dimension boundary data. Componentwise transport and displayed replay through E, K, P, N preserve that route, while quotient covers, countable choice, host sigma-algebras, and ambient measure primitives remain absent from the carrier. □

Falsifiable prediction: An accepted $\mathsf{HausdorffMeasure}^{\uparrow}$ consumer that reaches a Hausdorff-measure read without first exposing a MetricUp source row, a DyadicRatCore scale row, a RealUp value seal, a finite dyadic cover packet, a finite cover-sum ledger, an OuterMeasureUp handoff, a BoxDimensionUp comparison row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row refutes the carrier surface.

Independence witness: metric, dyadicratcore, real, outermeasure, boxdimension: $\mathsf{HausdorffMeasure}^{\uparrow}$ is not bijective to any listed sibling because it binds metric diameter data, dyadic scales, Real-sealed finite cover sums, outer-measure cover boundaries, and box-dimension scale counts into one finite cover-stability NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffMeasure}^{\uparrow}$ packet is generated from a MetricUp source row, DyadicRatCore scale row, RealUp value-seal row, finite OuterMeasureUp handoff, BoxDimensionUp comparison row, finite dyadic cover packet, cover-sum ledger, scale-stability ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5808.1, Definition 5808.2, and Definition 5808.3 seed the finite dyadic-cover Hausdorff-measure interface over MetricUp, DyadicRatCoreUp, RealUp, OuterMeasureUp, and BoxDimensionUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.HausdorffMeasureUp.HausdorffMeasureTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim quotient cover families, selected infima, countable choice over covers, host sigma-algebra completion, ambient measure primitives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic scale exposure, finite cover admission, cover-sum exactness, scale-stability replay, outer-measure handoff, box-dimension comparison, transport, provenance, and no-escape for BEDC.Derived.HausdorffMeasureUp.

Chapter 4785

A Concrete Naming Certificate for $\mathsf{LocallyConnected}^{\uparrow}$

Following Kelley and Bourbaki on local connectedness, the $\mathsf{LocallyConnected}^{\uparrow}$ packet records finite neighbourhood-component data rather than a selected basis of connected open sets. It sits beside the global connectedness carrier of chapter 2353, the compact metric source discipline of chapter 129, the metric ball rows of chapter 57, and the open-neighbourhood ledger of chapter 88. The packet exposes the local component route needed by compact-metric and connected-space consumers without importing path selection, arc connectedness, open-cover compactness, or a host topological basis.

Definition 4785.1 (Locally connected carrier)**.** *A* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (T, M, G, K, B, C, H, R, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *open-neighbourhood row whose entries name the ambient open requests.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *ball-observation row used when the local request is metric.*
3. *G is the* $\mathsf{ConnectedSpace}^{\uparrow}$ *global component row available to consumers that compare local and global connectedness.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-source row available to compact-metric consumers.*
5. *B is the finite neighbourhood-refinement row: each displayed point and open request has a named smaller neighbourhood row.*
6. *C is the local connected-component row attached to the refinement in B.*
7. *H records componentwise* hsame *transport for the topology, metric, connectedness, compact-metric, refinement, component, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from an ambient open request through metric ball observations when present, the finite refinement row, and the local component row.*
9. *P is the* Pkg *provenance over* $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ConnectedSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, M, G, K, B, C, H, R, P, N$. It has no coordinate for selected paths, arcs, arbitrary open-cover compactness, quotient component spaces, or a host basis of connected neighbourhoods.

Lean4 ✓ `BEDC.Derived.LocallyConnectedUp.TasteGate.LocallyConnectedTasteGate single carrier alignment`

Theorem 4785.2 (Locally connected NameCert obligations)**.** *For every accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier* $L = (T, M, G, K, B, C, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$ *surface consists exactly of carrier admission for the topology, metric, connected-space, compact-metric, finite neighbourhood-refinement, local component, transport, replay, provenance, and naming rows; neighbourhood refinement from T through B; component exposure through C; metric compatibility through M when the request is ball-based; compact-metric compatibility through K for compact finite-source consumers; connected-space comparison through G; and non-escape from selected paths, arcs, arbitrary open-cover compactness, quotient component spaces, and host basis choice.*

Proof. Project the carrier of Definition 5809.1. The projection exposes exactly the rows $T, M, G, K, B, C, H, R, P, N$ so every local naming obligation must be read from those coordinates.

The neighbourhood part is finite. An ambient open request is first read in T, then refined by the displayed row B, and only then receives the local component row C.

The metric and compact-metric rows are compatibility rows rather than extra selectors. A ball-based request may inspect M, and a compact-metric consumer may inspect K, but both routes still pass through the same B and C rows before local connectedness is exported.

Finally, H and R transport and replay the displayed route, while P and N source and name it. Since paths, arcs, arbitrary open-cover compactness, quotient component spaces, and host basis choice are not rows of the carrier, the NameCert surface cannot export them. □

Theorem 4785.3 (Locally connected neighbourhood component route)**.** *Every connected-space or compact-metric consumer of an accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *packet reaches local connectedness through*

$$\mathsf{Topology}^{\uparrow},\quad \mathsf{Met}^{\uparrow},\quad \mathsf{ConnectedSpace}^{\uparrow},\quad \mathsf{CompactMetric}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

The finite route reads an ambient neighbourhood, optionally reads metric ball observations, refines to a displayed smaller neighbourhood, and then reads the named local connected component. It does not select a path, an arc, a subcover, a quotient component representative, or a host connected-neighbourhood basis.

Proof. Start with a consumer that asks for local connectedness around a displayed point. Carrier admission gives the consumer the topology row T, the metric row M when a ball observation is part of the request, the global connectedness row G, and the compact-metric row K.

The route then passes through B and C. The row B supplies the finite neighbourhood refinement, and C supplies the local component attached to that refinement.

The structural rows H, R, P, N do not add a hidden selector. They transport, replay, source, and name the same finite route, so no path, arc, arbitrary subcover, quotient representative, or host basis can replace the displayed neighbourhood-component data. □

Theorem 4785.4 (Locally connected obligation closure surface)**.** *For every accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier* $L = (T, M, G, K, B, C, H, R, P, N)$*, the obligation-closure surface is exhausted by the displayed finite topology, metric, connected-space, compact-metric, neighbourhood-refinement, local-component, transport, replay, provenance, and naming rows. The row T supplies the open-neighbourhood*

source, M supplies metric-ball observations, G supplies connected-space comparison, K supplies compact-metric finite-source compatibility, B, C supply the local refinement and component rows, and H, R, P, N supply transport, replay, provenance, and local naming.

The local component route therefore consumes the connected-space carrier of chapter 2353, the compact-metric finite neighbourhood discipline of chapter 129, the metric-ball rows of chapter 57, and the topology neighbourhood ledger of chapter 88 before a local component can be named.

Proof. Apply Definition 5809.2 to the accepted carrier. It identifies the complete NameCert surface with the rows $T, M, G, K, B, C, H, R, P, N$.

Apply Definition 5809.3. The route from an open request to a local component passes through topology, optional metric-ball observations, connected-space comparison, compact-metric compatibility, finite refinement, and component rows before the structural rows transport and name the result.

The sibling lattice is read in that order: topology supplies the neighbourhood ledger, metric supplies ball observations, connected-space supplies the comparison carrier, and compact metric supplies the finite neighbourhood discipline. The local refinement and component rows then bind those sibling contributions into the $\mathsf{LocallyConnected}^{\uparrow}$ packet.

Thus the obligation surface is the stated finite route. Path or arc selection, open-cover compactness, quotient components, and a host basis are refused because none of them is a carrier coordinate or a row used by the two preceding theorems. □

Falsifiable prediction: Every accepted $\mathsf{LocallyConnected}^{\uparrow}$ read must expose a $\mathsf{Topology}^{\uparrow}$ open-neighbourhood row, optional $\mathsf{Met}^{\uparrow}$ ball observations, the $\mathsf{ConnectedSpace}^{\uparrow}$ comparison row when a global consumer is present, the $\mathsf{CompactMetric}^{\uparrow}$ finite-source row when a compact-metric consumer is present, a finite neighbourhood-refinement row, a local component row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: topology, metric, connected-space, compactmetric: $\mathsf{LocallyConnected}^{\uparrow}$ is not bijective to any listed sibling because it binds a local neighbourhood-refinement row to a local component row before connected-space or compact-metric consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5809.1, Definition 5809.2, and Definition 5809.3 seed the finite local neighbourhood-component route over topology, metric, connected-space, and compact-metric rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close path connectedness, arc connectedness, arbitrary open-cover compactness, quotient component spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, neighbourhood refinement, local component exposure, connected-space comparison, compact-metric compatibility, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.LocallyConnectedUp.

Constructive story: A $\mathsf{LocallyConnected}^{\uparrow}$ packet is generated from an open-neighbourhood row, optional metric ball observations, connected-space and compact-metric compatibility rows, a finite neighbourhood-refinement row, a local component row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 4786

A Concrete Naming Certificate for $\mathsf{BishopCauchyMean}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, the $\mathsf{BishopCauchyMean}^{\uparrow}$ packet records the finite averaging step used when a Cauchy source is read through displayed rational windows and sealed as a Real-facing name. It sits after the $\mathsf{Cauchy}^{\uparrow}$ source route of chapter 3413, the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names finite averages of observed Cauchy data; it does not assert a selected limit, quotient stream equality, host real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4786.1 (Bishop Cauchy mean carrier)**.** *A* $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, D, W, R, A, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Cauchy}^{\uparrow}$ *source row naming the Cauchy data whose finite observations are being averaged.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the requested dyadic radius, denominator budget, and comparison scale for the average.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing exactly the source entries inspected at tolerance D.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the inspected stream window into regular rational data.*
5. *A is the finite averaging ledger: it lists the inspected rational entries, their displayed weights, the denominator row, the partial-sum row, and the final mean row consumed by the certificate.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, W, R, A have been displayed.*
7. *H records componentwise* hsame *transport for the source, tolerance, window, readback, averaging ledger, Real seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a finite mean request through $S, D, W, R, A, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyMean}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $S, D, W, R, A, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, host real equality, countable choice, ambient completeness of $\mathsf{Real}^{\uparrow}$*, or an infinite averaging oracle.*

Lean4 ✓ `BEDC.Derived.BishopCauchyMeanUp.BishopCauchyMeanTasteGate single carrier alignment`

Theorem 4786.2 (Bishop Cauchy mean NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier*

$$M = (S, D, W, R, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$ *surface consists exactly of carrier admission for the Cauchy source row, dyadic tolerance row, finite stream window, regular rational readback, finite averaging ledger, terminal Real seal, componentwise transport row, displayed continuation replay, package provenance, and local naming row.*

The obligation surface requires Cauchy-source visibility through S, tolerance accounting through D, finite-window visibility through W, regular rational readback through R, average-ledger exactness through A, Real-seal nonescape through E, transport and replay stability through H and C, provenance through P, and local naming through N. It refuses selected limits, quotient stream equality, host real equality, countable choice, and ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the accepted carrier of Definition 5810.1. The only analytic rows are the Cauchy source S, the dyadic tolerance D, the finite window W, the regular rational readback R, the averaging ledger A, and the terminal Real seal E.

The averaging step is finite. The ledger A displays the inspected rational entries, their weights, the denominator row, the partial sums, and the final mean; no later consumer can ask for an average outside this listed window.

The terminal seal is downstream of the displayed route. Since the carrier has no coordinate for quotient stream equality, a selected limit, host real equality, countable choice, ambient completeness, or an infinite averaging oracle, those objects cannot enter the local NameCert surface.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. They preserve the displayed rows and do not add analytic content. □

Theorem 4786.3 (Bishop Cauchy mean finite-average stability)**.** *Let*

$$M = (S, D, W, R, A, E, H, C, P, N)$$

be an accepted $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier. Every accepted consumer read of the mean row factors through the finite route*

$$\mathsf{Cauchy}^{\uparrow}(S),\ \mathsf{DyadicRatCore}^{\uparrow}(D),\ \mathsf{StreamName}^{\uparrow}(W),\ \mathsf{RegSeqRat}^{\uparrow}(R),\ A,\ \mathsf{Real}^{\uparrow}(E).$$

If the source row, tolerance row, finite window, readback row, and averaging ledger are transported componentwise by the displayed hsame *rows in H and replayed through C, then the consumer-visible mean row is unchanged as a* $\mathsf{BishopCauchyMean}^{\uparrow}$ *read. No quotient stream equality, selected limit, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row participates in the stability claim.*

Proof. Start with the consumer route. By the carrier definition, a mean read must first inspect the Cauchy source S, choose the displayed dyadic tolerance D, open the finite window W, and read the regular rational row R.

The average itself is then the ledger row A. Its entries, weights, denominator, partial sums, and final mean are finite displayed data, so componentwise hsame transport preserves exactly the rows that the consumer can inspect.

Replay through C exposes the transported packet with the same provenance and local naming rows P, N. The terminal Real seal E is reached from that transported finite route, not from a quotient stream or selected limit.

Thus any consumer-visible equality of mean reads is exhausted by $S, D, W, R, A, E, H, C, P, N$. The excluded rows are absent from the carrier and cannot affect the stability conclusion. □

Falsifiable prediction: Every accepted $\mathsf{BishopCauchyMean}^{\uparrow}$ read must expose a Cauchy source, dyadic tolerance, StreamName window, RegSeqRat readback, finite averaging ledger, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a Real or Completion consumer can read the mean boundary.

Independence witness: cauchy, dyadicratcore, streamname, regseqrat, real: $\mathsf{BishopCauchyMean}^{\uparrow}$ is not bijective to any listed sibling because it binds a finite averaging ledger between regular rational readback and the Real seal.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyMean}^{\uparrow}$ packet is generated from a Cauchy source row, DyadicRatCore tolerance row, StreamName finite window, RegSeqRat readback, finite averaging ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5810.1, Definition 5810.2, and Definition 5810.3 seed the finite Cauchy-mean certificate over Cauchy, DyadicRatCore, StreamName, RegSeqRat, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite average ledger exactness, tolerance-window readback, regular rational handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyMeanUp.

Chapter 4787

A Concrete Naming Certificate for $\mathsf{BishopFixedPointInterval}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopFixedPointInterval}^{\uparrow}$ packet records the constructive interval fixed-point route as finite NameCert data. It sits after the located interval source of chapter 394, the bisection discipline of chapter 1465, the finite Cauchy-modulus rows used by chapter 292, the regular rational readback of chapter 301, the finite name windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the fixed-point certificate for a displayed interval self-map; it does not import a host compactness theorem, quotient real equality, choice-selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4787.1 (Bishop fixed-point interval carrier)**.** *A* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, T, M, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the closed located interval, its endpoint reads, and its dyadic radius ledger.*
2. *T is the contraction self-map row over I, recording that every admitted interval point is sent back into the same located interval.*
3. *M is an explicit* $\mathsf{CauchyModulus}^{\uparrow}$ *or Lipschitz modulus row that turns each tolerance request into a finite contraction budget.*
4. *B is the* $\mathsf{IntervalBisection}^{\uparrow}$ *or nested located interval row that records the displayed shrinking interval chain.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the rational midpoint, endpoint, and radius observations.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *fixed-point seal reached only after the interval, contraction, modulus, bisection, and readback rows have been exposed.*
7. *H records componentwise* hsame *transport for I, T, M, B, R, E and for the structural rows.*
8. *C records displayed* Cont *replay for interval requests, contraction reads, modulus reads, nested interval reads, rational readback, and real-seal requests.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopFixedPointInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{IntervalBisection}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, T, M, B, R, E, H, C, P, N$. It has no coordinate for a host fixed-point theorem, quotient completion, selected limit, trichotomy, countable choice, or ambient compactness principle.

Lean4 ✓ `BEDC.Derived.BishopFixedPointIntervalUp.BishopFixedPointIntervalTasteGate single carrier alignment`

Theorem 4787.2 (Bishop fixed-point interval NameCert obligations)**.** *For every accepted* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *carrier*

$$F = (I, T, M, B, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}$ *surface consists exactly of carrier admission for the located interval row I, contraction self-map row T, explicit modulus row M, nested bisection row B, regular rational readback row R, terminal real seal E, componentwise transport row H, displayed replay row C, provenance row P, and local naming row N. Every fixed-point consumer must read these rows in the displayed order and cannot replace them by host interval compactness, quotient real equality, a selected limit, or an unrecorded convergence principle.*

Proof. Carrier admission is the finite packet of Definition 5811.1. The rows $I, T, M, B, R, E, H, C, P, N$ are the only coordinates available to the local certificate.

The positive interval route is then forced. The interval source is I, the self-map evidence is T, the contraction budget is M, and the nested interval chain is B; each row is compared only through the componentwise transport row H and replayed only through C.

The readback and seal are downstream. Rational observations pass through R and the dyadic and stream-name data named in P before the terminal $\mathsf{Real}^{\uparrow}$ row E is exposed. Since no host compactness, quotient equality, selected limit, or external convergence coordinate occurs in the carrier, the listed rows exhaust the NameCert surface. □

Theorem 4787.3 (Bishop fixed-point interval Cauchy-modulus route)**.** *Let $F = (I, T, M, B, R, E, H, C, P, N)$ be an accepted* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *packet. Each tolerance request for the fixed-point name is answered by first reading the* $\mathsf{LocatedInterval}^{\uparrow}$ *row I, then the contraction self-map row T, then the explicit* $\mathsf{CauchyModulus}^{\uparrow}$ *or Lipschitz row M, and only then the* $\mathsf{IntervalBisection}^{\uparrow}$ *or nested located interval row B. The resulting finite observations are read through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *as recorded by P, so no consumer can infer convergence from an unbounded host iteration or a choice-selected subsequence.*

Proof. Start with a tolerance request. The packet has no direct convergence row, so the request must project I to know the interval source and T to know that the displayed map remains inside the interval.

Next read the modulus row M. This row converts the tolerance into a finite contraction or Lipschitz budget. The nested row B can then expose only the finite bisection or located-interval observations licensed by that budget.

Finally use the readback rows listed in P. Stream windows, dyadic tolerances, and regular rational observations feed R, and H, C, N transport and name the same route. Thus the Cauchy route is explicit and finite, with no unbounded host iteration or selected subsequence. □

Theorem 4787.4 (Bishop fixed-point interval real-seal nonescape)**.** *For every accepted* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *packet, the terminal row* E *is exposed only as the* $\mathsf{Real}^{\uparrow}$ *seal of the displayed nested interval and Cauchy-modulus route*

$$I, T, M, B, R \longmapsto E \longmapsto H, C, P, N.$$

The seal may be consumed as the named fixed-point endpoint of the packet, but it cannot escape as quotient real equality, a proof of ambient $\mathsf{Real}^{\uparrow}$ *completeness, a host fixed-point theorem, an unrestricted interval compactness principle, or a selected representative outside the displayed rows.*

Proof. Read E from the carrier. It is terminal in the packet: the interval, self-map, modulus, nested interval, and rational readback rows precede it, and the structural rows only transport, replay, source, and name the resulting read.

Apply Definition 5811.3. Every tolerance request reaching E has already passed through the finite interval, contraction, modulus, bisection, stream, dyadic, and regular rational observations recorded by I, T, M, B, R, P.

It remains to rule out escape. The carrier has no coordinate for quotient real equality, ambient completeness, a host fixed-point theorem, unrestricted compactness, or selected representatives. Therefore E seals only the displayed fixed-point name of this packet. □

Falsifiable prediction: An accepted $\mathsf{BishopFixedPointInterval}^{\uparrow}$ consumer that reaches the terminal $\mathsf{Real}^{\uparrow}$ row E without first reading $I, T, M, B, R, H, C, P, N$ refutes the carrier surface.

Independence witness: locatedinterval, intervalbisection, cauchymodulus, regseqrat, streamname, dyadicratcore, real: no listed sibling supplies the full interval self-map packet $F = (I, T, M, B, R, E, H, C, P, N$ because each sibling contributes only a located interval source, a bisection route, a modulus row, a readback row, a finite name window, a dyadic ledger, or a terminal real seal while this chapter binds them into one fixed-point NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopFixedPointInterval}^{\uparrow}$ packet is generated from a located interval row, contraction self-map row, explicit Cauchy or Lipschitz modulus row, nested bisection row, regular rational readback row, terminal Real seal, componentwise transport, displayed replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5811.1, Definition 5811.2, Definition 5811.3, and Definition 5811.4 seed the finite constructive interval fixed-point route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host fixed-point compactness, quotient real equality, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction self-map admission, explicit modulus routing, nested interval readback, terminal Real seal nonescape, and a Lean carrier/obligation formalization for BEDC.Derived.BishopFixedPointIntervalUp.

Chapter 4788

A Concrete Naming Certificate for $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$

The $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ packet realizes the private-coordinate minimal-cover theorem of Definition 9462.1678 as finite NameCert data. It records a trigger-coordinate carrier, a support-family cover ledger, and one private-coordinate witness row for each displayed support before any minimal-trigger criterion may be consumed. The packet keeps the enumeration theorem auditable without identifying it with a generic finite set, word list, Boolean classifier, regular-language recognizer, or finite automaton presentation.

Falsifiable prediction: Every accepted $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ consumer must display a cover row and one private-coordinate witness row for each support before using the minimal-trigger criterion.

Independence witness: finset, list, bool, regularlanguage, finite-automaton: $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ is not bijective to these siblings because it carries a support-family cover ledger plus a private-coordinate witness for every support row.

Definition 4788.1 (Private-coordinate trigger carrier)**.** *A* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the finite trigger-coordinate row.*
2. A *is the finite support-family row whose entries are displayed subsets of* Ω*.*
3. U *is the cover ledger asserting that the displayed supports cover every coordinate of* Ω*.*
4. V *is the private-coordinate witness ledger, with one row for each support in* A*.*
5. π *maps each support row to its selected private coordinate and records membership in that support.*
6. E *records exclusion from every other support row for the selected private coordinate.*
7. K *is the minimal-cover criterion row, readable only after* U, V, π, E *have been displayed.*
8. H *stores componentwise* hsame *transport for coordinate, support, cover, witness, exclusion, and criterion rows.*

9. *C stores* Cont *replay from a trigger query through the cover ledger and the private-coordinate witness rows.*
10. *P stores* Pkg *provenance over* BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $\Omega, A, U, V, \pi, E, K, H, C, P, N$. It has no coordinate for a bare finite set, unordered list, Boolean truth table, regular-language recognizer, finite automaton run, or support family without displayed private witnesses.

Theorem 4788.2 (Private-coordinate trigger NameCert obligations)**.** *For every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier*

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$ *surface consists exactly of coordinate exposure, support-family exposure, cover-ledger replay, one private-coordinate witness row for each support, membership and exclusion checks for the selected witnesses, minimal-cover criterion exposure, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Project the carrier of Definition 5812.1. The rows Ω, A, U display the finite coordinate space, the support family, and the fact that the supports cover the full coordinate row.

The rows V, π, E attach a private coordinate to each support. Membership is recorded by π, and exclusion from every other support is recorded by E, so deleting the support removes at least one displayed coordinate from the cover.

The criterion row K is therefore readable only after the cover and private-witness rows have been exposed. The remaining rows H, C, P, N preserve transport, replay, provenance, and local naming for the same finite packet, and no omitted sibling surface supplies the private-coordinate ledger. □

Theorem 4788.3 (Private-coordinate minimal-cover criterion)**.** *Every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier exposes a minimal full trigger exactly through the displayed cover row U together with the private-coordinate witness rows V, π, E. A consumer may use the criterion row K only after reading a cover of Ω and one witness coordinate for every support row in A that belongs to that support and belongs to no other displayed support. The packet does not turn the support family into a regular language, finite automaton, Boolean table, or list quotient.*

Proof. The forward read uses the cover ledger U and the private-coordinate witness rows. If a support row is removed, its selected witness coordinate remains outside all other displayed supports by E, so the remaining family no longer covers Ω.

For the reverse read, the cover row already gives full coverage. The witness rows ensure that every support has a coordinate lost by deleting that support, so no displayed support is redundant.

Thus the criterion row K is exactly the finite private-coordinate minimal-cover test. The transport, replay, provenance, and local naming rows carry this test without converting it into any sibling classifier. □

Theorem 4788.4 (Private-coordinate trigger finite-set cover route)**.** *Every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *packet reads its support-family row as a finite-set-indexed cover through chapter 112. The exclusions from regular-language and automaton presentations are bounded by chapter 351 and chapter 2364: the private-coordinate carrier may display finite support rows, recognizer-like acceptance tests, or transition-like exclusion checks, but it exports the minimal-cover criterion only through the rows $\Omega, A, U, V, \pi, E, K, H, C, P, N$.*

Proof. Project the accepted carrier

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N).$$

The row Ω is the displayed coordinate object, and A is read as a finite family of supports indexed by the finite-set surface. The cover ledger U then witnesses coverage of every coordinate in Ω by those displayed supports.

The rows V, π, E are the extra private-coordinate ledger. They attach one witness coordinate to each support, record membership in that support, and record exclusion from every other displayed support. These rows are not supplied by the finite-set sibling, nor by the regular-language or finite-automaton presentations.

Consequently K is a private-coordinate minimal-cover read rather than a bare finite-set cover, a regular-language recognizer, or an automaton acceptance predicate. The structural rows H, C, P, N transport and replay only this displayed packet, so the sibling route records the finite-combinatorial surface without replacing the private-coordinate data. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$.

Constructive story: A $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ packet is generated from a finite trigger-coordinate row, support-family row, cover ledger, per-support private-coordinate witness ledger, membership and exclusion rows, minimal-cover criterion row, componentwise transport, continuation replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5812.1, Definition 5812.2, Definition 5812.3, and Definition 5812.4 seed the finite NameCert packet for private-coordinate minimal-cover witnesses.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, regular-language recognition, finite-automaton minimization, Boolean classifier completeness, or enumeration beyond the displayed private-coordinate criterion.

Upgrade path: Obligation closure requires checked carrier admission, cover-ledger replay, private-coordinate witness coverage, exclusion exactness, minimal-cover criterion replay, TasteGate nontriviality, FieldFaithful projection, transport, replay, provenance, and local naming for BEDC.Derived.PrivateCoordinateTriggerUp.

Chapter 4789

A Concrete Naming Certificate for $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet records the finite modulus by which a located real comparison request is read through displayed apartness or equality evidence, dyadic tolerances, explicit Cauchy-modulus schedules, regular rational readback, and the terminal real-name seal. It sits after the comparison surface of chapter 1730, the tail envelope of chapter 1769, the Cauchy-modulus bridge of chapter 5728, the rational readback of chapter 301, and the public real route of chapter 38. The packet names a finite comparison-schedule carrier; it is not trichotomy, quotient real equality, a selected representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4789.1 (Located real comparison modulus carrier)**.** *A* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, A, D, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{LocatedRealComparison}^{\uparrow}$ *request row for the two located real endpoints and the comparison direction being inspected.*
2. *A is the located evidence row. It records the displayed positive apartness witness when the request separates the endpoints, or the displayed equality-facing refusal row when the request reaches only an overlap tolerance.*
3. *D is the dyadic tolerance schedule. It lists the requested precision, comparison slack, endpoint radii, and finite tolerance refinements consumed by the comparison read.*
4. *B is the* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *route connecting the comparison request to an explicit Cauchy-modulus schedule before regular rational readback is allowed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected rational tails exposed by B and bounded by D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the comparison-facing read, available only after Q, A, D, B, R have been displayed.*
7. *H records componentwise* hsame *transport for the comparison request, evidence row, dyadic tolerance schedule, bridge route, readback, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from the comparison request through located evidence, dyadic scheduling, Cauchy-modulus bridging, regular rational readback, and Real sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$, $\mathsf{LocatedRealComparison}^{\uparrow}$, LocatedRealTailEnvelop $\mathsf{CauchyModulusBridge}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, A, D, B, R, E, H, C, P, N$. It has no coordinate for trichotomy, quotient real equality, a hidden selector, countable choice, a host comparison oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedRealComparisonModulusUp.LocatedRealComparisonModulusTasteGate`
`single carrier alignment`

Theorem 4789.2 (Located real comparison modulus obligations)**.** *For every accepted* LocatedRealComparisonModu *carrier*

$$M = (Q, A, D, B, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$ *surface consists exactly of comparison-request admission, located apartness-or-equality evidence, dyadic tolerance scheduling,* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *routing,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any consumer of the comparison schedule must read those rows in the displayed order and receives no trichotomy split, quotient real equality, hidden selector, countable-choice schedule, host comparison oracle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier of Definition 5813.1. The comparison request is Q, and the only evidence row attached to it is A.

The schedule is then forced through D and B. The dyadic row D records the finite tolerances to be inspected, while the $\mathsf{CauchyModulusBridge}^{\uparrow}$ row B turns those tolerance requests into explicit tail thresholds before any rational readback is exposed.

The terminal read is downstream. The regular rational row R reads only the displayed tails opened by B, and the $\mathsf{Real}^{\uparrow}$ seal E is available only after that readback.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the carrier has no coordinate for the excluded host-level or choice-level objects, the listed rows exhaust the local NameCert surface. □

Theorem 4789.3 (Located real comparison modulus nontrichotomy boundary)**.** *Every accepted* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ *packet exports a positive schedule for comparison reads without exporting trichotomy. If the evidence row A records positive apartness, a downstream consumer may read that apartness only through Q, D, B, R, E; if A records only an equality-facing overlap tolerance, the consumer receives the displayed tolerance route and no forced left-or-right order verdict.*

Proof. Read the evidence row A together with the comparison request Q. The carrier does not contain a three-way order coordinate, so the two possible reads are positive displayed apartness or finite overlap tolerance.

For the positive branch, the dyadic tolerance row D and bridge row B determine which tails are inspected before R and E can be consumed. The apartness read is therefore a finite schedule read, not a global order split.

For the overlap branch, the same schedule exposes only the inspected tolerance data. Since no trichotomy coordinate or hidden selector appears in $M = (Q, A, D, B, R, E, H, C, P, N)$, the packet refuses any forced left-or-right verdict not displayed by the rows. □

Falsifiable prediction: An accepted $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet is refuted if a comparison consumer reaches the $\mathsf{Real}^{\uparrow}$ seal while omitting the $\mathsf{LocatedRealComparison}^{\uparrow}$ request row Q, the evidence row A, the dyadic tolerance schedule D, the $\mathsf{CauchyModulusBridge}^{\uparrow}$ route B, or the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Independence witness: LocatedRealComparison, LocatedRealTailEnvelope, CauchyModulusBridge, RegSeqRat, Real: none is bijective with $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ because the packet jointly carries a comparison request, apartness-or-equality evidence, dyadic tolerance scheduling, explicit Cauchy-modulus bridging, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet is generated from a LocatedRealComparison request row, located apartness-or-equality evidence, a dyadic tolerance schedule, a CauchyModulusBridge route, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5813.1, Definition 5813.2, and Definition 5813.3 seed the finite comparison-modulus route over LocatedRealComparisonUp, LocatedRealTailEnvelopeUp, CauchyModulusBridgeUp, RegSeqRatUp, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected representatives, countable choice, host comparison oracles, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, evidence-row exactness, dyadic schedule determinacy, Cauchy-modulus bridge routing, regular rational readback, Real-seal confinement, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealComparisonModulusUp.

Chapter 4790

A Concrete Naming Certificate for $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$

The $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet realizes the boundary-shadow and observer-expansion route of chapter 9463 as finite cocycle-level NameCert data. It sits after the boundary-shadow route of chapter 3813, the observer-shadow metric of chapter 4154, the Busemann cocycle of chapter 4134, the horosphere-flow ledger of chapter 4051, and the observer-expansion packet of chapter 4167. The chapter names a finite expansion cocycle over displayed boundary and horosphere rows; it is not a completed hyperbolic boundary, quotient geodesic ray space, physical observer dynamics, selected ideal point, or ambient manifold theorem.

Definition 4790.1 (Boundary-shadow expansion cocycle carrier)**.** *A* $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, O, B, F, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row recording the visible boundary shadow through which the cocycle is read.*
2. *O is the* $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$ *row recording the observer-facing shadow metric comparison for the same boundary read.*
3. *B is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *row recording the additive Busemann comparison consumed by the expansion read.*
4. *F is the* $\mathsf{HorosphereFlowLedger}^{\uparrow}$ *row recording the horosphere-flow level through which boundary and Busemann rows are replayed.*
5. *E is the* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *row recording the displayed observer-expansion magnitude or direction attached to S, O, B, F.*
6. *H records componentwise* hsame *transport for boundary shadow, observer-shadow metric, Busemann cocycle, horosphere-flow ledger, observer expansion, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through boundary-shadow admission, observer-shadow metric readback, Busemann cocycle comparison, horosphere-flow ledger inspection, and observer-expansion read.*

8. *P is the* Pkg *provenance over* $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HorosphereFlowLedger}^{\uparrow}$, HyperbolicObserverExp BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, O, B, F, E, H, C, P, N$. It has no coordinate for completed boundary points, quotient geodesic rays, a hidden expansion selector, physical observer dynamics, selected ideal endpoints, or ambient hyperbolic manifold data.

Theorem 4790.2 (Boundary-shadow expansion cocycle NameCert obligations)**.** *For every accepted* $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ *carrier*

$$X = (S, O, B, F, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}$ *surface consists exactly of boundary-shadow admission, observer-shadow metric readback, Busemann cocycle comparison, horosphere-flow ledger inspection, observer-expansion read, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any accepted expansion read that omits either the boundary-shadow row S or the Busemann cocycle row B is outside the packet.*

Proof. Project the carrier of Definition 5814.1. The boundary-facing rows are S and O, while the cocycle and horosphere-flow rows are B and F.

The expansion row E is downstream from those four rows. It can be read only after the visible boundary shadow, observer-shadow metric, Busemann cocycle, and horosphere-flow ledger have all been displayed.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for completed boundary data, quotient geodesic rays, hidden selectors, physical observer dynamics, selected endpoints, or ambient manifold structure, the listed rows exhaust the local NameCert surface. □

Theorem 4790.3 (Boundary-shadow expansion cocycle dependency route)**.** *Every accepted* BoundaryShadowExpan *read factors through*

$\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, HorosphereFlowLed

before a consumer may inspect the expansion cocycle as a local NameCert row. The route is finite and preserves the boundary-shadow row and Busemann cocycle row as separate coordinates.

Proof. Use Definition 5814.2. It places the boundary-shadow row, observer-shadow metric row, Busemann cocycle row, and horosphere-flow ledger before the expansion row.

The cocycle dependency is not reducible to one sibling. The boundary-shadow row supplies the boundary face, the observer-shadow metric supplies the observer-facing comparison, the Busemann row supplies the additive cocycle read, and the horosphere-flow row supplies the level ledger.

Only after those rows are present can E, H, C, P, N expose the expansion cocycle as a local packet. Therefore a consumer cannot collapse the route to a single hyperbolic object or bypass the separate boundary-shadow and Busemann coordinates. □

Falsifiable prediction: Any accepted $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet is refuted if the expansion read omits either the boundary-shadow row S or the Busemann cocycle row B.

Independence witness: hyperbolic_boundary_shadow, hyperbolic_observer_shadow_metric, hyperbolic_busemann_cocycle, horosphere_flow_ledger, hyperbolic_observer_expansion: none

is bijective with $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ because the packet jointly carries boundary shadow, observer-shadow metric, Busemann cocycle, horosphere-flow level, observer expansion, transport, replay, provenance, and local naming.

The Lean TasteGate route for this packet must provide `Nontrivial BoundaryShadowExpansionCocycleUp` and `FieldFaithful BoundaryShadowExpansionCocycleUp` instances in `lean4/BEDC/Derived/BoundaryShadowE` Those instances must preserve $S, O, B, F, E, H, C, P, N$ as distinct fields before a checked carrier-alignment theorem can serve as the TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet is generated from HyperbolicBoundaryShadow rows, HyperbolicObserverShadowMetric rows, HyperbolicBusemannCocycle rows, HorosphereFlowLedger rows, HyperbolicObserverExpansion rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5814.1, Definition 5814.2, and Definition 5814.3 seed the finite boundary-shadow expansion cocycle route over boundary, observer-shadow, Busemann, horosphere-flow, expansion, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic boundaries, quotient geodesic ray spaces, physical observer dynamics, selected ideal endpoints, ambient manifold theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-shadow exactness, observer-shadow metric readback, Busemann cocycle separation, horosphere-flow routing, observer-expansion exposure, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.BoundaryShadowExpansionCocycleUp.

The $\mathsf{HellyBraySelection}^{\uparrow}$ hub routes bounded-variation selection through chapter 398, chapter 2069, chapter 301, chapter 126, and chapter 38 before the child files expose the finite selection packet.

Chapter 4791

A Concrete Naming Certificate for $\mathsf{HellyBraySelection}^{\uparrow}$

Following Helly and Bray, the $\mathsf{HellyBraySelection}^{\uparrow}$ packet records the finite selection surface by which bounded-variation source data are read through Jordan signed-variation rows, finite stream windows, regular rational readback, and terminal real seals before a downstream selection consumer may use the packet. It sits after the bounded-variation carrier of chapter 398, the Jordan variation decomposition rows of chapter 2069, the regular rational readback route of chapter 301, the finite observation windows of chapter 126, and the terminal real-name boundary of chapter 38. Helly–Bray selection also feeds distribution-facing compactness through chapter 186, chapter 92, and chapter 4008 when the bounded-variation read is consumed as a tight probability-family route. The chapter names a finite BEDC selection packet, not host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4791.1 (Helly–Bray selection carrier)**.** *A* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, J, S, R, E, T, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BoundedVariation}^{\uparrow}$ *source row, carrying the bounded-variation object, finite variation ledger, and endpoint budget exposed to the selection request.*
2. *J is the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *row, displaying the signed-variation split and the positive and negative variation rows read from B.*
3. *S is the family of* $\mathsf{StreamName}^{\uparrow}$ *finite windows opened by the inspected variation rows and by the downstream Real-facing request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows, recording the rational comparisons used before any Real seal is visible.*
5. *E is the finite family of* $\mathsf{Real}^{\uparrow}$ *seal rows reached only after B, J, S, R have been displayed.*
6. *T records componentwise* hsame *transport for the bounded-variation source, Jordan rows, finite windows, readbacks, Real seals, continuation, provenance, and local naming.*
7. *C records displayed* Cont *replay from bounded-variation data through Jordan signed-variation rows, finite windows, regular rational readback, Real seals, transport, provenance, and local naming.*

8. *P is the* Pkg *provenance over* $\mathsf{HellyBraySelection}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{JordanVariationDecomposition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, J, S, R, E, T, C, P, N$. The carrier has no coordinate for host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4791.2 (Helly–Bray selection NameCert obligations)**.** *For every accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier*

$$H = (B, J, S, R, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the bounded-variation source row, Jordan signed-variation decomposition row, StreamName finite windows, RegSeqRat readback row, Real seal rows, transport, replay, provenance, and local naming;*
2. *variation-source exposure, requiring every selection-facing read to begin with B and then pass through the signed-variation rows J rather than through a host weak-convergence theorem;*
3. *finite-window locality, requiring S to list the exact stream windows opened by the variation rows and the Real-facing request;*
4. *readback ordering, requiring R to consume the displayed windows in S before any row of E is exposed;*
5. *componentwise transport, displayed replay, provenance, and local naming for the same rows through T, C, P, N;*
6. *nonescape, excluding host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No Helly–Bray selection obligation is stored outside these rows.

Proof. Project the accepted carrier. The only source coordinate is the bounded-variation row B, and the only signed-variation coordinate is the Jordan row J.

The finite observation surface is then forced by row order. The StreamName windows S are opened from the displayed variation rows, the RegSeqRat readback R reads only those windows, and the Real seals E appear only after that readback has been displayed.

Transport and replay preserve the same route componentwise through T and C. Provenance P and local naming N record that route as the local certificate surface.

Since none of the excluded objects occurs as a carrier coordinate, a consumer cannot add weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient Real completeness to the local NameCert obligations. □

Theorem 4791.3 (Helly–Bray selection finite-window route)**.** *Every Real-facing or variation-facing consumer of an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier factors its read through*

$$\mathsf{BoundedVariation}^{\uparrow} \longmapsto \mathsf{JordanVariationDecomposition}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto T, C, P, N.$$

Thus the consumer receives bounded-variation source data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, componentwise transport, continuation replay, provenance, and local naming. The route supplies no host weak convergence, measure completion, quotient function equality, selected subsequence, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the carrier $H = (B, J, S, R, E, T, C, P, N)$. The first projection gives the bounded-variation source row B, and the next projection gives the Jordan signed-variation row J over that source.

The finite-window part is local. The windows S are the only observation rows available to the packet, and R is the only regular rational readback attached to those windows.

The Real-facing boundary is reached only at E. The remaining rows T, C, P, N transport, replay, source, and name the same finite route; they do not add a new selection principle.

Because the carrier omits host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, and ambient Real completeness, every accepted consumer read is exhausted by the displayed finite-window route. □

Theorem 4791.4 (Helly–Bray distribution forward link)**.** *Every* $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, *or* $\mathsf{ProkhorovTightProbabi}$ *consumer that cites an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier must first read the* $\mathsf{BoundedVariation}^{\uparrow}$ *source row, the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *signed-variation row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows of Definition 5815.1. The downstream route to chapter 186, chapter 92, and chapter 4008 therefore receives only bounded-variation source data, Jordan variation data, displayed windows, rational readback, Real seals, componentwise transport, replay, provenance, and local naming. It receives no host weak convergence theorem, measure completion, quotient equality, selected subsequence, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $H = (B, J, S, R, E, T, C, P, N)$. The only distribution-facing source row is B, and the only signed-measure decomposition row available to the packet is J.

Use the finite-window route of Definition 5815.3. It forces every Real-facing and variation-facing read through S, R, E before the transport, replay, provenance, and local naming rows can be consumed.

Now attach a downstream distribution, measure, or tight-probability request. Since those consumers cite the Helly–Bray packet only through the displayed route, the request reaches chapter 186, chapter 92, or chapter 4008 after $B, J, S, R, E, T, C, P, N$ have already been displayed.

The excluded objects are not carrier coordinates. Thus the forward link cannot export host weak convergence, measure completion, quotient equality, selected subsequences, countable choice, or ambient Real completeness to any distribution-facing consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5815.1, Definition 5815.2, Definition 5815.3, and Definition 5815.4 seed the finite Helly–Bray selection route over bounded-variation data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, transport, replay, provenance, local naming, and distribution-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, variation-source exposure, finite-window locality, readback ordering, transport, replay, provenance, local naming, and finite-window routing for BEDC.Derived.HellyBraySelectionUp.

Constructive story: A $\mathsf{HellyBraySelection}^{\uparrow}$ packet is generated from bounded-variation source data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

The Helly–Bray route is a distribution-facing read of the finite selection surface already named by chapter 1732; its bounded real sequence and compactness rows are supplied through chapter 1415 before the distribution consumer is allowed to inspect the signed-variation packet.

Theorem 4791.5 (Helly–Bray Helly-selection dependency route)**.** *Every* $\mathsf{Distribution}^{\uparrow}$ *or compactness-facing consumer of an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *packet must first expose the finite* $\mathsf{HellySelection}^{\uparrow}$ *selection surface of chapter 1732 together with the bounded real sequence route of chapter 1415. In carrier notation, the read passes through the bounded-variation source row, Jordan signed-variation row, finite window rows, regular rational readback, terminal Real seals, componentwise transport, replay, provenance, and local naming rows before the distribution-facing route of Definition 5815.4 is public. It is therefore not a free weak-convergence theorem, measure-completion theorem, quotient-function equality, choice-selected subsequence, or ambient compactness principle.*

Proof. Start with the carrier of Definition 5815.1. Its only sequence-facing data are the bounded-variation row, Jordan signed-variation row, finite windows, regular rational readback, and terminal Real seals.

Read those rows through the finite-window route of Definition 5815.3. The same bounded source discipline is the one exported by the $\mathsf{HellySelection}^{\uparrow}$ packet, and the bounded real sequence route supplies the finite window and bound rows before any compactness-facing consumer can inspect them.

Finally attach the distribution forward link. Since Definition 5815.4 exposes distribution consumers only after the Helly–Bray carrier rows have been displayed, the downstream route receives the Helly-selection and bounded-sequence surfaces as dependencies rather than as hidden host compactness or choice principles. □

Chapter 4792

A Concrete Naming Certificate for DiniFiniteMinimumBudget$^{\uparrow}$

Following Dini's theorem and Bishop–Bridges constructive compactness, the DiniFiniteMinimumBudget$^{\uparrow}$ packet records the finite extraction row that turns a monotone compact-window Dini certificate into one displayed tolerance budget. It consumes the CompactMetric$^{\uparrow}$ source, monotone ContinuousMap$^{\uparrow}$ family rows, the DiniTheorem$^{\uparrow}$ compact-window route, UniformModulus$^{\uparrow}$ handoff data, DyadicRatCore$^{\uparrow}$ tolerance cells, the terminal Real$^{\uparrow}$ seal, BHist history rows, hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data. The packet names only the finite minimum-budget route; it is not host supremum selection, a selected minimum outside the carrier, open-cover compactness, quotient equality, or ambient Real$^{\uparrow}$ completeness.

The dependency surface is horizontal: chapter 1387 supplies the compact-window Dini route, chapter 129 supplies the inspected compact carrier, chapter 130 supplies the monotone continuous-family rows, and chapter 369 receives the extracted budget. Thus the minimum-budget row is a downstream finite extraction from those sibling carriers, not an isolated tolerance selector.

Definition 4792.1 (Dini finite-minimum budget carrier)**.** *A* DiniFiniteMinimumBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, F, D, U, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row naming the finite compact-metric windows inspected by the extraction.*
2. *F is the monotone* ContinuousMap$^{\uparrow}$ *family row, including the displayed pointwise comparison ledger used by the Dini route.*
3. *D is the* DiniTheorem$^{\uparrow}$ *row that supplies the monotone uniform-window certificate over K and F.*
4. *U is the* UniformModulus$^{\uparrow}$ *handoff row consumed by uniform-limit and compact-uniform-modulus readers.*
5. *Q is the* DyadicRatCore$^{\uparrow}$ *tolerance row, listing the candidate dyadic budgets and their finite comparison cells.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row reached by every displayed tolerance and value comparison.*
7. *H records componentwise* hsame *transport for $K, F, D, U, Q, E, C, P, N$.*

8. *C records displayed* Cont *replay from compact windows and monotone family rows through the Dini row, the finite dyadic budget comparisons, the uniform-modulus handoff, and the Real seal.*
9. *P is the* Pkg *provenance over* DiniFiniteMinimumBudget$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, DiniTheorem$^{\uparrow}$, UniformModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for an ambient supremum, an externally selected minimum, open-cover compactness, quotient equality of real names, countable choice, or host Real completeness.

Lean4 ✓ `BEDC.Derived.DiniFiniteMinimumBudgetUp.DiniFiniteMinimumBudgetTasteGate single carrier alignment`

Theorem 4792.2 (Dini compact finite-minimum budget)**.** *For every accepted* DiniFiniteMinimumBudget$^{\uparrow}$ *carrier*

$$B = (K, F, D, U, Q, E, H, C, P, N),$$

the finite probe cover displayed by K, F, D and the dyadic tolerance cells displayed by Q determine one displayed minimum tolerance budget before the uniform-modulus handoff U is exported. The extraction route is

$$K, F, D, Q, E, H, C, P, N \longrightarrow U.$$

Thus a UniformLimit$^{\uparrow}$ *or compact-uniform-modulus consumer receives a finite* DyadicRatCore$^{\uparrow}$ *budget sealed by* Real$^{\uparrow}$ *and transported by* hsame *and* Cont*, without host supremum, selected minimum outside the carrier, open-cover compactness, quotient equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the accepted packet. The compact source row K, monotone family row F, and Dini row D are the only rows that can name the finite probe cover for the tolerance request.

The dyadic row Q lists the candidate tolerance cells. Since the carrier is finite, the budget comparison is a displayed finite comparison among the cells in Q, with every real-valued read sealed through E before the handoff row is exposed.

The route to U is then replayed by C and transported componentwise by H. The provenance and naming rows P, N record the same finite route as the local certificate surface.

No excluded object is a coordinate of B. Consequently the exported budget is the displayed finite minimum-budget row inside the carrier, not an ambient supremum, external selector, open-cover argument, quotient equality, choice schedule, or completeness argument. □

Falsifiable prediction: Every accepted DiniFiniteMinimumBudget$^{\uparrow}$ consumer that exports a UniformModulus$^{\uparrow}$ handoff must first expose the compact-metric windows, monotone continuous-family rows, DiniTheorem route, finite DyadicRatCore$^{\uparrow}$ budget cells, Real$^{\uparrow}$ seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: dini-theorem, compactmetric, continuousmap, uniformmodulus, dyadicratcore, real: DiniFiniteMinimumBudget$^{\uparrow}$ is not bijective to any listed sibling because it binds the finite Dini probe cover to one displayed dyadic minimum-budget handoff before uniform-limit or compact-uniform-modulus consumers may read the result.

Closure status for NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$, seed)

Scope closed: Definition 5816.1 and Definition 5816.2 seed the finite minimum-budget extraction route from compact Dini data to a uniform-modulus-facing handoff.

Formal verification: FormalStatus(NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host supremum selection, selected minima outside the carrier, open-cover compactness, quotient equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite probe-cover exposure, dyadic minimum-budget extraction, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.DiniFiniteMinimumBudgetUp.

Constructive story: A DiniFiniteMinimumBudget$^{\uparrow}$ packet is generated from compact-metric source rows, monotone ContinuousMap family rows, a DiniTheorem compact-window route, UniformModulus handoff rows, DyadicRatCore tolerance cells, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 4793

A Concrete Naming Certificate for $\mathsf{FiniteCauchyFilter}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteCauchyFilter}^{\uparrow}$ packet records the finite directed-tail surface used when a completion consumer asks for Cauchy-filter evidence before reading a regular rational name or a terminal real-name seal. It sits beside the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite filter basis for tail requests; it is not a quotient filter, a selected limit, countable choice, host real equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 4793.1 (Finite Cauchy filter carrier)**.** *A* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (W, T, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *row recording the finite source windows inspected by the filter request.*
2. T *is the directed-tail request row, naming the finite family of later-window obligations and their refinement order.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii and comparison budgets used by the directed tails.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and tolerance ledger.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reachable only after* W, T, D, R *have been exposed.*
6. H *records componentwise* hsame *transport for the stream windows, tail requests, dyadic ledgers, regular readback, and real seal.*
7. C *records displayed* Cont *replay of the same finite filter route.*
8. P *records* Pkg *provenance over* $\mathsf{FiniteCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, T, D, R, E, H, C, P, N$*. It has no coordinate for quotient filters, selected limits, countable choice, host equality of streams, host real equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.FiniteCauchyFilterUp.FiniteCauchyFilterTasteGate single carrier alignment`

Theorem 4793.2 (Finite Cauchy filter NameCert obligations)**.** *For the carrier of Definition 5817.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$ *surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure, directed-tail request visibility,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-ledger preservation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal access, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the accepted packet $F = (W, T, D, R, E, H, C, P, N)$. The rows W, T, D expose the finite source windows, directed tail requests, and dyadic tolerance budgets before any regular-rational or real-facing read is admitted.

The readback row R is then determined by the displayed windows and tolerance ledger. Since the carrier stores no second regular-rational coordinate, every $\mathsf{RegSeqRat}^{\uparrow}$ consumer reads the same finite route.

The seal row E is downstream of W, T, D, R. The transport row H, continuation row C, package provenance row P, and local naming row N preserve exactly that route and provide no coordinate for quotient filters, selected limits, countable choice, host stream equality, host real equality, or ambient completeness. □

Theorem 4793.3 (Finite Cauchy filter Real route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *carrier factors through the finite route*

$$W, T, D, R, E, H, C, P, N.$$

In particular, the consumer must first read $\mathsf{StreamName}^{\uparrow}$ *windows, directed tail requests,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*

Proof. Start with the carrier definition. The only real-facing row is E, and it is displayed after the stream windows, directed-tail row, dyadic ledger, and regular readback row.

Apply Definition 5817.2. The local NameCert surface admits the real seal only as part of the same transport, continuation, provenance, and naming route.

Thus any Real-facing consumer receives the finite packet $W, T, D, R, E, H, C, P, N$ and no quotient-filter, selected-limit, countable-choice, host-equality, or ambient-completeness substitute. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCauchyFilter}^{\uparrow}$ packet is generated from finite StreamName windows, directed tail requests, DyadicRatCore tolerance ledgers, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$, seed)

Scope closed: Definition 5817.1, Definition 5817.2, and Definition 5817.3 specify the finite directed-tail filter carrier and its Real-facing route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filter construction, selected limits, countable choice, host stream equality, host real equality, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for directed-tail visibility, tolerance-ledger preservation, readback, Real seal routing, transport, replay, provenance, and local naming.

Chapter 4794

A Concrete Naming Certificate for DNAWindowSixTranslationBoundary$^{\uparrow}$

The DNAWindowSixTranslationBoundary$^{\uparrow}$ packet realizes the local translation-boundary branch of subsection 9462.28.21 as finite NameCert data. It consumes the codon-window and stop-tile boundary analysis in the source vision, the curated code-boundary ledger of **??**, and the trigger-threshold surface of chapter 4217. The packet names only a finite window-six translation-boundary carrier; biological translation realization, universality, protein function, and evolutionary mechanism remain outside the BEDC kernel packet.

Definition 4794.1 (DNA window-six translation-boundary carrier)**.** *A* DNAWindowSixTranslationBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, S, T, L, R, V, H, C, P, N)$$

with the following displayed rows:

1. *Q is the codon Q_6 window row recording the six-bit coordinate readback for the inspected codon window.*
2. *S is the stop-tile boundary row recording the local halt boundary and continuation-corner split from the source vision.*
3. *T is the translation-classifier row supplied by external biological bridge data.*
4. *L is the curated code-boundary ledger row inherited from* BioRealityQSixLeaveOneCodeBoundaryLedger$^{\uparrow}$*.*
5. *R is the release-factor or release-mechanism row that records which external recognition boundary is being tested.*
6. *V is the finite validation row recording which observed table, organismal code row, or assay class is used for the test.*
7. *H records componentwise* hsame *transport for the window, tile, classifier, ledger, release, and validation rows.*
8. *C records displayed* Cont *replay of the boundary read through those rows.*
9. *P records* Pkg *provenance over the source vision, the bio-reality ledger sibling,* DNAWindowSixTriggerThreshold$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and local naming rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for biological necessity, global identification of the genetic code with the window-six fold, protein-folding realization, universal stop assignment, hidden BEDC channel tokens, or untested mechanism.

Theorem 4794.2 (DNA window-six translation-boundary obligations)**.** *For the carrier of Definition 5818.1, the local* $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$ *surface consists exactly of codon-window exposure, stop-tile boundary visibility, external translation-classifier disclosure, curated code-ledger preservation, release-boundary test exposure, finite validation-row visibility, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the accepted packet $B = (Q, S, T, L, R, V, H, C, P, N)$. The rows Q, S, T expose the finite codon window, the local translation boundary, and the external classifier before any biological reading is admitted.

The ledger and release rows L, R keep the packet anchored to the bio-reality boundary sibling and to a displayed recognition test. The validation row V records the observed table or assay class being tested, so the packet has a falsifiable contact surface rather than a kernel claim of biological necessity.

The structural rows H, C, P, N transport, replay, source, and name exactly the displayed boundary route. Since no further coordinate is present, the carrier cannot export global window-six identity, universal stop assignment, protein-folding realization, hidden channel tokens, or untested mechanism. □

Theorem 4794.3 (DNA window-six translation-boundary sibling handoff)**.** *Every accepted* DNAWindowSixTranslat *read that reaches a translation-boundary consumer must first expose the source-vision stop-tile row of subsection 9462.28.21, the curated code-boundary ledger row of* **??**, *and the finite trigger-threshold row of chapter 4217. The handoff is therefore a concrete finite boundary-tile NameCert route, not a narrative-only direction.*

Proof. Use Definition 5818.1. The source-vision row is carried by S, the code-boundary ledger is carried by L, and the trigger-facing finite boundary read is recorded in the same package provenance P.

Now apply Definition 5818.2. The local NameCert requires those rows before the translation-boundary consumer can read N. Hence the consumer sees the source vision, the bio-reality ledger sibling, and the trigger-threshold sibling as displayed packet data rather than as detached prose. □

Falsifiable prediction: An accepted $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet must expose a finite validation row naming the observed code table, organismal code row, or release-factor assay class before it can export a translation-boundary reading.

Independence witness: bioreality-q-six-leave-one-code-boundary-ledger, dna-window-six-trigger-threshold, synonymous-transition: the $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet is not bijective to any listed sibling because it jointly carries codon-window, stop-tile, external translation-classifier, curated code-ledger, release-boundary, validation, transport, replay, provenance, and local naming rows.

The Lean follow-up must provide $\mathsf{Nontrivial}\ \mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{DNAWindowSi}$ TasteGate instances before this packet can move beyond seed closure.

Closure status for $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet is generated from codon Q-six window rows, stop-tile boundary rows, external translation-classifier rows, curated code-boundary ledgers, release-boundary tests, finite validation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\mathsf{DNAWindowSixTranslationBoundary}\uparrow}$, seed)

Scope closed: Definition 5818.1, Definition 5818.2, and Definition 5818.3 specify the finite translation-boundary carrier and sibling route.

Formal verification: FormalStatus(NameCert$_{\mathsf{DNAWindowSixTranslationBoundary}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim biological-code necessity, global window-six identity, universal stop assignment, protein-folding realization, hidden BEDC channel tokens, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding, TasteGate nontriviality, field faithfulness, validation-row exactness, sibling-route preservation, transport, replay, provenance, and local naming.

Chapter 4795

A Concrete Naming Certificate for $\mathsf{RegulatedConvergence}^{\uparrow}$

Following Bishop and Bridges on regulated functions and uniform convergence, the $\mathsf{RegulatedConvergence}^{\uparrow}$ packet records the finite route by which a displayed sequence of regulated real functions converges uniformly to a regulated endpoint. It sits after the regulated-function carrier of chapter 1906, the regulated-integral consumer boundary of chapter 1557, the uniform-convergence ledger of chapter 3417, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite convergence-and-handoff surface; it does not import measure completion, quotient equality of functions, selected host limits, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4795.1 (Regulated convergence carrier)**.** *A* $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, U, W, R, E, I, H, C, P, N)$$

with the following displayed rows:

1. *F is the source row naming the regulated-function family through* $\mathsf{RegulatedFunction}^{\uparrow}$ *data, including the displayed interval, step-window, endpoint, and oscillation ledgers available to each inspected member.*
2. *U is the* $\mathsf{UniformConvergence}^{\uparrow}$ *tail row, recording one shared tolerance schedule for the whole regulated family rather than pointwise schedules chosen separately at each argument.*
3. *W is the finite window row exposing exactly the function indices, domain windows, and endpoint reads used by the shared tail schedule.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the real-valued observations in those windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after F, U, W, R have been displayed.*
6. *I is the* $\mathsf{RegulatedIntegral}^{\uparrow}$ *handoff row; it records that integral-facing consumers may read the regulated endpoint only through the same finite regulated-function, uniform-tail, window, readback, and Real-seal route.*
7. *H records componentwise* hsame *transport for F, U, W, R, E, I and for the structural rows.*
8. *C records displayed* Cont *replay for regulated-function reads, uniform-tail requests, finite window reads, regular rational readback, Real-seal requests, and integral handoff requests.*

9. *P is the* Pkg *provenance over* $\mathsf{RegulatedConvergence}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{UniformConvergence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, U, W, R, E, I, H, C, P, N$. It has no coordinate for a host function quotient, selected limiting function, measure completion, pointwise-only convergence, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RegulatedConvergenceUp.RegulatedConvergenceTasteGate single carrier alignment`

Theorem 4795.2 (Regulated convergence NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier*

$$G = (F, U, W, R, E, I, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission for the regulated-function family row F, uniform-convergence tail row U, finite window row W, regular rational readback row R, terminal Real seal E, regulated-integral handoff row I, componentwise transport row H, displayed replay row C, package provenance row P, and local naming row N. Every endpoint-facing or integral-facing consumer must read these rows in the displayed route and cannot replace them by pointwise convergence, a selected host limit, quotient equality of functions, measure completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegulatedConvergenceUp.RegulatedConvergenceCarrier namecert obligations`

Proof. Project the accepted carrier of Definition 5819.1. The only analytic rows are the regulated-function family F, the shared uniform tail ledger U, the finite window row W, the regular rational readback R, the terminal Real seal E, and the integral handoff I.

The convergence route is uniform. A consumer must read the single tail schedule U before it can inspect the windows W and the regular readback R, so pointwise-only schedules and externally selected host limits are not part of the packet.

The endpoint and integral rows are downstream. The seal E is exposed only after F, U, W, R, and the integral-facing row I reads that same route rather than a separate measure-completion or function-quotient object.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded row occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 4795.3 (Regulated convergence integral handoff)**.** *Let*

$$G = (F, U, W, R, E, I, H, C, P, N)$$

be an accepted $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier. Every* $\mathsf{RegulatedIntegral}^{\uparrow}$ *consumer read of the limiting regulated function factors through the finite route*

$$\mathsf{RegulatedFunction}^{\uparrow}(F),\ \mathsf{UniformConvergence}^{\uparrow}(U),\ W,\ \mathsf{RegSeqRat}^{\uparrow}(R),\ \mathsf{Real}^{\uparrow}(E),\ \mathsf{RegulatedIntegral}^{\uparrow}(I).$$

Thus the handoff to integration uses the same regulated-family rows, shared uniform-tail ledger, finite windows, regular rational readback, and Real seal as the convergence certificate. It supplies no measure completion, quotient function equality, selected limiting function, open-cover compactness, or ambient real-completeness principle.

Proof. Start with an integral-facing request. By the carrier definition, the only integral row is I, and its replay route in C passes through the same regulated-family and convergence rows used by endpoint-facing consumers.

Read the regulated source through F and the uniform tail through U. The finite windows W then expose the inspected function indices and domain reads, and the regular rational row R records the real-valued observations visible at those windows.

Only after this route is displayed can the terminal seal E be consumed and handed to I. Componentwise transport in H and replay in C preserve the same rows, while P and N record their provenance and local naming.

The carrier has no coordinate for measure completion, quotient function equality, selected limits, open-cover compactness, or ambient real completeness. Therefore every regulated-integral handoff is confined to the finite route displayed in the statement. □

Falsifiable prediction: An accepted $\mathsf{RegulatedConvergence}^{\uparrow}$ consumer that reaches a $\mathsf{RegulatedIntegral}^{\uparrow}$ handoff without first reading $F, U, W, R, E, H, C, P, N$ refutes the carrier surface.

Independence witness: regulated-function, regulated-integral, uniform-convergence, regseqrat, real: none is bijective to $\mathsf{RegulatedConvergence}^{\uparrow}$ because this packet jointly binds a regulated-function family, a shared uniform tail ledger, finite windows, regular rational readback, terminal Real seal, integral handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedConvergence}^{\uparrow}$ packet is generated from a regulated-function family row, UniformConvergence tail row, finite window row, RegSeqRat readback, terminal Real seal, RegulatedIntegral handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5819.1, Definition 5819.2, and Definition 5819.3 seed the finite regulated-convergence route over regulated functions, uniform convergence, regular rational readback, Real seals, and regulated-integral consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure completion, quotient function equality, selected host limits, pointwise-only convergence, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regulated-family visibility, uniform-tail exactness, finite window readback, Real-seal nonescape, regulated-integral handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegulatedConvergenceUp.

Chapter 4796

A Concrete Naming Certificate for $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$

Following Cantor and Bishop–Bridges, the $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ packet records the finite located nested-interval route by which displayed interval windows become a regular rational Cauchy name and then a terminal real seal. It refines the nested dyadic Cauchy route of chapter 1811, reads endpoint and radius rows through chapter 291, schedules finite observations through chapter 126, hands the scheduled rows to chapter 301, and reaches only the seal boundary of chapter 38. The chapter isolates the located interval-to-name handoff; it does not claim a host intersection point, quotient stream equality, selected limit, countable choice, or ambient completeness.

Definition 4796.1 (Located nested-interval limit carrier)**.** *A* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite nested located-interval window. It records the inspected interval chain, endpoint rows, located containment witnesses, and the finite separation reads available at each displayed stage.*
2. *D is the dyadic shrink ledger. It records the dyadic endpoint comparisons, width bounds, and tolerance requests read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row. It names exactly the finite endpoint, midpoint, and shrink-ledger observations that may be queried before regular rational readback.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the scheduled located-interval observations and the dyadic shrink ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after I, D, S, R have been displayed.*
6. *H records componentwise* hsame *transport for interval windows, shrink ledgers, stream schedules, regular rational handoffs, real seals, replay rows, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a located nested-interval request through I, D, S, R, E and then through the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$*,* $\mathsf{NestedDyadicCauchy}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, S, R, E, H, C, P, N$. It has no coordinate for completed interval intersections, quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.LocatedNestedIntervalLimitUp.LocatedNestedIntervalLimitTasteGate single carrier alignment`

Theorem 4796.2 (Located nested-interval limit NameCert obligations)**.** *For every accepted* LocatedNestedIntervalL *carrier*

$$L = (I, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the finite located interval window, dyadic shrink ledger, StreamName schedule, RegSeqRat handoff, Real seal, transport, replay, provenance, and local naming row;*
2. *located nesting exposure, requiring every interval read to be one of the displayed rows of I together with its displayed containment and located separation witnesses;*
3. *dyadic shrink exactness, requiring every tolerance request to be discharged by a visible width or endpoint comparison stored in D and read through* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
4. *schedule compatibility, requiring S to expose only the finite interval, endpoint, midpoint, and ledger observations used by D and R;*
5. *RegSeqRat handoff exactness, requiring R to be formed only after the interval window, shrink ledger, and schedule rows have been projected;*
6. *Real-seal nonescape, requiring E to be consumed only after I, D, S, R and the structural rows H, C, P, N have been displayed.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 5820.1. The projection exposes one finite located nested-interval window, one dyadic shrink ledger, one StreamName schedule, one RegSeqRat handoff, one Real seal, and the transport, replay, provenance, and naming rows.

Located nesting exposure is forced by I. A consumer may inspect only interval rows already present in the finite window, and each such row carries its displayed containment and located separation witnesses.

Dyadic shrink exactness is forced by D. Each tolerance request is answered by a displayed dyadic width or endpoint comparison, so no host intersection or selected limit is needed to choose a tail.

The schedule and handoff rows are downstream. The row S records the finite observations that may be opened, and R repacks exactly those observations under the shrink ledger as a regular rational Cauchy surface.

Finally E, H, C, P, N close the route. The Real seal is reachable only after the regular handoff has been displayed, while the structural rows only transport, replay, source, and name the same finite data. Therefore no completed intersection, quotient stream equality, host real equality, countable choice, ambient completeness, Lean verification, or bridge-checking coordinate is present. □

Theorem 4796.3 (Located nested-interval RegSeqRat handoff)**.** *Let* $L = (I, D, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer read exported by* L *factors through the displayed route*

$$I \longmapsto D \longmapsto S \longmapsto R \longmapsto H, C, P, N.$$

The route reads a finite located nested-interval window, a dyadic shrink ledger, and the scheduled endpoint observations before it exports the regular rational Cauchy row. The terminal $\mathsf{Real}^{\uparrow}$ *seal* E *is available only after this handoff has been displayed.*

Proof. Start with the displayed located interval window I. Its rows give the only endpoint, midpoint, containment, and located separation data available to a regular rational consumer.

Use the dyadic shrink ledger D to answer the displayed tolerance request. The chosen comparison is part of the same finite packet and is read through $\mathsf{DyadicRatCore}^{\uparrow}$, so there is no external modulus, choice-selected tail, or host interval intersection.

The schedule row S then fixes which interval observations are opened. The handoff row R is obtained by reading those scheduled observations under the shrink discipline and repacking them as the $\mathsf{RegSeqRat}^{\uparrow}$ surface.

The rows H, C, P, N transport, replay, source, and name that handoff, and the seal row E remains downstream of it. Since the carrier has no quotient-stream, host-real, selected-limit, choice, or completeness coordinate, every regular rational read factors through the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5820.1, Definition 5820.2, and Definition 5820.3 seed the finite located nested-interval route from displayed interval windows and dyadic shrink ledgers to a RegSeqRat handoff and terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed interval intersections, quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located nesting exposure, dyadic shrink exactness, schedule compatibility, RegSeqRat handoff exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedNestedIntervalLimitUp.

Constructive story: A $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ packet is generated from a finite nested located-interval window, a dyadic shrink ledger, a StreamName schedule, a RegSeqRat handoff row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4797

A Concrete Naming Certificate for $\mathsf{CauchyTailRequest}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyTailRequest}^{\uparrow}$ packet isolates the finite directed-tail request that a Cauchy or completion consumer must expose before it can read a regular rational name or a terminal real-name seal. It sits beside the finite window carrier of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal seal of chapter 38, and the finite filter surface of chapter 5817. The packet names the request row consumed by those sibling routes; it is not a quotient filter, a selected limit, a countable-choice schedule, host stream equality, host real equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 4797.1 (Cauchy tail request carrier)**.** *A* $\mathsf{CauchyTailRequest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (W, Q, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *row recording the finite source windows inspected by the request.*
2. Q *is the directed tail request row, naming the finite later-window obligations and their refinement order.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the directed tail request.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the displayed windows and tolerances.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reachable only after* W, Q, D, R *have been exposed.*
6. H *records componentwise* hsame *transport for the window, request, tolerance, readback, seal, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay of the same finite directed-tail route.*
8. P *records* Pkg *provenance over* $\mathsf{CauchyTailRequest}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteCauchyFilter}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, Q, D, R, E, H, C, P, N$*. It has no coordinate for quotient filters, selected limits, countable choice, host equality of streams, host real equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 (definition) `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestUp`

Lean4 ✓ `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestTasteGate single carrier alignment`

Theorem 4797.2 (Cauchy tail request NameCert obligations)**.** *For the carrier of Definition 5821.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$ *surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure, directed-tail visibility,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance preservation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *consumer that reads a directed-tail row receives it through this displayed request surface.*

Lean4 ✓ `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestCarrier namecert obligations`

Proof. Project the accepted packet $T = (W, Q, D, R, E, H, C, P, N)$. The rows W, Q, D expose the finite windows, directed tail request, and dyadic tolerance ledger before any regular-rational or real-facing read is admitted.

The readback row R is downstream of those displayed rows. It therefore records only the $\mathsf{RegSeqRat}^{\uparrow}$ observation generated from the named windows and tolerance ledger, not an external sequence or choice schedule.

The seal row E is terminal for the request route. Transport through H and replay through C preserve exactly the displayed route, while P and N record provenance and local naming.

Finally compare the route with Definition 5817.2. The finite filter packet consumes its directed-tail row as a request coordinate, and the rows above are precisely the admitted request surface available to that consumer. Since no remaining coordinate exists, quotient filters, selected limits, countable choice, host equality, Real completeness, Lean verification, and bridge checking are outside the chapter claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyTailRequest}^{\uparrow}$ packet is generated from finite StreamName windows, a directed tail request row, DyadicRatCore tolerance data, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$, seed)

Scope closed: Definition 5821.1 and Definition 5821.2 specify the finite directed-tail request carrier and its filter-facing route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected limits, countable choice, host equality, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for tail visibility, tolerance preservation, readback, seal routing, transport, replay, provenance, and local naming.

Chapter 4798

A Concrete Naming Certificate for $\mathsf{QuotientLeakageMarkov}^{\uparrow}$

The $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ packet realizes the quotient leakage transition matrix of Definition 9462.1376 as finite NameCert data. It consumes the DNA window-six boundary-tile source of subsection 9462.28.21, the codon-window carrier of chapter 2234, the boundary-tile packet of chapter 3393, the six-boundary coverage route of chapter 3470, and the translation-boundary packet of chapter 5818. The packet names a finite six-state Markov ledger only; it is not a biological stochastic model, empirical evolutionary claim, host quotient-codon semantics, or unrestricted state-space enumeration.

Definition 4798.1 (QuotientLeakageMarkov carrier)**.** *A* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, T, O, E, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the six-state orbit row listing* AGR*,* Anchor_6*,* $\mathrm{StopStart}_6$*,* UUR*,* CUR*, and* CUY*.*
2. *T is the transient transition-matrix row of Definition 9462.1376, with entries read as exact rational finite counts.*
3. *O is the outside-probability row recording* $1/3, 1/3, 1/3, 1/6, 1/2, 2/3$ *for the six displayed states.*
4. *E is the expected-exit ledger row recording the rational exit values of Definition 9462.1380.*
5. *W is the finite window-six source row tying the orbit states to the codon-window and boundary-tile siblings.*
6. *H records componentwise* hsame *transport for the state, transition, outside-probability, exit-ledger, source, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the finite Markov read through* S, T, O, E, W, H, P, N*.*
8. *P is the* Pkg *provenance over* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$*,* $\mathsf{CodonSixBitWindow}^{\uparrow}$*,* $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$*,* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$*,* $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$*, the source vision of subsection 9462.28.21,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, O, E, W, H, C, P, N$*. It has no coordinate for biological transition realization, hidden codon quotient semantics, empirical fitness, unbounded simulation, or a completed stochastic process.*

Theorem 4798.2 (QuotientLeakageMarkov NameCert obligations)**.** *For the carrier of Definition 5822.1, the local* $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$ *surface consists exactly of six-state exposure, transition-matrix exactness, outside-probability preservation, expected-exit ledger exposure, window-six sibling routing, componentwise transport, displayed replay, provenance, and local naming. Every accepted read preserves the outside probabilities displayed in Definition 9462.1378.*

Proof. Project the accepted carrier $Q = (S, T, O, E, W, H, C, P, N)$. The state row S fixes the six orbit states, and the transition row T is the only source of one-bit flip probabilities.

The outside-probability row O is read from the outside column of T and matches the finite rational list in Definition 9462.1378. Thus an accepted packet cannot alter leakage rates without changing a displayed row.

The expected-exit row E is downstream of the same finite matrix and records the rational ledger of Definition 9462.1380. The source row W ties these finite state rows back to the codon-window, boundary-tile, coverage, and translation-boundary siblings.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since no other coordinate is present, the NameCert surface cannot export biological mechanism, hidden quotient semantics, empirical fitness, unbounded simulation, or a completed stochastic process. □

Theorem 4798.3 (QuotientLeakageMarkov sibling dependency route)**.** *Every accepted* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ *consumer first reads the finite codon-window source, boundary-tile classifier, six-boundary coverage route, and translation-boundary packet before it consumes the transition row* T*, outside row* O*, or expected-exit row* E*. The dependency route is*

$$\mathsf{CodonSixBitWindow}^{\uparrow}, \mathsf{DnaWindowSixBoundaryTile}^{\uparrow}, \mathsf{SixBoundaryTileCoverage}^{\uparrow}, \mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$$

Proof. Use the provenance row P and source row W of Definition 5822.1. These rows name the finite codon-window and boundary-tile sources before the Markov matrix is admitted.

The transition row T then reads the six-state quotient matrix of Definition 9462.1376. The outside-probability row O and expected-exit row E are downstream ledger rows, so they cannot be consumed before the sibling source route has been displayed.

Transport and replay by H and C preserve this order, while N names it locally. Hence the consumer receives a concrete dependency route rather than a detached numerical table. □

Falsifiable prediction: Every accepted $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ read preserves the displayed outside probabilities $1/3, 1/3, 1/3, 1/6, 1/2, 2/3$ for AGR, Anchor_6, StopStart_6, UUR, CUR, and CUY.

Independence witness: codon-six-bit-window, dna-window-six-boundary-tile, six-boundary-tile-coverage, dna-window-six-translation-boundary: $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries six orbit states, a rational transition matrix, outside probabilities, expected-exit ledgers, window-source routing, transport, replay, provenance, and local naming.

The Lean follow-up must provide explicit $\mathsf{Nontrivial}\ \mathsf{QuotientLeakageMarkov}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{QuotientLeakageM}$ TasteGate instances preserving $S, T, O, E, W, H, C, P, N$ as distinct displayed rows.

Closure status for $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$**.**

Constructive story: A $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ packet is generated from six orbit states, a rational transition matrix, outside-probability rows, expected-exit ledgers, a finite window-six source row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5822.1, Definition 5822.2, and Definition 5822.3 specify the finite quotient-leakage Markov carrier and sibling dependency route.

Formal verification: FormalStatus(NameCert$_{\text{QuotientLeakageMarkov}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close biological transition realization, empirical evolutionary mechanism, hidden codon quotient semantics, unbounded simulation, completed stochastic processes, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-matrix exactness, outside-probability preservation, expected-exit ledger exposure, sibling routing, transport, replay, provenance, and local naming for BEDC.Derived.QuotientLeakage

Chapter 4799

A Concrete Naming Certificate for $\mathsf{CauchyCriterionUniform}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyCriterionUniform}^{\uparrow}$ packet records the uniform Cauchy criterion route used when a Real and Completion consumer asks for one displayed threshold discipline across a finite family of stream windows. It sits beside the finite stream-window interface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the Cauchy hub of chapter 3413. The packet names a uniform criterion surface; it is not a quotient Cauchy class, selected limit, host equality theorem, countable-choice schedule, trichotomy principle, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 4799.1 (Cauchy criterion uniform carrier)**.** *A* $\mathsf{CauchyCriterionUniform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, D, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *S records the* $\mathsf{StreamName}^{\uparrow}$ *window family inspected by the uniform criterion request.*
2. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the dyadic radii and comparison budgets shared by the family.*
3. *R records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the displayed windows and dyadic tolerances.*
4. *E records the terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing row, available only after S, D, R, M have been exposed.*
5. *M records the uniform modulus row, naming the common threshold discipline for all displayed windows in the family.*
6. *H records componentwise* hsame *transport for the stream windows, dyadic tolerances, regular readback, Real seal, uniform modulus, replay route, provenance, and local name.*
7. *C records displayed* Cont *replay of the same finite route.*
8. *P records* Pkg *provenance over* $\mathsf{CauchyCriterionUniform}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N records the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, R, E, M, H, C, P, N$. It has no coordinate for a quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUniformUp.CauchyCriterionUniformTasteGate single carrier alignment`

Theorem 4799.2 (Cauchy criterion uniform NameCert obligations)**.** *For the carrier of Definition 5823.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the finite packet* $U = (S, D, R, E, M, H, C, P, N)$*;*
2. *uniform window exposure through the* $\mathsf{StreamName}^{\uparrow}$ *row* S *and the common modulus row* M*;*
3. *dyadic tolerance exactness through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D*;*
4. *regular readback through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*;*
5. *ledger non-escape through* H, C, P, N*.*

Proof. Project the accepted packet $U = (S, D, R, E, M, H, C, P, N)$. Carrier admission is exactly the admission of this finite tuple, so a consumer can inspect only the displayed coordinates.

The uniform window obligation reads S together with the common threshold discipline M. The dyadic tolerance obligation reads D, and the regular readback obligation reads R before any terminal seal row E is available.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since the carrier has no remaining coordinate, the ledger cannot export a quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient completeness claim. □

Theorem 4799.3 (Cauchy criterion uniform Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{CauchyCriterionUniform}^{\uparrow}$ *carrier factors through the finite route*

$$S, D, R, M \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer must read stream windows, dyadic tolerances, regular readback, and the uniform modulus before the terminal real seal is exposed. The route exports no quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 5823.1. The only terminal real-facing coordinate is E, and the definition places it downstream of the finite stream-window, dyadic-tolerance, regular-readback, and uniform-modulus rows.

Apply Definition 5823.2. The NameCert surface admits the real seal only as part of the same transport, continuation, provenance, and naming route.

Therefore any Real-facing consumer receives exactly the finite packet route displayed above. No quotient Cauchy class, selected limit, host equality, countable-choice schedule, trichotomy row, or ambient-completeness coordinate supplies another path to the seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCriterionUniform}^{\uparrow}$ packet is generated from finite StreamName windows, DyadicRatCore tolerance ledgers, RegSeqRat readback, a RealUp seal row, a uniform modulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$, seed)

Scope closed: Definition 5823.1, Definition 5823.2, and Definition 5823.3 specify the finite uniform Cauchy criterion carrier and its Real-facing seal route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient Cauchy classes, selected limits, host equality, countable choice, trichotomy, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for uniform window exposure, dyadic tolerance exactness, regular readback, Real seal routing, transport, replay, provenance, and local naming.

Chapter 4800

A Concrete Naming Certificate for CauchyProductCompletionProjection$^{\uparrow}$

Following Bishop and Bridges on constructive products of Cauchy completions and Kelley on product uniformities, the CauchyProductCompletionProjection$^{\uparrow}$ packet records the coordinate projection surface for an accepted product-completion read. It sits downstream of the product packet of chapter 3797 and the completion-product route of chapter 1540, while every coordinate read still passes through the StreamName$^{\uparrow}$ windows of chapter 126, the RegSeqRat$^{\uparrow}$ readbacks of chapter 301, the DyadicRatCore$^{\uparrow}$ budgets of chapter 291, and the terminal Real$^{\uparrow}$ seal of chapter 38.

Definition 4800.1 (CauchyProductCompletionProjection carrier)**.** *A* CauchyProductCompletionProjection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N)$$

with the following displayed rows:

1. *Q is the accepted* CauchyProductCompletion$^{\uparrow}$ *product-completion packet whose coordinate route is being inspected.*
2. *π_0, π_1 are the left and right projection selector rows, each naming which displayed coordinate window is exposed.*
3. *S_0, S_1 are the coordinate* StreamName$^{\uparrow}$ *windows opened by the two projection selectors.*
4. *D_0, D_1 are the* DyadicRatCore$^{\uparrow}$ *budget rows attached to the finite coordinate observations read from those windows.*
5. *R_0, R_1 are the* RegSeqRat$^{\uparrow}$ *readback rows obtained from the same coordinate windows and dyadic budgets.*
6. *L_0, L_1 are the coordinate completion-seal rows witnessing that each projected read remains inside the product-completion packet.*
7. *H records componentwise* hsame *transport for the product packet, selectors, stream windows, dyadic budgets, regular readbacks, and coordinate completion seals.*
8. *C records the* Cont *replay from the product-completion packet through the selected coordinate window, dyadic budget, regular readback, and completion seal.*
9. *P is the* Pkg *provenance over* CauchyProductCompletionProjection$^{\uparrow}$, CauchyProductCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$ *row.*
The carrier compares accepted projections only through $Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, countable choice, host product equality, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.CauchyProductCompletionProjectionUp.CauchyProductCompletionProjectionTasteGate`
`single carrier alignment`

Theorem 4800.2 (CauchyProductCompletionProjection NameCert obligations)**.** *For an accepted packet*

$$J = (Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$ *surface consists exactly of product-packet admission, selector exposure, coordinate stream-window exposure, dyadic-budget accounting, regular readback, coordinate completion-seal nonescape, componentwise transport, replay, provenance, and local naming for the displayed rows.*

Proof. Project the carrier of Definition 5824.1. The row Q supplies the already displayed product-completion packet, while π_0, π_1 determine which coordinate route is being opened.

For each selector, the corresponding stream window is read before any dyadic budget or regular readback is available. Thus S_0, S_1 precede D_0, D_1, and the regular rows R_0, R_1 are exposed only through those windows and budgets.

The completion-seal rows L_0, L_1 bind the coordinate read back to Q. The transport table H and replay table C preserve the same product packet, selector, window, budget, readback, and seal rows, while P and N record provenance and local naming.

Since these are the only carrier coordinates, the NameCert surface has no route to quotient completion equality, selected representatives, countable choice, host product equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 4800.3 (CauchyProductCompletionProjection route)**.** *Every coordinate read exported by an accepted* $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$ *carrier factors through*

$$\mathsf{CauchyProductCompletion}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameC}$$

The left and right selectors expose only the displayed coordinate windows and their completion seals; they do not turn the product-completion packet into a host tuple, a quotient-completion equality, or a chosen representative.

Proof. Start with an accepted carrier J. The selector rows π_0, π_1 are not host projections; they are displayed BEDC rows attached to the product-completion packet Q.

Reading either selector first opens the matching $\mathsf{StreamName}^{\uparrow}$ window. The dyadic budget row is then inspected, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback is obtained from the same finite coordinate window.

The coordinate completion seal is the last coordinate-facing row before export. It keeps the read inside the product-completion packet named by Q, and the structural rows H, C, P, N attach transport, replay, provenance, and local naming to the same route.

Thus every projection read remains a finite NameCert route through the displayed rows. No coordinate of J supplies quotient completion equality, selected representatives, countable choice, host product equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$ packet is generated from an accepted CauchyProductCompletion packet, left and right projection selector rows, coordinate StreamName windows, DyadicRatCore budgets, RegSeqRat readbacks, coordinate completion seals, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5824.1, Definition 5824.2, and Definition 5824.3 seed the finite coordinate-projection route for product completions.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host product equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification can encode carrier admission, selector exposure, coordinate window accounting, regular readback, completion-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductCompletionPro

Chapter 4801

A Concrete Naming Certificate for $\mathsf{CauchyModulusSubsequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ packet records the finite route by which a bounded regular Cauchy source exposes a modulus-indexed subsequence schedule without exporting an infinite selector. It sits between the bounded subsequence envelope of chapter 1698, the regular subsequence route of chapter 381, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet is a constructive completion-facing certificate: it supplies a monotone cofinal schedule, finite windows, tolerance accounting, and a Real seal, but not countable choice, quotient stream equality, a selected infinite subsequence, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4801.1 (Cauchy modulus subsequence carrier)**.** *A* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, M, T, W, D, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the accepted* $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$ *source row whose bounded regular Cauchy data are available before any subsequence-modulus request is read.*
2. *M is the modulus row. It records the requested Cauchy tolerance discipline and the finite comparison budget used by the subsequence schedule.*
3. *T is the monotone cofinal schedule row. It records the finite evidence that requested indices are sent to later source windows and that the schedule is cofinal in the displayed source.*
4. *W records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows selected by the schedule row T at the requested modulus levels.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed windows and dyadic tolerances.*
7. *R is the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff row reached from B, M, T, W, D, Q.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the bounded source, modulus, schedule, windows, tolerance ledger, regular readback, and regular subsequence handoff have been displayed.*

9. *H records componentwise* hsame *transport for the bounded source, modulus, cofinal schedule, windows, dyadic ledger, regular readback, regular subsequence handoff, terminal seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a subsequence-modulus request through $B, M, T, W, D, Q, R, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$, $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, M, T, W, D, Q, R, E, H, C, P, N$. It has no coordinate for a selected infinite subsequence, quotient stream equality, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusSubsequenceUp.CauchyModulusSubsequenceTasteGate single carrier alignment`

Theorem 4801.2 (Cauchy modulus subsequence NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier $S = (B, M, T, W, D, Q, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequ}}$ *surface consists exactly of carrier admission, bounded-source admission through B, modulus monotonicity through M, monotone cofinal schedule admission through T, finite-window determinacy through W, dyadic tolerance accounting through D, regular rational readback through Q,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff through R, Real-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5825.1. Its analytic coordinates are exactly the bounded source B, modulus row M, monotone cofinal schedule T, finite windows W, dyadic tolerance ledger D, regular readback Q, regular subsequence handoff R, and terminal Real seal E.

The modulus and schedule obligations are displayed before any support row is inspected. The row M supplies the tolerance discipline, while T records monotonicity and cofinality for the finite requested indices. The window row W and tolerance row D then determine which $\mathsf{StreamName}^{\uparrow}$ windows and dyadic bounds are visible at those requests.

The readback and seal obligations remain downstream. The row Q reads the visible windows as $\mathsf{RegSeqRat}^{\uparrow}$ data, R records the $\mathsf{RegularCauchySubsequence}^{\uparrow}$ handoff, and E is reachable only after the preceding rows have been displayed. Rows H, C, P, N transport, replay, source, and name that same finite route, so no further NameCert obligation remains outside the listed coordinates. □

Theorem 4801.3 (Cauchy modulus subsequence window determinacy)**.** *Every consumer admitted by an accepted* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier must read the bounded source B, modulus row M, monotone cofinal schedule T, finite windows W, dyadic tolerance ledger D, regular rational readback Q, regular subsequence handoff R, and terminal Real seal E before reading the transport, replay, provenance, or local naming rows. The packet exports no selected infinite subsequence, quotient stream equality, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer read. By Definition 5825.1, the only consumer-facing route before the support rows is the ordered list B, M, T, W, D, Q, R, E.

The rows B, M, T fix the source, tolerance request, and monotone cofinal schedule. The row W then supplies only the finite windows named by that schedule, and D supplies the dyadic tolerance ledger attached to those windows. Thus the visible subsequence data are determined by displayed finite requests, not by an externally selected infinite object.

The remaining analytic rows are also fixed by the displayed windows. The readback row Q converts those windows into $\mathsf{RegSeqRat}^{\uparrow}$ data, R records the regular subsequence handoff, and E is the terminal Real seal for that route. Since the carrier contains no coordinate for quotient stream equality, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the support rows H, C, P, N can only preserve the displayed finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ packet is generated from a bounded regular Cauchy source, a modulus row, a monotone cofinal schedule, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RegularCauchySubsequence handoff, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5825.1, Definition 5825.2, and Definition 5825.3 seed the constructive subsequence-modulus route over bounded regular Cauchy data, finite windows, dyadic tolerances, regular readback, regular subsequence handoff, Real sealing, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite subsequences, quotient stream equality, countable choice, host equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Lean verification requires carrier admission, modulus monotonicity, cofinal schedule admission, finite-window determinacy, dyadic tolerance accounting, RegSeqRat readback, RegularCauchySubsequence handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusSubsequenceUp.

Chapter 4802

A Concrete Naming Certificate for $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$

Following Mac Lane on monads and Eilenberg–Moore comparison, together with Bishop–Bridges constructive completion, the $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ packet records the finite BEDC surface where the L10 completion monad, its algebra action, the Kleisli route, the universal-property row, and the dense-embedding unit route are compared as one NameCert boundary. The packet reads chapter 378, chapter 1845, chapter 1981, chapter 397, chapter 3351, chapter 126, chapter 301, chapter 291, and chapter 38. It names the comparison surface only; it does not assert quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient completeness, or full $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4802.1 (CauchyCompletionMonadicity carrier)**.** *A* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, A, K, U, D, W, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *completion-monad row, displaying the unit and bind schedule before any algebra or comparison read is consumed.*
2. *A is the* $\mathsf{CauchyCompletionAlgebra}^{\uparrow}$ *action row, recording the Eilenberg–Moore algebra action over the displayed completion route.*
3. *K is the* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *row, exposing the unit, bind, and reassociated-bind consumer route.*
4. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row, carrying the extension and uniqueness ledger used by comparison consumers.*
5. *D is the* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *unit route, displaying the dense source-to-completion image before the algebra or universal-property read is exported.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row used by the monad, algebra, Kleisli, universal-property, and dense-embedding rows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to the same finite windows.*
8. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare completion-facing reads at the same finite precision.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *readback seal reached only after W, R, Q have all been displayed.*
10. *H records componentwise* hsame *transport for the monad, algebra action, Kleisli route, universal-property row, dense-embedding unit route, readback rows, replay, provenance, and local naming.*
11. *C records displayed* Cont *replay from comparison requests through $T, A, K, U, D, W, R, Q, E, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, CauchyCompletionAlgebr $\mathsf{CauchyCompletionKleisli}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, A, K, U, D, W, R, Q, E, H, C, P, N$. The carrier has no coordinate for quotient completion classes, selected limit representatives, host equality of completed objects, countable-choice schedules, ambient completeness, full $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadicityUp.TasteGate.CauchyCompletionMonadicityTasteGate`
`single carrier alignment`

Theorem 4802.2 (CauchyCompletionMonadicity NameCert obligations)**.** *For every accepted* CauchyCompletionM *carrier*

$$M = (T, A, K, U, D, W, R, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$ *surface consists exactly of carrier admission, completion-monad visibility, algebra-action exposure, Kleisli-route exposure, universal-property handoff, dense-embedding unit visibility, StreamName–RegSeqRat–DyadicRatCore–Real readback discipline, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No local obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5827.1. The displayed tuple lists every row available to the classifier, so local comparison can inspect only the completion monad, algebra action, Kleisli route, universal-property row, dense-embedding unit route, readback rows, transport, replay, provenance, and local naming.

The monadicity-facing rows are read in order. The monad row T displays the unit and bind schedule, the algebra row A records the Eilenberg–Moore action over that schedule, and the Kleisli row K keeps unit, bind, and reassociated-bind consumers on the same finite route.

The universal and dense rows then bind the comparison surface. The row U supplies extension and uniqueness data, while D supplies the dense source-to-completion unit route used before the comparison is exported.

Finally the readback and structural rows close the NameCert surface. The rows W, R, Q, E give finite windows, regular rational readback, dyadic tolerances, and the terminal Real seal; the rows H, C, P, N transport, replay, source, and name exactly that packet. Since no excluded coordinate occurs, no additional local obligation is available. □

Theorem 4802.3 (CauchyCompletionMonadicity comparison surface)**.** *Every comparison consumer of an accepted* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ *carrier factors through the finite route*

$$T, A, K, U, D \longmapsto W \longmapsto R \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus the completion-monad route, the algebra action, the Kleisli route, the universal-property row, and the dense-embedding unit route are compared only after the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$,

$\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readback surface has been displayed. The comparison exports no quotient completion equality, selected limit, host equality of completed objects, countable choice, ambient completeness, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the monad and algebra rows. The row T supplies the displayed completion transformer, and A reads its algebra action only as a row over that transformer.

Next attach the Kleisli and universal-property rows. The row K exposes the unit, bind, and reassociated-bind route, while U records the extension and uniqueness ledger for completion-facing consumers.

Now read the dense-embedding unit route D. It displays the source-to-completion image before the comparison reaches any terminal seal, so the route is a visible unit comparison rather than a selected representative.

Finally consume the readback and structural rows. The finite window W, regular readback R, dyadic tolerance ledger Q, and Real seal E precede transport, replay, provenance, and naming through H, C, P, N. Since the carrier contains no coordinate for the excluded objects, the comparison surface cannot export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ packet is generated from a CauchyCompletionMonad route, CauchyCompletionAlgebra action row, CauchyCompletionKleisli route, CompletionUniversalProperty row, MetricCompletionDenseEmbedding unit route, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5827.1, Definition 5827.2, and Definition 5827.3 seed the finite monadicity comparison boundary for the L10 completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient completeness, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completion-monad visibility, algebra-action exposure, Kleisli-route exposure, universal-property handoff, dense-embedding unit visibility, readback discipline, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionMonadicityUp.

Chapter 4803

A Concrete Naming Certificate for $\mathsf{BorsukUlam}^{\uparrow}$

Following Borsuk and Ulam, the $\mathsf{BorsukUlam}^{\uparrow}$ packet records the antipodal obstruction theorem as finite BEDC NameCert data rather than as a host topological principle. It sits after the degree surface of chapter 3745, the continuous-map rows of chapter 130, the real-name seal of chapter 38, the compact metric source of chapter 129, and the circle boundary model of chapter 58. The packet names the displayed antipodal route consumed by obstruction and degree-facing chapters; it does not select antipodal points, import unrestricted classical degree theory, identify quotient spheres, choose representatives, or appeal to ambient completeness.

Definition 4803.1 (Borsuk-Ulam carrier)**.** *A* $\mathsf{BorsukUlam}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, A, F, D, C, R, H, K, P, N)$$

with the following displayed rows:

1. *S is the compact metric sphere row read through the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *surface and the* $\mathsf{S}^{1\uparrow}$ *boundary model.*
2. *A is the antipodal-pair ledger, exposing only named paired source rows and the finite equality-refusal data attached to them.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the map whose antipodal comparison is being inspected.*
4. *D is the* $\mathsf{BrouwerDegree}^{\uparrow}$ *obstruction row, read only through the displayed degree certificate and never through unrestricted host degree theory.*
5. *C is the* $\mathsf{Real}^{\uparrow}$ *comparison-seal row for the coordinate difference or collapsed real-valued comparison consumed by the obstruction route.*
6. *R is the refusal row excluding selected antipodal points, quotient equality of sphere points, choice, unrestricted classical degree theory, and ambient completeness.*
7. *H records componentwise* hsame *transport for the compact source, antipodal ledger, continuous-map row, degree row, real comparison seal, refusal row, provenance, and local naming.*
8. *K records displayed* Cont *replay from the compact metric source through the antipodal ledger, continuous-map row, degree obstruction, real comparison seal, and refusal row.*
9. *P is the* Pkg *provenance over* $\mathsf{BorsukUlam}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{BrouwerDegree}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{BorsukUlam}^\uparrow}$ *row.*
The classifier compares accepted packets only through $S, A, F, D, C, R, H, K, P, N$. It has no coordinate for a chosen antipodal pair, quotient equality on the sphere, unrestricted classical degree theory, countable choice, or ambient Real completeness.

Lean4 (definition) `BEDC.Derived.BorsukUlamUp.BorsukUlamUp`
Lean4 ✓ `BEDC.Derived.BorsukUlamUp.BorsukUlamTasteGate single carrier alignment`

Theorem 4803.2 (Borsuk-Ulam NameCert obligations)**.** *For every accepted* $\mathsf{BorsukUlam}^\uparrow$ *carrier* $U = (S, A, F, D, C, R, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BorsukUlam}^\uparrow}$ *surface consists exactly of compact metric sphere admission, antipodal-pair ledger exposure, continuous-map readback, Brouwer-degree obstruction routing, Real comparison sealing, refusal of host and quotient shortcuts, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every obstruction-facing consumer must read*

$$S, A, F \longmapsto D, C \longmapsto R, H, K, P, N$$

before treating the packet as a Borsuk-Ulam certificate.

Proof. Project the carrier of Definition 5828.1. The compact source row S, antipodal ledger A, and continuous-map row F are the only rows available before the obstruction is read.

The degree and real-comparison rows D, C are downstream of that source route. The degree row is the displayed $\mathsf{BrouwerDegree}^\uparrow$ certificate, and the real row is the displayed $\mathsf{Real}^\uparrow$ seal for the comparison consumed by the obstruction.

Finally R, H, K, P, N refuse shortcuts, transport the same rows, replay the finite route, source it, and name it locally. Since the carrier has no coordinate for selected antipodal points, quotient equality, unrestricted host degree theory, countable choice, or ambient Real completeness, no consumer can export those objects from the certificate. □

Theorem 4803.3 (Borsuk-Ulam antipodal route)**.** *Every accepted* $\mathsf{BorsukUlam}^\uparrow$ *antipodal-obstruction read factors through the displayed compact metric sphere row, the* $\mathsf{S}^{1\uparrow}$ *boundary model, the antipodal-pair ledger, the* $\mathsf{ContinuousMap}^\uparrow$ *row, the* $\mathsf{BrouwerDegree}^\uparrow$ *obstruction row, the terminal* $\mathsf{Real}^\uparrow$ *comparison seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert*. The route exports no selected antipodal point, unrestricted classical degree theorem, quotient equality of sphere points, choice principle, ambient completeness, Lean verification, or bridge-checked surface.*

Proof. Start with an accepted carrier $U = (S, A, F, D, C, R, H, K, P, N)$. The source read begins at S and A, so the antipodal data is visible only as a finite paired ledger over the displayed compact metric and circle rows.

Read the map through F and then the obstruction through D, C. The $\mathsf{ContinuousMap}^\uparrow$ row supplies the function-facing data, the $\mathsf{BrouwerDegree}^\uparrow$ row supplies the obstruction route, and the $\mathsf{Real}^\uparrow$ row supplies only the comparison seal reached from those displayed rows.

The refusal and structural rows close the route. The row R blocks selected points, quotient equality, unrestricted degree theory, choice, and ambient completeness, while H, K, P, N preserve the same finite certificate under transport, replay, provenance, and local naming. □

Falsifiable prediction: Every accepted $\mathsf{BorsukUlam}^\uparrow$ consumer reads compact metric sphere data, an antipodal-pair ledger, a ContinuousMap row, a BrouwerDegree obstruction row, a Real

comparison seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before it treats the packet as an antipodal obstruction certificate.

Independence witness: brouwer-degree, continuousmap, real, compactmetric, s1: $\mathsf{BorsukUlam}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds compact sphere data, antipodal pairing, continuous-map readback, degree obstruction, real comparison sealing, refusal, transport, replay, provenance, and local naming into one obstruction-facing certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}$.

Constructive story: A $\mathsf{BorsukUlam}^{\uparrow}$ packet is generated from a compact metric sphere row, an S1 boundary model, an antipodal-pair ledger, a ContinuousMap row, a BrouwerDegree obstruction row, a RealUp comparison seal, shortcut refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5828.1, Definition 5828.2, and Definition 5828.3 seed the finite antipodal obstruction route over compact metric, circle, continuous-map, degree, real-seal, transport, replay, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected antipodal points, unrestricted classical degree theory, quotient equality, choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, antipodal ledger exposure, continuous-map readback, Brouwer-degree obstruction routing, Real comparison sealing, transport, replay, provenance, and local naming for BEDC.Derived.BorsukUlamUp.

Chapter 4804

A Concrete Naming Certificate for $\mathsf{DenjoyYoungSaks}^{\uparrow}$

Following Saks and Bishop–Bridges constructive real analysis, the $\mathsf{DenjoyYoungSaks}^{\uparrow}$ packet records the finite boundary at which a real-valued interval map can expose upper and lower Dini-derivative rows without importing the classical almost-everywhere Denjoy–Young–Saks theorem. It sits next to the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ observation window of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet is a finite classification boundary for displayed Dini rows, oscillation windows, regular-rational readback, and terminal Real seals; it is not a measure theorem, an almost-everywhere classifier, or a host-real differentiability principle.

Definition 4804.1 (Denjoy–Young–Saks finite Dini carrier)**.** *A* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the inspected interval row, listing the finitely presented source intervals and endpoint cells on which the local boundary is read.*
2. *F is the function-observation row, recording the finite source and target windows used to compare difference quotients.*
3. *U is the upper Dini row, storing the displayed upper right, upper left, and two-sided upper derivative bounds visible at the inspected windows.*
4. *L is the lower Dini row, storing the corresponding lower right, lower left, and two-sided lower derivative bounds.*
5. *O is the oscillation-window row, recording the finite alternation and stabilization tests used to classify a displayed window as one of the Dini-boundary cases.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule opened by I, F, O and no hidden stream coordinates.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational data extracted from the finite stream windows.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger supporting the difference-quotient comparisons and oscillation bounds.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after the interval, function-observation, Dini, oscillation, stream, readback, and dyadic rows have been exposed.*
10. *H records componentwise* hsame *transport for intervals, function observations, Dini rows, oscillation windows, stream schedules, regular readbacks, dyadic ledgers, Real seals, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from the inspected interval and function rows through U, L, O, S, R, D and into the Real seal E.*
12. *P is the* Pkg *provenance over* $\mathsf{DenjoyYoungSaks}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, U, L, O, S, R, D, E, H, C, P, N$. It has no coordinate for measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, host real order trichotomy, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.DenjoyYoungSaksUp.DenjoyYoungSaksTasteGate single carrier alignment`

Theorem 4804.2 (Denjoy–Young–Saks finite boundary obligations)**.** *For every accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier $Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the inspected interval, function-observation, upper Dini, lower Dini, oscillation-window, stream-schedule, regular-readback, dyadic-ledger, Real-seal, transport, replay, provenance, and local naming rows;*
2. *interval and observation exactness, requiring every Dini comparison to read its source cell from I and its finite function window from F before any derivative row is accepted;*
3. *upper and lower Dini-row exactness, requiring U and L to store only the finite upper and lower derivative bounds justified by the displayed difference-quotient windows;*
4. *oscillation-window classification, requiring O to record the finite alternation, stabilization, and gap tests that separate the visible Dini-boundary cases;*
5. *stream, readback, and dyadic exactness, requiring S, R, D to expose only the finite observations, regular rational readbacks, and dyadic tolerance rows demanded by I, F, U, L, O;*
6. *Real seal nonescape, requiring E to remain downstream of I, F, U, L, O, S, R, D and never to serve as a selected derivative, a host real equality witness, or an almost-everywhere theorem;*
7. *componentwise transport, replay, provenance, and local naming, requiring H, C, P, N to preserve exactly the displayed finite route.*

No $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *obligation is stored outside these rows, and the packet makes no claim that the classical Denjoy–Young–Saks alternatives hold almost everywhere.*

Proof. Carrier admission is projection from Definition 5829.1. The accepted packet displays exactly the inspected interval row I, function-observation row F, upper and lower Dini rows U, L, oscillation row O, stream schedule S, regular readback R, dyadic ledger D, Real seal E, and structural rows H, C, P, N.

Interval and observation exactness follow from the row order. A Dini comparison first reads the source cell in I and the finite function-observation window in F; only then may it inspect the upper row U, lower row L, or oscillation row O attached to that window.

The stream, regular-readback, and dyadic rows are downstream of the same finite windows. The schedule S opens only the observations demanded by I, F, O, the row R records the resulting regular rational readback, and D stores the tolerance comparisons needed for the displayed difference-quotient bounds.

Finally, the Real seal E is terminal for this finite boundary route. The transport row H, replay row C, provenance row P, and local naming row N preserve the same packet, so measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, and ambient completeness cannot become local obligations. □

Theorem 4804.3 (Denjoy–Young–Saks Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{StreamName}^{\uparrow}$ *consumer of an accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier reads the displayed route*

$$I, F, U, L, O, S, R, D, E, H, C, P, N.$$

Consequently the consumer may inspect finite interval cells, function observations, upper and lower Dini rows, oscillation windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal Real seal, componentwise transport, replay, provenance, and local naming. It cannot read a measure structure, an almost-everywhere assertion, a selected derivative, quotient real equality, host real trichotomy, countable choice, or ambient completeness from the packet.

Proof. Project the accepted carrier through Definition 5829.1. Its Real-facing and readback-facing rows are exactly S, R, D, E together with the preceding interval, function, Dini, and oscillation rows I, F, U, L, O and the structural rows H, C, P, N.

The route reaches E only after the finite Dini and oscillation boundary has been displayed. Thus any consumer that asks for a Real seal or regular rational readback must already have passed through the interval cells, function observations, upper and lower Dini rows, oscillation windows, stream schedule, and dyadic tolerance ledger.

Since the carrier has no row for measure, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, or ambient completeness, none of those objects can be read by a downstream consumer. □

Theorem 4804.4 (Denjoy–Young–Saks oscillation-window induction)**.** *For an accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier* $Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$*, induction over the finite oscillation-window row* O *preserves the separation between the upper Dini row* U *and the lower Dini row* L*. At every displayed stage the packet remains a finite boundary classifier over the rows of Definition 5829.1; the induction cannot promote the packet to an almost-everywhere measure theorem, cannot select a derivative, and cannot export a host-real differentiability principle.*

Proof. Induct over the displayed list of oscillation windows in O. The empty row has no Dini comparison to transport, so the upper and lower rows remain separated by the carrier projection.

For the step, assume the previously displayed windows preserve the separation of U and L. The next window is admitted only through the oscillation-window classification row in Definition 5829.2, so it may inspect the finite alternation, stabilization, and gap tests attached to that window but cannot rewrite the carrier outside $I, F, U, L, O, S, R, D, E, H, C, P, N$.

The Real-seal nonescape theorem Definition 5829.3 keeps every downstream read behind the same finite route. Thus adjoining the next oscillation window preserves the visible upper/lower Dini separation and leaves measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, and ambient completeness outside the packet. □

Falsifiable prediction: Every $\mathsf{DenjoyYoungSaks}^{\uparrow}$ Real-facing or readback-facing read factors through finite interval cells, function-observation windows, upper and lower Dini rows, oscillation windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: real, regseqrat, streamname, dyadicratcore: $\mathsf{DenjoyYoungSaks}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries upper and lower Dini rows, oscillation-window classification, regular-rational readback, dyadic tolerance data, and a terminal Real seal in one finite boundary packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$.

Constructive story: A $\mathsf{DenjoyYoungSaks}^{\uparrow}$ packet is generated from inspected interval cells, function-observation windows, upper and lower Dini rows, oscillation-window classifications, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5829.1, Definition 5829.2, and Definition 5829.3 seed the finite Denjoy–Young–Saks boundary route over Dini rows, oscillation windows, regular-rational readback, dyadic tolerance rows, and terminal Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.DenjoyYoungSaksUp.DenjoyYoungSaksTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close the classical almost-everywhere Denjoy–Young–Saks theorem, measure-null exceptional sets, selected derivatives, quotient real equality, trichotomy, countable choice, ambient completeness, or bridge checking beyond the carrier-alignment Lean target.

Upgrade path: Obligation closure requires checked carrier admission, Dini-row exactness, oscillation-window classification, stream-readback-dyadic exactness, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.DenjoyYoungSaksUp.

Chapter 4805

A Concrete Naming Certificate for $\mathsf{UniformlyConvexSpace}^{\uparrow}$

Following Clarkson's uniformly convex Banach-space reading and Bishop–Bridges constructive normed-space practice, the $\mathsf{UniformlyConvexSpace}^{\uparrow}$ packet records a finite modulus-of-convexity surface over the normed-space carrier of chapter 1950. It consumes the $\mathsf{NormedSpace}^{\uparrow}$ row, the real-valued norm and midpoint reads through chapter 38, the metric handoff of chapter 57, and the completion-facing route of chapter 95 and chapter 3413. The packet gives Banach, Hilbert, fixed-point, and convexity consumers a named uniform-convexity certificate without importing host Banach-space equality, selected minimizers, quotient completions, or choice.

Definition 4805.1 (UniformlyConvexSpace carrier)**.** *A* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (N, R, A, M, \Delta, Q, H, T, P, C)$$

with the following displayed rows:

1. *N is the* $\mathsf{NormedSpace}^{\uparrow}$ *row, exposing vector operations, the norm read, and the induced metric only through the normed-space NameCert surface.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *row used by norm values, radius comparisons, midpoint estimates, and positive modulus outputs.*
3. *A is the midpoint row, reading $(x + y)/2$ through the vector addition, scalar action, and real scalar rows already visible in N and R.*
4. *M is the metric handoff row, routing distance and unit-ball comparisons through the* $\mathsf{Met}^{\uparrow}$ *read induced by N.*
5. *Δ is the convexity-modulus row: for each displayed positive separation request it supplies a positive real margin forcing the midpoint norm below the unit bound whenever the two admitted unit vectors are separated by that request.*
6. *Q is the completion-facing row, allowing Cauchy and completion consumers to read the same norm, metric, midpoint, and modulus data without selecting a completed point.*
7. *H records componentwise* hsame *transport for N, R, A, M, Δ, Q and for the local structural rows.*
8. *T records displayed* Cont *replay from a uniform-convexity request through $N, R, A, M, \Delta, Q, H, P, C$.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformlyConvexSpace}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. C is the local $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for host Banach-space equality, strict-convexity as a pointwise substitute, quotient completion, selected closest points, compactness, reflexivity, or a choice principle.

Theorem 4805.2 (UniformlyConvexSpace NameCert obligations)**.** *For every accepted* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *carrier* $U = (N, R, A, M, \Delta, Q, H, T, P, C)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, normed-space visibility, real-valued norm and midpoint readback, metric separation handoff, positive modulus admission, midpoint contraction under the displayed separation request, completion-facing nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside* $N, R, A, M, \Delta, Q, H, T, P, C$*.*

Lean4 ✓ `BEDC.Derived.UniformlyConvexSpaceUp.UniformlyConvexSpaceTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 5831.1. The rows $N, R, A, M, \Delta, Q, H, T, P, C$ are the whole accepted packet.

The normed-space, Real, midpoint, and metric obligations are read first. The row N supplies the normed vector carrier, R supplies real-valued comparisons, A supplies midpoint formation, and M supplies the induced metric separation route.

The uniform-convexity content is isolated in Δ. For a displayed positive separation request, Δ supplies a positive margin and forces the midpoint norm read through A, N, R below the unit bound. Since Q, H, T, P, C only hand off, transport, replay, source, and name the same route, no host Banach-space equality, quotient completion, selected point, compactness, reflexivity, or choice coordinate can enter. □

Theorem 4805.3 (UniformlyConvexSpace modulus convexity route)**.** *Every accepted* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *consumer that asks for uniform convexity factors through*

$$\mathsf{NormedSpace}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{Completion}^{\uparrow}, \mathsf{Cauchy}^{\uparrow} \longmapsto H, T, P, C.$$

The modulus row Δ may be read only after the normed-space carrier, real norm values, midpoint operation, and metric separation row have been displayed. The route exports a finite modulus-of-convexity NameCert surface, not host strict convexity, a selected minimizer, quotient completion equality, compactness, reflexivity, or countable choice.

Proof. Begin with a uniform-convexity request. The normed-space row N supplies the only vector and norm data, while R supplies the real-valued unit-ball and positivity comparisons.

Read midpoint and separation next. The midpoint row A is formed from the displayed operations of N and R, and the metric handoff M reads separation through the induced metric of the same normed-space packet.

Only then can the modulus row Δ answer the request. Its output is tied to the displayed positive separation and midpoint norm route, and the completion-facing row Q sends Cauchy or completion consumers through the same route rather than through a selected completed point.

Finally H, T, P, C transport, replay, source, and name the packet. The excluded host strict-convexity, selected-minimizer, quotient-completion, compactness, reflexivity, and choice objects are absent from the carrier, so the finite modulus route is the whole exported surface. □

Falsifiable prediction: An accepted $\mathsf{UniformlyConvexSpace}^{\uparrow}$ read is refuted if a consumer obtains a uniform-convexity margin without first displaying the $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, midpoint, $\mathsf{Met}^{\uparrow}$, completion-facing, transport, replay, provenance, and local $\mathsf{NameCert}$ rows.

Independence witness: normedspace, real, metric, completion, cauchy: no listed sibling is bijective to $\mathsf{UniformlyConvexSpace}^{\uparrow}$ because the packet jointly carries normed-space data, real norm comparisons, midpoint formation, metric separation, a positive convexity modulus, completion-facing handoff, transport, replay, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformlyConvexSpace}^{\uparrow}$ packet is generated from a NormedSpace row, Real norm-comparison rows, a midpoint row, an induced Metric separation row, a convexity-modulus row, a Completion and Cauchy handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5831.1, Definition 5831.2, and Definition 5831.3 seed the finite modulus-of-convexity route over normed-space, real, metric, completion, and Cauchy rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.UniformlyConvexSpaceUp.UniformlyConvexSpaceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host Banach-space equality, strict-convexity substitution, selected minimizers, quotient completions, compactness, reflexivity, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, midpoint formation, metric separation, positive modulus exactness, completion-facing nonescape, and local naming for BEDC.Derived.UniformlyConvexSpaceUp.

Chapter 4806

A Concrete Naming Certificate for $\mathsf{HyperbolicTranslationLength}^{\uparrow}$

Following the classical translation length of a hyperbolic isometry, the $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ packet records the finite invariant-length route visible to the hyperbolic phase geometry of chapter 9463. It consumes the metric-read surface of chapter 3474, the routed geodesic-flow surface of chapter 3856, the additive Busemann cocycle route of chapter 4134, the four-boundary-point comparison of chapter 3948, and the terminal real seal of chapter 38. The packet names stable displacement growth as finite BEDC data; it does not import a host hyperbolic manifold, quotient ideal boundary, selected axis, spectral radius, or global curvature theorem.

Definition 4806.1 (HyperbolicTranslationLength carrier)**.** *A* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, F, B, X, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row, exposing displacement reads for the source and its iterated image.*
2. *F is the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *row, recording the finite routed-flow data used to compare iterates along the same visible geodesic route.*
3. *B is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *row, supplying additive boundary-cocycle comparisons for the same displayed endpoints.*
4. *X is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *row, recording the four-boundary-point invariant used to stabilize the length read.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *row used by displacement values, additive cocycle values, cross-ratio reads, and the final nonnegative length seal.*
6. *D is the displacement-growth row, comparing the displayed iterate window through M, F, B, X, R without selecting an infinite orbit or an axis.*
7. *E is the endpoint-stability row, stating that the same boundary data are replayed by the metric, flow, Busemann, and cross-ratio rows.*
8. *H records componentwise* hsame *transport for M, F, B, X, R, D, E and for the local structural rows.*

9. *C records displayed* Cont *replay from a translation-length request through $M, F, B, X, R, D, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host isometry group, selected invariant axis, quotient boundary equality, spectral radius, completed hyperbolic manifold, or physical expansion law.

Lean4 ✓ `BEDC.Derived.HyperbolicTranslationLengthUp.HyperbolicTranslationLengthTasteGate single carrier alignment`

Theorem 4806.2 (HyperbolicTranslationLength NameCert obligations)**.** *For every accepted* HyperbolicTranslation *carrier $L = (M, F, B, X, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$ *surface consists exactly of metric displacement visibility, geodesic-flow routing, Busemann additivity, cross-ratio stabilization, real-valued length sealing, displacement-growth comparison, endpoint stability, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside $M, F, B, X, R, D, E, H, C, P, N$.*

Proof. Project the carrier of Definition 5832.1. The rows $M, F, B, X, R, D, E, H, C, P, N$ are the whole visible packet.

The geometric route is read first. Metric displacement comes from M, routed iteration from F, additive boundary comparison from B, and four-boundary-point stabilization from X.

The Real and displacement rows then seal the length read. The row R supplies the real-valued comparison surface, while D and E ensure that the same endpoint data are used by the metric, flow, Busemann, and cross-ratio reads.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate names a host isometry group, selected invariant axis, quotient boundary equality, spectral radius, completed manifold, or physical expansion law, the listed obligations exhaust the local surface. □

Theorem 4806.3 (HyperbolicTranslationLength invariant route)**.** *Every accepted* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ *read factors through*

$$\mathsf{HyperbolicMetric}^{\uparrow}, \mathsf{HyperbolicGeodesicFlow}^{\uparrow}, \mathsf{HyperbolicBusemannCocycle}^{\uparrow}, \mathsf{HyperbolicCrossRatio}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto H, C, P$$

The finite route records displacement growth and boundary stabilization as a real-sealed invariant length, and it exports no host hyperbolic isometry, selected axis, quotient ideal-boundary equality, spectral radius, completed hyperbolic manifold, or cosmological expansion claim.

Proof. Begin with the displacement request. The metric row M supplies finite distance reads, and the geodesic-flow row F keeps the iterated comparison on the same displayed route.

Read boundary stabilization next. The Busemann cocycle row B supplies additive endpoint comparison, while the cross-ratio row X records the four-boundary-point invariant. The endpoint-stability row E requires these boundary reads to describe the same displayed data.

The Real row R and displacement-growth row D seal the invariant length as a finite real-valued read. The structural rows H, C, P, N preserve, replay, source, and name that route, while the excluded host and quotient objects remain absent from the carrier. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ consumer is refuted if it obtains an invariant length without displaying the $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}$ $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, displacement-growth, endpoint-stability, transport, replay, provenance, and local $\mathsf{NameCert}$ rows.

Independence witness: hyperbolicmetric, hyperbolic-geodesic-flow, hyperbolic-busemann-cocycle, hyperbolic-cross-ratio, real: no listed sibling is bijective to $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ because the packet jointly carries metric displacement, routed flow, additive boundary cocycle, cross-ratio stabilization, Real sealing, displacement-growth comparison, endpoint stability, transport, replay, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ packet is generated from HyperbolicMetric displacement rows, HyperbolicGeodesicFlow routing rows, HyperbolicBusemannCocycle additive boundary rows, HyperbolicCrossRatio stabilization rows, Real sealing rows, displacement-growth and endpoint-stability rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5832.1, Definition 5832.2, and Definition 5832.3 seed the finite invariant-length packet over metric, flow, Busemann, cross-ratio, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host hyperbolic isometries, selected axes, quotient ideal-boundary equality, spectral radii, completed hyperbolic manifolds, physical expansion laws, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, displacement visibility, flow routing, Busemann additivity, cross-ratio stabilization, Real length sealing, endpoint stability, and local naming for BEDC.Derived.HyperbolicTranslationLengthUp.

Chapter 4807

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$

Following Bishop and Bridges on constructive real completion, the $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ packet records the finite envelope that carries a regular Cauchy rational readback into the terminal Real naming seal. It sits after the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational sequence interface of chapter 301, the terminal real-name packet of chapter 38, and the completion route of chapter 1506. The packet is a finite NameCert envelope for the handoff itself; it does not assert that the host real line is complete.

Definition 4807.1 (Regular Cauchy completion envelope carrier)**.** *A* $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ *carrier is a finite packet*

$$E = (W, D, R, E_R, M, T, C, P, N)$$

where W *is the displayed* $\mathsf{StreamName}^{\uparrow}$ *window row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row,* E_R *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row,* M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row,* T *records componentwise* $\mathsf{BHist/hsame}$ *transport,* C *records displayed* Cont *replay,* P *is* Pkg *provenance over the displayed rows, and* N *is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}$ *row. A consumer of the carrier receives the completion handoff only through these nine coordinates.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionEnvelopeUp.RegularCauchyCompletionEnvelopeTasteGate`
`single carrier alignment`

Theorem 4807.2 (Regular Cauchy completion envelope obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompletion}$ *carrier*

$$E = (W, D, R, E_R, M, T, C, P, N),$$

the local NameCert surface consists exactly of window admission, tolerance admission, regular readback admission, terminal Real-seal admission, metric-completion route admission, transport stability, continuation replay, provenance preservation, and local naming preservation for the displayed packet. No quotient stream equality, selected representative, countable choice schedule, host completeness principle, or $\mathsf{Real}^{\uparrow}$ *completeness theorem is a coordinate of this surface.*

Proof. Project the carrier of Definition 5833.1. Its only data rows are $W, D, R, E_R, M, T, C, P, N$, so the local NameCert can inspect exactly those displayed coordinates.

The first four rows bind the finite observation, dyadic tolerance, regular rational readback, and terminal Real seal. The metric-completion row M is therefore read as a route row over those data, not as an ambient completeness object.

The structural rows T, C, P, N preserve the same packet under componentwise transport, continuation replay, provenance, and local naming. Since the carrier has no slot for quotient stream equality, selected representatives, countable choice, host completeness, or Real completeness, none of those objects can be exported by the obligation surface. □

Theorem 4807.3 (Regular Cauchy completion envelope Real handoff)**.** *Every Real-facing completion consumer of an accepted* $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ *carrier reads the terminal handoff through the ordered finite route*

$$W, D, R, E_R, M, T, C, P, N.$$

In particular, the consumer reaches the terminal $\mathsf{Real}^{\uparrow}$ *seal only after the* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback have been displayed inside the same envelope.*

Proof. Start from Definition 5833.2. It makes $W, D, R, E_R, M, T, C, P, N$ the entire accepted surface of the envelope.

Read the Real-facing route through W, D, R, E_R. The StreamName windows expose the finite observations, the dyadic ledger records the tolerance budget, the regular-rational row gives the readback, and the terminal row gives the Real seal inside the same packet.

The completion route M and the structural rows T, C, P, N only replay and name that displayed handoff. Thus the consumer cannot replace the handoff by quotient stream equality, a chosen representative, countable choice, host completeness, or a completeness theorem for $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5833.1, Definition 5833.2, and Definition 5833.3 seed the finite regular-Cauchy-to-Real completion envelope.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchyCompletionEnvelopeUp.RegularCauchyCompletionEnvelopeTasteGate\_single\_car`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, host completeness, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, row order, Real handoff, transport stability, replay stability, provenance preservation, and local NameCert preservation for BEDC.Derived.RegularCauchyCompletionEnvelopeUp.

Constructive story: A $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ packet is generated from StreamName windows, DyadicRatCore tolerance, RegSeqRat readback, terminal Real seal, metric-completion routing, transport, replay, provenance, and local NameCert rows.

Chapter 4808

A Concrete Naming Certificate for $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$

Following Bishop–Bridges constructive locatedness, the $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ packet records the finite interval-selection surface that can be read by Cauchy and Real interval consumers without selecting an endpoint or importing compactness. It sits over the located interval carrier of chapter 394, the rational cell ledger of chapter 354, the optional dyadic refinement rows of chapter 306, the endpoint observation windows of chapter 126, the regular rational readbacks of chapter 301, and the terminal Real seal of chapter 38. The packet names a finite route through displayed interval data; it does not assert endpoint choice, Heine–Borel compactness, trichotomy, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4808.1 (WeaklyLocatedIntervalSelection carrier)**.** *A* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, Q, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the source interval and its locatedness probes.*
2. *Q is the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger listing the rational subinterval cells visible to the selection route.*
3. *D is an optional* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement row; when present, it refines cells already displayed by Q and adds no independent selector.*
4. *W is the paired* $\mathsf{StreamName}^{\uparrow}$ *endpoint-window row through which finite endpoint observations are read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same endpoint windows and rational cells.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by any Real-facing endpoint or interval consumer.*
7. *H records componentwise* hsame *transport for $L, Q, D, W, R, E, C, P, N$.*
8. *C records displayed* Cont *replay from located interval probes through rational cells, optional dyadic refinements, endpoint windows, regular readbacks, and the Real seal.*
9. *P is* Pkg *provenance over* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$*,* $\mathsf{LocatedInterval}^{\uparrow}$*,* $\mathsf{RationalInterval}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets componentwise through these ten rows. There is no coordinate for an endpoint selector, an open-cover compactness argument, a trichotomy oracle, quotient equality of Real names, or host Real completeness.

Lean4 ✓ `BEDC.Derived.WeaklyLocatedIntervalSelectionUp.WeaklyLocatedIntervalSelectionTasteGate`
`single carrier alignment`

Theorem 4808.2 (WeaklyLocatedIntervalSelection NameCert obligations)**.** *For every accepted* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ *carrier*

$$S = (L, Q, D, W, R, E, H, C, P, N),$$

the local NameCert surface consists exactly of the following obligations:

1. *carrier admission for the finite* BHist *packet S and its displayed rows;*
2. *located-cell visibility from the* $\mathsf{LocatedInterval}^{\uparrow}$ *row L into the* $\mathsf{RationalInterval}^{\uparrow}$ *ledger Q;*
3. *finite selection-route exactness through the visible rational cells and any displayed* $\mathsf{DyadicInterval}^{\uparrow}$ *refinements D;*
4. *endpoint-window transport from Q, D into the* $\mathsf{StreamName}^{\uparrow}$ *windows W and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks R;*
5. *Real-seal nonescape, requiring every Real-facing read to pass through the displayed* $\mathsf{Real}^{\uparrow}$ *row E;*
6. *componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance preservation, and local* NameCert *preservation through H, C, P, N.*

No endpoint choice principle, Heine–Borel theorem, trichotomy principle, quotient equality of Real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem is an obligation or an output of this surface.*

Theorem 4808.3 (Weakly located interval selection route exhaustion)**.** *For every accepted* WeaklyLocatedIntervalSe
carrier

$$S = (L, Q, D, W, R, E, H, C, P, N),$$

every endpoint, interval, or Real-facing consumer factors through the displayed rows $L, Q, D, W, R, E, H, C, P, N$. Such a consumer cannot read endpoint choice, Heine–Borel compactness, trichotomy, quotient equality of Real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows of Definition 5834.1. The located interval source is L, the rational cell ledger is Q, and the optional dyadic refinement row is D.

Located-cell visibility therefore passes through L, Q, D. Endpoint or interval reads have no route around these rows because the packet stores no detached endpoint selector or host interval object.

The endpoint windows and regular rational readbacks are then W and R. A Real-facing consumer reaches the seal row E only after those finite windows and readbacks are visible.

Finally H, C, P, N transport, replay, source, and name the same route. Since endpoint choice, Heine–Borel compactness, trichotomy, quotient equality, and ambient completeness are absent from the tuple, the displayed rows exhaust every admitted consumer read. □

Closure status for $\mathsf{NameCert}_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}$ **·**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5834.1, Definition 5834.2, and Definition 5834.3 seed the finite weakly located interval-selection route over chapter 394, chapter 354, chapter 306, chapter 126, chapter 301, and chapter 38.

Formal verification: FormalStatus(NameCert$_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close endpoint choice, Heine–Borel compactness, trichotomy, quotient real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-cell visibility, finite selection-route exactness, endpoint-window transport, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.WeaklyLocatedIntervalSelectionUp.

Constructive story: A WeaklyLocatedIntervalSelection$^{\uparrow}$ packet is generated from LocatedInterval rows, RationalInterval cell ledgers, optional DyadicInterval refinements, StreamName endpoint windows, RegSeqRat readbacks, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 4809

A Concrete Naming Certificate for $\mathsf{UniformInverseModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{UniformInverseModulus}^{\uparrow}$ packet records compact inverse-modulus extraction from uniform homeomorphism data as finite NameCert data. It reads the homeomorphism and inverse-graph surface of chapter 1815, the compact finite-net rows of chapter 129, the graph and pointwise continuity rows of chapter 130, the exported modulus interface of chapter 369, the metric-source and metric-target rows of chapter 4230, and the terminal real-name seal of chapter 38. The chapter names the finite compact route that turns displayed inverse radii into a uniform inverse modulus; it is not a selected inverse function, host function equality, quotient real equality, open-cover compactness, or ambient completeness principle.

Definition 4809.1 (Uniform inverse modulus carrier)**.** *A* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A)$$

with the following displayed rows:

1. *X is the compact source row, exposing the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net data used to cover the compact domain of the homeomorphism.*
2. *Y is the target metric row, including the distance ledger into which the inverse-modulus estimate is reported.*
3. *F is the* $\mathsf{UniformHomeomorphism}^{\uparrow}$ *graph row from X to Y, carrying the forward graph and the homeomorphism naming data.*
4. *G is the inverse graph row displayed by the same homeomorphism packet.*
5. *E is the positive precision row, read through* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoint histories when the consumer presents a real tolerance.*
6. *N is the finite net row of the compact source at the scale needed for the inverse-modulus extraction.*
7. *R lists the pointwise inverse radius rows attached to the centers named by N.*
8. *M is the finite radius-fold row, obtained only by folding the finite family R over the index list of N.*
9. *T is the target estimate row, combining inverse-graph exactness, finite-net coverage, the folded radius row, and the target metric triangle ledger.*

10. *H records componentwise* hsame *transport for the compact source, target metric, homeomorphism graph, inverse graph, precision, finite-net, inverse-radius, radius-fold, and estimate rows.*
11. *C records the displayed* Cont *replay route from compact homeomorphism data and pointwise inverse radii to the* $\mathsf{UniformModulus}^{\uparrow}$ *export.*
12. *P records* Pkg *provenance over* $\mathsf{UniformInverseModulus}^{\uparrow}$, $\mathsf{UniformHomeomorphism}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, RegSeqRat$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *A is the local* $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$ *row.*

The carrier exposes only displayed compact finite nets, graph rows, inverse-graph rows, endpoint readbacks, finite radius rows, componentwise transport, replay, provenance, and local naming. It has no coordinate for a host inverse function, selected inverse choice, host function equality, quotient real equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformInverseModulusUp.UniformInverseModulusTasteGate single carrier alignment`

Theorem 4809.2 (Uniform inverse modulus obligations)**.** *For every accepted* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A),$$

the local $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the compact source, target metric, homeomorphism graph, inverse graph, precision, finite-net, inverse-radius, radius-fold, target-estimate, transport, replay, provenance, and local naming rows;*
2. *inverse-graph exactness, requiring every inverse read to pass through the displayed row G attached to the homeomorphism row F;*
3. *compact finite-net handoff, requiring the compact source row X and precision row E to determine the finite row N before any inverse radius is folded;*
4. *finite radius fold, requiring M to be obtained only by folding the pointwise inverse radius rows R over the finite indices of N;*
5. *target estimate, requiring T to combine compact-net coverage, inverse-graph exactness, folded-radius data, and the target metric ledger;*
6. *transport, replay, and provenance, requiring H, C, P, A to source the same displayed route componentwise;*
7. *nonescape, requiring the packet to export no host inverse function, selected inverse choice, host function equality, quotient real equality, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 5835.1. The projection exposes exactly the rows $X, Y, F, G, E, N, R, M, T, H$ so carrier admission and row inventory are finite.

The inverse read is confined to G. Since G is listed as a row of the same homeomorphism packet that supplies F, inverse-graph exactness is consumed as displayed graph data rather than as host function equality or selected inverse choice.

The compact handoff reads X and E before radius data. These rows determine the finite net N, and the pointwise inverse radii in R are indexed only by the centers listed by N.

Fold R over that finite index list to obtain M. The target estimate row T then combines the compact-net coverage, inverse-graph exactness, folded radius, and target metric triangle route. Finally H, C, P, A transport, replay, source, and name the same route, so no excluded equality, choice, open-cover, trichotomy, or completeness coordinate is introduced. □

Theorem 4809.3 (Uniform inverse modulus compact handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *export from an accepted* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A)$$

factors through the displayed finite route

$$X, F, G, E \longmapsto N, R \longmapsto M, T \longmapsto H, C, P, A.$$

Thus the inverse-modulus export is a compact finite-net and radius-fold handoff. It exports no host function equality, selected inverse choice, quotient real equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from a $\mathsf{UniformModulus}^{\uparrow}$ consumer of I. By Definition 5835.2, the consumer must read the compact source, homeomorphism graph, inverse graph, and precision rows before the finite-net row is available.

The only finite-net row is N, and the only pointwise inverse-radius inventory is R. Hence the consumer reaches the exported modulus row M only after the finite fold over R indexed by N.

The target estimate T is downstream of that fold. It cannot be read as a host inverse function or as quotient equality of inverse values, because the carrier contains only displayed graph and metric-ledger rows.

Finally the structural rows H, C, P, A transport, replay, source, and name the same compact route. Since the carrier contains no coordinate for selected inverse choice, trichotomy, open-cover compactness, or ambient completeness, the export factors through exactly the displayed finite-net and radius-fold handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformInverseModulus}^{\uparrow}$ packet is generated from UniformHomeomorphism graph and inverse-graph rows, CompactMetric finite-net rows, ContinuousMap pointwise inverse-radius rows, UniformModulus export rows, MetricSpace distance ledgers, RealUp and RegSeqRat endpoint readbacks, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$, seed)

Scope closed: Definition 5835.1, Definition 5835.2, and Definition 5835.3 seed the finite compact route from displayed inverse radii to a UniformModulus consumer.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient completeness, host inverse functions, selected inverse choice, quotient real equality, trichotomy, open-cover compactness, Lean verification, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, inverse-graph exactness, compact finite-net handoff, finite radius fold, target estimate, transport, replay, provenance, and local naming for BEDC.Derived.UniformInverseModulusUp.

Chapter 4810

A Concrete Naming Certificate for $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$

Following Bishop and Bridges on constructive real intervals, the $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ packet records a bounded interval together with the finite nested-window route used by Real and completion consumers. It sits over the dyadic rational arithmetic of chapter 291, the stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names a bounded interval principle for displayed nested windows; it does not assert open-cover compactness, a global supremum operator, quotient real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4810.1 (BoundedCompleteRealInterval carrier)**.** *A* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the bounded interval row. It records the inspected lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint names, the boundedness witness visible to the packet, and the local containment predicate for interval windows.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger. It records the dyadic rational cuts used to compare successive windows and to certify the displayed diameter bound.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It lists exactly the finite endpoint and interval observations that may be inspected by the nested-window route.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same dyadic cuts and stream windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by every Real-facing extraction from B, D, W, R.*
6. *H records componentwise* hsame *transport for bounded interval rows, dyadic ledgers, stream windows, regular rational readbacks, Real seals, replay, provenance, and the local name.*
7. *C records displayed* Cont *replay from a nested-window request through B, D, W, R, E.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, D, W, R, E, H, C, P, N$. There is no coordinate for open-cover compactness, a selected supremum, host interval equality, quotient equality of Real names, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedCompleteRealIntervalUp.TasteGate.BoundedCompleteRealIntervalTasteGate single carrier alignment`

Theorem 4810.2 (BoundedCompleteRealInterval NameCert obligations)**.** *For every accepted* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier*

$$I = (B, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the bounded interval row, dyadic endpoint ledger, stream windows, regular rational readback, Real seal, componentwise transport, continuation replay, package provenance, and local naming row;*
2. *bounded-window visibility, requiring every interval read to pass through the displayed lower-upper row B and its local containment predicate;*
3. *dyadic diameter discipline, requiring D to witness the inspected endpoint comparisons and the shrinking-width estimates used by the extraction route;*
4. *stream-readback exactness, requiring W and R to reuse the same finite endpoint observations and dyadic cuts rather than selecting a second Real representative;*
5. *Real-seal nonescape, requiring every Real-facing output to pass through E after B, D, W, R have all been projected;*
6. *structural preservation through H, C, P, N, with no exported row for open-cover compactness, selected suprema, host interval equality, quotient Real equality, countable choice, trichotomy, or ambient Real completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5836.1. The accepted packet displays exactly the bounded interval row, dyadic endpoint ledger, stream windows, regular rational readback, Real seal, and the structural rows.

Bounded-window visibility is forced by B. A consumer can inspect only the finite lower-upper interval data and the local containment predicate already present in the carrier.

Dyadic diameter discipline is forced by D. The endpoint comparisons and shrinking-width estimates used by the packet are the only numerical rows available to the later stream and readback rows.

The rows W and R are downstream of the same dyadic ledger. They schedule finite observations and repack them as regular rational readback without replacing the bounded interval by a second Real representative.

Finally, E, H, C, P, N close the route. The Real seal is reached only after B, D, W, R, while transport, replay, provenance, and naming preserve the same displayed data. Since no excluded coordinate occurs in the carrier, the local NameCert surface has exactly the listed obligations. □

Theorem 4810.3 (BoundedCompleteRealInterval nested-interval extraction)**.** *Let $I = (B, D, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier. Every nested-window extraction exported by I factors through the finite route*

$$B \longmapsto D \longmapsto W \longmapsto R \longmapsto E$$

before it can inspect transport, replay, provenance, or local naming rows. The extracted Real-facing read is therefore determined by the bounded interval row, the dyadic diameter ledger, the stream windows, and the regular rational readback visible in the packet.

Proof. Begin with a nested-window extraction from I. The carrier gives no source row before the bounded interval row B, so the lower-upper interval data and local containment predicate are inspected first.

The extraction then projects the dyadic ledger D. This fixes the endpoint comparisons and diameter estimates available to the finite window schedule.

Next the extraction passes through W and R. The stream row exposes only the finite endpoint observations allowed by B, D, and the regular rational row repacks those same observations as the readback consumed by the Real seal.

Only after this route has been displayed can the extraction reach E. The remaining rows H, C, P, N preserve, replay, source, and name the same route, so the exported extraction is exhausted by the displayed bounded-window data. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5836.1, Definition 5836.2, and Definition 5836.3 seed the bounded real interval packet over dyadic endpoint ledgers, StreamName windows, RegSeqRat readbacks, and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, a global supremum operator, host interval equality, quotient real equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-window visibility, dyadic diameter discipline, stream-readback exactness, Real-seal nonescape, structural preservation, and nested-window extraction for BEDC.Derived.BoundedCompleteRealIntervalUp.

Constructive story: A $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ packet is generated from a bounded Real interval row, a DyadicRatCore endpoint ledger, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 4811

A Concrete Naming Certificate for $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$

Following Bishop and Bridges on constructive completion and Mac Lane on functoriality, the $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ packet records the finite BEDC surface where a displayed real-completion request is read functorially through bounded windows rather than through a quotient completion object. It sits over the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the completion-map discipline of chapter 1937. The packet gives downstream completion consumers one named window-functor route before any quotient stream, selected limit, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle is available.

Definition 4811.1 (RealCompletionWindowFunctor carrier)**.** *A* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (W, D, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row naming the source and target observation windows used by the completion request.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger comparing the source and target windows at the requested precision.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows and tolerances.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, D, R have all been displayed.*
5. *F is the functorial map row, read through* $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$*, recording how the displayed source window is transported to the displayed target window.*
6. *H records componentwise* hsame *transport for W, D, R, E, F, C, P, N.*
7. *C records displayed* Cont *replay from a completion-window request through W, D, R, E, F, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionFunctoriality}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the nine displayed rows. It has no coordinate for quotient completion classes, selected representatives, host real equality, countable-choice schedules, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RealCompletionWindowFunctorUp.RealCompletionWindowFunctorTasteGate single carrier alignment`

Theorem 4811.2 (RealCompletionWindowFunctor NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ *carrier*

$$Q = (W, D, R, E, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed finite packet* Q*;*
2. *analytic readback order* $W \longmapsto D \longmapsto R \longmapsto E$*;*
3. *functorial map exposure through the row* F *over the same windows and tolerances;*
4. *structural stability through* hsame *transport and displayed* Cont *replay;*
5. *provenance and local naming through* P *and* N*.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5777.1. The accepted packet displays exactly $W, D, R, E, F, H, C, P, N$, so every local NameCert read must be a read of one of those coordinates.

The analytic route is ordered by the displayed rows. The finite StreamName windows W are inspected before the dyadic tolerance ledger D, the regular rational readback R, and the terminal Real seal E.

The functorial row F is attached to the same window and tolerance ledger through $\mathsf{CauchyCompletionFunctoriality}$ Thus a completion consumer receives only the displayed map action on the finite route, not a quotient completion map or a selected representative.

Finally the rows H, C, P, N transport, replay, source, and name the same packet. Since no excluded object occurs as a carrier coordinate, no additional local obligation is available. □

Theorem 4811.3 (RealCompletionWindowFunctor finite route)**.** *Every completion-facing read exported by an accepted* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ *carrier factors through the finite route*

$$W \longmapsto D \longmapsto R \longmapsto E \longmapsto F \longmapsto H, C, P, N.$$

Consequently the functorial completion-map row is consumed only after the StreamName windows, DyadicRatCore tolerance ledger, RegSeqRat readback, and Real seal boundary have been displayed inside the same packet.

Proof. Apply Definition 5777.2. Its obligation surface exposes exactly carrier admission, analytic readback order, functorial map exposure, structural stability, provenance, and local naming.

Read the analytic side first. The rows W, D, R, E display the finite observation windows, dyadic tolerance ledger, regular rational readback, and terminal Real seal.

Then read the functorial side through F and the structural rows. The rows H, C, P, N keep that map action attached to the same finite packet. Therefore the completion consumer cannot detach the functorial map from the displayed window route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5777.1, Definition 5777.2, and Definition 5777.3 seed the finite completion-window functor route over StreamName, DyadicRatCore, RegSeqRat, Real, CauchyCompletionFunctoriality, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletionWindowFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, full functor laws for all completion objects, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window order, tolerance readback, Real-seal routing, functorial-map exposure, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletionWindowFunctorUp.

Constructive story: A $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ packet is generated from StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a terminal Real seal, a CauchyCompletionFunctoriality map row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4812

A Concrete Naming Certificate for $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$

The $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ packet realizes the Real and Completion route of chapter 9238 as finite window-functor data before any completion consumer reads a limit-facing object. It binds the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the displayed completion functor row of chapter 5777. The packet names a finite completion-window functor surface for the Real completeness spine; it does not assert quotient completion equality, selected limits, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4812.1 (RealCompletenessWindowFunctor carrier)**.** *A* $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (V, W, D, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *V is the originating Real-completeness request row read from chapter 9238.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row exposed before any regular-rational or Real-seal read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same window request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that consumes W and D.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, D, R have been displayed.*
6. *F is the* $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$ *row that packages the finite functorial completion handoff.*
7. *H records componentwise* hsame *transport for $V, W, D, R, E, F, C, P, N$.*
8. *C records displayed* Cont *replay from a Real-completeness request through $V, W, D, R, E, F, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$, $\mathsf{RealCompletionWindowFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these ten rows. It has no coordinate for quotient completion classes, selected representatives, countable-choice schedules, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 4812.2 (RealCompletenessWindowFunctor NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ *carrier*

$$Q = (V, W, D, R, E, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}$ *surface consists exactly of carrier admission, originating Real-completeness request exposure, StreamName window exposure, DyadicRatCore tolerance exposure, RegSeqRat readback exposure, Real seal exposure, finite completion-window functor exposure, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Carrier admission is projection from Definition 5778.1. The tuple displays exactly $V, W, D, R, E, F, H, C, P, N$ so the local NameCert can inspect only those rows.

The Real-completeness request row V is read before the finite analytic route. The rows W, D, R, E then display StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, and the terminal Real seal.

The functorial row F is the only completion-window handoff. It packages the Real-completion functorial read after the displayed analytic route rather than replacing it by a quotient completion object.

The rows H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded coordinate occurs, no additional local obligation is available. □

Falsifiable prediction: Every accepted $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ read displays $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ seal rows before any completion consumer reads the packet.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchycompletionfunctoriality: $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ is not bijective to any listed sibling because it jointly retains the originating Real-completeness request, finite StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, Real seal, completion-window functor row, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5778.1 and Definition 5778.2 seed the finite Real-completeness completion-window functor route over StreamName, DyadicRatCore, RegSeqRat, Real, RealCompletionWindowFunctor, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletenessWindowFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, full Real-completeness proof, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request exposure, finite-window exposure, tolerance exposure, regular readback, Real-seal exposure, completion-window functor exposure, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletenessWindowFunctorUp.

Constructive story: A $\mathsf{RealCompletenessWindowFunctor}^{\uparrow}$ packet is generated from a Real-completeness request row, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a Real seal, a RealCompletionWindowFunctor row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4813

A Concrete Naming Certificate for $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ packet records the explicit modulus route by which a bounded compact-real sequence yields inspected subsequence windows before any downstream consumer reads a real cluster seal. It sits over the constructive subsequence packet of chapter 5830, the sibling Bolzano–Weierstrass route of chapter 1254, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite subsequence-modulus carrier for compact-real consumers; it is not an open-cover compactness theorem, not an arbitrary-choice selector, not quotient real equality, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4813.1 (Compact real subsequence modulus carrier)**.** *A* $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, S, B, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact real source row, exposing the bounded* $\mathsf{Real}^{\uparrow}$ *sequence request and the compact-metric inspection data visible to the packet.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing exactly the finite source windows inspected by the modulus.*
3. *B is the* $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ *and* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *route row, carrying the interval-refinement and subsequence scheduling surface without adding a host compactness principle.*
4. *W is the subsequence-modulus row, recording selected indices, monotonicity, cofinal scheduling, and the finite window assignment for each requested precision.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording radius requests, split budgets, comparison windows, and common-scale data used by the selected windows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same selected windows and tolerance ledger.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *cluster seal, visible only after K, S, B, W, D, R have been displayed.*
8. *H records componentwise* hsame *transport for the source, stream windows, route, modulus, tolerance, readback, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a compact-real subsequence request through source inspection, stream windows, route selection, modulus scheduling, dyadic tolerance accounting, regular rational readback, and the real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$, $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$, $\mathsf{BolzanoWeierstrass}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, S, B, W, D, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, arbitrary choice, quotient real equality, selected least cluster points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactRealSubsequenceModulusUp.TasteGate.CompactRealSubsequenceModulusTasteGate single carrier alignment`

Theorem 4813.2 (Compact real subsequence modulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ *carrier*

$$M = (K, S, B, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}$ *surface consists exactly of compact real source exposure through K, finite stream-window exposure through S, constructive Bolzano–Weierstrass route exposure through B, subsequence-modulus scheduling through W, dyadic tolerance accounting through D, regular rational readback through R, terminal real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5779.1. Its analytic rows are the compact real source K, stream windows S, constructive route B, subsequence modulus W, tolerance ledger D, regular readback R, and real seal E.

The modulus obligation is finite because W records selected indices, monotonicity, cofinal scheduling, and selected windows as packet data. The route row B imports the displayed ConstructiveBolzanoWeierst and $\mathsf{BolzanoWeierstrass}^{\uparrow}$ subsequence construction rather than an ambient compactness theorem.

The readback obligation then passes through D and R. The same selected windows receive the dyadic tolerance budget before they can be read as a $\mathsf{RegSeqRat}^{\uparrow}$ sequence.

Finally E, H, C, P, N seal, transport, replay, source, and name only those rows. Since the carrier contains no open-cover, arbitrary-choice, quotient-equality, selected-least-cluster, or ambient-completeness coordinate, the listed rows exhaust the local certificate surface. □

Theorem 4813.3 (Constructive Bolzano–Weierstrass modulus route)**.** *Every* $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ *consumer that reads a compact real subsequence route from an accepted carrier must factor through*

$$\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow},\quad \mathsf{BolzanoWeierstrass}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

The factorization exposes finite source windows, a displayed subsequence-modulus row, dyadic tolerance accounting, regular rational readback, and a terminal real seal; it exports no open-cover compactness, arbitrary-choice selector, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness datum.*

Proof. Apply Definition 5779.2. It places the constructive and sibling Bolzano–Weierstrass route row before the modulus row and before any regular rational readback.

The finite windows are exactly the row S, and the selected windows are exactly the row W. Thus any consumer that changes the source window or selected window must leave the displayed carrier.

The dyadic tolerance ledger D is read before R, and R is read before the terminal real seal E. This orders the packet through the stated route and prevents the excluded host principles from entering the subsequence-modulus handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5779.1, Definition 5779.2, and Definition 5779.3 seed the explicit compact-real subsequence-modulus route through finite windows, dyadic tolerances, regular readback, and real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactRealSubsequenceModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, arbitrary choice, quotient real equality, selected least cluster points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stream-window exactness, constructive Bolzano–Weierstrass route exposure, subsequence-modulus scheduling, dyadic tolerance accounting, RegSeqRat readback, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactRealSubsequenceModulusUp.

Constructive story: A $\mathsf{CompactRealSubsequenceModulus}^{\uparrow}$ packet is generated from compact real source data, finite StreamName windows, ConstructiveBolzanoWeierstrass and BolzanoWeierstrass route data, subsequence-modulus scheduling, DyadicRatCore tolerance accounting, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, provenance, and a local NameCert row.

Chapter 4814

A Concrete Naming Certificate for MetaCICNormalEndpointComparator$^{\uparrow}$

The MetaCICNormalEndpointComparator$^{\uparrow}$ packet realizes the bounded-conversion endpoint bridge named by the MetaCIC decidability audit map of chapter 9379. It sits between the bounded normal conversion bridge of chapter 3439, the decidable conversion frontier of chapter 4097, the normalization frontier of chapter 892, the normal-form consistency seal of chapter 740, and the critical-path packet of chapter 765. The packet is a finite comparator for finished bounded normal endpoints; it is not a global beta-conversion decider, not a strong-normalization theorem, and not a host equality oracle.

Definition 4814.1 (MetaCIC normal endpoint comparator carrier)**.** *A* MetaCICNormalEndpointComparator$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (T, L, R, B, F, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed closed-term pair row supplied by the decidable conversion frontier.*
2. *L and R are the left and right bounded-normal computation traces, each carrying fuel, output syntax, and finished-endpoint evidence.*
3. *B is the* BoundedNormalConversionBridge$^{\uparrow}$ *row, exposing the bounded comparison result and its soundness route.*
4. *F is the* MetaCICNormalizationFrontier$^{\uparrow}$ *row, recording that both bounded traces have reached named normal endpoints at the comparator fuel.*
5. *S is the* NormalFormConsistencySeal$^{\uparrow}$ *row, checking that the two endpoint witnesses are read through the same normal-form consistency surface.*
6. *Q is the* MetaCICCriticalPath$^{\uparrow}$ *row that keeps the comparator tied to the decidability and normalization critical path rather than to an unrestricted conversion oracle.*
7. *H records componentwise* hsame *transport for the term pair, endpoint traces, bridge, frontier, seal, critical-path, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a bounded conversion request through endpoint computation, finished-normal evidence, endpoint comparison, consistency sealing, and critical-path accounting.*

9. *P is the* Pkg *provenance over* MetaCICNormalEndpointComparator$^{\uparrow}$, MetaCICDecidableConversionFrontier$^{\uparrow}$, BoundedNormalConversionBridge$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, NormalFormConsistencySeal$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, L, R, B, F, S, Q, H, C, P, N$. It has no coordinate for unrestricted conversion decidability, fuel-erased normalization, strong normalization, proof irrelevance, quotienting of syntax, or host equality.

Theorem 4814.2 (MetaCIC normal endpoint comparator NameCert obligations)**.** *For every accepted* MetaCICNormalEndpointComparator$^{\uparrow}$ *carrier*

$$E = (T, L, R, B, F, S, Q, H, C, P, N),$$

the local NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$ *surface consists exactly of typed closed-term pair admission through T, left and right bounded endpoint traces through L, R, bounded conversion bridge exposure through B, normalization-frontier endpoint evidence through F, normal-form consistency sealing through S, critical-path accounting through Q, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5780.1. The computational rows are exactly the term pair T, the endpoint traces L, R, the bounded conversion bridge B, the normalization frontier F, the consistency seal S, and the critical-path row Q.

The endpoint evidence is finite because L and R carry bounded traces at a displayed fuel. The row F records that those traces have reached finished normal endpoints before the comparator is consumed.

The comparison then passes through B and S. The bridge supplies the bounded conversion handoff, and the seal checks that the endpoint witnesses are compared through the same normal-form consistency surface.

Finally Q, H, C, P, N keep the packet on the MetaCIC critical path, transport it componentwise, replay it, source it, and name it. Since the carrier contains no unrestricted conversion, fuel-erased normalization, strong-normalization, proof-irrelevance, syntax-quotient, or host-equality coordinate, the listed rows exhaust the local certificate surface. □

Theorem 4814.3 (Bounded conversion endpoint handoff)**.** *Every* MetaCICNormalEndpointComparator$^{\uparrow}$ *consumer that promotes bounded conversion evidence to a finished endpoint comparison must factor through*

MetaCICDecidableConversionFrontier$^{\uparrow}$, BoundedNormalConversionBridge$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, No

The handoff supplies only typed closed-term pair data, bounded traces, finished endpoint evidence, endpoint consistency, critical-path accounting, transport, replay, provenance, and local naming.

Proof. Use Definition 5780.2. The typed closed-term pair is read first through T, while L and R record the bounded normal computations to be compared.

The row F is the endpoint boundary: it must be displayed before a bounded comparison can be read as a finished normal-form comparison. The bridge row B and seal row S then compare those endpoints through the bounded-conversion and normal-form consistency surfaces.

The critical-path row Q prevents the handoff from being read as a global conversion theorem. The structural rows H, C, P, N preserve and name only this finite route, so the consumer receives no unrestricted conversion decider or host equality oracle. □

Theorem 4814.4 (Closed-normal comparator vision obligations)**.** *The* MetaCICNormalEndpointComparator$^{\uparrow}$ *packet exposes exactly the finite comparator surface consumed by chapter 9376: closed normal endpoint rows, false-endpoint exclusion rows, and comparator determinacy rows are read through the displayed term pair T, bounded traces L, R, bounded conversion bridge B, normalization frontier F, normal-form consistency seal S, critical-path row Q, componentwise transport H, replay C, provenance P, and local naming N. No consumer of this surface receives unrestricted conversion decidability, fuel-erased normalization, proof irrelevance, syntax quotient equality, or host equality.*

Proof. Project the carrier of Definition 5780.1. The closed normal endpoint rows are precisely the finished bounded traces L, R read together with the normalization-frontier evidence F.

The false-endpoint exclusion row is read through the normal-form consistency seal S and the critical-path row Q. Those rows are the only coordinates tying the finished endpoint comparison to the closed-normal consistency boundary of chapter 9376.

Comparator determinacy is then read through the bounded conversion bridge B over the same typed pair T. The structural rows H, C, P, N transport, replay, source, and name this finite route.

Since the carrier contains no unrestricted conversion decider, fuel-erased normalizer, proof-irrelevance coordinate, syntax quotient, or host equality oracle, the listed rows are the complete comparator obligation surface consumed by the closed-normal consistency route. □

Falsifiable prediction: A MetaCIC conversion consumer that reads a finished endpoint comparison while omitting either bounded endpoint trace, the bounded-normal-conversion bridge, the normalization-frontier endpoint evidence, the normal-form consistency seal, the critical-path row, transport, replay, provenance, or local naming refutes MetaCICNormalEndpointComparator$^{\uparrow}$.

Independence witness: metacic-decidable-conversion-frontier, bounded-normal-conversion-bridge, metacicnormalizationfrontier, normal-form-consistency-seal, metaciccriticalpath: MetaCICNormalEndpointCompara is not bijective to any listed sibling because it jointly carries typed closed-term pair data, two bounded endpoint traces, bounded conversion bridge data, finished-normal endpoint evidence, consistency sealing, critical-path accounting, transport, replay, provenance, and local NameCert rows in one comparator packet.

The Lean follow-up must provide explicit Nontrivial MetaCICNormalEndpointComparator$^{\uparrow}$ and FieldFaithful MetaCICNormalEndpointComparator$^{\uparrow}$ instances in TasteGate.lean for the same finite carrier.

Closure status for NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$**.**

Theory closure: TheoryGate(NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$, seed)

Scope closed: Definition 5780.1, Definition 5780.2, and Definition 5780.3 seed the finite comparator that hands bounded conversion evidence to finished normal endpoints.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICNormalEndpointComparator}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim unrestricted conversion decidability, fuel-erased normalization, strong normalization, proof irrelevance, quotient syntax equality, host equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint trace exactness, bounded bridge exposure, normalization-frontier endpoint evidence, normal-form consistency sealing, critical-path accounting, transport, replay, provenance, local naming, and TasteGate nontriviality with field faithfulness for BEDC.Derived.MetaCICNormalEndpointComparatorUp.

Constructive story: A MetaCICNormalEndpointComparator$^{\uparrow}$ packet is generated from typed closed-term pair data, two bounded endpoint traces, BoundedNormalConversionBridge data, MetaCICNormalizationFrontier endpoint evidence, NormalFormConsistencySeal data, MetaCICCriticalPath accounting, componentwise hsame transport, displayed Cont replay, provenance, and a local NameCert row.

Chapter 4815

A Concrete Naming Certificate for $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$

Following Riemann and Bishop–Bridges constructive integration, the $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ packet records the finite route by which a continuous function on a located closed real interval receives a Darboux/Riemann integrability certificate. It consumes the pointwise-modulus surface of chapter 59, the tag-bearing finite interval route of chapter 4296, the Darboux upper/lower boundary of chapter 1880, the integrability carrier of chapter 1960, the weak located interval selector of chapter 5834, and the real-name seal of chapter 38. The packet gives integration consumers a finite NameCert surface for continuous functions without importing measure integration, open-cover compactness, quotient equality of real names, selected limiting values, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4815.1 (Continuous Riemann integrability carrier)**.** *A* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (F, T, D, J, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{Continuous}^{\uparrow}$ *row exposing the pointwise modulus and graph-stability data of the integrand over the displayed interval source.*
2. *T is the* $\mathsf{TaggedRealPartition}^{\uparrow}$ *row naming the finite partition cells, tag containment, window reads, regular readbacks, and terminal real seals used for integration.*
3. *D is the* $\mathsf{DarbouxSum}^{\uparrow}$ *row carrying lower and upper finite sums over the same displayed partition route.*
4. *J is the* $\mathsf{RiemannIntegrable}^{\uparrow}$ *handoff row, read only after the Darboux gap row has been displayed.*
5. *W is the* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ *row that exposes located cells and endpoint windows for the closed interval source.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family opened for interval endpoints, partition tags, and pointwise modulus reads.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family attached to the same finite windows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, T, D, J, W, S, R have been displayed.*

9. *H records componentwise* hsame *transport for the continuous row, tagged partition, Darboux rows, integrability handoff, weak interval selector, window and readback rows, real seal, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from pointwise modulus requests through located cells, finite tagged partitions, Darboux lower/upper rows, the integrability handoff, and the terminal real seal.*

11. *P is the* Pkg *provenance over* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{TaggedRealPartition}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegrable}^{\uparrow}$, $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, T, D, J, W, S, R, E, H, C, P, N$. It has no coordinate for full integration theory, measure integration, open-cover compactness, quotient equality, selected limits, or ambient real completeness.

Theorem 4815.2 (Continuous Riemann integrability NameCert obligations)**.** *For every accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier*

$$I = (F, T, D, J, W, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the finite* BHist *packet and the displayed rows $F, T, D, J, W, S, R, E, H, C, P, N$;*

2. *interval-source visibility through the weakly located interval row W and its located cell, endpoint-window, and regular-readback route;*

3. *pointwise modulus exposure through the continuous-function row F, with every modulus read tied to displayed interval cells and finite windows;*

4. *finite tagged partition coverage through T, including cell containment, tag containment, and the same* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows;*

5. *Darboux gap control through D, read as finite lower and upper sums over the displayed tagged partition route;*

6. *integrability handoff through J, allowed only after the Darboux gap row and partition coverage rows are visible;*

7. *Real-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

No full integration theory, measure integration, open-cover compactness, quotient equality of real names, selected limiting value, Lean verification, or bridge checking is an obligation or output of this packet.

Proof. Carrier admission is the projection of Definition 5838.1. The accepted packet displays the continuous row, tagged partition, Darboux row, integrability handoff, weak interval selector, window family, regular readback, real seal, transport, replay, provenance, and local name.

The interval and modulus rows are read first. The row W supplies located cells and endpoint windows, while F supplies pointwise modulus data only over those displayed cells and windows.

The finite partition route is then exposed by T. Tags and endpoints are read through S and R, so the integration-facing partition is a finite BEDC object rather than a host partition or a selected representative family.

The Darboux and integrability rows are downstream. The row D computes lower and upper finite sums over the displayed partition route, and J exports integrability evidence only after that gap control is visible.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since the carrier has no coordinate for the excluded analytic objects, the listed rows exhaust the local NameCert surface. □

Theorem 4815.3 (Continuous Riemann integrability Darboux handoff)**.** *Every integration-facing consumer of an accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier factors through the finite partition and Darboux rows*

$$W, F \longmapsto T, S, R \longmapsto D \longmapsto J \longmapsto E, H, C, P, N.$$

Consequently the consumer receives a finite located-cell, pointwise-modulus, tagged-partition, lower/upper Darboux, integrability-handoff, and Real-seal route rather than quotient reals, host equality, choice-selected witnesses, or ambient Real completeness.

Proof. Begin with an integration-facing read. The weak interval selector W and continuous row F force the request through located cells, endpoint windows, and pointwise modulus rows before any partition or sum row can be inspected.

Next read the tagged partition route T, S, R. The finite cells and tags are displayed together with their StreamName windows and RegSeqRat readbacks, so later rows cannot detach the partition from the interval source.

The Darboux row D is then read as lower and upper finite sums over those displayed cells and tags. The integrability row J is therefore a handoff from finite Darboux gap control, not from a quotient real or host equality judgment.

The terminal seal and structural rows E, H, C, P, N preserve that route. No excluded object is stored in the carrier, so every consumer factors through the displayed finite partition and Darboux rows. □

Theorem 4815.4 (Continuous Riemann integrability uniform-modulus handoff)**.** *Every accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier whose continuous row factors through a displayed uniform-modulus or composed-modulus route passes the Darboux gap and* $\mathsf{RiemannIntegrable}^{\uparrow}$ *handoff through the finite chain*

$$\mathsf{Continuous}^{\uparrow},\ \mathsf{UniformContinuityComposition}^{\uparrow},\ \mathsf{TaggedRealPartition}^{\uparrow},\ \mathsf{DarbouxSum}^{\uparrow},\ \mathsf{RiemannIntegrable}^{\uparrow},\ \mathsf{StreamNar}$$

The handoff therefore reads composed modulus data before the Darboux row and exports no host integral selector, quotient function equality, open-cover compactness argument, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5838.1. The displayed rows are the continuous row F, tagged partition row T, Darboux row D, Riemann-integrable handoff J, weak interval selector W, StreamName windows S, RegSeqRat readbacks R, Real seal E, transport, replay, provenance, and local naming rows.

Use Definition 5838.2 for row exhaustion. When the continuous row is supplied by a uniform-modulus or composed-modulus route, the only admitted modulus source is the displayed $\mathsf{Continuous}^{\uparrow}$ row together with the $\mathsf{UniformContinuityComposition}^{\uparrow}$ composed-modulus handoff of chapter 3891.

Now apply Definition 5838.3. The tagged partition, Darboux lower and upper sums, and integrability row must be read after the same StreamName windows, RegSeqRat readbacks, and terminal Real seal, so the composed-modulus source cannot bypass the finite Darboux route.

Since the carrier stores no host integral selector, quotient function equality, open-cover compactness proof, or ambient completeness object, the listed finite rows are the whole uniform-modulus handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$.

Constructive story: A $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ packet is generated from a Continuous row, TaggedRealPartition row, DarbouxSum row, RiemannIntegrable handoff row, WeaklyLocatedIntervalSelection row, StreamName windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5838.1, Definition 5838.2, Definition 5838.3, and Definition 5838.4 seed the finite Darboux/Riemann integrability route for continuous functions on located closed real intervals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full integration theory, measure integration, open-cover compactness, quotient equality, selected limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-source visibility, pointwise modulus exposure, finite tagged partition coverage, Darboux gap control, integrability handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ContinuousRiemannIntegrabilityUp.

Chapter 4816

A Concrete Naming Certificate for $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy approximations, the $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ packet binds Cauchy mesh refinement, cofinal dyadic mesh selection, and diagonal Real mesh budgets into one finite common-refinement route. It sits over the two-request refinement carrier of chapter 3832, the cofinal dyadic selector of chapter 2254, the diagonal mesh-budget surface of chapter 618, and the terminal real-name seal of chapter 38. The packet gives Real-completeness consumers a finite cofinal mesh handoff without quotient streams, selected limits, countable choice, host real equality, or ambient completeness as an extra row.

Definition 4816.1 (Regular Cauchy mesh cofinality carrier)**.** *A* $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, R, D, B, S, A, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{CauchyMeshRefinement}^{\uparrow}$ *row exposing source Cauchy requests, two displayed dyadic meshes, and their common finite refinement.*
2. *R is the* $\mathsf{CofinalDyadicMesh}^{\uparrow}$ *row refining the incoming observation request to a dyadic mesh window.*
3. *D is the* $\mathsf{RealDiagonalMeshBudget}^{\uparrow}$ *row listing the inspected diagonal indices, selected windows, dyadic tolerances, and aggregation ledger.*
4. *B is the shared budget row aligning the request precision of Q, the cofinal selector depth of R, and the diagonal finite mesh budget of D.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family opened by the shared budget.*
6. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family over the same windows, with all dyadic tolerances read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, R, D, B, S, A have been displayed.*
8. *H records componentwise* hsame *transport for the refinement row, cofinal selector row, diagonal budget row, shared budget, window and readback rows, seal row, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from an observation request through*

$$Q, R, D \longmapsto B \longmapsto S \longmapsto A \longmapsto E.$$

10. *P is the* Pkg *provenance over* RegularCauchyMeshCofinality$^{\uparrow}$, CauchyMeshRefinement$^{\uparrow}$, CofinalDyadicMesh$^{\uparrow}$, RealDiagonalMeshBudget$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{RegularCauchyMeshCofinality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, R, D, B, S, A, E, H, C, P, N$. It has no coordinate for quotient streams, hidden subnets, selected limits, countable-choice schedules, host real equality, trichotomy, or ambient Real completeness.

Theorem 4816.2 (Regular Cauchy mesh cofinality NameCert obligations)**.** *For every accepted* RegularCauchyMeshCofinality$^{\uparrow}$ *carrier*

$$K = (Q, R, D, B, S, A, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyMeshCofinality}^{\uparrow}}$ *surface consists exactly of carrier admission, Cauchy mesh-refinement exposure through Q, cofinal dyadic mesh exposure through R, Real diagonal mesh-budget exposure through D, shared precision and mesh-budget alignment through B, finite* StreamName$^{\uparrow}$ *window exposure through S,* RegSeqRat$^{\uparrow}$ *readback and* DyadicRatCore$^{\uparrow}$ *tolerance visibility through A, terminal* Real$^{\uparrow}$ *seal admission through E, componentwise transport through H, route replay through C, provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 5839.1. The accepted packet displays exactly the Cauchy refinement, cofinal selector, diagonal budget, shared budget, windows, readbacks, seal, transports, replay, provenance, and local name.

The three mesh sources are read before any Real-facing seal. The row Q displays the common refinement of source Cauchy meshes, R displays the cofinal dyadic selector for the observation request, and D displays the finite diagonal mesh budget.

The shared row B aligns these sources. It is the only place where the precision request, cofinal selector depth, and diagonal inspected indices meet, so the window row S and regular readback row A inherit one finite route.

The seal and structural rows E, H, C, P, N preserve that route. Since the carrier has no coordinate for the excluded completion objects, the listed rows exhaust the local certificate surface. □

Theorem 4816.3 (Regular Cauchy mesh cofinality Real-completeness handoff)**.** *Every Real-completeness or diagonal-limit consumer of an accepted* RegularCauchyMeshCofinality$^{\uparrow}$ *carrier receives its seal-facing data only through the cofinal finite route*

$$Q, R, D \longmapsto B \longmapsto S \longmapsto A \longmapsto E, H, C, P, N.$$

Thus the consumer factors through Cauchy mesh refinement, cofinal dyadic mesh selection, Real diagonal mesh budgeting, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, and the RealUp seal before any completion-facing conclusion is exported.

Proof. Start from a Real-completeness consumer request. The packet first exposes Q, so the two source Cauchy requests and their common refinement are finite displayed data.

The request then passes through R and D. The cofinal dyadic selector supplies a finite mesh window, while the diagonal mesh-budget row supplies the finite inspected indices and dyadic tolerance ledger.

The budget row B is the common meeting point. It forces the StreamName windows S and RegSeqRat readbacks A to use the same finite refinement and the same dyadic tolerance rows.

Only after this route is displayed may the Real seal E be read. Transport, replay, provenance, and local naming preserve the route, and the excluded quotient or choice-based completion objects are absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ packet is generated from CauchyMeshRefinement, CofinalDyadicMesh, RealDiagonalMeshBudget, a shared precision and mesh-budget row, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5839.1, Definition 5839.2, and Definition 5839.3 seed the finite cofinal common-refinement mesh route used by Real-completeness and diagonal-limit consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, hidden subnets, selected limits, countable choice, host real equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy mesh-refinement exposure, cofinal dyadic mesh exposure, Real diagonal mesh-budget exposure, shared-budget alignment, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance visibility, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyMeshCofinalityUp.

Chapter 4817

A Concrete Naming Certificate for $\mathsf{OneSidedLimit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{OneSidedLimit}^{\uparrow}$ packet records the left- and right-hand real-limit interface as finite BEDC data. It sits next to the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ observation schedule of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet names only displayed side-tagged approach windows, regular rational reads, dyadic tolerance rows, transport, replay, provenance, and a terminal Real seal; it does not import two-sided completeness, host real equality, quotient streams, trichotomy, or a selected limiting point.

Definition 4817.1 (One-sided limit carrier)**.** *A* $\mathsf{OneSidedLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, L, W, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the approach-anchor row, naming the source point or endpoint cell at which the one-sided read is taken.*
2. *L is the side classifier row, with each visible approach window tagged as left-hand or right-hand before any limiting seal is inspected.*
3. *W is the finite approach-window row, listing only windows compatible with the tag in L and the anchor in A.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule opened by the side-tagged windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational data observed on S.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the displayed one-sided comparisons.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from A, L, W, S, R, D.*
8. *H records componentwise* hsame *transport for the anchor, side classifier, windows, stream schedule, regular readback, dyadic ledger, Real seal, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from the side-tagged approach windows through the stream, readback, dyadic, and Real-seal rows.*
10. *P is the* Pkg *provenance over* $\mathsf{OneSidedLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $A, L, W, S, R, D, E, H, C, P, N$. It has no coordinate for a two-sided completion theorem, quotient real equality, host order trichotomy, countable choice, or a selected limit outside the named side-tagged windows.

Lean4 ✓ `BEDC.Derived.OneSidedLimitUp.OneSidedLimitTasteGate single carrier alignment`

Theorem 4817.2 (One-sided limit NameCert obligations)**.** *For every accepted* $\mathsf{OneSidedLimit}^{\uparrow}$ *carrier $K = (A, L, W, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the approach anchor, side classifier, approach windows, stream schedule, regular readback, dyadic ledger, Real seal, transport, replay, provenance, and local naming rows;*
2. *side classifier stability, requiring each transported window to retain its left-hand or right-hand tag before a readback row is consumed;*
3. *dyadic tolerance ledger exactness, requiring D to expose only the tolerance rows demanded by the side-tagged windows in W;*
4. $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, requiring S and R to read only the finite observations selected by A, L, W;*
5. *Real seal nonescape, requiring E to remain downstream of A, L, W, S, R, D and never to serve as a two-sided completeness witness or host real equality row;*
6. *componentwise transport, replay, provenance, and local naming through H, C, P, N.*

No $\mathsf{OneSidedLimit}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5841.1. The accepted packet displays the approach anchor A, side classifier L, finite approach windows W, stream schedule S, regular readback R, dyadic ledger D, Real seal E, and structural rows H, C, P, N.

Side classifier stability is componentwise. A transported window may be read only with the left-hand or right-hand tag already recorded in L, and the replay row C keeps the same tag attached while the stream and regular-rational rows are inspected.

The tolerance and readback rows are downstream of the same finite windows. The ledger D records the dyadic comparisons demanded by W, the schedule S opens only those observations, and R records the regular rational readback.

Finally, the Real seal E is terminal for the route. Since the carrier contains no row for two-sided completeness, quotient real equality, host order trichotomy, countable choice, or a selected limit outside the displayed windows, those objects cannot become local obligations. □

Theorem 4817.3 (One-sided limit Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{OneSidedLimit}^{\uparrow}$ *packet reads the proposed one-sided limit only through the displayed finite route*

$$A, L, W, S, R, D, E, H, C, P, N.$$

Consequently the handoff to $\mathsf{Real}^{\uparrow}$ *is available only after the approach anchor, side classifier, finite approach windows, StreamName schedule, RegSeqRat readback, and DyadicRatCore tolerance ledger have been exposed. The handoff exports no two-sided completeness theorem, quotient stream equality, host real equality, order trichotomy, countable choice principle, or selected limiting point.*

Proof. Project the accepted carrier through Definition 5841.1. Its Real-facing row is the single terminal coordinate E, and the only route to E passes through A, L, W, S, R, D and the structural rows H, C, P, N.

The finite approach windows determine the side of approach before readback begins. Thus a consumer that asks for a Real seal must already have read the side classifier, the compatible windows, the stream schedule, the regular rational row, and the dyadic tolerance ledger.

The remaining coordinates transport and name the same route. Because no carrier row stores a two-sided completion principle, quotient equality, host equality, trichotomy, choice, or an independent selected limit, the Real-seal handoff cannot export any of those objects. □

Falsifiable prediction: Every $\mathsf{OneSidedLimit}^{\uparrow}$ Real-facing read factors through an approach anchor, a left/right side classifier, finite approach windows, a StreamName schedule, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: real, regseqrat, streamname, dyadicratcore: $\mathsf{OneSidedLimit}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a side classifier, finite approach windows, scheduled regular-rational readback, dyadic tolerance data, and a terminal Real seal in one one-sided packet.

Closure status for $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{OneSidedLimit}^{\uparrow}$ packet is generated from an approach anchor, a left/right side classifier, finite approach windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5841.1, Definition 5841.2, and Definition 5841.3 seed the finite one-sided real-limit route through side-tagged approach windows and terminal Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.OneSidedLimitUp.OneSidedLimitTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close two-sided real completeness, quotient stream equality, host real equality, trichotomy, countable choice, selected limits outside the displayed windows, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, side classifier stability, dyadic tolerance exactness, StreamName and RegSeqRat readback, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.OneSidedLimitUp.

Chapter 4818

A Concrete Naming Certificate for $\mathsf{BertrandSeriesTest}^{\uparrow}$

Following Bertrand's logarithmic refinement of ratio-type convergence tests and Bishop–Bridges constructive real-series practice, the $\mathsf{BertrandSeriesTest}^{\uparrow}$ packet records the finite second-order quotient-defect route that turns displayed positive-series tail data into a regular Cauchy comparison handoff. It sits beside the neighboring quotient-defect surfaces of chapter 1719, chapter 2113, and chapter 2130, refines the ratio and comparison routes of chapter 1461 and chapter 1459, and exports endpoints only through the dyadic, stream, regular-rational, and Real seals of chapter 291, chapter 126, chapter 301, and chapter 38. The packet names finite Bertrand-test evidence only through inspected source windows, adjacent quotient windows, a logarithmic defect ledger, dyadic domination, comparison-test routing, regular rational readback, and terminal Real sealing; it is not host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 4818.1 (Bertrand series test carrier)**.** *A* $\mathsf{BertrandSeriesTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, Q, L, D, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source real-series row, exposing only positive-term windows, partial-sum windows, and tail-threshold requests used by the current convergence test.*
2. *Q is the adjacent quotient-window row, recording the inspected neighboring-term quotients on the same displayed tail window.*
3. *L is the logarithmic defect ledger, storing the finite index, logarithmic scale, rational margin, and second-order defect rows used by the Bertrand comparison.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *domination ledger, converting the displayed logarithmic defect and margin rows into a finite majorant or minorant comparison.*
5. *T is the* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *handoff row that consumes S, Q, L, D before any convergence conclusion is exposed.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the source, quotient, logarithmic defect, domination, and comparison rows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached only after the comparison handoff and stream windows have been displayed.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for endpoint-facing consumers.*
9. *H stores componentwise* hsame *transport for the source, quotient, logarithmic defect, domination, comparison, window, readback, seal, replay, provenance, and local naming rows.*
10. *C stores displayed* Cont *replay from each tail request through Q, L, D, T, W, R, E.*
11. *P is the* Pkg *provenance over* $\mathsf{BertrandSeriesTest}^{\uparrow}$, $\mathsf{RaabeDuhamelTest}^{\uparrow}$, $\mathsf{KummerTest}^{\uparrow}$, $\mathsf{GaussTest}^{\uparrow}$, $\mathsf{RegularCauchyRatioTest}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, L, D, T, W, R, E, H, C, P, N$. It has no coordinate for host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.BertrandSeriesTestUp.BertrandSeriesTestTasteGate single carrier alignment`

Theorem 4818.2 (Bertrand series test NameCert obligations)**.** *For every accepted* $\mathsf{BertrandSeriesTest}^{\uparrow}$ *carrier*

$$B = (S, Q, L, D, T, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source real-series windows, adjacent quotient windows, logarithmic defect ledger, dyadic domination ledger, comparison-test handoff, stream windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming row;*
2. *quotient-window exactness, requiring every quotient read used by the Bertrand defect to be read from the displayed neighboring positive-term windows in S and Q;*
3. *logarithmic-defect stability, requiring the finite index, logarithmic scale, rational margin, and second-order defect rows in L to remain attached to the accepted tail request;*
4. *dyadic domination routing, requiring D and W to convert the displayed logarithmic defect data into the same finite comparison windows consumed by T;*
5. *regular and Real handoff, requiring endpoint-facing data to pass through T, W, R, E in that order before a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer receives data;*
6. *ledger non-escape, requiring H, C, P, N to transport, replay, source, and name only the displayed rows and to exclude host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 5842.1. Carrier admission is exactly the inventory $S, Q, L, D, T, W, R, E, H, C$ so the local certificate has no detached row for an infinite sum, quotient series equality, selected sum, or ambient completeness theorem.

The quotient and logarithmic-defect clauses are read before the comparison handoff. The row S exposes only inspected positive-term and partial-sum windows, the row Q exposes only neighboring-term quotient windows, and L records the finite index, logarithmic scale, rational margin, and second-order defect attached to the current tail request.

The domination route is then forced through D, W, T. The dyadic ledger D converts the displayed logarithmic defect data into comparison evidence, the window row W fixes the finite stream windows, and the comparison-test row T is the only route that may export a regular Cauchy conclusion.

Finally, R and E supply the regular rational and Real-facing endpoint route. The structural rows H, C, P, N preserve, replay, source, and name the same route, so none of them can introduce host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge data. □

Theorem 4818.3 (Bertrand series test tail route)**.** *Every endpoint-facing read of an accepted* $\mathsf{BertrandSeriesTest}^{\uparrow}$ *carrier factors through*

$$\mathsf{RaabeDuhamelTest}^{\uparrow},\ \mathsf{KummerTest}^{\uparrow},\ \mathsf{GaussTest}^{\uparrow},\ \mathsf{RegularCauchyRatioTest}^{\uparrow},\ \mathsf{RegularCauchyComparisonTest}^{\uparrow},\ \mathsf{Dyadic}$$

Concretely, the read consumes source real-series windows and adjacent quotient rows, reads the logarithmic second-order defect ledger, converts that ledger into dyadic domination and stream-window evidence, enters the $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *handoff, and reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *only through the displayed readback and seal rows.*

Proof. Begin with an endpoint-facing read of an accepted carrier. By Definition 5842.1, the only source data available before the defect estimate are the source windows in S and the adjacent quotient windows in Q.

The Bertrand-specific data are then read from L and D. The logarithmic ledger supplies the finite index, logarithmic scale, rational margin, and second-order defect, while the dyadic ledger turns those rows into the domination evidence needed for comparison.

The neighboring quotient-defect tests are reference faces in the same lattice. The Raabe–Duhamel, Kummer, and Gauss packets identify the adjacent first-order and auxiliary defect surfaces, while the ratio route supplies the shared adjacent-quotient discipline. The accepted $\mathsf{BertrandSeriesTest}^{\uparrow}$ endpoint route still has to enter the comparison handoff T.

After T is displayed, the route proceeds through the finite $\mathsf{StreamName}^{\uparrow}$ windows in W, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R, and the terminal $\mathsf{Real}^{\uparrow}$ seal E. The transport, replay, provenance, and naming rows keep the same route, so no host summability, quotient series equality, selected sums, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness can enter. □

Falsifiable prediction: Every accepted $\mathsf{BertrandSeriesTest}^{\uparrow}$ endpoint-facing read factors through source real-series windows, adjacent quotient rows, a logarithmic defect ledger, dyadic domination, a RegularCauchyComparisonTest handoff, StreamName windows, RegSeqRat readback, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: raabeduhameltest, kummertest, gausstest, regularcauchyratiotest, regularcauchycomparisontest, dyadicratcore, streamname, regseqrat, real: $\mathsf{BertrandSeriesTest}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source series windows, adjacent quotient windows, a logarithmic second-order defect ledger, dyadic domination, comparison-test routing, regular rational readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BertrandSeriesTest}^{\uparrow}$ packet is generated from source real-series windows, adjacent quotient windows, a logarithmic second-order defect ledger, dyadic domination, a RegularCauchyComparisonTest handoff, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5842.1, Definition 5842.2, and Definition 5842.3 seed the finite Bertrand convergence-test boundary over displayed source series, quotient, logarithmic defect, comparison, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BertrandSeriesTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean theorems for carrier admission, quotient-window exactness, logarithmic-defect stability, dyadic domination routing, regular and Real handoff, ledger non-escape, and TasteGate field faithfulness for BEDC.Derived.BertrandSeriesTestUp.

Chapter 4819

A Concrete Naming Certificate for $\mathsf{RationalCanonicalForm}^{\uparrow}$

Following Frobenius and standard linear algebra treatments of finite-dimensional operators, the $\mathsf{RationalCanonicalForm}^{\uparrow}$ packet records the rational canonical form of a displayed finite linear operator as BEDC NameCert data. It consumes the finite matrix rows of chapter 49, the linear-map surface of chapter 48, the polynomial source of chapter 50, the module and vector-space carriers of chapter 46 and chapter 47, and the invariant-factor route supplied by chapter 2262. The packet names only a finite certificate surface for companion-block assembly; it does not assert a host Jordan form theorem, algebraic closure, eigenvalue selection, basis choice outside the displayed rows, or a global classification oracle.

Definition 4819.1 (Rational canonical form carrier)**.** *A* $\mathsf{RationalCanonicalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (V, L, M, S, I, B, A, H, C, P, N)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *or* $\mathsf{Module}^{\uparrow}$ *source row naming the finite underlying carrier and its scalar action.*
2. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row naming the endomorphism whose canonical form is being read.*
3. *M is the* $\mathsf{Mat}^{\uparrow}$ *presentation row for the same endomorphism over the displayed finite basis data already carried by V and L.*
4. *S is the consumed* $\mathsf{SmithNormalForm}^{\uparrow}$ *dependency row applied to the polynomial matrix route attached to M.*
5. *I is the invariant-factor* $\mathsf{Poly}^{\uparrow}$ *row, listing monic polynomial factors with the divisibility ledger exposed by S.*
6. *B is the companion-block row, assembling one finite block for each invariant factor in I and recording the row and column positions used by the assembly.*
7. *A is the block-assembly exactness row, stating that the displayed* $\mathsf{Mat}^{\uparrow}$ *presentation is transported to the companion-block matrix through the same* $\mathsf{LinMap}^{\uparrow}$ *and* $\mathsf{Poly}^{\uparrow}$ *rows.*
8. *H stores componentwise* hsame *transport for the vector or module source, linear map, matrix presentation, Smith-normal dependency, invariant factors, companion blocks, assembly row, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from a canonical-form request through V, L, M, S, I, B, A and back to the same finite operator surface.*
10. *P is the* Pkg *provenance over* $\mathsf{RationalCanonicalForm}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Module}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{SmithNormalForm}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalCanonicalForm}^{\uparrow}}$ *row.*

The carrier has no coordinate for selected eigenvalues, algebraic closure, host similarity classification, non-displayed basis choice, quotient matrix equality, or a detached canonical-form oracle.

Lean4 ✓ `BEDC.Derived.RationalCanonicalFormUp.TasteGate.RationalCanonicalFormTasteGate single carrier alignment`

Theorem 4819.2 (Rational canonical form NameCert obligations)**.** *For every accepted* $\mathsf{RationalCanonicalForm}^{\uparrow}$ *carrier*

$$F = (V, L, M, S, I, B, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RationalCanonicalForm}^{\uparrow}}$ *surface consists exactly of finite source admission for V, L, M, Smith-normal dependency routing through S, invariant-factor exposure through I, companion-block assembly through B, block-assembly exactness through A, componentwise* hsame *stability through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5843.1. The algebraic source rows are exactly the vector or module carrier V, the endomorphism row L, the finite matrix presentation M, the Smith-normal dependency row S, the invariant-factor row I, and the companion-block assembly rows B, A.

The invariant factors are not read from a host classification theorem. They are exposed as $\mathsf{Poly}^{\uparrow}$ rows whose divisibility and matrix-reduction dependency is routed through $\mathsf{SmithNormalForm}^{\uparrow}$ before any companion block is assembled.

The companion-block row B is finite because it is indexed by the displayed invariant-factor list I. The exactness row A then compares the assembled block matrix with the original $\mathsf{Mat}^{\uparrow}$ presentation through the same $\mathsf{LinMap}^{\uparrow}$ endpoint and componentwise hsame transport.

Finally H, C, P, N transport, replay, source, and name only this finite route. Since the carrier contains no coordinate for eigenvalue selection, algebraic closure, host similarity classification, non-displayed basis choice, quotient matrix equality, or a detached canonical-form oracle, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: A $\mathsf{RationalCanonicalForm}^{\uparrow}$ consumer that exports a canonical-form matrix while omitting the Smith-normal dependency row, invariant-factor polynomial row, companion-block assembly row, componentwise hsame, displayed Cont, Pkg, or local NameCert rows refutes the carrier of Definition 5843.1.

Independence witness: matrix, linearmap, polynomial, module, vecspace, smith-normal-form: $\mathsf{RationalCanonicalForm}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite operator source, matrix presentation, invariant-factor polynomial ledger, Smith-normal dependency, companion-block assembly, exactness row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalCanonicalForm}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RationalCanonicalForm}^{\uparrow}$ packet is generated from VecSpaceUp or ModuleUp source data, a LinearMapUp endomorphism row, a MatrixUp presentation, a SmithNormalFormUp dependency route, invariant-factor PolynomialUp rows, companion-block assembly rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RationalCanonicalForm}\uparrow}$, seed)

Scope closed: Definition 5843.1 and Definition 5843.2 seed the finite rational-canonical-form packet over matrix, linear-map, polynomial, module, vector-space, and Smith-normal rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{RationalCanonicalForm}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim eigenvalue selection, algebraic closure, host similarity classification, non-displayed basis choice, quotient matrix equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, invariant-factor exposure, Smith-normal dependency routing, companion-block assembly, exactness, transport, replay, provenance, and local naming for BEDC.Derived.RationalCanonicalForn

Chapter 4820

A Concrete Naming Certificate for $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$

The $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ packet realizes the Rule 110 pattern-classifier branch of chapter 9390 as finite BEDC NameCert data. It consumes the cellular automaton carrier of chapter 934, the row-classifier surface of chapter 941, the pattern catalog of chapter 995, the local-stencil observation route of chapter 1036, and the Rule 110 glider catalog of chapter 1045. The packet names finite row windows, transition-table reads, orbit prefixes, pattern tags, transport, replay, provenance, and a local NameCert row; it is not a universality theorem, an infinite-orbit classifier, an undecidable continuation oracle, or a hidden substrate semantics.

Definition 4820.1 (Rule 110 pattern classifier carrier)**.** *A* $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (W, T, O, G, K, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite row-window row, naming the inspected Rule 110 space-time rectangle and its boundary cells.*
2. *T is the transition-table row, exposing the eight local update cases used to advance the window.*
3. *O is the orbit-prefix row, recording the finite sequence of rows replayed from the initial window by T.*
4. *G is the glider and ether catalog row consumed from* $\mathsf{RuleOneTenGliderCatalog}^{\uparrow}$ *and* $\mathsf{CellularPatternCatalog}^{\uparrow}$*.*
5. *K is the classifier-tag row, assigning each inspected subwindow to a displayed ether, glider, collision, boundary, or unknown tag.*
6. *H stores componentwise* hsame *transport for windows, transition-table rows, orbit prefixes, tags, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from a classifier request through W, T, O, G, K.*
8. *P is the* Pkg *provenance over* $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$*,* $\mathsf{CellularAutomaton}^{\uparrow}$*,* $\mathsf{CellularRowClassifier}^{\uparrow}$*,* $\mathsf{CellularPatternCatalog}^{\uparrow}$*,* $\mathsf{RuleOneTenGliderCatalog}^{\uparrow}$*,* $\mathsf{LocalStencilObservation}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$ *row.*

The carrier has no coordinate for infinite continuation, termination of all continuations, host universality, unbounded pattern search, quotient orbit equality, or a substrate semantics outside the displayed rows.

Theorem 4820.2 (Rule 110 pattern classifier NameCert obligations)**.** *For every accepted* RuleOneTenPatternClassif *carrier*

$$R = (W, T, O, G, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$ *surface consists exactly of row-window admission through* W*, transition-table exposure through* T*, orbit-prefix replay through* O*, catalog lookup through* G*, classifier-tag exactness through* K*, componentwise* hsame *stability through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier of Definition 5844.1. The finite cellular rows are exactly the inspected window W, transition table T, orbit prefix O, catalog row G, classifier row K, and the structural rows H, C, P, N.

The transition-table row is read before the orbit prefix, so every displayed successor row is justified by the same eight local Rule 110 cases. The classifier tag is then attached to a finite subwindow already present in O and compared against the catalog row G.

The transport and replay rows preserve that order. Since the carrier contains no infinite continuation coordinate, no all-continuations termination field, no unbounded pattern search, no quotient orbit equality, and no host universality proof, the local NameCert obligations are exhausted by the listed finite rows. □

Falsifiable prediction: A $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ classifier read that assigns a glider, ether, collision, boundary, or unknown tag without exposing the finite row window, transition-table row, orbit-prefix row, catalog row, componentwise hsame, displayed Cont, Pkg, and local NameCert rows refutes the carrier of Definition 5844.1.

Independence witness: continuationautomaton, finiteprefixautomaton, continuationtermination, typecheckingmembershiptrace, classifiermorphism: $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Rule 110 row windows, the transition table, orbit prefixes, catalog tags, classifier transport, replay, provenance, and local NameCert rows.

The Lean TasteGate file for this packet must provide Nontrivial $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ and FieldFaithful $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ instances for the displayed rows $W, T, O, G, K, H, C, P, N$ before the classifier can serve as a verified taste-gate consumer.

Closure status for $\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ packet is generated from a finite Rule 110 row window, transition table, orbit prefix, pattern catalog, classifier tags, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$, seed)

Scope closed: Definition 5844.1 and Definition 5844.2 seed the finite Rule 110 pattern-classifier packet over row-window, transition-table, orbit-prefix, catalog, tag, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RuleOneTenPatternClassifier}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a universality theorem, infinite-orbit classification, continuation termination, unbounded pattern search, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked row-window admission, transition-table exposure, orbit-prefix replay, catalog lookup, classifier-tag exactness, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.RuleOneTenPatternClassifierUp.

Chapter 4821

A Concrete Naming Certificate for $\mathsf{ObservabilityGramian}^{\uparrow}$

The $\mathsf{ObservabilityGramian}^{\uparrow}$ interface records the finite observability Gramian packet of a finite-dimensional linear control system. Its textbook source is the finite-horizon observability Gramian in Kalman's control-theoretic duality and the matrix-ledger presentation used by Kailath, Sayed, and Hassibi for linear estimation. The BEDC packet is the finite dual certificate read beside $\mathsf{ReachabilityGramian}^{\uparrow}$ in chapter 455; it is not an ambient analytic observability theorem.

The dependency anchors are the finite observation surface of chapter 294, the reachability dual surface of chapter 297, the matrix rows of chapter 49, the vector-space rows of chapter 47, and the linear-map rows of chapter 48. These anchors force the Gramian to be read as displayed $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, and $\mathsf{LinMap}^{\uparrow}$ data before a control consumer can compare it with the reachability Gramian.

4821.1 Carrier definition

Definition 4821.1 (ObservabilityGramianUp finite carrier)**.** *An* $\mathsf{ObservabilityGramian}^{\uparrow}$ *carrier is a finite* BHist *packet with rows*

$$(A, C, n, W, L, R, P, N).$$

Here A is the displayed transition-matrix row, C is the displayed output-matrix row, n is a unary finite-horizon row, W is the displayed finite Gramian-sum ledger with summand rows

$$C^{\mathsf{T}}C, \quad A^{\mathsf{T}}C^{\mathsf{T}}CA, \quad (A^{\mathsf{T}})^2C^{\mathsf{T}}CA^2, \quad \ldots, \quad (A^{\mathsf{T}})^{n-1}C^{\mathsf{T}}CA^{n-1},$$

L is the componentwise hsame *transport ledger for the transition, output, horizon, summand, and Gramian endpoint rows, R is the finite dual-readback row comparing W with the observation-matrix rows $C, CA, \ldots, CA^{n-1}$ of* $\mathsf{ControlObservability}^{\uparrow}$*, P is the* Pkg *provenance over* $\mathsf{ObservabilityGramian}^{\uparrow}$*,* $\mathsf{ControlObservability}^{\uparrow}$*,* $\mathsf{ControlControllability}^{\uparrow}$*,* $\mathsf{ReachabilityGramian}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*, and N is the local* $\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by componentwise hsame *transport of the A, C, n, W, L, R, P, N rows. It does not quotient by a host unobservable subspace, analytic trajectory family, Riccati equation, spectral factorization, infinite-horizon Gramian, or external estimator object.*

Lean4 ✓ `BEDC.Derived.ObservabilityGramianUp.ObservabilityGramianTasteGate single carrier alignment`

4821.2 Certificate surface

Theorem 4821.2 (ObservabilityGramianUp NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}$ *obligation surface has exactly five finite rows:*

1. *carrier admission for the displayed* A, C, n, W, L, R, P, N *packet of Definition 5787.1;*
2. *classifier transport under componentwise* hsame *of the transition, output, horizon, Gramian, summand-ledger, dual-readback, package, and local certificate rows;*
3. *finite sum ledger exactness, saying that the Gramian endpoint inside* W *is read only as the finite sum of the displayed adjoint-output summands inside* W*;*
4. *observability handoff, saying that the observation-matrix surface of* $\mathsf{ControlObservability}^{\uparrow}$ *can consume* A*,* C*,* n*,* W*,* L*, and* R *only through the displayed* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* Cont*, and* Pkg *rows;*
5. *dual non-escape, saying that no accepted route exports a host unobservable subspace, analytic output trajectory, Riccati solution, spectral factorization, infinite-horizon Gramian, covariance process, or external estimator.*

Proof. The carrier row is Definition 5787.1. It displays the transition row, output row, unary horizon, Gramian endpoint, summand ledger, transport ledger, dual-readback row, package provenance, and local naming row as finite BHist coordinates.

Classifier transport is componentwise. Replacing each displayed coordinate by an hsame-matched coordinate leaves the same finite packet shape, so the transported packet is again admitted by the carrier.

For finite sum exactness, inspect W. Each summand is a displayed matrix product formed from A, C, and transposes, and the Gramian endpoint is the finite fold of precisely those rows. The readback row R ties that ledger to the observation rows without introducing a host observability theorem.

The observability handoff is a projection to the shared A, C, and n rows, to the finite observation rows of $\mathsf{ControlObservability}^{\uparrow}$, and to the Gramian sum named by W. Because those rows are already packaged with $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, and $\mathsf{LinMap}^{\uparrow}$ provenance, a downstream observability certificate can read them without importing analytic control-system semantics.

Dual non-escape follows from constructor inspection of the carrier. The packet has no coordinate for a host unobservable subspace, analytic output trajectory, Riccati solution, spectral factorization, infinite-horizon Gramian, covariance process, or external estimator, so none of those objects can be projected by a consumer route. □

Theorem 4821.3 (ObservabilityGramianUp finite dual handoff)**.** *Every* $\mathsf{ControlObservability}^{\uparrow}$*,* $\mathsf{ControlControllability}^{\uparrow}$*, or* $\mathsf{ReachabilityGramian}^{\uparrow}$ *consumer of an accepted* $\mathsf{ObservabilityGramian}^{\uparrow}$ *packet can read only the displayed* A *row,* C *row, unary horizon row* n*, finite Gramian-summand and endpoint row* W*,* hsame *transport ledger* L*, dual-readback row* R*,* Pkg *provenance, and local* NameCert *row of Definition 5787.1. The handoff supplies the finite dual route from observation rows to the reachability-side Gramian ledger, but it supplies no host Kalman decomposition, no analytic trajectory semantics, and no infinite-horizon duality theorem.*

Proof. Project the accepted packet to the rows A, C, n, W, L, R, P, N. The first three rows are the finite control-system coordinates shared with $\mathsf{ControlObservability}^{\uparrow}$, while W records the finite adjoint-output Gramian ledger and L records componentwise transport over those same coordinates.

The dual-readback row R ties the summands in W to the observation rows $C, CA, \ldots, CA^{n-1}$. Thus a $\mathsf{ControlObservability}^{\uparrow}$ consumer reads the packet through the observation matrix surface, and a $\mathsf{ControlControllability}^{\uparrow}$ or $\mathsf{ReachabilityGramian}^{\uparrow}$ consumer reads only the dual comparison route named by the shared package provenance.

The carrier contains no row for a host Kalman decomposition, analytic trajectory semantics, or infinite-horizon duality theorem. Therefore the handoff is exactly the finite BEDC packet projection and does not add a control-theory semantic bridge. □

Theorem 4821.4 (ObservabilityGramianUp ledger non-escape)**.** *Every exported route from an accepted* $\mathsf{ObservabilityGramian}^{\uparrow}$ *packet factors through the finite rows* A, C, n, W, L, R, P, N *of Definition 5787.1. In particular, the packet exports no ambient unobservable subspace, no analytic output trajectory family, no Riccati solution, no spectral factorization, no stochastic covariance process, no infinite-horizon Gramian, and no external numerical estimator.*

Proof. Take an exported consumer route and project the carrier. The available coordinates are exactly the transition row, output row, horizon row, finite Gramian-summand and endpoint row, transport ledger, dual-readback row, package provenance, and local certificate row.

The NameCert obligations account for carrier admission, classifier transport, finite sum exactness, observability handoff, and dual non-escape. Each obligation is stated over those displayed coordinates and is preserved by the stored hsame, Cont, and Pkg rows.

Thus every export factors through the listed finite coordinates. Since the carrier contains no ambient unobservable subspace, analytic output trajectory family, Riccati solution, spectral factorization, stochastic covariance process, infinite-horizon Gramian, or external numerical estimator, no accepted route can supply one downstream. □

Closure status for $\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}$**.**

Constructive story: An $\mathsf{ObservabilityGramian}^{\uparrow}$ packet is generated from displayed transition and output matrix rows, a unary finite horizon, the finite adjoint-output Gramian summand and endpoint row, componentwise hsame transport ledger, a dual-readback row to the observation-matrix surface, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5787.1, Definition 5787.2, Definition 5787.3, and Definition 5787.4 bind the finite carrier, five-row NameCert surface, dual handoff, and non-escape boundary for observability Gramian packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ObservabilityGramian}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host unobservable-subspace semantics, analytic output trajectories, Riccati theory, spectral factorization, stochastic covariance, infinite-horizon Gramians, numerical estimators, or a checked Lean certificate.

Upgrade path: Obligation closure requires a Lean carrier encoding and checked finite-ledger theorems for finite sum exactness, dual handoff, and non-escape.

Chapter 4822

A Concrete Naming Certificate for $\mathsf{HelmholtzDecomposition}^{\uparrow}$

Following Helmholtz and Hodge-style decomposition theory, the $\mathsf{HelmholtzDecomposition}^{\uparrow}$ packet records the finite BEDC surface by which a displayed vector-field row is read as the sum of a gradient-potential row and a divergence-free row over a Hilbert source. It consumes the Hilbert carrier of chapter 91, the vector-space operations of chapter 47, the linear-map rows of chapter 48, and the projection-theorem surface of chapter 2374. The packet names only the displayed analytic decomposition route; it does not assert PDE solvability, global boundary regularity, unique gauges, Sobolev completeness, or a host Hodge theorem.

Definition 4822.1 (Helmholtz decomposition carrier)**.** *A* $\mathsf{HelmholtzDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (H, V, G, D, O, B, T, C, P, N)$$

with the following displayed rows:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *source row. It supplies the ambient inner-product and norm-facing carrier on which the vector field and both components are read.*
2. *V is the vector-field row. It records the admitted field endpoint together with the* $\mathsf{VecSpace}^{\uparrow}$ *addition, subtraction, and scalar rows used to state the splitting.*
3. *G is the gradient-potential row. It names a potential window and the displayed* $\mathsf{LinMap}^{\uparrow}$ *route that reads its gradient as a vector-field component.*
4. *D is the divergence-free row. It records the classifier saying that the second component lies in the displayed kernel row selected by the divergence operator.*
5. *O is the orthogonal-projection row. It reads the gradient component and the divergence-free component through the projection-theorem surface of chapter 2374.*
6. *B is the boundary ledger. It records exactly which boundary observations are available before a projection or divergence-free read is exposed.*
7. *T records componentwise* hsame *transport for the Hilbert source, vector field, gradient-potential row, divergence-free row, projection row, boundary ledger, replay row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from a Helmholtz-decomposition request through $H, V, G, D, O, B, T, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{HelmholtzDecomposition}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, OrthogonalProjectionThec BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $H, V, G, D, O, B, T, C, P, N$. It has no coordinate for a host PDE solution operator, selected gauge, ambient Sobolev space, hidden boundary regularity theorem, quotient vector-field equality, or unrestricted Hodge decomposition.

Lean4 ✓ `BEDC.Derived.HelmholtzDecompositionUp.HelmholtzDecompositionTasteGate single carrier alignment`

Theorem 4822.2 (Helmholtz decomposition NameCert obligations)**.** *For every accepted* $\mathsf{HelmholtzDecomposition}^{\uparrow}$ *carrier $K = (H, V, G, D, O, B, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}^{\uparrow}}$ *surface consists exactly of the following finite obligation families:*

1. *Hilbert-source admission for the displayed* $\mathsf{Hilbert}^{\uparrow}$ *row H;*
2. *vector-field admission for the field endpoint and* $\mathsf{VecSpace}^{\uparrow}$ *operations stored in V;*
3. *gradient-potential admission for the potential window and* $\mathsf{LinMap}^{\uparrow}$ *gradient route stored in G;*
4. *divergence-free admission for the kernel classifier stored in D;*
5. *orthogonal-projection admission for the projection row O over the gradient and divergence-free components;*
6. *boundary-ledger admission for the displayed boundary observations stored in B;*
7. *componentwise transport, displayed replay, provenance, and local naming through T, C, P, N.*

Consequently a downstream PDE, variational, or Hodge-facing consumer may read Helmholtz data only through the displayed Hilbert, vector-space, linear-map, projection, boundary, transport, replay, provenance, and local naming rows. The packet exports no host PDE solver, gauge selector, Sobolev-completion theorem, quotient vector-field equality, or unrestricted Hodge decomposition.

Proof. Project the carrier of Definition 5788.1. The visible analytic rows are the Hilbert source H, the vector-field row V, the gradient-potential row G, the divergence-free row D, the orthogonal-projection row O, and the boundary ledger B.

The source and algebraic rows are read first. The Hilbert row comes from chapter 91, while V supplies the vector operations inherited from chapter 47. Thus the decomposition statement is formed only inside a displayed carrier.

Next the two component rows are exposed. The gradient-potential row G factors its gradient read through the linear-map surface of chapter 48, and the divergence-free row D supplies the displayed kernel classifier before any splitting conclusion is available.

The projection and boundary rows then bind the route. The row O reads the orthogonal splitting discipline through chapter 2374, while B restricts the boundary observations available to that read.

Finally T, C, P, N transport, replay, source, and name the same displayed rows. Since no excluded analytic object is a coordinate of K, the listed obligation families exhaust the local NameCert surface. □

Theorem 4822.3 (Helmholtz decomposition orthogonal splitting route)**.** *Every splitting read accepted from a* $\mathsf{HelmholtzDecomposition}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{Hilbert}^{\uparrow} \longmapsto \mathsf{VecSpace}^{\uparrow} \longmapsto \mathsf{LinMap}^{\uparrow} \longmapsto \mathsf{OrthogonalProjectionTheorem}^{\uparrow} \longmapsto \mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}^{\uparrow}}.$$

The exported surface is a displayed field row together with a gradient-potential component, a divergence-free component, an orthogonal projection ledger, and a boundary ledger. It does not provide a global PDE solution operator, a selected gauge, Sobolev regularity, quotient equality of vector fields, or the full Hodge decomposition theorem.

Proof. Start from an accepted packet $K = (H, V, G, D, O, B, T, C, P, N)$. A consumer first opens the Hilbert row H, so every norm, orthogonality, and projection read remains attached to the same displayed source.

The vector-space row V then supplies the algebra needed to read the field as the sum of two displayed components. This step uses only the finite operations exposed by chapter 47.

The gradient-potential component is read through G and the linear-map surface of chapter 48. The divergence-free component is read through D, whose kernel classifier is already part of the packet.

The orthogonal splitting claim is finally routed through O and the projection-theorem packet of chapter 2374. The boundary ledger B records the available boundary observations before the local name N is exposed.

Transport and replay through T and C preserve this order, while P records the provenance of the same finite route. No host solver, gauge selector, Sobolev regularity theorem, quotient equality, or unrestricted Hodge theorem is introduced. □

Closure status for $\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5788.1, Definition 5788.2, and Definition 5788.3 seed the finite Helmholtz decomposition packet over Hilbert, vector-space, linear-map, projection, boundary, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HelmholtzDecomposition}\uparrow}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.HelmholtzDecompositionUp.HelmholtzDecompositionTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim PDE solvability, global gauges, Sobolev regularity, quotient vector-field equality, unrestricted Hodge decomposition, or bridge checking.

Upgrade path: Obligation closure asks for checked Hilbert-source admission, vector-field admission, gradient-potential admission, divergence-free admission, orthogonal-projection admission, boundary-ledger admission, transport, replay, provenance, and local naming for BEDC.Derived.HelmholtzDecompositionUp.

Constructive story: A $\mathsf{HelmholtzDecomposition}^{\uparrow}$ packet is generated from a displayed Hilbert source, a vector-field row, a gradient-potential row read through LinearMapUp, a divergence-free kernel row, an orthogonal-projection row, a boundary ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4823

A Concrete Naming Certificate for $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ packet records the separated completion boundary needed by the L10 Real and Completion route as finite BEDC data. It sits after the separation predicate of chapter 1925, the separated-completion carrier of chapter 1612, the metric completion route of chapter 1506, the finite stream interface of chapter 126, the dyadic tolerance core of chapter 291, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the envelope through displayed rows only; it does not quotient filters, select representatives, identify host equalities, invoke countable choice, or import ambient completeness.

Definition 4823.1 (Hausdorff completion envelope carrier)**.** *A* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier is a finite packet*

$$E = (H, S, M, W, D, R, L, T, K, P, N)$$

where H *is the displayed* $\mathsf{HausdorffSpace}^{\uparrow}$ *separation row,* S *is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *boundary row,* M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row,* W *is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* L *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal,* T *is componentwise* $\mathsf{BHist/hsame}$ *transport,* K *is displayed* Cont *replay,* P *is* Pkg *provenance, and* N *is the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$ *row. A consumer of* E *receives a separated completion boundary only through these coordinates.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeTasteGate single carrier alignment`

Theorem 4823.2 (Hausdorff completion envelope obligations)**.** *Every accepted* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$ *read must expose the carrier of Definition 5789.1 in the order*

$$H, S, M, W, D, R, L, T, K, P, N.$$

The separation row H *and separated-completion row* S *are available before metric completion, stream observation, dyadic tolerance, regular readback, and real-seal rows are consumed; the transport, replay, provenance, and naming rows preserve the same displayed packet.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeNameCertObligations`

Proof. Project the carrier of Definition 5789.1. The packet has no completion-facing coordinates except $H, S, M, W, D, R, L, T, K, P, N$.

The Hausdorff and separated-completion rows are the first boundary data in the packet. Thus a consumer cannot inspect the metric completion route, finite stream windows, dyadic tolerances, regular readback, or terminal real seal without first reading the displayed separation surface.

Finally, the structural rows T, K, P, N only transport, replay, source, and name the same finite packet. They do not create quotient filters, selected representatives, host equality, choice-selected routes, or ambient completeness. □

Theorem 4823.3 (Hausdorff completion separated metric route)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of a* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier factors through the separated route*

$$H, S \longmapsto M \longmapsto W, D, R, L.$$

The route records a separated metric-completion boundary for the L10 Real and Completion interface, not a quotient completion, a host equality theorem, a choice-selected representative, or an ambient completeness principle.

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeCarrier separated metric route`

Proof. Start from Definition 5789.2. It places the Hausdorff row H and separated-completion row S before the metric completion row M and before the stream, dyadic, regular-rational, and real-seal rows.

Read the metric completion route through M. Since M is downstream of H, S, every completion-facing use of M carries the displayed separated boundary with it.

The final Real-facing read is the finite route W, D, R, L. Because these rows are still coordinates of the same carrier, the route cannot be replaced by quotient representatives, host equality, countable choice, or ambient completeness. □

Theorem 4823.4 (Hausdorff completion envelope sibling route)**.** *A* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *consumer may hand its separated boundary to* $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ *only through the displayed* $\mathsf{HausdorffSpace}^{\uparrow}$*,* $\mathsf{SeparatedCompletion}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows of*

$$E = (H, S, M, W, D, R, L, T, K, P, N).$$

The handoff contains no quotient-filter coordinate, representative-selection coordinate, host-equality coordinate, or ambient-completeness coordinate.

Proof. Apply Definition 5789.2. It places the Hausdorff row H, separated-completion row S, metric-completion row M, stream row W, dyadic row D, regular-rational row R, and terminal Real row L inside one displayed packet.

Next use Definition 5789.3. The separated boundary H, S is already carried through the metric and Real-facing route M, W, D, R, L.

The sibling $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ consumer therefore reads the same separated boundary as its input surface rather than receiving a separate primitive. Since the carrier only has the displayed rows and the structural rows T, K, P, N, quotient filters, selected representatives, host equality, and ambient completeness remain outside the handoff. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeCarrier sibling route`

Theorem 4823.5 (Hausdorff completion envelope Cauchy-net consumer link)**.** *Every* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ *carrier must read the same* $\mathsf{HausdorffSpace}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows before its directed-net completion route is consumed. The downstream sibling is chapter 3794, and the handoff is the displayed route*

$$H, S, M, W, D, R, L \longmapsto \mathsf{CauchyNetCompletion}^{\uparrow}.$$

It exports no quotient net, selected representative, host equality, countable-choice schedule, or ambient completeness coordinate.

Proof. Project the carrier $E = (H, S, M, W, D, R, L, T, K, P, N)$ of Definition 5789.1. The only completion-facing rows available to a consumer are the Hausdorff row H, separated-completion row S, metric-completion route M, finite stream row W, dyadic tolerance row D, regular readback row R, and terminal Real row L.

Apply Definition 5789.2. It places H, S, M, W, D, R, L inside one displayed packet before the structural rows T, K, P, N are used for transport, replay, provenance, and local naming.

Next use Definition 5789.3. The separated boundary H, S is already carried through the metric and Real-facing route M, W, D, R, L.

Therefore a downstream $\mathsf{CauchyNetCompletion}^{\uparrow}$ read can only consume the envelope through the same separated metric route before its directed-net completion surface is inspected. Since the packet has no quotient-net, selected-representative, host-equality, countable-choice, or ambient-completeness row, none of those objects can enter the handoff. □

Lean4 ✓ `BEDC.Derived.HausdorffCompletionEnvelopeUp.HausdorffCompletionEnvelopeForwardLink`

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5789.1, Definition 5789.2, and Definition 5789.3 name the separated completion envelope surface for the L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, host equality, choice-selected representatives, or ambient completeness.

Upgrade path: Obligation closure requires the carrier route to be tied to the sibling completion obligation theorems and then exposed as a public chapter surface.

Constructive story: A $\mathsf{HausdorffCompletionEnvelope}^{\uparrow}$ packet is generated from Hausdorff separation, separated-completion boundary, metric-completion route, finite stream windows, dyadic tolerance, regular-rational readback, Real seal, transport, replay, provenance, and local NameCert rows.

Chapter 4824

A Concrete Naming Certificate for $\mathsf{BoundedLinearFunctional}^{\uparrow}$

Following Banach and Bourbaki functional analysis, the $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet records the scalar-valued bounded-linear-operator row that duality and weak-star consumers inspect before any host dual space is available. It sits over the linear-map route of chapter 48, the bounded-linear-operator surface of chapter 1644, the scalar-bound neighbour chapter 3603, the Banach-dual row of chapter 2265, the finite weak-star window of chapter 3420, the scalar endpoint seal of chapter 38, and the normed source surface of chapter 1950. The chapter names only displayed scalar-functional data: source rows, linearity rows, scalar target readback, norm-bound evidence, transport, replay, provenance, and local naming.

Definition 4824.1 (Bounded linear functional carrier)**.** *For a displayed* $\mathsf{NormedSpace}^{\uparrow}$ *source row* E *over the scalar endpoint surface of* $\mathsf{Real}^{\uparrow}$*, a* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E)$ *carrier is a finite* BHist *packet*

$$\Lambda = (E, L, T, K, O, H, C, P, N)$$

with the following displayed rows:

1. *E is the source normed-space row, including its carrier endpoints, scalar action, additive row, norm row, and classifier.*
2. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row from E to the scalar* $\mathsf{Real}^{\uparrow}$ *target.*
3. *T is the scalar-valued* $\mathsf{BoundedLinearOperator}^{\uparrow}(E, \mathsf{Real}^{\uparrow})$ *row carrying the same endpoint action as L.*
4. *K is the* $\mathsf{Real}^{\uparrow}$ *nonnegative bound endpoint for the functional.*
5. *O is the* $\mathsf{OperatorNorm}^{\uparrow}$ *handoff row exposing where the bound K is used.*
6. *H records componentwise* hsame *transport for the source, linear-map row, bounded-operator row, scalar bound, operator-norm handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a scalar-functional request through E, L, T, K, O, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedLinearFunctional}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{BanachDual}^{\uparrow}$, $\mathsf{BanachAlaoglu}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed source classifier, scalar endpoint transport, bounded-operator transport, bound transport, norm-bound ledger transport, replay, provenance, and local naming rows. It has no coordinate for a host dual space, quotient equality of functions, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.BoundedLinearFunctionalUp.BoundedLinearFunctionalTasteGate single carrier alignment`

Theorem 4824.2 (Bounded linear functional NameCert obligations)**.** *For every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *carrier* $\Lambda = (E, L, T, K, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$ *surface consists exactly of source normed-space admission, linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm ledger exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from host dual objects. A consumer may inspect* $E, L, T, K, O, H, C, P, N$*, but it receives no ambient function space, quotient operator equality, selected representative, Hahn–Banach witness, unrestricted weak-star compactness theorem, or bridge data.*

Proof. Project the carrier rows. The analytic coordinates are exactly the source normed-space row E, the linear-map row L, the scalar-valued bounded-operator row T, the RealUp bound endpoint K, and the operator-norm handoff O.

The linearity obligation is read through $\mathsf{LinMap}^{\uparrow}$, while boundedness is read through $\mathsf{BoundedLinearOperator}^{\uparrow}(E,$ The scalar target is already the displayed $\mathsf{Real}^{\uparrow}$ endpoint surface, so the functional row never becomes a host-level function.

The bound exactness is the shared route through K and O. The operator-norm handoff records where the scalar bound is used, and componentwise hsame transport moves the source, action, bound, ledger, replay, provenance, and local naming rows together.

No remaining coordinate can manufacture a dual-space quotient, selected representative, Hahn–Banach witness, unrestricted compactness theorem, or bridge check. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 4824.3 (Bounded linear functional operator-norm handoff)**.** *Every accepted* $\mathsf{BoundedLinearFunctional}^{\uparrow}(E$ *packet exports the finite route*

$$\mathsf{LinMap}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{OperatorNorm}^{\uparrow} \longmapsto \mathsf{BoundedLinearFunctional}^{\uparrow}$$

to functional-analysis consumers. The route first exposes the carried scalar-valued linear action, then the bounded-operator row, then the RealUp bound endpoint and operator-norm ledger; it does not expose a host supremum, quotient equality of functionals, selected norm-attaining vector, or hidden Banach completeness.

Proof. Begin with an accepted packet $\Lambda = (E, L, T, K, O, H, C, P, N)$. The read of L supplies only the displayed linear-map action from the source row to the scalar target.

The read of T then packages the same action as a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row. Its target row is $\mathsf{Real}^{\uparrow}$, and its bound endpoint is the displayed scalar K.

Finally the operator-norm handoff O records the norm-bound ledger that downstream consumers may inspect. Because no host norm function, quotient functional equality, selected vector, or hidden completion row is present, the exported handoff is exactly the displayed scalar-bound route. □

Theorem 4824.4 (Bounded linear functional dual-row nonescape)**.** *Any read of a* $\mathsf{BanachDual}^{\uparrow}$ *or* $\mathsf{BanachAlaoglu}^{\uparrow}$ *consumer that uses a* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *row factors through the same source normed-space row, scalar-valued bounded-operator row, RealUp bound endpoint, operator-norm handoff, componentwise transport, replay, provenance, and local naming rows of Definition 5790.1. The duality consumer receives a finite scalar-functional row, not a host dual space, a quotient function class, an unrestricted weak-star compactness theorem, or a selected cluster point.*

Proof. Read the duality consumer first. A $\mathsf{BanachDual}^{\uparrow}$ request needs a scalar-functional row over a displayed source, while a $\mathsf{BanachAlaoglu}^{\uparrow}$ request needs a finite family of such scalar-functional observations.

In either case the only scalar-functional packet available here is Λ. Its source row, bounded-operator row, bound endpoint, operator-norm handoff, and structural rows are projected in the order displayed by Definition 5790.1.

The downstream dual chapters may reuse those rows, but they cannot add coordinates that are absent from the packet. Thus quotient dual objects, host function classes, unrestricted weak-star compactness, selected cluster points, and bridge checks remain outside the read. □

Falsifiable prediction: Every accepted $\mathsf{BoundedLinearFunctional}^{\uparrow}$ scalar-functional read factors through a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ action row, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, and the local hsame, Cont, Pkg, and NameCert rows.

Independence witness: linearmap, boundedlinearoperator, operatornorm, banachdual, banachalaoglu, real, and normedspace: no listed sibling is bijective to $\mathsf{BoundedLinearFunctional}^{\uparrow}$ because this packet stores the scalar target restriction, the dual-facing provenance row, the operator-norm handoff, transport, replay, and local naming together as one finite scalar-functional surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BoundedLinearFunctional}^{\uparrow}$ packet is generated from a displayed $\mathsf{NormedSpace}^{\uparrow}$ source, a $\mathsf{LinMap}^{\uparrow}$ scalar action, a scalar-valued $\mathsf{BoundedLinearOperator}^{\uparrow}$ row, a $\mathsf{Real}^{\uparrow}$ bound endpoint, an $\mathsf{OperatorNorm}^{\uparrow}$ ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5790.1, Definition 5790.2, Definition 5790.3, and Definition 5790.4 seed the scalar-functional row consumed by BanachDualUp and BanachAlaogluUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedLinearFunctional}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host dual spaces, quotient equality of functionals, selected representatives, Hahn–Banach separation, unrestricted weak-star compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, scalar linear-map admission, scalar-valued bounded-operator admission, RealUp bound exactness, operator-norm handoff exactness, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.BoundedLinearFunctionalUp.

Chapter 4825

A Concrete Naming Certificate for $\mathsf{CompletionModulusCategory}^{\uparrow}$

Following Bishop and Bridges on constructive completion and the functorial treatment of completions, the $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet records the finite category surface whose arrows preserve displayed completion moduli. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the completion functor of chapter 426, and the Cauchy completion functor of chapter 423. The packet names modulus-preserving completion morphisms as BEDC rows; it does not export quotient completions, selected representatives, host continuous maps, countable choice, or ambient completeness.

Definition 4825.1 (CompletionModulusCategory carrier)**.** *A* $\mathsf{CompletionModulusCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (O, A, S, R, D, E, F, H, C, P, N)$$

with the following displayed rows:

1. *O is the object ledger. Each object row records a completion-facing source, its displayed Cauchy-modulus discipline, and the local completion target read through the surrounding completion chapters.*
2. *A is the arrow ledger. Each arrow row records a finite morphism request together with the modulus transformation that sends source tolerances to target tolerances.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the source and target names of an arrow.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after the stream windows have been displayed.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare source and target moduli.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row read only after S, R, D have supplied the displayed tolerance route.*
7. *F records identity and composition rows for the completion functoriality surface, with identity arrows preserving the same modulus and composite arrows composing the displayed modulus transformations.*
8. *H records componentwise* hsame *transport for object rows, arrow rows, stream windows, regular readback, dyadic tolerances, Real seals, functoriality rows, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from an arrow request through $O, A, S, R, D, E, F, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CompletionModulusCategory}^{\uparrow}$, $\mathsf{CompletionFunctor}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite category packet for modulus-preserving completion morphisms. It has no coordinate for quotient completion points, selected representatives, host functions, global choice schedules, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryTasteGate single carrier alignment`

Theorem 4825.2 (CompletionModulusCategory NameCert obligations)**.** *For every accepted* CompletionModulusCa *carrier $M = (O, A, S, R, D, E, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed object ledger, arrow ledger, stream windows, regular rational readback, dyadic tolerance ledger, Real seal, identity and composition rows, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface additionally requires each arrow row in A to expose its source modulus, target modulus, and modulus transformation before any $\mathsf{Real}^{\uparrow}$*-facing read is accepted; each identity row in F to preserve the displayed modulus without adding a choice coordinate; and each composition row in F to compose the two displayed modulus transformations before the downstream seal is visible.*

Proof. Project the accepted carrier. The packet contains only the rows $O, A, S, R, D, E, F, H, C, P, N$, so carrier admission and ledger exhaustion are componentwise.

An arrow-facing request first reads the object and arrow ledgers O, A. The source and target names are then inspected through the finite stream windows S, regular rational readback R, and dyadic tolerance ledger D.

The functoriality rows F are local to the same displayed moduli. Identity preserves the stored modulus transformation, and composition combines the two stored transformations before the terminal seal E can be read.

Finally H, C, P, N transport, replay, source, and name this same finite route. Since quotient completions, selected representatives, host functions, global choice schedules, and ambient completeness are not carrier coordinates, they cannot be exported by the local NameCert. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryNameCertObligations`

Theorem 4825.3 (CompletionModulusCategory modulus functoriality)**.** *Every completion-facing consumer of an accepted* $\mathsf{CompletionModulusCategory}^{\uparrow}$ *packet reads a modulus-preserving morphism through the finite route*

$$O, A, S, R, D, F, E, H, C, P, N.$$

Thus identity and composition of completion morphisms preserve the displayed modulus data before any $\mathsf{Real}^{\uparrow}$ *seal or completion-functor read is exposed. The route factors through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompletionFunctor}^{\uparrow}$, *and* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *rather than through quotient completion equality, selected representatives, host continuous maps, countable choice, or ambient completeness.*

Proof. Start with a completion-facing morphism request. The object ledger O fixes the source and target completion rows, and the arrow ledger A fixes the modulus transformation to be checked.

The readback rows S, R, D display the inspected stream windows, regular rational observations, and dyadic tolerance comparisons. These rows are the only route by which the requested modulus can face the terminal Real seal.

The functoriality row F then supplies the identity or composition clause. In the identity case the same displayed modulus is replayed. In the composition case the two displayed modulus transformations are composed as finite rows before the result is handed to E.

The structural rows H, C, P, N preserve and name the same route. Therefore every completion-functor consumer receives finite modulus preservation data and no excluded quotient, selection, host-map, choice, or ambient-completeness surface. □

Lean4 ✓ `BEDC.Derived.CompletionModulusCategoryUp.CompletionModulusCategoryModulusFunctoriality`

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}$.

Constructive story: A $\mathsf{CompletionModulusCategory}^{\uparrow}$ packet is generated from completion object rows, modulus-preserving arrow rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, RealUp seals, identity and composition rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5791.1, Definition 5791.2, and Definition 5791.3 seed the finite category surface for modulus-preserving completion morphisms.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionModulusCategory}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, host continuous maps, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-preserving arrow exactness, identity and composition rows, tolerance readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompletionModulusCategoryUp.

Chapter 4826

A Concrete Naming Certificate for $\mathsf{MarkovTriggerDynamics}^{\uparrow}$

The $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet realizes the finite rank-trigger dynamics of Definition 9462.1541, Definition 9462.1542, and Definition 9462.1546 as BEDC NameCert data. It records the state, support-rank, transition-count, drift, trigger-time, classifier, continuation, provenance, and naming rows needed by a downstream finite-dynamics consumer. The packet is a finite BHist surface for trigger-time readback; it is not a stochastic process on an ambient probability space, not an infinite sample path, not a hidden field model, and not a host Markov-chain object.

Definition 4826.1 (MarkovTriggerDynamics carrier)**.** *A* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, K, A, D, G, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite state row. It records the consumed external-codon count m and the covered support rank r for the current trigger state.*
2. *K is the support-rank row. It records the finite support coordinates currently covered by the observed codon rows and the rank read from that support.*
3. *A is the transition-count row. It stores the finite count of rank-preserving and rank-increasing next draws available from the current state.*
4. *D is the drift row. It records the displayed one-step rank drift computed from the same transition counts.*
5. *G is the trigger-time row. It records the finite recursion for the time to reach full rank and the deterministic threshold row consumed by trigger-time readers.*
6. *H records componentwise* hsame *transport for state, support-rank, transition-count, drift, trigger-time, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a state read through S, K, A, D, G, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$, BHist, hsame, Cont, *finite rank-trigger rows, finite transition-count rows, finite trigger-time rows, and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient probability space, hidden generator field, infinite sample path, external random oracle, host Markov-chain semantics, or unstated independence assumption.

Lean4 ✓ `BEDC.Derived.MarkovTriggerDynamicsUp.MarkovTriggerDynamicsTasteGate single carrier alignment`

Theorem 4826.2 (MarkovTriggerDynamics NameCert obligations)**.** *For every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *carrier* $T = (S, K, A, D, G, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed state row, support-rank row, transition-count row, drift row, trigger-time row, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming row.*

The obligation surface requires the transition-count row A *to be computed from the finite support-rank row* K*, the drift row* D *to read only the transition counts in* A*, and the trigger-time row* G *to replay the finite recursion from the displayed state row* S *without adding an external probability carrier.*

Proof. Project the accepted carrier. The packet exposes only $S, K, A, D, G, H, C, P, N$, so every NameCert obligation is a componentwise obligation on those rows.

The state and support rows S, K determine the finite rank-trigger situation. The transition-count row A counts rank-preserving and rank-increasing next draws from that finite support surface.

The drift row D is downstream of A, and the trigger-time row G is downstream of the same state and transition-count data. Thus the trigger-time read is a finite recursion over displayed rows, not an imported Markov-chain object.

Transport, replay, provenance, and local naming preserve the same coordinates. Since the excluded ambient and hidden objects are not coordinates of T, no consumer can read them from the packet. □

Theorem 4826.3 (MarkovTriggerDynamics finite trigger readback)**.** *Every trigger-time consumer of an accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *packet reads the finite route*

$$S, K, A, D, G, H, C, P, N.$$

Consequently the transition law, drift, and trigger-time rows are all determined by finite BHist transition-count data. No trigger-time read exports an infinite sample path, host Markov process, hidden field, or unstated independence source.

Proof. Start with the state row S and support-rank row K. They display the finite input state and the rank information that determines which next-draw counts are available.

The transition-count row A is the only row from which the drift row D may be read. The trigger-time row G then replays the finite recursion from those same transition counts.

Finally H, C, P, N transport, replay, source, and name the finite trigger route. Because no other row exists in the carrier, the stated nonescape clauses follow. □

Falsifiable prediction: Every $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ trigger-time read factors through finite state, support-rank, transition-count, drift, trigger-time, hsame, Cont, Pkg, and NameCert rows.

Independence witness: dna-boundary-tile, rank-trigger, finite-markov-transition: $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries state rows, support-rank rows, transition-count rows, drift rows, trigger-time rows, componentwise hsame transport, displayed Cont replay, provenance, and local naming.

Theorem 4826.4 (MarkovTriggerDynamics sibling dependency route)**.** *Every accepted* $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ *trigger-time read routes its finite state and transition-count rows through chapter 189 or chapter 4074 when the carrier is read as a Markov surface, through chapter 195 when it is read as finite transition evolution, and through chapter 3508 for the DNA boundary-trigger consumer.*

Proof. Project the existing carrier rows $S, K, A, D, G, H, C, P, N$. The state row S, support-rank row K, and transition-count row A provide exactly the finite Markov read, so a Markov-surface consumer reaches this packet through the Markov-chain or finite Markov-partition certificates.

The same rows, together with drift row D and trigger-time row G, form the finite transition-evolution route consumed by the dynamical-system certificate. The structural rows H, C, P, N then transport, replay, source, and name that route for the DNA boundary-trigger consumer.

This is a dependency route only. It does not add an ambient probability space, infinite sample path, unstated independence source, or host Markov-chain object to the carrier. □

Nontrivial TasteGate and FieldFaithful instances remain required before this finite trigger surface can be read as a checked biological field-faithfulness claim.

Closure status for $\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MarkovTriggerDynamics}^{\uparrow}$ packet is generated from finite state rows, support-rank rows, transition-count rows, drift rows, trigger-time recursion rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5792.1, Definition 5792.2, and Definition 5792.3 seed the finite rank-trigger Markov readback surface for DNA boundary-tile dynamics.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarkovTriggerDynamics}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient probability spaces, infinite sample paths, hidden field models, host Markov-chain semantics, biological field-faithfulness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-count exactness, drift readback, trigger-time recursion, nontrivial TasteGate coverage, FieldFaithful evidence, transport, replay, provenance, and local naming for BEDC.Derived.MarkovTriggerDynamicsUp.

Chapter 4827

A Concrete Naming Certificate for $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet records the finite constructive route from regular Cauchy rational names to located completion data and then to the terminal $\mathsf{Real}^{\uparrow}$ seal. It reads the dyadic arithmetic surface of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the completion service exposed by chapter 128, and the real-name boundary of chapter 38. The packet supplies a located completion neighbour for the regular-Cauchy real route without asserting quotient completion equality, selected representatives, host order completeness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4827.1 (Regular Cauchy located completion carrier)**.** *A* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, Q, K, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the Cauchy name is inspected at requested precision scales.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic ledger for tolerance comparison, shrinkage, and rational distance estimates.*
4. *Q is the located completion row, recording the displayed located-distance and approximation data extracted from S, R, D.*
5. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row used only as a finite completion handoff for the displayed located data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular readback and located completion rows have been displayed.*
7. *H records componentwise* hsame *transport for stream windows, regular rational readbacks, dyadic arithmetic, located completion data, completion service, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a located-completion request through $S, R, D, Q, K, E, H, P, N$.*

9. *P is the* Pkg *provenance over* RegularCauchyLocatedCompletion$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CompleteMetric$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{RegularCauchyLocatedCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, Q, K, E, H, C, P, N$. The carrier has no coordinate for quotient completion equality, selected representatives, countable choice, host order completeness, ambient Real$^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchyLocatedCompletionUp.RegularCauchyLocatedCompletionTasteGate single carrier alignment`

Theorem 4827.2 (Regular Cauchy located completion obligations)**.** *For every accepted* RegularCauchyLocatedCom *carrier*

$$L = (S, R, D, Q, K, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyLocatedCompletion}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the stream-window row, regular rational readback row, dyadic arithmetic ledger, located completion row, complete-metric handoff, real seal, transport, replay, provenance, and local name;*
2. *window-readback coherence, requiring S to expose the finite inspection windows before R may be consumed as a regular rational name;*
3. *dyadic locatedness, requiring D to supply the tolerance comparisons and distance estimates used by the located completion row Q;*
4. *completion handoff ordering, requiring Q to be displayed before the* CompleteMetric$^{\uparrow}$ *row K is exposed;*
5. *real-seal ordering, requiring E to be read only after S, R, D, Q, K have been displayed;*
6. *classifier stability, requiring componentwise* hsame *transport and displayed* Cont *replay to preserve all visible rows;*
7. *non-escape, requiring H, C, P, N to transport, replay, source, and name no quotient completion equality, selected representative, countable choice, host order completeness, ambient* Real$^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 5793.1. Its rows list the finite stream windows, regular rational readback, dyadic arithmetic ledger, located completion data, complete-metric handoff, real seal, and the structural rows.

Window-readback coherence follows because R has no independent observation coordinate in this packet. The regular rational read must pass through S, and the tolerance computations used by that read are then checked against the dyadic row D.

The located completion row Q is the only row that records located-distance data. The completion handoff K consumes that displayed row, and the real seal E is exposed only after the handoff has been displayed.

Transport, replay, provenance, and local naming are exhausted by H, C, P, N. Since quotient completion equality, selected representatives, countable choice, host order completeness, and ambient Real$^{\uparrow}$ completeness are absent from the carrier, no NameCert obligation can export them. □

Theorem 4827.3 (Regular Cauchy located completion Real seal route)**.** *Let* $L = (S, R, D, Q, K, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer of the located completion read factors through the finite route*

$$S, R, D \longmapsto Q \longmapsto K \longmapsto E \longmapsto H, C, P, N.$$

Thus the packet reaches the real-name boundary only through displayed $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance arithmetic, located completion data, and the* $\mathsf{CompleteMetric}^{\uparrow}$ *handoff. It does not export quotient completion equality, selected representatives, countable choice, host order completeness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing read of the packet. The only observable name data are the stream windows S and the regular rational readback R, so any request for a real seal must first inspect those rows.

The dyadic row D supplies the tolerance and distance comparisons used by the located completion data Q. The complete-metric handoff K is then read as a service row for that displayed located data, not as an ambient completeness theorem.

Finally the seal row E exposes the $\mathsf{Real}^{\uparrow}$ boundary, and H, C, P, N transport, replay, source, and name the same displayed route. No remaining carrier coordinate can provide quotient completion equality, selected representatives, choice data, host order completeness, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5793.1, Definition 5793.2, and Definition 5793.3 seed a finite route from regular Cauchy names through located completion data to the $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host order completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window-readback coherence, dyadic locatedness, completion handoff ordering, real-seal ordering, classifier stability, and non-escape proofs for BEDC.Derived.RegularCauchyLocatedCompletionU

Constructive story: A $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore arithmetic, located completion data, a CompleteMetric handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4828

A Concrete Naming Certificate for $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$

Following Banach, Picard, and Bishop–Bridges constructive analysis, the $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet records the finite handoff from an explicit contraction estimate to the Cauchy threshold consumed by the regular-rational and real endpoint routes. It sits between the Banach fixed-point modulus packet of chapter 4188, the Picard iteration and error-estimate packets of chapter 2359 and chapter 2233, and the regular Cauchy completion boundary of chapter 5793. The packet gives the endpoint route a single displayed Cauchy-threshold surface without selecting a fixed point, quotienting completion names, or importing ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4828.1 (Picard threshold Cauchy handoff carrier)**.** *A* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, I, E, M, R, K, S, T, C, P, N)$$

with the following visible rows:

1. *B is the* $\mathsf{BanachFixedPointModulus}^{\uparrow}$ *source row whose contraction-rate route has already exposed the rational Lipschitz and finite Picard ledgers.*
2. *I is the* $\mathsf{PicardIteration}^{\uparrow}$ *ledger of adjacent iterate windows and replay order.*
3. *E is the* $\mathsf{PicardErrorEstimate}^{\uparrow}$ *row, carrying the residual-and-ratio estimate used to bound the Picard tail.*
4. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *threshold row produced from B, I, E for each requested dyadic or rational tolerance.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row made available only after the threshold row M has been displayed.*
6. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row consumed at the handoff boundary, not an ambient completeness theorem.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, R, K have been read.*
8. *T stores componentwise* hsame *transports for the Banach-modulus, Picard-iteration, error-estimate, Cauchy-threshold, regular-rational, complete-metric, real-seal, replay, provenance, and local naming rows.*

9. *C stores displayed* Cont *replay from the contraction-rate request through $B, I, E, M, R, K, S, T, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$, $\mathsf{BanachFixedPointModulus}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{PicardErrorEstimate}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, I, E, M, R, K, S, T, C, P, N$. It has no coordinate for a selected fixed point, host fixed-point equality, quotient completion equality, detached Cauchy selector, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.PicardThresholdCauchyHandoffUp.PicardThresholdCauchyHandoffTasteGate`
`single carrier alignment`

Theorem 4828.2 (Picard threshold Cauchy handoff NameCert obligations)**.** *For every accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier $H = (B, I, E, M, R, K, S, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyH}}$ *surface consists exactly of carrier admission for the displayed rows; Banach-modulus source visibility through B; Picard-iteration visibility through I; error-estimate visibility through E; Cauchy-threshold construction through M; regular-rational readback through R; complete-metric service access through K; real seal access through S; classifier stability through T and C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 5794.1. The accepted packet exposes exactly the Banach-modulus source row, the Picard-iteration ledger, the error-estimate row, the Cauchy-threshold row, the regular-rational readback, the complete-metric service, the real seal, and the structural rows.

The threshold rows are ordered. The rows B, I, E must be displayed before M can answer a tolerance request, since M is the only coordinate that records the finite Cauchy threshold.

The endpoint rows are downstream. The row R reads the threshold as regular rational data, K is the visible complete-metric service row, and S is exposed only after those rows have been displayed. Transport, replay, provenance, and local naming are exhausted by T, C, P, N, so no further NameCert obligation is present. □

Theorem 4828.3 (Picard threshold Cauchy handoff Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing endpoint read of an accepted* $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{BanachFixedPointModulus}^{\uparrow},\ \mathsf{PicardIteration}^{\uparrow},\ \mathsf{PicardErrorEstimate}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Complete}$$

Thus the real seal is reached only after the explicit Picard threshold has been displayed as a $\mathsf{CauchyModulus}^{\uparrow}$ *row and repacked through the regular-rational and complete-metric handoff rows. The route exports no selected fixed point, quotient completion equality, detached Cauchy selector, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a real-facing endpoint request. The only contraction-rate source row is B, and its Picard data are refined in the visible rows I and E, so the request first reads those rows.

The threshold stage is forced by M. Apply the Banach fixed-point modulus route of Definition 4188.3 together with the Picard iteration surface of chapter 2359 and the error-estimate surface of chapter 2233. These sources supply the displayed threshold row without adding a selected endpoint.

After M is fixed, the readback and completion rows R and K expose the regular-rational and complete-metric boundary used by chapter 301 and chapter 128. The seal row S is then the only $\mathsf{Real}^{\uparrow}$ coordinate, and the structural rows T, C, P, N preserve the same route. □

Closure status for $\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5794.1, Definition 5794.2, and Definition 5794.3 seed the finite Picard-threshold handoff from BanachFixedPointModulus, PicardIteration, and PicardErrorEstimate rows to CauchyModulus, RegSeqRat, CompleteMetric, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected fixed points, host fixed-point equality, quotient completion equality, detached Cauchy selectors, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Picard-threshold construction, regular-rational readback, complete-metric service access, real-seal ordering, classifier stability, provenance, and local naming for BEDC.Derived.PicardThreshol

Constructive story: A $\mathsf{PicardThresholdCauchyHandoff}^{\uparrow}$ packet is generated from a BanachFixedPointModulus source row, PicardIteration ledger, PicardErrorEstimate row, CauchyModulus threshold, RegSeqRat readback, CompleteMetric service row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4829

A Concrete Naming Certificate for $\mathsf{DiniUniformLimitModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the classical Dini theorem, the $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ packet extracts the finite uniform-modulus ledger visible in compact-metric monotone convergence data. It sits over chapter 2196, chapter 1436, chapter 129, chapter 130, chapter 463, chapter 369, chapter 301, and chapter 38. The packet names the finite net, rational tolerance budget, and extracted modulus route; it does not import open-cover compactness, chosen limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4829.1 (Dini uniform-limit modulus carrier)**.** *A* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row naming the compact-metric finite-source observations consumed by the extraction.*
2. *F is the monotone* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, recording the displayed continuous approximants and their pointwise monotone order.*
3. *W is the pointwise window row supplied by the Dini-continuity and Dini-uniform-convergence routes.*
4. *E is the finite net row over K, naming the finite mesh on which pointwise windows are inspected.*
5. *Q is the rational tolerance-budget row, storing the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerances assigned to the finite net and to the later readback.*
6. *U is the extracted* $\mathsf{UniformModulus}^{\uparrow}$ *row, obtained from E, Q, W and the monotone continuous family row F.*
7. *L is the* $\mathsf{UniformLimit}^{\uparrow}$ *handoff row, exposing only the modulus-controlled limit route supplied by U.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational tolerance transport.*
9. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row, naming the real-valued read without adding ambient real completeness.*
10. *H records componentwise* hsame *transport for compact-metric source, monotone family, pointwise window, finite net, rational tolerance, extracted modulus, uniform-limit handoff, rational readback, real seal, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from the compact-metric source and monotone family through the finite net, tolerance budget, extracted modulus, and uniform-limit handoff.*
12. *P is the* Pkg *provenance over* $\mathsf{DiniUniformLimitModulus}^{\uparrow}$, $\mathsf{DiniContinuity}^{\uparrow}$, $\mathsf{DiniUniformConvergence}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, W, E, Q, U, L, R, S, H, C, P, N$. It has no coordinate for open-cover compactness, selected limiting values, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DiniUniformLimitModulusUp.TasteGate.DiniUniformLimitModulusTasteGate single carrier alignment`

Theorem 4829.2 (Dini uniform-limit modulus NameCert obligations)**.** *For every accepted* DiniUniformLimitModulu *carrier*

$$D = (K, F, W, E, Q, U, L, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed compact-metric source, monotone continuous family, pointwise window, finite net, rational tolerance budget, extracted uniform modulus, UniformLimit handoff, RegSeqRat readback, Real seal, componentwise transport, replay, provenance, and local naming rows.*

The obligation surface requires monotone-window visibility through F and W, finite-net extraction through E and Q, modulus handoff through U and L, Real-seal nonescape through S, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses open-cover compactness, selected limiting values, quotient function equality, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier. The only computational rows are the compact-metric source K, monotone family F, pointwise windows W, finite net E, rational budget Q, extracted modulus U, uniform-limit handoff L, rational readback R, and real seal S.

The monotone-window step is local to F and W. The finite-net step is local to E and Q, so the modulus row U is extracted from displayed finite data rather than from an open cover or a choice of limiting values.

The handoff to $\mathsf{UniformLimit}^{\uparrow}$ passes only through U and L. The rational and real readback rows R and S name the downstream values without adding quotient function equality or ambient completeness.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded objects are not coordinates of D, no NameCert consumer can read them from this carrier. □

Falsifiable prediction: Every accepted $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ read must expose compact-metric source rows, monotone continuous-family rows, pointwise window rows, a finite net, a rational tolerance budget, an extracted uniform modulus, a UniformLimit handoff, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dini-continuity, diniuniformconvergence, compactmetric, continuousmap, uniformlimit, uniformmodulus, regseqrat, real: $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ is not bijective to any

listed sibling because it binds the finite net and rational tolerance budget to an extracted uniform-modulus handoff before UniformLimit and Real consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5795.1 and Definition 5795.2 seed the finite uniform-modulus ledger extracted from compact-metric monotone convergence data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiniUniformLimitModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected limiting values, quotient function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone-window visibility, finite-net extraction, modulus handoff, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.DiniUniformLimitModulusUp.

Constructive story: A $\mathsf{DiniUniformLimitModulus}^{\uparrow}$ packet is generated from compact-metric source rows, monotone continuous-family rows, pointwise windows, finite net rows, rational tolerance-budget rows, extracted uniform-modulus rows, UniformLimit handoff rows, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 4830

A Concrete Naming Certificate for $\mathsf{SummationByParts}^{\uparrow}$

Following Abel and Dirichlet, the $\mathsf{SummationByParts}^{\uparrow}$ packet records the finite identity surface by which displayed partial sums, coefficient windows, adjacent differences, and endpoint terms are bound into one NameCert row. It sits beside the Abel-summation route of chapter 1763, the Abel-test consumer of chapter 1496, and the Dirichlet-test consumer of chapter 1497. Its source rows use the finite series carrier of chapter 121; its regular readback, dyadic tolerance, and endpoint seal use chapter 301, chapter 291, and chapter 38. The packet names a finite algebraic identity for downstream convergence tests; it does not import infinite sums, quotient series equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4830.1 (Summation by parts carrier)**.** *A* $\mathsf{SummationByParts}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Series}^{\uparrow}$ *source row, exposing only the inspected finite term window and its displayed partial sums.*
2. *A is the coefficient-window row, naming the coefficient entries read over the same finite interval.*
3. *Δ is the adjacent-difference row, recording the displayed values $a_k - a_{k+1}$ used by the identity.*
4. *P is the partial-sum-window row, naming the cumulative sums paired with A and Δ.*
5. *B is the boundary-term row, displaying the endpoint products and the finite interior products determined by S, A, Δ, P.*
6. *T is the convergence-test handoff row consumed by* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$.
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed finite identity data.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the finite additions, subtractions, products, and endpoint comparisons used by B.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after $S, A, \Delta, P, B, T, R, D$ have been displayed.*
10. *H records componentwise* hsame *transport for the source, coefficient, difference, partial-sum, boundary, handoff, readback, dyadic, endpoint, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay of the route*

$$S, A, \Delta, P, B, T, R, D \longmapsto E.$$

12. *Q is the* Pkg *provenance over* $\mathsf{SummationByParts}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, A, \Delta, P, B, T, R, D, E, H, C, Q, N$. It has no coordinate for an infinite sum, quotient series equality, selected convergence witness, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SummationByPartsUp.SummationByPartsTasteGate single carrier alignment`

Theorem 4830.2 (Summation by parts NameCert obligations)**.** *For every accepted* $\mathsf{SummationByParts}^{\uparrow}$ *carrier*

$$K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite packet; source and partial-sum exposure through S and P; coefficient-window and adjacent-difference exposure through A and Δ; boundary-term exactness through B; convergence-test handoff through T; regular readback, dyadic accounting, and endpoint sealing through R, D, E; and transport, replay, provenance, and local naming through H, C, Q, N.*

Proof. Project the accepted carrier. The projection exposes exactly the rows $S, A, \Delta, P, B, T, R, D, E, H, C, Q, N$, so every naming obligation must be read from one of those displayed coordinates.

The identity rows are finite. The source row S and partial-sum row P display the inspected cumulative sums, the coefficient row A displays the paired coefficients, and Δ displays the adjacent differences used by the interior terms. The boundary row B records only the endpoint products and interior products determined by those rows.

The consumer handoff is downstream of the identity. A convergence-test consumer first reads T, and the regular and real-facing route then passes through R, D, E. These rows can transport the displayed finite calculation, but they do not introduce an independent summation principle.

Finally H, C, Q, N preserve, replay, source, and name the same route. Because the carrier has no coordinate for infinite sums, quotient series equality, selected convergence witnesses, countable choice, trichotomy, or ambient real completeness, the stated rows exhaust the local NameCert surface. □

Theorem 4830.3 (Summation by parts Cauchy-series handoff)**.** *Every accepted* $\mathsf{SummationByParts}^{\uparrow}$ *packet that is consumed by an* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$ *route hands off only the finite identity chain*

$$\mathsf{Series}^{\uparrow} \longmapsto S, A, \Delta, P, B, T \longmapsto R, D, E, H, C, Q, N.$$

Thus a Cauchy-series or real-seal consumer may read the summation-by-parts row only after the series window, coefficient window, adjacent-difference ledger, partial-sum window, boundary ledger, and test handoff have been displayed. The handoff supplies no infinite sum, quotient series equality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a convergence-test read. Carrier admission exposes the source row S and the finite identity rows A, Δ, P, B before the handoff row T is available.

The downstream chapters may add their own test-specific rows. The $\mathsf{AbelSummation}^{\uparrow}$ consumer reads the displayed finite identity as its transform row, the $\mathsf{AbelTest}^{\uparrow}$ consumer combines it with a monotone null coefficient ledger, and the $\mathsf{DirichletTest}^{\uparrow}$ consumer combines it with bounded partial sums and a null-tail schedule. In each case the summation-by-parts contribution remains the same displayed finite packet.

The Cauchy-facing route is therefore forced through R and D before E can seal the endpoint. Transport, replay, provenance, and local naming preserve that same route, so no excluded summation or completeness datum can be read from the packet. □

Falsifiable prediction: An accepted $\mathsf{SummationByParts}^{\uparrow}$ consumer that reaches an $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ row without reading the displayed source, coefficient, adjacent-difference, partial-sum, boundary-term, and handoff rows refutes the carrier surface.

Independence witness: abel-summation, abel-test, dirichlet-test, series, regseqrat, dyadicratcore, real: no listed sibling supplies the whole thirteen-row packet $K = (S, A, \Delta, P, B, T, R, D, E, H, C, Q, N)$, because each sibling contributes only a transform consumer, convergence-test consumer, source series, regular readback, dyadic ledger, or endpoint seal while this chapter binds the finite identity itself.

Closure status for $\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$.

Constructive story: A $\mathsf{SummationByParts}^{\uparrow}$ packet is generated from a SeriesUp finite source row, coefficient windows, adjacent-difference rows, partial-sum windows, boundary-term ledgers, AbelSummation/AbelTest/DirichletTest handoff rows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$, seed)

Scope closed: Definition 5796.1, Definition 5796.2, and Definition 5796.3 seed the finite summation-by-parts identity packet over $\mathsf{Series}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SummationByParts}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close infinite summation, quotient series equality, selected convergence witnesses, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite identity exactness, convergence-test handoff, Cauchy-series readback, dyadic accounting, endpoint sealing, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.SummationByPartsUp.

Chapter 4831

A Concrete Naming Certificate for $\mathsf{RealLineOrder}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealLineOrder}^{\uparrow}$ packet records the constructive real-line order and apartness boundary visible to finite BEDC NameCert consumers. It sits over the dyadic tolerance ledger of chapter 291, the stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, the rational Cauchy completion route of chapter 3670, and the Bishop regular Cauchy limit seal of chapter 1821. The packet gives L10 consumers a located comparison interface before any real-order algebra can read it; it does not import trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4831.1 (Real line order carrier)**.** *A* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (D, S, R, L, A, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the positive dyadic radius used by every finite comparison request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing only the finite stream observations inspected at that tolerance.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the inspected stream windows into regular rational comparison data.*
4. *L is the located comparison row, recording the finite verdict surface for $x < y$ as a witnessed positive gap at the displayed tolerance, an unresolved window requiring a smaller displayed tolerance, or a symmetric failure of the current request.*
5. *A is the apartness row, recording positive-gap readback for $x \# y$ only through D, S, R, L.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the same displayed stream and regular-rational data, not from host real equality.*
7. *H records componentwise* hsame *transport for dyadic tolerance, stream windows, regular-rational readback, located comparison, apartness, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite order request through $D, S, R, L, A, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RealLineOrder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, R, L, A, E, H, C, P, N$. It has no coordinate for trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RealLineOrderUp.RealLineOrderTasteGate single carrier alignment`

Theorem 4831.2 (Real line order NameCert obligations)**.** *For every accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier*

$$O = (D, S, R, L, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance row, stream-window row, regular-rational readback row, located comparison row, apartness row,* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise transport row, replay row, provenance row, and local naming row.*

The obligation surface requires finite tolerance visibility through D, window visibility through S, regular-rational comparison readback through R, located order exposure through L, apartness exposure through A, real-seal nonescape through E, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the accepted carrier of Definition 5797.1. The only analytic rows are the dyadic tolerance D, the finite stream windows S, the regular-rational readback R, the located comparison row L, the apartness row A, and the terminal real seal E.

The comparison step is located rather than trichotomic. A finite request may display a positive gap, request a smaller displayed tolerance, or fail symmetrically at the current window; none of these outcomes supplies a global three-way case split.

The equality-sensitive routes are absent. The readback row R is regular-rational data over the displayed windows, and the seal row E is reached only after D, S, R, L, A have been inspected. Thus the packet refuses quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since the excluded principles are not coordinates of O, no local NameCert obligation can demand them. □

Lean4 ✓ `BEDC.Derived.RealLineOrderUp.RealLineOrderNameCertObligations`

Theorem 4831.3 (Real line order apartness readback)**.** *Every apartness read exported by an accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RealLineOrder}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The apartness row A may expose only a positive-gap witness already visible through D, S, R, L. It exports no trichotomy datum, quotient equality, selected representative, host real equality, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Proof. Start with an apartness request. The request must first choose a displayed positive dyadic tolerance in D and inspect the finite windows in S.

The regular-rational readback R is then the only comparison source. The located comparison row L reads this finite data and either displays a positive gap at the requested tolerance or leaves the request unresolved for a smaller displayed tolerance.

The apartness row A can cite only the positive-gap branch already exposed by L. It refuses trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$ because those objects are not carrier rows.

The terminal seal E preserves the same finite route into $\mathsf{Real}^{\uparrow}$. Transport and replay through H and C keep the route stable, while P and N only record provenance and local naming. □

Theorem 4831.4 (Real line order L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{RealLineOrder}^{\uparrow}$ *carrier must read the dyadic tolerance, stream-window, regular-rational readback, located comparison, apartness, and* $\mathsf{Real}^{\uparrow}$ *seal rows in the order*

$$D, S, R, L, A, E.$$

Consequently the handoff supplies a finite non-quotient comparison boundary for later real algebra and order packets, while refusing trichotomy, quotient equality, selected representatives, host real equality, and ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. An L10 order request begins with finite tolerance data. The row D fixes the displayed dyadic radius, and S opens only the stream windows inspected at that radius.

The row R repacks those windows as regular-rational readback. The located comparison row L can then answer only with the finite comparison surface generated from D, S, R.

Apartness is downstream of located comparison. The row A may expose a positive gap only when L has already displayed one, and E seals the same finite route as a $\mathsf{Real}^{\uparrow}$-facing endpoint.

Because no earlier or later row stores trichotomy, quotient equality, selected representatives, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$, the L10 handoff cannot export those principles to later consumers. □

Falsifiable prediction: Every accepted $\mathsf{RealLineOrder}^{\uparrow}$ read must expose dyadic tolerance, StreamName windows, RegSeqRat readback, located comparison, apartness, RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before an L10 order consumer can read a comparison boundary.

Independence witness: dyadicratcore, streamname, regseqrat, real, rational-cauchy-completion, bishop-regular-cauchy-limit-seal: $\mathsf{RealLineOrder}^{\uparrow}$ is not bijective to any listed sibling because it binds located comparison and apartness rows to the finite readback route before the RealUp seal is available.

Closure status for $\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5797.1, Definition 5797.2, Definition 5797.3, and Definition 5797.4 seed the finite non-quotient order and apartness boundary for displayed RealUp names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealLineOrder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient equality, selected representatives, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite tolerance visibility, stream-window visibility, regular-rational readback, located comparison, apartness readback, RealUp seal handoff, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.RealLineOrderUp.

Constructive story: A $\mathsf{RealLineOrder}^{\uparrow}$ packet is generated from a DyadicRatCoreUp tolerance row, StreamName finite windows, RegSeqRat readback, located comparison, apartness, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4832

A Concrete Naming Certificate for $\mathsf{SchwartzKernel}^{\uparrow}$

Following Schwartz and Gelfand–Shilov, the $\mathsf{SchwartzKernel}^{\uparrow}$ packet records the finite NameCert route by which a distribution kernel is read as a bilinear action between Schwartz test probes and tempered-distribution endpoints. It sits over the Schwartz-function carrier of chapter 3399, the tempered-distribution endpoint of chapter 2310, the nuclear factorization row of chapter 215, the projective tensor norm route of chapter 4088, the tensor-product source of chapter 87, and the real seal of chapter 38. The chapter exposes the kernel theorem as finite action, tensor, nuclearity, bound, transport, replay, provenance, and local naming rows; it does not import a host distribution space, quotient test-function equality, selected representatives, or an unrestricted topological-vector-space oracle.

Definition 4832.1 (Schwartz kernel carrier)**.** *A* $\mathsf{SchwartzKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, U, J, B, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SchwartzFunction}^{\uparrow}$ *test-probe row naming the finite seminorm windows inspected on the source side.*
2. *T is the* $\mathsf{TemperedDistribution}^{\uparrow}$ *endpoint row naming the distributional action read after the test windows are displayed.*
3. *U is the* $\mathsf{TensorProduct}^{\uparrow}$ *row naming the finite tensor source on which the two test-probe sides are paired.*
4. *J is the* ***??*** *row recording the projective-tensor bound used to compare the paired test windows.*
5. *B is the* $\mathsf{Nuclear}^{\uparrow}$ *factorization row, exposing the finite nuclear decomposition route by which the kernel action is read.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed scalar bounds and kernel-action readbacks.*
7. *H records componentwise* hsame *transport for test probes, tempered endpoint, tensor source, projective bound, nuclear factorization, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite kernel request through $S, T, U, J, B, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{SchwartzKernel}^{\uparrow}$, $\mathsf{SchwartzFunction}^{\uparrow}$, $\mathsf{TemperedDistribution}^{\uparrow}$, $\mathsf{Nuclear}^{\uparrow}$, ***??***, $\mathsf{TensorProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^\uparrow}$ *row.*

The classifier compares accepted carriers only through $S, T, U, J, B, R, H, C, P, N$. It has no coordinate for a host distribution space, quotient equality of test functions, selected representatives, ambient bornological completeness, or a topological-vector-space theorem outside the displayed rows.

Lean4 ✓ `BEDC.Derived.SchwartzKernelUp.SchwartzKernelTasteGate single carrier alignment`

Theorem 4832.2 (Schwartz kernel NameCert obligations)**.** *For every accepted* $\mathsf{SchwartzKernel}^\uparrow$ *carrier*

$$K = (S, T, U, J, B, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^\uparrow}$ *surface consists exactly of Schwartz test-probe admission through S, tempered-distribution endpoint admission through T, tensor-source admission through U, projective-bound exposure through J, nuclear-factorization exposure through B, scalar RealUp sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every kernel consumer must read the distributional action through these ten rows. No consumer may replace them by an ambient kernel theorem, quotient test-function equality, selected representative, hidden topological vector space, or host nuclear-space completion.

Proof. Project the accepted carrier of Definition 5798.1. The analytic rows are the Schwartz test row S, the tempered-distribution endpoint T, the tensor source U, the projective bound J, the nuclear factorization B, and the RealUp seal R.

The action route is finite. The tensor row U supplies the paired test-probe source, J records the displayed projective bound, and B records the nuclear factorization by which the kernel action becomes readable by a finite consumer.

Transport and replay do not create new analytic structure. The rows H and C preserve the displayed packet componentwise and replay only the same kernel request. The provenance and naming rows P, N package the route without adding host quotient equality or a hidden completion theorem.

Thus the listed rows are exactly the local NameCert obligations for $\mathsf{SchwartzKernel}^\uparrow$. □

Theorem 4832.3 (Schwartz kernel nuclear factorization boundary)**.** *Every accepted* $\mathsf{SchwartzKernel}^\uparrow$ *read factors through the finite route*

$$\mathsf{SchwartzFunction}^\uparrow,\ \mathsf{TensorProduct}^\uparrow,\ ??,\ \mathsf{Nuclear}^\uparrow \longmapsto \mathsf{TemperedDistribution}^\uparrow \longmapsto \mathsf{Real}^\uparrow.$$

The nuclear row may expose only the displayed factorization and bound data already routed through S, U, J. It exports no host theorem identifying all kernels with all continuous bilinear forms, no quotient equality of test probes, no selected representative of a distribution, and no ambient completeness claim for the surrounding function spaces.

Proof. Start with a kernel read. The request first displays the finite Schwartz windows in S and the tensor source U on which the two test-probe sides are paired.

The projective tensor bound J is the only bound row available to the consumer. The nuclear factorization row B can cite only this displayed tensor-bound route, so its readback is a finite factorization certificate rather than an ambient nuclear-space theorem.

The tempered-distribution endpoint T then reads the resulting action, and R seals the scalar outputs as RealUp data. Transport through H and replay through C keep the same row order, while P and N record source and local naming.

Since no carrier coordinate stores host quotient equality, selected representatives, or ambient completeness, those principles cannot be exported by the factorization boundary. □

Falsifiable prediction: Every accepted $\mathsf{SchwartzKernel}^{\uparrow}$ packet must expose SchwartzFunctionUp test probes, TensorProductUp source data, ProjectiveTensorNormUp bounds, NuclearUp factorization, TemperedDistributionUp endpoint action, RealUp scalar sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before a kernel consumer can read the action.

Independence witness: schwartz-function, tempered-distribution, nuclear, projective-tensor-norm, tensorproduct, real: $\mathsf{SchwartzKernel}^{\uparrow}$ is not bijective to any listed sibling because it binds the test-probe tensor route, nuclear factorization boundary, distribution endpoint, and scalar seal as one finite kernel-action packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}$.

Constructive story: A $\mathsf{SchwartzKernel}^{\uparrow}$ packet is generated from SchwartzFunctionUp test probes, a TemperedDistributionUp endpoint, TensorProductUp source data, ProjectiveTensorNormUp bounds, NuclearUp factorization, RealUp scalar seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5798.1, Definition 5798.2, Definition 5798.3, the falsifiable prediction, and the independence witness seed the finite kernel-action route over Schwartz, tempered-distribution, tensor, nuclear, bound, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchwartzKernel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host distribution-space semantics, quotient equality of test functions, selected distribution representatives, ambient nuclear-space completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, test-probe visibility, tensor-source admission, projective-bound exactness, nuclear-factorization exposure, tempered-endpoint action, RealUp scalar sealing, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.SchwartzKernelUp.

Chapter 4833

A Concrete Naming Certificate for $\mathsf{SynonymousTransition}^{\uparrow}$

The $\mathsf{SynonymousTransition}^{\uparrow}$ packet realizes the finite synonymous-transition geometry of Definition 9462.1186 as BEDC NameCert data. It sits beside the six-bit codon-window carrier of chapter 2234, the codon transition matrix of chapter 2245, the DNA boundary-tile packet of chapter 3393, the window-coverage trigger algebra of chapter 3478, and the DNA-window trigger threshold of chapter 4217. The packet names finite codon-window, class-adjacency, boundary-spectrum, threshold, transport, replay, provenance, and local naming rows; it is not a biological mechanism, stochastic fitness model, quotient codon semantics, or unrecorded enumeration oracle.

Definition 4833.1 (Synonymous transition carrier)**.** *A* $\mathsf{SynonymousTransition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (W, M, A, B, T, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *row naming the finite Q_6 codon-window surface.*
2. *M is the* $\mathsf{CodonTransitionMatrix}^{\uparrow}$ *row naming one-bit codon transitions inspected by the packet.*
3. *A is the class-adjacency row recording the displayed synonymous and cross-class adjacency counts, including the largest weights of Definition 9462.1186.*
4. *B is the boundary-spectrum row recording internal edge counts, external boundary degrees, and the control-pair corner-contact data.*
5. *T is the* $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$ *row naming the finite threshold at which an adjacency or boundary-spectrum read may trigger a downstream tile consumer.*
6. *H records componentwise* hsame *transport for codon windows, transition matrix, class adjacency, boundary spectrum, trigger threshold, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite synonymous-transition request through W, M, A, B, T, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{SynonymousTransition}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{CodonTransitionMatrix}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{WindowCoverageTriggerAlgebra}^{\uparrow}$, $\mathsf{DNAWindowSixTriggerThreshold}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $W, M, A, B, T, H, C, P, N$. It has no coordinate for biological mechanism, stochastic fitness, quotient codon equality, hidden enumeration, or an ambient graph-theory oracle outside the displayed finite rows.

Theorem 4833.2 (Synonymous transition NameCert obligations)**.** *For every accepted* $\mathsf{SynonymousTransition}^{\uparrow}$ *carrier*

$$G = (W, M, A, B, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$ *surface consists exactly of codon-window admission through W, transition-matrix admission through M, class-adjacency exposure through A, boundary-spectrum exposure through B, trigger-threshold exposure through T, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Every downstream synonymous-transition consumer must read the graph through these nine rows. It cannot replace them by biological causation, stochastic selection, quotient codon semantics, an unrecorded enumeration, or a hidden graph oracle.

Proof. Project the accepted carrier of Definition 5799.1. The finite codon surface is W, the one-bit transition source is M, and the named graph data are the class-adjacency row A and boundary-spectrum row B.

The trigger row T records when the displayed adjacency or boundary-spectrum data may be read by a downstream tile or trigger consumer. It does not add a biological mechanism or a stochastic model; it only names the finite threshold over the same graph rows.

Transport and replay are componentwise. The rows H and C preserve and replay W, M, A, B, T with the same finite endpoints, while P and N record provenance and local naming.

Since the carrier has no coordinate for quotient codon equality, hidden enumeration, biological causation, or ambient graph semantics, the listed rows exhaust the local NameCert obligations. □

Theorem 4833.3 (Synonymous transition boundary-spectrum handoff)**.** *Every accepted* $\mathsf{SynonymousTransition}^{\uparrow}$ *read factors through the finite route*

$$\mathsf{CodonSixBitWindow}^{\uparrow},\ \mathsf{CodonTransitionMatrix}^{\uparrow} \longmapsto \mathsf{SynonymousTransition}^{\uparrow} \longmapsto \mathsf{DnaWindowSixBoundaryTile}^{\uparrow},\ \mathsf{Windo}$$

The handoff exposes class-adjacency weights, internal-edge counts, external boundary degrees, and control-pair corner contacts only as finite packet rows. It exports no biological mechanism, stochastic fitness model, quotient codon semantics, or unrecorded enumeration oracle.

Proof. Start with the codon-window row W and the one-bit transition matrix row M. These rows supply the finite Q_6 source and the adjacency relation inspected by the packet.

The class-adjacency row A records the largest displayed weights, and B records the boundary-spectrum data. The downstream boundary-tile and trigger-algebra consumers therefore receive a finite graph packet rather than a biological or stochastic explanation.

The threshold row T names when the finite rows can be consumed by the trigger route. Transport through H and replay through C keep the same graph rows visible, while P and N only package their provenance and local name.

Thus every public read of the synonymous-transition geometry remains inside the finite codon-window, transition, adjacency, boundary-spectrum, threshold, transport, replay, provenance, and naming surface. □

Falsifiable prediction: Every accepted $\mathsf{SynonymousTransition}^{\uparrow}$ packet must expose CodonSixBitWindowUp, CodonTransitionMatrixUp, class-adjacency, boundary-spectrum, DNAWindowSixTriggerThresholdUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before a downstream tile or trigger consumer can read the synonymous-transition graph.

Independence witness: codon-six-bit-window, codon-transition-matrix, dna-window-six-boundary-tile, window-coverage-trigger-algebra, dna-window-six-trigger-threshold: $\mathsf{SynonymousTransition}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries class-adjacency weights, boundary-spectrum rows, and trigger-threshold handoff over the finite codon-window graph.

Closure status for $\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}$.

Constructive story: A $\mathsf{SynonymousTransition}^{\uparrow}$ packet is generated from a CodonSixBitWindowUp source, a CodonTransitionMatrixUp one-bit transition row, class-adjacency counts, boundary-spectrum data, DNAWindowSixTriggerThresholdUp rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5799.1, Definition 5799.2, Definition 5799.3, the falsifiable prediction, and the independence witness seed the finite synonymous-transition packet over codon-window, transition, adjacency, boundary-spectrum, threshold, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SynonymousTransition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close biological mechanism, stochastic fitness, quotient codon semantics, hidden enumeration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, codon-window visibility, transition-matrix exactness, class-adjacency exposure, boundary-spectrum exposure, trigger-threshold handoff, componentwise transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.SynonymousTransitionUp.

Chapter 4834

A Concrete Naming Certificate for $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$

Following Feller and Billingsley on finite-sum normal approximation, the $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ packet records the finite BEDC surface by which an iid random-variable window is centered, scaled, read as a distribution row, and handed to a real-normal comparison seal. It sits after the probability source of chapter 184, the measurable random-variable rows of chapter 185, the law readback of chapter 186, the regular rational window of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite central-limit-facing certificate; it is not an asymptotic central limit theorem, a characteristic-function convergence theorem, a host probability-limit operator, countable choice, quotient distribution equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4834.1 (Central-limit finite-window carrier)**.** *A* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(P, V, S, K, D, R, E, H, C, Q, N).$$

Here P is the source $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the event classifier and total-mass normalization. The row V is the displayed iid* $\mathsf{RandomVar}^{\uparrow}$ *window over P, including the finite index range and the shared law token read by the window. The row S is the finite partial-sum ledger naming the displayed sum, the sample count, and the centered numerator. The row K is the centering and scaling row, recording the finite mean token, variance or spread token, positive scale request, and normalized finite-sum expression. The row D is the* $\mathsf{Distribution}^{\uparrow}$ *readback for the normalized finite sum and its comparison request. The row R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *window that presents rational test intervals, tolerances, and finite comparison samples for the distribution read. The row E is the* $\mathsf{Real}^{\uparrow}$ *normal-window seal naming the terminal real comparison against the displayed normal row at the requested finite window. The row H records componentwise* hsame *transport for the probability source, iid window, partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat window, Real normal-window seal, continuation, provenance, and local naming rows. The row C records* Cont *replay from a normal-facing read through P, V, S, K, D, R, E and then through the structural rows. The row Q is the* Pkg *provenance over* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert. *The row N is the local* $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$ *row. The classifier compares accepted carriers only through these eleven rows.*

Lean4 ✓ `BEDC.Derived.CentralLimitFiniteWindowUp.TasteGate.CentralLimitFiniteWindowTasteGate single carrier alignment`

Theorem 4834.2 (Central-limit finite-window NameCert obligations)**.** *For every accepted* CentralLimitFiniteWindo *carrier* $(P, V, S, K, D, R, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$ *surface consists exactly of the finite rows in Definition 5800.1. Carrier admission displays the probability source, iid random-variable window, finite partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat comparison window, RealUp normal-window seal, transport, replay, provenance, and local naming row. The certificate imports no host asymptotic central limit theorem, characteristic-function limit, Lindeberg replacement principle, countable-choice schedule, quotient distribution equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Project the carrier rows in order. The probability source P and iid random-variable window V are the only stochastic data exposed to the certificate, and the partial-sum ledger S fixes the finite sum before any normal-facing read is visible.

The centering and scaling row K then determines the normalized finite expression. The distribution row D and RegSeqRat window R provide the only comparison surface through which a finite law read can reach the terminal $\mathsf{Real}^{\uparrow}$ normal-window seal E.

Finally H, C, Q, N transport, replay, source, and name the same displayed route. Since the carrier has no coordinate for an asymptotic theorem, characteristic-function limit, quotient law equality, countable choice, or ambient completeness, the listed rows exhaust the local finite NameCert surface. □

Theorem 4834.3 (Central-limit finite-window normal handoff)**.** *Every normal-facing read of an accepted* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ *carrier factors through the finite route*

$$P \longmapsto V \longmapsto S \longmapsto K \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, Q, N$$

before any consumer receives a normal-window comparison. Thus the read is the displayed iid finite-sum, normalization, distribution, RegSeqRat, and RealUp handoff itself; it exports no host asymptotic CLT, countable choice, quotient distribution equality, characteristic-function convergence principle, or ambient real completeness.

Proof. Begin with a normal-facing request. The only probability data available are the source row P and the finite iid window V, so the request must first read the displayed sample range and shared law token.

The partial-sum row S and normalization row K are then forced. They provide the finite sum, centering token, scaling token, and normalized expression that the downstream distribution read consumes.

The request can reach a normal-window comparison only through D, R, E. The distribution row D names the finite law read, the RegSeqRat row R exposes rational windows and tolerances, and the RealUp row E seals the displayed normal comparison. The structural rows H, C, Q, N preserve that route without adding analytic content.

Therefore every accepted read factors through the finite iid-sum, normalization, distribution, RegSeqRat, and RealUp rows. The excluded asymptotic, choice, quotient, characteristic-function, and completeness principles cannot be inserted into the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ packet is generated from a probability source row, iid random-variable window, finite partial-sum ledger, centering and scaling row, distribution readback, RegSeqRat comparison window, RealUp normal-window seal, componentwise hsame transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CentralLimitFiniteWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5800.1, Definition 5800.2, and Definition 5800.3 seed the finite central-limit-facing handoff through ProbSpace, RandomVar, Distribution, RegSeqRat, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CentralLimitFiniteWindow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close the asymptotic central limit theorem, characteristic-function convergence, Lindeberg replacement, countable-choice schedules, quotient distribution equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, iid-window routing, partial-sum ledger exactness, normalization stability, distribution-to-RegSeqRat handoff, RealUp normal-window nonescape, transport, replay, provenance, and local naming for future BEDC.Derived.CentralLimitFiniteWindowUp.

Chapter 4835

A Concrete Naming Certificate for $\mathsf{LipschitzRealMap}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LipschitzRealMap}^{\uparrow}$ packet records a constructive real-map certificate whose continuity is controlled by a displayed dyadic Lipschitz constant and finite regular-rational windows. It sits after the dyadic tolerance ledger of chapter 291, the countable-name window surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the located order and apartness neighbour of chapter 5797. The packet names the finite L10 route by which later continuous-map and metric-uniform-continuity consumers may read a real-valued map without importing host function extensionality, quotient representatives, selected limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4835.1 (Lipschitz real-map carrier)**.** *A* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, K, W, R, M, H, C, P, N)$$

with the following rows:

1. *S is the source* $\mathsf{Real}^{\uparrow}$ *seal row naming the accepted real input surface through displayed* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *data.*
2. *T is the target* $\mathsf{Real}^{\uparrow}$ *seal row naming the accepted real output surface through the same kind of finite readback.*
3. *K is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *Lipschitz constant row, including the positive dyadic bound and the displayed tolerance ledger used by every modulus request.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row for the source and target names inspected by the request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the displayed source and target windows into rational comparison data.*
6. *M is the modulus-inequality row, recording that every accepted finite pair of source reads with displayed apartness or distance bound is sent to a target read whose displayed difference is bounded by the dyadic constant in K times the source bound, up to the requested displayed tolerance.*
7. *H records componentwise* hsame *transport for source seal, target seal, dyadic constant, finite windows, regular-rational readback, modulus inequality, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a finite map request through $S, T, K, W, R, M, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{LipschitzRealMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealLineOrder}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, T, K, W, R, M, H, C, P, N$. It has no coordinate for host function equality, quotient equality of real presentations, selected Cauchy representatives, global uniform continuity, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LipschitzRealMapUp.LipschitzRealMapTasteGate single carrier alignment`

Theorem 4835.2 (Lipschitz real-map NameCert obligations)**.** *For every accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier*

$$F = (S, T, K, W, R, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$ *surface consists exactly of carrier admission for the source* $\mathsf{Real}^{\uparrow}$ *seal, target* $\mathsf{Real}^{\uparrow}$ *seal, dyadic Lipschitz constant, finite StreamName windows, RegSeqRat readback, modulus inequality, componentwise transport, replay, provenance, and local naming rows.*

The obligation surface requires finite source and target visibility through S and T, dyadic bound visibility through K, finite window visibility through W, rational readback through R, modulus-inequality exposure through M, transport and replay stability through H and C, provenance through P, and local naming through N. It explicitly refuses host function extensionality, quotient equality of real presentations, selected representatives, global uniform-continuity principles, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5801.1. The source and target real seals are the only real-name endpoints, and both are read through finite StreamName and RegSeqRat windows rather than through host real equality.

The Lipschitz datum is the dyadic row K. A map request can inspect only the finite windows W and their rational readback R before the modulus row M exposes the displayed inequality for the requested tolerance.

The structural rows do not add analytic content. The transport row H preserves the already displayed source, target, constant, window, readback, and modulus rows componentwise, while C replays the same route and P, N record provenance and local naming.

Since no carrier coordinate stores host function equality, quotient real equality, selected representatives, global uniform continuity, or ambient completeness, no local NameCert obligation can require those objects. □

Theorem 4835.3 (Lipschitz real-map modulus stability)**.** *Let F_0 and F_1 be accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carriers whose source seals, target seals, dyadic Lipschitz constant rows, finite StreamName windows, and RegSeqRat readback rows are componentwise* hsame*-transported. Then every displayed modulus-inequality read exported by F_0 transports to the corresponding displayed modulus-inequality read exported by F_1.*

The stability claim is confined to the finite rows $S, T, K, W, R, M, H, C, P, N$. It does not identify host functions, quotient real presentations, selected Cauchy names, or ambient complete metric structures.

Proof. Start with a displayed modulus request for F_0. Its source and target real seals are read only through the finite StreamName windows and RegSeqRat readback rows named by S, T, W, R.

Use the componentwise hsame hypotheses. They transport the dyadic constant row K and the finite window/readback rows into the corresponding rows of F_1, so the same displayed source tolerance and target tolerance are available after transport.

The modulus row M is a row of the carrier rather than a host theorem about all representatives. Therefore the transported request reads the F_1 modulus row with the same displayed dyadic bound and the transported finite readback data.

Finally C, P, N replay, source, and name the transported route. No quotient equality, host function equality, selected representative, or ambient completeness principle is introduced by this transport. □

Theorem 4835.4 (Lipschitz real-map L10 handoff)**.** *Every L10 consumer of an accepted* $\mathsf{LipschitzRealMap}^{\uparrow}$ *carrier must read the route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RealLineOrder}^{\uparrow} \longmapsto \mathsf{LipschitzRealMap}^{\uparrow}$$

through the finite source seal, target seal, dyadic constant, finite windows, regular-rational readback, modulus inequality, transport, replay, provenance, and local NameCert rows. The handoff supplies a finite Lipschitz-control surface for later continuous-map and metric-uniform-continuity packets, while refusing host function extensionality, quotient equality, selected representatives, global uniform-continuity principles, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. An L10 map request begins with source and target real-name seals. By the carrier definition, these seals are visible only through the finite StreamName windows and RegSeqRat readback rows used by S, T, W, R.

The request then reads the dyadic constant row K and the located comparison surface supplied by the real-line order neighbour. These rows provide the displayed source difference and target tolerance against which the modulus inequality is checked.

The modulus row M is the only analytic output of the packet. It hands a consumer a finite inequality route, not a host-level function theorem.

The rows H, C, P, N transport, replay, source, and name the same route. Thus later continuous-map and metric-uniform-continuity packets can consume the finite Lipschitz surface without receiving quotient equality, selected representatives, host function extensionality, or ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$.

Constructive story: A $\mathsf{LipschitzRealMap}^{\uparrow}$ packet is generated from source and target RealUp seal rows, a DyadicRatCore Lipschitz constant, finite StreamName windows, RegSeqRat readback, a displayed modulus-inequality row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$, seed)

Scope closed: Definition 5801.1, Definition 5801.2, Definition 5801.3, and Definition 5801.4 seed the finite Lipschitz real-map surface over the current L10 real and completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LipschitzRealMap}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function extensionality, quotient equality of real presentations, selected Cauchy representatives, global uniform continuity, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source and target RealUp sealing, dyadic constant visibility, finite window readback, modulus-inequality stability, transport, replay, provenance, and local naming for future BEDC.Derived.LipschitzRealMapUp.

Chapter 4836

A Concrete Naming Certificate for HyperbolicQuasiGeodesicShadow$^{\uparrow}$

The HyperbolicQuasiGeodesicShadow$^{\uparrow}$ packet realizes the observer-expansion shadow route of section 9463.4 as finite quasi-geodesic, boundary, visual-metric, Busemann, and lamination-compatible rows. It sits after disk readout through chapter 377, the metric surface of chapter 3474, the visual-metric packet of chapter 3866, the Busemann cocycle route of chapter 4134, the geodesic-lamination packet of chapter 4203, and the observer-expansion packet of chapter 4167. The packet names a finite shadow tied to a displayed quasi-geodesic route; it does not complete the boundary, choose a global geodesic representative, identify quotient ideal points, or import host hyperbolic geometry.

Definition 4836.1 (Hyperbolic quasi-geodesic shadow carrier)**.** *A* HyperbolicQuasiGeodesicShadow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, G, E, V, B, L, H, C, P, A, N)$$

with the following rows:

1. *D is the disk readout row, exposing only displayed* UnitDisk$^{\uparrow}$ *coordinates and the associated* HyperbolicMetric$^{\uparrow}$ *metric-read data.*
2. *G is the quasi-geodesic route row, recording the finite path samples, distortion budget, endpoint-facing direction, and local route ledger inspected by the shadow request.*
3. *E is the boundary endpoint row named by the displayed route, not by a completed ideal-boundary quotient.*
4. *V is the visual-metric shadow row, recording the finite shadow window read through* HyperbolicVisualMetric$^{\uparrow}$ *and the boundary endpoint E.*
5. *B is the Busemann cocycle tolerance row, recording the displayed additive tolerance used to compare the route and the shadow window.*
6. *L is the geodesic-lamination compatibility row, recording whether the displayed route is compatible with the finite noncrossing leaf data consumed by* HyperbolicGeodesicLamination$^{\uparrow}$.
7. *H records componentwise* hsame *transport for disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow, Busemann tolerance, lamination compatibility, replay, provenance, refusal, and local naming rows.*
8. *C records displayed* Cont *replay from an observer-expansion shadow request through $D, G, E, V, B, L, H, P, A, N$.*

9. *P is the* Pkg *provenance over* HyperbolicQuasiGeodesicShadow$^{\uparrow}$, UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicVisualMetric$^{\uparrow}$, HyperbolicBusemannCocycle$^{\uparrow}$, HyperbolicGeodesicLamination$^{\uparrow}$, HyperbolicObserverExpar BHist, hsame, Cont, *and* NameCert.
10. *A is the refusal row excluding completed boundary quotients, selected global geodesics, ambient hyperbolic compactification, physical observer trajectories, and host curvature semantics.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, G, E, V, B, L, H, C, P, A, N$.

Theorem 4836.2 (Hyperbolic quasi-geodesic shadow NameCert obligations)**.** *For every accepted* HyperbolicQuasiGeodesicShadow$^{\uparrow}$ *carrier*

$$Q = (D, G, E, V, B, L, H, C, P, A, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$ *surface consists exactly of disk-readout visibility, quasi-geodesic route visibility, boundary endpoint exposure, visual-metric shadow-window exposure, Busemann cocycle tolerance, geodesic-lamination compatibility, componentwise transport, replay, provenance, refusal, and local naming rows.*

The packet exports no completed ideal boundary, quotient boundary equality, selected global geodesic, ambient hyperbolic compactification, physical observer trajectory, host curvature theorem, or global field semantics.

Proof. Project the carrier rows in order. The disk readout D supplies the only coordinate and metric source, while G supplies the displayed route samples and distortion budget inspected by the request.

The endpoint and shadow rows are downstream of that route. The endpoint row E names only the boundary read visible from G, and the visual row V records the finite shadow window tied to that endpoint.

The comparison rows B and L keep the shadow route finite. The Busemann tolerance is a displayed cocycle budget, and lamination compatibility is a finite noncrossing-leaf check, not a global geodesic-foliation theorem.

Finally H, C, P, A, N transport, replay, source, refuse, and name the same packet. Since the excluded host objects are not carrier rows, they cannot appear as NameCert obligations. □

Theorem 4836.3 (Hyperbolic quasi-geodesic shadow stability)**.** *Let Q_0 and Q_1 be accepted* HyperbolicQuasiGeodesi *carriers whose disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow window, Busemann tolerance, lamination compatibility, refusal, provenance, and local naming rows are componentwise* hsame*-transported. Then every observer-expansion consumer reads the same finite shadow surface through Q_0 and Q_1.*

The stability claim is confined to the finite rows $D, G, E, V, B, L, H, C, P, A, N$. It does not identify completed boundaries, quotient ideal points, selected geodesics, ambient compactifications, physical observer trajectories, host curvature data, or global fields.

Proof. Start with an observer-expansion shadow request for Q_0. The request must read disk coordinates and metric data through D and then the finite route samples and distortion budget through G.

Use the componentwise hsame transport. It carries the endpoint E, visual shadow window V, Busemann tolerance B, and lamination compatibility row L to the corresponding rows of Q_1.

The refusal row is transported with the same packet. Therefore the transported consumer sees the same excluded host objects and cannot insert completed boundary quotients, selected global geodesics, ambient compactifications, physical trajectories, curvature theorems, or global fields.

The replay row C and the provenance and naming rows P, N then present the transported shadow as the same finite observer-expansion surface. □

Theorem 4836.4 (Hyperbolic quasi-geodesic shadow vision handoff)**.** *Every observer-expansion consumer of an accepted* $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ *carrier must read the route*

$\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HyperbolicGeodesicLaminatio}$

through disk readout, quasi-geodesic route, boundary endpoint, visual-metric shadow, Busemann tolerance, lamination compatibility, transport, replay, provenance, refusal, and local NameCert rows. The handoff realizes the vision-level shadow route as finite NameCert data without turning observer expansion into physical cosmology or a host hyperbolic-boundary theorem.

Proof. The vision handoff begins with disk and metric data. Rows D and G ensure that the consumer reads only displayed disk observations, metric readouts, finite route samples, and a distortion budget.

The endpoint and shadow window are then forced. Rows E and V bind the boundary endpoint and visual-metric shadow to the same route, while B records the Busemann tolerance needed to compare route and shadow.

Lamination compatibility is read through L. This makes the packet consumable by geodesic-lamination and observer-expansion rows without selecting a global geodesic representative or completing the boundary.

The rows H, C, P, A, N transport, replay, source, refuse, and name the handoff. Thus the vision-level quasi-geodesic shadow is realized as finite NameCert data and not as ambient hyperbolic geometry. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ read must expose a boundary endpoint, visual-metric shadow window, Busemann cocycle tolerance, quasi-geodesic route, transport row, provenance row, refusal row, and local NameCert before any observer-expansion consumer may read the shadow.

Independence witness: hyperbolic-visual-metric, hyperbolic-busemann-cocycle, hyperbolic-geodesic-lamination, hyperbolic-observer-expansion: $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ is not bijective to these siblings because it binds the quasi-geodesic route and shadow window together before the observer-expansion packet may consume the boundary read.

The Lean TasteGate for this packet must later provide $\mathsf{Nontrivial}\ \mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ in `lean4/BEDC/Derived/HyperbolicQuasiGeodesicShadowUp/` Those instances must keep $D, G, E, V, B, L, H, C, P, A, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}$ packet is generated from disk readout rows, a quasi-geodesic route, a boundary endpoint, a visual-metric shadow window, Busemann cocycle tolerance, geodesic-lamination compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, refusal, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5802.1, Definition 5802.2, Definition 5802.3, and Definition 5802.4 seed the finite quasi-geodesic shadow route for observer-expansion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicQuasiGeodesicShadow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed boundary quotients, selected global geodesics, ambient hyperbolic compactification, physical observer trajectories, host curvature semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk readout, quasi-geodesic route admission, endpoint exposure, visual-metric shadow windows, Busemann tolerance, lamination compatibility, TasteGate nontriviality, field faithfulness, refusal exactness, transport, replay, provenance, and local naming for future BEDC.Derived.HyperbolicQuasiGeodesicShadowUp.

Chapter 4837

A Concrete Naming Certificate for $\mathsf{Dendrite}^{\uparrow}$

Following Nadler and Kuratowski on continuum theory, the $\mathsf{Dendrite}^{\uparrow}$ packet records the finite BEDC surface for a locally connected compact metric continuum whose tree-like form is read through unique arcs and cutpoint separation. It sits over the compact metric carrier of chapter 129, the locally connected surface of chapter 5809, the Peano continuum boundary of chapter 2160, and the tree certificate of chapter 119. The packet names displayed endpoint, unique-arc, and cutpoint-separation rows; it does not import host continua, arbitrary path spaces, open-cover compactness, or quotient equality of arcs.

Definition 4837.1 (Dendrite carrier)**.** *A* $\mathsf{Dendrite}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, L, P, T, E, A, C, H, R, G, Q, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the metric distance rows, finite ProbeBundle-net rows, complete-limit witness rows, and rational tolerance comparisons already certified by the compact-metric chapter.*
2. *L is the* $\mathsf{LocallyConnected}^{\uparrow}$ *row, recording the displayed connected neighbourhood refinements through which local arc and cutpoint requests are inspected.*
3. *P is the* $\mathsf{PeanoContinuum}^{\uparrow}$ *row, binding the compact metric and locally connected continuum surfaces before any dendrite consumer reads an arc boundary.*
4. *T is the* $\mathsf{Tree}^{\uparrow}$ *row, recording the finite tree-like separation surface used to rule out cycle-shaped routes.*
5. *E is the endpoint ledger, listing endpoint rows and their neighbourhood-read witnesses.*
6. *A is the unique-arc ledger, recording for every displayed endpoint or carried point pair the finite arc row, its endpoint membership rows, and its non-branching comparison rows.*
7. *C is the cutpoint-separation ledger, recording the displayed separation rows used when removing a carried point disconnects the relevant finite tree-like boundary.*
8. *H records componentwise* hsame *transport for compact metric data, local connectedness data, Peano-continuum data, tree data, endpoint rows, unique-arc rows, cutpoint-separation rows, replay, provenance, and local naming.*

9. *R records displayed* Cont *replay from a dendrite request through $K, L, P, T, E, A, C, H, G, Q, N$.*
10. *G is the* Pkg *provenance over* $\mathsf{Dendrite}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{PeanoContinuum}^{\uparrow}$, $\mathsf{Tree}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *Q records the local source and consumer provenance for endpoint, unique-arc, and cutpoint-separation reads.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{Dendrite}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host continuum, arbitrary path selection, open-cover compactness, cycle elimination by excluded middle, or quotient equality of arcs.

Lean4 ✓ `BEDC.Derived.DendriteUp.DendriteTasteGate single carrier alignment`

Theorem 4837.2 (Dendrite NameCert obligations)**.** *For every accepted* $\mathsf{Dendrite}^{\uparrow}$ *carrier*

$$D = (K, L, P, T, E, A, C, H, R, G, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{Dendrite}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact metric source, locally connected row, Peano-continuum row, tree row, endpoint ledger, unique-arc ledger, cutpoint-separation ledger, transport, replay, provenance, source provenance, and local naming;*
2. *compact-continuum visibility, requiring every dendrite consumer to read compact metric and local connectedness data through K, L, P before reading endpoint or arc rows;*
3. *tree-like exactness, requiring the non-cycle and separation information to pass through T and the cutpoint-separation ledger C;*
4. *unique-arc exactness, requiring every arc-facing read to use the displayed ledger A with its endpoint membership and non-branching comparison rows;*
5. *endpoint exactness, requiring endpoint reads to use only the displayed endpoint ledger E and not a host boundary predicate;*
6. hsame, Cont, *and* Pkg *stability, requiring componentwise transport, displayed replay, and provenance to preserve precisely the listed rows;*
7. *non-escape, excluding host continua, arbitrary path spaces, open-cover compactness, selected arc representatives, and quotient equality of arcs.*

No dendrite obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5803.1. The accepted tuple displays exactly the compact metric source, local connectedness, Peano-continuum row, tree row, endpoint ledger, unique-arc ledger, cutpoint-separation ledger, transport, replay, provenance, source provenance, and local naming.

The compact-continuum route is K, L, P. The compact metric source supplies distance, finite-net, complete-limit, and tolerance-comparison rows; the locally connected row supplies connected neighbourhood refinements; and the Peano-continuum row binds those surfaces before endpoint or arc data are exposed.

The tree-like route is T, E, A, C. The tree row supplies the finite non-cycle surface, the endpoint ledger records boundary reads, the unique-arc ledger records the displayed arc row between

carried point pairs, and the cutpoint-separation ledger records the separation witnesses used by downstream consumers.

Finally, H, R, G, Q, N transport, replay, source, and name the same finite packet. Since the carrier has no row for a host continuum, arbitrary path space, open-cover compactness principle, selected arc representative, or quotient equality of arcs, the listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$ surface. □

Theorem 4837.3 (Dendrite unique-arc handoff)**.** *Every unique-arc or cutpoint-facing consumer of an accepted* $\mathsf{Dendrite}^\uparrow$ *carrier must read the finite route*

$$\mathsf{CompactMetric}^\uparrow,\ \mathsf{LocallyConnected}^\uparrow,\ \mathsf{PeanoContinuum}^\uparrow,\ \mathsf{Tree}^\uparrow \longmapsto E, A, C, H, R, G, Q, N.$$

The handoff exposes endpoint rows, unique-arc rows, cutpoint-separation rows, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It does not expose arbitrary host paths, open-cover compactness, selected arc representatives, quotient equality of arcs, or a continuum object outside the displayed packet.*

Proof. Start with the compact-continuum source. The rows K, L, P force a consumer to read the compact metric, locally connected, and Peano-continuum surfaces before any arc-facing data can be inspected.

Next read the tree row T. This is the only row carrying the tree-like non-cycle surface, so a later cutpoint or arc argument cannot replace it by a host graph or a classical continuum theorem.

The endpoint and arc data are then E, A, C. Endpoint reads pass through E, unique-arc reads pass through A, and cutpoint-separation reads pass through C; the three ledgers remain tied to the same compact-continuum and tree source rows.

The structural rows H, R, G, Q, N preserve this route under transport, replay, provenance, and local naming. Because no excluded host-side row appears in the carrier, the consumer receives exactly the displayed unique-arc handoff and nothing stronger. □

Falsifiable prediction: Every accepted $\mathsf{Dendrite}^\uparrow$ read must expose CompactMetric, LocallyConnected, PeanoContinuum, Tree, endpoint, unique-arc, cutpoint-separation, componentwise hsame, displayed Cont, Pkg, source provenance, and local NameCert rows before a continuum or arc consumer can inspect the dendrite boundary.

Independence witness: compactmetric, locally-connected, peano-continuum, tree: $\mathsf{Dendrite}^\uparrow$ is not bijective to any listed sibling because it binds endpoint, unique-arc, and cutpoint-separation ledgers over their common compact-continuum and tree-like source.

Closure status for $\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$**.**

Constructive story: A $\mathsf{Dendrite}^\uparrow$ packet is generated from CompactMetricUp, LocallyConnectedUp, PeanoContinuumUp, TreeUp, endpoint rows, unique-arc rows, cutpoint-separation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, source provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$, seed)

Scope closed: Definition 5803.1, Definition 5803.2, and Definition 5803.3 seed the finite dendrite certificate over compact metric, locally connected, Peano-continuum, tree, endpoint, unique-arc, cutpoint-separation, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Dendrite}^\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host continua, arbitrary path spaces, open-cover compactness, selected arc representatives, quotient equality of arcs, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-continuum visibility, tree-like exactness, endpoint exactness, unique-arc exactness, cutpoint-separation exactness, transport, replay, provenance, and local naming for BEDC.Derived.DendriteUp.

Chapter 4838

A Concrete Naming Certificate for $\mathsf{YoungIntegration}^{\uparrow}$

Following Young's integration theorem and Bishop–Bridges constructive analysis, the $\mathsf{YoungIntegration}^{\uparrow}$ packet records the finite dyadic route for integrating one Holder-controlled path against another. It sits beside the Holder-continuity surface of chapter 1766, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the tagged-mesh Riemann integral boundary of chapter 1526. The chapter names only a finite partition-and-error certificate; it does not import host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4838.1 (Young integration finite partition carrier)**.** *A* $\mathsf{YoungIntegration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (F, G, A, B, W, V, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the integrand path row, read through a* $\mathsf{HolderContinuity}^{\uparrow}$ *packet with its source interval observations, target Real estimates, rational exponent, and displayed Holder constant.*
2. *G is the integrator path row, read through a second* $\mathsf{HolderContinuity}^{\uparrow}$ *packet with its own source interval observations, target Real estimates, rational exponent, and displayed Holder constant.*
3. *A and B are the two Holder exponent ledgers. They include the finite comparison row witnessing that the displayed exponents have a Young margin for the dyadic partition family.*
4. *W is the dyadic partition-window row. It lists the inspected endpoints, dyadic mesh refinements, cell order, adjacent-cell handoffs, and the finite cells on which the integration read is allowed to form sums.*
5. *V is the cross-variation tolerance ledger. It records the cellwise oscillation products, Holder-bound products, Young-margin comparisons, and finite sum-difference tolerances consumed by the route.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger for endpoint radii, mesh widths, exponent-comparison margins, oscillation products, and final error bounds.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational trace of dyadic Young sums.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the integral value, reached only after the two Holder rows, dyadic windows, cross-variation ledger, dyadic tolerances, and regular readback have been displayed.*
9. *H records componentwise* hsame *transport for the two Holder paths, exponent ledgers, partition windows, cross-variation ledger, dyadic ledger, readback, Real seal, replay, provenance, and local name.*
10. *C records displayed* Cont *replay from a Young-integration request through Holder admission, dyadic partition windows, cross-variation tolerances, regular rational readback, and the Real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{YoungIntegration}^{\uparrow}$, $\mathsf{HolderContinuity}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, G, A, B, W, V, D, R, E, H, C, P, N$. It has no coordinate for an ambient path space, quotient equality of functions, a selected sequence of partitions, a hidden limiting argument, countable choice, measure completion, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.YoungIntegrationUp.YoungIntegrationTasteGate single carrier alignment`

Theorem 4838.2 (Young integration NameCert obligations)**.** *For every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *carrier $Y = (F, G, A, B, W, V, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$ *surface is exhausted by admission of two* $\mathsf{HolderContinuity}^{\uparrow}$ *path rows, exponent-margin comparison, dyadic partition-window formation, cross-variation tolerance accounting,* $\mathsf{DyadicRatCore}^{\uparrow}$ *exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No accepted consumer may replace these rows by host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, or ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5804.1. The rows F and G expose the two Holder-controlled paths, and A, B expose only the finite exponent and Young-margin comparisons attached to those rows.

The partition and tolerance data are then forced. The row W lists the dyadic windows available to the route, while V records the cross-variation products and sum-difference tolerances over exactly those windows.

The terminal read is D, R, E. Dyadic exactness is read through D, the regular rational trace through R, and the Real integral seal through E only after the preceding rows have been consumed.

Finally H, C, P, N transport, replay, source, and name the same displayed route. Since the excluded objects have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 4838.3 (Young integration dyadic error budget)**.** *Every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *read that reaches the* $\mathsf{Real}^{\uparrow}$ *seal factors through the finite dyadic budget*

$$\mathsf{HolderContinuity}^{\uparrow}, \mathsf{HolderContinuity}^{\uparrow} \longmapsto \mathsf{DyadicPartition}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The row V must display the cross-variation tolerance consumed between the partition windows and the rational readback. Therefore the exported integral value is a finite dyadic Young-sum seal, not a Riemann-integral replacement, a measure-completion integral, a quotient path equality, a selected limiting partition, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the two Holder rows. Their displayed exponents and constants are read through F, G, A, B, so the route has only the finite power-law data needed to bound oscillations on dyadic cells.

Next read the dyadic partition windows. The row W fixes the cells, endpoints, mesh refinements, and adjacent-cell handoffs before any sum-difference comparison is requested.

The error budget is the pair V, D. The cross-variation ledger V records the oscillation products and Young-margin comparisons, and the dyadic ledger D records the exact rational tolerances used to compare any two displayed sums.

The readback and seal are downstream. The regular sequence row R is the only rational trace exported from the finite budgets, and E is the only Real seal. Thus the consumer cannot obtain any of the excluded host-level or choice-level objects from the packet. □

Theorem 4838.4 (Young integration Riemann boundary)**.** *Every* $\mathsf{RiemannIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *packet reads it only as a finite tagged-mesh boundary: two Holder path rows, a dyadic partition-window row, a cross-variation tolerance ledger, dyadic exactness, regular rational readback, Real sealing, transport, replay, provenance, and local naming. The consumer receives no independent Riemann-integral certificate, no Darboux gap claim, no quotient equality of integrands, no measure-completion object, and no selected mesh-limit principle.*

Proof. The only Riemann-facing data in the carrier are the displayed dyadic windows and finite sum budgets. The two Holder path rows provide values to be sampled, while W supplies the finite tagged-mesh boundary.

The cross-variation ledger is not a Darboux or measure-theoretic claim. It records only the tolerance comparisons needed for the Young-sum route before the regular rational readback is sealed as a Real value.

The provenance row may name $\mathsf{RiemannIntegral}^{\uparrow}$ as a consumer boundary, but the local certificate remains $F, G, A, B, W, V, D, R, E, H, C, P, N$. Therefore a Riemann-integral consumer receives a finite boundary row rather than any independent integral theorem or hidden limiting principle. □

Theorem 4838.5 (Young integration Cauchy-modulus consumer)**.** *Every accepted* $\mathsf{YoungIntegration}^{\uparrow}$ *packet whose cross-variation ledger* V *requests a tail precision must consume the* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *route before* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *sealing. The route remains finite: it exports the displayed Young partition windows, dyadic error budget, explicit Cauchy-modulus handoff, regular rational readback, and terminal Real seal, but it exports no selected limiting partition, countable-choice schedule, hidden modulus oracle, or ambient completion theorem.*

Proof. Project the carrier of Definition 5804.1. The rows W, V, D, R, E expose the partition windows, cross-variation tolerance ledger, dyadic error budget, regular rational readback, and terminal Real seal.

Use Definition 5804.3. The row V is the place where sum-difference tolerances and tail precision demands are recorded, and D is the dyadic ledger that makes those demands finite.

When such a tail precision is requested, apply the effective handoff of Definition 5728.3 and the schedule determinacy of Definition 5728.4. They force the precision request through an explicit $\mathsf{CauchyModulusBridge}^{\uparrow}$ schedule before R can be read and before E can seal the result.

The remaining rows H, C, P, N transport, replay, source, and name the same finite route. Since neither the Young carrier nor the bridge carrier contains a selected limiting partition, countable-choice schedule, hidden oracle, or ambient completion coordinate, no such object is exported. □

Falsifiable prediction: An accepted $\mathsf{YoungIntegration}^{\uparrow}$ packet is refuted if a consumer reaches the $\mathsf{Real}^{\uparrow}$ seal while omitting either $\mathsf{HolderContinuity}^{\uparrow}$ path row, the dyadic partition-window row W, the cross-variation ledger V, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D, or the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Independence witness: HolderContinuity, DyadicPartition, DyadicRatCore, RegSeqRat, Real, RiemannIntegral: none is bijective with $\mathsf{YoungIntegration}^{\uparrow}$ because the packet jointly carries two Holder paths, Young-margin exponent rows, dyadic partition windows, cross-variation tolerances, dyadic exactness, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}$.

Constructive story: A $\mathsf{YoungIntegration}^{\uparrow}$ packet is generated from two HolderContinuityUp path rows, exponent-margin ledgers, dyadic partition windows, cross-variation tolerance accounting, DyadicRatCore exactness, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5804.1, Definition 5804.2, Definition 5804.3, Definition 5804.4, and Definition 5804.5 seed the finite dyadic Young-integration route over HolderContinuityUp, DyadicPartitionUp, DyadicRatCoreUp, CauchyModulusBridgeUp, RegSeqRatUp, RealUp, and RiemannIntegralUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{YoungIntegration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host path spaces, quotient equality of functions, selected limiting partitions, countable choice, measure completion, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked two-path admission, exponent-margin comparison, dyadic partition-window formation, cross-variation tolerance accounting, dyadic exactness, regular rational readback, Real-seal nonescape, and structural transport for BEDC.Derived.YoungIntegrationUp.

Chapter 4839

A Concrete Naming Certificate for $\mathsf{VariationDiminishing}^{\uparrow}$

Following Schoenberg and Karlin, the $\mathsf{VariationDiminishing}^{\uparrow}$ packet records a finite analysis row for transformations that do not increase displayed sign variation. It consumes the total-variation function surface of chapter 2257, the bounded-variation real-function carrier of chapter 3654, the regulated-function source of chapter 1554, and the tagged integration boundary of chapter 1526. The packet names the finite comparison by which a kernel or transformation row is read as variation-diminishing without importing a host operator algebra, total-positivity theorem, selected partitions, quotient functions, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4839.1 (Variation-diminishing carrier)**.** *A* $\mathsf{VariationDiminishing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (B, T, R, I, K, M, H, C, P, N)$$

with the following rows:

1. *B is the* $\mathsf{BoundedVariationRealFunction}^{\uparrow}$ *source row naming the accepted bounded-variation input surface.*
2. *T is the* $\mathsf{TotalVariationFunction}^{\uparrow}$ *row naming the displayed total-variation ledger used to count variation before and after the transformation.*
3. *R is the* $\mathsf{RegulatedRealFunction}^{\uparrow}$ *row naming the regulated readback through which input and output functions are compared by finite step windows.*
4. *I is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *row naming the finite tagged-mesh integration boundary used when the transformation is read by kernel action or integral averaging.*
5. *K is the kernel or transformation row, including its displayed positivity-order or sign-regularity window.*
6. *M is the variation comparison row recording that each accepted finite sign-change ledger for the output is routed to a no-larger sign-change ledger for the input.*
7. *H records componentwise* hsame *transport for bounded-variation source, total-variation ledger, regulated readback, integral boundary, kernel row, comparison row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite transformation request through $B, T, R, I, K, M, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{VariationDiminishing}^{\uparrow}$, $\mathsf{BoundedVariationRealFunction}^{\uparrow}$, $\mathsf{TotalVariationFunction}^{\uparrow}$, $\mathsf{RegulatedRealFunction}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and sibling* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, T, R, I, K, M, H, C, P, N$. It has no coordinate for host function equality, quotient representatives, selected limiting partitions, a global total-positivity theorem, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.VariationDiminishingUp.VariationDiminishingTasteGate single carrier alignment`

Theorem 4839.2 (Variation-diminishing NameCert obligations)**.** *For every accepted* $\mathsf{VariationDiminishing}^{\uparrow}$ *carrier*

$$V = (B, T, R, I, K, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded-variation source row B, total-variation ledger T, regulated-function readback R, Riemann-integral boundary I, kernel or transformation row K, variation comparison row M, componentwise transport H, displayed replay C, provenance P, and local naming N.*

The obligation surface requires every output variation read to pass through the displayed comparison row M after B, T, R, I, K have been projected. It refuses host operator equality, quotient equality of functions, selected partitions, unrestricted total positivity, measure-theoretic kernels, and ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 5805.1. The source row B supplies the bounded-variation input, while T supplies the total-variation ledger on which finite sign-change comparisons can be read.

The rows R and I keep the analytic route finite. Regulated readback gives step-window access to input and output functions, and the Riemann-integral boundary records only the tagged-mesh action needed by a kernel or averaging read.

The row K names the transformation window, and M is the only row that compares variation before and after the transformation. Thus the NameCert consumer obtains a variation-diminishing assertion only through the displayed comparison row, not through a host theorem about all kernels.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate stores quotient functions, selected limiting partitions, unrestricted total positivity, measure completion, or ambient real completeness, no local obligation can require them. □

Theorem 4839.3 (Variation-diminishing total-variation route)**.** *Every accepted* $\mathsf{VariationDiminishing}^{\uparrow}$ *consumer read factors through the route*

$$\mathsf{BoundedVariationRealFunction}^{\uparrow},\ \mathsf{TotalVariationFunction}^{\uparrow},\ \mathsf{RegulatedRealFunction}^{\uparrow},\ \mathsf{RiemannIntegral}^{\uparrow} \longmapsto \mathsf{VariationD}$$

The output variation ledger is accepted only after the bounded-variation input, cumulative total-variation ledger, regulated readback, tagged integration boundary, kernel row, and comparison row have been displayed. The route exports no selected limit, quotient function equality, global total-positivity principle, measure-completion object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness assertion.*

Proof. A variation-diminishing request first projects B and T. These rows bind the input function to the bounded-variation and total-variation sibling surfaces, so the requested comparison starts from finite variation data rather than from a host function space.

Next project R and I. The regulated row supplies finite step-window readback, while the integral boundary supplies the tagged-mesh route through which a kernel or averaging transformation can be inspected.

The transformation row K and comparison row M then give the only accepted variation comparison. They state that the displayed output sign-change ledger routes to a no-larger input ledger in the same finite packet.

Finally H, C, P, N preserve the route under transport, replay, provenance, and local naming. Hence every public read of $\mathsf{VariationDiminishing}^{\uparrow}$ passes through the four cited sibling anchors and does not acquire the excluded host-level principles. □

Falsifiable prediction: A $\mathsf{VariationDiminishing}^{\uparrow}$ packet whose output variation read bypasses the displayed total-variation ledger or the regulated readback row is not accepted by the local NameCert.

Independence witness: total-variation-function, bounded-variation-real-function, regulatedrealfunction, riemannintegral: $\mathsf{VariationDiminishing}^{\uparrow}$ is not bijective to any listed sibling because it binds the source variation ledger, regulated readback, tagged integration boundary, transformation row, and no-increase comparison as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}$.

Constructive story: A $\mathsf{VariationDiminishing}^{\uparrow}$ packet is generated from bounded-variation source data, a total-variation ledger, regulated readback, Riemann tagged-mesh boundary, a kernel or transformation row, a variation comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5805.1, Definition 5805.2, Definition 5805.3, the falsifiable prediction, and the independence witness seed the finite variation-diminishing route over the current analysis rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VariationDiminishing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host operator equality, quotient equality of functions, selected limiting partitions, unrestricted total positivity, measure completion, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, bounded-variation source visibility, total-variation ledger exactness, regulated readback, tagged integration boundary, transformation-row exposure, comparison-row stability, transport, replay, provenance, and local naming for future BEDC.Derived.VariationDiminishingUp.

$\mathsf{FrobeniusReciprocity}^{\uparrow}$ routes induction–restriction comparison through chapter 247, chapter 246, and chapter 245 before the child file states the local certificate.

Chapter 4840

A Concrete Naming Certificate for $\mathsf{FrobeniusReciprocity}^{\uparrow}$

Following Frobenius on induced characters, Serre's finite-group representation theory, and the induction–restriction formulation used by Fulton–Harris, the $\mathsf{FrobeniusReciprocity}^{\uparrow}$ packet records the finite comparison row between induction from a subgroup and restriction to that subgroup. It consumes the action rows of chapter 3662, the subgroup source of chapter 80, the representation-ring ledger of chapter 246, the induction–restriction packet of chapter 247, and the character-pairing surface of chapter 245. The packet names only finite source rows, adjunction ledgers, character-pairing boundaries, transport, replay, provenance, and downstream handoff rows; it does not assert a host category of representations, a functor equality, semisimplicity, Schur orthogonality, or a completed character table.

Theorem 4840.1 (FrobeniusReciprocityUp source obligations)**.** *For every accepted* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet, the source surface is the displayed finite tuple*

$$\mathcal{F} = (G, H, R, I, Q, \Phi, \eta, \epsilon, \chi, \lambda, C, P, N),$$

where G is the consumed $\mathsf{FiniteGroupRepresentation}^{\uparrow}$ *action row, H is the consumed* $\mathsf{Subgroup}^{\uparrow}$ *row, R is the consumed* $\mathsf{RepresentationRing}^{\uparrow}$ *ledger, I is the consumed* $\mathsf{InducedRep}^{\uparrow}$ *induction–restriction row, Q is the consumed* $\mathsf{CharacterTheory}^{\uparrow}$ *pairing row, Φ is the Frobenius comparison row, η, ϵ are the displayed unit and counit rows, χ is the character-pairing boundary, λ is the finite ledger of visible source and endpoint reads, C is componentwise* Cont *replay, P is* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *row. No source obligation is imported from a host representation category, quotient carrier, functor category, or external adjunction object.*

Proof. Project the accepted packet. The source rows are precisely G, H, R, I, Q together with the local comparison rows $\Phi, \eta, \epsilon, \chi, \lambda, C, P, N$.

The consumed rows are already finite BEDC certificates. The finite-group representation row supplies the action display, the subgroup row supplies the inclusion boundary, the representation-ring row supplies the Grothendieck ledger, the induced-representation row supplies the induction–restriction endpoints, and the character-theory row supplies the pairing surface.

Since the tuple has no coordinate for a host representation category, quotient carrier, functor category, or external adjunction object, the listed rows exhaust the source obligations. □

Theorem 4840.2 (FrobeniusReciprocityUp adjunction ledger)**.** *The adjunction data of an accepted* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet are exactly the finite rows $\Phi, \eta, \epsilon, \lambda$ over the consumed sources*

H, R, I. The row Φ compares the displayed induction endpoint with the displayed restriction endpoint, η and ϵ record the unit and counit witnesses as BHist *rows, and λ records the visible continuations among source, endpoint, and Frobenius reads. The ledger exports no host naturality square, functor equality, adjunction object, or semisimple decomposition.*

Proof. Begin with the induction–restriction source. The packet consumes the $\mathsf{InducedRep}^{\uparrow}$ row I, so the available endpoints are the displayed induction and restriction rows already carried by that certificate.

The Frobenius comparison is read through Φ. The unit and counit witnesses are read through η and ϵ, and every visible path among source and endpoint reads is recorded by the finite ledger λ.

Exactness is projection from the tuple. Any row outside $\Phi, \eta, \epsilon, \lambda$ is not part of the adjunction ledger, and no host naturality square or functor equality can be recovered from a coordinate that the packet does not carry. □

Theorem 4840.3 (FrobeniusReciprocityUp character-pairing boundary)**.** *Every character-pairing read of a* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet factors through the consumed* $\mathsf{CharacterTheory}^{\uparrow}$ *row Q, the representation-ring source R, the induction–restriction source I, and the displayed pairing boundary χ before it can inspect Φ, η, ϵ or λ. The boundary supplies only the finite character-pairing comparison needed for reciprocity and does not export Schur orthogonality, irreducible decomposition, character-table computation, or a completed class-function algebra.*

Proof. Read the character side first. The only character-theory coordinate is Q, and the only representation-ring coordinate feeding it is R.

The induction and restriction endpoints enter through I. The displayed pairing boundary χ then names the finite comparison used by the Frobenius row before the ledger reads $\Phi, \eta, \epsilon, \lambda$.

Because the tuple has no coordinate for Schur orthogonality, irreducible decomposition, character-table computation, or a completed class-function algebra, every character-pairing read remains inside the stated finite boundary. □

Theorem 4840.4 (FrobeniusReciprocityUp NameCert surface)**.** *The* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *obligation surface is the conjunction of the source obligations of Definition 5806.1, the adjunction ledger of Definition 5806.2, the character-pairing boundary of Definition 5806.3, componentwise* hsame *transport on all displayed source and ledger rows, finite* Cont *replay through C, and* Pkg *provenance through P. The surface exports no obligation outside the displayed tuple $\mathcal{F}$.*

Proof. First combine the source obligations with the adjunction ledger. The source theorem identifies the consumed BEDC certificates, and the ledger theorem identifies the only Frobenius comparison, unit, counit, and continuation rows.

Next add the character-pairing boundary. It places every character read behind Q, R, I, χ before the Frobenius ledger can be inspected.

Finally apply componentwise transport and replay. The rows C and P preserve exactly the displayed tuple, and the local row N names the resulting certificate. Since no obligation outside $\mathcal{F}$ is available, these clauses give the stated NameCert surface. □

Theorem 4840.5 (FrobeniusReciprocityUp consumer handoff)**.** *A downstream consumer of* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *may read exactly the consumed finite-group action row G, subgroup row H, representation-ring row R, induced-representation row I, character-theory row Q, Frobenius rows Φ, η, ϵ, character-pairing boundary χ, visible ledger λ, replay row C, provenance row P, and local name row N. Any consumer handoff to* $\mathsf{InducedRep}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, *or* $\mathsf{CharacterTheory}^{\uparrow}$ *factors through those*

rows and cannot bypass them through a host category, functor equality, semisimplicity theorem, or character-table computation.

Proof. Start with a downstream read. The only visible source coordinates are G, H, R, I, Q, and the only local Frobenius coordinates are $\Phi, \eta, \epsilon, \chi, \lambda, C, P, N$.

For an $\mathsf{InducedRep}^{\uparrow}$ consumer, the handoff is through I together with the Frobenius rows. For a $\mathsf{RepresentationRing}^{\uparrow}$ consumer, the handoff is through R and the source ledger. For a $\mathsf{CharacterTheory}^{\uparrow}$ consumer, the handoff is through Q and the pairing boundary χ.

The replay and provenance rows preserve the same finite route. Thus a consumer cannot bypass the displayed packet through a host category, functor equality, semisimplicity theorem, or character-table computation. □

Theorem 4840.6 (FrobeniusReciprocityUp sibling lattice)**.** *The* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *packet is a finite comparison consumer of the sibling carriers in chapter 3662, chapter 80, chapter 246, chapter 247, and chapter 245. Its local rows compare induction and restriction after those carriers are visible; they do not form an isolated kernel row and do not replace the representation, subgroup, ring, induced-representation, or character-theory certificates.*

Proof. Read the source tuple of Definition 5806.1. The rows G, H, R, I, Q are precisely the five sibling certificates named in the statement.

The consumer handoff of Definition 5806.5 permits downstream reads only through those rows together with the Frobenius comparison, unit, counit, pairing boundary, ledger, replay, provenance, and local name rows.

Therefore the packet sits inside the displayed representation-theory lattice. It is a comparison consumer over the sibling carriers, not a standalone kernel surface from which the sibling certificates can be reconstructed. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5806.1, Definition 5806.2, Definition 5806.3, Definition 5806.4, Definition 5806.5, and Definition 5806.6 seed the finite Frobenius reciprocity certificate over displayed finite-group representation, subgroup, representation-ring, induced-representation, and character-theory rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, semisimplicity, Schur orthogonality, irreducible decomposition, character-table computation, functor-category equality, or a host adjunction theorem.

Upgrade path: Obligation closure requires checked carrier admission, adjunction-ledger exactness, character-pairing boundary, NameCert surface, and downstream handoff for the same finite packet.

Constructive story: A $\mathsf{FrobeniusReciprocity}^{\uparrow}$ packet is generated from consumed finite-group representation, subgroup, representation-ring, induced-representation, and character-theory rows, then records a finite Frobenius comparison, unit and counit rows, character-pairing boundary, visible continuation ledger, package provenance, and local NameCert evidence.

Chapter 4841

A Concrete Naming Certificate for $\mathsf{NormalOperator}^{\uparrow}$

Following Reed and Simon, the $\mathsf{NormalOperator}^{\uparrow}$ packet records the standard normal-operator surface as finite NameCert data over displayed Hilbert and inner-product candidates. It consumes the inner-product carrier of chapter 86, the Hilbert carrier of chapter 91, the linear-map rows of chapter 48, the operator-norm boundary of chapter 3603, and the downstream spectral-theorem consumer of chapter 214. The packet exposes only a bounded linear operator, its displayed adjoint-action row, the norm ledger, and the normality commutator row; it does not claim spectral measure existence, functional calculus, diagonalization, projection-valued measures, or a host operator algebra.

Definition 4841.1 (NormalOperator carrier)**.** *For a displayed* $\mathsf{Hilbert}^{\uparrow}$ *candidate* H *with* $\mathsf{InnerProduct}^{\uparrow}$ *row* I*, a* $\mathsf{NormalOperator}^{\uparrow}(H)$ *carrier is a finite* BHist *packet*

$$\mathcal{N} = (H, I, T, T^*, A, K, Q, L, H_T, C, P, N)$$

with the following ten displayed fields:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *carrier row and I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row over the same point-history carrier.*
2. *T is a bounded* $\mathsf{LinMap}^{\uparrow}$ *endpoint action on the carried Hilbert endpoints.*
3. *T^* is the displayed adjoint-action row, certified by the finite inner-product comparison*

   $$\langle Tx, y\rangle_I \ \mathsf{hsame}\ \langle x, T^*y\rangle_I$$

   for the vector histories inspected by the packet.
4. *A is the adjoint-domain ledger, recording that the adjoint row is read over the same Hilbert, inner-product, linear-map, and boundedness surfaces as T.*
5. *K is the* $\mathsf{OperatorNorm}^{\uparrow}$ *bound row for T and for the displayed adjoint action T^*.*
6. *Q is the normality commutator row*

   $$T^*T \ \mathsf{hsame}\ TT^*$$

   read only on certified vector histories.
7. *L is the operator graph ledger: it stores inspected input histories, output histories, linearity rows, adjoint rows, norm-bound rows, and the commutator row.*

8. *H_T records componentwise* hsame *transport for the Hilbert source, inner-product row, endpoint actions, adjoint row, norm row, commutator row, and ledger.*
9. *C records displayed* Cont *replay for endpoint action requests, adjoint-action requests, norm-bound requests, and commutator inspections.*
10. *P, N are the* Pkg *provenance and local* $\mathsf{NameCert}_{\mathsf{NormalOperator}^\uparrow}$ *naming rows.*

The classifier compares accepted carriers by action agreement on certified vector histories, adjoint-action agreement on the same inspected histories, transport of the operator-norm row, and transport of the graph, adjoint, normality, continuation, provenance, and local-name ledgers. It has no coordinate for host operator equality, quotient completion, spectral measures, eigenvector bases, or external functional calculus.

Lean4 ✓ `BEDC.Derived.NormalOperatorUp.NormalOperatorTasteGate single carrier alignment`

Theorem 4841.2 (NormalOperator NameCert obligations)**.** *For every accepted* $\mathsf{NormalOperator}^\uparrow$ *carrier*

$$\mathcal{N} = (H, I, T, T^*, A, K, Q, L, H_T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NormalOperator}^\uparrow}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the common* $\mathsf{Hilbert}^\uparrow$ *and* $\mathsf{InnerProduct}^\uparrow$ *rows;*
2. *bounded* $\mathsf{LinMap}^\uparrow$ *action for T on certified vector histories;*
3. *adjoint-action agreement for T^* against the displayed inner product;*
4. $\mathsf{OperatorNorm}^\uparrow$ *bound rows for the operator action and adjoint action;*
5. *normality commutator exactness through the displayed row Q;*
6. *graph-ledger exactness for input histories, output histories, linearity rows, adjoint rows, norm rows, and commutator rows;*
7. *classifier transport by action agreement, adjoint-action agreement, norm-row agreement, and componentwise ledger transport;*
8. Cont *replay,* Pkg *provenance, and local naming for exactly the displayed packet;*
9. *refusal of spectral measure existence, diagonalization, projection-valued measures, host operator quotients, and unrecorded functional calculus.*

Proof. Project the carrier of Definition 5807.1. The Hilbert and inner-product source rows, endpoint action, adjoint-action row, adjoint-domain ledger, norm row, commutator row, graph ledger, transport row, continuation row, provenance row, and local name are the full displayed inventory.

The adjoint and boundedness obligations are read before any spectral consumer appears. The adjoint row is the finite inner-product comparison for certified vector histories, and the norm row is the displayed $\mathsf{OperatorNorm}^\uparrow$ bound attached to both endpoint actions.

Normality is exactly the commutator row Q. Because Q compares T^*T and TT^* only through inspected vector histories and their graph ledger, the packet does not appeal to host equality of operators.

Finally H_T, C, P, N transport, replay, source, and name those rows. Since the carrier has no spectral-measure, diagonalization, projection-valued-measure, quotient, or functional-calculus coordinate, the listed rows exhaust the local normal-operator NameCert obligations. □

Theorem 4841.3 (NormalOperator InnerProduct spectral anchor)**.** *Every downstream spectral read of an accepted* $\mathsf{NormalOperator}^{\uparrow}$ *packet factors through the common Hilbert and inner-product rows, the bounded linear action, the displayed adjoint-action row, the operator-norm bound, and the normality commutator ledger before it can be consumed by the* $\mathsf{SpectralTheorem}^{\uparrow}$ *surface. The route is*

$$(H, I) \longmapsto (T, T^*, A, K, Q, L) \longmapsto (H_T, C, P, N),$$

and it exports no spectral projection, spectral measure, eigenbasis, Borel functional calculus, or host operator-algebra equality.

Proof. Expose the accepted packet by Definition 5807.1. The only analytic source rows are the Hilbert carrier, inner-product comparison row, endpoint action, displayed adjoint action, norm bound, and normality commutator.

Apply Definition 5807.2. The graph ledger forces the operator action, adjoint action, boundedness evidence, and commutator evidence to be read from one finite packet, and classifier transport keeps the operator and adjoint rows over the same certified vector histories.

It remains to hand the packet to spectral consumers. The $\mathsf{SpectralTheorem}^{\uparrow}$ chapter may consume the normality anchor only through the displayed rows already named here. Because no spectral projection, spectral measure, eigenbasis, Borel functional calculus, or host operator-algebra equality is a field of the carrier, the anchor supplies a pre-spectral normal-operator surface rather than a spectral theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5807.1, Definition 5807.2, and Definition 5807.3 seed the normal-operator surface over Hilbert, inner-product, bounded linear-map, adjoint-action, operator-norm, and commutator rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NormalOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim spectral measures, spectral projections, diagonalization, eigenbasis construction, Borel functional calculus, host operator quotients, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, adjoint-action agreement, norm-bound stability, normality commutator exactness, classifier transport, graph-ledger exactness, spectral-consumer nonescape, and bridge data for BEDC.Derived.NormalOperatorUp.

Constructive story: A $\mathsf{NormalOperator}^{\uparrow}$ packet is generated from a Hilbert source, an inner-product row, a bounded linear endpoint action, a displayed adjoint action, operator-norm bounds, a normality commutator row, graph and transport ledgers, continuation replay, provenance, and a local NameCert row.

Chapter 4842

A Concrete Naming Certificate for $\mathsf{HausdorffMeasure}^{\uparrow}$

Following Hausdorff and Federer's metric measure theory, the $\mathsf{HausdorffMeasure}^{\uparrow}$ packet records the finite dyadic-cover surface through which Hausdorff content and scale-stable measure reads become visible inside BEDC. It sits over the metric carrier of chapter 57, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the cover-valued outer-measure boundary of chapter 3385, and the finite scale-cover comparison surface of chapter 3877. The packet names only displayed dyadic cover packets, diameter budgets, weighted cover sums, scale comparison, transport, replay, provenance, and local naming; it is not a quotient cover family, not a selected infimum, not countable choice over covers, and not an ambient measure primitive.

Definition 4842.1 (Hausdorff measure dyadic-cover carrier)**.** *A* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (M, D, R, O, B, C, S, T, E, K, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the finite point classifier and distance comparisons used to bound cover diameters.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row, naming the dyadic radius budget and dyadic exponent used by the cover packet.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *value-seal row for diameter powers and finite cover sums.*
4. *O is the* $\mathsf{OuterMeasure}^{\uparrow}$ *handoff row, read only as a finite cover-valued boundary and not as a completed measure primitive.*
5. *B is the* $\mathsf{BoxDimension}^{\uparrow}$ *comparison row, exposing finite scale-cover counts against the same dyadic scale.*
6. *C is the finite dyadic cover packet, listing the displayed cover cells, their metric diameter witnesses, and their membership reads.*
7. *S is the cover-sum ledger, recording the finite Real-sealed sum of dyadic diameter weights.*
8. *T is the scale-stability ledger, recording that dyadic refinement reads the same metric source, outer-measure boundary, and box-dimension comparison rows.*
9. *E records componentwise* hsame *transport for metric, dyadic scale, Real seal, outer-measure handoff, box-dimension comparison, cover packet, cover sum, and stability rows.*

10. *K records displayed* Cont *replay from a metric source and dyadic scale through C, S, T, E, P, N.*
11. *P is the* Pkg *provenance over* $\mathsf{HausdorffMeasure}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{OuterMeasure}^{\uparrow}$, $\mathsf{BoxDimension}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, D, R, O, B, C, S, T, E, K, P, N$. It has no coordinate for quotient cover families, selected infima, countable-choice schedules over covers, host sigma-algebras, or ambient measure primitives.

Lean4 ✓ `BEDC.Derived.HausdorffMeasureUp.HausdorffMeasureTasteGate single carrier alignment`

Theorem 4842.2 (Hausdorff measure NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier $H = (M, D, R, O, B, C, S, T, E, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$ *surface consists exactly of metric source admission, dyadic scale exposure, Real value sealing, finite outer-measure handoff, box-dimension scale comparison, finite dyadic cover admission, cover-sum exactness, scale-stability replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every measure-facing or dimension-facing consumer must read the displayed route*

$$\mathsf{Met}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto C, S, T \longmapsto \mathsf{OuterMeasure}^{\uparrow}, \mathsf{BoxDimension}^{\uparrow} \longmapsto E, K, P, N$$

before treating the packet as a Hausdorff-measure read.

Proof. Project the carrier of Definition 5808.1. The metric row M, dyadic row D, and Real seal row R are the only sources for distances, scales, and finite value readback.

The cover packet C and cover-sum ledger S are finite rows. They record displayed cover cells and dyadic diameter weights, so no step selects a minimizing cover family or takes an external infimum.

The outer-measure and box-dimension rows O, B are downstream comparison boundaries. They can read the same finite cover data, but they do not add a completed host measure, a quotient of covers, or countable choice over refinements.

Finally T, E, K, P, N transport, replay, source, and name the same finite route. Since every exported obligation is one of the listed rows, the local classifier cannot expose an ambient measure primitive or any detached cover selector. □

Theorem 4842.3 (Hausdorff measure dyadic-cover stability)**.** *Let $H = (M, D, R, O, B, C, S, T, E, K, P, N)$ be an accepted* $\mathsf{HausdorffMeasure}^{\uparrow}$ *carrier. For any displayed dyadic refinement of the scale row D, the scale-stability ledger T forces the refined read to reuse the same* $\mathsf{Met}^{\uparrow}$ *source, the same* $\mathsf{Real}^{\uparrow}$ *value-seal route, the same finite* $\mathsf{OuterMeasure}^{\uparrow}$ *cover boundary, and the same* $\mathsf{BoxDimension}^{\uparrow}$ *scale-count comparison before any consumer reads a Hausdorff-measure claim. The stable route is*

$$M, D, R, C, S, T \longmapsto O, B \longmapsto E, K, P, N.$$

It exports no quotient cover family, selected infimum, countable-choice cover schedule, host sigma-algebra closure, or ambient measure primitive.

Proof. Read the carrier of Definition 5808.1. A dyadic refinement changes only the displayed scale request inside D and the finite cover packet admitted by C.

Use the stability ledger T. It records that the refined cover is replayed against the same metric source and that its finite cover sum is sealed through the same Real row, so the refinement cannot introduce a detached minimizing cover or a host infimum.

The comparison rows O and B then read the refined packet as finite outer-measure and box-dimension boundary data. Componentwise transport and displayed replay through E, K, P, N preserve that route, while quotient covers, countable choice, host sigma-algebras, and ambient measure primitives remain absent from the carrier. □

Falsifiable prediction: An accepted $\mathsf{HausdorffMeasure}^{\uparrow}$ consumer that reaches a Hausdorff-measure read without first exposing a MetricUp source row, a DyadicRatCore scale row, a RealUp value seal, a finite dyadic cover packet, a finite cover-sum ledger, an OuterMeasureUp handoff, a BoxDimensionUp comparison row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row refutes the carrier surface.

Independence witness: metric, dyadicratcore, real, outermeasure, boxdimension: $\mathsf{HausdorffMeasure}^{\uparrow}$ is not bijective to any listed sibling because it binds metric diameter data, dyadic scales, Real-sealed finite cover sums, outer-measure cover boundaries, and box-dimension scale counts into one finite cover-stability NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffMeasure}^{\uparrow}$ packet is generated from a MetricUp source row, DyadicRatCore scale row, RealUp value-seal row, finite OuterMeasureUp handoff, BoxDimensionUp comparison row, finite dyadic cover packet, cover-sum ledger, scale-stability ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5808.1, Definition 5808.2, and Definition 5808.3 seed the finite dyadic-cover Hausdorff-measure interface over MetricUp, DyadicRatCoreUp, RealUp, OuterMeasureUp, and BoxDimensionUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffMeasure}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.HausdorffMeasureUp.HausdorffMeasureTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim quotient cover families, selected infima, countable choice over covers, host sigma-algebra completion, ambient measure primitives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic scale exposure, finite cover admission, cover-sum exactness, scale-stability replay, outer-measure handoff, box-dimension comparison, transport, provenance, and no-escape for BEDC.Derived.HausdorffMeasureUp.

Chapter 4843

A Concrete Naming Certificate for $\mathsf{LocallyConnected}^{\uparrow}$

Following Kelley and Bourbaki on local connectedness, the $\mathsf{LocallyConnected}^{\uparrow}$ packet records finite neighbourhood-component data rather than a selected basis of connected open sets. It sits beside the global connectedness carrier of chapter 2353, the compact metric source discipline of chapter 129, the metric ball rows of chapter 57, and the open-neighbourhood ledger of chapter 88. The packet exposes the local component route needed by compact-metric and connected-space consumers without importing path selection, arc connectedness, open-cover compactness, or a host topological basis.

Definition 4843.1 (Locally connected carrier)**.** *A* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (T, M, G, K, B, C, H, R, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *open-neighbourhood row whose entries name the ambient open requests.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *ball-observation row used when the local request is metric.*
3. *G is the* $\mathsf{ConnectedSpace}^{\uparrow}$ *global component row available to consumers that compare local and global connectedness.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-source row available to compact-metric consumers.*
5. *B is the finite neighbourhood-refinement row: each displayed point and open request has a named smaller neighbourhood row.*
6. *C is the local connected-component row attached to the refinement in B.*
7. *H records componentwise* hsame *transport for the topology, metric, connectedness, compact-metric, refinement, component, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from an ambient open request through metric ball observations when present, the finite refinement row, and the local component row.*
9. *P is the* Pkg *provenance over* $\mathsf{LocallyConnected}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ConnectedSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, M, G, K, B, C, H, R, P, N$. It has no coordinate for selected paths, arcs, arbitrary open-cover compactness, quotient component spaces, or a host basis of connected neighbourhoods.

Lean4 ✓ `BEDC.Derived.LocallyConnectedUp.TasteGate.LocallyConnectedTasteGate single carrier alignment`

Theorem 4843.2 (Locally connected NameCert obligations)**.** *For every accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier $L = (T, M, G, K, B, C, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$ *surface consists exactly of carrier admission for the topology, metric, connected-space, compact-metric, finite neighbourhood-refinement, local component, transport, replay, provenance, and naming rows; neighbourhood refinement from T through B; component exposure through C; metric compatibility through M when the request is ball-based; compact-metric compatibility through K for compact finite-source consumers; connected-space comparison through G; and non-escape from selected paths, arcs, arbitrary open-cover compactness, quotient component spaces, and host basis choice.*

Proof. Project the carrier of Definition 5809.1. The projection exposes exactly the rows $T, M, G, K, B, C, H, R, P, N$ so every local naming obligation must be read from those coordinates.

The neighbourhood part is finite. An ambient open request is first read in T, then refined by the displayed row B, and only then receives the local component row C.

The metric and compact-metric rows are compatibility rows rather than extra selectors. A ball-based request may inspect M, and a compact-metric consumer may inspect K, but both routes still pass through the same B and C rows before local connectedness is exported.

Finally, H and R transport and replay the displayed route, while P and N source and name it. Since paths, arcs, arbitrary open-cover compactness, quotient component spaces, and host basis choice are not rows of the carrier, the NameCert surface cannot export them. □

Theorem 4843.3 (Locally connected neighbourhood component route)**.** *Every connected-space or compact-metric consumer of an accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *packet reaches local connectedness through*

$$\mathsf{Topology}^{\uparrow},\quad \mathsf{Met}^{\uparrow},\quad \mathsf{ConnectedSpace}^{\uparrow},\quad \mathsf{CompactMetric}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

The finite route reads an ambient neighbourhood, optionally reads metric ball observations, refines to a displayed smaller neighbourhood, and then reads the named local connected component. It does not select a path, an arc, a subcover, a quotient component representative, or a host connected-neighbourhood basis.

Proof. Start with a consumer that asks for local connectedness around a displayed point. Carrier admission gives the consumer the topology row T, the metric row M when a ball observation is part of the request, the global connectedness row G, and the compact-metric row K.

The route then passes through B and C. The row B supplies the finite neighbourhood refinement, and C supplies the local component attached to that refinement.

The structural rows H, R, P, N do not add a hidden selector. They transport, replay, source, and name the same finite route, so no path, arc, arbitrary subcover, quotient representative, or host basis can replace the displayed neighbourhood-component data. □

Theorem 4843.4 (Locally connected obligation closure surface)**.** *For every accepted* $\mathsf{LocallyConnected}^{\uparrow}$ *carrier $L = (T, M, G, K, B, C, H, R, P, N)$, the obligation-closure surface is exhausted by the displayed finite topology, metric, connected-space, compact-metric, neighbourhood-refinement, local-component, transport, replay, provenance, and naming rows. The row T supplies the open-neighbourhood*

source, M supplies metric-ball observations, G supplies connected-space comparison, K supplies compact-metric finite-source compatibility, B, C supply the local refinement and component rows, and H, R, P, N supply transport, replay, provenance, and local naming.

The local component route therefore consumes the connected-space carrier of chapter 2353, the compact-metric finite neighbourhood discipline of chapter 129, the metric-ball rows of chapter 57, and the topology neighbourhood ledger of chapter 88 before a local component can be named.

Proof. Apply Definition 5809.2 to the accepted carrier. It identifies the complete NameCert surface with the rows $T, M, G, K, B, C, H, R, P, N$.

Apply Definition 5809.3. The route from an open request to a local component passes through topology, optional metric-ball observations, connected-space comparison, compact-metric compatibility, finite refinement, and component rows before the structural rows transport and name the result.

The sibling lattice is read in that order: topology supplies the neighbourhood ledger, metric supplies ball observations, connected-space supplies the comparison carrier, and compact metric supplies the finite neighbourhood discipline. The local refinement and component rows then bind those sibling contributions into the $\mathsf{LocallyConnected}^{\uparrow}$ packet.

Thus the obligation surface is the stated finite route. Path or arc selection, open-cover compactness, quotient components, and a host basis are refused because none of them is a carrier coordinate or a row used by the two preceding theorems. □

Falsifiable prediction: Every accepted $\mathsf{LocallyConnected}^{\uparrow}$ read must expose a $\mathsf{Topology}^{\uparrow}$ open-neighbourhood row, optional $\mathsf{Met}^{\uparrow}$ ball observations, the $\mathsf{ConnectedSpace}^{\uparrow}$ comparison row when a global consumer is present, the $\mathsf{CompactMetric}^{\uparrow}$ finite-source row when a compact-metric consumer is present, a finite neighbourhood-refinement row, a local component row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: topology, metric, connected-space, compactmetric: $\mathsf{LocallyConnected}^{\uparrow}$ is not bijective to any listed sibling because it binds a local neighbourhood-refinement row to a local component row before connected-space or compact-metric consumers may read the result.

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5809.1, Definition 5809.2, and Definition 5809.3 seed the finite local neighbourhood-component route over topology, metric, connected-space, and compact-metric rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocallyConnected}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close path connectedness, arc connectedness, arbitrary open-cover compactness, quotient component spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, neighbourhood refinement, local component exposure, connected-space comparison, compact-metric compatibility, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.LocallyConnectedUp.

Constructive story: A $\mathsf{LocallyConnected}^{\uparrow}$ packet is generated from an open-neighbourhood row, optional metric ball observations, connected-space and compact-metric compatibility rows, a finite neighbourhood-refinement row, a local component row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 4844

A Concrete Naming Certificate for $\mathsf{BishopCauchyMean}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, the $\mathsf{BishopCauchyMean}^{\uparrow}$ packet records the finite averaging step used when a Cauchy source is read through displayed rational windows and sealed as a Real-facing name. It sits after the $\mathsf{Cauchy}^{\uparrow}$ source route of chapter 3413, the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names finite averages of observed Cauchy data; it does not assert a selected limit, quotient stream equality, host real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4844.1 (Bishop Cauchy mean carrier)**.** *A* $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, D, W, R, A, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Cauchy}^{\uparrow}$ *source row naming the Cauchy data whose finite observations are being averaged.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the requested dyadic radius, denominator budget, and comparison scale for the average.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing exactly the source entries inspected at tolerance D.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the inspected stream window into regular rational data.*
5. *A is the finite averaging ledger: it lists the inspected rational entries, their displayed weights, the denominator row, the partial-sum row, and the final mean row consumed by the certificate.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, W, R, A have been displayed.*
7. *H records componentwise* hsame *transport for the source, tolerance, window, readback, averaging ledger, Real seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a finite mean request through $S, D, W, R, A, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyMean}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $S, D, W, R, A, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, host real equality, countable choice, ambient completeness of $\mathsf{Real}^{\uparrow}$*, or an infinite averaging oracle.*

Lean4 ✓ `BEDC.Derived.BishopCauchyMeanUp.BishopCauchyMeanTasteGate single carrier alignment`

Theorem 4844.2 (Bishop Cauchy mean NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier*

$$M = (S, D, W, R, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$ *surface consists exactly of carrier admission for the Cauchy source row, dyadic tolerance row, finite stream window, regular rational readback, finite averaging ledger, terminal Real seal, componentwise transport row, displayed continuation replay, package provenance, and local naming row.*

The obligation surface requires Cauchy-source visibility through S, tolerance accounting through D, finite-window visibility through W, regular rational readback through R, average-ledger exactness through A, Real-seal nonescape through E, transport and replay stability through H and C, provenance through P, and local naming through N. It refuses selected limits, quotient stream equality, host real equality, countable choice, and ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the accepted carrier of Definition 5810.1. The only analytic rows are the Cauchy source S, the dyadic tolerance D, the finite window W, the regular rational readback R, the averaging ledger A, and the terminal Real seal E.

The averaging step is finite. The ledger A displays the inspected rational entries, their weights, the denominator row, the partial sums, and the final mean; no later consumer can ask for an average outside this listed window.

The terminal seal is downstream of the displayed route. Since the carrier has no coordinate for quotient stream equality, a selected limit, host real equality, countable choice, ambient completeness, or an infinite averaging oracle, those objects cannot enter the local NameCert surface.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. They preserve the displayed rows and do not add analytic content. □

Theorem 4844.3 (Bishop Cauchy mean finite-average stability)**.** *Let*

$$M = (S, D, W, R, A, E, H, C, P, N)$$

be an accepted $\mathsf{BishopCauchyMean}^{\uparrow}$ *carrier. Every accepted consumer read of the mean row factors through the finite route*

$$\mathsf{Cauchy}^{\uparrow}(S),\ \mathsf{DyadicRatCore}^{\uparrow}(D),\ \mathsf{StreamName}^{\uparrow}(W),\ \mathsf{RegSeqRat}^{\uparrow}(R),\ A,\ \mathsf{Real}^{\uparrow}(E).$$

If the source row, tolerance row, finite window, readback row, and averaging ledger are transported componentwise by the displayed hsame *rows in H and replayed through C, then the consumer-visible mean row is unchanged as a* $\mathsf{BishopCauchyMean}^{\uparrow}$ *read. No quotient stream equality, selected limit, host real equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row participates in the stability claim.*

Proof. Start with the consumer route. By the carrier definition, a mean read must first inspect the Cauchy source S, choose the displayed dyadic tolerance D, open the finite window W, and read the regular rational row R.

The average itself is then the ledger row A. Its entries, weights, denominator, partial sums, and final mean are finite displayed data, so componentwise hsame transport preserves exactly the rows that the consumer can inspect.

Replay through C exposes the transported packet with the same provenance and local naming rows P, N. The terminal Real seal E is reached from that transported finite route, not from a quotient stream or selected limit.

Thus any consumer-visible equality of mean reads is exhausted by $S, D, W, R, A, E, H, C, P, N$. The excluded rows are absent from the carrier and cannot affect the stability conclusion. □

Falsifiable prediction: Every accepted $\mathsf{BishopCauchyMean}^{\uparrow}$ read must expose a Cauchy source, dyadic tolerance, StreamName window, RegSeqRat readback, finite averaging ledger, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a Real or Completion consumer can read the mean boundary.

Independence witness: cauchy, dyadicratcore, streamname, regseqrat, real: $\mathsf{BishopCauchyMean}^{\uparrow}$ is not bijective to any listed sibling because it binds a finite averaging ledger between regular rational readback and the Real seal.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyMean}^{\uparrow}$ packet is generated from a Cauchy source row, DyadicRatCore tolerance row, StreamName finite window, RegSeqRat readback, finite averaging ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5810.1, Definition 5810.2, and Definition 5810.3 seed the finite Cauchy-mean certificate over Cauchy, DyadicRatCore, StreamName, RegSeqRat, RealUp, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyMean}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite average ledger exactness, tolerance-window readback, regular rational handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyMeanUp.

Chapter 4845

A Concrete Naming Certificate for $\mathsf{BishopFixedPointInterval}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopFixedPointInterval}^{\uparrow}$ packet records the constructive interval fixed-point route as finite NameCert data. It sits after the located interval source of chapter 394, the bisection discipline of chapter 1465, the finite Cauchy-modulus rows used by chapter 292, the regular rational readback of chapter 301, the finite name windows of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the fixed-point certificate for a displayed interval self-map; it does not import a host compactness theorem, quotient real equality, choice-selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4845.1 (Bishop fixed-point interval carrier)**.** *A* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, T, M, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the closed located interval, its endpoint reads, and its dyadic radius ledger.*
2. *T is the contraction self-map row over I, recording that every admitted interval point is sent back into the same located interval.*
3. *M is an explicit* $\mathsf{CauchyModulus}^{\uparrow}$ *or Lipschitz modulus row that turns each tolerance request into a finite contraction budget.*
4. *B is the* $\mathsf{IntervalBisection}^{\uparrow}$ *or nested located interval row that records the displayed shrinking interval chain.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the rational midpoint, endpoint, and radius observations.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *fixed-point seal reached only after the interval, contraction, modulus, bisection, and readback rows have been exposed.*
7. *H records componentwise* hsame *transport for I, T, M, B, R, E and for the structural rows.*
8. *C records displayed* Cont *replay for interval requests, contraction reads, modulus reads, nested interval reads, rational readback, and real-seal requests.*

9. *P is the* Pkg *provenance over* BishopFixedPointInterval$^{\uparrow}$, LocatedInterval$^{\uparrow}$, IntervalBisection$^{\uparrow}$, CauchyModulus$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{BishopFixedPointInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, T, M, B, R, E, H, C, P, N$. It has no coordinate for a host fixed-point theorem, quotient completion, selected limit, trichotomy, countable choice, or ambient compactness principle.

Lean4 ✓ `BEDC.Derived.BishopFixedPointIntervalUp.BishopFixedPointIntervalTasteGate single carrier alignment`

Theorem 4845.2 (Bishop fixed-point interval NameCert obligations)**.** *For every accepted* BishopFixedPointInterval$^{\uparrow}$ *carrier*

$$F = (I, T, M, B, R, E, H, C, P, N),$$

the local NameCert$_{\text{BishopFixedPointInterval}^{\uparrow}}$ *surface consists exactly of carrier admission for the located interval row I, contraction self-map row T, explicit modulus row M, nested bisection row B, regular rational readback row R, terminal real seal E, componentwise transport row H, displayed replay row C, provenance row P, and local naming row N. Every fixed-point consumer must read these rows in the displayed order and cannot replace them by host interval compactness, quotient real equality, a selected limit, or an unrecorded convergence principle.*

Proof. Carrier admission is the finite packet of Definition 5811.1. The rows $I, T, M, B, R, E, H, C, P, N$ are the only coordinates available to the local certificate.

The positive interval route is then forced. The interval source is I, the self-map evidence is T, the contraction budget is M, and the nested interval chain is B; each row is compared only through the componentwise transport row H and replayed only through C.

The readback and seal are downstream. Rational observations pass through R and the dyadic and stream-name data named in P before the terminal Real$^{\uparrow}$ row E is exposed. Since no host compactness, quotient equality, selected limit, or external convergence coordinate occurs in the carrier, the listed rows exhaust the NameCert surface. □

Theorem 4845.3 (Bishop fixed-point interval Cauchy-modulus route)**.** *Let $F = (I, T, M, B, R, E, H, C, P, N)$ be an accepted* BishopFixedPointInterval$^{\uparrow}$ *packet. Each tolerance request for the fixed-point name is answered by first reading the* LocatedInterval$^{\uparrow}$ *row I, then the contraction self-map row T, then the explicit* CauchyModulus$^{\uparrow}$ *or Lipschitz row M, and only then the* IntervalBisection$^{\uparrow}$ *or nested located interval row B. The resulting finite observations are read through* StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, *and* RegSeqRat$^{\uparrow}$ *as recorded by P, so no consumer can infer convergence from an unbounded host iteration or a choice-selected subsequence.*

Proof. Start with a tolerance request. The packet has no direct convergence row, so the request must project I to know the interval source and T to know that the displayed map remains inside the interval.

Next read the modulus row M. This row converts the tolerance into a finite contraction or Lipschitz budget. The nested row B can then expose only the finite bisection or located-interval observations licensed by that budget.

Finally use the readback rows listed in P. Stream windows, dyadic tolerances, and regular rational observations feed R, and H, C, N transport and name the same route. Thus the Cauchy route is explicit and finite, with no unbounded host iteration or selected subsequence. □

Theorem 4845.4 (Bishop fixed-point interval real-seal nonescape)**.** *For every accepted* $\mathsf{BishopFixedPointInterval}^{\uparrow}$ *packet, the terminal row* E *is exposed only as the* $\mathsf{Real}^{\uparrow}$ *seal of the displayed nested interval and Cauchy-modulus route*

$$I, T, M, B, R \longmapsto E \longmapsto H, C, P, N.$$

The seal may be consumed as the named fixed-point endpoint of the packet, but it cannot escape as quotient real equality, a proof of ambient $\mathsf{Real}^{\uparrow}$ *completeness, a host fixed-point theorem, an unrestricted interval compactness principle, or a selected representative outside the displayed rows.*

Proof. Read E from the carrier. It is terminal in the packet: the interval, self-map, modulus, nested interval, and rational readback rows precede it, and the structural rows only transport, replay, source, and name the resulting read.

Apply Definition 5811.3. Every tolerance request reaching E has already passed through the finite interval, contraction, modulus, bisection, stream, dyadic, and regular rational observations recorded by I, T, M, B, R, P.

It remains to rule out escape. The carrier has no coordinate for quotient real equality, ambient completeness, a host fixed-point theorem, unrestricted compactness, or selected representatives. Therefore E seals only the displayed fixed-point name of this packet. □

Falsifiable prediction: An accepted $\mathsf{BishopFixedPointInterval}^{\uparrow}$ consumer that reaches the terminal $\mathsf{Real}^{\uparrow}$ row E without first reading $I, T, M, B, R, H, C, P, N$ refutes the carrier surface.

Independence witness: locatedinterval, intervalbisection, cauchymodulus, regseqrat, streamname, dyadicratcore, real: no listed sibling supplies the full interval self-map packet $F = (I, T, M, B, R, E, H, C, P, N$ because each sibling contributes only a located interval source, a bisection route, a modulus row, a readback row, a finite name window, a dyadic ledger, or a terminal real seal while this chapter binds them into one fixed-point NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopFixedPointInterval}^{\uparrow}$ packet is generated from a located interval row, contraction self-map row, explicit Cauchy or Lipschitz modulus row, nested bisection row, regular rational readback row, terminal Real seal, componentwise transport, displayed replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5811.1, Definition 5811.2, Definition 5811.3, and Definition 5811.4 seed the finite constructive interval fixed-point route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopFixedPointInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host fixed-point compactness, quotient real equality, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction self-map admission, explicit modulus routing, nested interval readback, terminal Real seal nonescape, and a Lean carrier/obligation formalization for BEDC.Derived.BishopFixedPointIntervalUp.

Chapter 4846

A Concrete Naming Certificate for $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$

The $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ packet realizes the private-coordinate minimal-cover theorem of Definition 9462.1678 as finite NameCert data. It records a trigger-coordinate carrier, a support-family cover ledger, and one private-coordinate witness row for each displayed support before any minimal-trigger criterion may be consumed. The packet keeps the enumeration theorem auditable without identifying it with a generic finite set, word list, Boolean classifier, regular-language recognizer, or finite automaton presentation.

Falsifiable prediction: Every accepted $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ consumer must display a cover row and one private-coordinate witness row for each support before using the minimal-trigger criterion.

Independence witness: finset, list, bool, regularlanguage, finite-automaton: $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ is not bijective to these siblings because it carries a support-family cover ledger plus a private-coordinate witness for every support row.

Definition 4846.1 (Private-coordinate trigger carrier)**.** *A* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the finite trigger-coordinate row.*
2. A *is the finite support-family row whose entries are displayed subsets of* Ω*.*
3. U *is the cover ledger asserting that the displayed supports cover every coordinate of* Ω*.*
4. V *is the private-coordinate witness ledger, with one row for each support in* A*.*
5. π *maps each support row to its selected private coordinate and records membership in that support.*
6. E *records exclusion from every other support row for the selected private coordinate.*
7. K *is the minimal-cover criterion row, readable only after* U, V, π, E *have been displayed.*
8. H *stores componentwise* hsame *transport for coordinate, support, cover, witness, exclusion, and criterion rows.*

9. *C stores* Cont *replay from a trigger query through the cover ledger and the private-coordinate witness rows.*
10. *P stores* Pkg *provenance over* BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $\Omega, A, U, V, \pi, E, K, H, C, P, N$. It has no coordinate for a bare finite set, unordered list, Boolean truth table, regular-language recognizer, finite automaton run, or support family without displayed private witnesses.

Theorem 4846.2 (Private-coordinate trigger NameCert obligations)**.** *For every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier*

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$ *surface consists exactly of coordinate exposure, support-family exposure, cover-ledger replay, one private-coordinate witness row for each support, membership and exclusion checks for the selected witnesses, minimal-cover criterion exposure, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Project the carrier of Definition 5812.1. The rows Ω, A, U display the finite coordinate space, the support family, and the fact that the supports cover the full coordinate row.

The rows V, π, E attach a private coordinate to each support. Membership is recorded by π, and exclusion from every other support is recorded by E, so deleting the support removes at least one displayed coordinate from the cover.

The criterion row K is therefore readable only after the cover and private-witness rows have been exposed. The remaining rows H, C, P, N preserve transport, replay, provenance, and local naming for the same finite packet, and no omitted sibling surface supplies the private-coordinate ledger. □

Theorem 4846.3 (Private-coordinate minimal-cover criterion)**.** *Every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *carrier exposes a minimal full trigger exactly through the displayed cover row U together with the private-coordinate witness rows V, π, E. A consumer may use the criterion row K only after reading a cover of Ω and one witness coordinate for every support row in A that belongs to that support and belongs to no other displayed support. The packet does not turn the support family into a regular language, finite automaton, Boolean table, or list quotient.*

Proof. The forward read uses the cover ledger U and the private-coordinate witness rows. If a support row is removed, its selected witness coordinate remains outside all other displayed supports by E, so the remaining family no longer covers Ω.

For the reverse read, the cover row already gives full coverage. The witness rows ensure that every support has a coordinate lost by deleting that support, so no displayed support is redundant.

Thus the criterion row K is exactly the finite private-coordinate minimal-cover test. The transport, replay, provenance, and local naming rows carry this test without converting it into any sibling classifier. □

Theorem 4846.4 (Private-coordinate trigger finite-set cover route)**.** *Every accepted* $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ *packet reads its support-family row as a finite-set-indexed cover through chapter 112. The exclusions from regular-language and automaton presentations are bounded by chapter 351 and chapter 2364: the private-coordinate carrier may display finite support rows, recognizer-like acceptance tests, or transition-like exclusion checks, but it exports the minimal-cover criterion only through the rows $\Omega, A, U, V, \pi, E, K, H, C, P, N$.*

Proof. Project the accepted carrier

$$T = (\Omega, A, U, V, \pi, E, K, H, C, P, N).$$

The row Ω is the displayed coordinate object, and A is read as a finite family of supports indexed by the finite-set surface. The cover ledger U then witnesses coverage of every coordinate in Ω by those displayed supports.

The rows V, π, E are the extra private-coordinate ledger. They attach one witness coordinate to each support, record membership in that support, and record exclusion from every other displayed support. These rows are not supplied by the finite-set sibling, nor by the regular-language or finite-automaton presentations.

Consequently K is a private-coordinate minimal-cover read rather than a bare finite-set cover, a regular-language recognizer, or an automaton acceptance predicate. The structural rows H, C, P, N transport and replay only this displayed packet, so the sibling route records the finite-combinatorial surface without replacing the private-coordinate data. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}$.

Constructive story: A $\mathsf{PrivateCoordinateTrigger}^{\uparrow}$ packet is generated from a finite trigger-coordinate row, support-family row, cover ledger, per-support private-coordinate witness ledger, membership and exclusion rows, minimal-cover criterion row, componentwise transport, continuation replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5812.1, Definition 5812.2, Definition 5812.3, and Definition 5812.4 seed the finite NameCert packet for private-coordinate minimal-cover witnesses.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrivateCoordinateTrigger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, regular-language recognition, finite-automaton minimization, Boolean classifier completeness, or enumeration beyond the displayed private-coordinate criterion.

Upgrade path: Obligation closure requires checked carrier admission, cover-ledger replay, private-coordinate witness coverage, exclusion exactness, minimal-cover criterion replay, TasteGate nontriviality, FieldFaithful projection, transport, replay, provenance, and local naming for BEDC.Derived.PrivateCoordinateTriggerUp.

Chapter 4847

A Concrete Naming Certificate for $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet records the finite modulus by which a located real comparison request is read through displayed apartness or equality evidence, dyadic tolerances, explicit Cauchy-modulus schedules, regular rational readback, and the terminal real-name seal. It sits after the comparison surface of chapter 1730, the tail envelope of chapter 1769, the Cauchy-modulus bridge of chapter 5728, the rational readback of chapter 301, and the public real route of chapter 38. The packet names a finite comparison-schedule carrier; it is not trichotomy, quotient real equality, a selected representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4847.1 (Located real comparison modulus carrier)**.** *A* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, A, D, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{LocatedRealComparison}^{\uparrow}$ *request row for the two located real endpoints and the comparison direction being inspected.*
2. *A is the located evidence row. It records the displayed positive apartness witness when the request separates the endpoints, or the displayed equality-facing refusal row when the request reaches only an overlap tolerance.*
3. *D is the dyadic tolerance schedule. It lists the requested precision, comparison slack, endpoint radii, and finite tolerance refinements consumed by the comparison read.*
4. *B is the* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *route connecting the comparison request to an explicit Cauchy-modulus schedule before regular rational readback is allowed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected rational tails exposed by B and bounded by D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the comparison-facing read, available only after Q, A, D, B, R have been displayed.*
7. *H records componentwise* hsame *transport for the comparison request, evidence row, dyadic tolerance schedule, bridge route, readback, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from the comparison request through located evidence, dyadic scheduling, Cauchy-modulus bridging, regular rational readback, and Real sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$, $\mathsf{LocatedRealComparison}^{\uparrow}$, LocatedRealTailEnvelop $\mathsf{CauchyModulusBridge}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, A, D, B, R, E, H, C, P, N$. It has no coordinate for trichotomy, quotient real equality, a hidden selector, countable choice, a host comparison oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedRealComparisonModulusUp.LocatedRealComparisonModulusTasteGate`
`single carrier alignment`

Theorem 4847.2 (Located real comparison modulus obligations)**.** *For every accepted* LocatedRealComparisonModu *carrier*

$$M = (Q, A, D, B, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$ *surface consists exactly of comparison-request admission, located apartness-or-equality evidence, dyadic tolerance scheduling,* $\mathsf{CauchyModulusBridge}^{\uparrow}$ *routing,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any consumer of the comparison schedule must read those rows in the displayed order and receives no trichotomy split, quotient real equality, hidden selector, countable-choice schedule, host comparison oracle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier of Definition 5813.1. The comparison request is Q, and the only evidence row attached to it is A.

The schedule is then forced through D and B. The dyadic row D records the finite tolerances to be inspected, while the $\mathsf{CauchyModulusBridge}^{\uparrow}$ row B turns those tolerance requests into explicit tail thresholds before any rational readback is exposed.

The terminal read is downstream. The regular rational row R reads only the displayed tails opened by B, and the $\mathsf{Real}^{\uparrow}$ seal E is available only after that readback.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the carrier has no coordinate for the excluded host-level or choice-level objects, the listed rows exhaust the local NameCert surface. □

Theorem 4847.3 (Located real comparison modulus nontrichotomy boundary)**.** *Every accepted* $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ *packet exports a positive schedule for comparison reads without exporting trichotomy. If the evidence row A records positive apartness, a downstream consumer may read that apartness only through Q, D, B, R, E; if A records only an equality-facing overlap tolerance, the consumer receives the displayed tolerance route and no forced left-or-right order verdict.*

Proof. Read the evidence row A together with the comparison request Q. The carrier does not contain a three-way order coordinate, so the two possible reads are positive displayed apartness or finite overlap tolerance.

For the positive branch, the dyadic tolerance row D and bridge row B determine which tails are inspected before R and E can be consumed. The apartness read is therefore a finite schedule read, not a global order split.

For the overlap branch, the same schedule exposes only the inspected tolerance data. Since no trichotomy coordinate or hidden selector appears in $M = (Q, A, D, B, R, E, H, C, P, N)$, the packet refuses any forced left-or-right verdict not displayed by the rows. □

Falsifiable prediction: An accepted $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet is refuted if a comparison consumer reaches the $\mathsf{Real}^{\uparrow}$ seal while omitting the $\mathsf{LocatedRealComparison}^{\uparrow}$ request row Q, the evidence row A, the dyadic tolerance schedule D, the $\mathsf{CauchyModulusBridge}^{\uparrow}$ route B, or the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Independence witness: LocatedRealComparison, LocatedRealTailEnvelope, CauchyModulusBridge, RegSeqRat, Real: none is bijective with $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ because the packet jointly carries a comparison request, apartness-or-equality evidence, dyadic tolerance scheduling, explicit Cauchy-modulus bridging, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealComparisonModulus}^{\uparrow}$ packet is generated from a LocatedRealComparison request row, located apartness-or-equality evidence, a dyadic tolerance schedule, a CauchyModulusBridge route, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5813.1, Definition 5813.2, and Definition 5813.3 seed the finite comparison-modulus route over LocatedRealComparisonUp, LocatedRealTailEnvelopeUp, CauchyModulusBridgeUp, RegSeqRatUp, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealComparisonModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected representatives, countable choice, host comparison oracles, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, evidence-row exactness, dyadic schedule determinacy, Cauchy-modulus bridge routing, regular rational readback, Real-seal confinement, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealComparisonModulusUp.

Chapter 4848

A Concrete Naming Certificate for $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$

The $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet realizes the boundary-shadow and observer-expansion route of chapter 9463 as finite cocycle-level NameCert data. It sits after the boundary-shadow route of chapter 3813, the observer-shadow metric of chapter 4154, the Busemann cocycle of chapter 4134, the horosphere-flow ledger of chapter 4051, and the observer-expansion packet of chapter 4167. The chapter names a finite expansion cocycle over displayed boundary and horosphere rows; it is not a completed hyperbolic boundary, quotient geodesic ray space, physical observer dynamics, selected ideal point, or ambient manifold theorem.

Definition 4848.1 (Boundary-shadow expansion cocycle carrier)**.** *A* $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, O, B, F, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row recording the visible boundary shadow through which the cocycle is read.*
2. *O is the* $\mathsf{HyperbolicObserverShadowMetric}^{\uparrow}$ *row recording the observer-facing shadow metric comparison for the same boundary read.*
3. *B is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *row recording the additive Busemann comparison consumed by the expansion read.*
4. *F is the* $\mathsf{HorosphereFlowLedger}^{\uparrow}$ *row recording the horosphere-flow level through which boundary and Busemann rows are replayed.*
5. *E is the* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *row recording the displayed observer-expansion magnitude or direction attached to S, O, B, F.*
6. *H records componentwise* hsame *transport for boundary shadow, observer-shadow metric, Busemann cocycle, horosphere-flow ledger, observer expansion, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through boundary-shadow admission, observer-shadow metric readback, Busemann cocycle comparison, horosphere-flow ledger inspection, and observer-expansion read.*

8. *P is the* Pkg *provenance over* BoundaryShadowExpansionCocycle$^{\uparrow}$, HyperbolicBoundaryShadow$^{\uparrow}$, HyperbolicObserverShadowMetric$^{\uparrow}$, HyperbolicBusemannCocycle$^{\uparrow}$, HorosphereFlowLedger$^{\uparrow}$, HyperbolicObserverExp BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* NameCert$_{\text{BoundaryShadowExpansionCocycle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, O, B, F, E, H, C, P, N$. It has no coordinate for completed boundary points, quotient geodesic rays, a hidden expansion selector, physical observer dynamics, selected ideal endpoints, or ambient hyperbolic manifold data.

Theorem 4848.2 (Boundary-shadow expansion cocycle NameCert obligations)**.** *For every accepted* BoundaryShadowExpansionCocycle$^{\uparrow}$ *carrier*

$$X = (S, O, B, F, E, H, C, P, N),$$

the local NameCert$_{\text{BoundaryShadowExpansionCocycle}^{\uparrow}}$ *surface consists exactly of boundary-shadow admission, observer-shadow metric readback, Busemann cocycle comparison, horosphere-flow ledger inspection, observer-expansion read, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any accepted expansion read that omits either the boundary-shadow row S or the Busemann cocycle row B is outside the packet.*

Proof. Project the carrier of Definition 5814.1. The boundary-facing rows are S and O, while the cocycle and horosphere-flow rows are B and F.

The expansion row E is downstream from those four rows. It can be read only after the visible boundary shadow, observer-shadow metric, Busemann cocycle, and horosphere-flow ledger have all been displayed.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for completed boundary data, quotient geodesic rays, hidden selectors, physical observer dynamics, selected endpoints, or ambient manifold structure, the listed rows exhaust the local NameCert surface. □

Theorem 4848.3 (Boundary-shadow expansion cocycle dependency route)**.** *Every accepted* BoundaryShadowExpan *read factors through*

HyperbolicBoundaryShadow$^{\uparrow}$, HyperbolicObserverShadowMetric$^{\uparrow}$, HyperbolicBusemannCocycle$^{\uparrow}$, HorosphereFlowLed

before a consumer may inspect the expansion cocycle as a local NameCert row. The route is finite and preserves the boundary-shadow row and Busemann cocycle row as separate coordinates.

Proof. Use Definition 5814.2. It places the boundary-shadow row, observer-shadow metric row, Busemann cocycle row, and horosphere-flow ledger before the expansion row.

The cocycle dependency is not reducible to one sibling. The boundary-shadow row supplies the boundary face, the observer-shadow metric supplies the observer-facing comparison, the Busemann row supplies the additive cocycle read, and the horosphere-flow row supplies the level ledger.

Only after those rows are present can E, H, C, P, N expose the expansion cocycle as a local packet. Therefore a consumer cannot collapse the route to a single hyperbolic object or bypass the separate boundary-shadow and Busemann coordinates. □

Falsifiable prediction: Any accepted BoundaryShadowExpansionCocycle$^{\uparrow}$ packet is refuted if the expansion read omits either the boundary-shadow row S or the Busemann cocycle row B.

Independence witness: hyperbolic_boundary_shadow, hyperbolic_observer_shadow_metric, hyperbolic_busemann_cocycle, horosphere_flow_ledger, hyperbolic_observer_expansion: none

is bijective with $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ because the packet jointly carries boundary shadow, observer-shadow metric, Busemann cocycle, horosphere-flow level, observer expansion, transport, replay, provenance, and local naming.

The Lean TasteGate route for this packet must provide `Nontrivial BoundaryShadowExpansionCocycleUp` and `FieldFaithful BoundaryShadowExpansionCocycleUp` instances in `lean4/BEDC/Derived/BoundaryShadowE` Those instances must preserve $S, O, B, F, E, H, C, P, N$ as distinct fields before a checked carrier-alignment theorem can serve as the TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}$ packet is generated from HyperbolicBoundaryShadow rows, HyperbolicObserverShadowMetric rows, HyperbolicBusemannCocycle rows, HorosphereFlowLedger rows, HyperbolicObserverExpansion rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5814.1, Definition 5814.2, and Definition 5814.3 seed the finite boundary-shadow expansion cocycle route over boundary, observer-shadow, Busemann, horosphere-flow, expansion, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundaryShadowExpansionCocycle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic boundaries, quotient geodesic ray spaces, physical observer dynamics, selected ideal endpoints, ambient manifold theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-shadow exactness, observer-shadow metric readback, Busemann cocycle separation, horosphere-flow routing, observer-expansion exposure, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.BoundaryShadowExpansionCocycleUp.

The $\mathsf{HellyBraySelection}^{\uparrow}$ hub routes bounded-variation selection through chapter 398, chapter 2069, chapter 301, chapter 126, and chapter 38 before the child files expose the finite selection packet.

Chapter 4849

A Concrete Naming Certificate for $\mathsf{HellyBraySelection}^{\uparrow}$

Following Helly and Bray, the $\mathsf{HellyBraySelection}^{\uparrow}$ packet records the finite selection surface by which bounded-variation source data are read through Jordan signed-variation rows, finite stream windows, regular rational readback, and terminal real seals before a downstream selection consumer may use the packet. It sits after the bounded-variation carrier of chapter 398, the Jordan variation decomposition rows of chapter 2069, the regular rational readback route of chapter 301, the finite observation windows of chapter 126, and the terminal real-name boundary of chapter 38. Helly–Bray selection also feeds distribution-facing compactness through chapter 186, chapter 92, and chapter 4008 when the bounded-variation read is consumed as a tight probability-family route. The chapter names a finite BEDC selection packet, not host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4849.1 (Helly–Bray selection carrier)**.** *A* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (B, J, S, R, E, T, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BoundedVariation}^{\uparrow}$ *source row, carrying the bounded-variation object, finite variation ledger, and endpoint budget exposed to the selection request.*
2. *J is the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *row, displaying the signed-variation split and the positive and negative variation rows read from B.*
3. *S is the family of* $\mathsf{StreamName}^{\uparrow}$ *finite windows opened by the inspected variation rows and by the downstream Real-facing request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows, recording the rational comparisons used before any Real seal is visible.*
5. *E is the finite family of* $\mathsf{Real}^{\uparrow}$ *seal rows reached only after B, J, S, R have been displayed.*
6. *T records componentwise* hsame *transport for the bounded-variation source, Jordan rows, finite windows, readbacks, Real seals, continuation, provenance, and local naming.*
7. *C records displayed* Cont *replay from bounded-variation data through Jordan signed-variation rows, finite windows, regular rational readback, Real seals, transport, provenance, and local naming.*

8. *P is the* Pkg *provenance over* $\mathsf{HellyBraySelection}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{JordanVariationDecomposition}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, J, S, R, E, T, C, P, N$. The carrier has no coordinate for host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 4849.2 (Helly–Bray selection NameCert obligations)**.** *For every accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier*

$$H = (B, J, S, R, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the bounded-variation source row, Jordan signed-variation decomposition row, StreamName finite windows, RegSeqRat readback row, Real seal rows, transport, replay, provenance, and local naming;*
2. *variation-source exposure, requiring every selection-facing read to begin with B and then pass through the signed-variation rows J rather than through a host weak-convergence theorem;*
3. *finite-window locality, requiring S to list the exact stream windows opened by the variation rows and the Real-facing request;*
4. *readback ordering, requiring R to consume the displayed windows in S before any row of E is exposed;*
5. *componentwise transport, displayed replay, provenance, and local naming for the same rows through T, C, P, N;*
6. *nonescape, excluding host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No Helly–Bray selection obligation is stored outside these rows.

Proof. Project the accepted carrier. The only source coordinate is the bounded-variation row B, and the only signed-variation coordinate is the Jordan row J.

The finite observation surface is then forced by row order. The StreamName windows S are opened from the displayed variation rows, the RegSeqRat readback R reads only those windows, and the Real seals E appear only after that readback has been displayed.

Transport and replay preserve the same route componentwise through T and C. Provenance P and local naming N record that route as the local certificate surface.

Since none of the excluded objects occurs as a carrier coordinate, a consumer cannot add weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, or ambient Real completeness to the local NameCert obligations. □

Theorem 4849.3 (Helly–Bray selection finite-window route)**.** *Every Real-facing or variation-facing consumer of an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier factors its read through*

$$\mathsf{BoundedVariation}^{\uparrow} \longmapsto \mathsf{JordanVariationDecomposition}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto T, C, P, N$$

Thus the consumer receives bounded-variation source data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, componentwise transport, continuation replay, provenance, and local naming. The route supplies no host weak convergence, measure completion, quotient function equality, selected subsequence, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the carrier $H = (B, J, S, R, E, T, C, P, N)$. The first projection gives the bounded-variation source row B, and the next projection gives the Jordan signed-variation row J over that source.

The finite-window part is local. The windows S are the only observation rows available to the packet, and R is the only regular rational readback attached to those windows.

The Real-facing boundary is reached only at E. The remaining rows T, C, P, N transport, replay, source, and name the same finite route; they do not add a new selection principle.

Because the carrier omits host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, and ambient Real completeness, every accepted consumer read is exhausted by the displayed finite-window route. □

Theorem 4849.4 (Helly–Bray distribution forward link)**.** *Every* $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, *or* $\mathsf{ProkhorovTightProbabi}$ *consumer that cites an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *carrier must first read the* $\mathsf{BoundedVariation}^{\uparrow}$ *source row, the* $\mathsf{JordanVariationDecomposition}^{\uparrow}$ *signed-variation row, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal rows of Definition 5815.1. The downstream route to chapter 186, chapter 92, and chapter 4008 therefore receives only bounded-variation source data, Jordan variation data, displayed windows, rational readback, Real seals, componentwise transport, replay, provenance, and local naming. It receives no host weak convergence theorem, measure completion, quotient equality, selected subsequence, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier $H = (B, J, S, R, E, T, C, P, N)$. The only distribution-facing source row is B, and the only signed-measure decomposition row available to the packet is J.

Use the finite-window route of Definition 5815.3. It forces every Real-facing and variation-facing read through S, R, E before the transport, replay, provenance, and local naming rows can be consumed.

Now attach a downstream distribution, measure, or tight-probability request. Since those consumers cite the Helly–Bray packet only through the displayed route, the request reaches chapter 186, chapter 92, or chapter 4008 after $B, J, S, R, E, T, C, P, N$ have already been displayed.

The excluded objects are not carrier coordinates. Thus the forward link cannot export host weak convergence, measure completion, quotient equality, selected subsequences, countable choice, or ambient Real completeness to any distribution-facing consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5815.1, Definition 5815.2, Definition 5815.3, and Definition 5815.4 seed the finite Helly–Bray selection route over bounded-variation data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, transport, replay, provenance, local naming, and distribution-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HellyBraySelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host weak convergence, measure completion, quotient function equality, selected subsequences, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, variation-source exposure, finite-window locality, readback ordering, transport, replay, provenance, local naming, and finite-window routing for BEDC.Derived.HellyBraySelectionUp.

Constructive story: A $\mathsf{HellyBraySelection}^{\uparrow}$ packet is generated from bounded-variation source data, Jordan signed-variation rows, finite StreamName windows, RegSeqRat readback, Real seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

The Helly–Bray route is a distribution-facing read of the finite selection surface already named by chapter 1732; its bounded real sequence and compactness rows are supplied through chapter 1415 before the distribution consumer is allowed to inspect the signed-variation packet.

Theorem 4849.5 (Helly–Bray Helly-selection dependency route)**.** *Every* $\mathsf{Distribution}^{\uparrow}$ *or compactness-facing consumer of an accepted* $\mathsf{HellyBraySelection}^{\uparrow}$ *packet must first expose the finite* $\mathsf{HellySelection}^{\uparrow}$ *selection surface of chapter 1732 together with the bounded real sequence route of chapter 1415. In carrier notation, the read passes through the bounded-variation source row, Jordan signed-variation row, finite window rows, regular rational readback, terminal Real seals, componentwise transport, replay, provenance, and local naming rows before the distribution-facing route of Definition 5815.4 is public. It is therefore not a free weak-convergence theorem, measure-completion theorem, quotient-function equality, choice-selected subsequence, or ambient compactness principle.*

Proof. Start with the carrier of Definition 5815.1. Its only sequence-facing data are the bounded-variation row, Jordan signed-variation row, finite windows, regular rational readback, and terminal Real seals.

Read those rows through the finite-window route of Definition 5815.3. The same bounded source discipline is the one exported by the $\mathsf{HellySelection}^{\uparrow}$ packet, and the bounded real sequence route supplies the finite window and bound rows before any compactness-facing consumer can inspect them.

Finally attach the distribution forward link. Since Definition 5815.4 exposes distribution consumers only after the Helly–Bray carrier rows have been displayed, the downstream route receives the Helly-selection and bounded-sequence surfaces as dependencies rather than as hidden host compactness or choice principles. □

Chapter 4850

A Concrete Naming Certificate for DiniFiniteMinimumBudget$^{\uparrow}$

Following Dini's theorem and Bishop–Bridges constructive compactness, the DiniFiniteMinimumBudget$^{\uparrow}$ packet records the finite extraction row that turns a monotone compact-window Dini certificate into one displayed tolerance budget. It consumes the CompactMetric$^{\uparrow}$ source, monotone ContinuousMap$^{\uparrow}$ family rows, the DiniTheorem$^{\uparrow}$ compact-window route, UniformModulus$^{\uparrow}$ handoff data, DyadicRatCore$^{\uparrow}$ tolerance cells, the terminal Real$^{\uparrow}$ seal, BHist history rows, hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data. The packet names only the finite minimum-budget route; it is not host supremum selection, a selected minimum outside the carrier, open-cover compactness, quotient equality, or ambient Real$^{\uparrow}$ completeness.

The dependency surface is horizontal: chapter 1387 supplies the compact-window Dini route, chapter 129 supplies the inspected compact carrier, chapter 130 supplies the monotone continuous-family rows, and chapter 369 receives the extracted budget. Thus the minimum-budget row is a downstream finite extraction from those sibling carriers, not an isolated tolerance selector.

Definition 4850.1 (Dini finite-minimum budget carrier)**.** *A* DiniFiniteMinimumBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, F, D, U, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row naming the finite compact-metric windows inspected by the extraction.*
2. *F is the monotone* ContinuousMap$^{\uparrow}$ *family row, including the displayed pointwise comparison ledger used by the Dini route.*
3. *D is the* DiniTheorem$^{\uparrow}$ *row that supplies the monotone uniform-window certificate over K and F.*
4. *U is the* UniformModulus$^{\uparrow}$ *handoff row consumed by uniform-limit and compact-uniform-modulus readers.*
5. *Q is the* DyadicRatCore$^{\uparrow}$ *tolerance row, listing the candidate dyadic budgets and their finite comparison cells.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row reached by every displayed tolerance and value comparison.*
7. *H records componentwise* hsame *transport for $K, F, D, U, Q, E, C, P, N$.*

8. *C records displayed* Cont *replay from compact windows and monotone family rows through the Dini row, the finite dyadic budget comparisons, the uniform-modulus handoff, and the Real seal.*
9. *P is the* Pkg *provenance over* DiniFiniteMinimumBudget$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, DiniTheorem$^{\uparrow}$, UniformModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for an ambient supremum, an externally selected minimum, open-cover compactness, quotient equality of real names, countable choice, or host Real completeness.

Lean4 ✓ `BEDC.Derived.DiniFiniteMinimumBudgetUp.DiniFiniteMinimumBudgetTasteGate single carrier alignment`

Theorem 4850.2 (Dini compact finite-minimum budget)**.** *For every accepted* DiniFiniteMinimumBudget$^{\uparrow}$ *carrier*

$$B = (K, F, D, U, Q, E, H, C, P, N),$$

the finite probe cover displayed by K, F, D and the dyadic tolerance cells displayed by Q determine one displayed minimum tolerance budget before the uniform-modulus handoff U is exported. The extraction route is

$$K, F, D, Q, E, H, C, P, N \longrightarrow U.$$

Thus a UniformLimit$^{\uparrow}$ *or compact-uniform-modulus consumer receives a finite* DyadicRatCore$^{\uparrow}$ *budget sealed by* Real$^{\uparrow}$ *and transported by* hsame *and* Cont*, without host supremum, selected minimum outside the carrier, open-cover compactness, quotient equality, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the accepted packet. The compact source row K, monotone family row F, and Dini row D are the only rows that can name the finite probe cover for the tolerance request.

The dyadic row Q lists the candidate tolerance cells. Since the carrier is finite, the budget comparison is a displayed finite comparison among the cells in Q, with every real-valued read sealed through E before the handoff row is exposed.

The route to U is then replayed by C and transported componentwise by H. The provenance and naming rows P, N record the same finite route as the local certificate surface.

No excluded object is a coordinate of B. Consequently the exported budget is the displayed finite minimum-budget row inside the carrier, not an ambient supremum, external selector, open-cover argument, quotient equality, choice schedule, or completeness argument. □

Falsifiable prediction: Every accepted DiniFiniteMinimumBudget$^{\uparrow}$ consumer that exports a UniformModulus$^{\uparrow}$ handoff must first expose the compact-metric windows, monotone continuous-family rows, DiniTheorem route, finite DyadicRatCore$^{\uparrow}$ budget cells, Real$^{\uparrow}$ seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: dini-theorem, compactmetric, continuousmap, uniformmodulus, dyadicratcore, real: DiniFiniteMinimumBudget$^{\uparrow}$ is not bijective to any listed sibling because it binds the finite Dini probe cover to one displayed dyadic minimum-budget handoff before uniform-limit or compact-uniform-modulus consumers may read the result.

Closure status for NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$, seed)

Scope closed: Definition 5816.1 and Definition 5816.2 seed the finite minimum-budget extraction route from compact Dini data to a uniform-modulus-facing handoff.

Formal verification: FormalStatus(NameCert$_{\text{DiniFiniteMinimumBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host supremum selection, selected minima outside the carrier, open-cover compactness, quotient equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite probe-cover exposure, dyadic minimum-budget extraction, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.DiniFiniteMinimumBudgetUp.

Constructive story: A DiniFiniteMinimumBudget$^{\uparrow}$ packet is generated from compact-metric source rows, monotone ContinuousMap family rows, a DiniTheorem compact-window route, UniformModulus handoff rows, DyadicRatCore tolerance cells, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 4851

A Concrete Naming Certificate for $\mathsf{FiniteCauchyFilter}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteCauchyFilter}^{\uparrow}$ packet records the finite directed-tail surface used when a completion consumer asks for Cauchy-filter evidence before reading a regular rational name or a terminal real-name seal. It sits beside the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite filter basis for tail requests; it is not a quotient filter, a selected limit, countable choice, host real equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 4851.1 (Finite Cauchy filter carrier)**.** *A* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (W, T, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *row recording the finite source windows inspected by the filter request.*
2. T *is the directed-tail request row, naming the finite family of later-window obligations and their refinement order.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii and comparison budgets used by the directed tails.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and tolerance ledger.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reachable only after* W, T, D, R *have been exposed.*
6. H *records componentwise* hsame *transport for the stream windows, tail requests, dyadic ledgers, regular readback, and real seal.*
7. C *records displayed* Cont *replay of the same finite filter route.*
8. P *records* Pkg *provenance over* $\mathsf{FiniteCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, T, D, R, E, H, C, P, N$*. It has no coordinate for quotient filters, selected limits, countable choice, host equality of streams, host real equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.FiniteCauchyFilterUp.FiniteCauchyFilterTasteGate single carrier alignment`

Theorem 4851.2 (Finite Cauchy filter NameCert obligations)**.** *For the carrier of Definition 5817.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$ *surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure, directed-tail request visibility,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-ledger preservation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal access, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the accepted packet $F = (W, T, D, R, E, H, C, P, N)$. The rows W, T, D expose the finite source windows, directed tail requests, and dyadic tolerance budgets before any regular-rational or real-facing read is admitted.

The readback row R is then determined by the displayed windows and tolerance ledger. Since the carrier stores no second regular-rational coordinate, every $\mathsf{RegSeqRat}^{\uparrow}$ consumer reads the same finite route.

The seal row E is downstream of W, T, D, R. The transport row H, continuation row C, package provenance row P, and local naming row N preserve exactly that route and provide no coordinate for quotient filters, selected limits, countable choice, host stream equality, host real equality, or ambient completeness. □

Theorem 4851.3 (Finite Cauchy filter Real route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *carrier factors through the finite route*

$$W, T, D, R, E, H, C, P, N.$$

In particular, the consumer must first read $\mathsf{StreamName}^{\uparrow}$ *windows, directed tail requests,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*

Proof. Start with the carrier definition. The only real-facing row is E, and it is displayed after the stream windows, directed-tail row, dyadic ledger, and regular readback row.

Apply Definition 5817.2. The local NameCert surface admits the real seal only as part of the same transport, continuation, provenance, and naming route.

Thus any Real-facing consumer receives the finite packet $W, T, D, R, E, H, C, P, N$ and no quotient-filter, selected-limit, countable-choice, host-equality, or ambient-completeness substitute. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCauchyFilter}^{\uparrow}$ packet is generated from finite StreamName windows, directed tail requests, DyadicRatCore tolerance ledgers, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$, seed)

Scope closed: Definition 5817.1, Definition 5817.2, and Definition 5817.3 specify the finite directed-tail filter carrier and its Real-facing route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteCauchyFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filter construction, selected limits, countable choice, host stream equality, host real equality, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for directed-tail visibility, tolerance-ledger preservation, readback, Real seal routing, transport, replay, provenance, and local naming.

Chapter 4852

A Concrete Naming Certificate for DNAWindowSixTranslationBoundary$^{\uparrow}$

The DNAWindowSixTranslationBoundary$^{\uparrow}$ packet realizes the local translation-boundary branch of subsection 9462.28.21 as finite NameCert data. It consumes the codon-window and stop-tile boundary analysis in the source vision, the curated code-boundary ledger of **??**, and the trigger-threshold surface of chapter 4217. The packet names only a finite window-six translation-boundary carrier; biological translation realization, universality, protein function, and evolutionary mechanism remain outside the BEDC kernel packet.

Definition 4852.1 (DNA window-six translation-boundary carrier)**.** *A* DNAWindowSixTranslationBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, S, T, L, R, V, H, C, P, N)$$

with the following displayed rows:

1. *Q is the codon Q_6 window row recording the six-bit coordinate readback for the inspected codon window.*
2. *S is the stop-tile boundary row recording the local halt boundary and continuation-corner split from the source vision.*
3. *T is the translation-classifier row supplied by external biological bridge data.*
4. *L is the curated code-boundary ledger row inherited from* BioRealityQSixLeaveOneCodeBoundaryLedger$^{\uparrow}$*.*
5. *R is the release-factor or release-mechanism row that records which external recognition boundary is being tested.*
6. *V is the finite validation row recording which observed table, organismal code row, or assay class is used for the test.*
7. *H records componentwise* hsame *transport for the window, tile, classifier, ledger, release, and validation rows.*
8. *C records displayed* Cont *replay of the boundary read through those rows.*
9. *P records* Pkg *provenance over the source vision, the bio-reality ledger sibling,* DNAWindowSixTriggerThreshold$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and local naming rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for biological necessity, global identification of the genetic code with the window-six fold, protein-folding realization, universal stop assignment, hidden BEDC channel tokens, or untested mechanism.

Theorem 4852.2 (DNA window-six translation-boundary obligations)**.** *For the carrier of Definition 5818.1, the local* $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$ *surface consists exactly of codon-window exposure, stop-tile boundary visibility, external translation-classifier disclosure, curated code-ledger preservation, release-boundary test exposure, finite validation-row visibility, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the accepted packet $B = (Q, S, T, L, R, V, H, C, P, N)$. The rows Q, S, T expose the finite codon window, the local translation boundary, and the external classifier before any biological reading is admitted.

The ledger and release rows L, R keep the packet anchored to the bio-reality boundary sibling and to a displayed recognition test. The validation row V records the observed table or assay class being tested, so the packet has a falsifiable contact surface rather than a kernel claim of biological necessity.

The structural rows H, C, P, N transport, replay, source, and name exactly the displayed boundary route. Since no further coordinate is present, the carrier cannot export global window-six identity, universal stop assignment, protein-folding realization, hidden channel tokens, or untested mechanism. □

Theorem 4852.3 (DNA window-six translation-boundary sibling handoff)**.** *Every accepted* DNAWindowSixTranslat *read that reaches a translation-boundary consumer must first expose the source-vision stop-tile row of subsection 9462.28.21, the curated code-boundary ledger row of* **??**, *and the finite trigger-threshold row of chapter 4217. The handoff is therefore a concrete finite boundary-tile NameCert route, not a narrative-only direction.*

Proof. Use Definition 5818.1. The source-vision row is carried by S, the code-boundary ledger is carried by L, and the trigger-facing finite boundary read is recorded in the same package provenance P.

Now apply Definition 5818.2. The local NameCert requires those rows before the translation-boundary consumer can read N. Hence the consumer sees the source vision, the bio-reality ledger sibling, and the trigger-threshold sibling as displayed packet data rather than as detached prose. □

Falsifiable prediction: An accepted $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet must expose a finite validation row naming the observed code table, organismal code row, or release-factor assay class before it can export a translation-boundary reading.

Independence witness: bioreality-q-six-leave-one-code-boundary-ledger, dna-window-six-trigger-threshold, synonymous-transition: the $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet is not bijective to any listed sibling because it jointly carries codon-window, stop-tile, external translation-classifier, curated code-ledger, release-boundary, validation, transport, replay, provenance, and local naming rows.

The Lean follow-up must provide $\mathsf{Nontrivial}\ \mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{DNAWindowSi}$ TasteGate instances before this packet can move beyond seed closure.

Closure status for $\mathsf{NameCert}_{\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$ packet is generated from codon Q-six window rows, stop-tile boundary rows, external translation-classifier rows, curated code-boundary ledgers, release-boundary tests, finite validation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\mathsf{DNAWindowSixTranslationBoundary}\uparrow}$, seed)

Scope closed: Definition 5818.1, Definition 5818.2, and Definition 5818.3 specify the finite translation-boundary carrier and sibling route.

Formal verification: FormalStatus(NameCert$_{\mathsf{DNAWindowSixTranslationBoundary}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim biological-code necessity, global window-six identity, universal stop assignment, protein-folding realization, hidden BEDC channel tokens, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding, TasteGate nontriviality, field faithfulness, validation-row exactness, sibling-route preservation, transport, replay, provenance, and local naming.

Chapter 4853

A Concrete Naming Certificate for $\mathsf{RegulatedConvergence}^{\uparrow}$

Following Bishop and Bridges on regulated functions and uniform convergence, the $\mathsf{RegulatedConvergence}^{\uparrow}$ packet records the finite route by which a displayed sequence of regulated real functions converges uniformly to a regulated endpoint. It sits after the regulated-function carrier of chapter 1906, the regulated-integral consumer boundary of chapter 1557, the uniform-convergence ledger of chapter 3417, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite convergence-and-handoff surface; it does not import measure completion, quotient equality of functions, selected host limits, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 4853.1 (Regulated convergence carrier)**.** *A* $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, U, W, R, E, I, H, C, P, N)$$

with the following displayed rows:

1. *F is the source row naming the regulated-function family through* $\mathsf{RegulatedFunction}^{\uparrow}$ *data, including the displayed interval, step-window, endpoint, and oscillation ledgers available to each inspected member.*
2. *U is the* $\mathsf{UniformConvergence}^{\uparrow}$ *tail row, recording one shared tolerance schedule for the whole regulated family rather than pointwise schedules chosen separately at each argument.*
3. *W is the finite window row exposing exactly the function indices, domain windows, and endpoint reads used by the shared tail schedule.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the real-valued observations in those windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal reached only after F, U, W, R have been displayed.*
6. *I is the* $\mathsf{RegulatedIntegral}^{\uparrow}$ *handoff row; it records that integral-facing consumers may read the regulated endpoint only through the same finite regulated-function, uniform-tail, window, readback, and Real-seal route.*
7. *H records componentwise* hsame *transport for F, U, W, R, E, I and for the structural rows.*
8. *C records displayed* Cont *replay for regulated-function reads, uniform-tail requests, finite window reads, regular rational readback, Real-seal requests, and integral handoff requests.*

9. *P is the* Pkg *provenance over* $\mathsf{RegulatedConvergence}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{UniformConvergence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, U, W, R, E, I, H, C, P, N$. It has no coordinate for a host function quotient, selected limiting function, measure completion, pointwise-only convergence, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RegulatedConvergenceUp.RegulatedConvergenceTasteGate single carrier alignment`

Theorem 4853.2 (Regulated convergence NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier*

$$G = (F, U, W, R, E, I, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission for the regulated-function family row F, uniform-convergence tail row U, finite window row W, regular rational readback row R, terminal Real seal E, regulated-integral handoff row I, componentwise transport row H, displayed replay row C, package provenance row P, and local naming row N. Every endpoint-facing or integral-facing consumer must read these rows in the displayed route and cannot replace them by pointwise convergence, a selected host limit, quotient equality of functions, measure completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegulatedConvergenceUp.RegulatedConvergenceCarrier namecert obligations`

Proof. Project the accepted carrier of Definition 5819.1. The only analytic rows are the regulated-function family F, the shared uniform tail ledger U, the finite window row W, the regular rational readback R, the terminal Real seal E, and the integral handoff I.

The convergence route is uniform. A consumer must read the single tail schedule U before it can inspect the windows W and the regular readback R, so pointwise-only schedules and externally selected host limits are not part of the packet.

The endpoint and integral rows are downstream. The seal E is exposed only after F, U, W, R, and the integral-facing row I reads that same route rather than a separate measure-completion or function-quotient object.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded row occurs in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 4853.3 (Regulated convergence integral handoff)**.** *Let*

$$G = (F, U, W, R, E, I, H, C, P, N)$$

be an accepted $\mathsf{RegulatedConvergence}^{\uparrow}$ *carrier. Every* $\mathsf{RegulatedIntegral}^{\uparrow}$ *consumer read of the limiting regulated function factors through the finite route*

$$\mathsf{RegulatedFunction}^{\uparrow}(F),\ \mathsf{UniformConvergence}^{\uparrow}(U),\ W,\ \mathsf{RegSeqRat}^{\uparrow}(R),\ \mathsf{Real}^{\uparrow}(E),\ \mathsf{RegulatedIntegral}^{\uparrow}(I).$$

Thus the handoff to integration uses the same regulated-family rows, shared uniform-tail ledger, finite windows, regular rational readback, and Real seal as the convergence certificate. It supplies no measure completion, quotient function equality, selected limiting function, open-cover compactness, or ambient real-completeness principle.

Proof. Start with an integral-facing request. By the carrier definition, the only integral row is I, and its replay route in C passes through the same regulated-family and convergence rows used by endpoint-facing consumers.

Read the regulated source through F and the uniform tail through U. The finite windows W then expose the inspected function indices and domain reads, and the regular rational row R records the real-valued observations visible at those windows.

Only after this route is displayed can the terminal seal E be consumed and handed to I. Componentwise transport in H and replay in C preserve the same rows, while P and N record their provenance and local naming.

The carrier has no coordinate for measure completion, quotient function equality, selected limits, open-cover compactness, or ambient real completeness. Therefore every regulated-integral handoff is confined to the finite route displayed in the statement. □

Falsifiable prediction: An accepted $\mathsf{RegulatedConvergence}^{\uparrow}$ consumer that reaches a $\mathsf{RegulatedIntegral}^{\uparrow}$ handoff without first reading $F, U, W, R, E, H, C, P, N$ refutes the carrier surface.

Independence witness: regulated-function, regulated-integral, uniform-convergence, regseqrat, real: none is bijective to $\mathsf{RegulatedConvergence}^{\uparrow}$ because this packet jointly binds a regulated-function family, a shared uniform tail ledger, finite windows, regular rational readback, terminal Real seal, integral handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedConvergence}^{\uparrow}$ packet is generated from a regulated-function family row, UniformConvergence tail row, finite window row, RegSeqRat readback, terminal Real seal, RegulatedIntegral handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$, seed)

Scope closed: Definition 5819.1, Definition 5819.2, and Definition 5819.3 seed the finite regulated-convergence route over regulated functions, uniform convergence, regular rational readback, Real seals, and regulated-integral consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegulatedConvergence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close measure completion, quotient function equality, selected host limits, pointwise-only convergence, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regulated-family visibility, uniform-tail exactness, finite window readback, Real-seal nonescape, regulated-integral handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegulatedConvergenceUp.

Chapter 4854

A Concrete Naming Certificate for $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$

Following Cantor and Bishop–Bridges, the $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ packet records the finite located nested-interval route by which displayed interval windows become a regular rational Cauchy name and then a terminal real seal. It refines the nested dyadic Cauchy route of chapter 1811, reads endpoint and radius rows through chapter 291, schedules finite observations through chapter 126, hands the scheduled rows to chapter 301, and reaches only the seal boundary of chapter 38. The chapter isolates the located interval-to-name handoff; it does not claim a host intersection point, quotient stream equality, selected limit, countable choice, or ambient completeness.

Definition 4854.1 (Located nested-interval limit carrier)**.** *A* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite nested located-interval window. It records the inspected interval chain, endpoint rows, located containment witnesses, and the finite separation reads available at each displayed stage.*
2. *D is the dyadic shrink ledger. It records the dyadic endpoint comparisons, width bounds, and tolerance requests read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row. It names exactly the finite endpoint, midpoint, and shrink-ledger observations that may be queried before regular rational readback.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the scheduled located-interval observations and the dyadic shrink ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after I, D, S, R have been displayed.*
6. *H records componentwise* hsame *transport for interval windows, shrink ledgers, stream schedules, regular rational handoffs, real seals, replay rows, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a located nested-interval request through I, D, S, R, E and then through the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$*,* $\mathsf{NestedDyadicCauchy}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, S, R, E, H, C, P, N$. It has no coordinate for completed interval intersections, quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.LocatedNestedIntervalLimitUp.LocatedNestedIntervalLimitTasteGate single carrier alignment`

Theorem 4854.2 (Located nested-interval limit NameCert obligations)**.** *For every accepted* LocatedNestedIntervalL *carrier*

$$L = (I, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the finite located interval window, dyadic shrink ledger, StreamName schedule, RegSeqRat handoff, Real seal, transport, replay, provenance, and local naming row;*
2. *located nesting exposure, requiring every interval read to be one of the displayed rows of I together with its displayed containment and located separation witnesses;*
3. *dyadic shrink exactness, requiring every tolerance request to be discharged by a visible width or endpoint comparison stored in D and read through* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
4. *schedule compatibility, requiring S to expose only the finite interval, endpoint, midpoint, and ledger observations used by D and R;*
5. *RegSeqRat handoff exactness, requiring R to be formed only after the interval window, shrink ledger, and schedule rows have been projected;*
6. *Real-seal nonescape, requiring E to be consumed only after I, D, S, R and the structural rows H, C, P, N have been displayed.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 5820.1. The projection exposes one finite located nested-interval window, one dyadic shrink ledger, one StreamName schedule, one RegSeqRat handoff, one Real seal, and the transport, replay, provenance, and naming rows.

Located nesting exposure is forced by I. A consumer may inspect only interval rows already present in the finite window, and each such row carries its displayed containment and located separation witnesses.

Dyadic shrink exactness is forced by D. Each tolerance request is answered by a displayed dyadic width or endpoint comparison, so no host intersection or selected limit is needed to choose a tail.

The schedule and handoff rows are downstream. The row S records the finite observations that may be opened, and R repacks exactly those observations under the shrink ledger as a regular rational Cauchy surface.

Finally E, H, C, P, N close the route. The Real seal is reachable only after the regular handoff has been displayed, while the structural rows only transport, replay, source, and name the same finite data. Therefore no completed intersection, quotient stream equality, host real equality, countable choice, ambient completeness, Lean verification, or bridge-checking coordinate is present. □

Theorem 4854.3 (Located nested-interval RegSeqRat handoff)**.** *Let* $L = (I, D, S, R, E, H, C, P, N)$ *be an accepted* $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer read exported by* L *factors through the displayed route*

$$I \longmapsto D \longmapsto S \longmapsto R \longmapsto H, C, P, N.$$

The route reads a finite located nested-interval window, a dyadic shrink ledger, and the scheduled endpoint observations before it exports the regular rational Cauchy row. The terminal $\mathsf{Real}^{\uparrow}$ *seal* E *is available only after this handoff has been displayed.*

Proof. Start with the displayed located interval window I. Its rows give the only endpoint, midpoint, containment, and located separation data available to a regular rational consumer.

Use the dyadic shrink ledger D to answer the displayed tolerance request. The chosen comparison is part of the same finite packet and is read through $\mathsf{DyadicRatCore}^{\uparrow}$, so there is no external modulus, choice-selected tail, or host interval intersection.

The schedule row S then fixes which interval observations are opened. The handoff row R is obtained by reading those scheduled observations under the shrink discipline and repacking them as the $\mathsf{RegSeqRat}^{\uparrow}$ surface.

The rows H, C, P, N transport, replay, source, and name that handoff, and the seal row E remains downstream of it. Since the carrier has no quotient-stream, host-real, selected-limit, choice, or completeness coordinate, every regular rational read factors through the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5820.1, Definition 5820.2, and Definition 5820.3 seed the finite located nested-interval route from displayed interval windows and dyadic shrink ledgers to a RegSeqRat handoff and terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedNestedIntervalLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed interval intersections, quotient stream equality, host real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located nesting exposure, dyadic shrink exactness, schedule compatibility, RegSeqRat handoff exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedNestedIntervalLimitUp.

Constructive story: A $\mathsf{LocatedNestedIntervalLimit}^{\uparrow}$ packet is generated from a finite nested located-interval window, a dyadic shrink ledger, a StreamName schedule, a RegSeqRat handoff row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 4855

A Concrete Naming Certificate for $\mathsf{CauchyTailRequest}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyTailRequest}^{\uparrow}$ packet isolates the finite directed-tail request that a Cauchy or completion consumer must expose before it can read a regular rational name or a terminal real-name seal. It sits beside the finite window carrier of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal seal of chapter 38, and the finite filter surface of chapter 5817. The packet names the request row consumed by those sibling routes; it is not a quotient filter, a selected limit, a countable-choice schedule, host stream equality, host real equality, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 4855.1 (Cauchy tail request carrier)**.** *A* $\mathsf{CauchyTailRequest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (W, Q, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. W *is the* $\mathsf{StreamName}^{\uparrow}$ *row recording the finite source windows inspected by the request.*
2. Q *is the directed tail request row, naming the finite later-window obligations and their refinement order.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the directed tail request.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the displayed windows and tolerances.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reachable only after* W, Q, D, R *have been exposed.*
6. H *records componentwise* hsame *transport for the window, request, tolerance, readback, seal, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay of the same finite directed-tail route.*
8. P *records* Pkg *provenance over* $\mathsf{CauchyTailRequest}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteCauchyFilter}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, Q, D, R, E, H, C, P, N$*. It has no coordinate for quotient filters, selected limits, countable choice, host equality of streams, host real equality, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Lean4 (definition) `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestUp`

Lean4 ✓ `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestTasteGate single carrier alignment`

Theorem 4855.2 (Cauchy tail request NameCert obligations)**.** *For the carrier of Definition 5821.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$ *surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure, directed-tail visibility,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance preservation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every* $\mathsf{FiniteCauchyFilter}^{\uparrow}$ *consumer that reads a directed-tail row receives it through this displayed request surface.*

Lean4 ✓ `BEDC.Derived.CauchyTailRequestUp.CauchyTailRequestCarrier namecert obligations`

Proof. Project the accepted packet $T = (W, Q, D, R, E, H, C, P, N)$. The rows W, Q, D expose the finite windows, directed tail request, and dyadic tolerance ledger before any regular-rational or real-facing read is admitted.

The readback row R is downstream of those displayed rows. It therefore records only the $\mathsf{RegSeqRat}^{\uparrow}$ observation generated from the named windows and tolerance ledger, not an external sequence or choice schedule.

The seal row E is terminal for the request route. Transport through H and replay through C preserve exactly the displayed route, while P and N record provenance and local naming.

Finally compare the route with Definition 5817.2. The finite filter packet consumes its directed-tail row as a request coordinate, and the rows above are precisely the admitted request surface available to that consumer. Since no remaining coordinate exists, quotient filters, selected limits, countable choice, host equality, Real completeness, Lean verification, and bridge checking are outside the chapter claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyTailRequest}^{\uparrow}$ packet is generated from finite StreamName windows, a directed tail request row, DyadicRatCore tolerance data, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$, seed)

Scope closed: Definition 5821.1 and Definition 5821.2 specify the finite directed-tail request carrier and its filter-facing route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyTailRequest}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected limits, countable choice, host equality, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for tail visibility, tolerance preservation, readback, seal routing, transport, replay, provenance, and local naming.

Chapter 4856

A Concrete Naming Certificate for $\mathsf{QuotientLeakageMarkov}^{\uparrow}$

The $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ packet realizes the quotient leakage transition matrix of Definition 9462.1376 as finite NameCert data. It consumes the DNA window-six boundary-tile source of subsection 9462.28.21, the codon-window carrier of chapter 2234, the boundary-tile packet of chapter 3393, the six-boundary coverage route of chapter 3470, and the translation-boundary packet of chapter 5818. The packet names a finite six-state Markov ledger only; it is not a biological stochastic model, empirical evolutionary claim, host quotient-codon semantics, or unrestricted state-space enumeration.

Definition 4856.1 (QuotientLeakageMarkov carrier)**.** *A* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, T, O, E, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the six-state orbit row listing* AGR*,* Anchor_6*,* $\mathrm{StopStart}_6$*,* UUR*,* CUR*, and* CUY*.*
2. *T is the transient transition-matrix row of Definition 9462.1376, with entries read as exact rational finite counts.*
3. *O is the outside-probability row recording* $1/3, 1/3, 1/3, 1/6, 1/2, 2/3$ *for the six displayed states.*
4. *E is the expected-exit ledger row recording the rational exit values of Definition 9462.1380.*
5. *W is the finite window-six source row tying the orbit states to the codon-window and boundary-tile siblings.*
6. *H records componentwise* hsame *transport for the state, transition, outside-probability, exit-ledger, source, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the finite Markov read through* S, T, O, E, W, H, P, N*.*
8. *P is the* Pkg *provenance over* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$*,* $\mathsf{CodonSixBitWindow}^{\uparrow}$*,* $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$*,* $\mathsf{SixBoundaryTileCoverage}^{\uparrow}$*,* $\mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$*, the source vision of subsection 9462.28.21,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, O, E, W, H, C, P, N$*. It has no coordinate for biological transition realization, hidden codon quotient semantics, empirical fitness, unbounded simulation, or a completed stochastic process.*

Theorem 4856.2 (QuotientLeakageMarkov NameCert obligations)**.** *For the carrier of Definition 5822.1, the local* $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$ *surface consists exactly of six-state exposure, transition-matrix exactness, outside-probability preservation, expected-exit ledger exposure, window-six sibling routing, componentwise transport, displayed replay, provenance, and local naming. Every accepted read preserves the outside probabilities displayed in Definition 9462.1378.*

Proof. Project the accepted carrier $Q = (S, T, O, E, W, H, C, P, N)$. The state row S fixes the six orbit states, and the transition row T is the only source of one-bit flip probabilities.

The outside-probability row O is read from the outside column of T and matches the finite rational list in Definition 9462.1378. Thus an accepted packet cannot alter leakage rates without changing a displayed row.

The expected-exit row E is downstream of the same finite matrix and records the rational ledger of Definition 9462.1380. The source row W ties these finite state rows back to the codon-window, boundary-tile, coverage, and translation-boundary siblings.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since no other coordinate is present, the NameCert surface cannot export biological mechanism, hidden quotient semantics, empirical fitness, unbounded simulation, or a completed stochastic process. □

Theorem 4856.3 (QuotientLeakageMarkov sibling dependency route)**.** *Every accepted* $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ *consumer first reads the finite codon-window source, boundary-tile classifier, six-boundary coverage route, and translation-boundary packet before it consumes the transition row* T*, outside row* O*, or expected-exit row* E*. The dependency route is*

$$\mathsf{CodonSixBitWindow}^{\uparrow}, \mathsf{DnaWindowSixBoundaryTile}^{\uparrow}, \mathsf{SixBoundaryTileCoverage}^{\uparrow}, \mathsf{DNAWindowSixTranslationBoundary}^{\uparrow}$$

Proof. Use the provenance row P and source row W of Definition 5822.1. These rows name the finite codon-window and boundary-tile sources before the Markov matrix is admitted.

The transition row T then reads the six-state quotient matrix of Definition 9462.1376. The outside-probability row O and expected-exit row E are downstream ledger rows, so they cannot be consumed before the sibling source route has been displayed.

Transport and replay by H and C preserve this order, while N names it locally. Hence the consumer receives a concrete dependency route rather than a detached numerical table. □

Falsifiable prediction: Every accepted $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ read preserves the displayed outside probabilities $1/3, 1/3, 1/3, 1/6, 1/2, 2/3$ for AGR, Anchor_6, StopStart_6, UUR, CUR, and CUY.

Independence witness: codon-six-bit-window, dna-window-six-boundary-tile, six-boundary-tile-coverage, dna-window-six-translation-boundary: $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries six orbit states, a rational transition matrix, outside probabilities, expected-exit ledgers, window-source routing, transport, replay, provenance, and local naming.

The Lean follow-up must provide explicit $\mathsf{Nontrivial}\ \mathsf{QuotientLeakageMarkov}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{QuotientLeakageM}$ TasteGate instances preserving $S, T, O, E, W, H, C, P, N$ as distinct displayed rows.

Closure status for $\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}$**.**

Constructive story: A $\mathsf{QuotientLeakageMarkov}^{\uparrow}$ packet is generated from six orbit states, a rational transition matrix, outside-probability rows, expected-exit ledgers, a finite window-six source row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{QuotientLeakageMarkov}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5822.1, Definition 5822.2, and Definition 5822.3 specify the finite quotient-leakage Markov carrier and sibling dependency route.

Formal verification: FormalStatus(NameCert$_{\text{QuotientLeakageMarkov}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close biological transition realization, empirical evolutionary mechanism, hidden codon quotient semantics, unbounded simulation, completed stochastic processes, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-matrix exactness, outside-probability preservation, expected-exit ledger exposure, sibling routing, transport, replay, provenance, and local naming for BEDC.Derived.QuotientLeakage

Chapter 4857

A Concrete Naming Certificate for $\mathsf{CauchyCriterionUniform}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyCriterionUniform}^{\uparrow}$ packet records the uniform Cauchy criterion route used when a Real and Completion consumer asks for one displayed threshold discipline across a finite family of stream windows. It sits beside the finite stream-window interface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the Cauchy hub of chapter 3413. The packet names a uniform criterion surface; it is not a quotient Cauchy class, selected limit, host equality theorem, countable-choice schedule, trichotomy principle, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 4857.1 (Cauchy criterion uniform carrier)**.** *A* $\mathsf{CauchyCriterionUniform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, D, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *S records the* $\mathsf{StreamName}^{\uparrow}$ *window family inspected by the uniform criterion request.*
2. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the dyadic radii and comparison budgets shared by the family.*
3. *R records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the displayed windows and dyadic tolerances.*
4. *E records the terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing row, available only after S, D, R, M have been exposed.*
5. *M records the uniform modulus row, naming the common threshold discipline for all displayed windows in the family.*
6. *H records componentwise* hsame *transport for the stream windows, dyadic tolerances, regular readback, Real seal, uniform modulus, replay route, provenance, and local name.*
7. *C records displayed* Cont *replay of the same finite route.*
8. *P records* Pkg *provenance over* $\mathsf{CauchyCriterionUniform}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N records the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, R, E, M, H, C, P, N$. It has no coordinate for a quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCriterionUniformUp.CauchyCriterionUniformTasteGate single carrier alignment`

Theorem 4857.2 (Cauchy criterion uniform NameCert obligations)**.** *For the carrier of Definition 5823.1, the local* $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the finite packet* $U = (S, D, R, E, M, H, C, P, N)$*;*
2. *uniform window exposure through the* $\mathsf{StreamName}^{\uparrow}$ *row* S *and the common modulus row* M*;*
3. *dyadic tolerance exactness through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D*;*
4. *regular readback through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *before the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*;*
5. *ledger non-escape through* H, C, P, N*.*

Proof. Project the accepted packet $U = (S, D, R, E, M, H, C, P, N)$. Carrier admission is exactly the admission of this finite tuple, so a consumer can inspect only the displayed coordinates.

The uniform window obligation reads S together with the common threshold discipline M. The dyadic tolerance obligation reads D, and the regular readback obligation reads R before any terminal seal row E is available.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since the carrier has no remaining coordinate, the ledger cannot export a quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient completeness claim. □

Theorem 4857.3 (Cauchy criterion uniform Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{CauchyCriterionUniform}^{\uparrow}$ *carrier factors through the finite route*

$$S, D, R, M \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer must read stream windows, dyadic tolerances, regular readback, and the uniform modulus before the terminal real seal is exposed. The route exports no quotient Cauchy class, selected limit, host equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 5823.1. The only terminal real-facing coordinate is E, and the definition places it downstream of the finite stream-window, dyadic-tolerance, regular-readback, and uniform-modulus rows.

Apply Definition 5823.2. The NameCert surface admits the real seal only as part of the same transport, continuation, provenance, and naming route.

Therefore any Real-facing consumer receives exactly the finite packet route displayed above. No quotient Cauchy class, selected limit, host equality, countable-choice schedule, trichotomy row, or ambient-completeness coordinate supplies another path to the seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCriterionUniform}^{\uparrow}$ packet is generated from finite StreamName windows, DyadicRatCore tolerance ledgers, RegSeqRat readback, a RealUp seal row, a uniform modulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$, seed)

Scope closed: Definition 5823.1, Definition 5823.2, and Definition 5823.3 specify the finite uniform Cauchy criterion carrier and its Real-facing seal route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCriterionUniform}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient Cauchy classes, selected limits, host equality, countable choice, trichotomy, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean carrier encoding and checked theorems for uniform window exposure, dyadic tolerance exactness, regular readback, Real seal routing, transport, replay, provenance, and local naming.

Chapter 4858

A Concrete Naming Certificate for CauchyProductCompletionProjection$^{\uparrow}$

Following Bishop and Bridges on constructive products of Cauchy completions and Kelley on product uniformities, the CauchyProductCompletionProjection$^{\uparrow}$ packet records the coordinate projection surface for an accepted product-completion read. It sits downstream of the product packet of chapter 3797 and the completion-product route of chapter 1540, while every coordinate read still passes through the StreamName$^{\uparrow}$ windows of chapter 126, the RegSeqRat$^{\uparrow}$ readbacks of chapter 301, the DyadicRatCore$^{\uparrow}$ budgets of chapter 291, and the terminal Real$^{\uparrow}$ seal of chapter 38.

Definition 4858.1 (CauchyProductCompletionProjection carrier)**.** *A* CauchyProductCompletionProjection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N)$$

with the following displayed rows:

1. *Q is the accepted* CauchyProductCompletion$^{\uparrow}$ *product-completion packet whose coordinate route is being inspected.*
2. *π_0, π_1 are the left and right projection selector rows, each naming which displayed coordinate window is exposed.*
3. *S_0, S_1 are the coordinate* StreamName$^{\uparrow}$ *windows opened by the two projection selectors.*
4. *D_0, D_1 are the* DyadicRatCore$^{\uparrow}$ *budget rows attached to the finite coordinate observations read from those windows.*
5. *R_0, R_1 are the* RegSeqRat$^{\uparrow}$ *readback rows obtained from the same coordinate windows and dyadic budgets.*
6. *L_0, L_1 are the coordinate completion-seal rows witnessing that each projected read remains inside the product-completion packet.*
7. *H records componentwise* hsame *transport for the product packet, selectors, stream windows, dyadic budgets, regular readbacks, and coordinate completion seals.*
8. *C records the* Cont *replay from the product-completion packet through the selected coordinate window, dyadic budget, regular readback, and completion seal.*
9. *P is the* Pkg *provenance over* CauchyProductCompletionProjection$^{\uparrow}$, CauchyProductCompletion$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$ *row.*
The carrier compares accepted projections only through $Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, countable choice, host product equality, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.CauchyProductCompletionProjectionUp.CauchyProductCompletionProjectionTasteGate`
`single carrier alignment`

Theorem 4858.2 (CauchyProductCompletionProjection NameCert obligations)**.** *For an accepted packet*

$$J = (Q, \pi_0, \pi_1, S_0, S_1, D_0, D_1, R_0, R_1, L_0, L_1, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$ *surface consists exactly of product-packet admission, selector exposure, coordinate stream-window exposure, dyadic-budget accounting, regular readback, coordinate completion-seal nonescape, componentwise transport, replay, provenance, and local naming for the displayed rows.*

Proof. Project the carrier of Definition 5824.1. The row Q supplies the already displayed product-completion packet, while π_0, π_1 determine which coordinate route is being opened.

For each selector, the corresponding stream window is read before any dyadic budget or regular readback is available. Thus S_0, S_1 precede D_0, D_1, and the regular rows R_0, R_1 are exposed only through those windows and budgets.

The completion-seal rows L_0, L_1 bind the coordinate read back to Q. The transport table H and replay table C preserve the same product packet, selector, window, budget, readback, and seal rows, while P and N record provenance and local naming.

Since these are the only carrier coordinates, the NameCert surface has no route to quotient completion equality, selected representatives, countable choice, host product equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 4858.3 (CauchyProductCompletionProjection route)**.** *Every coordinate read exported by an accepted* $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$ *carrier factors through*

$\mathsf{CauchyProductCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameC

The left and right selectors expose only the displayed coordinate windows and their completion seals; they do not turn the product-completion packet into a host tuple, a quotient-completion equality, or a chosen representative.

Proof. Start with an accepted carrier J. The selector rows π_0, π_1 are not host projections; they are displayed BEDC rows attached to the product-completion packet Q.

Reading either selector first opens the matching $\mathsf{StreamName}^{\uparrow}$ window. The dyadic budget row is then inspected, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback is obtained from the same finite coordinate window.

The coordinate completion seal is the last coordinate-facing row before export. It keeps the read inside the product-completion packet named by Q, and the structural rows H, C, P, N attach transport, replay, provenance, and local naming to the same route.

Thus every projection read remains a finite NameCert route through the displayed rows. No coordinate of J supplies quotient completion equality, selected representatives, countable choice, host product equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$ packet is generated from an accepted CauchyProductCompletion packet, left and right projection selector rows, coordinate StreamName windows, DyadicRatCore budgets, RegSeqRat readbacks, coordinate completion seals, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5824.1, Definition 5824.2, and Definition 5824.3 seed the finite coordinate-projection route for product completions.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductCompletionProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host product equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification can encode carrier admission, selector exposure, coordinate window accounting, regular readback, completion-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductCompletionPro

Chapter 4859

A Concrete Naming Certificate for $\mathsf{CauchyModulusSubsequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ packet records the finite route by which a bounded regular Cauchy source exposes a modulus-indexed subsequence schedule without exporting an infinite selector. It sits between the bounded subsequence envelope of chapter 1698, the regular subsequence route of chapter 381, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet is a constructive completion-facing certificate: it supplies a monotone cofinal schedule, finite windows, tolerance accounting, and a Real seal, but not countable choice, quotient stream equality, a selected infinite subsequence, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4859.1 (Cauchy modulus subsequence carrier)**.** *A* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, M, T, W, D, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the accepted* $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$ *source row whose bounded regular Cauchy data are available before any subsequence-modulus request is read.*
2. *M is the modulus row. It records the requested Cauchy tolerance discipline and the finite comparison budget used by the subsequence schedule.*
3. *T is the monotone cofinal schedule row. It records the finite evidence that requested indices are sent to later source windows and that the schedule is cofinal in the displayed source.*
4. *W records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows selected by the schedule row T at the requested modulus levels.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to those windows.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed windows and dyadic tolerances.*
7. *R is the* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff row reached from B, M, T, W, D, Q.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the bounded source, modulus, schedule, windows, tolerance ledger, regular readback, and regular subsequence handoff have been displayed.*

9. *H records componentwise* hsame *transport for the bounded source, modulus, cofinal schedule, windows, dyadic ledger, regular readback, regular subsequence handoff, terminal seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a subsequence-modulus request through $B, M, T, W, D, Q, R, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$, $\mathsf{BoundedRegularCauchySubsequence}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, M, T, W, D, Q, R, E, H, C, P, N$. It has no coordinate for a selected infinite subsequence, quotient stream equality, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusSubsequenceUp.CauchyModulusSubsequenceTasteGate single carrier alignment`

Theorem 4859.2 (Cauchy modulus subsequence NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier $S = (B, M, T, W, D, Q, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequ}}$ *surface consists exactly of carrier admission, bounded-source admission through B, modulus monotonicity through M, monotone cofinal schedule admission through T, finite-window determinacy through W, dyadic tolerance accounting through D, regular rational readback through Q,* $\mathsf{RegularCauchySubsequence}^{\uparrow}$ *handoff through R, Real-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 5825.1. Its analytic coordinates are exactly the bounded source B, modulus row M, monotone cofinal schedule T, finite windows W, dyadic tolerance ledger D, regular readback Q, regular subsequence handoff R, and terminal Real seal E.

The modulus and schedule obligations are displayed before any support row is inspected. The row M supplies the tolerance discipline, while T records monotonicity and cofinality for the finite requested indices. The window row W and tolerance row D then determine which $\mathsf{StreamName}^{\uparrow}$ windows and dyadic bounds are visible at those requests.

The readback and seal obligations remain downstream. The row Q reads the visible windows as $\mathsf{RegSeqRat}^{\uparrow}$ data, R records the $\mathsf{RegularCauchySubsequence}^{\uparrow}$ handoff, and E is reachable only after the preceding rows have been displayed. Rows H, C, P, N transport, replay, source, and name that same finite route, so no further NameCert obligation remains outside the listed coordinates. □

Theorem 4859.3 (Cauchy modulus subsequence window determinacy)**.** *Every consumer admitted by an accepted* $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ *carrier must read the bounded source B, modulus row M, monotone cofinal schedule T, finite windows W, dyadic tolerance ledger D, regular rational readback Q, regular subsequence handoff R, and terminal Real seal E before reading the transport, replay, provenance, or local naming rows. The packet exports no selected infinite subsequence, quotient stream equality, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer read. By Definition 5825.1, the only consumer-facing route before the support rows is the ordered list B, M, T, W, D, Q, R, E.

The rows B, M, T fix the source, tolerance request, and monotone cofinal schedule. The row W then supplies only the finite windows named by that schedule, and D supplies the dyadic tolerance ledger attached to those windows. Thus the visible subsequence data are determined by displayed finite requests, not by an externally selected infinite object.

The remaining analytic rows are also fixed by the displayed windows. The readback row Q converts those windows into $\mathsf{RegSeqRat}^{\uparrow}$ data, R records the regular subsequence handoff, and E is the terminal Real seal for that route. Since the carrier contains no coordinate for quotient stream equality, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the support rows H, C, P, N can only preserve the displayed finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusSubsequence}^{\uparrow}$ packet is generated from a bounded regular Cauchy source, a modulus row, a monotone cofinal schedule, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RegularCauchySubsequence handoff, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5825.1, Definition 5825.2, and Definition 5825.3 seed the constructive subsequence-modulus route over bounded regular Cauchy data, finite windows, dyadic tolerances, regular readback, regular subsequence handoff, Real sealing, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite subsequences, quotient stream equality, countable choice, host equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Lean verification requires carrier admission, modulus monotonicity, cofinal schedule admission, finite-window determinacy, dyadic tolerance accounting, RegSeqRat readback, RegularCauchySubsequence handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusSubsequenceUp.

$\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ reads its comparison surface through chapter 126, chapter 301, chapter 291, chapter 1820, and chapter 38 before the child NameCert body is input.

Chapter 4860

A Concrete Naming Certificate for $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ packet records the finite comparison surface at which two regular Cauchy presentations can be inspected before a real-name or completion-facing consumer reads them. It sits on the finite observation windows of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the non-quotient classifier boundary of chapter 1820.

Falsifiable prediction: If a purported $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ consumer compares two regular Cauchy presentations without exposing finite StreamName windows, RegSeqRat readbacks, the DyadicRatCore tolerance ledger, the CauchyEquivalenceSetoid classifier, and the terminal Real seal, then the consumer has left the certificate.

Definition 4860.1 (Regular Cauchy sequence comparison carrier)**.** *A* $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. S_0 *and* S_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows available to the comparison request.*
2. R_0 *and* R_1 *are the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows, exposing regular rational values before any real-name seal is consumed.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the displayed precision cells and refinement rows used by the comparison.*
4. Q *is the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier row over* S_0, S_1, R_0, R_1, D.
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite windows, readbacks, tolerance ledger, and classifier row are visible.*
6. H *records componentwise* hsame *transport for the two stream rows, two readback rows, dyadic ledger, classifier, real seal, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay from a comparison request through* $S_0, S_1, R_0, R_1, D, Q, E, H, P, N$.
8. P *is the* Pkg *provenance over* $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchySequenceComparison}^{\uparrow}}$ *row.*
The carrier compares accepted packets only through $S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, host real equality, choice of representatives, selected limits, or ambient completeness.

`single carrier alignment`

Theorem 4860.2 (Regular Cauchy sequence comparison NameCert obligations)**.** *For the carrier of Definition 5826.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySequenceComparison}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$K = (S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N),$$

finite StreamName window exposure through S_0, S_1, regular rational readback through R_0, R_1, dyadic tolerance accountability through D, Cauchy-equivalence classifier exposure through Q, Real seal nonescape through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.

Proof. Carrier admission is projection from Definition 5826.1. The projection exposes exactly the two StreamName windows, two RegSeqRat readbacks, DyadicRatCore tolerance ledger, CauchyEquivalenceSetoid classifier, Real seal, transport, replay, provenance, and local naming rows.

The comparison route reads those rows in order. The two finite windows are inspected before the regular rational readbacks, the readbacks feed the dyadic tolerance ledger, and the ledger feeds the classifier row Q.

The Real seal E is downstream of the displayed comparison surface. The rows H, C, P, N transport, replay, source, and name that same finite route; none of them adds quotient stream equality, selected representatives, host real equality, choice, or ambient completeness. □

Theorem 4860.3 (Regular Cauchy sequence comparison carrier transport)**.** *Let*

$$K = (S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N)$$

and

$$K' = (S'_0, S'_1, R'_0, R'_1, D', Q', E', H', C', P', N')$$

be $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *carrier packets. If the displayed row H supplies componentwise* hsame *transport from each row of K to the corresponding row of K', then carrier admission for K transports to carrier admission for K' along exactly the rows*

$$S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N.$$

The transported packet has no added coordinate for quotient stream equality, host real equality, selected representative, countable choice, selected limit, or ambient completeness.

Proof. Project the carrier tuple of Definition 5826.1. The only exposed coordinates are the two StreamName rows, two RegSeqRat readback rows, DyadicRatCore tolerance ledger, classifier, Real seal, transport, replay, provenance, and local naming rows.

Use the NameCert obligations of Definition 5826.2. They require componentwise transport to act row by row on the displayed packet rather than by replacing the packet with a host quotient or selected real representative.

The sibling routes keep each transported row inside its own finite surface: StreamName supplies finite windows, RegSeqRat supplies rational readbacks, DyadicRatCore supplies tolerance cells,

CauchyEquivalenceSetoid supplies the classifier boundary, and Real supplies only the terminal seal. Therefore the transported accepted packet is still read through the same carrier coordinates, and no excluded equality, choice, limit, or completeness datum is introduced. □

Theorem 4860.4 (Regular Cauchy sequence comparison classifier stability)**.** *For an accepted packet*

$$K = (S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N),$$

replace the finite StreamName windows, RegSeqRat readbacks, and DyadicRatCore tolerance rows by rows displayed in H as componentwise hsame*-stable. Then the CauchyEquivalenceSetoid classifier row Q remains the classifier row for the transported comparison route. In particular, classifier stability is witnessed before any Real seal is consumed and does not use quotient stream equality or host real equality.*

Proof. Start from the carrier projection in Definition 5826.1. The row Q is named there only over S_0, S_1, R_0, R_1, D, so its inputs are the finite StreamName windows, the RegSeqRat readbacks, and the DyadicRatCore tolerance ledger.

Apply the obligation surface of Definition 5826.2. It places componentwise transport in the displayed row H and keeps replay in C, so replacing the finite windows, readbacks, and tolerance rows by H-stable rows preserves the same inspected classifier boundary.

The chapter's sibling routes enforce the order of reading: finite windows first, regular rational readbacks next, dyadic tolerance accounting next, and only then the CauchyEquivalenceSetoid row. The Real seal E is downstream, so classifier stability is decided without a host quotient, host equality, selected representative, choice, selected limit, or ambient completeness row. □

Theorem 4860.5 (Regular Cauchy sequence comparison ledger exactness)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing consumer of an accepted* $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *comparison packet factors through exactly*

$$S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N.$$

The exported ledger gives the consumer finite StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, the CauchyEquivalenceSetoid classifier, the Real seal, componentwise transport, displayed replay, provenance, and local naming, and gives no selected representative, quotient equality, host real equality, countable choice, selected limit, or ambient completeness row.

Proof. Project the accepted carrier of Definition 5826.1. Its displayed coordinates are exactly $S_0, S_1, R_0, R_1, D, Q, E, H, C, P, N$, and the definition explicitly leaves out representative selection, quotient equality, host equality, choice, selected limits, and ambient completeness.

Use Definition 5826.2 to read the ledger as a NameCert surface. Carrier admission exposes the finite windows, readbacks, tolerance ledger, classifier, Real seal, transport, replay, provenance, and local name as the complete comparison route.

The StreamName, RegSeqRat, DyadicRatCore, CauchyEquivalenceSetoid, and Real sibling chapters provide only their named local rows to this route. Hence any $\mathsf{Real}^{\uparrow}$ or completion-facing consumer receives precisely the displayed packet rows and cannot obtain any excluded external equality, selection, choice, limit, or completeness datum from the ledger. □

Theorem 4860.6 (Regular Cauchy sequence comparison transitive window)**.** *Let*

$$K_{01} = (S_0, S_1, R_0, R_1, D_{01}, Q_{01}, E_{01}, H_{01}, C_{01}, P_{01}, N_{01})$$

and

$$K_{12} = (S_1', S_2, R_1', R_2, D_{12}, Q_{12}, E_{12}, H_{12}, C_{12}, P_{12}, N_{12})$$

be accepted $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *packets. If the middle presentation rows* S_1, R_1 *and* S_1', R_1' *are linked by the displayed componentwise* hsame *transport, and the dyadic tolerance/readback rows* D_{01} *and* D_{12} *expose compatible comparison windows, then the composed comparison from the first presentation to the third is forced through the same finite route*

$$S_0, S_1, S_2, R_0, R_1, R_2, D_{01}, D_{12}, Q_{01}, Q_{12}, E_{01}, E_{12}, H_{01}, H_{12}, C_{01}, C_{12}, P_{01}, P_{12}, N_{01}, N_{12}.$$

In particular, a Real or Completion consumer of the composed read receives only finite $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *rows, and receives no quotient stream equality, selected representative, host real equality, countable choice, selected limit, or ambient completeness datum.*

Proof. Project the two accepted carriers. The first packet exposes the finite route from S_0, R_0 to S_1, R_1 through $D_{01}, Q_{01}, E_{01}, H_{01}, C_{01}, P_{01}, N_{01}$, and the second exposes the corresponding route from S_1', R_1' to S_2, R_2 through $D_{12}, Q_{12}, E_{12}, H_{12}, C_{12}, P_{12}, N_{12}$.

Use the displayed componentwise hsame data on the shared middle presentation. It identifies only the carried StreamName and RegSeqRat rows needed to splice the two finite comparison windows; it does not create a quotient equality of streams or a host equality of real names.

The compatible dyadic rows concatenate the displayed tolerance/readback windows. Therefore the composed read is still inspected through the listed StreamName, RegSeqRat, DyadicRatCore, classifier, Real seal, transport, replay, provenance, and local naming rows.

Since neither carrier has a coordinate for selected representatives, host real equality, selected limits, choice, or ambient completeness, the composed comparison has no such coordinate either. The transitive window is exactly the finite route displayed above. □

Theorem 4860.7 (Regular Cauchy sequence comparison RegSeqRat handoff)**.** *Every completion-facing or Real-facing consumer of an accepted* $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *packet reads the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff before it reaches the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *classifier or the* $\mathsf{Real}^{\uparrow}$ *seal. More precisely, every exported comparison factors through*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto Q \longmapsto E \longmapsto H, C, P, N$$

and no consumer receives quotient stream equality, host real equality, selected representatives, countable choice, or ambient completeness from the packet.

Proof. Project the carrier of Definition 5826.1. The only pre-classifier rows are the finite StreamName windows S_0, S_1, the RegSeqRat readbacks R_0, R_1, and the DyadicRatCore ledger D.

Apply the NameCert obligations of Definition 5826.2. They force the CauchyEquivalenceSetoid classifier row Q to be read through those finite windows, readbacks, and tolerance rows before the Real seal E is available.

Finally use the sibling routes named in the chapter introduction: StreamName supplies finite windows, RegSeqRat supplies regular rational readback, DyadicRatCore supplies tolerance cells, CauchyEquivalenceSetoid supplies the non-quotient classifier, and Real supplies the terminal seal. The carrier contains no row for any excluded equality or selection principle. □

Theorem 4860.8 (Regular Cauchy sequence comparison Real-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ *packet reads comparison evidence only after passing through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and the* $\mathsf{CauchyEquivalenceSetoid}^{\uparrow}$ *boundary. Thus equality or separation evidence is available only along the finite route*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto Q \longmapsto E \longmapsto H, C, P, N,$$

and not through host quotient equality, a selected representative, countable choice, selected limits, or ambient completeness.

Proof. Start with the RegSeqRat handoff of Definition 5826.7. It already forces every completion-facing or Real-facing read through finite StreamName windows, RegSeqRat readbacks, and the DyadicRatCore ledger before the classifier row Q and Real seal E are available.

The classifier row Q is the Cauchy-equivalence boundary for the displayed rows S_0, S_1, R_0, R_1, D. Reading equality or separation evidence before Q would skip the boundary named by the carrier, while reading it after E without Q would replace the packet by a host quotient.

The structural rows H, C, P, N preserve and name the same route. This is therefore a substantive sibling dependency among StreamName, RegSeqRat, DyadicRatCore, CauchyEquivalenceSetoid, and Real, not a host quotient or a selected representative. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySequenceComparison}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchySequenceComparison}^{\uparrow}$ packet is generated from two StreamName finite-window rows, two RegSeqRat readback rows, a DyadicRatCore tolerance ledger, a CauchyEquivalenceSetoid classifier row, a Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchySequenceComparison}^{\uparrow}}$, obligation)

Scope closed: Definition 5826.1, Definition 5826.2, Definition 5826.3, Definition 5826.4, Definition 5826.5, Definition 5826.6, and Definition 5826.7 bind the obligation surface for the finite comparison route of regular Cauchy presentations.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchySequenceComparison}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real equality, selected representatives, countable choice, selected limits, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires binding the displayed BHist, hsame, Cont, Pkg, NameCert, StreamName, RegSeqRat, DyadicRatCore, CauchyEquivalenceSetoid, and Real rows as the complete BEDC primitive scope for the same comparison packet.

Chapter 4861

A Concrete Naming Certificate for $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$

Following Mac Lane on monads and Eilenberg–Moore comparison, together with Bishop–Bridges constructive completion, the $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ packet records the finite BEDC surface where the L10 completion monad, its algebra action, the Kleisli route, the universal-property row, and the dense-embedding unit route are compared as one NameCert boundary. The packet reads chapter 378, chapter 1845, chapter 1981, chapter 397, chapter 3351, chapter 126, chapter 301, chapter 291, and chapter 38. It names the comparison surface only; it does not assert quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient completeness, or full $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4861.1 (CauchyCompletionMonadicity carrier)**.** *A* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, A, K, U, D, W, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *completion-monad row, displaying the unit and bind schedule before any algebra or comparison read is consumed.*
2. *A is the* $\mathsf{CauchyCompletionAlgebra}^{\uparrow}$ *action row, recording the Eilenberg–Moore algebra action over the displayed completion route.*
3. *K is the* $\mathsf{CauchyCompletionKleisli}^{\uparrow}$ *row, exposing the unit, bind, and reassociated-bind consumer route.*
4. *U is the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *row, carrying the extension and uniqueness ledger used by comparison consumers.*
5. *D is the* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *unit route, displaying the dense source-to-completion image before the algebra or universal-property read is exported.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row used by the monad, algebra, Kleisli, universal-property, and dense-embedding rows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to the same finite windows.*
8. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare completion-facing reads at the same finite precision.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *readback seal reached only after W, R, Q have all been displayed.*
10. *H records componentwise* hsame *transport for the monad, algebra action, Kleisli route, universal-property row, dense-embedding unit route, readback rows, replay, provenance, and local naming.*
11. *C records displayed* Cont *replay from comparison requests through $T, A, K, U, D, W, R, Q, E, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, CauchyCompletionAlgebr $\mathsf{CauchyCompletionKleisli}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, A, K, U, D, W, R, Q, E, H, C, P, N$. The carrier has no coordinate for quotient completion classes, selected limit representatives, host equality of completed objects, countable-choice schedules, ambient completeness, full $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionMonadicityUp.TasteGate.CauchyCompletionMonadicityTasteGate`
`single carrier alignment`

Theorem 4861.2 (CauchyCompletionMonadicity NameCert obligations)**.** *For every accepted* CauchyCompletionM *carrier*

$$M = (T, A, K, U, D, W, R, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$ *surface consists exactly of carrier admission, completion-monad visibility, algebra-action exposure, Kleisli-route exposure, universal-property handoff, dense-embedding unit visibility, StreamName–RegSeqRat–DyadicRatCore–Real readback discipline, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No local obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5827.1. The displayed tuple lists every row available to the classifier, so local comparison can inspect only the completion monad, algebra action, Kleisli route, universal-property row, dense-embedding unit route, readback rows, transport, replay, provenance, and local naming.

The monadicity-facing rows are read in order. The monad row T displays the unit and bind schedule, the algebra row A records the Eilenberg–Moore action over that schedule, and the Kleisli row K keeps unit, bind, and reassociated-bind consumers on the same finite route.

The universal and dense rows then bind the comparison surface. The row U supplies extension and uniqueness data, while D supplies the dense source-to-completion unit route used before the comparison is exported.

Finally the readback and structural rows close the NameCert surface. The rows W, R, Q, E give finite windows, regular rational readback, dyadic tolerances, and the terminal Real seal; the rows H, C, P, N transport, replay, source, and name exactly that packet. Since no excluded coordinate occurs, no additional local obligation is available. □

Theorem 4861.3 (CauchyCompletionMonadicity comparison surface)**.** *Every comparison consumer of an accepted* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ *carrier factors through the finite route*

$$T, A, K, U, D \longmapsto W \longmapsto R \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus the completion-monad route, the algebra action, the Kleisli route, the universal-property row, and the dense-embedding unit route are compared only after the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$,

$\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *readback surface has been displayed. The comparison exports no quotient completion equality, selected limit, host equality of completed objects, countable choice, ambient completeness, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the monad and algebra rows. The row T supplies the displayed completion transformer, and A reads its algebra action only as a row over that transformer.

Next attach the Kleisli and universal-property rows. The row K exposes the unit, bind, and reassociated-bind route, while U records the extension and uniqueness ledger for completion-facing consumers.

Now read the dense-embedding unit route D. It displays the source-to-completion image before the comparison reaches any terminal seal, so the route is a visible unit comparison rather than a selected representative.

Finally consume the readback and structural rows. The finite window W, regular readback R, dyadic tolerance ledger Q, and Real seal E precede transport, replay, provenance, and naming through H, C, P, N. Since the carrier contains no coordinate for the excluded objects, the comparison surface cannot export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ packet is generated from a CauchyCompletionMonad route, CauchyCompletionAlgebra action row, CauchyCompletionKleisli route, CompletionUniversalProperty row, MetricCompletionDenseEmbedding unit route, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5827.1, Definition 5827.2, and Definition 5827.3 seed the finite monadicity comparison boundary for the L10 completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadicity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient completeness, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completion-monad visibility, algebra-action exposure, Kleisli-route exposure, universal-property handoff, dense-embedding unit visibility, readback discipline, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionMonadicityUp.

Chapter 4862

A Concrete Naming Certificate for $\mathsf{BorsukUlam}^{\uparrow}$

Following Borsuk and Ulam, the $\mathsf{BorsukUlam}^{\uparrow}$ packet records the antipodal obstruction theorem as finite BEDC NameCert data rather than as a host topological principle. It sits after the degree surface of chapter 3745, the continuous-map rows of chapter 130, the real-name seal of chapter 38, the compact metric source of chapter 129, and the circle boundary model of chapter 58. The packet names the displayed antipodal route consumed by obstruction and degree-facing chapters; it does not select antipodal points, import unrestricted classical degree theory, identify quotient spheres, choose representatives, or appeal to ambient completeness.

Definition 4862.1 (Borsuk-Ulam carrier)**.** *A* $\mathsf{BorsukUlam}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, A, F, D, C, R, H, K, P, N)$$

with the following displayed rows:

1. *S is the compact metric sphere row read through the displayed* $\mathsf{CompactMetric}^{\uparrow}$ *surface and the* $\mathsf{S}^{1\uparrow}$ *boundary model.*
2. *A is the antipodal-pair ledger, exposing only named paired source rows and the finite equality-refusal data attached to them.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the map whose antipodal comparison is being inspected.*
4. *D is the* $\mathsf{BrouwerDegree}^{\uparrow}$ *obstruction row, read only through the displayed degree certificate and never through unrestricted host degree theory.*
5. *C is the* $\mathsf{Real}^{\uparrow}$ *comparison-seal row for the coordinate difference or collapsed real-valued comparison consumed by the obstruction route.*
6. *R is the refusal row excluding selected antipodal points, quotient equality of sphere points, choice, unrestricted classical degree theory, and ambient completeness.*
7. *H records componentwise* hsame *transport for the compact source, antipodal ledger, continuous-map row, degree row, real comparison seal, refusal row, provenance, and local naming.*
8. *K records displayed* Cont *replay from the compact metric source through the antipodal ledger, continuous-map row, degree obstruction, real comparison seal, and refusal row.*
9. *P is the* Pkg *provenance over* $\mathsf{BorsukUlam}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{BrouwerDegree}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{BorsukUlam}^\uparrow}$ *row.*
The classifier compares accepted packets only through $S, A, F, D, C, R, H, K, P, N$. It has no coordinate for a chosen antipodal pair, quotient equality on the sphere, unrestricted classical degree theory, countable choice, or ambient Real completeness.

Lean4 (definition) `BEDC.Derived.BorsukUlamUp.BorsukUlamUp`
Lean4 ✓ `BEDC.Derived.BorsukUlamUp.BorsukUlamTasteGate single carrier alignment`

Theorem 4862.2 (Borsuk-Ulam NameCert obligations)**.** *For every accepted* $\mathsf{BorsukUlam}^\uparrow$ *carrier* $U = (S, A, F, D, C, R, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BorsukUlam}^\uparrow}$ *surface consists exactly of compact metric sphere admission, antipodal-pair ledger exposure, continuous-map readback, Brouwer-degree obstruction routing, Real comparison sealing, refusal of host and quotient shortcuts, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every obstruction-facing consumer must read*

$$S, A, F \longmapsto D, C \longmapsto R, H, K, P, N$$

before treating the packet as a Borsuk-Ulam certificate.

Proof. Project the carrier of Definition 5828.1. The compact source row S, antipodal ledger A, and continuous-map row F are the only rows available before the obstruction is read.

The degree and real-comparison rows D, C are downstream of that source route. The degree row is the displayed $\mathsf{BrouwerDegree}^\uparrow$ certificate, and the real row is the displayed $\mathsf{Real}^\uparrow$ seal for the comparison consumed by the obstruction.

Finally R, H, K, P, N refuse shortcuts, transport the same rows, replay the finite route, source it, and name it locally. Since the carrier has no coordinate for selected antipodal points, quotient equality, unrestricted host degree theory, countable choice, or ambient Real completeness, no consumer can export those objects from the certificate. □

Theorem 4862.3 (Borsuk-Ulam antipodal route)**.** *Every accepted* $\mathsf{BorsukUlam}^\uparrow$ *antipodal-obstruction read factors through the displayed compact metric sphere row, the* $\mathsf{S}^{1\uparrow}$ *boundary model, the antipodal-pair ledger, the* $\mathsf{ContinuousMap}^\uparrow$ *row, the* $\mathsf{BrouwerDegree}^\uparrow$ *obstruction row, the terminal* $\mathsf{Real}^\uparrow$ *comparison seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert*. The route exports no selected antipodal point, unrestricted classical degree theorem, quotient equality of sphere points, choice principle, ambient completeness, Lean verification, or bridge-checked surface.*

Proof. Start with an accepted carrier $U = (S, A, F, D, C, R, H, K, P, N)$. The source read begins at S and A, so the antipodal data is visible only as a finite paired ledger over the displayed compact metric and circle rows.

Read the map through F and then the obstruction through D, C. The $\mathsf{ContinuousMap}^\uparrow$ row supplies the function-facing data, the $\mathsf{BrouwerDegree}^\uparrow$ row supplies the obstruction route, and the $\mathsf{Real}^\uparrow$ row supplies only the comparison seal reached from those displayed rows.

The refusal and structural rows close the route. The row R blocks selected points, quotient equality, unrestricted degree theory, choice, and ambient completeness, while H, K, P, N preserve the same finite certificate under transport, replay, provenance, and local naming. □

Falsifiable prediction: Every accepted $\mathsf{BorsukUlam}^\uparrow$ consumer reads compact metric sphere data, an antipodal-pair ledger, a ContinuousMap row, a BrouwerDegree obstruction row, a Real

comparison seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before it treats the packet as an antipodal obstruction certificate.

Independence witness: brouwer-degree, continuousmap, real, compactmetric, s1: $\mathsf{BorsukUlam}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds compact sphere data, antipodal pairing, continuous-map readback, degree obstruction, real comparison sealing, refusal, transport, replay, provenance, and local naming into one obstruction-facing certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}$.

Constructive story: A $\mathsf{BorsukUlam}^{\uparrow}$ packet is generated from a compact metric sphere row, an S1 boundary model, an antipodal-pair ledger, a ContinuousMap row, a BrouwerDegree obstruction row, a RealUp comparison seal, shortcut refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5828.1, Definition 5828.2, and Definition 5828.3 seed the finite antipodal obstruction route over compact metric, circle, continuous-map, degree, real-seal, transport, replay, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BorsukUlam}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected antipodal points, unrestricted classical degree theory, quotient equality, choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, antipodal ledger exposure, continuous-map readback, Brouwer-degree obstruction routing, Real comparison sealing, transport, replay, provenance, and local naming for BEDC.Derived.BorsukUlamUp.

Chapter 4863

A Concrete Naming Certificate for $\mathsf{DenjoyYoungSaks}^{\uparrow}$

Following Saks and Bishop–Bridges constructive real analysis, the $\mathsf{DenjoyYoungSaks}^{\uparrow}$ packet records the finite boundary at which a real-valued interval map can expose upper and lower Dini-derivative rows without importing the classical almost-everywhere Denjoy–Young–Saks theorem. It sits next to the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ observation window of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet is a finite classification boundary for displayed Dini rows, oscillation windows, regular-rational readback, and terminal Real seals; it is not a measure theorem, an almost-everywhere classifier, or a host-real differentiability principle.

Definition 4863.1 (Denjoy–Young–Saks finite Dini carrier)**.** *A* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the inspected interval row, listing the finitely presented source intervals and endpoint cells on which the local boundary is read.*
2. *F is the function-observation row, recording the finite source and target windows used to compare difference quotients.*
3. *U is the upper Dini row, storing the displayed upper right, upper left, and two-sided upper derivative bounds visible at the inspected windows.*
4. *L is the lower Dini row, storing the corresponding lower right, lower left, and two-sided lower derivative bounds.*
5. *O is the oscillation-window row, recording the finite alternation and stabilization tests used to classify a displayed window as one of the Dini-boundary cases.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule opened by I, F, O and no hidden stream coordinates.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational data extracted from the finite stream windows.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger supporting the difference-quotient comparisons and oscillation bounds.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after the interval, function-observation, Dini, oscillation, stream, readback, and dyadic rows have been exposed.*

10. *H records componentwise* hsame *transport for intervals, function observations, Dini rows, oscillation windows, stream schedules, regular readbacks, dyadic ledgers, Real seals, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from the inspected interval and function rows through U, L, O, S, R, D and into the Real seal E.*

12. *P is the* Pkg *provenance over* $\mathsf{DenjoyYoungSaks}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, U, L, O, S, R, D, E, H, C, P, N$. It has no coordinate for measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, host real order trichotomy, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.DenjoyYoungSaksUp.DenjoyYoungSaksTasteGate single carrier alignment`

Theorem 4863.2 (Denjoy–Young–Saks finite boundary obligations)**.** *For every accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier $Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the inspected interval, function-observation, upper Dini, lower Dini, oscillation-window, stream-schedule, regular-readback, dyadic-ledger, Real-seal, transport, replay, provenance, and local naming rows;*

2. *interval and observation exactness, requiring every Dini comparison to read its source cell from I and its finite function window from F before any derivative row is accepted;*

3. *upper and lower Dini-row exactness, requiring U and L to store only the finite upper and lower derivative bounds justified by the displayed difference-quotient windows;*

4. *oscillation-window classification, requiring O to record the finite alternation, stabilization, and gap tests that separate the visible Dini-boundary cases;*

5. *stream, readback, and dyadic exactness, requiring S, R, D to expose only the finite observations, regular rational readbacks, and dyadic tolerance rows demanded by I, F, U, L, O;*

6. *Real seal nonescape, requiring E to remain downstream of I, F, U, L, O, S, R, D and never to serve as a selected derivative, a host real equality witness, or an almost-everywhere theorem;*

7. *componentwise transport, replay, provenance, and local naming, requiring H, C, P, N to preserve exactly the displayed finite route.*

No $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *obligation is stored outside these rows, and the packet makes no claim that the classical Denjoy–Young–Saks alternatives hold almost everywhere.*

Proof. Carrier admission is projection from Definition 5829.1. The accepted packet displays exactly the inspected interval row I, function-observation row F, upper and lower Dini rows U, L, oscillation row O, stream schedule S, regular readback R, dyadic ledger D, Real seal E, and structural rows H, C, P, N.

Interval and observation exactness follow from the row order. A Dini comparison first reads the source cell in I and the finite function-observation window in F; only then may it inspect the upper row U, lower row L, or oscillation row O attached to that window.

The stream, regular-readback, and dyadic rows are downstream of the same finite windows. The schedule S opens only the observations demanded by I, F, O, the row R records the resulting regular rational readback, and D stores the tolerance comparisons needed for the displayed difference-quotient bounds.

Finally, the Real seal E is terminal for this finite boundary route. The transport row H, replay row C, provenance row P, and local naming row N preserve the same packet, so measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, and ambient completeness cannot become local obligations. □

Theorem 4863.3 (Denjoy–Young–Saks Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{StreamName}^{\uparrow}$ *consumer of an accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier reads the displayed route*

$$I, F, U, L, O, S, R, D, E, H, C, P, N.$$

Consequently the consumer may inspect finite interval cells, function observations, upper and lower Dini rows, oscillation windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal Real seal, componentwise transport, replay, provenance, and local naming. It cannot read a measure structure, an almost-everywhere assertion, a selected derivative, quotient real equality, host real trichotomy, countable choice, or ambient completeness from the packet.

Proof. Project the accepted carrier through Definition 5829.1. Its Real-facing and readback-facing rows are exactly S, R, D, E together with the preceding interval, function, Dini, and oscillation rows I, F, U, L, O and the structural rows H, C, P, N.

The route reaches E only after the finite Dini and oscillation boundary has been displayed. Thus any consumer that asks for a Real seal or regular rational readback must already have passed through the interval cells, function observations, upper and lower Dini rows, oscillation windows, stream schedule, and dyadic tolerance ledger.

Since the carrier has no row for measure, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, or ambient completeness, none of those objects can be read by a downstream consumer. □

Theorem 4863.4 (Denjoy–Young–Saks oscillation-window induction)**.** *For an accepted* $\mathsf{DenjoyYoungSaks}^{\uparrow}$ *carrier* $Y = (I, F, U, L, O, S, R, D, E, H, C, P, N)$*, induction over the finite oscillation-window row* O *preserves the separation between the upper Dini row* U *and the lower Dini row* L*. At every displayed stage the packet remains a finite boundary classifier over the rows of Definition 5829.1; the induction cannot promote the packet to an almost-everywhere measure theorem, cannot select a derivative, and cannot export a host-real differentiability principle.*

Proof. Induct over the displayed list of oscillation windows in O. The empty row has no Dini comparison to transport, so the upper and lower rows remain separated by the carrier projection.

For the step, assume the previously displayed windows preserve the separation of U and L. The next window is admitted only through the oscillation-window classification row in Definition 5829.2, so it may inspect the finite alternation, stabilization, and gap tests attached to that window but cannot rewrite the carrier outside $I, F, U, L, O, S, R, D, E, H, C, P, N$.

The Real-seal nonescape theorem Definition 5829.3 keeps every downstream read behind the same finite route. Thus adjoining the next oscillation window preserves the visible upper/lower Dini separation and leaves measure-null exceptional sets, almost-everywhere validity, selected derivatives, quotient real equality, trichotomy, countable choice, and ambient completeness outside the packet. □

Falsifiable prediction: Every $\mathsf{DenjoyYoungSaks}^{\uparrow}$ Real-facing or readback-facing read factors through finite interval cells, function-observation windows, upper and lower Dini rows, oscillation windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: real, regseqrat, streamname, dyadicratcore: $\mathsf{DenjoyYoungSaks}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries upper and lower Dini rows, oscillation-window classification, regular-rational readback, dyadic tolerance data, and a terminal Real seal in one finite boundary packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}$.

Constructive story: A $\mathsf{DenjoyYoungSaks}^{\uparrow}$ packet is generated from inspected interval cells, function-observation windows, upper and lower Dini rows, oscillation-window classifications, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5829.1, Definition 5829.2, and Definition 5829.3 seed the finite Denjoy–Young–Saks boundary route over Dini rows, oscillation windows, regular-rational readback, dyadic tolerance rows, and terminal Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DenjoyYoungSaks}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.DenjoyYoungSaksUp.DenjoyYoungSaksTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close the classical almost-everywhere Denjoy–Young–Saks theorem, measure-null exceptional sets, selected derivatives, quotient real equality, trichotomy, countable choice, ambient completeness, or bridge checking beyond the carrier-alignment Lean target.

Upgrade path: Obligation closure requires checked carrier admission, Dini-row exactness, oscillation-window classification, stream-readback-dyadic exactness, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.DenjoyYoungSaksUp.

Chapter 4864

A Concrete Naming Certificate for $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ packet records the bounded-sequence subsequence route in the form used by constructive real analysis: finite inspection of a bounded $\mathsf{Real}^{\uparrow}$ sequence, repeated interval refinement, monotone-cofinal subsequence scheduling, regular rational readback, and only then a $\mathsf{Real}^{\uparrow}$ cluster seal. The packet is anchored by the existing $\mathsf{BolzanoWeierstrass}^{\uparrow}$ route of chapter 1254, the sequential compactness naming surface of chapter 2372, the compact metric carrier of chapter 129, finite stream windows from chapter 126, regular rational readback from chapter 301, and the real-name seal of chapter 38. It is a displayed subsequence construction for bounded real sequences, not an open-cover compactness theorem, a quotient equality of real names, an ambient completeness principle, or a choice-selected arbitrary subsequence.

Definition 4864.1 (Constructive Bolzano–Weierstrass carrier)**.** *A* $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, B, I, T, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the bounded* $\mathsf{Real}^{\uparrow}$ *sequence source, read through finite* $\mathsf{StreamName}^{\uparrow}$ *windows and the bounded-source handoff of chapter 1415.*
2. *B is the* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *carrier row, exposing the interval-net and regular-subsequence route without adding a separate host compactness object.*
3. *I is the finite interval-refinement ledger, read through the closed bounded interval net and compact metric rows consumed by the sibling* $\mathsf{BolzanoWeierstrass}^{\uparrow}$ *packet.*
4. *T is the* $\mathsf{SequentialCompact}^{\uparrow}$ *comparison row, recording that the same finite subsequence schedule is the sequential-compactness-facing surface of the construction.*
5. *R is the monotone-cofinal subsequence row, read as a regular Cauchy schedule before any cluster seal is exposed.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the selected finite windows and their dyadic tolerance comparisons.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *cluster seal, reached only after S, B, I, T, R, Q have been displayed.*

8. *H records componentwise* hsame *transport for the bounded sequence, interval ledger, sequential compactness row, subsequence schedule, regular rational readback, and real seal.*
9. *C records displayed* Cont *replay from finite bounded-sequence inspection through interval refinement, subsequence scheduling, RegSeqRat readback, and Real sealing.*
10. *P is the* Pkg *provenance over* $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$, $\mathsf{BolzanoWeierstrass}^{\uparrow}$, $\mathsf{SequentialCompact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, B, I, T, R, Q, E, H, C, P, N$. It has no coordinate for open-cover compactness, quotient real equality, a selected least cluster point, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ConstructiveBolzanoWeierstrassUp.ConstructiveBolzanoWeierstrassTasteGate`
`single carrier alignment`

Theorem 4864.2 (Constructive Bolzano–Weierstrass NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ *carrier*

$$W = (S, B, I, T, R, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}}$ *surface consists exactly of bounded sequence admission through S, Bolzano–Weierstrass route admission through B, finite interval-refinement admission through I, sequential compactness comparison through T, monotone-cofinal subsequence scheduling through R, RegSeqRat readback through Q, RealUp cluster sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 5830.1. The rows $S, B, I, T, R, Q, E, H, C, P, N$ are the only coordinates exposed to a consumer.

The bounded source is read first through S, and the sibling $\mathsf{BolzanoWeierstrass}^{\uparrow}$ row B supplies the interval-net and regular-subsequence route. The interval ledger I keeps that route finite and tied to compact metric inspection rather than open-cover compactness.

The comparison row T then records the sequential compactness view of the same subsequence schedule. Rows R and Q expose the monotone-cofinal indices and regular rational readback before the real seal E can be consumed.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since the carrier contains no further coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 4864.3 (Constructive bounded Real subsequence obligation)**.** *Every* $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ *consumer that reads a bounded* $\mathsf{Real}^{\uparrow}$ *sequence from an accepted carrier must traverse the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{BolzanoWeierstrass}^{\uparrow} \longmapsto \mathsf{SequentialCompact}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exposes finite source windows, interval-refinement rows, a monotone-cofinal subsequence schedule, regular rational readback, and a terminal Real seal; it does not export an arbitrary subsequence selector, quotient real equality, open-cover compactness, or ambient completeness.

Proof. Use Definition 5830.2. It places S and the finite stream windows before the interval-refinement ledger I and before any subsequence schedule is read.

The row B imports the existing Bolzano–Weierstrass naming route as a displayed carrier row, while T records the sequential compactness comparison over the same finite schedule. Neither row adds a host open-cover object or a choice coordinate.

Rows R and Q provide the cofinal subsequence schedule and the regular rational readback. Only after these rows are displayed may E be consumed as a $\mathsf{Real}^{\uparrow}$ cluster seal, so the consumer route is the stated finite subsequence route. □

Theorem 4864.4 (Constructive cluster seal boundary obligation)**.** *For an accepted* ConstructiveBolzanoWeierstrass *carrier* $W = (S, B, I, T, R, Q, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *cluster seal* E *is downstream of the bounded source row, the interval-refinement ledger, the sequential compactness comparison, the monotone-cofinal subsequence schedule, and the RegSeqRat readback. Any consumer of* E *must preserve the same* H, C, P, N *support rows and receives no additional host completeness, quotient equality, or open-cover compactness datum.*

Proof. Start from the bounded subsequence route of Definition 5830.3. It identifies the finite route through source windows, compact metric inspection, the sibling Bolzano–Weierstrass packet, sequential compactness comparison, and regular rational readback.

In the carrier definition the seal row E occurs only after S, B, I, T, R, Q. The support rows H, C, P, N can transport, replay, source, and name that route, but they cannot introduce a new endpoint selector or an ambient completeness principle.

Thus the cluster seal is a boundary object for the displayed constructive route. It is a $\mathsf{Real}^{\uparrow}$ seal over the named finite data, not a quotient-real equality witness, open-cover compactness theorem, or hidden host-level limit. □

Theorem 4864.5 (Constructive finite subsequence envelope)**.** *For an accepted* $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ *carrier* $W = (S, B, I, T, R, Q, E, H, C, P, N)$*, the monotone-cofinal subsequence row* R *is determined by the finite* $\mathsf{StreamName}^{\uparrow}$ *windows in* S*, the interval-refinement ledger rows in* I*, the* $\mathsf{SequentialCompact}^{\uparrow}$ *comparison row* T*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q *before the* $\mathsf{Real}^{\uparrow}$ *cluster seal* E *is exposed. Consequently every endpoint consumer reads the same finite envelope and receives no arbitrary subsequence selector, countable-choice schedule, quotient equality, or ambient completeness datum.*

Proof. Use the carrier definition of Definition 5830.1. It places the bounded source windows S, the sibling Bolzano–Weierstrass route B, the interval ledger I, and the sequential compactness comparison row T before the subsequence schedule R and the readback row Q.

The bounded-real-subsequence route of Definition 5830.3 identifies this as a finite route through StreamName windows, compact metric inspection, interval refinement, sequential compactness comparison, and RegSeqRat readback. Thus R is not an independently selected subsequence coordinate; it is the schedule visible through the same finite rows.

The cluster seal boundary of Definition 5830.4 keeps E downstream of S, B, I, T, R, Q and the support rows H, C, P, N. Any endpoint consumer therefore receives the same finite envelope before the seal.

Since the carrier has no row for an arbitrary subsequence selector, countable choice, quotient equality, or ambient completeness, none of those data can be exported by the cluster read. □

Theorem 4864.6 (Constructive Bolzano–Weierstrass selector nonescape)**.** *For an accepted* ConstructiveBolzanoWe *carrier*

$$W = (S, B, I, T, R, Q, E, H, C, P, N),$$

the $\mathsf{Real}^{\uparrow}$ *cluster-seal read* E *is available only through the displayed interval-refinement ledger* I*, the finite subsequence envelope* S, B, I, T, R, Q*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, and the terminal Real seal row* E *together with* H, C, P, N*. No consumer may detach* R *as a hidden selector, replace the route by countable choice, or read a cluster point without the finite interval-refinement and regular-rational rows.*

Proof. Start from the bounded Real subsequence route of Definition 5830.3. It forces every accepted read through finite StreamName windows, compact metric inspection, the sibling Bolzano–Weierstrass route, sequential compactness comparison, RegSeqRat readback, and the Real seal.

Apply the cluster seal boundary theorem Definition 5830.4. The seal row E is downstream of S, B, I, T, R, Q, and the support rows H, C, P, N preserve that route without adding a selected endpoint.

Use the finite subsequence envelope of Definition 5830.5. The subsequence schedule R is determined by the visible source windows, interval ledger, sequential compactness comparison, and regular rational readback before E is exposed.

Thus the selector cannot escape the displayed envelope. A consumer that reads R or E without the interval-refinement, finite envelope, RegSeqRat, and Real-seal rows is no longer reading an accepted $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}$ packet is generated from a bounded RealUp sequence source, the sibling Bolzano–Weierstrass interval route, compact metric inspection, sequential compactness comparison, monotone-cofinal subsequence scheduling, RegSeqRat readback, a RealUp cluster seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5830.1, Definition 5830.2, Definition 5830.3, Definition 5830.4, and Definition 5830.5 seed the Bishop-style bounded Real sequence subsequence route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveBolzanoWeierstrass}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, quotient equality of real names, selected least cluster points, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-refinement exactness, sequential compactness comparison, subsequence scheduling, RegSeqRat readback, Real cluster sealing, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveBolzanoWeierstrassUp.

Chapter 4865

A Concrete Naming Certificate for $\mathsf{UniformlyConvexSpace}^{\uparrow}$

Following Clarkson's uniformly convex Banach-space reading and Bishop–Bridges constructive normed-space practice, the $\mathsf{UniformlyConvexSpace}^{\uparrow}$ packet records a finite modulus-of-convexity surface over the normed-space carrier of chapter 1950. It consumes the $\mathsf{NormedSpace}^{\uparrow}$ row, the real-valued norm and midpoint reads through chapter 38, the metric handoff of chapter 57, and the completion-facing route of chapter 95 and chapter 3413. The packet gives Banach, Hilbert, fixed-point, and convexity consumers a named uniform-convexity certificate without importing host Banach-space equality, selected minimizers, quotient completions, or choice.

Definition 4865.1 (UniformlyConvexSpace carrier)**.** *A* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (N, R, A, M, \Delta, Q, H, T, P, C)$$

with the following displayed rows:

1. *N is the* $\mathsf{NormedSpace}^{\uparrow}$ *row, exposing vector operations, the norm read, and the induced metric only through the normed-space NameCert surface.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *row used by norm values, radius comparisons, midpoint estimates, and positive modulus outputs.*
3. *A is the midpoint row, reading $(x + y)/2$ through the vector addition, scalar action, and real scalar rows already visible in N and R.*
4. *M is the metric handoff row, routing distance and unit-ball comparisons through the* $\mathsf{Met}^{\uparrow}$ *read induced by N.*
5. *Δ is the convexity-modulus row: for each displayed positive separation request it supplies a positive real margin forcing the midpoint norm below the unit bound whenever the two admitted unit vectors are separated by that request.*
6. *Q is the completion-facing row, allowing Cauchy and completion consumers to read the same norm, metric, midpoint, and modulus data without selecting a completed point.*
7. *H records componentwise* hsame *transport for N, R, A, M, Δ, Q and for the local structural rows.*
8. *T records displayed* Cont *replay from a uniform-convexity request through $N, R, A, M, \Delta, Q, H, P, C$.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformlyConvexSpace}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. C is the local $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for host Banach-space equality, strict-convexity as a pointwise substitute, quotient completion, selected closest points, compactness, reflexivity, or a choice principle.

Theorem 4865.2 (UniformlyConvexSpace NameCert obligations)**.** *For every accepted* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *carrier* $U = (N, R, A, M, \Delta, Q, H, T, P, C)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, normed-space visibility, real-valued norm and midpoint readback, metric separation handoff, positive modulus admission, midpoint contraction under the displayed separation request, completion-facing nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside* $N, R, A, M, \Delta, Q, H, T, P, C$*.*

Lean4 ✓ `BEDC.Derived.UniformlyConvexSpaceUp.UniformlyConvexSpaceTasteGate single carrier alignment`

Proof. Carrier admission is projection from Definition 5831.1. The rows $N, R, A, M, \Delta, Q, H, T, P, C$ are the whole accepted packet.

The normed-space, Real, midpoint, and metric obligations are read first. The row N supplies the normed vector carrier, R supplies real-valued comparisons, A supplies midpoint formation, and M supplies the induced metric separation route.

The uniform-convexity content is isolated in Δ. For a displayed positive separation request, Δ supplies a positive margin and forces the midpoint norm read through A, N, R below the unit bound. Since Q, H, T, P, C only hand off, transport, replay, source, and name the same route, no host Banach-space equality, quotient completion, selected point, compactness, reflexivity, or choice coordinate can enter. □

Theorem 4865.3 (UniformlyConvexSpace modulus convexity route)**.** *Every accepted* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *consumer that asks for uniform convexity factors through*

$$\mathsf{NormedSpace}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{Completion}^{\uparrow}, \mathsf{Cauchy}^{\uparrow} \longmapsto H, T, P, C.$$

The modulus row Δ may be read only after the normed-space carrier, real norm values, midpoint operation, and metric separation row have been displayed. The route exports a finite modulus-of-convexity NameCert surface, not host strict convexity, a selected minimizer, quotient completion equality, compactness, reflexivity, or countable choice.

Proof. Begin with a uniform-convexity request. The normed-space row N supplies the only vector and norm data, while R supplies the real-valued unit-ball and positivity comparisons.

Read midpoint and separation next. The midpoint row A is formed from the displayed operations of N and R, and the metric handoff M reads separation through the induced metric of the same normed-space packet.

Only then can the modulus row Δ answer the request. Its output is tied to the displayed positive separation and midpoint norm route, and the completion-facing row Q sends Cauchy or completion consumers through the same route rather than through a selected completed point.

Finally H, T, P, C transport, replay, source, and name the packet. The excluded host strict-convexity, selected-minimizer, quotient-completion, compactness, reflexivity, and choice objects are absent from the carrier, so the finite modulus route is the whole exported surface. □

Falsifiable prediction: An accepted $\mathsf{UniformlyConvexSpace}^{\uparrow}$ read is refuted if a consumer obtains a uniform-convexity margin without first displaying the $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, midpoint, $\mathsf{Met}^{\uparrow}$, completion-facing, transport, replay, provenance, and local $\mathsf{NameCert}$ rows.

Independence witness: normedspace, real, metric, completion, cauchy: no listed sibling is bijective to $\mathsf{UniformlyConvexSpace}^{\uparrow}$ because the packet jointly carries normed-space data, real norm comparisons, midpoint formation, metric separation, a positive convexity modulus, completion-facing handoff, transport, replay, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformlyConvexSpace}^{\uparrow}$ packet is generated from a NormedSpace row, Real norm-comparison rows, a midpoint row, an induced Metric separation row, a convexity-modulus row, a Completion and Cauchy handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5831.1, Definition 5831.2, and Definition 5831.3 seed the finite modulus-of-convexity route over normed-space, real, metric, completion, and Cauchy rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformlyConvexSpace}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.UniformlyConvexSpaceUp.UniformlyConvexSpaceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host Banach-space equality, strict-convexity substitution, selected minimizers, quotient completions, compactness, reflexivity, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, midpoint formation, metric separation, positive modulus exactness, completion-facing nonescape, and local naming for BEDC.Derived.UniformlyConvexSpaceUp.

Chapter 4866

A Concrete Naming Certificate for $\mathsf{HyperbolicTranslationLength}^{\uparrow}$

Following the classical translation length of a hyperbolic isometry, the $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ packet records the finite invariant-length route visible to the hyperbolic phase geometry of chapter 9463. It consumes the metric-read surface of chapter 3474, the routed geodesic-flow surface of chapter 3856, the additive Busemann cocycle route of chapter 4134, the four-boundary-point comparison of chapter 3948, and the terminal real seal of chapter 38. The packet names stable displacement growth as finite BEDC data; it does not import a host hyperbolic manifold, quotient ideal boundary, selected axis, spectral radius, or global curvature theorem.

Definition 4866.1 (HyperbolicTranslationLength carrier)**.** *A* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, F, B, X, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row, exposing displacement reads for the source and its iterated image.*
2. *F is the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *row, recording the finite routed-flow data used to compare iterates along the same visible geodesic route.*
3. *B is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *row, supplying additive boundary-cocycle comparisons for the same displayed endpoints.*
4. *X is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *row, recording the four-boundary-point invariant used to stabilize the length read.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *row used by displacement values, additive cocycle values, cross-ratio reads, and the final nonnegative length seal.*
6. *D is the displacement-growth row, comparing the displayed iterate window through M, F, B, X, R without selecting an infinite orbit or an axis.*
7. *E is the endpoint-stability row, stating that the same boundary data are replayed by the metric, flow, Busemann, and cross-ratio rows.*
8. *H records componentwise* hsame *transport for M, F, B, X, R, D, E and for the local structural rows.*

9. *C records displayed* Cont *replay from a translation-length request through $M, F, B, X, R, D, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host isometry group, selected invariant axis, quotient boundary equality, spectral radius, completed hyperbolic manifold, or physical expansion law.

Lean4 ✓ `BEDC.Derived.HyperbolicTranslationLengthUp.HyperbolicTranslationLengthTasteGate single carrier alignment`

Theorem 4866.2 (HyperbolicTranslationLength NameCert obligations)**.** *For every accepted* HyperbolicTranslation *carrier $L = (M, F, B, X, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$ *surface consists exactly of metric displacement visibility, geodesic-flow routing, Busemann additivity, cross-ratio stabilization, real-valued length sealing, displacement-growth comparison, endpoint stability, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside $M, F, B, X, R, D, E, H, C, P, N$.*

Proof. Project the carrier of Definition 5832.1. The rows $M, F, B, X, R, D, E, H, C, P, N$ are the whole visible packet.

The geometric route is read first. Metric displacement comes from M, routed iteration from F, additive boundary comparison from B, and four-boundary-point stabilization from X.

The Real and displacement rows then seal the length read. The row R supplies the real-valued comparison surface, while D and E ensure that the same endpoint data are used by the metric, flow, Busemann, and cross-ratio reads.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate names a host isometry group, selected invariant axis, quotient boundary equality, spectral radius, completed manifold, or physical expansion law, the listed obligations exhaust the local surface. □

Theorem 4866.3 (HyperbolicTranslationLength invariant route)**.** *Every accepted* $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ *read factors through*

$$\mathsf{HyperbolicMetric}^{\uparrow}, \mathsf{HyperbolicGeodesicFlow}^{\uparrow}, \mathsf{HyperbolicBusemannCocycle}^{\uparrow}, \mathsf{HyperbolicCrossRatio}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto H, C, P$$

The finite route records displacement growth and boundary stabilization as a real-sealed invariant length, and it exports no host hyperbolic isometry, selected axis, quotient ideal-boundary equality, spectral radius, completed hyperbolic manifold, or cosmological expansion claim.

Proof. Begin with the displacement request. The metric row M supplies finite distance reads, and the geodesic-flow row F keeps the iterated comparison on the same displayed route.

Read boundary stabilization next. The Busemann cocycle row B supplies additive endpoint comparison, while the cross-ratio row X records the four-boundary-point invariant. The endpoint-stability row E requires these boundary reads to describe the same displayed data.

The Real row R and displacement-growth row D seal the invariant length as a finite real-valued read. The structural rows H, C, P, N preserve, replay, source, and name that route, while the excluded host and quotient objects remain absent from the carrier. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ consumer is refuted if it obtains an invariant length without displaying the $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}$ $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, displacement-growth, endpoint-stability, transport, replay, provenance, and local $\mathsf{NameCert}$ rows.

Independence witness: hyperbolicmetric, hyperbolic-geodesic-flow, hyperbolic-busemann-cocycle, hyperbolic-cross-ratio, real: no listed sibling is bijective to $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ because the packet jointly carries metric displacement, routed flow, additive boundary cocycle, cross-ratio stabilization, Real sealing, displacement-growth comparison, endpoint stability, transport, replay, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicTranslationLength}^{\uparrow}$ packet is generated from HyperbolicMetric displacement rows, HyperbolicGeodesicFlow routing rows, HyperbolicBusemannCocycle additive boundary rows, HyperbolicCrossRatio stabilization rows, Real sealing rows, displacement-growth and endpoint-stability rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5832.1, Definition 5832.2, and Definition 5832.3 seed the finite invariant-length packet over metric, flow, Busemann, cross-ratio, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicTranslationLength}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host hyperbolic isometries, selected axes, quotient ideal-boundary equality, spectral radii, completed hyperbolic manifolds, physical expansion laws, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, displacement visibility, flow routing, Busemann additivity, cross-ratio stabilization, Real length sealing, endpoint stability, and local naming for BEDC.Derived.HyperbolicTranslationLengthUp.

Chapter 4867

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$

Following Bishop and Bridges on constructive real completion, the $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ packet records the finite envelope that carries a regular Cauchy rational readback into the terminal Real naming seal. It sits after the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational sequence interface of chapter 301, the terminal real-name packet of chapter 38, and the completion route of chapter 1506. The packet is a finite NameCert envelope for the handoff itself; it does not assert that the host real line is complete.

Definition 4867.1 (Regular Cauchy completion envelope carrier)**.** *A* $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ *carrier is a finite packet*

$$E = (W, D, R, E_R, M, T, C, P, N)$$

where W *is the displayed* $\mathsf{StreamName}^{\uparrow}$ *window row,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row,* E_R *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row,* M *is the* $\mathsf{MetricCompletion}^{\uparrow}$ *route row,* T *records componentwise* $\mathsf{BHist/hsame}$ *transport,* C *records displayed* Cont *replay,* P *is* Pkg *provenance over the displayed rows, and* N *is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}$ *row. A consumer of the carrier receives the completion handoff only through these nine coordinates.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCompletionEnvelopeUp.RegularCauchyCompletionEnvelopeTasteGate`
`single carrier alignment`

Theorem 4867.2 (Regular Cauchy completion envelope obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompletion}$ *carrier*

$$E = (W, D, R, E_R, M, T, C, P, N),$$

the local NameCert surface consists exactly of window admission, tolerance admission, regular readback admission, terminal Real-seal admission, metric-completion route admission, transport stability, continuation replay, provenance preservation, and local naming preservation for the displayed packet. No quotient stream equality, selected representative, countable choice schedule, host completeness principle, or $\mathsf{Real}^{\uparrow}$ *completeness theorem is a coordinate of this surface.*

Proof. Project the carrier of Definition 5833.1. Its only data rows are $W, D, R, E_R, M, T, C, P, N$, so the local NameCert can inspect exactly those displayed coordinates.

The first four rows bind the finite observation, dyadic tolerance, regular rational readback, and terminal Real seal. The metric-completion row M is therefore read as a route row over those data, not as an ambient completeness object.

The structural rows T, C, P, N preserve the same packet under componentwise transport, continuation replay, provenance, and local naming. Since the carrier has no slot for quotient stream equality, selected representatives, countable choice, host completeness, or Real completeness, none of those objects can be exported by the obligation surface. □

Theorem 4867.3 (Regular Cauchy completion envelope Real handoff)**.** *Every Real-facing completion consumer of an accepted* $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ *carrier reads the terminal handoff through the ordered finite route*

$$W, D, R, E_R, M, T, C, P, N.$$

In particular, the consumer reaches the terminal $\mathsf{Real}^{\uparrow}$ *seal only after the* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback have been displayed inside the same envelope.*

Proof. Start from Definition 5833.2. It makes $W, D, R, E_R, M, T, C, P, N$ the entire accepted surface of the envelope.

Read the Real-facing route through W, D, R, E_R. The StreamName windows expose the finite observations, the dyadic ledger records the tolerance budget, the regular-rational row gives the readback, and the terminal row gives the Real seal inside the same packet.

The completion route M and the structural rows T, C, P, N only replay and name that displayed handoff. Thus the consumer cannot replace the handoff by quotient stream equality, a chosen representative, countable choice, host completeness, or a completeness theorem for $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5833.1, Definition 5833.2, and Definition 5833.3 seed the finite regular-Cauchy-to-Real completion envelope.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegularCauchyCompletionEnvelopeUp.RegularCauchyCompletionEnvelopeTasteGate\_single\_car`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, host completeness, or $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, row order, Real handoff, transport stability, replay stability, provenance preservation, and local NameCert preservation for BEDC.Derived.RegularCauchyCompletionEnvelopeUp.

Constructive story: A $\mathsf{RegularCauchyCompletionEnvelope}^{\uparrow}$ packet is generated from StreamName windows, DyadicRatCore tolerance, RegSeqRat readback, terminal Real seal, metric-completion routing, transport, replay, provenance, and local NameCert rows.

Chapter 4868

A Concrete Naming Certificate for $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$

Following Bishop–Bridges constructive locatedness, the $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ packet records the finite interval-selection surface that can be read by Cauchy and Real interval consumers without selecting an endpoint or importing compactness. It sits over the located interval carrier of chapter 394, the rational cell ledger of chapter 354, the optional dyadic refinement rows of chapter 306, the endpoint observation windows of chapter 126, the regular rational readbacks of chapter 301, and the terminal Real seal of chapter 38. The packet names a finite route through displayed interval data; it does not assert endpoint choice, Heine–Borel compactness, trichotomy, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4868.1 (WeaklyLocatedIntervalSelection carrier)**.** *A* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, Q, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the source interval and its locatedness probes.*
2. *Q is the* $\mathsf{RationalInterval}^{\uparrow}$ *cell ledger listing the rational subinterval cells visible to the selection route.*
3. *D is an optional* $\mathsf{DyadicInterval}^{\uparrow}$ *refinement row; when present, it refines cells already displayed by Q and adds no independent selector.*
4. *W is the paired* $\mathsf{StreamName}^{\uparrow}$ *endpoint-window row through which finite endpoint observations are read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same endpoint windows and rational cells.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by any Real-facing endpoint or interval consumer.*
7. *H records componentwise* hsame *transport for $L, Q, D, W, R, E, C, P, N$.*
8. *C records displayed* Cont *replay from located interval probes through rational cells, optional dyadic refinements, endpoint windows, regular readbacks, and the Real seal.*
9. *P is* Pkg *provenance over* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$*,* $\mathsf{LocatedInterval}^{\uparrow}$*,* $\mathsf{RationalInterval}^{\uparrow}$*,* $\mathsf{DyadicInterval}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets componentwise through these ten rows. There is no coordinate for an endpoint selector, an open-cover compactness argument, a trichotomy oracle, quotient equality of Real names, or host Real completeness.

Lean4 ✓ `BEDC.Derived.WeaklyLocatedIntervalSelectionUp.WeaklyLocatedIntervalSelectionTasteGate`
`single carrier alignment`

Theorem 4868.2 (WeaklyLocatedIntervalSelection NameCert obligations)**.** *For every accepted* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ *carrier*

$$S = (L, Q, D, W, R, E, H, C, P, N),$$

the local NameCert surface consists exactly of the following obligations:

1. *carrier admission for the finite* BHist *packet S and its displayed rows;*
2. *located-cell visibility from the* $\mathsf{LocatedInterval}^{\uparrow}$ *row L into the* $\mathsf{RationalInterval}^{\uparrow}$ *ledger Q;*
3. *finite selection-route exactness through the visible rational cells and any displayed* $\mathsf{DyadicInterval}^{\uparrow}$ *refinements D;*
4. *endpoint-window transport from Q, D into the* $\mathsf{StreamName}^{\uparrow}$ *windows W and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks R;*
5. *Real-seal nonescape, requiring every Real-facing read to pass through the displayed* $\mathsf{Real}^{\uparrow}$ *row E;*
6. *componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance preservation, and local* NameCert *preservation through H, C, P, N.*

No endpoint choice principle, Heine–Borel theorem, trichotomy principle, quotient equality of Real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem is an obligation or an output of this surface.*

Theorem 4868.3 (Weakly located interval selection route exhaustion)**.** *For every accepted* WeaklyLocatedIntervalSe
carrier

$$S = (L, Q, D, W, R, E, H, C, P, N),$$

every endpoint, interval, or Real-facing consumer factors through the displayed rows $L, Q, D, W, R, E, H, C, P, N$. Such a consumer cannot read endpoint choice, Heine–Borel compactness, trichotomy, quotient equality of Real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows of Definition 5834.1. The located interval source is L, the rational cell ledger is Q, and the optional dyadic refinement row is D.

Located-cell visibility therefore passes through L, Q, D. Endpoint or interval reads have no route around these rows because the packet stores no detached endpoint selector or host interval object.

The endpoint windows and regular rational readbacks are then W and R. A Real-facing consumer reaches the seal row E only after those finite windows and readbacks are visible.

Finally H, C, P, N transport, replay, source, and name the same route. Since endpoint choice, Heine–Borel compactness, trichotomy, quotient equality, and ambient completeness are absent from the tuple, the displayed rows exhaust every admitted consumer read. □

Formal verification: FormalStatus(NameCert$_{\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close endpoint choice, Heine–Borel compactness, trichotomy, quotient real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-cell visibility, finite selection-route exactness, endpoint-window transport, Real-seal nonescape, transport and replay stability, provenance exhaustion, and local naming for BEDC.Derived.WeaklyLocatedIntervalSelectionUp.

Constructive story: A WeaklyLocatedIntervalSelection$^{\uparrow}$ packet is generated from LocatedInterval rows, RationalInterval cell ledgers, optional DyadicInterval refinements, StreamName endpoint windows, RegSeqRat readbacks, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 4869

A Concrete Naming Certificate for $\mathsf{UniformInverseModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{UniformInverseModulus}^{\uparrow}$ packet records compact inverse-modulus extraction from uniform homeomorphism data as finite NameCert data. It reads the homeomorphism and inverse-graph surface of chapter 1815, the compact finite-net rows of chapter 129, the graph and pointwise continuity rows of chapter 130, the exported modulus interface of chapter 369, the metric-source and metric-target rows of chapter 4230, and the terminal real-name seal of chapter 38. The chapter names the finite compact route that turns displayed inverse radii into a uniform inverse modulus; it is not a selected inverse function, host function equality, quotient real equality, open-cover compactness, or ambient completeness principle.

Definition 4869.1 (Uniform inverse modulus carrier)**.** *A* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A)$$

with the following displayed rows:

1. *X is the compact source row, exposing the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net data used to cover the compact domain of the homeomorphism.*
2. *Y is the target metric row, including the distance ledger into which the inverse-modulus estimate is reported.*
3. *F is the* $\mathsf{UniformHomeomorphism}^{\uparrow}$ *graph row from X to Y, carrying the forward graph and the homeomorphism naming data.*
4. *G is the inverse graph row displayed by the same homeomorphism packet.*
5. *E is the positive precision row, read through* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoint histories when the consumer presents a real tolerance.*
6. *N is the finite net row of the compact source at the scale needed for the inverse-modulus extraction.*
7. *R lists the pointwise inverse radius rows attached to the centers named by N.*
8. *M is the finite radius-fold row, obtained only by folding the finite family R over the index list of N.*
9. *T is the target estimate row, combining inverse-graph exactness, finite-net coverage, the folded radius row, and the target metric triangle ledger.*

10. *H records componentwise* hsame *transport for the compact source, target metric, homeomorphism graph, inverse graph, precision, finite-net, inverse-radius, radius-fold, and estimate rows.*
11. *C records the displayed* Cont *replay route from compact homeomorphism data and pointwise inverse radii to the* $\mathsf{UniformModulus}^{\uparrow}$ *export.*
12. *P records* Pkg *provenance over* $\mathsf{UniformInverseModulus}^{\uparrow}$, $\mathsf{UniformHomeomorphism}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, RegSeqRat$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *A is the local* $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$ *row.*

The carrier exposes only displayed compact finite nets, graph rows, inverse-graph rows, endpoint readbacks, finite radius rows, componentwise transport, replay, provenance, and local naming. It has no coordinate for a host inverse function, selected inverse choice, host function equality, quotient real equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.UniformInverseModulusUp.UniformInverseModulusTasteGate single carrier alignment`

Theorem 4869.2 (Uniform inverse modulus obligations)**.** *For every accepted* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A),$$

the local $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the compact source, target metric, homeomorphism graph, inverse graph, precision, finite-net, inverse-radius, radius-fold, target-estimate, transport, replay, provenance, and local naming rows;*
2. *inverse-graph exactness, requiring every inverse read to pass through the displayed row G attached to the homeomorphism row F;*
3. *compact finite-net handoff, requiring the compact source row X and precision row E to determine the finite row N before any inverse radius is folded;*
4. *finite radius fold, requiring M to be obtained only by folding the pointwise inverse radius rows R over the finite indices of N;*
5. *target estimate, requiring T to combine compact-net coverage, inverse-graph exactness, folded-radius data, and the target metric ledger;*
6. *transport, replay, and provenance, requiring H, C, P, A to source the same displayed route componentwise;*
7. *nonescape, requiring the packet to export no host inverse function, selected inverse choice, host function equality, quotient real equality, trichotomy, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 5835.1. The projection exposes exactly the rows $X, Y, F, G, E, N, R, M, T, H$ so carrier admission and row inventory are finite.

The inverse read is confined to G. Since G is listed as a row of the same homeomorphism packet that supplies F, inverse-graph exactness is consumed as displayed graph data rather than as host function equality or selected inverse choice.

The compact handoff reads X and E before radius data. These rows determine the finite net N, and the pointwise inverse radii in R are indexed only by the centers listed by N.

Fold R over that finite index list to obtain M. The target estimate row T then combines the compact-net coverage, inverse-graph exactness, folded radius, and target metric triangle route. Finally H, C, P, A transport, replay, source, and name the same route, so no excluded equality, choice, open-cover, trichotomy, or completeness coordinate is introduced. □

Theorem 4869.3 (Uniform inverse modulus compact handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *export from an accepted* $\mathsf{UniformInverseModulus}^{\uparrow}$ *carrier*

$$I = (X, Y, F, G, E, N, R, M, T, H, C, P, A)$$

factors through the displayed finite route

$$X, F, G, E \longmapsto N, R \longmapsto M, T \longmapsto H, C, P, A.$$

Thus the inverse-modulus export is a compact finite-net and radius-fold handoff. It exports no host function equality, selected inverse choice, quotient real equality, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from a $\mathsf{UniformModulus}^{\uparrow}$ consumer of I. By Definition 5835.2, the consumer must read the compact source, homeomorphism graph, inverse graph, and precision rows before the finite-net row is available.

The only finite-net row is N, and the only pointwise inverse-radius inventory is R. Hence the consumer reaches the exported modulus row M only after the finite fold over R indexed by N.

The target estimate T is downstream of that fold. It cannot be read as a host inverse function or as quotient equality of inverse values, because the carrier contains only displayed graph and metric-ledger rows.

Finally the structural rows H, C, P, A transport, replay, source, and name the same compact route. Since the carrier contains no coordinate for selected inverse choice, trichotomy, open-cover compactness, or ambient completeness, the export factors through exactly the displayed finite-net and radius-fold handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformInverseModulus}^{\uparrow}$ packet is generated from UniformHomeomorphism graph and inverse-graph rows, CompactMetric finite-net rows, ContinuousMap pointwise inverse-radius rows, UniformModulus export rows, MetricSpace distance ledgers, RealUp and RegSeqRat endpoint readbacks, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$, seed)

Scope closed: Definition 5835.1, Definition 5835.2, and Definition 5835.3 seed the finite compact route from displayed inverse radii to a UniformModulus consumer.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformInverseModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient completeness, host inverse functions, selected inverse choice, quotient real equality, trichotomy, open-cover compactness, Lean verification, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, inverse-graph exactness, compact finite-net handoff, finite radius fold, target estimate, transport, replay, provenance, and local naming for BEDC.Derived.UniformInverseModulusUp.

Chapter 4870

A Concrete Naming Certificate for $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$

Following Bishop and Bridges on constructive real intervals, the $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ packet records a bounded interval together with the finite nested-window route used by Real and completion consumers. It sits over the dyadic rational arithmetic of chapter 291, the stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names a bounded interval principle for displayed nested windows; it does not assert open-cover compactness, a global supremum operator, quotient real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4870.1 (BoundedCompleteRealInterval carrier)**.** *A* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the bounded interval row. It records the inspected lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint names, the boundedness witness visible to the packet, and the local containment predicate for interval windows.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger. It records the dyadic rational cuts used to compare successive windows and to certify the displayed diameter bound.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row. It lists exactly the finite endpoint and interval observations that may be inspected by the nested-window route.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same dyadic cuts and stream windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by every Real-facing extraction from B, D, W, R.*
6. *H records componentwise* hsame *transport for bounded interval rows, dyadic ledgers, stream windows, regular rational readbacks, Real seals, replay, provenance, and the local name.*
7. *C records displayed* Cont *replay from a nested-window request through B, D, W, R, E.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, D, W, R, E, H, C, P, N$. There is no coordinate for open-cover compactness, a selected supremum, host interval equality, quotient equality of Real names, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BoundedCompleteRealIntervalUp.TasteGate.BoundedCompleteRealIntervalTasteGate single carrier alignment`

Theorem 4870.2 (BoundedCompleteRealInterval NameCert obligations)**.** *For every accepted* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier*

$$I = (B, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the bounded interval row, dyadic endpoint ledger, stream windows, regular rational readback, Real seal, componentwise transport, continuation replay, package provenance, and local naming row;*
2. *bounded-window visibility, requiring every interval read to pass through the displayed lower-upper row B and its local containment predicate;*
3. *dyadic diameter discipline, requiring D to witness the inspected endpoint comparisons and the shrinking-width estimates used by the extraction route;*
4. *stream-readback exactness, requiring W and R to reuse the same finite endpoint observations and dyadic cuts rather than selecting a second Real representative;*
5. *Real-seal nonescape, requiring every Real-facing output to pass through E after B, D, W, R have all been projected;*
6. *structural preservation through H, C, P, N, with no exported row for open-cover compactness, selected suprema, host interval equality, quotient Real equality, countable choice, trichotomy, or ambient Real completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 5836.1. The accepted packet displays exactly the bounded interval row, dyadic endpoint ledger, stream windows, regular rational readback, Real seal, and the structural rows.

Bounded-window visibility is forced by B. A consumer can inspect only the finite lower-upper interval data and the local containment predicate already present in the carrier.

Dyadic diameter discipline is forced by D. The endpoint comparisons and shrinking-width estimates used by the packet are the only numerical rows available to the later stream and readback rows.

The rows W and R are downstream of the same dyadic ledger. They schedule finite observations and repack them as regular rational readback without replacing the bounded interval by a second Real representative.

Finally, E, H, C, P, N close the route. The Real seal is reached only after B, D, W, R, while transport, replay, provenance, and naming preserve the same displayed data. Since no excluded coordinate occurs in the carrier, the local NameCert surface has exactly the listed obligations. □

Theorem 4870.3 (BoundedCompleteRealInterval nested-interval extraction)**.** *Let $I = (B, D, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ *carrier. Every nested-window extraction exported by I factors through the finite route*

$$B \longmapsto D \longmapsto W \longmapsto R \longmapsto E$$

before it can inspect transport, replay, provenance, or local naming rows. The extracted Real-facing read is therefore determined by the bounded interval row, the dyadic diameter ledger, the stream windows, and the regular rational readback visible in the packet.

Proof. Begin with a nested-window extraction from I. The carrier gives no source row before the bounded interval row B, so the lower-upper interval data and local containment predicate are inspected first.

The extraction then projects the dyadic ledger D. This fixes the endpoint comparisons and diameter estimates available to the finite window schedule.

Next the extraction passes through W and R. The stream row exposes only the finite endpoint observations allowed by B, D, and the regular rational row repacks those same observations as the readback consumed by the Real seal.

Only after this route has been displayed can the extraction reach E. The remaining rows H, C, P, N preserve, replay, source, and name the same route, so the exported extraction is exhausted by the displayed bounded-window data. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5836.1, Definition 5836.2, and Definition 5836.3 seed the bounded real interval packet over dyadic endpoint ledgers, StreamName windows, RegSeqRat readbacks, and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedCompleteRealInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, a global supremum operator, host interval equality, quotient real equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-window visibility, dyadic diameter discipline, stream-readback exactness, Real-seal nonescape, structural preservation, and nested-window extraction for BEDC.Derived.BoundedCompleteRealIntervalUp.

Constructive story: A $\mathsf{BoundedCompleteRealInterval}^{\uparrow}$ packet is generated from a bounded Real interval row, a DyadicRatCore endpoint ledger, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 4871

A Concrete Naming Certificate for $\mathsf{FreeGroup}^{\uparrow}$

Following Magnus–Karrass–Solitar, *Combinatorial Group Theory*, the $\mathsf{FreeGroup}^{\uparrow}$ packet records the free group on a displayed finite generator interface as reduced signed words rather than as a quotient presentation. It sits after the word carrier of chapter 36, the unit and multiplication rows of chapter 40, and the inverse-bearing algebra surface of chapter 41. The packet gives the algebra hierarchy a finite reduced-word constructor; it does not identify a quotient group, complete a presentation theory, select normal forms outside the carrier, or assert host equality of generated subgroups.

Definition 4871.1 (Free group reduced-word carrier)**.** *A* $\mathsf{FreeGroup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (G, S, W, R, M, I, U, J, H, C, P, N)$$

with the following displayed rows:

1. *G is the finite generator row, exposing exactly the accepted generator names.*
2. *S is the signed-generator row, whose entries are pairs of a generator from G and an orientation bit.*
3. *W is the finite word row over S, read through the list discipline of chapter 36.*
4. *R is the reduction row that deletes adjacent inverse pairs until no adjacent cancellation cell remains.*
5. *M is the multiplication row, concatenating two word rows and then applying R.*
6. *I is the inverse row, reversing the word row and flipping each orientation bit.*
7. *U is the unit row, naming the empty reduced word.*
8. *J is the handoff row into the* $\mathsf{Group}^{\uparrow}$ *surface of chapter 41.*
9. *H records componentwise* hsame *transport for $G, S, W, R, M, I, U, J, C, P, N$.*
10. *C records displayed* Cont *replay from generator inspection through signed words, reduction, multiplication, inverse, unit, and the group handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{FreeGroup}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*,* $\mathsf{Monoid}^{\uparrow}$*,* $\mathsf{Group}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

12. N is the local $\mathsf{NameCert}_{\mathsf{FreeGroup}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these twelve rows. It has no coordinate for quotient presentation equality, a host word problem solver, a chosen normal form outside R, unrestricted subgroup generation, or completed presentation theory.

Lean4 ✓ `BEDC.Derived.FreeGroupUp.taste gate`

Theorem 4871.2 (Free group NameCert obligations)**.** *For every accepted* $\mathsf{FreeGroup}^{\uparrow}$ *packet* $F = (G, S, W, R, M, I, U, J, H, C, P, N)$*, carrier admission, signed-generator classification, reduced-word stability, multiplication replay, inverse replay, unit exposure, and the group-facing handoff are all exhausted by the displayed rows of Definition 5837.1. Any* $\mathsf{Group}^{\uparrow}$ *consumer receives the finite reduced-word packet through J after $G, S, W, R, M, I, U, H, C, P, N$ have been displayed.*

Proof. Project the carrier. The generator row G, signed row S, word row W, reduction row R, multiplication row M, inverse row I, unit row U, and handoff row J are the only algebraic coordinates available to a consumer.

The list-facing part is finite because W is read through chapter 36. The monoid-facing operation is not a host concatenation oracle: it is the displayed concatenate-then-reduce row M, with U as the empty reduced word and R as the cancellation boundary.

The inverse-bearing group-facing part is then exposed through I and J. Componentwise transport H, replay C, provenance P, and local naming N preserve the same rows under accepted package reads, so no quotient presentation equality, selected external normal form, subgroup-generation closure, or completed presentation theory can enter the certificate. □

Theorem 4871.3 (Free group reduction normal-form stability)**.** *In an accepted* $\mathsf{FreeGroup}^{\uparrow}$ *packet, the reduction row R is stable under the finite cancellation scan: if a signed word has no adjacent inverse pair after R has acted, then concatenating with the unit row U, applying the inverse row I twice, or transporting the word componentwise by H leaves the same reduced-word row for every downstream read.*

Proof. Begin with the finite word row W and reduction row R. The scan performed by R inspects adjacent signed-generator cells in the displayed list and deletes only inverse neighbours, so the result is a word row whose remaining adjacent cells are not inverse pairs.

The unit cases use the empty word row U. Concatenating a reduced word with U on either side introduces no signed-generator cell, hence no new adjacent inverse pair, and the reduction row returns the same displayed word row.

For inverse stability, I reverses the word and flips orientations. Applying I twice restores the original finite list of signed cells, and R has no new cancellation cell to remove beyond those already absent after the first reduction.

Finally, H transports the generator, signed-word, reduction, multiplication, inverse, and unit rows componentwise. Therefore normal-form stability is a property of the displayed reduced-word rows, not of an external quotient or a selected host representative. □

Theorem 4871.4 (Free group universal word handoff)**.** *Every group-facing consumer of an accepted* $\mathsf{FreeGroup}^{\uparrow}$ *packet must receive the handoff*

$$G, S, W, R, M, I, U, H, C, P, N \longrightarrow J$$

before it reads the target $\mathsf{Group}^{\uparrow}$ *surface. The handoff says that a generator interpretation is consumed as finite signed words, reduction, multiplication, inverse, unit, transport, replay, provenance, and local naming; it does not export quotient group equality, a completed presentation, or a proof that every external group element has a selected word representative.*

Proof. Read the handoff row J through the carrier. Its source rows are exactly the generator row, signed-generator row, word row, reduction row, multiplication row, inverse row, unit row, transport row, replay row, provenance row, and local name row.

Use the obligation surface of Definition 5837.2. Any $\mathsf{Group}^{\uparrow}$ consumer has already passed through the list, monoid, and group sibling surfaces named in the chapter introduction, so the only algebra it sees is the finite reduced-word packet.

The normal-form stability of Definition 5837.3 supplies the cancellation boundary needed by the handoff. Since the packet has no quotient-presentation coordinate, no selected external representative, and no completed presentation row, the universal read is a finite word handoff into $\mathsf{Group}^{\uparrow}$ rather than a claim of quotient group equality. □

Falsifiable prediction: Every accepted $\mathsf{FreeGroup}^{\uparrow}$ consumer that reaches the $\mathsf{Group}^{\uparrow}$ handoff first exposes finite generator rows, signed-generator rows, finite list-word rows, cancellation reduction, multiplication, inverse, unit, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: list, monoid, group: $\mathsf{FreeGroup}^{\uparrow}$ is not bijective to any listed sibling because it binds signed-generator words and cancellation reduction before exposing the inverse-bearing group handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{FreeGroup}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FreeGroup}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5837.1, Definition 5837.2, Definition 5837.3, and Definition 5837.4 seed the finite reduced-word constructor and its group-facing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FreeGroup}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient group equality, completed presentation theory, subgroup generation, selected external normal forms, host word-problem decidability, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, signed-generator classification, cancellation reduction stability, multiplication and inverse replay, unit stability, and group handoff exactness for BEDC.Derived.FreeGroupUp.

Constructive story: A $\mathsf{FreeGroup}^{\uparrow}$ packet is generated from finite generator rows, signed-generator rows, finite list-word rows, cancellation reduction rows, multiplication, inverse, unit, a group-facing handoff, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 4872

A Concrete Naming Certificate for $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$

Following Riemann and Bishop–Bridges constructive integration, the $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ packet records the finite route by which a continuous function on a located closed real interval receives a Darboux/Riemann integrability certificate. It consumes the pointwise-modulus surface of chapter 59, the tag-bearing finite interval route of chapter 4296, the Darboux upper/lower boundary of chapter 1880, the integrability carrier of chapter 1960, the weak located interval selector of chapter 5834, and the real-name seal of chapter 38. The packet gives integration consumers a finite NameCert surface for continuous functions without importing measure integration, open-cover compactness, quotient equality of real names, selected limiting values, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 4872.1 (Continuous Riemann integrability carrier)**.** *A* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (F, T, D, J, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{Continuous}^{\uparrow}$ *row exposing the pointwise modulus and graph-stability data of the integrand over the displayed interval source.*
2. *T is the* $\mathsf{TaggedRealPartition}^{\uparrow}$ *row naming the finite partition cells, tag containment, window reads, regular readbacks, and terminal real seals used for integration.*
3. *D is the* $\mathsf{DarbouxSum}^{\uparrow}$ *row carrying lower and upper finite sums over the same displayed partition route.*
4. *J is the* $\mathsf{RiemannIntegrable}^{\uparrow}$ *handoff row, read only after the Darboux gap row has been displayed.*
5. *W is the* $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$ *row that exposes located cells and endpoint windows for the closed interval source.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family opened for interval endpoints, partition tags, and pointwise modulus reads.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family attached to the same finite windows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after F, T, D, J, W, S, R have been displayed.*

9. *H records componentwise* hsame *transport for the continuous row, tagged partition, Darboux rows, integrability handoff, weak interval selector, window and readback rows, real seal, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from pointwise modulus requests through located cells, finite tagged partitions, Darboux lower/upper rows, the integrability handoff, and the terminal real seal.*

11. *P is the* Pkg *provenance over* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{TaggedRealPartition}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegrable}^{\uparrow}$, $\mathsf{WeaklyLocatedIntervalSelection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, T, D, J, W, S, R, E, H, C, P, N$. It has no coordinate for full integration theory, measure integration, open-cover compactness, quotient equality, selected limits, or ambient real completeness.

Theorem 4872.2 (Continuous Riemann integrability NameCert obligations)**.** *For every accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier*

$$I = (F, T, D, J, W, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the finite* BHist *packet and the displayed rows $F, T, D, J, W, S, R, E, H, C, P, N$;*

2. *interval-source visibility through the weakly located interval row W and its located cell, endpoint-window, and regular-readback route;*

3. *pointwise modulus exposure through the continuous-function row F, with every modulus read tied to displayed interval cells and finite windows;*

4. *finite tagged partition coverage through T, including cell containment, tag containment, and the same* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows;*

5. *Darboux gap control through D, read as finite lower and upper sums over the displayed tagged partition route;*

6. *integrability handoff through J, allowed only after the Darboux gap row and partition coverage rows are visible;*

7. *Real-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

No full integration theory, measure integration, open-cover compactness, quotient equality of real names, selected limiting value, Lean verification, or bridge checking is an obligation or output of this packet.

Proof. Carrier admission is the projection of Definition 5838.1. The accepted packet displays the continuous row, tagged partition, Darboux row, integrability handoff, weak interval selector, window family, regular readback, real seal, transport, replay, provenance, and local name.

The interval and modulus rows are read first. The row W supplies located cells and endpoint windows, while F supplies pointwise modulus data only over those displayed cells and windows.

The finite partition route is then exposed by T. Tags and endpoints are read through S and R, so the integration-facing partition is a finite BEDC object rather than a host partition or a selected representative family.

The Darboux and integrability rows are downstream. The row D computes lower and upper finite sums over the displayed partition route, and J exports integrability evidence only after that gap control is visible.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since the carrier has no coordinate for the excluded analytic objects, the listed rows exhaust the local NameCert surface. □

Theorem 4872.3 (Continuous Riemann integrability Darboux handoff)**.** *Every integration-facing consumer of an accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier factors through the finite partition and Darboux rows*

$$W, F \longmapsto T, S, R \longmapsto D \longmapsto J \longmapsto E, H, C, P, N.$$

Consequently the consumer receives a finite located-cell, pointwise-modulus, tagged-partition, lower/upper Darboux, integrability-handoff, and Real-seal route rather than quotient reals, host equality, choice-selected witnesses, or ambient Real completeness.

Proof. Begin with an integration-facing read. The weak interval selector W and continuous row F force the request through located cells, endpoint windows, and pointwise modulus rows before any partition or sum row can be inspected.

Next read the tagged partition route T, S, R. The finite cells and tags are displayed together with their StreamName windows and RegSeqRat readbacks, so later rows cannot detach the partition from the interval source.

The Darboux row D is then read as lower and upper finite sums over those displayed cells and tags. The integrability row J is therefore a handoff from finite Darboux gap control, not from a quotient real or host equality judgment.

The terminal seal and structural rows E, H, C, P, N preserve that route. No excluded object is stored in the carrier, so every consumer factors through the displayed finite partition and Darboux rows. □

Theorem 4872.4 (Continuous Riemann integrability uniform-modulus handoff)**.** *Every accepted* $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ *carrier whose continuous row factors through a displayed uniform-modulus or composed-modulus route passes the Darboux gap and* $\mathsf{RiemannIntegrable}^{\uparrow}$ *handoff through the finite chain*

$$\mathsf{Continuous}^{\uparrow},\ \mathsf{UniformContinuityComposition}^{\uparrow},\ \mathsf{TaggedRealPartition}^{\uparrow},\ \mathsf{DarbouxSum}^{\uparrow},\ \mathsf{RiemannIntegrable}^{\uparrow},\ \mathsf{StreamNar}$$

The handoff therefore reads composed modulus data before the Darboux row and exports no host integral selector, quotient function equality, open-cover compactness argument, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 5838.1. The displayed rows are the continuous row F, tagged partition row T, Darboux row D, Riemann-integrable handoff J, weak interval selector W, StreamName windows S, RegSeqRat readbacks R, Real seal E, transport, replay, provenance, and local naming rows.

Use Definition 5838.2 for row exhaustion. When the continuous row is supplied by a uniform-modulus or composed-modulus route, the only admitted modulus source is the displayed $\mathsf{Continuous}^{\uparrow}$ row together with the $\mathsf{UniformContinuityComposition}^{\uparrow}$ composed-modulus handoff of chapter 3891.

Now apply Definition 5838.3. The tagged partition, Darboux lower and upper sums, and integrability row must be read after the same StreamName windows, RegSeqRat readbacks, and terminal Real seal, so the composed-modulus source cannot bypass the finite Darboux route.

Since the carrier stores no host integral selector, quotient function equality, open-cover compactness proof, or ambient completeness object, the listed finite rows are the whole uniform-modulus handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}$.

Constructive story: A $\mathsf{ContinuousRiemannIntegrability}^{\uparrow}$ packet is generated from a Continuous row, TaggedRealPartition row, DarbouxSum row, RiemannIntegrable handoff row, WeaklyLocatedIntervalSelection row, StreamName windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5838.1, Definition 5838.2, Definition 5838.3, and Definition 5838.4 seed the finite Darboux/Riemann integrability route for continuous functions on located closed real intervals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContinuousRiemannIntegrability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full integration theory, measure integration, open-cover compactness, quotient equality, selected limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-source visibility, pointwise modulus exposure, finite tagged partition coverage, Darboux gap control, integrability handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ContinuousRiemannIntegrabilityUp.

Chapter 4873

A Concrete Naming Certificate for $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy approximations, the $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ packet binds Cauchy mesh refinement, cofinal dyadic mesh selection, and diagonal Real mesh budgets into one finite common-refinement route. It sits over the two-request refinement carrier of chapter 3832, the cofinal dyadic selector of chapter 2254, the diagonal mesh-budget surface of chapter 618, and the terminal real-name seal of chapter 38. The packet gives Real-completeness consumers a finite cofinal mesh handoff without quotient streams, selected limits, countable choice, host real equality, or ambient completeness as an extra row.

Definition 4873.1 (Regular Cauchy mesh cofinality carrier)**.** *A* $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, R, D, B, S, A, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{CauchyMeshRefinement}^{\uparrow}$ *row exposing source Cauchy requests, two displayed dyadic meshes, and their common finite refinement.*
2. *R is the* $\mathsf{CofinalDyadicMesh}^{\uparrow}$ *row refining the incoming observation request to a dyadic mesh window.*
3. *D is the* $\mathsf{RealDiagonalMeshBudget}^{\uparrow}$ *row listing the inspected diagonal indices, selected windows, dyadic tolerances, and aggregation ledger.*
4. *B is the shared budget row aligning the request precision of Q, the cofinal selector depth of R, and the diagonal finite mesh budget of D.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family opened by the shared budget.*
6. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family over the same windows, with all dyadic tolerances read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, R, D, B, S, A have been displayed.*
8. *H records componentwise* hsame *transport for the refinement row, cofinal selector row, diagonal budget row, shared budget, window and readback rows, seal row, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from an observation request through*

$$Q, R, D \longmapsto B \longmapsto S \longmapsto A \longmapsto E.$$

10. *P is the* Pkg *provenance over* RegularCauchyMeshCofinality$^{\uparrow}$, CauchyMeshRefinement$^{\uparrow}$, CofinalDyadicMesh$^{\uparrow}$, RealDiagonalMeshBudget$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{RegularCauchyMeshCofinality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, R, D, B, S, A, E, H, C, P, N$. It has no coordinate for quotient streams, hidden subnets, selected limits, countable-choice schedules, host real equality, trichotomy, or ambient Real completeness.

Theorem 4873.2 (Regular Cauchy mesh cofinality NameCert obligations)**.** *For every accepted* RegularCauchyMeshCofinality$^{\uparrow}$ *carrier*

$$K = (Q, R, D, B, S, A, E, H, C, P, N),$$

the local NameCert$_{\text{RegularCauchyMeshCofinality}^{\uparrow}}$ *surface consists exactly of carrier admission, Cauchy mesh-refinement exposure through Q, cofinal dyadic mesh exposure through R, Real diagonal mesh-budget exposure through D, shared precision and mesh-budget alignment through B, finite* StreamName$^{\uparrow}$ *window exposure through S,* RegSeqRat$^{\uparrow}$ *readback and* DyadicRatCore$^{\uparrow}$ *tolerance visibility through A, terminal* Real$^{\uparrow}$ *seal admission through E, componentwise transport through H, route replay through C, provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 5839.1. The accepted packet displays exactly the Cauchy refinement, cofinal selector, diagonal budget, shared budget, windows, readbacks, seal, transports, replay, provenance, and local name.

The three mesh sources are read before any Real-facing seal. The row Q displays the common refinement of source Cauchy meshes, R displays the cofinal dyadic selector for the observation request, and D displays the finite diagonal mesh budget.

The shared row B aligns these sources. It is the only place where the precision request, cofinal selector depth, and diagonal inspected indices meet, so the window row S and regular readback row A inherit one finite route.

The seal and structural rows E, H, C, P, N preserve that route. Since the carrier has no coordinate for the excluded completion objects, the listed rows exhaust the local certificate surface. □

Theorem 4873.3 (Regular Cauchy mesh cofinality Real-completeness handoff)**.** *Every Real-completeness or diagonal-limit consumer of an accepted* RegularCauchyMeshCofinality$^{\uparrow}$ *carrier receives its seal-facing data only through the cofinal finite route*

$$Q, R, D \longmapsto B \longmapsto S \longmapsto A \longmapsto E, H, C, P, N.$$

Thus the consumer factors through Cauchy mesh refinement, cofinal dyadic mesh selection, Real diagonal mesh budgeting, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, and the RealUp seal before any completion-facing conclusion is exported.

Proof. Start from a Real-completeness consumer request. The packet first exposes Q, so the two source Cauchy requests and their common refinement are finite displayed data.

The request then passes through R and D. The cofinal dyadic selector supplies a finite mesh window, while the diagonal mesh-budget row supplies the finite inspected indices and dyadic tolerance ledger.

The budget row B is the common meeting point. It forces the StreamName windows S and RegSeqRat readbacks A to use the same finite refinement and the same dyadic tolerance rows.

Only after this route is displayed may the Real seal E be read. Transport, replay, provenance, and local naming preserve the route, and the excluded quotient or choice-based completion objects are absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyMeshCofinality}^{\uparrow}$ packet is generated from CauchyMeshRefinement, CofinalDyadicMesh, RealDiagonalMeshBudget, a shared precision and mesh-budget row, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5839.1, Definition 5839.2, and Definition 5839.3 seed the finite cofinal common-refinement mesh route used by Real-completeness and diagonal-limit consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyMeshCofinality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, hidden subnets, selected limits, countable choice, host real equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy mesh-refinement exposure, cofinal dyadic mesh exposure, Real diagonal mesh-budget exposure, shared-budget alignment, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance visibility, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyMeshCofinalityUp.

Chapter 4874

A Concrete Naming Certificate for LocatedCauchyFilterBasis$^{\uparrow}$

Following Bishop and Bridges, the LocatedCauchyFilterBasis$^{\uparrow}$ packet names the finite located-basis interface used by the L10 Real and Completion route before the data are promoted to a located Cauchy filter. It refines the basis-generator surface of chapter 1501 and the located filter route of chapter 1661; its finite reads pass through chapter 126, chapter 301, chapter 291, and finally the downstream seal boundary of chapter 38. The chapter isolates the basis-level located witness, not a completed filter, quotient Cauchy name, selected real, or ambient completeness principle.

Definition 4874.1 (Located Cauchy filter basis carrier)**.** *A* LocatedCauchyFilterBasis$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, L, S, R, D, W, T, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* CauchyFilterBasis$^{\uparrow}$ *row naming the finite basis elements and their common-refinement witnesses.*
2. *L is the located-basis request row. It records the displayed dyadic ball request and the basis element that is asserted to meet it.*
3. *S is the* StreamName$^{\uparrow}$ *finite-window row attached to the same located request.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the windows in S.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger for the requested ball, inclusion comparison, and refinement radius.*
6. *W is the finite witness row that the selected basis element meets the requested located ball after S, R, D have been replayed.*
7. *T is the tail-refinement row sending the located basis witness to the filter-level route of* LocatedCauchyFilter$^{\uparrow}$.
8. *E is the downstream* Real$^{\uparrow}$ *seal boundary, reachable only after the basis, located request, finite windows, readback, tolerance, witness, and tail-refinement rows have been consumed.*
9. *H records componentwise* hsame *transport for all displayed rows.*
10. *C records displayed* Cont *replay from a located basis request through $B, L, S, R, D, W, T, E, H, P, N$.*
11. *P is the* Pkg *provenance over* LocatedCauchyFilterBasis$^{\uparrow}$, CauchyFilterBasis$^{\uparrow}$, LocatedCauchyFilter$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterBasis}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for completed filters, quotient stream equality, selected representatives, countable choice, trichotomy, host real equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterBasisUp.LocatedCauchyFilterBasisTasteGate single carrier alignment`

Theorem 4874.2 (Located Cauchy filter basis NameCert obligations)**.** *For every accepted* LocatedCauchyFilterBasis *carrier* $K = (B, L, S, R, D, W, T, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterBasis}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the finite basis row, located request row, stream windows, regular rational readback, dyadic tolerance ledger, located witness, tail-refinement handoff, seal boundary, transport, continuation, provenance, and local naming row;*
2. *located basis classification, requiring two accepted reads to agree precisely when their displayed requests admit a common basis refinement after H transports the B, L, S, R, D, W rows;*
3. *finite-window replay, requiring the located request to inspect only the windows in S before the readback row R and tolerance ledger D are available;*
4. *witness exactness, requiring W to show that the displayed basis element meets the requested dyadic ball using only the finite rows S, R, D;*
5. *tail refinement, requiring T to hand the located basis witness to the* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *route before any real-facing seal can be read;*
6. *nonescape, excluding completed filters, quotient streams, selected representatives, countable choice, trichotomy, host real equality, and* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterBasisUp.LocatedCauchyFilterBasisCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 5840.1. The visible rows are exactly the finite basis data, located request, stream windows, rational readback, dyadic ledger, witness, tail refinement, seal boundary, transport, replay, provenance, and name.

The dependency anchors are the basis carrier of chapter 1501 and the located filter consumer of chapter 1661. The finite observations, rational readbacks, tolerance ledgers, and terminal seal are read through chapter 126, chapter 301, chapter 291, and chapter 38.

Classifier comparison is componentwise. Transport by H moves the basis row, located request, window row, readback row, tolerance ledger, and witness row to a common finite comparison surface, while C replays the same order.

The located witness is finite. A request first reads S, then R, then D, and only then may W certify that the displayed basis element meets the requested dyadic ball.

The tail-refinement row T is the only route to $\mathsf{LocatedCauchyFilter}^{\uparrow}$, and E is downstream from that route. Hence P and N cannot export completed filters, quotient streams, selected representatives, choice, trichotomy, host real equality, or real completeness. □

Theorem 4874.3 (Located Cauchy filter basis tail refinement)**.** *Let* $K = (B, L, S, R, D, W, T, E, H, C, P, N)$ *be an accepted* $\mathsf{LocatedCauchyFilterBasis}^{\uparrow}$ *carrier. Every located basis read factors through the finite route*

$$B, L \longmapsto S \longmapsto R \longmapsto D \longmapsto W \longmapsto T.$$

The row T then exposes the same witness as a filter-level located tail request for $\mathsf{LocatedCauchyFilter}^{\uparrow}$*, with no bypass around the* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, or* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger.*

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterBasisUp.LocatedCauchyFilterBasisCarrier tail refinement`

Proof. Start with a located basis read. The rows B and L fix the displayed basis element and the dyadic ball request; neither row contains a sequence readback or a filter-level located-tail witness by itself.

Replay the continuation row C. The request reaches the finite window row S, then the regular rational readback row R, and then the dyadic tolerance ledger D.

Only after those finite rows have been consumed can W certify the located hit. The row T repackages that same finite witness for the $\mathsf{LocatedCauchyFilter}^{\uparrow}$ route, so the handoff cannot skip the StreamName, RegSeqRat, or DyadicRatCore ledgers. □

Theorem 4874.4 (Located Cauchy filter basis Real seal handoff)**.** *For every accepted* $\mathsf{LocatedCauchyFilterBasis}^{\uparrow}$ *carrier* $K = (B, L, S, R, D, W, T, E, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$*-facing read exposed by* P *factors through the tail-refinement row* T *and then through the seal boundary* E*. Equivalently, the only real-facing route visible in the packet is*

$$B, L, S, R, D, W \longmapsto T \longmapsto E \longmapsto H, C, P, N.$$

Thus the Real seal is downstream of the located basis witness and cannot be read from basis elements, windows, rational readbacks, or dyadic tolerances alone.

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterBasisUp.LocatedCauchyFilterBasisCarrier real seal handoff`

Proof. Project the seal boundary row. The carrier lists E after the finite basis route and after the tail-refinement row T, so the seal is not a coordinate of B, L, S, R, D, or W.

Replay the route by C. A real-facing request must first consume the basis row, located request, window row, readback row, tolerance ledger, and located witness, and must then pass through T.

Transport by H preserves the same dependency order under classifier comparison. The provenance and local naming rows therefore record a downstream Real seal handoff rather than a selected limit, quotient equality, host real equality, or completeness witness. □

Theorem 4874.5 (Located Cauchy filter basis nonescape)**.** *An accepted* $\mathsf{LocatedCauchyFilterBasis}^{\uparrow}$ *packet cannot export any consumer route that reaches outside the finite rows*

$$B, L, S, R, D, W, T, E, H, C, P, N.$$

In particular, any consumer asking for a completed filter, quotient Cauchy name, selected representative, countable-choice schedule, trichotomy decision, host real equality, or ambient completeness proof is refused by the carrier and by the local $\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterBasis}^{\uparrow}}$ *obligations.*

Lean4 ✓ `BEDC.Derived.LocatedCauchyFilterBasisUp.LocatedCauchyFilterBasisRealNonescape`

Proof. Inspect the carrier rows of Definition 5840.1. They include only finite BHist data, hsame transport, Cont replay, dyadic tolerance ledgers, StreamName windows, RegSeqRat readbacks, the located basis witness, the LocatedCauchyFilter tail route, and the Real seal boundary.

The obligation surface of Definition 5840.2 is exhaustive. Every accepted consumer must pass through those listed rows, and no obligation names a hidden completed filter, quotient stream, selected representative, choice schedule, trichotomy decision, host equality, or completeness proof.

The tail and seal theorems keep the downstream routes ordered. Since T and E are reached only after the finite located basis witness is replayed, the packet has no escape path around its displayed finite data. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterBasis}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterBasis}\uparrow}, \mathsf{seed})$

Scope closed: Definition 5840.1, Definition 5840.2, Definition 5840.3, Definition 5840.4, and Definition 5840.5 seed the located finite-basis interface between CauchyFilterBasis, LocatedCauchyFilter, StreamName, RegSeqRat, DyadicRatCore, and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCauchyFilterBasis}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed filters, quotient Cauchy names, selected representatives, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Lean closure requires carrier admission, the located basis obligation surface, tail refinement, Real seal handoff, and nonescape for BEDC.Derived.LocatedCauchyFilterBasisUp.

Constructive story: The construction starts from a CauchyFilterBasis row, reads a located dyadic request through StreamName windows, RegSeqRat readbacks, and DyadicRatCore ledgers, packages the finite witness as a LocatedCauchyFilter tail route, and treats Real access only as downstream seal provenance.

Chapter 4875

A Concrete Naming Certificate for $\mathsf{OneSidedLimit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{OneSidedLimit}^{\uparrow}$ packet records the left- and right-hand real-limit interface as finite BEDC data. It sits next to the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ observation schedule of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet names only displayed side-tagged approach windows, regular rational reads, dyadic tolerance rows, transport, replay, provenance, and a terminal Real seal; it does not import two-sided completeness, host real equality, quotient streams, trichotomy, or a selected limiting point.

Definition 4875.1 (One-sided limit carrier)**.** *A* $\mathsf{OneSidedLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, L, W, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the approach-anchor row, naming the source point or endpoint cell at which the one-sided read is taken.*
2. *L is the side classifier row, with each visible approach window tagged as left-hand or right-hand before any limiting seal is inspected.*
3. *W is the finite approach-window row, listing only windows compatible with the tag in L and the anchor in A.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule opened by the side-tagged windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational data observed on S.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the displayed one-sided comparisons.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from A, L, W, S, R, D.*
8. *H records componentwise* hsame *transport for the anchor, side classifier, windows, stream schedule, regular readback, dyadic ledger, Real seal, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from the side-tagged approach windows through the stream, readback, dyadic, and Real-seal rows.*
10. *P is the* Pkg *provenance over* $\mathsf{OneSidedLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $A, L, W, S, R, D, E, H, C, P, N$. It has no coordinate for a two-sided completion theorem, quotient real equality, host order trichotomy, countable choice, or a selected limit outside the named side-tagged windows.

Lean4 ✓ `BEDC.Derived.OneSidedLimitUp.OneSidedLimitTasteGate single carrier alignment`

Theorem 4875.2 (One-sided limit NameCert obligations)**.** *For every accepted* $\mathsf{OneSidedLimit}^{\uparrow}$ *carrier $K = (A, L, W, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the approach anchor, side classifier, approach windows, stream schedule, regular readback, dyadic ledger, Real seal, transport, replay, provenance, and local naming rows;*
2. *side classifier stability, requiring each transported window to retain its left-hand or right-hand tag before a readback row is consumed;*
3. *dyadic tolerance ledger exactness, requiring D to expose only the tolerance rows demanded by the side-tagged windows in W;*
4. $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, requiring S and R to read only the finite observations selected by A, L, W;*
5. *Real seal nonescape, requiring E to remain downstream of A, L, W, S, R, D and never to serve as a two-sided completeness witness or host real equality row;*
6. *componentwise transport, replay, provenance, and local naming through H, C, P, N.*

No $\mathsf{OneSidedLimit}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 5841.1. The accepted packet displays the approach anchor A, side classifier L, finite approach windows W, stream schedule S, regular readback R, dyadic ledger D, Real seal E, and structural rows H, C, P, N.

Side classifier stability is componentwise. A transported window may be read only with the left-hand or right-hand tag already recorded in L, and the replay row C keeps the same tag attached while the stream and regular-rational rows are inspected.

The tolerance and readback rows are downstream of the same finite windows. The ledger D records the dyadic comparisons demanded by W, the schedule S opens only those observations, and R records the regular rational readback.

Finally, the Real seal E is terminal for the route. Since the carrier contains no row for two-sided completeness, quotient real equality, host order trichotomy, countable choice, or a selected limit outside the displayed windows, those objects cannot become local obligations. □

Theorem 4875.3 (One-sided limit Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{OneSidedLimit}^{\uparrow}$ *packet reads the proposed one-sided limit only through the displayed finite route*

$$A, L, W, S, R, D, E, H, C, P, N.$$

Consequently the handoff to $\mathsf{Real}^{\uparrow}$ *is available only after the approach anchor, side classifier, finite approach windows, StreamName schedule, RegSeqRat readback, and DyadicRatCore tolerance ledger have been exposed. The handoff exports no two-sided completeness theorem, quotient stream equality, host real equality, order trichotomy, countable choice principle, or selected limiting point.*

Proof. Project the accepted carrier through Definition 5841.1. Its Real-facing row is the single terminal coordinate E, and the only route to E passes through A, L, W, S, R, D and the structural rows H, C, P, N.

The finite approach windows determine the side of approach before readback begins. Thus a consumer that asks for a Real seal must already have read the side classifier, the compatible windows, the stream schedule, the regular rational row, and the dyadic tolerance ledger.

The remaining coordinates transport and name the same route. Because no carrier row stores a two-sided completion principle, quotient equality, host equality, trichotomy, choice, or an independent selected limit, the Real-seal handoff cannot export any of those objects. □

Falsifiable prediction: Every $\mathsf{OneSidedLimit}^{\uparrow}$ Real-facing read factors through an approach anchor, a left/right side classifier, finite approach windows, a StreamName schedule, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: real, regseqrat, streamname, dyadicratcore: $\mathsf{OneSidedLimit}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a side classifier, finite approach windows, scheduled regular-rational readback, dyadic tolerance data, and a terminal Real seal in one one-sided packet.

Closure status for $\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{OneSidedLimit}^{\uparrow}$ packet is generated from an approach anchor, a left/right side classifier, finite approach windows, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 5841.1, Definition 5841.2, and Definition 5841.3 seed the finite one-sided real-limit route through side-tagged approach windows and terminal Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OneSidedLimit}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.OneSidedLimitUp.OneSidedLimitTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close two-sided real completeness, quotient stream equality, host real equality, trichotomy, countable choice, selected limits outside the displayed windows, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, side classifier stability, dyadic tolerance exactness, StreamName and RegSeqRat readback, Real seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.OneSidedLimitUp.

Chapter 4876

A Concrete Naming Certificate for $\mathsf{BertrandSeriesTest}^{\uparrow}$

Following Bertrand's logarithmic refinement of ratio-type convergence tests and Bishop–Bridges constructive real-series practice, the $\mathsf{BertrandSeriesTest}^{\uparrow}$ packet records the finite second-order quotient-defect route that turns displayed positive-series tail data into a regular Cauchy comparison handoff. It sits beside the neighboring quotient-defect surfaces of chapter 1719, chapter 2113, and chapter 2130, refines the ratio and comparison routes of chapter 1461 and chapter 1459, and exports endpoints only through the dyadic, stream, regular-rational, and Real seals of chapter 291, chapter 126, chapter 301, and chapter 38. The packet names finite Bertrand-test evidence only through inspected source windows, adjacent quotient windows, a logarithmic defect ledger, dyadic domination, comparison-test routing, regular rational readback, and terminal Real sealing; it is not host summability, quotient series equality, selected sums, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Definition 4876.1 (Bertrand series test carrier)**.** *A* $\mathsf{BertrandSeriesTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, Q, L, D, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source real-series row, exposing only positive-term windows, partial-sum windows, and tail-threshold requests used by the current convergence test.*
2. *Q is the adjacent quotient-window row, recording the inspected neighboring-term quotients on the same displayed tail window.*
3. *L is the logarithmic defect ledger, storing the finite index, logarithmic scale, rational margin, and second-order defect rows used by the Bertrand comparison.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *domination ledger, converting the displayed logarithmic defect and margin rows into a finite majorant or minorant comparison.*
5. *T is the* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *handoff row that consumes S, Q, L, D before any convergence conclusion is exposed.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the source, quotient, logarithmic defect, domination, and comparison rows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached only after the comparison handoff and stream windows have been displayed.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for endpoint-facing consumers.*
