Next apply Theorem 33.162 to the transported classifier witness. This leaves the two possible public branches at the normalized endpoints.

In the absent branch, the exactness data gives $\mathsf{hsame}(u, \mathsf{e})$ and $\mathsf{hsame}(u', \mathsf{e})$. Any presentation $\mathsf{hsame}(u, \mathsf{E0}(t))$ or $\mathsf{hsame}(u', \mathsf{E0}(t))$ composes with the corresponding empty presentation and contradicts E0-versus-empty generated-history no-confusion.

In the present branch, exactness exposes payloads $x, y : \mathsf{BHist}$ with $\mathsf{hsame}(u, \mathsf{E1}(x))$ and $\mathsf{hsame}(u', \mathsf{E1}(y))$. Any zero-tag presentation at either endpoint composes with the corresponding one-tag presentation and contradicts zero-versus-one generated-history no-confusion.

Since the branch analysis covers every transported normalized classifier witness, both normalized endpoints reject every malformed zero-tag tail. □

Lean4 ✓ BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier composite normalized zero endpoint exclusion

Theorem 33.251 (Tagged option composite image classifier normalized public endpoint shape certificate)**.** *Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source, intermediate, and target carriers, let $\sim_S$, $\sim_T$, and $\sim_U$ be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$, $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$, and $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$. Assume $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$, $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$, and $\mathsf{TaggedOptionSou}$). For final endpoints $m, m' : \mathsf{BHist}$ and normalized endpoints $u, u' : \mathsf{BHist}$, if

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u'),$$

then the normalized public endpoint shape certificate consists of the following two fields.

1. *Either*
   - *(a)* $\mathsf{hsame}(u, \mathsf{e}) \wedge \mathsf{hsame}(u', \mathsf{e})$*;*
   - *(b)* $\neg\exists x, y : \mathsf{BHist}.\ U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y))$*;*
   - *(c) there exist $k, k' : \mathsf{BHist}$ such that*
     - *i.* $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$*;*
     - *ii.* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u')$*;*
     - *iii.* $\mathsf{hsame}(k, \mathsf{e}) \wedge \mathsf{hsame}(k', \mathsf{e})$*;*
     - *iv.* $\neg\exists p, q : \mathsf{BHist}.\ T(p) \wedge T(q) \wedge \mathsf{hsame}(k, \mathsf{E1}(p)) \wedge \mathsf{hsame}(k', \mathsf{E1}(q))$.

   or there exist $x, y, k, k', p, q, a, b : \mathsf{BHist}$ such that
   - *(a)* $U(x)$, $U(y)$, $\mathsf{hsame}(u, \mathsf{E1}(x))$, $\mathsf{hsame}(u', \mathsf{E1}(y))$, *and* $x \sim_U y$*;*
   - *(b)* $\neg\mathsf{hsame}(u, \mathsf{e})$ *and* $\neg\mathsf{hsame}(u', \mathsf{e})$*;*

(c) $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$;

(d) $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u')$;

(e) $T(p)$, $T(q)$, $U(\epsilon.\mathsf{map}(p))$, *and* $U(\epsilon.\mathsf{map}(q))$;

(f) $\mathsf{hsame}(k, \mathsf{E1}(p))$, $\mathsf{hsame}(k', \mathsf{E1}(q))$, $\mathsf{hsame}(x, \epsilon.\mathsf{map}(p))$, *and* $\mathsf{hsame}(y, \epsilon.\mathsf{map}(q))$;

(g) $S(a)$, $S(b)$, $a \sim_S b$, $T(\delta.\mathsf{map}(a))$, *and* $T(\delta.\mathsf{map}(b))$;

(h) $\mathsf{hsame}(p, \delta.\mathsf{map}(a))$ *and* $\mathsf{hsame}(q, \delta.\mathsf{map}(b))$;

(i) $p \sim_T q$;

(j) *for all* $x', y' : \mathsf{BHist}$, *if* $U(x')$, $U(y')$, $\mathsf{hsame}(u, \mathsf{E1}(x'))$, *and* $\mathsf{hsame}(u', \mathsf{E1}(y'))$, *then* $\mathsf{hsame}(x, x') \wedge \mathsf{hsame}(y, y') \wedge x' \sim_U y'$;

(k) *for every* $x_L : \mathsf{BHist}$, *if* $U(x_L)$ *and* $\mathsf{hsame}(u, \mathsf{E1}(x_L))$, *then* $\mathsf{hsame}(x, x_L)$ *and* $x_L \sim_U y$;

(l) *for every* $y_R : \mathsf{BHist}$, *if* $U(y_R)$ *and* $\mathsf{hsame}(u', \mathsf{E1}(y_R))$, *then* $\mathsf{hsame}(y, y_R)$ *and* $x \sim_U y_R$.

2. *For every* $t : \mathsf{BHist}$,

$$(\mathsf{hsame}(u, \mathsf{E0}(t)) \to \bot) \wedge (\mathsf{hsame}(u', \mathsf{E0}(t)) \to \bot).$$

Proof. First apply Theorem 33.249 to the displayed composite witness, endpoint normalization witnesses, descent data, preservation fields, stability field, certificates, and compatibility fields. This gives the factored absent-or-present public readback completion at (u, u').

For the malformed zero-tag field, transport the composite classifier from (m, m') to (u, u'). Apply Theorem 33.204 to the composite witness and the two normalization witnesses.

Apply Theorem 33.162 to the transported classifier witness. In the absent branch, the exactness data gives $\mathsf{hsame}(u, \mathsf{e})$ and $\mathsf{hsame}(u', \mathsf{e})$; any presentation $\mathsf{hsame}(u, \mathsf{E0}(t))$ or $\mathsf{hsame}(u', \mathsf{E0}(t))$ contradicts $\mathsf{E0}$-versus-empty generated-history no-confusion.

In the present branch, exactness exposes payloads $x, y : \mathsf{BHist}$ with $\mathsf{hsame}(u, \mathsf{E1}(x))$ and $\mathsf{hsame}(u', \mathsf{E1}(y))$. Any zero-tag presentation at either endpoint contradicts zero-versus-one generated-history no-confusion. Pair the zero-tag exclusion with the public readback completion field. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier composite normalized public endpoint shape certificate`

Theorem 33.252 (Tagged option composite image classifier normalized absent intermediate constructor exclusion)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized functorial* OptionUp *absent public factorization with intermediate constructor exclusion; the BEDC source is* BHist *with two composable descent maps; the carrier and image classifier are* TaggedOptionPayloadDescentImageCarrier *and* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are endpoint* hsame *transport, map-relation composition factorization, empty-branch preservation, and empty-versus-nonempty constructor no-confusion; the ledger is the normalized absent public pair together with constructor-normal intermediate endpoints; the core theorem is absent intermediate constructor exclusion; exactness says each intermediate endpoint rejects every nonempty generated-history presentation; the standard bridge is* none *normalized public readback; and the status is* ProofTarget.

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$, $\sim_T$, *and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for the second descent:

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Write $\epsilon \circ \delta$ for the descent certificate whose map field is $a \mapsto \epsilon.\mathsf{map}(\delta.\mathsf{map}(a))$ and whose respects field sends $r : a \sim_S b$ to $\epsilon.\mathsf{respects}(\delta.\mathsf{respects}(r))$. Define

$$\rho_{\epsilon\circ\delta}(a, Sa) = \rho_\epsilon(\delta.\mathsf{map}(a), \rho_\delta(a, Sa)).$$

Let $\mathsf{cert}_S : \mathsf{NameCert}(S, \sim_S)$, $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$, *and* $\mathsf{cert}_U : \mathsf{NameCert}(U, \sim_U)$. *Assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$, $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$, *and* TaggedOptionSou). *For final endpoints $m, m' : \mathsf{BHist}$ and normalized endpoints $u, u' : \mathsf{BHist}$, if*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_{\epsilon\circ\delta}(S, U, \rho_{\epsilon\circ\delta}; m, m')$$

and

$$\mathsf{hsame}(m, u) \wedge \mathsf{hsame}(m', u')$$

and

$$\mathsf{hsame}(u, \mathsf{e}) \wedge \mathsf{hsame}(u', \mathsf{e}),$$

then there exist $k, k' : \mathsf{BHist}$ such that

1. $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$;
2. $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u')$;
3. $\mathsf{hsame}(k, \mathsf{e}) \wedge \mathsf{hsame}(k', \mathsf{e})$;
4. *for every $t : \mathsf{BHist}$,* $(\mathsf{hsame}(k, \mathsf{E0}(t)) \to \bot) \wedge (\mathsf{hsame}(k, \mathsf{E1}(t)) \to \bot)$;
5. *for every $t : \mathsf{BHist}$,* $(\mathsf{hsame}(k', \mathsf{E0}(t)) \to \bot) \wedge (\mathsf{hsame}(k', \mathsf{E1}(t)) \to \bot)$.

Proof. First apply Theorem 33.240 to the composite image-classifier witness, the endpoint normalizations, the displayed descent, preservation, stability, certificate, compatibility data, and the two absent normalized presentations. This supplies intermediate endpoints k, k', the δ image-classifier factor, the two ϵ map-relation witnesses, the intermediate absent presentations $\mathsf{hsame}(k, \mathsf{e})$ and $\mathsf{hsame}(k', \mathsf{e})$, and the excluded simultaneous visible intermediate pair.

For the left endpoint, fix $t : \mathsf{BHist}$. A presentation $\mathsf{hsame}(k, \mathsf{E0}(t))$ composes with $\mathsf{hsame}(k, \mathsf{e})$ to identify e with $\mathsf{E0}(t)$, contradicting empty-versus-zero generated-history no-confusion. A presentation $\mathsf{hsame}(k, \mathsf{E1}(t))$ composes with the same empty presentation to identify e with $\mathsf{E1}(t)$, contradicting empty-versus-one generated-history no-confusion.

For the right endpoint, fix $t : \mathsf{BHist}$. A presentation $\mathsf{hsame}(k', \mathsf{E0}(t))$ composes with $\mathsf{hsame}(k', \mathsf{e})$ to identify e with $\mathsf{E0}(t)$, contradicting empty-versus-zero generated-history no-confusion. A presentation $\mathsf{hsame}(k', \mathsf{E1}(t))$ composes with the same empty presentation to identify e with $\mathsf{E1}(t)$, contradicting empty-versus-one generated-history no-confusion.

Package the same k, k' with the retained factorization data, the retained intermediate empty presentations, and the two constructor-exclusion functions. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier composite normalized absent intermediate constructor exclusion`

Theorem 33.253 (Tagged option composite image classifier normalized present intermediate constructor exclusion)**.** *This theorem fits the per-object template as follows: the traditional target is endpoint-normalized functorial* OptionUp *present public factorization with intermediate constructor exclusion; the BEDC source is* BHist *with two composable descent maps; the carrier and image classifier are* TaggedOptionPayloadDescentImageCarrier *and* TaggedOptionPayloadDescentImageClassifier*; the stability obligations are endpoint* hsame *transport, selected visible public factorization, present-branch readback, and empty/zero-versus-one constructor no-confusion; the ledger is the normalized visible public pair together with constructor-normal intermediate endpoints; the core theorem is present intermediate constructor exclusion; exactness says each selected intermediate endpoint rejects empty and zero-tag generated-history presentations; the standard bridge is* some *normalized public readback; and the status is* ProofTarget.

Let the carriers S, T, U, classifiers $\sim_S, \sim_T, \sim_U$, descents δ, ϵ, preservation fields $\rho_\delta, \rho_\epsilon$, endpoint-stability field η_ϵ, certificates $\mathsf{cert}_S, \mathsf{cert}_T, \mathsf{cert}_U$, compatibility fields, endpoints m, m', u, u', and selected visible payloads x, y satisfy exactly the hypotheses of Theorem 33.236. Then there exist $k, k', p, q, a, b : \mathsf{BHist}$ such that

1. *the ten selected visible public factorization clauses of Theorem 33.236 hold for k, k', p, q, a, b;*
2. *for every $t : \mathsf{BHist}$, $(\mathsf{hsame}(k, \mathsf{e}) \to \bot) \wedge (\mathsf{hsame}(k, \mathsf{E0}(t)) \to \bot)$ and $(\mathsf{hsame}(k', \mathsf{e}) \to \bot) \wedge (\mathsf{hsame}(k', \mathsf{E0}(t)) \to \bot)$.*

Proof. Apply Theorem 33.236 to the displayed carrier, classifier, descent, preservation, stability, certificate, compatibility, endpoint, and selected visible payload data. This supplies k, k', p, q, a, b together with the ten selected visible public factorization clauses, in particular $\mathsf{hsame}(k, \mathsf{E1}(p))$ and $\mathsf{hsame}(k', \mathsf{E1}(q))$.

For the left intermediate endpoint, fix $t : \mathsf{BHist}$. A competing presentation $\mathsf{hsame}(k, \mathsf{e})$ composes with $\mathsf{hsame}(k, \mathsf{E1}(p))$ and contradicts empty-versus-one generated-history no-confusion. A competing presentation $\mathsf{hsame}(k, \mathsf{E0}(t))$ composes with $\mathsf{hsame}(k, \mathsf{E1}(p))$ and contradicts zero-versus-one generated-history no-confusion.

For the right intermediate endpoint, the same argument uses $\mathsf{hsame}(k', \mathsf{E1}(q))$. Any presentation $\mathsf{hsame}(k', \mathsf{e})$ contradicts empty-versus-one no-confusion, and any presentation $\mathsf{hsame}(k', \mathsf{E0}(t))$ contradicts zero-versus-one no-confusion.

Package the selected visible public factorization witnesses with these four constructor-exclusion functions for each t. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier composite normalized present intermediate constructor exclusion`

33.25 Tagged option composite factorization intermediate classifier determinacy

Theorem 33.254 (Tagged option composite factorization intermediate classifier)**.** *This theorem fits the ten-field template as follows: the traditional target is functorial* $\mathsf{Option}^{\uparrow}$ *middle determinacy; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is* $\mathsf{TaggedOptionHistoryCarrier}_T$*; the classifier is* $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}$*; the stability obligation is branch preservation plus middle endpoint classifier construction; the ledger records absent*

or present intermediate endpoint provenance; the core theorem is the displayed classifier conclusion; exactness is absent-or-same-present exhaustion; the standard bridge is equality of the none *and* some *middle option; and the status is* ProofTarget.

Let $S, T, U : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source, intermediate, and target carriers, let* $\sim_S$, $\sim_T$, *and* $\sim_U$ *be their classifiers, and let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$$

and

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U).$$

Assume payload preservation fields

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a))$$

and

$$\rho_\epsilon : \forall b.\ T(b) \to U(\epsilon.\mathsf{map}(b)).$$

Assume endpoint stability for both descents:

$$\eta_\delta : \forall x\, y.\ S(x) \to S(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\delta.\mathsf{map}(x), \delta.\mathsf{map}(y))$$

and

$$\eta_\epsilon : \forall x\, y.\ T(x) \to T(y) \to \mathsf{hsame}(x, y) \to \mathsf{hsame}(\epsilon.\mathsf{map}(x), \epsilon.\mathsf{map}(y)).$$

Let $\mathsf{cert}_T : \mathsf{NameCert}(T, \sim_T)$. *For histories* $h, k, k', m : \mathsf{BHist}$, *suppose the same composed endpoint pair factors through both* k *and* k'*:*

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k) \wedge \mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, m)$$

and

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k') \wedge \mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', m).$$

Then the two intermediate tagged-option endpoints are classified:

$$\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k').$$

Proof. Apply Theorem 33.246 to the two displayed δ factors, the two displayed ϵ factors, and the preservation and stability data. This gives the canonical intermediate endpoint split.

In the absent branch, the canonical split supplies $\mathsf{hsame}(k, \mathsf{e})$ and $\mathsf{hsame}(k', \mathsf{e})$. Use these two empty presentations to build the absent–absent branch of $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k')$.

In the present branch, retain the source payload a and the intermediate payload witness $T(\delta.\mathsf{map}(a))$. The canonical split supplies

$$\mathsf{hsame}(k, \mathsf{E1}(\delta.\mathsf{map}(a))) \wedge \mathsf{hsame}(k', \mathsf{E1}(\delta.\mathsf{map}(a))).$$

Use these two one-payload presentations and $\mathsf{cert}_T.\mathsf{equiv_refl}$ at $\delta.\mathsf{map}(a)$ to build the present–present branch of $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k')$.

The classifier is therefore determined by the same absent-or-same-present exhaustion that controls the canonical intermediate endpoint presentation. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel composite factorization intermediate classifier`

33.26 Option composite image classifier normalized present intermediate payload determinacy

Theorem 33.255 (Tagged option composite image classifier normalized present intermediate payload determinacy)**.** *Let the carriers S, T, U, classifiers $\sim_S, \sim_T, \sim_U$, descents δ, ϵ, preservation fields $\rho_\delta, \rho_\epsilon$, endpoint-stability field η_ϵ, certificates $\mathsf{cert}_S, \mathsf{cert}_T, \mathsf{cert}_U$, compatibility fields, endpoints m, m', u, u', and selected visible payloads x, y satisfy exactly the hypotheses of Theorem 33.236. Then there exist $k, k', p, q, a, b : \mathsf{BHist}$ such that*

1. *the ten selected visible public factorization clauses of Theorem 33.236 hold for k, k', p, q, a, b;*
2. *the left present intermediate payload is determined:*

$$\forall r : \mathsf{BHist}.\ \mathsf{hsame}(k, \mathsf{E1}(r)) \to \mathsf{hsame}(p, r);$$

3. *the right present intermediate payload is determined:*

$$\forall s : \mathsf{BHist}.\ \mathsf{hsame}(k', \mathsf{E1}(s)) \to \mathsf{hsame}(q, s).$$

Proof. Apply Theorem 33.236 to the displayed carrier, classifier, descent, preservation, stability, certificate, compatibility, endpoint, and selected visible payload data. This supplies k, k', p, q, a, b together with the ten selected visible public factorization clauses, including $\mathsf{hsame}(k, \mathsf{E1}(p))$ and $\mathsf{hsame}(k', \mathsf{E1}(q))$.

For the left intermediate endpoint, fix $r : \mathsf{BHist}$ and assume $\mathsf{hsame}(k, \mathsf{E1}(r))$. Apply Theorem 33.122 at k to the selected presentation $\mathsf{hsame}(k, \mathsf{E1}(p))$ and the competing presentation $\mathsf{hsame}(k, \mathsf{E1}(r))$. This yields $\mathsf{hsame}(p, r)$.

For the right intermediate endpoint, fix $s : \mathsf{BHist}$ and assume $\mathsf{hsame}(k', \mathsf{E1}(s))$. Apply Theorem 33.122 at k' to the selected presentation $\mathsf{hsame}(k', \mathsf{E1}(q))$ and the competing presentation $\mathsf{hsame}(k', \mathsf{E1}(s))$. This yields $\mathsf{hsame}(q, s)$.

Package the selected visible public factorization witnesses with the two payload-determinacy functions. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier composite normalized present intermediate payload determinacy`

33.27 Option history classifier unary two-sided context

Theorem 33.256 (Option history carrier unary two-sided context)**.** *Let $p, q, h : \mathsf{BHist}$. If $\mathsf{UnaryHistory}(p)$ and $\mathsf{UnaryHistory}(q)$ hold, then*

$$\mathsf{OptionHistoryCarrier}_{\mathsf{UnaryHistory}}(h) \iff \mathsf{OptionHistoryCarrier}_{\mathsf{UnaryHistory}}(\mathsf{append}(p, \mathsf{append}(h, q))).$$

Proof. For the forward direction, first apply Theorem 33.6 with suffix q. Then apply Theorem 33.5 with prefix p.

For the reverse direction, split the contextual nullable carrier witness.

In the absent branch, use $\mathsf{hsame_iff_eq}$ to turn the empty contextual endpoint witness into equality. Apply $\mathsf{append_eq_empty_iff}$ to the outer append, and then again to the inner append, recovering $\mathsf{hsame}(h, \mathsf{e})$.

In the source branch, use $\mathsf{unary_append_right_factor}$ on the outer append to recover $\mathsf{UnaryHistory}(\mathsf{append}(h, q))$. Then use $\mathsf{unary_append_left_factor}$ on the inner append to recover $\mathsf{UnaryHistory}(h)$.

These two recovered branches are exactly the nullable carrier alternatives for h. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryCarrier unary two sided context iff`

Theorem 33.257 (Option history classifier unary two-sided context)**.** *This theorem fits the ten-field template as follows: the traditional target is context-stable nullable optional history classification; the BEDC source is* BHist *with* UnaryHistory, append, *and* hsame*; the carrier is* $\mathsf{OptionHistoryCarrier}_{\mathsf{UnaryHistory}}$*; the classifier is* $\mathsf{OptionHistoryClassifier}_{\mathsf{UnaryHistory}}$*; the stability obligations are unary prefix and suffix closure together with cancellation; the ledger is the hidden common unary context; the core theorem is the displayed equivalence; exactness is recovery of the uncloaked classifier by append cancellation and unary factor readback; the standard bridge is option values under common unary context; and the status is* ProofTarget*.*

Let $p, q, h, k : \mathsf{BHist}$*. If* $\mathsf{UnaryHistory}(p)$ *and* $\mathsf{UnaryHistory}(q)$ *hold, then*

$$\mathsf{OptionHistoryClassifier}_{\mathsf{UnaryHistory}}(h,k) \iff \mathsf{OptionHistoryClassifier}_{\mathsf{UnaryHistory}}(\mathsf{append}(p,\mathsf{append}(h,q)),\mathsf{append}(p,\mathsf{appe}$$

Proof. For the forward direction, first apply Theorem 33.9 with suffix q to place the common unary right context on both endpoints. Then apply Theorem 33.8 with prefix p to place the common unary left context.

For the reverse direction, unpack the contextual nullable classifier into its two endpoint carrier witnesses and the contextual hsame field. Each endpoint carrier is read back from the surrounding context. In an absent branch, use hsame_iff_eq and append_eq_empty_iff twice to recover the corresponding uncloaked empty endpoint witness.

In a source branch, use unary_append_right_factor on the outer append and unary_append_left_factor on the inner append to recover $\mathsf{UnaryHistory}(h)$ or $\mathsf{UnaryHistory}(k)$ as required by the nullable carrier.

It remains to recover the uncloaked classifier relation. Convert the contextual hsame field to equality, cancel the common left prefix by append_left_cancel, and then cancel the common right suffix by append_right_cancel. Repack the two recovered endpoint carriers together with the recovered $\mathsf{hsame}(h,k)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier unary two sided context iff`

Theorem 33.258 (Option unary context composition law)**.** *Let* $p, q, r, s, h, k : \mathsf{BHist}$*. For histories* u, v, x*, write* $C_{u,v}(x) := \mathsf{append}(u, \mathsf{append}(x, v))$*. If* $\mathsf{UnaryHistory}(p)$*,* $\mathsf{UnaryHistory}(q)$*,* $\mathsf{UnaryHistory}(r)$*, and* $\mathsf{UnaryHistory}(s)$ *hold, then*

$$\mathsf{OptionHistoryClassifier}_{\mathsf{UnaryHistory}}(h,k) \iff \mathsf{OptionHistoryClassifier}_{\mathsf{UnaryHistory}}(C_{p,q}(C_{r,s}(h)), C_{\mathsf{append}(p,r),\mathsf{append}(s,q)}(k)).$$

Proof. Set $L := \mathsf{append}(p,r)$ and $R := \mathsf{append}(s,q)$. Unary append closure applied to p, r and to s, q gives $\mathsf{UnaryHistory}(L)$ and $\mathsf{UnaryHistory}(R)$. The associativity laws for BEDC append identify $C_{p,q}(C_{r,s}(x))$ with $C_{L,R}(x)$ for every history x; in particular, they provide the hsame witnesses needed to move classifiers between the nested source endpoint and the normalized endpoint.

For the forward direction, apply Theorem 33.257 to the classifier between h and k with unary contexts L and R. This gives

$$\mathsf{OptionHistoryClassifier}_{\mathsf{UnaryHistory}}(C_{L,R}(h), C_{L,R}(k)).$$

Transport the source endpoint along the associativity hsame witness from $C_{L,R}(h)$ to $C_{p,q}(C_{r,s}(h))$. The target endpoint is already $C_{L,R}(k) = C_{\mathsf{append}(p,r),\mathsf{append}(s,q)}(k)$ by the definitions of L and R.

For the reverse direction, start with the displayed classifier and transport its source endpoint back across the same associativity witness. This produces

$$\mathsf{OptionHistoryClassifier}_{\mathsf{UnaryHistory}}(C_{L,R}(h), C_{L,R}(k)).$$

Apply the reverse implication of Theorem 33.257 with contexts L and R. Append cancellation inside that theorem removes the common normalized ledger and recovers $\mathsf{OptionHistoryClassifier}_{\mathsf{UnaryHistory}}(h, k)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.OptionHistoryClassifier unary context composition iff`

Theorem 33.259 (Option finite-data scoped row exhaustion)**.** *The* $\mathsf{Option}^{\uparrow}$ *finite-data public surface exports only the following rows: nullable and tagged option carrier rows; absent and present branch readbacks; payload-descent image carrier and image-classifier rows; componentwise* hsame *transports;* Cont *routes induced by the displayed branch data; source* NameCert *rows; and the visible* Pkg *provenance already listed by the unary-context, tagged-option semantic, and payload-descent public packages. It exports no host* Option *object, quotient row, hidden payload equality row, or unlogged branch eliminator.*

Proof. The nullable side is exhausted by the moved unary-context theorems above. They only transport $\mathsf{OptionHistoryCarrier}_{\mathsf{UnaryHistory}}$ and $\mathsf{OptionHistoryClassifier}_{\mathsf{UnaryHistory}}$ through common unary ledgers, and their proofs recover the uncloaked rows by append cancellation and constructor-branch readback.

The tagged semantic rows are the explicit carrier, classifier, exactness, and NameCert rows recorded in the tagged option semantic package. Their branch analysis has only the absent constructor and the present constructor carrying a source witness, so projecting any public row yields either e readback or an $\mathsf{E1}(a)$ readback together with the source certificate data.

The payload-descent image rows are exhausted by the public readback and image classifier blocks. A target endpoint is public only through a source tagged endpoint and a displayed TaggedOptionMapRel route; a classified target pair is public only through two such routes and a source tagged classifier witness.

Combining these projections gives row exhaustion. Constructor branch exhaustion accounts for absent and present cases, componentwise hsame transport accounts for endpoint replacement, Cont records only the displayed routes, and Pkg provenance records only the listed certificates and descent data. None of these projections produces a host option value, a quotient representative, a payload equality outside hsame or the source classifier, or a branch eliminator without a logged constructor case. □

The absent/present tag row for $\mathsf{Option}^{\uparrow}$ consumes the finite tag discipline of chapter 32 before adding its payload classifier. The option ledger therefore extends $\mathsf{Bool}^{\uparrow}$ with an optional payload coordinate rather than introducing a second tag carrier.

33.28 Tagged option map relation R-corner classifier coherence

Theorem 33.260 (Tagged option map relation R-corner classifier coherence)**.** *This theorem fits the per-object template as follows: the traditional target is right-corner option-map endpoint determinacy; the BEDC source is* BHist *with one* DescentCertificate*; the carrier is the tagged option endpoint shape; the classifiers are* $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}$ *and* $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}$*; the stability obligations are shared-target source reflection and shared-source target normal form; the ledger records the three R-corner legs; the core theorem is simultaneous source and target endpoint classification; exactness is absent-or-present exhaustion on both axes; the standard bridge is* none/some *map readback; and the status is* ProofTarget*.*

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source and target carriers, let* $\sim_S$ *and* $\sim_T$ *be their classifiers, let*

$$\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T),$$

and assume payload preservation

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Assume $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$ *and reflected source readback from visible target equality,*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\delta(S, \sim_S).$$

For histories h, h', k, k'*, if*

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k),$$

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h', k),$$

and

$$\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h', k'),$$

then

$$\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, h') \wedge \mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k').$$

Proof. First compare the two legs with shared target endpoint k. Apply Theorem 33.144 to the map-relation witnesses $\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h, k)$ and $\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h', k)$, using the reflected source readback hypothesis. This gives $\mathsf{TaggedOptionHistoryClassifier}_{S,\sim_S}(h, h')$.

Next compare the two legs with shared source endpoint h'. Apply Theorem 33.146 to the map-relation witnesses $\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h', k)$ and $\mathsf{TaggedOptionMapRel}_\delta(S, T, \rho_\delta; h', k')$, using source hsame compatibility. This gives $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k')$.

Pairing these two classifier conclusions yields the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionMapRel R corner classifier coherence`

Theorem 33.261 (Tagged option common-right visible payload classification)**.** *Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history carrier and let* $R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be a symmetric and transitive payload classifier. Assume that visible* hsame *between source payloads is reflected into* R*. For histories* h, r, k, a, c, b*, if*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,R}(h, k) \quad \textit{and} \quad \mathsf{TaggedOptionHistoryClassifier}_{S,R}(r, k),$$

and a, c, b *are displayed source payloads with*

$$\mathsf{hsame}(h, \mathsf{E1}(a)), \qquad \mathsf{hsame}(r, \mathsf{E1}(c)), \qquad \mathsf{hsame}(k, \mathsf{E1}(b)),$$

then $R(a, c)$*.*

Proof. Use right-visible branch inversion on both classifiers at the common right presentation $\mathsf{hsame}(k, \mathsf{E1}(b))$. The first classifier exposes a left payload classified with a right payload history-same to b, while the second exposes a right payload chain with the same visible b.

Invert the two visible E1 presentations at h and r to compare the displayed payloads a and c with the exposed classifier payloads. The source-hsame reflection converts these payload comparisons into R-legs. Transitivity composes a to the common visible payload b through the first classifier. The second classifier composes c to the same b; symmetry turns that leg around, and one final transitivity step yields $R(a, c)$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier common right visible payload classificatio`

Theorem 33.262 (Tagged option present-chain visible endpoint classification)**.** *Let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history carrier and let* $R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be a transitive payload classifier. Assume that visible* hsame *between source payloads is reflected into* R*. For histories* h, k, r, a, c*, if*

$$\mathsf{TaggedOptionHistoryClassifier}_{S,R}(h,k) \quad \textit{and} \quad \mathsf{TaggedOptionHistoryClassifier}_{S,R}(k,r),$$

if $S(a)$ *and* $S(c)$ *hold, and if the endpoints are visibly present as*

$$\mathsf{hsame}(h, \mathsf{E1}(a)), \qquad \mathsf{hsame}(r, \mathsf{E1}(c)),$$

then $R(a, c)$*.*

Proof. Compose the two tagged classifiers by transitivity of R to classify h and r. The absent branch would present h as both e and $\mathsf{E1}(a)$, which is impossible by BEDC constructor no-confusion. In the present branch, invert the two visible $\mathsf{E1}$ presentations to compare a and c with the exposed payload witnesses. The source-hsame reflection supplies the two outer R-legs, and transitivity composes them with the exposed payload classifier. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionHistoryClassifier present chain visible endpoint classification`

33.29 Tagged option payload descent image target classifier closure

Theorem 33.263 (Tagged option payload descent image classifier target classifier closure)**.** *This theorem fits the per-object template as follows: the traditional target is functorial* OptionUp *target classifier closure; the BEDC source is* BHist *with a descent certificate; the carrier is the transported target tagged-option carrier; the classifier is* $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}$*; the stability obligation is branch exactness plus descent respect; the ledger is absent or transported present payload provenance; the core theorem is the displayed classifier implication; exactness is the branch split; the standard bridge is* none/some *classifier closure; and the status is* ProofTarget*.*

Let $S, T : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history carriers, let* $\sim_S$ *and* $\sim_T$ *be classifiers, let* $\delta : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_S, \sim_T)$*, and assume payload preservation*

$$\rho_\delta : \forall a.\ S(a) \to T(\delta.\mathsf{map}(a)).$$

Let $\mathsf{cert} : \mathsf{NameCert}(S, \sim_S)$ *and assume* $\mathsf{TaggedOptionSourceHsameCompatible}(S, \sim_S)$*. For target endpoints* $k, k' : \mathsf{BHist}$*,*

$$\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k') \to \mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k').$$

Proof. Apply Theorem 33.162 to the displayed carrier, classifier, descent, preservation, certificate, compatibility, and endpoint data. The resulting branch split is either absent-absent target presentation or transported present-payload presentation.

In the absent branch, the split supplies $\mathsf{hsame}(k, \mathsf{e})$ and $\mathsf{hsame}(k', \mathsf{e})$. Use the absent-absent constructor of $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}$.

In the present branch, keep the witnesses $a, b : \mathsf{BHist}$, the source carrier witnesses, $a \sim_S b$, the two transported target carrier witnesses, and the two target endpoint presentations. The descent certificate's respect field gives

$$\delta.\mathsf{respects}(a \sim_S b) : \delta.\mathsf{map}(a) \sim_T \delta.\mathsf{map}(b).$$

Use the present-present constructor of $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}$ with target witnesses $\delta.\mathsf{map}(a)$ and $\delta.\mathsf{map}(b)$, their two T witnesses, the transported classifier witness, and the two endpoint presentations. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier target classifier closure`

33.30 Option composite image classifier normalized present intermediate classifier determinacy

Theorem 33.264 (Tagged option composite image classifier normalized present intermediate classifier determinacy)**.** *This theorem fits the per-object template as follows: the traditional target is classifier-level readback for the intermediate public endpoints in functorial* OptionUp*; the BEDC source is* BHist *with two composable* DescentCertificate *maps; the carrier is the selected intermediate* E1 *endpoint shape; the classifier is* $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}$*; the stability obligations are selected visible public factorization, present-payload determinacy,* $\mathsf{TaggedOptionSourceHsameCompatible}(T, \sim_T)$*, and the equivalence fields of* cert_T*; the ledger records selected intermediate endpoints and competing visible intermediate payloads; the core theorem is classifier-level determinacy; exactness says every competing visible intermediate pair lies in the same* $\sim_T$ *class; the standard bridge is some-payload functorial readback; and the status is* ProofTarget*. Let the carriers* S, T, U*, classifiers* $\sim_S, \sim_T, \sim_U$*, descents* δ, ϵ*, preservation fields* $\rho_\delta, \rho_\epsilon$*, endpoint-stability field* η_ϵ*, certificates* $\mathsf{cert}_S, \mathsf{cert}_T, \mathsf{cert}_U$*, compatibility fields, endpoints* m, m', u, u'*, and selected visible payloads* x, y *satisfy exactly the hypotheses of Theorem 33.236. Then there exist* $k, k', p, q, a, b : \mathsf{BHist}$ *such that*

1. *the ten selected visible public factorization clauses of Theorem 33.236 hold for* k, k', p, q, a, b*;*
2. *the selected intermediate endpoints are classified by*

$$\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k');$$

3. *every competing visible intermediate pair lies in the selected intermediate classifier class:*

$$\forall r, s : \mathsf{BHist}.\ T(r) \to T(s) \to \mathsf{hsame}(k, \mathsf{E1}(r)) \to \mathsf{hsame}(k', \mathsf{E1}(s)) \to r \sim_T s.$$

Proof. Apply Theorem 33.255 to the displayed carrier, classifier, descent, preservation, stability, certificate, compatibility, endpoint, and selected visible payload data. This supplies k, k', p, q, a, b, the ten selected visible public factorization clauses, and the two present-payload determinacy functions.

The present branch of the ten factorization clauses gives $T(p)$, $T(q)$, $\mathsf{hsame}(k, \mathsf{E1}(p))$, $\mathsf{hsame}(k', \mathsf{E1}(q))$, and $p \sim_T q$. These witnesses assemble

$$\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k')$$

by the present constructor of the tagged option history classifier.

Now fix competing visible intermediate payloads $r, s : \mathsf{BHist}$ with $T(r)$, $T(s)$, $\mathsf{hsame}(k, \mathsf{E1}(r))$, and $\mathsf{hsame}(k', \mathsf{E1}(s))$. The two determinacy functions yield $\mathsf{hsame}(p, r)$ and $\mathsf{hsame}(q, s)$.

Target hsame compatibility converts these to $p \sim_T r$ and $q \sim_T s$. Using the symmetry field of cert_T on $p \sim_T r$ gives $r \sim_T p$; two applications of the transitivity field of cert_T compose $r \sim_T p$, $p \sim_T q$, and $q \sim_T s$ into $r \sim_T s$. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier composite normalized present intermediate classifier determinacy`

Theorem 33.265 (Tagged option composite image classifier normalized intermediate classifier coverage)**.** *This theorem fits the per-object template as follows: the traditional target is branch-complete functorial* OptionUp *intermediate classifier coverage; the BEDC source is* BHist *with two composable descents; the carrier is the intermediate endpoint pair supplied by normalized public factorization; the classifier is* $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}$*; the stability obligations are normalized public readback completion, absent endpoint factorization, present payload determinacy, and source compatibility for* T*; the ledger records absent intermediate endpoints or selected visible present intermediate payloads; the core theorem is classified intermediate coverage; exactness says each normalized composite classifier has an absent or present intermediate factor whose two intermediate endpoints are classified; the standard bridge is none/some functorial composition; and the status is* ProofTarget*.*

Let the carriers S, T, U*, classifiers* $\sim_S, \sim_T, \sim_U$*, descents* δ, ϵ*, preservation fields* $\rho_\delta, \rho_\epsilon$*, endpoint-stability field* η_ϵ*, certificates* $\mathsf{cert}_S, \mathsf{cert}_T, \mathsf{cert}_U$*, compatibility fields, and endpoints* m, m', u, u' *satisfy exactly the hypotheses of Theorem 33.249. Then either*

1. *the normalized public endpoints are absent:*

$$\mathsf{hsame}(u, \mathsf{e}) \wedge \mathsf{hsame}(u', \mathsf{e});$$

2. *there is no visible present public pair:*

$$\neg\exists x, y : \mathsf{BHist}.\ U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y));$$

3. *there exist* $k, k' : \mathsf{BHist}$ *such that*

   (a) $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$*;*

   (b) $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u')$*;*

   (c) $\mathsf{hsame}(k, \mathsf{e}) \wedge \mathsf{hsame}(k', \mathsf{e})$*;*

   (d) $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k')$*;*

   (e) no visible present intermediate pair occurs:

$$\neg\exists p, q : \mathsf{BHist}.\ T(p) \wedge T(q) \wedge \mathsf{hsame}(k, \mathsf{E1}(p)) \wedge \mathsf{hsame}(k', \mathsf{E1}(q)).$$

or there exist $x, y, k, k', p, q, a, b : \mathsf{BHist}$ *such that*

1. *the ten selected visible public factorization clauses of Theorem 33.236 hold for* x, y, k, k', p, q, a, b*;*

2. *the selected intermediate endpoints are classified:*

$$\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k');$$

3. every competing visible intermediate payload pair lies in the selected intermediate classifier class:

$$\forall r, s : \mathsf{BHist}.\ T(r) \to T(s) \to \mathsf{hsame}(k, \mathsf{E1}(r)) \to \mathsf{hsame}(k', \mathsf{E1}(s)) \to r \sim_T s.$$

Proof. Apply Theorem 33.249 to the displayed composite witness, endpoint normalization witnesses, descents, preservation fields, stability field, certificates, and compatibility fields. This gives the normalized factored public readback completion at (u, u').

In the absent branch, retain the absent public endpoint presentations, the public visible-pair exclusion, and the intermediate witnesses k, k'. The factored completion supplies the δ image-classifier factor, the two ϵ map-relation links to u, u', the presentations $\mathsf{hsame}(k, \mathsf{e})$ and $\mathsf{hsame}(k', \mathsf{e})$, and the exclusion of visible present intermediate pairs.

Build

$$\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k')$$

by the absent-absent constructor from $\mathsf{hsame}(k, \mathsf{e})$ and $\mathsf{hsame}(k', \mathsf{e})$. Package this classifier with the retained absent data.

In the present branch, retain the displayed payloads x, y, k, k', p, q, a, b and the selected visible factorization clauses supplied by the factored completion. Apply Theorem 33.264 to the same displayed data and selected visible payloads.

That theorem supplies the classifier

$$\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k')$$

and the universal competing visible intermediate payload conclusion. Package these two fields with the retained selected visible public factorization clauses. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier composite normalized intermediate classifier coverage`

33.31 Option composite image classifier normalized intermediate factor coherence

Theorem 33.266 (Tagged option composite image classifier normalized intermediate factor coherence)**.** *Let $T, U : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history carriers, let $\sim_T$ and $\sim_U$ be their classifiers, let*

$$\epsilon : \mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, \sim_T, \sim_U),$$

and assume payload preservation

$$\rho_\epsilon : \forall a.\ T(a) \to U(\epsilon.\mathsf{map}(a)).$$

Assume reflected source readback from visible public equality,

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\epsilon(T, \sim_T).$$

For histories k, l, k', l', u, u', if

$$\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u),$$

$$\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; l, u),$$

$$\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u'),$$

and

$$\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; l', u'),$$

then

$$\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, l) \wedge \mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k', l').$$

Proof. First compare the two intermediate factors over the normalized public endpoint u. Apply Theorem 33.243 to the two map-relation witnesses $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$ and $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; l, u)$. This gives either simultaneous empty presentations of k, l, u or a present-payload package ending in $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, l)$.

Next compare the two intermediate factors over the normalized public endpoint u'. Apply Theorem 33.243 to the two map-relation witnesses $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u')$ and $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; l', u')$. This gives either simultaneous empty presentations of k', l', u' or a present-payload package ending in $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k', l')$.

In an absent branch of the comparison over u, the empty presentations of k and l assemble the absent branch of $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, l)$. In its present branch, retain the classifier supplied by the reflected normal form.

In an absent branch of the comparison over u', the empty presentations of k' and l' assemble the absent branch of $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k', l')$. In its present branch, retain the classifier supplied by the reflected normal form.

Combining the classifier obtained over u with the classifier obtained over u' yields the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier composite normalized intermediate factor coherence`

33.32 Option composite image classifier normalized selected intermediate factor uniqueness

Theorem 33.267 (Tagged option composite image classifier normalized selected intermediate factor uniqueness)**.** *Let the carriers S, T, U, classifiers $\sim_S, \sim_T, \sim_U$, descents δ, ϵ, preservation fields $\rho_\delta, \rho_\epsilon$, endpoint-stability field η_ϵ, certificates $\mathsf{cert}_S, \mathsf{cert}_T, \mathsf{cert}_U$, compatibility fields, endpoints m, m', u, u', and selected visible payloads x, y satisfy exactly the hypotheses of Theorem 33.236. Assume also reflected source readback from visible public equality,*

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\epsilon(T, \sim_T).$$

Then there exist $k, k', p, q, a, b : \mathsf{BHist}$ such that

1. *the ten selected visible public factorization clauses of Theorem 33.236 hold for k, k', p, q, a, b;*
2. *the selected intermediate factors are unique against every competing intermediate factor over the same normalized public endpoints:*

$$\forall l, l' : \mathsf{BHist}.\ \mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; l, u) \to \mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; l', u') \to \mathsf{TaggedOptionHistor}$$

Proof. Apply Theorem 33.236 to the displayed carrier, classifier, descent, preservation, stability, certificate, compatibility, endpoint, and selected visible payload data. This supplies k, k', p, q, a, b together with the ten selected visible public factorization clauses.

The second selected factorization clause supplies the two selected ϵ map-relation legs

$$\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$$

and

$$\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u').$$

Fix competing intermediate endpoints $l, l' : \mathsf{BHist}$ with map-relation witnesses from l to u and from l' to u'. Apply Theorem 33.266 to the selected left leg, the competing left leg, the selected right leg, and the competing right leg, using the reflected source readback hypothesis. This gives

$$\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, l) \wedge \mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k', l').$$

Package the selected factorization clauses with this universal comparison against arbitrary competing intermediate factors over u and u'. □

Theorem 33.268 (Tagged option composite image classifier normalized unique intermediate factor coverage)**.** *This theorem fits the per-object template as follows: the traditional target is branch-complete functorial* OptionUp *factor uniqueness; the BEDC source is* BHist *with two composable descent certificate maps; the carrier is the selected intermediate endpoint pair; the classifier is* $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}$*; the stability obligations are normalized readback completion, selected visible factorization, reflected source readback, and factor coherence; the ledger records absent or selected present intermediate provenance; the core theorem is displayed uniqueness coverage; exactness says every admitted intermediate factor over the same normalized public endpoints lies in the same classifier class; the standard bridge is none/some functorial composition; and the status is* ProofTarget.

Let the carriers S, T, U, classifiers $\sim_S, \sim_T, \sim_U$, descents δ, ϵ, preservation fields $\rho_\delta, \rho_\epsilon$, endpoint-stability field η_ϵ, certificates $\mathsf{cert}_S, \mathsf{cert}_T, \mathsf{cert}_U$, compatibility fields, and endpoints m, m', u, u' satisfy exactly the hypotheses of Theorem 33.249. Assume also reflected source readback from visible public equality,

$$\mathsf{TaggedOptionPayloadDescentReflectsSource}_\epsilon(T, \sim_T).$$

Then either

1. *the normalized public endpoints are absent:*

$$\mathsf{hsame}(u, \mathsf{e}) \wedge \mathsf{hsame}(u', \mathsf{e});$$

2. *there is no visible present public pair:*

$$\neg\exists x, y : \mathsf{BHist}.\ U(x) \wedge U(y) \wedge \mathsf{hsame}(u, \mathsf{E1}(x)) \wedge \mathsf{hsame}(u', \mathsf{E1}(y));$$

3. *there exist k, k' : BHist such that*

   (a) $\mathsf{TaggedOptionPayloadDescentImageClassifier}_\delta(S, T, \rho_\delta; k, k')$*;*

   (b) $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k, u)$ *and* $\mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; k', u')$*;*

   (c) $\mathsf{hsame}(k, \mathsf{e}) \wedge \mathsf{hsame}(k', \mathsf{e})$*;*

   (d) $\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k')$*;*

(e) *no visible present intermediate pair occurs:*

$$\neg\exists p, q : \mathsf{BHist}.\ T(p) \wedge T(q) \wedge \mathsf{hsame}(k, \mathsf{E1}(p)) \wedge \mathsf{hsame}(k', \mathsf{E1}(q)).$$

(f) *every admitted intermediate factor over the same normalized public endpoints lies in the selected absent classifier class:*

$$\forall l, l' : \mathsf{BHist}.\ \mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; l, u) \to \mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; l', u') \to \mathsf{TaggedOptionH}$$

or there exist $x, y, k, k', p, q, a, b : \mathsf{BHist}$ *such that*

1. *the ten selected visible public factorization clauses of Theorem 33.236 hold for* x, y, k, k', p, q, a, b*;*
2. *the selected intermediate endpoints are classified:*

$$\mathsf{TaggedOptionHistoryClassifier}_{T,\sim_T}(k, k');$$

3. *every admitted intermediate factor over the same normalized public endpoints lies in the selected present classifier class:*

$$\forall l, l' : \mathsf{BHist}.\ \mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; l, u) \to \mathsf{TaggedOptionMapRel}_\epsilon(T, U, \rho_\epsilon; l', u') \to \mathsf{TaggedOptionHistor}$$

Proof. Apply Theorem 33.265 to the displayed carrier, classifier, descent, preservation, stability, certificate, compatibility, and endpoint data. This gives the normalized branch split with classified intermediate witnesses.

In the absent branch, retain the absent public endpoint presentations, the visible public exclusion, and the witnesses k, k' with their δ image-classifier factor, ϵ map-relation links, absent intermediate presentations, selected classifier, and visible intermediate exclusion.

Fix arbitrary intermediate endpoints $l, l' : \mathsf{BHist}$ mapping to the same normalized public endpoints u, u'. Apply Theorem 33.266 to the selected absent map-relation legs and the competing map-relation legs, using reflected source readback. This yields the required classifier comparison between k, l and between k', l'.

In the present branch, retain the selected visible factorization data and the selected intermediate classifier supplied by the coverage theorem. Apply Theorem 33.267 to the same displayed carrier, classifier, descent, preservation, stability, certificate, compatibility, endpoint, selected visible payload, and reflected source readback data.

The selected uniqueness theorem supplies the universal comparison against arbitrary admitted intermediate factors over u and u'. Package that comparison with the selected visible factorization clauses and the retained intermediate classifier. □

Lean4 ✓ `BEDC.Derived.OptionUp.TaggedOptionPayloadDescentImageClassifier composite normalized unique intermediate factor coverage`

Theorem 33.269 (Option finite-data public exit package)**.** *The rows named by* OptionHistoryCarrier*,* OptionHistoryClassifier*,* OptionHistoryLedgerPolicy*, carrier transport, classifier symmetry and transitivity, absent-source separation, exclusive readback, and ledger endpoint transport assemble the public finite-data exit package for* $\mathsf{Option}^{\uparrow}$*. The public package exposes only the finite* BHist *carrier rows,* hsame *classifier rows,* Cont *transport rows,* Pkg *provenance rows, and the displayed* $\mathsf{NameCert}_{\mathsf{Option}^{\uparrow}}$ *certificate rows; it exports no host option type, external quotient, or hidden payload selector.*

Proof. The carrier and classifier rows are the unary-context and scoped-row surfaces of Definition 33.256, Definition 33.257, and Definition 33.259. These blocks provide the finite BHist rows, the hsame comparison relation, and the displayed Cont routes used by every public endpoint.

The readback and separation rows are Definition 33.194, Definition 33.197, and the payload-descent image readback blocks. They split absent and present endpoints, rule out mixed source readback, and keep every transported endpoint inside the same finite ledger.

Finally the semantic name certificate option_history_semantic_name_certificate packages these rows as the canonical $\mathsf{NameCert}_{\mathsf{Option}^{\uparrow}}$ surface. Since each cited block factors through BHist, hsame, Cont, Pkg, and the displayed certificate rows, the public exit has no additional data channel. □

Lean4 ✓ `BEDC.Derived.OptionUp.option history semantic name certificate`

Theorem 33.270 (Option payload-map totality)**.** *Every public payload-map read of an accepted* $\mathsf{Option}^{\uparrow}$ *packet first reads the visible* $\mathsf{Bool}^{\uparrow}$ *tag. If the tag is the displayed absent endpoint, the read returns the displayed none witness and exposes no payload row. If the tag is the displayed present endpoint, the read exposes exactly one payload row through the present-payload classifier and the* $\mathsf{Option}^{\uparrow}$ *classifier, with replay and provenance carried by the same* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}_{\mathsf{Option}^{\uparrow}}$ *rows used by the public exit package.*

Proof. Begin with the public finite-data exit package of Definition 33.269. It restricts every public read to the displayed finite carrier, classifier, replay, provenance, and certificate rows, so a payload-map consumer has no channel before the visible tag is inspected.

The absent case is fixed by the exclusive branch readback and cross-source separation theorems. The displayed absent endpoint is the none witness, and the visible payload classification theorems rule out any present payload row in that branch.

In the present case, use map relation coherence together with visible payload classification. The intermediate factor coverage and unique intermediate factor statements in this file identify the single present payload row read by the public map relation, and the option classifier records it as the displayed some witness.

Thus the payload-map read is total as a visible $\mathsf{Option}^{\uparrow}$ witness: absent reads return none, present reads return one classified payload row, and both branches stay inside the same displayed public package. □

Closure status for $\mathsf{NameCert}_{\mathsf{Option}^{\uparrow}}$**.**

Constructive story: An $\mathsf{Option}^{\uparrow}$ packet is generated from the finite nullable envelope over $\mathsf{Bool}^{\uparrow}$ tags, the tagged absent and present constructor rows, exclusive branch readback, payload descent image classifiers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local semantic NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Option}^{\uparrow}}$, maturePackageClosed)

Scope closed: The closure binds the nullable envelope, tagged constructor surface, exclusive branch readback, payload descent image classifier, finite tag dependency on $\mathsf{Bool}^{\uparrow}$, and public finite-data exit package for $\mathsf{Option}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Option}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.OptionUp.option\_history\_semantic\_name\_certificate`

Bridge status: bridgeChecked

Not claimed: The chapter does not close full option monad laws, arbitrary eliminators into certified targets, dependent options, host option equality, or quotient payload selection.

Upgrade path: No further upgrade – chapter at top of formal axis.

$\mathsf{Prod}^{\uparrow}$ finite-data product envelope is consumed by the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ product-window routes of chapter 126 and chapter 301.

Chapter 34

A Concrete Naming Certificate for $\mathsf{Prod}^{\uparrow}$

The product interface $\mathsf{Prod}^{\uparrow}$ has two classifier levels plus the checked envelope. ProdClassifierSpec is the typed finite-pair helper. $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}$ is the public BEDC-history certificate classifier induced by ProdPairRep and the source classifiers, while ProdHistoryClassifier is the checked envelope classifier using endpoint hsame. It is licensed only as a derived constructor over the two sources.

The finite-data sibling lattice enters the product chapter through chapter 32, chapter 33, chapter 35, and chapter 36. Bool supplies tag discipline, Option and Sum supply branch-tag boundary cases, and List supplies ordered spine discipline, while Product supplies the two-coordinate continuation envelope.

34.1 Roadmap template status

1. **Traditional target**: ordered product data with one left component and one right component.
2. **BEDC source**: the checked history-envelope certificate uses inhabited source-history predicates L and R; the explicit typed interface uses two licensed source carriers A and B, each with its own name certificate.
3. **Carrier choice**: the paired history carrier records a left history, a right history, and the continuation that combines them.
4. **Classifier choice**: ProdClassifierSpec is the typed finite-pair helper; $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}$ is the public history-level classifier from ProdPairRep and source classifiers; ProdHistoryClassifier is the checked envelope classifier using endpoint hsame.
5. **Stability obligations**: component transport, continuation transport, unary closure from components, history-envelope classifier symmetry and transitivity, typed classifier symmetry and transitivity, typed coordinate inversion, ProdPairRepCoherent, and componentwise-to-envelope descent.
6. **Ledger**: no product quotient is used; pairing records both component witnesses, their generated continuation, and the displayed pair ledger soundness needed by the public history-level certificate.

7. **Core theorem list**: append introduction, continuation introduction, carrier transport, unary closure, classifier equivalence, component-envelope inversion, ProdPairRepCoherent criteria, displayed pair ledger soundness, componentwise-to-envelope descent under hsame-sound source classifiers, and the semantic name certificate.
8. **Exactness predicate**: typed classification holds exactly when both finite-pair coordinates classify in their respective sources; public history-level classification holds through displayed ProdPairRep components and source classifiers; envelope classification uses endpoint hsame.
9. **Standard bridge**: the checked history-envelope bridge reads back only as a generated product endpoint with a displayed pair representation. Ordinary ordered-pair and componentwise history readback belong to the componentwise certificate target under $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$ and $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}$.
10. **Status**: Theorem 34.107 is the checked history-envelope certificate via BEDC.Derived.ProdUp.prod_history_sema The Phase Finite Data public-object product scope is the checked componentwise certificate at Theorem 34.60, supported by the checked componentwise classifier, ProdPairRepCoherent field, displayed-pair ledger, descent comparison, and endpoint-invariance rows.

34.2 Carrier definition

Definition 34.1 (Prod carrier)**.** *For licensed source carriers A and B, define a pair carrier with constructor* $\mathsf{pair}(a, b)$*.*

Lean4 (definition) `BEDC.Derived.ProdUp.ProdCarrier`

34.3 The certificate

Definition 34.2 (Prod source specification)**.** *For the checked history-envelope certificate, the source specification is a pair of inhabited predicates $L, R : \mathsf{BHist} \to \mathsf{Prop}$. The carrier is* $\mathsf{ProdHistoryCarrier}(L, R)$*, and the classifier is* $\mathsf{ProdHistoryClassifier}(L, R)$*; no source* NameCert *is required at this scope.*

For the explicit ordered-product interface, the source data are two licensed carriers with NameCert *witnesses. Those certificates are used for typed component transport, pair-representation coherence, and displayed component-exposure fields.*

Lean4 (definition) `BEDC.Derived.ProdUp.ProdHistoryCarrier`

Theorem 34.3 (Product history carrier append introduction)**.** *If l lies in the left source carrier and r lies in the right source carrier, then* $\mathsf{append}(l, r)$ *lies in the product history carrier.*

Proof. Use l and r as the two component witnesses. The BEDC continuation judgment is witnessed by reflexivity of the defining append result, so the product history carrier is rebuilt from the two source proofs and that continuation witness. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryCarrier append intro`

Theorem 34.4 (Product history carrier continuation introduction)**.** *If l lies in the left source carrier, r lies in the right source carrier, and* $\mathsf{Cont}(l, r, h)$*, then h lies in the product history carrier.*

Proof. Use l and r as the component witnesses. The supplied continuation proof is exactly the result witness required by the product history carrier. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryCarrier cont intro`

Theorem 34.5 (Product empty-result component exposure)**.** *If* $\mathsf{ProdHistoryCarrier}(L, R, \mathsf{Empty})$ *holds, then there are component histories* l *and* r *with* $L(l)$ *and* $R(r)$ *such that* $l\mathsf{hsameEmpty}$ *and* $r\mathsf{hsameEmpty}$*.*

Proof. Unpack the product carrier into component histories l and r, their source witnesses, and the continuation proof $\mathsf{Cont}(l, r, \mathsf{Empty})$. BEDC empty-result inversion for continuations forces both component histories to be the empty history, giving the two displayed hsame facts. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryCarrier empty result components`

Theorem 34.6 (Product visible-result component cases)**.** *If* $\mathsf{ProdHistoryCarrier}(L, R, \mathsf{E0}(tail))$ *holds, then its right component is either* e *and the left component is* hsame *to the visible result, or the right component is itself* E0*-headed and the stored continuation exposes its tail. The same dichotomy holds for visible result* $\mathsf{E1}(tail)$ *with an* E1*-headed right component.*

Proof. Unpack the product carrier into component histories l and r, source witnesses $L(l)$ and $R(r)$, and the continuation proof $\mathsf{Cont}(l, r, \mathsf{E0}(tail))$ or $\mathsf{Cont}(l, r, \mathsf{E1}(tail))$. Apply the corresponding BEDC continuation visible-result inversion theorem to the stored continuation. It yields exactly the empty-right case or the matching visible-headed right component case. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryCarrier visible result cases`

Theorem 34.7 (Product unary history closure)**.** *If a product history is generated from unary left and right histories, then the resulting product history is unary.*

Proof. Invert the product-history carrier into its left history, right history, unary component witnesses, and continuation proof. Unary closure under continuation turns the two unary component witnesses and the stored continuation proof into unary membership of the result history. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryCarrier unary`

Theorem 34.8 (Product history carrier transport)**.** *If two product histories are internally the same and the first is generated from a left witness, a right witness, and a continuation proof, then the second is generated from the same component witnesses and the transported continuation proof.*

Proof. Invert the product-history carrier into its left history, right history, component witnesses, and continuation proof. Transport the continuation result across hsame, and rebuild the product-history carrier with the same component witnesses. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryCarrier hsame transport`

Theorem 34.9 (Product history carrier unary from components)**.** *If the left and right source predicates each determine unary histories, then every product-history carrier generated from those predicates is unary.*

Proof. Unpack the product-history carrier into component histories l and r, their source witnesses, and the BEDC continuation witness for the result. The component assumptions give unary witnesses for l and r, and BEDC unary continuation closure gives unary membership of the product result. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryCarrier unary of components`

Definition 34.10 (Prod pattern specification)**.** *The pattern is paired generation from one A-witness and one B-witness.*

Definition 34.11 (Prod classifier specification)**.** *The typed classifier* ProdClassifierSpec *relates pairs componentwise using the classifiers of A and B. The typed wrapper* ProdClassifier *has the same componentwise content. Separately, the checked history-level scope is* $\mathsf{ProdHistoryClassifier}(L, R)$*: it relates histories h and k exactly when h lies in* $\mathsf{ProdHistoryCarrier}(L, R)$*, k lies in* $\mathsf{ProdHistoryCarrier}(L, R)$*, and* $\mathsf{hsame}(h, k)$ *holds.*

Lean4 (definition) `BEDC.Derived.ProdUp.ProdClassifierSpec`
Lean4 (definition) `BEDC.Derived.ProdUp.ProdHistoryClassifier`

Theorem 34.12 (Product typed classifier coordinate exactness)**.** *For types A and B, component classifiers $R_A : A \to A \to \mathsf{Prop}$ and $R_B : B \to B \to \mathsf{Prop}$, and elements $a, a' : A$ and $b, b' : B$, the product typed classifier is exact on coordinates:*

$$\mathsf{ProdClassifierSpec}(R_A, R_B, \mathsf{pair}(a, b), \mathsf{pair}(a', b')) \iff R_A(a, a') \wedge R_B(b, b').$$

Proof. Unfold ProdClassifierSpec. The forward direction is constructor inversion on the product classifier witness, yielding the two coordinate witnesses. The reverse direction pairs the two displayed coordinate witnesses to rebuild the product classifier witness. □

Lean4 ✓ `BEDC.Derived.ProdUp.prodClassifier iff`

Definition 34.13 (Product typed source carrier)**.** *For source carriers $L, R : \mathsf{BHist} \to \mathsf{Prop}$ and $x : \mathsf{ProdCarrier}(\mathsf{BHist}, \mathsf{BHist})$, define* $\mathsf{ProdTypedCarrier}_{L,R}(x)$ *by the displayed pair decomposition*

$$\mathsf{ProdTypedCarrier}_{L,R}(x) \iff \exists l, r : \mathsf{BHist}.\ x = \mathsf{pair}(l, r) \wedge L(l) \wedge R(r).$$

It is the typed source-carrier predicate for the explicit ordered-product interface: the left coordinate is licensed by L and the right coordinate is licensed by R.

Lean4 (definition) `BEDC.Derived.ProdUp.ProdTypedCarrier`

Theorem 34.14 (Product typed carrier transport from source certificates)**.** *Let $L, R : \mathsf{BHist} \to \mathsf{Prop}$ be source carriers and let $\sim_L, \sim_R$ be source classifiers. If* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$*,* $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$*, $x, y : \mathsf{ProdCarrier}(\mathsf{BHist}, \mathsf{BHist})$,* $\mathsf{ProdTypedCarrier}_{L,R}(x)$*, and* $\mathsf{ProdClassifierSpec}(\sim_L, \sim_R, x, y)$*, then* $\mathsf{ProdTypedCarrier}_{L,R}(y)$*.*

Proof. Invert the typed carrier witness for x to obtain coordinates l and r with $x = \mathsf{pair}(l, r)$, $L(l)$, and $R(r)$. Invert the product carrier y as $\mathsf{pair}(l', r')$. Apply Theorem 34.12 to the classifier witness for the two displayed pairs; this yields source classifier witnesses $l \sim_L l'$ and $r \sim_R r'$. The carrier_respects_equiv fields of cert_L and cert_R transport $L(l)$ to $L(l')$ and $R(r)$ to $R(r')$. Those transported witnesses rebuild $\mathsf{ProdTypedCarrier}_{L,R}(y)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdTypedCarrier transport from source certificates`

Theorem 34.15 (Product history classifier endpoint carrier exposure)**.** *For all source predicates $L, R : \mathsf{BHist} \to \mathsf{Prop}$ and histories $h, k : \mathsf{BHist}$, the following equivalence holds:*

$$\mathsf{ProdHistoryClassifier}(L, R, h, k) \iff \exists l, r, l', r' : \mathsf{BHist},\ L(l) \wedge R(r) \wedge \mathsf{Cont}(l, r, h) \wedge L(l') \wedge R(r') \wedge \mathsf{Cont}(l', r', k) \wedge \mathsf{hsame}($$

Componentwise equality and componentwise classification belong to ProdClassifierSpec*, not to the history-envelope classifier.*

Proof. For the forward direction of the displayed equivalence, unfold ProdHistoryClassifier. Its two endpoint premises are $\mathsf{ProdHistoryCarrier}(L, R, h)$ and $\mathsf{ProdHistoryCarrier}(L, R, k)$, and each carrier premise unfolds into one left witness, one right witness, the two source-membership proofs, and the continuation proof producing the visible endpoint. Pair those two carrier inversions with the stored $\mathsf{hsame}(h, k)$ witness for the forward direction. Conversely, the displayed data rebuild the two product-history carrier premises and then the classifier witness for the reverse direction of the equivalence. The result is endpoint exposure rather than coordinate projection. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryClassifier component inversion`

Theorem 34.16 (Product history classifier common-right component left equality)**.** *For source predicates* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *and histories* $h, k, l, l', r : \mathsf{BHist}$*, if*

$$\mathsf{ProdHistoryClassifier}(L, R, h, k), \qquad \mathsf{Cont}(l, r, h), \qquad \mathsf{Cont}(l', r, k),$$

then $\mathsf{hsame}(l, l')$*.*

Proof. The product-history classifier stores the endpoint equality $\mathsf{hsame}(h, k)$. Both displayed continuation witnesses use the same right component r. BEDC common-suffix cancellation for continuations therefore cancels the shared right component across the equal endpoints and yields $\mathsf{hsame}(l, l')$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryClassifier common right component left hsame`

Theorem 34.17 (Product history source monotonicity)**.** *The roadmap-template fit is: traditional target ordered-product stability under source refinement; BEDC source* BHist *with* Cont*; carrier* ProdHistoryCarrier*; classifier* ProdHistoryClassifier*; stability obligation source inclusion transport; ledger unchanged pair-continuation evidence; core theorem list carrier monotonicity plus classifier monotonicity; exactness predicate preservation of visible product endpoints under source refinement; standard bridge ordinary product source restriction; status* ProofTarget*.*

For predicates $L, R, L', R' : \mathsf{BHist} \to \mathsf{Prop}$*, suppose* $\forall h.\ L(h) \to L'(h)$ *and* $\forall h.\ R(h) \to R'(h)$*. Then every* $\mathsf{ProdHistoryCarrier}(L, R, h)$ *yields* $\mathsf{ProdHistoryCarrier}(L', R', h)$*. Under the same hypotheses, every* $\mathsf{ProdHistoryClassifier}(L, R, h, k)$ *yields* $\mathsf{ProdHistoryClassifier}(L', R', h, k)$*.*

Proof. For the carrier clause, unpack the product carrier into histories l and r, source witnesses $L(l)$ and $R(r)$, and the continuation witness $\mathsf{Cont}(l, r, h)$. Apply the two source inclusions to obtain $L'(l)$ and $R'(r)$, then rebuild $\mathsf{ProdHistoryCarrier}(L', R', h)$ with the same continuation evidence.

For the classifier clause, unfold the stored classifier data. Apply the carrier clause to both endpoint carriers, and keep the stored $\mathsf{hsame}(h, k)$ witness unchanged to rebuild $\mathsf{ProdHistoryClassifier}(L', R', h, k)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistorySource monotonicity`

Theorem 34.18 (Product history classifier right transport)**.** *If a product-history classifier relates* h *to* k*, and* k *is internally the same as* k'*, then the classifier relates* h *to* k'*.*

Proof. Invert the product-history classifier into the left carrier, the right carrier, and the stored $\mathsf{hsame}(h, k)$ witness. Transport the right carrier across $\mathsf{hsame}(k, k')$, then compose $\mathsf{hsame}(h, k)$ with $\mathsf{hsame}(k, k')$ for the classifier witness. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryClassifier right hsame transport`

Theorem 34.19 (Product history classifier endpoint transport)**.** *If a product-history classifier relates h to k, and h is internally the same as h' while k is internally the same as k', then the classifier relates h' to k'.*

Proof. Invert the product-history classifier into endpoint carriers and the stored $\mathsf{hsame}(h, k)$ witness. Transport both endpoint carriers across their respective hsame witnesses, then compose symmetry of $\mathsf{hsame}(h, h')$, the stored link, and $\mathsf{hsame}(k, k')$ to obtain $\mathsf{hsame}(h', k')$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryClassifier hsame transport`

Theorem 34.20 (Product history classifier symmetry)**.** *If a product-history classifier relates h to k, then it relates k to h.*

Proof. Unpack the classifier into the two endpoint product carriers and the stored $\mathsf{hsame}(h, k)$ link. Exchange the endpoint carriers and reverse the stored history-sameness link by symmetry. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryClassifier symm`

Theorem 34.21 (Product history classifier left transport)**.** *If a product-history classifier relates h to k, and h is internally the same as h', then the classifier relates h' to k.*

Proof. Invert the classifier witness. Transport the left carrier through the $\mathsf{hsame}(h, h')$ witness, keep the right carrier, and compose the symmetric $\mathsf{hsame}(h', h)$ link with the stored $\mathsf{hsame}(h, k)$ classifier witness. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryClassifier left hsame transport`

Theorem 34.22 (Product history classifier transitivity)**.** *For source-history predicates L and R on* BHist*, if* $\mathsf{ProdHistoryClassifier}(L, R, h, k)$ *and* $\mathsf{ProdHistoryClassifier}(L, R, k, u)$*, then* $\mathsf{ProdHistoryClassifier}(L, R, h, u)$*.*

Proof. Unpack the endpoint $\mathsf{ProdHistoryCarrier}(L, R)$ witnesses for h and k from the first classifier witness, and for k and u from the second. Keep the h endpoint carrier from the first witness and the u endpoint carrier from the second, compose the stored $\mathsf{hsame}(h, k)$ and $\mathsf{hsame}(k, u)$ links, and rebuild $\mathsf{ProdHistoryClassifier}(L, R, h, u)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryClassifier trans`

Theorem 34.23 (Product history classifier continuation congruence)**.** *Let L and R be source-history predicates on* BHist*. Assume the left and right transport fields*

$$\forall x\, y.\ L(x) \wedge \mathsf{hsame}(x, y) \to L(y)$$

and

$$\forall x\, y.\ R(x) \wedge \mathsf{hsame}(x, y) \to R(y).$$

If $L(l)$*,* $R(r)$*,* $\mathsf{hsame}(l, l')$*,* $\mathsf{hsame}(r, r')$*,* $\mathsf{Cont}(l, r, h)$*, and* $\mathsf{Cont}(l', r', h')$*, then* $\mathsf{ProdHistoryClassifier}(L, R, h, h')$*.*

Proof. Apply the displayed left transport field to $L(l)$ and $\mathsf{hsame}(l, l')$ to obtain $L(l')$, and apply the displayed right transport field to $R(r)$ and $\mathsf{hsame}(r, r')$ to obtain $R(r')$. Product history carrier continuation introduction builds endpoint carrier witnesses for h and h' from the two continuation witnesses. Continuation respect for hsame transports the result endpoints across the two component links, yielding $\mathsf{hsame}(h, h')$. These three pieces are exactly the history-envelope classifier fields. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryClassifier cont congr`

Definition 34.24 (Product pair representation)**.** *For source-history predicates* $L, R : \mathsf{BHist} \to \mathsf{Prop}$*, define* $\mathsf{ProdPairRep}_{L,R}(h, l, r)$ *to mean that* l *is a left source history,* r *is a right source history, and their continuation presents* h*:*

$$\mathsf{ProdPairRep}_{L,R}(h, l, r) \quad :\Longleftrightarrow \quad L(l) \wedge R(r) \wedge \mathsf{Cont}(l, r, h).$$

Lean4 (definition) `BEDC.Derived.ProdUp.ProdPairRep`

Theorem 34.25 (Product pair representation coverage)**.** *For source-history predicates* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *and history* h*,*

$$\mathsf{ProdHistoryCarrier}(L, R, h) \quad \Longleftrightarrow \quad \exists l, r : \mathsf{BHist}.\ \mathsf{ProdPairRep}_{L,R}(h, l, r).$$

Proof. Unfold ProdHistoryCarrier and ProdPairRep. In the forward direction, the carrier witness exposes component histories l and r, source witnesses $L(l)$ and $R(r)$, and the continuation witness $\mathsf{Cont}(l, r, h)$; these are exactly the displayed pair representation witnesses. In the reverse direction, a displayed pair representation supplies the same two component histories, source witnesses, and continuation witness, so it rebuilds the product history carrier witness for h. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdPairRep coverage`

Theorem 34.26 (Product pair representation endpoint transport)**.** *For source-history predicates* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *and histories* h, k, l, r*, if* $\mathsf{ProdPairRep}_{L,R}(h, l, r)$ *and* $\mathsf{hsame}(h, k)$*, then* $\mathsf{ProdPairRep}_{L,R}(k, l, r)$ *holds.*

Proof. The per-object fit is: traditional target ordered-pair endpoint stability; BEDC source BHist with Cont; carrier ProdPairRep; classifier endpoint hsame; stability obligation endpoint transport; ledger displayed pair representation; core theorem this transport law; exactness pair presentation preserved by endpoint sameness; standard bridge stable ordered-pair endpoint; status ProofTarget. Unfold ProdPairRep to keep $L(l)$ and $R(r)$, and transport the $\mathsf{Cont}(l, r, h)$ result across $\mathsf{hsame}(h, k)$ using continuation result transport. The transported continuation witness together with the unchanged source witnesses rebuilds $\mathsf{ProdPairRep}_{L,R}(k, l, r)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdPairRep hsame transport`

Theorem 34.27 (Product fixed-pair endpoint determinism)**.** *For source-history predicates* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *and histories* h, k, l, r*, if* $\mathsf{ProdPairRep}_{L,R}(h, l, r)$ *and* $\mathsf{ProdPairRep}_{L,R}(k, l, r)$*, then* $\mathsf{hsame}(h, k)$ *holds, and consequently* $\mathsf{ProdHistoryClassifier}(L, R, h, k)$ *holds.*

Proof. Unfold both displayed pair representations. The first supplies $L(l)$, $R(r)$, and $\mathsf{Cont}(l, r, h)$; the second supplies the same component source witnesses and $\mathsf{Cont}(l, r, k)$. Applying continuation determinism to the two continuation witnesses gives $\mathsf{hsame}(h, k)$. The same source witnesses and continuation witnesses rebuild $\mathsf{ProdHistoryCarrier}(L, R, h)$ and $\mathsf{ProdHistoryCarrier}(L, R, k)$, and these endpoint carriers together with the hsame witness rebuild $\mathsf{ProdHistoryClassifier}(L, R, h, k)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryClassifier fixed pair determinism`

This statement fixes both component histories; comparison of two different pair presentations of one endpoint is exactly the separate coherence datum in Definition 34.29.

Theorem 34.28 (Product fixed-pair endpoint exactness)**.** *For source-history predicates* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *and histories* h, k, l, r*, if* $\mathsf{ProdPairRep}_{L,R}(h, l, r)$ *holds, then*

$$\mathsf{ProdPairRep}_{L,R}(k, l, r) \iff \mathsf{hsame}(h, k).$$

Proof. The per-object fit is: traditional target ordered-pair endpoint readback; BEDC source BHist with Cont; carrier ProdPairRep; classifier endpoint hsame; stability by endpoint transport and continuation determinism; ledger fixed displayed pair; core theorem fixed-pair endpoint exactness; exactness predicate the displayed iff; standard bridge fixed ordered-pair endpoint. For the forward direction, apply Theorem 34.27 to the displayed base representation and the target representation, then project the $\mathsf{hsame}(h, k)$ conjunct. For the reverse direction, apply Theorem 34.26 to the base representation and the displayed endpoint sameness. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdPairRep fixed endpoint exactness`

Definition 34.29 (Product pair-representation coherence)**.** *For source classifiers* $\sim_L$ *and* $\sim_R$*, define* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$ *to mean that any two pair representations of the same product history classify their corresponding components:*

$$\forall h\, l\, r\, l'\, r'.\ \mathsf{ProdPairRep}_{L,R}(h, l, r) \wedge \mathsf{ProdPairRep}_{L,R}(h, l', r') \to (l \sim_L l') \wedge (r \sim_R r').$$

Theorem 34.30 (Product raw pair representation coherence is not automatic)**.** *Let* $\mathsf{TopCarrier}(h) := \mathsf{True}$ *for every* $h : \mathsf{BHist}$*, and take both source classifiers to be* hsame*. Then* $\neg\mathsf{ProdPairRepCoherent}_{\mathsf{TopCarrier},\mathsf{TopCarrier},\mathsf{h}}$ *holds.*

The per-object fit is: traditional target ordered-pair readback; BEDC source BHist *with* Cont *and* hsame*; carrier* ProdPairRep*; classifier* hsame*; stability obligation coherence; ledger displayed pair boundary; core theorem non-automaticity; exactness obstruction; standard bridge raw append ambiguity; status* ProofTarget*.*

Proof. The endpoint $\mathsf{E0}(\mathsf{e})$ has two raw pair presentations under TopCarrier. The left-unit presentation uses components $(\mathsf{e}, \mathsf{E0}(\mathsf{e}))$, and the right-unit presentation uses components $(\mathsf{E0}(\mathsf{e}), \mathsf{e})$. If product pair-representation coherence were automatic for the two hsame classifiers, applying it to these two presentations of the same endpoint would force $\mathsf{hsame}(\mathsf{e}, \mathsf{E0}(\mathsf{e}))$ on the left components, and also $\mathsf{hsame}(\mathsf{E0}(\mathsf{e}), \mathsf{e})$ on the right components. BEDC history no-confusion separates the empty history from a zero-step endpoint, so the forced $\mathsf{hsame}(\mathsf{e}, \mathsf{E0}(\mathsf{e}))$ is impossible. Thus the componentwise ordered-pair certificate needs displayed coherence data and cannot be recovered from raw continuation alone. □

Definition 34.31 (Product componentwise history classifier)**.** *For source-history carriers* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *and source classifiers* $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$*, define* $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim}$ *by the existence of component histories* l_h, r_h, l_k, r_k *such that*

$$\mathsf{ProdPairRep}_{L,R}(h, l_h, r_h) \wedge \mathsf{ProdPairRep}_{L,R}(k, l_k, r_k) \wedge l_h \sim_L l_k \wedge r_h \sim_R r_k.$$

Lean4 (definition) `BEDC.Derived.ProdUp.ProdComponentHistoryClassifier`

Theorem 34.32 (Product componentwise history classifier source refinement)**.** *The per-object fit is: traditional ordered-product classifier stability under source refinement; BEDC source* BHist *with* Cont*; carrier through* ProdPairRep*; classifier* ProdComponentHistoryClassifier*; ledger unchanged displayed pair representations; one-way classifier preservation under carrier and classifier inclusions; status* ProofTarget*.*

For carriers $L, R, L', R' : \mathsf{BHist} \to \mathsf{Prop}$*, classifiers* $\sim_L, \sim_R, \sim'_L, \sim'_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$*, and histories* $h, k : \mathsf{BHist}$*, suppose* $\forall u.\ L(u) \to L'(u)$*,* $\forall u.\ R(u) \to R'(u)$*,* $\forall x\, y.\ x \sim_L y \to x \sim'_L y$*, and* $\forall x\, y.\ x \sim_R y \to x \sim'_R y$*. Then* $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h,k)$ *implies* $\mathsf{ProdComponentHistoryClassifier}_{L',R',\sim'_L,\sim'_R}(h,k)$*.*

Proof. Unpack the componentwise classifier witness into displayed pair representations of h and k with components l_h, r_h, l_k, r_k, together with the two component classifier witnesses. Rebuild each displayed pair representation for L', R' by applying the carrier inclusions to the stored component source witnesses and keeping the same continuation evidence. Transport the two component classifier witnesses through the classifier implications, then repack these two rebuilt displayed pair representations and the transported component witnesses as a $\mathsf{ProdComponentHistoryClassifier}_{L',R',\sim'_L,\sim'_R}(h,k)$ witness. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdComponentHistoryClassifier source refinement`

Theorem 34.33 (Product componentwise history classifier endpoint transport)**.** *For source-history carriers* $L, R : \mathsf{BHist} \to \mathsf{Prop}$*, source classifiers* $\sim_L, \sim_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$*, and histories* h, k, h', k'*, if* $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h,k)$*,* $\mathsf{hsame}(h,h')$*, and* $\mathsf{hsame}(k,k')$ *hold, then* $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h',k')$ *holds.*

Proof. The per-object fit is: traditional target ordered-pair classifier endpoint stability; BEDC source BHist with Cont and hsame; carrier ProdHistoryCarrier through ProdPairRep; classifier ProdComponentHistory stability obligation endpoint transport; ledger displayed pair representations; core theorem this transport law; exactness classifier preservation under endpoint hsame; standard bridge stable ordered-pair endpoints; status ProofTarget. Unpack the componentwise classifier witness into pair representations for h and k and component classifier witnesses $l_h \sim_L l_k$ and $r_h \sim_R r_k$. Apply Theorem 34.26 to move the displayed representation of h along $\mathsf{hsame}(h,h')$, and apply the same theorem to move the displayed representation of k along $\mathsf{hsame}(k,k')$. The component classifier witnesses are unchanged, so the transported pair representations and the original component witnesses rebuild $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h',k')$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdComponentHistoryClassifier hsame transport`

The componentwise endpoint classifier uses the finite-data sibling classifiers only as classifier patterns: the Bool tag discipline of chapter 32, the Sum endpoint separation of chapter 35, and the List spine stability of chapter 36. The $\mathsf{Prod}^{\uparrow}$ packet pairs two histories componentwise, while those siblings supply the finite tag and constructor-classifier shapes that the product route must not collapse.

Theorem 34.34 (Product pair representation hsame coherence)**.** *For source-history carriers* $L, R : \mathsf{BHist} \to \mathsf{Prop}$*, source classifiers* $\sim_L, \sim_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$*, and histories* h, k, l, r, l', r'*, if* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$*,* $\mathsf{ProdPairRep}_{L,R}(h,l,r)$*,* $\mathsf{ProdPairRep}_{L,R}(k,l',r')$*, and* $\mathsf{hsame}(h,k)$ *hold, then* $(l \sim_L l') \wedge (r \sim_R r')$ *holds.*

The per-object fit is: traditional target ordered-pair component comparison; BEDC source BHist *with* Cont *and* hsame*; carrier* ProdPairRep*; classifier pair* $\sim_L, \sim_R$*; stability obligation endpoint-transported coherence; ledger displayed pair representations at internally same product endpoints; core theorem this hsame-coherence bridge; exactness component witnesses compared after endpoint transport; standard bridge ordered-pair readback over stable product endpoints; status* ProofTarget*.*

Proof. Transport the second displayed pair representation from k to h. Concretely, symmetry of $\mathsf{hsame}(h,k)$ gives $\mathsf{hsame}(k,h)$, and Theorem 34.26 sends $\mathsf{ProdPairRep}_{L,R}(k,l',r')$ to $\mathsf{ProdPairRep}_{L,R}(h,l',r')$

without changing the displayed components. Now apply $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$ at the single endpoint h to the two displayed representations $\mathsf{ProdPairRep}_{L,R}(h,l,r)$ and $\mathsf{ProdPairRep}_{L,R}(h,l',r')$. The coherence datum returns exactly $(l \sim_L l') \wedge (r \sim_R r')$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdPairRep hsame coherence`

Theorem 34.35 (Product componentwise history classifier endpoint carriers)**.** *Let $L, R : \mathsf{BHist} \to \mathsf{Prop}$ be source-history carriers and let $\sim_L, \sim_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ be source classifiers. If $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h,k)$ holds, then both $\mathsf{ProdHistoryCarrier}(L,R,h)$ and $\mathsf{ProdHistoryCarrier}(L,R,k)$ hold. The per-object template role is: traditional target ordered-pair classifier endpoint coverage; BEDC source* BHist *with* Cont*; carrier* ProdHistoryCarrier*; classifier* ProdComponentHistoryClassifier*; ledger displayed pair representation; core theorem endpoint carrier exposure; exactness classifier endpoints are generated product endpoints; status* ProofTarget*.*

Proof. Unpack the componentwise classifier witness to obtain component histories l_h, r_h, l_k, r_k and displayed pair representations $\mathsf{ProdPairRep}_{L,R}(h,l_h,r_h)$ and $\mathsf{ProdPairRep}_{L,R}(k,l_k,r_k)$. Apply pair-representation coverage to the first displayed pair representation to rebuild $\mathsf{ProdHistoryCarrier}(L,R,h)$ and to the second displayed pair representation to rebuild $\mathsf{ProdHistoryCarrier}(L,R,k)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdComponentHistoryClassifier endpoint carriers`

Theorem 34.36 (Product componentwise classifier empty-source exclusion)**.** *Let $L, R : \mathsf{BHist} \to \mathsf{Prop}$ be source-history carriers and let $\sim_L, \sim_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ be source classifiers. If*

$$(\forall l : \mathsf{BHist}.\ \neg L(l)) \vee (\forall r : \mathsf{BHist}.\ \neg R(r)),$$

then for all histories $h, k : \mathsf{BHist}$,

$$\neg\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h,k).$$

The ten-field fit is: traditional ordered-product impossibility boundary; BEDC source BHist *with* Cont*; carrier through* ProdPairRep*; classifier* ProdComponentHistoryClassifier*; ledger displayed pair representation; core theorem empty-source exclusion; exactness no public product classification without both source witnesses; status* ProofTarget*.*

Proof. Assume the displayed empty-source disjunction and fix histories h, k together with a componentwise classifier witness. Invert that witness to obtain component histories l_h, r_h, l_k, r_k and displayed pair representations for both endpoints.

The first representation $\mathsf{ProdPairRep}_{L,R}(h,l_h,r_h)$ exposes the source witnesses $L(l_h)$ and $R(r_h)$ carried by the displayed product endpoint. If the left source is empty, applying $\forall l.\ \neg L(l)$ to l_h contradicts $L(l_h)$.

If the right source is empty instead, applying $\forall r.\ \neg R(r)$ to r_h contradicts $R(r_h)$. Thus either side of the empty-source disjunction rules out the assumed public componentwise classification. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdComponentHistoryClassifier empty source exclusion`

Theorem 34.37 (Product history classifier hsame component cancellation)**.** *For source predicates $L, R : \mathsf{BHist} \to \mathsf{Prop}$ and histories $h, k, l, l', r, r' : \mathsf{BHist}$, suppose*

$$\mathsf{ProdHistoryClassifier}(L,R,h,k), \qquad \mathsf{Cont}(l,r,h), \qquad \mathsf{Cont}(l',r',k).$$

Then the displayed component comparisons determine each other:

$$(\mathsf{hsame}(l, l') \to \mathsf{hsame}(r, r')) \wedge (\mathsf{hsame}(r, r') \to \mathsf{hsame}(l, l')).$$

The ten-field fit is: traditional target ordered-pair component cancellation; BEDC source BHist *with* Cont *and* hsame*; carrier* ProdHistoryCarrier*; classifier* ProdHistoryClassifier*; stability from endpoint* hsame *plus continuation cancellation; ledger displayed pair continuations; core theorem this component-cancellation block; exactness component readback under one known component comparison; standard bridge ordered-pair cancellation; status* ProofTarget*.*

Proof. Unfold the product-history classifier only to expose the stored endpoint comparison $\mathsf{hsame}(h, k)$. The two displayed continuation witnesses already show that h is presented by (l, r) and k is presented by (l', r').

For the first implication, assume $\mathsf{hsame}(l, l')$. Use Definition 4.43 on the two displayed continuations, with the left contexts aligned by $\mathsf{hsame}(l, l')$ and the results aligned by the classifier endpoint comparison $\mathsf{hsame}(h, k)$. The left-context cancellation clause yields $\mathsf{hsame}(r, r')$.

For the second implication, assume $\mathsf{hsame}(r, r')$. Transport the right suffix of one displayed continuation along this comparison so the two continuations have a common suffix. Then apply the common-suffix cancellation clause recorded in Definition 4.52, using the same endpoint comparison $\mathsf{hsame}(h, k)$, to obtain $\mathsf{hsame}(l, l')$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryClassifier component hsame cancellation`

Theorem 34.38 (Product history classifier empty-left component inversion)**.** *For source predicates* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *and a history* $k : \mathsf{BHist}$*, if* $\mathsf{ProdHistoryClassifier}(L, R, \mathsf{Empty}, k)$ *holds, then there are component histories* l, r, l', r' *such that* $L(l)$*,* $R(r)$*,* $l\mathsf{hsameEmpty}$*,* $r\mathsf{hsameEmpty}$*,* $L(l')$*,* $R(r')$*,* $\mathsf{Cont}(l', r', k)$*, and* $\mathsf{Emptyhsame}k$ *all hold.*

Proof. Invert the product-history classifier into displayed product carrier witnesses for the empty left endpoint and for k. The empty endpoint carrier supplies a continuation $\mathsf{Cont}(l, r, \mathsf{Empty})$, and empty-result inversion for BEDC continuations forces both displayed components to be Empty. Keep the right endpoint continuation witness and the stored classifier endpoint equality to obtain the stated exposure. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryClassifier empty left component inversion`

Theorem 34.39 (Product pair-representation coherence obstruction from separated presentations)**.** *The ten-field fit is: traditional target ordered-pair presentation comparison; BEDC source* BHist *with* Cont*; carrier* ProdPairRep*; classifier pair* $\sim_L, \sim_R$*; stability obligation coherence; ledger displayed pair boundary; core theorem separated-presentation obstruction; exactness as failure of component comparison; standard bridge ordered-pair readback; status* ProofTarget*.*

Let $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, let* $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers, and let* $h, l, r, l', r' : \mathsf{BHist}$*. Suppose* $\mathsf{ProdPairRep}_{L,R}(h, l, r)$ *and* $\mathsf{ProdPairRep}_{L,R}(h, l', r')$ *hold. If either* $\neg(l \sim_L l')$ *or* $\neg(r \sim_R r')$ *holds, then*

$$\neg\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$$

holds.

Proof. Assume a coherence witness. Apply it to the two displayed representations of the same product history h. The coherence witness returns both component comparisons, namely $l \sim_L l'$ and $r \sim_R r'$. The separated component clause supplies either the negation of the left comparison or the negation of the right comparison, contradicting the corresponding returned component witness. □

Theorem 34.40 (Product pair coherence consumes finite tag separation)**.** *Before a* $\mathsf{Prod}^{\uparrow}$ *pair-representation coherence witness may publish componentwise classifier fields, it must preserve the same finite tag-separation discipline used by the nullable* $\mathsf{Option}^{\uparrow}$ *surface of chapter 33 and the disjoint-branch classifier surface of chapter 35. Concretely, an absent-or-present payload read cannot be folded into a component comparison unless the* $\mathsf{Option}^{\uparrow}$ *tag row has already separated the nullable case, and a left-or-right branch read cannot be paired across components unless the* $\mathsf{Sum}^{\uparrow}$ *classifier has already excluded mixed tags. The product row therefore receives componentwise classifier fields only after tag-separated finite constructors have fixed which payload comparisons are admissible.*

Proof. Start with the obstruction theorem above. A product coherence witness returns left and right component comparisons only after two displayed pair presentations have been matched at the same product history.

The $\mathsf{Option}^{\uparrow}$ dependency supplies the nullable tag boundary. Its absent and present rows determine whether a payload comparison is available at all, so a product component cannot treat the absent case as an ordinary source payload.

The $\mathsf{Sum}^{\uparrow}$ dependency supplies disjoint-branch separation. Its mixed-tag exclusion prevents a left payload and a right payload from being read as one component classifier row.

Thus the product classifier fields are published only after the two finite constructor disciplines have determined admissible component comparisons. The product packet adds no tag-erasing route of its own. □

Theorem 34.41 (Product componentwise history classifier carrier reflexivity from source certificates)**.** *The ten-field fit is: traditional target ordered-pair classifier reflexivity; BEDC source* BHist *with* Cont *and displayed pair representations; carrier* ProdHistoryCarrier*; classifier* ProdComponentHistoryClassifier*; stability obligation carrier-relative reflexivity from the two source certificates; ledger one displayed product pair representation; exactness component reflexivity at the same endpoints; standard bridge diagonal ordered-pair comparison; status* ProofTarget*.*

Let $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, let* $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers, and assume* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$ *and* $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$*. Then for every* $h : \mathsf{BHist}$*,*

$$\mathsf{ProdHistoryCarrier}(L, R, h) \to \mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, h).$$

Proof. Unpack the product carrier witness into displayed source histories l and r, source carrier witnesses for $L(l)$ and $R(r)$, and the corresponding pair representation of h. Use that same pair representation for both endpoints of the componentwise classifier. The source certificates provide $l \sim_L l$ and $r \sim_R r$ through their reflexivity fields, and these two component witnesses rebuild $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, h)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdComponentHistoryClassifier carrier reflexivity from source certificates`

Theorem 34.42 (Product componentwise history classifier symmetry from source certificates)**.** *The ten-field fit is: traditional target ordered-pair classifier symmetry; BEDC source* BHist *with* Cont *and displayed pair representations; carrier* ProdHistoryCarrier*; classifier* ProdComponentHistoryClassifier*; stability obligation source-certified symmetry for the two component classifiers; ledger displayed pair representations at both endpoints; exactness reversed component comparison; standard bridge symmetric ordered-pair comparison; status* ProofTarget*.*

Let L, R : BHist $\to$ Prop *be source-history carriers, let* $\sim_L, \sim_R$: BHist $\to$ BHist $\to$ Prop *be source classifiers, and assume* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$ *and* $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$*. Then for all* h, k : BHist*,*

$$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, k) \to \mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(k, h).$$

Proof. Unpack the componentwise classifier witness into displayed pair representations of h and k and component classifier witnesses $l_h \sim_L l_k$ and $r_h \sim_R r_k$. Apply cert_L.equiv_symm and cert_R.equiv_symm to reverse the two component comparisons. Swap the endpoint pair representations and rebuild the componentwise classifier from the reversed left and right witnesses. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdComponentHistoryClassifier symm from source certificates`

Theorem 34.43 (Product componentwise classifier self-readback exactness)**.** *The ten-field fit is: traditional target diagonal ordered-pair readback; BEDC source* BHist *with* Cont *and displayed pair representations; carrier* ProdHistoryCarrier*; classifier* ProdComponentHistoryClassifier*; stability obligation endpoint-carrier exposure together with carrier-relative reflexivity from the two source certificates; ledger one visible history used at both endpoints; core theorem self-readback exactness; exactness diagonal classifier truth if and only if product carrier membership; standard bridge ordered-pair self comparison; status* ProofTarget*.*

Let L, R : BHist $\to$ Prop *be source-history carriers, let* $\sim_L, \sim_R$: BHist $\to$ BHist $\to$ Prop *be source classifiers, and assume* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$ *and* $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$*. Then every* h : BHist *satisfies*

$$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, h) \iff \mathsf{ProdHistoryCarrier}(L, R, h).$$

Proof. For the forward direction, assume $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, h)$. Apply Theorem 34.35 to this diagonal classifier witness. It returns product-carrier witnesses for both endpoints, and either projection gives $\mathsf{ProdHistoryCarrier}(L, R, h)$.

For the reverse direction, assume $\mathsf{ProdHistoryCarrier}(L, R, h)$. Apply Theorem 34.41 with the two source certificates to the carrier witness. The result is exactly $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, h)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdComponentHistoryClassifier self readback iff`

Theorem 34.44 (Product componentwise classifier is independent of displayed pair representatives)**.** *The ten-field fit is: traditional target ordered-product componentwise readback well-definedness; BEDC source* BHist *with* Cont *and displayed* ProdPairRep *witnesses; carrier* ProdHistoryCarrier*; classifier* ProdComponentHistoryClassifier*; stability obligation representative independence under* ProdPairRepCoherent *and source* NameCert *symmetry and transitivity; ledger displayed pair representations at both endpoints; core theorem this law; exactness independence from chosen coherent representatives; standard bridge ordered-pair readback; status* ProofTarget*.*

Let L, R : BHist $\to$ Prop *be source-history carriers, let* $\sim_L, \sim_R$: BHist $\to$ BHist $\to$ Prop *be source classifiers, and assume* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$*,* $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$*, and* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$*.*

For all $h, k, l, r, l', r', u, v, u', v' : \mathsf{BHist}$*, if* $\mathsf{ProdPairRep}_{L,R}(h, l, r)$*,* $\mathsf{ProdPairRep}_{L,R}(h, l', r')$*,* $\mathsf{ProdPairRep}_{L,R}(k, u, v)$*, and* $\mathsf{ProdPairRep}_{L,R}(k, u', v')$ *hold, then*

$$(l \sim_L u) \wedge (r \sim_R v) \to (l' \sim_L u') \wedge (r' \sim_R v').$$

Proof. Apply $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$ at the source endpoint h to compare the displayed pairs (l', r') and (l, r). This gives $l' \sim_L l$ and $r' \sim_R r$. Apply the same coherence law at the target endpoint k to compare (u, v) with (u', v'), giving $u \sim_L u'$ and $v \sim_R v'$. The supplied component comparison gives $l \sim_L u$ and $r \sim_R v$. Two uses of cert_L.equiv_trans compose $l' \sim_L l \sim_L u \sim_L u'$, and two uses of cert_R.equiv_trans compose $r' \sim_R r \sim_R v \sim_R v'$. The resulting left and right witnesses form the displayed pair of component comparisons. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdComponentHistoryClassifier representative independence`

Theorem 34.45 (Product componentwise history classifier core fields)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, let* $\sim_L, \sim_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be their source classifiers, and assume* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$*,* $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$*, and* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$*. Write* $C(h, k)$ *for* $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, k)$*. Then its componentwise endpoint exposure is:*

$$\forall h\, k.\ C(h, k) \to \mathsf{ProdHistoryCarrier}(L, R, h) \wedge \mathsf{ProdHistoryCarrier}(L, R, k).$$

Its five core NameCert *fields for* $\mathsf{ProdHistoryCarrier}(L, R)$ *decompose as follows:*

1. *carrier inhabitation:*
$$\exists h.\ \mathsf{ProdHistoryCarrier}(L, R, h);$$
2. *carrier-relative reflexivity:*
$$\forall h.\ \mathsf{ProdHistoryCarrier}(L, R, h) \to C(h, h);$$
3. *source-certified symmetry:*
$$\forall h\, k.\ C(h, k) \to C(k, h);$$
4. *source-certified transitivity:*
$$\forall h\, k\, u.\ C(h, k) \to C(k, u) \to C(h, u);$$
5. *projection-derived NameCert-shaped classifier-induced carrier transport:*
$$\forall h\, k.\ C(h, k) \to \mathsf{ProdHistoryCarrier}(L, R, h) \to \mathsf{ProdHistoryCarrier}(L, R, k).$$

These five fields are the core NameCert *data used by Theorem 34.61.*

Proof. For carrier inhabitation, cert_L.carrier_inhabited and cert_R.carrier_inhabited supply histories l and r with $L(l)$ and $R(r)$. Applying Theorem 34.3 to those two source carrier witnesses gives $\mathsf{ProdHistoryCarrier}(L, R, \mathsf{append}(l, r))$, so the product carrier is inhabited. For carrier-relative reflexivity, unpack a $\mathsf{ProdHistoryCarrier}(L, R, h)$ witness and apply Theorem 34.41. For symmetry, apply Theorem 34.42 to the componentwise classifier witness. For transitivity, unpack $\mathsf{C}(h, k)$ and $\mathsf{C}(k, u)$ into pair representations (l_h, r_h), (l_k, r_k), (l'_k, r'_k), and (l_u, r_u). Pair-representation coherence at the middle history k gives both $l_k \sim_L l'_k$ and $r_k \sim_R r'_k$. The two source NameCert.equiv_trans

fields then compose the left chain $l_h \sim_L l_k \sim_L l'_k \sim_L l_u$ and the right chain $r_h \sim_R r_k \sim_R r'_k \sim_R r_u$ separately. For endpoint exposure, apply Theorem 34.35 directly to the classifier witness $C(h, k)$. For carrier transport, apply that endpoint exposure to $C(h, k)$, take the right projection $\mathsf{ProdHistoryCarrier}(L, R, k)$, and ignore the already supplied left carrier premise except as the required $\mathsf{NameCert}$ field input. Thus the displayed endpoint clause and five-field tuple are exactly the componentwise product core classifier data. □

Theorem 34.46 (Product componentwise history classifier transitivity from pair coherence)**.** *The ten-field fit is: traditional target ordered-pair classifier composition; BEDC source* BHist *with* Cont *and displayed pair representations; carrier* $\mathsf{ProdHistoryCarrier}$*; classifier* $\mathsf{ProdComponentHistoryClassifier}$*; stability obligation source-certified transitivity together with middle pair-representation coherence; ledger displayed pair representations; exactness component comparison through the shared middle endpoint; standard bridge ordered-pair composition; status* $\mathsf{ProofTarget}$.

Let $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, let* $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers, and assume* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$*,* $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$*, and* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$*. Then for all* $h, k, u : \mathsf{BHist}$*,*

$$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, k) \to \mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(k, u) \to \mathsf{ProdComponen}$$

Proof. Unpack the first componentwise classifier witness into displayed pair representations of h and k, and unpack the second into displayed pair representations of k and u. The two representations of the shared middle history k are compared by $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$, giving the middle left and right component comparisons. On the left side, $\mathsf{cert}_L.\mathsf{equiv_trans}$ first composes the h–k comparison with the middle left comparison, and then composes the result with the k–u comparison. On the right side, $\mathsf{cert}_R.\mathsf{equiv_trans}$ performs the same two-step composition through the middle right comparison. Reuse the original displayed pair representations of h and u together with these two composed component comparisons to rebuild $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, u)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdComponentHistoryClassifier trans from pair coherence`

Finite-data sibling lattice. The componentwise $\mathsf{Prod}^{\uparrow}$ transfer reads the same finite-data sibling lattice as the nullable, tagged, and iterated carriers: chapter 33 supplies the one-sided absent-or-present component case, chapter 35 supplies tagged branch separation for component choice, and chapter 36 supplies iterated component transport when a product certificate is replayed across a finite family. The transfer theorems below use those sibling surfaces only as finite carrier discipline; they do not add any coordinate beyond the displayed product pair rows.

Theorem 34.47 (Bounded hsame product pair-representation coherence)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers. Suppose there are histories* $l_0, r_0 : \mathsf{BHist}$ *such that*

$$\forall l.\ L(l) \to \mathsf{hsame}(l, l_0)$$

and

$$\forall r.\ R(r) \to \mathsf{hsame}(r, r_0).$$

With both source classifiers specialized to hsame*, the product pair-representation coherence condition holds:*

$$\mathsf{ProdPairRepCoherent}_{L,R,\mathsf{hsame},\mathsf{hsame}}.$$

Proof. Take two displayed pair representations of the same product history h, with components (l, r) and (l', r'). The pair-representation witnesses include $L(l)$, $L(l')$, $R(r)$, and $R(r')$. The boundedness hypotheses give $\mathsf{hsame}(l, l_0)$, $\mathsf{hsame}(l', l_0)$, $\mathsf{hsame}(r, r_0)$, and $\mathsf{hsame}(r', r_0)$. By symmetry of hsame, turn $\mathsf{hsame}(l', l_0)$ into $\mathsf{hsame}(l_0, l')$ and $\mathsf{hsame}(r', r_0)$ into $\mathsf{hsame}(r_0, r')$. By transitivity of hsame, compose l through l_0 to obtain $\mathsf{hsame}(l, l')$, and compose r through r_0 to obtain $\mathsf{hsame}(r, r')$. These are exactly the two component classifier conclusions required by $\mathsf{ProdPairRepCoherent}_{L,R,\mathsf{hsame},\mathsf{hsame}}$. □

Theorem 34.48 (Product pair-representation coherence from classifier-bounded sources)**.** *The ten-field fit is: traditional target ordered-product component readback through bounded source classifiers; BEDC source* BHist *with* Cont*; carriers L and R; classifiers $\sim_L$ and $\sim_R$; stability obligation pair-representation coherence; ledger displayed pair representation; core theorem classifier-bounded coherence; exactness component comparison through the source classifiers; standard bridge source certificates plus center histories; status* ProofTarget*.*

Let $L, R : \mathsf{BHist} \to \mathsf{Prop}$ be source-history carriers, let $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ be source classifiers, and assume $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$ and $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$. Suppose there are histories $l_0, r_0 : \mathsf{BHist}$ such that

$$\forall l.\ L(l) \to l \sim_L l_0$$

and

$$\forall r.\ R(r) \to r \sim_R r_0.$$

Then the product pair-representation coherence condition holds:

$$\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}.$$

Proof. Take two displayed pair representations of the same product history h, with components (l, r) and (l', r'). The displayed witnesses contain the source facts $L(l)$, $L(l')$, $R(r)$, and $R(r')$. The boundedness assumptions give $l \sim_L l_0$, $l' \sim_L l_0$, $r \sim_R r_0$, and $r' \sim_R r_0$. Apply the symmetry fields of cert_L and cert_R to turn the second left and right bounds into $l_0 \sim_L l'$ and $r_0 \sim_R r'$. Apply the transitivity fields of the two certificates to compose through the center histories, obtaining $l \sim_L l'$ and $r \sim_R r'$. These two component classifier witnesses are exactly the conclusion required by $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdPairRep classifier bounded coherence`

Theorem 34.49 (Singleton product pair-representation coherence)**.** *Fix histories $l_0, r_0 : \mathsf{BHist}$. Let $L(x) :\Longleftrightarrow \mathsf{hsame}(x, l_0)$ and $R(y) :\Longleftrightarrow \mathsf{hsame}(y, r_0)$. With both source classifiers specialized to* hsame*, the singleton source carriers satisfy product pair-representation coherence:*

$$\mathsf{ProdPairRepCoherent}_{L,R,\mathsf{hsame},\mathsf{hsame}}.$$

Proof. Apply Theorem 34.47. The required left bound sends a witness $L(l)$ to the displayed clause $\mathsf{hsame}(l, l_0)$, and the required right bound sends a witness $R(r)$ to the displayed clause $\mathsf{hsame}(r, r_0)$. □

Definition 34.50 (Product displayed pair ledger)**.** *Let $L, R : \mathsf{BHist} \to \mathsf{Prop}$ be source-history carriers. The product displayed pair ledger is the predicate*

$$\mathsf{ProdDisplayedPairLedger}_{L,R}(h) \Longleftrightarrow \exists l, r : \mathsf{BHist}.\ \mathsf{ProdPairRep}_{L,R}(h, l, r).$$

Theorem 34.51 (Product displayed pair ledger soundness)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers. For every history* $h : \mathsf{BHist}$*,*

$$\mathsf{ProdHistoryCarrier}(L, R, h) \to \mathsf{ProdDisplayedPairLedger}_{L,R}(h).$$

Proof. Assume $\mathsf{ProdHistoryCarrier}(L, R, h)$. Apply the forward direction of Theorem 34.25 to this carrier witness.

The theorem returns histories $l, r : \mathsf{BHist}$ with $\mathsf{ProdPairRep}_{L,R}(h, l, r)$. By Definition 34.50, this existential witness is exactly $\mathsf{ProdDisplayedPairLedger}_{L,R}(h)$. □

Theorem 34.52 (Product displayed pair ledger exactness and transport)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers. Write* $D(h) :\Longleftrightarrow \mathsf{ProdDisplayedPairLedger}_{L,R}(h)$*. For all histories* $h, k : \mathsf{BHist}$*,*

$$D(h) \Longleftrightarrow \mathsf{ProdHistoryCarrier}(L, R, h)$$

and

$$D(h) \wedge \mathsf{hsame}(h, k) \to D(k).$$

Proof. Unfold D and Definition 34.50. For the forward direction of the equivalence, a displayed pair ledger witness is a pair of histories l, r with $\mathsf{ProdPairRep}_{L,R}(h, l, r)$. Apply the reverse direction of Theorem 34.25 to obtain $\mathsf{ProdHistoryCarrier}(L, R, h)$.

For the reverse direction, start with $\mathsf{ProdHistoryCarrier}(L, R, h)$. Apply the forward direction of Theorem 34.25 to obtain histories l, r with $\mathsf{ProdPairRep}_{L,R}(h, l, r)$. Repack this displayed representation by Definition 34.50; this is $D(h)$.

For endpoint transport, assume $D(h)$ and $\mathsf{hsame}(h, k)$. Unfold D to obtain a displayed pair representation $\mathsf{ProdPairRep}_{L,R}(h, l, r)$. Apply Theorem 34.26 along $\mathsf{hsame}(h, k)$, keeping the same displayed component histories l, r, to obtain $\mathsf{ProdPairRep}_{L,R}(k, l, r)$. Repack this representation by Definition 34.50; the result is $D(k)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdDisplayedPairLedger exact and transport`

Theorem 34.53 (Product carrier single-valued displayed pair readback)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, let* $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers, and assume* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$*. For every history* $h : \mathsf{BHist}$*, if* $\mathsf{ProdHistoryCarrier}(L, R, h)$ *holds, then there exist* $l, r : \mathsf{BHist}$ *such that*

$$\mathsf{ProdPairRep}_{L,R}(h, l, r) \quad \textit{and} \quad \mathsf{ProdDisplayedPairLedger}_{L,R}(h)$$

and, for all $l', r' : \mathsf{BHist}$*,*

$$\mathsf{ProdPairRep}_{L,R}(h, l', r') \to (l \sim_L l') \wedge (r \sim_R r').$$

Proof. Assume $\mathsf{ProdHistoryCarrier}(L, R, h)$. Apply the forward direction of Theorem 34.25 to choose histories l, r with $\mathsf{ProdPairRep}_{L,R}(h, l, r)$.

By Definition 34.50, the same displayed representation gives $\mathsf{ProdDisplayedPairLedger}_{L,R}(h)$.

It remains to compare any competing representation $\mathsf{ProdPairRep}_{L,R}(h, l', r')$. Apply Definition 34.29 to the assumed $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$, the chosen representation, and the competing representation. The result is exactly $(l \sim_L l') \wedge (r \sim_R r')$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdCarrier single valued displayed pair readback`

Definition 34.54 (Product displayed pair ledger chain)**.** *For source carriers* $L, R : \mathsf{BHist} \to \mathsf{Prop}$*, the relation* $\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, z)$ *is the inductively generated displayed ledger-provenance relation on product histories with two constructors. A single displayed ledger gives a chain:*

$$\frac{\mathsf{ProdHistoryLedgerPolicy}(L, R, \rho, z)}{\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, z)}.$$

A displayed ledger followed by a chain through an intermediate history gives a chain:

$$\frac{\mathsf{ProdHistoryLedgerPolicy}(L, R, \rho, v) \quad \mathsf{ProdHistoryLedgerChain}_{L,R}(v, z)}{\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, z)}.$$

Lean4 (definition) `BEDC.Derived.ProdUp.ProdHistoryLedgerChain`

Theorem 34.55 (Product ledger chain envelope closure)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers and let* $\rho, z : \mathsf{BHist}$*. If* $\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, z)$ *holds, then* $\mathsf{ProdHistoryCarrier}(L, R, z)$ *and* $\mathsf{ProdHistoryClassifier}(L, R, \rho, z)$ *hold. Moreover, for every* $w : \mathsf{BHist}$ *both history-envelope endpoint-replacement clauses hold:*

$$\mathsf{ProdHistoryClassifier}(L, R, \rho, w) \iff \mathsf{ProdHistoryClassifier}(L, R, z, w)$$

and

$$\mathsf{ProdHistoryClassifier}(L, R, w, \rho) \iff \mathsf{ProdHistoryClassifier}(L, R, w, z).$$

Proof. Induct on the derivation of $\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, z)$.

In the one-ledger constructor, Theorem 34.92 gives $\mathsf{ProdHistoryCarrier}(L, R, z)$ from the displayed ledger, and Theorem 34.93 gives $\mathsf{ProdHistoryClassifier}(L, R, \rho, z)$. The left endpoint-replacement clause is Theorem 34.97. The right endpoint-replacement clause follows by composing through the same raw-visible classifier with symmetry and transitivity of the product history classifier.

In the cons constructor, write the first displayed ledger as $\mathsf{ProdHistoryLedgerPolicy}(L, R, \rho, v)$ and the remaining chain as $\mathsf{ProdHistoryLedgerChain}_{L,R}(v, z)$. The induction hypothesis supplies $\mathsf{ProdHistoryCarrier}(L, R, z)$, $\mathsf{ProdHistoryClassifier}(L, R, v, z)$, and the two endpoint equivalences from v to z.

The first ledger supplies $\mathsf{ProdHistoryClassifier}(L, R, \rho, v)$ by Theorem 34.93. Compose it with the induction classifier by Theorem 34.22 to obtain $\mathsf{ProdHistoryClassifier}(L, R, \rho, z)$. Compose the one-ledger endpoint equivalence from ρ to v with the induction endpoint equivalence from v to z for the left clause, and use the same endpoint transport through symmetry for the right clause. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerChain envelope closure`

Theorem 34.56 (Product ledger chain shared-raw visible classifier)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers and let* $\rho, z, z' : \mathsf{BHist}$*. If both* $\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, z)$ *and* $\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, z')$ *hold, then* $\mathsf{ProdHistoryClassifier}(L, R, z, z')$ *holds.*

Proof. Apply Definition 34.55 to both ledger chains. The first envelope gives $\mathsf{ProdHistoryClassifier}(L, R, \rho, z)$ and the second gives $\mathsf{ProdHistoryClassifier}(L, R, \rho, z')$. Reverse the first classifier by product classifier symmetry, then compose it with the second classifier by product classifier transitivity. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerChain shared raw visible classifier`

Theorem 34.57 (Product ledger chain displayed component readback)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers and let* $\sim_L, \sim_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers. Assume* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$*. For histories* $\rho, z, l, r : \mathsf{BHist}$*, if* $\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, z)$ *and* $\mathsf{ProdPairRep}_{L,R}(\rho, l, r)$ *hold, then there exist* $l', r' : \mathsf{BHist}$ *such that*

$$\mathsf{ProdPairRep}_{L,R}(z, l', r') \quad \textit{and} \quad l \sim_L l' \quad \textit{and} \quad r \sim_R r'.$$

Proof. Apply Theorem 34.55 to the ledger chain. It gives $\mathsf{ProdHistoryCarrier}(L, R, z)$ and $\mathsf{ProdHistoryClassifier}(L, R,$ Project the endpoint link $\mathsf{hsame}(\rho, z)$ from this envelope classifier.

Apply Theorem 34.25 to the final carrier to obtain $l', r' : \mathsf{BHist}$ with $\mathsf{ProdPairRep}_{L,R}(z, l', r')$.

Now apply Theorem 34.34 to the coherence witness, the source displayed representation $\mathsf{ProdPairRep}_{L,R}(\rho, l, r)$, the final displayed representation $\mathsf{ProdPairRep}_{L,R}(z, l', r')$, and the endpoint link $\mathsf{hsame}(\rho, z)$. It returns exactly $l \sim_L l'$ and $r \sim_R r'$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerChain displayed component readback`

Theorem 34.58 (Product ledger chain componentwise classifier endpoint equivalence)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, and let* $\sim_L, \sim_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers. If* $\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, z)$ *holds, then for every* $w : \mathsf{BHist}$ *both public componentwise endpoint-replacement clauses hold:*

$$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(\rho, w) \iff \mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(z, w)$$

and

$$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(w, \rho) \iff \mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(w, z).$$

Proof. Apply Theorem 34.55 to the ledger chain. It gives $\mathsf{ProdHistoryClassifier}(L, R, \rho, z)$, whose stored endpoint link is $\mathsf{hsame}(\rho, z)$.

For the first displayed equivalence, transport a witness of $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(\rho, w)$ along $\mathsf{hsame}(\rho, z)$ on the left endpoint and hsame-reflexivity on w by Theorem 34.33. The reverse direction uses hsame-symmetry on the same endpoint link and hsame-reflexivity on w.

For the second displayed equivalence, transport a witness of $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(w, \rho)$ along hsame-reflexivity on w and $\mathsf{hsame}(\rho, z)$ on the right endpoint. The reverse direction again uses hsame-reflexivity on w and hsame-symmetry of $\mathsf{hsame}(\rho, z)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerChain componentwise classifier endpoint equivalence`

Theorem 34.59 (Product componentwise history core certificate)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, let* $\sim_L, \sim_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be their source classifiers, and assume* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$*,* $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$*, and* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$*. Then the componentwise classifier carries the core product naming certificate:*

$$\mathsf{NameCert}(\mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}).$$

Proof. Invoke Theorem 34.45. Its five-field conclusion supplies carrier inhabitation, carrier-relative reflexivity, source-certified symmetry, source-certified transitivity, and classifier-induced carrier transport for $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}$ over $\mathsf{ProdHistoryCarrier}(L, R)$. Assemble these clauses as the corresponding fields of the core $\mathsf{NameCert}$ record. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdComponentHistoryClassifier name certificate`

Theorem 34.60 (Product componentwise history classifier semantic name certificate)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, let* $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be their source classifiers, and assume* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$, $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, *and* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$. *Then the componentwise classifier forms the semantic naming certificate whose source, pattern, and ledger predicates are all the concrete product history carrier:*

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdComponentHis}$$

Proof. The componentwise core name certificate is Theorem 34.59. Its source carrier is $\mathsf{ProdHistoryCarrier}(L, R)$. Since the semantic pattern and ledger predicates are the same concrete carrier, both soundness maps are the identity on product history carrier witnesses. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdComponentHistoryClassifier semantic name certificate`

Theorem 34.61 (Product componentwise history semantic certificate target)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, let* $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be their source classifiers, and assume* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$, $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, *and* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$. *Then the componentwise classifier forms the semantic naming certificate with the product displayed pair ledger:*

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdDisplayedPairLedger}_{L,R}, \mathsf{ProdComponent}$$

Proof. Apply Theorem 34.59 to the two source certificates and the pair-representation coherence hypothesis. This gives the core $\mathsf{NameCert}$ certificate for $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}$ over $\mathsf{ProdHistoryCarrier}(L, R)$. The semantic pattern carrier is $\mathsf{ProdHistoryCarrier}(L, R)$, so $\mathsf{pattern_sound}$ is identity on the carrier.

Ledger soundness is Theorem 34.51: every product history carrier witness exposes a named $\mathsf{ProdDisplayedPairLedger}_{L,R}$ witness. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdComponentHistoryClassifier displayed ledger semantic name certificate`

Theorem 34.62 (Product componentwise classifier exposes displayed pair ledgers)**.** *The ten-field fit is: traditional target ordered-product displayed ledger exposure; BEDC source* BHist *with* Cont*; carrier through* $\mathsf{ProdPairRep}$*; classifier* $\mathsf{ProdComponentHistoryClassifier}$*; ledger* $\mathsf{ProdDisplayedPairLedger}$*; core theorem endpoint ledger exposure; exactness classifier endpoints carry displayed pair representatives; standard bridge ordered-pair readback; status* $\mathsf{ProofTarget}$.

Let $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, and let* $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be component classifiers. For all histories* $h, k : \mathsf{BHist}$, *if*

$$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, k)$$

holds, then

$$\mathsf{ProdDisplayedPairLedger}_{L,R}(h) \wedge \mathsf{ProdDisplayedPairLedger}_{L,R}(k).$$

Proof. Unpack the componentwise classifier witness. Its endpoint data include a displayed pair representation of h by some left and right component histories and a displayed pair representation of k by some left and right component histories.

By Definition 34.50, the first representation is the named ledger witness for h, and the second representation is the named ledger witness for k. These two witnesses give the required conjunction. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdUp StdBridge`

Theorem 34.63 (Product componentwise public certificate package)**.** *The ten-field fit is: traditional target ordered-product public certificate package; BEDC source* BHist *with* Cont *and* hsame*; carrier* ProdHistoryCarrier *through* ProdPairRep*; classifier* ProdComponentHistoryClassifier*; stability inputs* ProdPairRepCoherent *and source* hsame*-soundness; ledger* ProdDisplayedPairLedger*; core theorem the semantic certificate, displayed pair ledger endpoints, and envelope descent together; exactness componentwise endpoint ledgers plus descent to* ProdHistoryClassifier*; standard bridge ordered-pair public readback; status* ProofTarget*. This theorem is not a variant of any one preceding theorem, because it composes certificate existence, ledger endpoints, and envelope descent in the single public-scope package required by the roadmap.*

Let $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, let* $\sim_L, \sim_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be their source classifiers, and assume* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$, $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, *and* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$. *Assume also that both source classifiers are* hsame*-sound:*

$$\forall x\, y.\ x \sim_L y \to \mathsf{hsame}(x, y) \qquad \textit{and} \qquad \forall x\, y.\ x \sim_R y \to \mathsf{hsame}(x, y).$$

Then the following three facts hold:

1.

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdDisplayedPairLedger}_{L,R}, \mathsf{ProdCompon}$$

2. For all histories $h, k : \mathsf{BHist}$,

$$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, k) \to \mathsf{ProdDisplayedPairLedger}_{L,R}(h) \wedge \mathsf{ProdDisplayedPairLedger}_{L,R}(k$$

3. For all histories $h, k : \mathsf{BHist}$,

$$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, k) \to \mathsf{ProdHistoryClassifier}(L, R, h, k).$$

Proof. For the semantic certificate clause, apply Theorem 34.61 to cert_L, cert_R, and the $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,}$ witness.

For the displayed ledger clause, fix histories h and k and a witness of $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h,$ Apply Theorem 34.62 to that witness; its conclusion is exactly the required pair of displayed ledger endpoints.

For the envelope descent clause, fix histories h and k and a witness of $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h$ Apply Theorem 34.79 with the two hsame-soundness hypotheses, giving $\mathsf{ProdHistoryClassifier}(L, R, h, k)$. □

Closure status for $\mathsf{NameCert}_{\mathsf{Prod}^\uparrow}$**.**

Constructive story: An ordered pair here is made by putting two already certified histories on one visible line: choose a left witness from L and a right witness from R, then let the kernel continuation assemble h by appending the right history above the left one. Nothing else enters the product carrier, and two assembled histories count as the same product exactly when their recovered left components agree by L's classifier and their recovered right components agree by R's, so equality of the joined history is tracked back through the two component views. The certificate therefore uses that same product-history predicate as its source, records in the pattern the displayed pair shape and the cancellation rows that recover both sides, and keeps the raw continuation witness and the visible product history in the same ledger. Since the component classifiers are equivalences and continuation is deterministic, an admitted component pair gives the carrier its witness, componentwise sameness is reflexive, symmetric, and transitive, and anything it recognizes remains an admitted product. A history h lies in the signature gap of a $\mathsf{Prod}^\uparrow$ token p when the source-domain accepts the assembled history, the signature relation pairs it with an answer history and evidence ledger, and the token-introduction relation names that

answer as p; unfolded, h must decompose into two component histories whose left and right classifiers identify them with the components encoded by p. The chapter registers this parallel-display construction under the name $\mathsf{Prod}^{\uparrow}$; an ordered pair is the kernel's continuation relation used as two named components in view, with no host tuple type or projection axiom introduced.

Theory closure: TheoryGate(NameCert$_{\mathsf{Prod}\uparrow}$, maturePackageClosed)

Upgrade path: No further upgrade – chapter at top of the formal axis.

The componentwise envelope route consumes the visible branch discipline before it forms the **??** pair ledger. The tag separation of chapter 32 and the visible-branch readbacks of chapter 35 and chapter 33 are the finite-data pattern: a product endpoint is readable only after its left and right component histories remain separately displayed, just as those siblings keep their branch or absence rows visible before a classifier is consumed.

Theorem 34.64 (Product ledger visible pair-representation readback)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history predicates and let* $\rho, v : \mathsf{BHist}$*. Define the displayed pair ledger* $D(h) :\Longleftrightarrow \exists l, r : \mathsf{BHist}.\ \mathsf{ProdPairRep}_{L,R}(h, l, r)$*. If* $\mathsf{ProdHistoryLedgerPolicy}(L, R, \rho, v)$ *holds, then both* $D(v)$ *and* $\mathsf{ProdHistoryClassifier}(L, R, \rho, v)$ *hold.*

Proof. The per-object fit is: traditional target ordered-product visible ledger readback; BEDC source BHist with Cont and hsame; carrier ProdHistoryCarrier through ProdPairRep; classifier ProdHistoryClassifier; stability endpoint transport; ledger ProdHistoryLedgerPolicy plus displayed pair ledger D; core theorem checked ledger descent; exactness visible endpoint pair representation; standard bridge ordered-pair visible readback; status ProofTarget. Unpack the ledger policy to obtain the raw product carrier and the raw-visible hsame endpoint link. Apply Theorem 34.25 to the raw carrier, giving histories l, r with $\mathsf{ProdPairRep}_{L,R}(\rho, l, r)$. Transport this displayed pair representation along the raw-visible endpoint link by Theorem 34.26; the result is the witness for $D(v)$. The classifier clause is exactly Theorem 34.93. □

Theorem 34.65 (Product checked envelope admits displayed pair ledger)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, and assume* $\exists l : \mathsf{BHist}.\ L(l)$ *and* $\exists r : \mathsf{BHist}.\ R(r)$*. Define the displayed pair ledger* $D(h) :\Longleftrightarrow \exists l, r : \mathsf{BHist}.\ \mathsf{ProdPairRep}_{L,R}(h, l, r)$*. Then*

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), D, \mathsf{ProdHistoryClassifier}(L, R))$$

holds.

Proof. The per-object fit is: traditional target ordered-product visible ledger; BEDC source BHist with Cont; carrier ProdHistoryCarrier; classifier ProdHistoryClassifier; ledger displayed pair representation; core theorem Theorem 34.107; exactness via pair-representation coverage; standard bridge ordinary ordered pairs; public certificate scope SemanticNameCert; status ProofTarget. Instantiate Theorem 34.107 with the two source-history witnesses. Its checked envelope certificate supplies the NameCert core fields and pattern soundness for source and pattern both equal to $\mathsf{ProdHistoryCarrier}(L, R)$. It remains only to replace the ledger field: given a source witness $\mathsf{ProdHistoryCarrier}(L, R, h)$, apply the forward direction of Theorem 34.25 to obtain histories l and r with $\mathsf{ProdPairRep}_{L,R}(h, l, r)$, which is exactly $D(h)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryCarrier displayed pair semantic name certificate`

Theorem 34.66 (Singleton history source certificate)**.** *Fix a BEDC history* $a_0 : \mathsf{BHist}$*, and define* $A_{a_0} : \mathsf{BHist} \to \mathsf{Prop}$ *by* $A_{a_0}(x) \iff \mathsf{hsame}(x, a_0)$*. Then* $\mathsf{NameCert}(A_{a_0}, \mathsf{hsame})$ *holds.*

Proof. The carrier is inhabited by a_0 using reflexivity of hsame. The reflexivity, symmetry, and transitivity fields of the certificate are exactly the corresponding fields of hsame. For carrier transport, start with $A_{a_0}(x)$, namely $\mathsf{hsame}(x, a_0)$, and a classifier witness $\mathsf{hsame}(x, y)$. Symmetry turns the classifier witness into $\mathsf{hsame}(y, x)$, and transitivity with $\mathsf{hsame}(x, a_0)$ yields $\mathsf{hsame}(y, a_0)$, which is $A_{a_0}(y)$. □

Lean4 ✓ `BEDC.Derived.SingletonSource.SingletonHistorySource name certificate`

Theorem 34.67 (Singleton componentwise product semantic certificate)**.** *Fix histories* $l_0, r_0 : \mathsf{BHist}$*. Define singleton source carriers* $L(x) :\iff \mathsf{hsame}(x, l_0)$ *and* $R(y) :\iff \mathsf{hsame}(y, r_0)$*. With displayed pair ledger* $D(h) :\iff \exists l, r : \mathsf{BHist}.\ \mathsf{ProdPairRep}_{L,R}(h, l, r)$*, the componentwise product classifier specialized to* hsame *forms the semantic certificate*

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), D, \mathsf{ProdComponentHistoryClassifier}_{L,R,\mathsf{hsame},\mathsf{hs}}$$

Proof. Apply Theorem 34.66 at l_0 and at r_0 to obtain the two singleton $\mathsf{NameCert}$ records for L and R. Theorem 34.49 supplies the pair-representation coherence hypothesis for these singleton carriers. Apply Theorem 34.61 with the two singleton certificates and this coherence witness. □

Theorem 34.68 (Singleton product componentwise classifier endpoint exactness)**.** *Fix histories* $l_0, r_0 : \mathsf{BHist}$*, and define* $L(x) :\iff \mathsf{hsame}(x, l_0)$ *and* $R(y) :\iff \mathsf{hsame}(y, r_0)$*. Then for all histories* $h, k : \mathsf{BHist}$*,*

$$\mathsf{ProdComponentHistoryClassifier}_{L,R,\mathsf{hsame},\mathsf{hsame}}(h, k) \iff \mathsf{hsame}(h, \mathsf{append}(l_0, r_0)) \wedge \mathsf{hsame}(k, \mathsf{append}(l_0, r_0)).$$

Proof. For the forward direction, unpack the componentwise classifier into displayed pair representations for h and k and component links between their left and right representatives. The singleton source facts identify the left representatives with l_0 and the right representatives with r_0.

Use transitivity of hsame to compare each displayed component with the fixed components l_0, r_0. The displayed representation of $\mathsf{append}(l_0, r_0)$ is obtained from reflexivity component witnesses and the canonical continuation result. Continuation determinism, applied to the displayed continuations for h and k against this fixed displayed continuation, yields the two endpoint witnesses $\mathsf{hsame}(h, \mathsf{append}(l_0, r_0))$ and $\mathsf{hsame}(k, \mathsf{append}(l_0, r_0))$.

For the reverse direction, start from the displayed representation of $\mathsf{append}(l_0, r_0)$ with components l_0, r_0. Transport this representation along the two endpoint hsame witnesses by Theorem 34.26, obtaining displayed pair representations for h and k with the same components.

The component comparison clauses are the reflexivity witnesses $\mathsf{hsame}(l_0, l_0)$ and $\mathsf{hsame}(r_0, r_0)$. Together with the two transported displayed representations, these witnesses rebuild $\mathsf{ProdComponentHistoryClassifie}$ □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdComponentHistoryClassifier singleton endpoint exactness`

Theorem 34.69 (Singleton product displayed pair ledger endpoint exactness)**.** *Fix histories* $l_0, r_0 : \mathsf{BHist}$*, and define* $L(x) :\iff \mathsf{hsame}(x, l_0)$ *and* $R(y) :\iff \mathsf{hsame}(y, r_0)$*. With displayed pair ledger* $D(h) :\iff \exists l, r : \mathsf{BHist}.\ \mathsf{ProdPairRep}_{L,R}(h, l, r)$*, every history* $h : \mathsf{BHist}$ *satisfies*

$$D(h) \iff \mathsf{hsame}(h, \mathsf{append}(l_0, r_0)).$$

Proof. For the forward direction, unpack $D(h)$ to obtain histories l, r and a displayed representation $\mathsf{ProdPairRep}_{L,R}(h, l, r)$. Its singleton source clauses give $\mathsf{hsame}(l, l_0)$ and $\mathsf{hsame}(r, r_0)$, while its continuation clause presents h from the displayed components.

Transport the displayed components to l_0, r_0 and compare the transported continuation with the canonical continuation for $\mathsf{append}(l_0, r_0)$. The fixed-pair endpoint determinism of Theorem 34.27, applied after this component transport, yields $\mathsf{hsame}(h, \mathsf{append}(l_0, r_0))$.

For the reverse direction, start from the canonical displayed pair representation of $\mathsf{append}(l_0, r_0)$ with components l_0, r_0. Given $\mathsf{hsame}(h, \mathsf{append}(l_0, r_0))$, symmetry converts it to the orientation needed to move that representation back to h.

Theorem 34.26 carries the canonical representation along this endpoint witness, keeping the displayed components l_0, r_0. The resulting $\mathsf{ProdPairRep}_{L,R}(h, l_0, r_0)$ supplies the existential witnesses for $D(h)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdPairRep singleton endpoint exactness iff`

Theorem 34.70 (Product componentwise certificate refines the checked envelope)**.** *Let $L, R : \mathsf{BHist} \to \mathsf{Prop}$ be source-history carriers, let $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ be their source classifiers, and assume $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$, $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, and $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$. Assume also that the source classifiers are* hsame*-sound:*

$$\forall x\, y.\ x \sim_L y \to \mathsf{hsame}(x, y) \qquad \textit{and} \qquad \forall x\, y.\ x \sim_R y \to \mathsf{hsame}(x, y).$$

With $D(h) :\Longleftrightarrow \exists l, r : \mathsf{BHist}.\ \mathsf{ProdPairRep}_{L,R}(h, l, r)$, both of the following hold:

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), D, \mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R})$$

and, for all histories h, k,

$$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, k) \to \mathsf{ProdHistoryClassifier}(L, R, h, k).$$

Proof. The first conclusion is Theorem 34.61 applied to the two source certificates and the pair-representation coherence witness. The second conclusion is Theorem 34.79 applied to the two hsame-soundness assumptions. □

Theorem 34.71 (Bounded classifier product certificate refines the checked envelope)**.** *Let $L, R : \mathsf{BHist} \to \mathsf{Prop}$ be source-history carriers, let $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ be their source classifiers, and assume $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$, $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$. Assume also that the source classifiers are* hsame*-sound:*

$$\forall x\, y.\ x \sim_L y \to \mathsf{hsame}(x, y) \qquad \textit{and} \qquad \forall x\, y.\ x \sim_R y \to \mathsf{hsame}(x, y).$$

Suppose there are histories $l_0, r_0 : \mathsf{BHist}$ such that

$$\forall l.\ L(l) \to l \sim_L l_0$$

and

$$\forall r.\ R(r) \to r \sim_R r_0.$$

With displayed pair ledger $D(h) :\Longleftrightarrow \exists l, r : \mathsf{BHist}.\ \mathsf{ProdPairRep}_{L,R}(h, l, r)$, the following three clauses hold:

1. *the componentwise public certificate*

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L,R), \mathsf{ProdHistoryCarrier}(L,R), D, \mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,}$$

2. *the checked envelope certificate*

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L,R), \mathsf{ProdHistoryCarrier}(L,R), \mathsf{ProdHistoryCarrier}(L,R), \mathsf{ProdHistoryClass}$$

3. *for all histories h, k,*

$$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h,k) \to D(h) \wedge D(k) \wedge \mathsf{ProdHistoryClassifier}(L,R,h,k).$$

Proof. Apply Theorem 34.48 to the two source certificates and the two center-history bounds. This yields $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$. The componentwise public certificate is Theorem 34.61 applied to the two source certificates and this coherence witness. The checked envelope certificate is Theorem 34.107, using the inhabited carrier fields of cert_L and cert_R as the two source-history witnesses. For the endpoint exposure clause, Theorem 34.62 supplies $D(h)$ and $D(k)$ from the componentwise classifier witness, while Theorem 34.79 supplies $\mathsf{ProdHistoryClassifier}(L,R,h,k)$ from the same witness and the two hsame-soundness hypotheses. Conjoin the three conclusions. □

Theorem 34.72 (Product componentwise certificate descends to the checked envelope)**.** *Let $L, R : \mathsf{BHist} \to \mathsf{Prop}$ be source-history carriers, let $\sim_L, \sim_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ be their source classifiers, and assume $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$, $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, and $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$. Assume also that both source classifiers are hsame-sound:*

$$\forall x\, y.\ x \sim_L y \to \mathsf{hsame}(x,y) \qquad \textit{and} \qquad \forall x\, y.\ x \sim_R y \to \mathsf{hsame}(x,y).$$

With displayed pair ledger $D(h) :\Longleftrightarrow \exists l, r : \mathsf{BHist}.\ \mathsf{ProdPairRep}_{L,R}(h,l,r)$, the following three clauses hold:

1. *the componentwise public certificate*

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L,R), \mathsf{ProdHistoryCarrier}(L,R), D, \mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,}$$

2. *the checked envelope certificate*

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L,R), \mathsf{ProdHistoryCarrier}(L,R), \mathsf{ProdHistoryCarrier}(L,R), \mathsf{ProdHistoryClass}$$

3. *for all histories h, k,*

$$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h,k) \to D(h) \wedge D(k) \wedge \mathsf{ProdHistoryClassifier}(L,R,h,k).$$

This theorem records componentwise-to-envelope compatibility and displayed ledger endpoint exposure for the ordered-product public scope; classifier equivalence is supplied by the hsame*-specialized Theorem 34.75.*

Proof. Theorem 34.70 supplies the componentwise public certificate and the descent implication from the componentwise classifier to the checked envelope classifier. Theorem 34.62 supplies $D(h)$ and $D(k)$ from the same componentwise classifier witness. Conjoin those two displayed ledger endpoints with the descent implication. The checked envelope certificate is Theorem 34.107: the inhabited carrier fields of cert_L and cert_R provide the left and right carrier witnesses required by that theorem. □

Theorem 34.73 (Product componentwise public scope is stable under endpoint transport)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, let* $\sim_L, \sim_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be their source classifiers, and assume that both source classifiers are* hsame*-sound:*

$$\forall x\, y.\ x \sim_L y \to \mathsf{hsame}(x, y) \qquad \textit{and} \qquad \forall x\, y.\ x \sim_R y \to \mathsf{hsame}(x, y).$$

Define the displayed pair ledger by $D(x) :\Longleftrightarrow \exists l, r : \mathsf{BHist}.\ \mathsf{ProdPairRep}_{L,R}(x, l, r)$*. For histories* $h, k, h', k' : \mathsf{BHist}$*, if*

$$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, k), \qquad \mathsf{hsame}(h, h'), \qquad \mathsf{hsame}(k, k')$$

hold, then

$$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h', k') \wedge D(h') \wedge D(k') \wedge \mathsf{ProdHistoryCarrier}(L, R, h') \wedge \mathsf{ProdHistoryCarrier}(L, R$$

The roadmap fit is: traditional target ordered-product public-scope endpoint stability; BEDC source BHist *with* Cont *and* hsame*; carrier* ProdHistoryCarrier*; classifier* ProdComponentHistoryClassifier*; stability inputs endpoint transport and* hsame*-sound envelope descent; ledger displayed pair representation* D*; core theorem the transported componentwise classifier plus displayed ledger endpoints and endpoint carrier exposure; exactness displayed ledger plus envelope classifier; standard bridge ordered-pair readback; status* ProofTarget*.*

Proof. Apply Theorem 34.33 to the componentwise classifier witness at (h, k) and the two endpoint hsame links, obtaining $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h', k')$.

Apply Theorem 34.62 to the transported classifier. This gives $D(h')$ and $D(k')$ for the displayed pair ledger.

Apply Theorem 34.35 to the same transported classifier. This exposes $\mathsf{ProdHistoryCarrier}(L, R, h')$ and $\mathsf{ProdHistoryCarrier}(L, R, k')$.

Finally apply Theorem 34.79 with the two hsame-soundness assumptions to the transported classifier, obtaining $\mathsf{ProdHistoryClassifier}(L, R, h', k')$. Conjoin the transported classifier with the two ledger endpoints, the two endpoint carriers, and the envelope classifier. □

Theorem 34.74 (Product envelope displayed-pair component exactness)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers and let* $\sim_L, \sim_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers. Assume* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$ *and assume both source classifiers are* hsame*-sound:*

$$\forall x\, y.\ x \sim_L y \to \mathsf{hsame}(x, y) \qquad \textit{and} \qquad \forall x\, y.\ x \sim_R y \to \mathsf{hsame}(x, y).$$

For histories $h, k, l, r, l', r' : \mathsf{BHist}$*, if* $\mathsf{ProdPairRep}_{L,R}(h, l, r)$ *and* $\mathsf{ProdPairRep}_{L,R}(k, l', r')$ *hold, then*

$$\mathsf{ProdHistoryClassifier}(L, R, h, k) \Longleftrightarrow (l \sim_L l') \wedge (r \sim_R r').$$

Proof. For the forward direction, unpack the checked envelope classifier to obtain the endpoint link $\mathsf{hsame}(h, k)$. Symmetry gives $\mathsf{hsame}(k, h)$, and Theorem 34.26 carries the displayed representation of k with components l', r' back to a displayed representation of h with the same components. The $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$ witness then compares this transported representation with the given displayed representation $\mathsf{ProdPairRep}_{L,R}(h, l, r)$ and yields $l \sim_L l'$ and $r \sim_R r'$.

For the reverse direction, use the two displayed representations and the two component links as a witness of $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, k)$. Apply Theorem 34.79 with the two hsame-soundness assumptions to obtain $\mathsf{ProdHistoryClassifier}(L, R, h, k)$. □

Theorem 34.75 (Product hsame componentwise certificate is envelope-equivalent)**.** *Let* L, R : $\mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers. Assume* $\mathsf{cert}_L : \mathsf{NameCert}(L, \mathsf{hsame})$, $\mathsf{cert}_R : \mathsf{NameCert}(R, \mathsf{hsame})$, *and* $\mathsf{ProdPairRepCoherent}_{L,R,\mathsf{hsame},\mathsf{hsame}}$. *With displayed pair ledger* $D(h) :\Longleftrightarrow \exists l, r : \mathsf{BHist}.\ \mathsf{ProdPairRep}_{L,R}(h, l, r)$, *both semantic certificates hold:*

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryClassifie}$$

and

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), D, \mathsf{ProdComponentHistoryClassifier}_{L,R,\mathsf{hsame},\mathsf{h}}$$

Moreover, for all histories h, k,

$$\mathsf{ProdHistoryClassifier}(L, R, h, k) \Longleftrightarrow \mathsf{ProdComponentHistoryClassifier}_{L,R,\mathsf{hsame},\mathsf{hsame}}(h, k).$$

Proof. The checked envelope certificate is Theorem 34.107 applied to cert_L.carrier_inhabited and cert_R.carrier_inhabited. The displayed componentwise certificate is Theorem 34.61 with both source classifiers specialized to hsame and with the given $\mathsf{ProdPairRepCoherent}_{L,R,\mathsf{hsame},\mathsf{hsame}}$ witness. The classifier equivalence is exactly Theorem 34.82. □

Theorem 34.76 (Bounded hsame product certificates are envelope-equivalent)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, and assume* $\mathsf{cert}_L : \mathsf{NameCert}(L, \mathsf{hsame})$ *and* $\mathsf{cert}_R : \mathsf{NameCert}(R, \mathsf{hsame})$. *Suppose there are histories* $l_0, r_0 : \mathsf{BHist}$ *such that*

$$\forall l.\ L(l) \to \mathsf{hsame}(l, l_0)$$

and

$$\forall r.\ R(r) \to \mathsf{hsame}(r, r_0).$$

With displayed pair ledger $D(h) :\Longleftrightarrow \exists l, r : \mathsf{BHist}.\ \mathsf{ProdPairRep}_{L,R}(h, l, r)$, *both semantic certificates hold:*

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryClassifie}$$

and

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), D, \mathsf{ProdComponentHistoryClassifier}_{L,R,\mathsf{hsame},\mathsf{h}}$$

Moreover, for all histories h, k,

$$\mathsf{ProdHistoryClassifier}(L, R, h, k) \Longleftrightarrow \mathsf{ProdComponentHistoryClassifier}_{L,R,\mathsf{hsame},\mathsf{hsame}}(h, k).$$

Proof. Apply Theorem 34.47 to the two center histories and the two boundedness hypotheses. This gives the coherence witness $\mathsf{ProdPairRepCoherent}_{L,R,\mathsf{hsame},\mathsf{hsame}}$. Then apply Theorem 34.75 to cert_L, cert_R, and that coherence witness. Its displayed ledger is exactly D, and its conclusion is the two semantic certificates together with the classifier equivalence for arbitrary histories h and k. □

Theorem 34.77 (Singleton hsame product certificates are envelope-equivalent)**.** *This theorem fits the per-object template as follows: the traditional target is the singleton ordered-product bridge; the BEDC source is* BHist *with* Cont *and* hsame*; the carrier is* $\mathsf{ProdHistoryCarrier}(L, R)$*; the classifier*

pair is the envelope classifier and the componentwise classifier; the stability data are the singleton source certificates and pair coherence; the ledger is the displayed pair representation; the core theorem is the pair of semantic certificates together with the classifier equivalence; exactness is the classifier equivalence; the standard bridge is singleton ordered-pair readback; and the status is ProofTarget. *Fix histories* $l_0, r_0 : \mathsf{BHist}$. *Define* $L(x) :\Longleftrightarrow \mathsf{hsame}(x, l_0)$ *and* $R(y) :\Longleftrightarrow \mathsf{hsame}(y, r_0)$. *With displayed pair ledger* $D(h) :\Longleftrightarrow \exists l, r : \mathsf{BHist}.\ \mathsf{ProdPairRep}_{L,R}(h, l, r)$, *both semantic certificates hold:*

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryClassifie}$$

and

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), D, \mathsf{ProdComponentHistoryClassifier}_{L,R,\mathsf{hsame},\mathsf{hs}}$$

Moreover, for all histories h, k,

$$\mathsf{ProdHistoryClassifier}(L, R, h, k) \Longleftrightarrow \mathsf{ProdComponentHistoryClassifier}_{L,R,\mathsf{hsame},\mathsf{hsame}}(h, k).$$

Proof. Obtain the two singleton source NameCert records from Theorem 34.66, first at l_0 and then at r_0. The singleton definitions of L and R supply the left and right carrier witnesses for the checked envelope. Theorem 34.49 gives the required pair-representation coherence. Applying Theorem 34.75 with these certificates, witnesses, and the coherence proof yields the two semantic certificates and the displayed classifier equivalence. □

Theorem 34.78 (Product componentwise history classifier inversion)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, let* $\sim_L, \sim_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be their source classifiers. Assume* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$ *and the displayed source transitivity laws*

$$\forall a\, b\, c.\ a \sim_L b \to b \sim_L c \to a \sim_L c \qquad \textit{and} \qquad \forall a\, b\, c.\ a \sim_R b \to b \sim_R c \to a \sim_R c.$$

If $\mathsf{ProdPairRep}_{L,R}(h, l, r)$, $\mathsf{ProdPairRep}_{L,R}(k, l', r')$, *and* $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, k)$ *hold, then* $l \sim_L l'$ *and* $r \sim_R r'$.

Proof. Unpack the componentwise classifier witness to obtain component histories l_h, r_h, l_k, r_k with pair representations for h and k, together with $l_h \sim_L l_k$ and $r_h \sim_R r_k$. Apply pair-representation coherence at h to the displayed representation (l, r) and the witness representation (l_h, r_h), yielding $l \sim_L l_h$ and $r \sim_R r_h$. Apply coherence at k to the witness representation (l_k, r_k) and the displayed representation (l', r'), yielding $l_k \sim_L l'$ and $r_k \sim_R r'$. The displayed source transitivity hypotheses compose the left chain $l \sim_L l_h \sim_L l_k \sim_L l'$ and the right chain $r \sim_R r_h \sim_R r_k \sim_R r'$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdComponentHistoryClassifier inversion`

The descent theorem instantiates the roadmap template as traditional ordered-pair descent over the BEDC source BHist with Cont, carrier ProdHistoryCarrier, classifier bridge from componentwise to envelope under hsame-sound source classifiers, ledger by displayed pair representations, and status ProofTarget.

Theorem 34.79 (Product componentwise history classifier descends to envelope)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers and let* $\sim_L, \sim_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers. Assume the source classifiers are* hsame*-sound:*

$$\forall x\, y.\ x \sim_L y \to \mathsf{hsame}(x, y) \qquad \textit{and} \qquad \forall x\, y.\ x \sim_R y \to \mathsf{hsame}(x, y).$$

If $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, k)$ *holds, then* $\mathsf{ProdHistoryClassifier}(L, R, h, k)$ *holds.*

Proof. Unpack the componentwise classifier into component histories l_h, r_h, l_k, r_k, pair representations $\mathsf{ProdPairRep}_{L,R}(h, l_h, r_h)$ and $\mathsf{ProdPairRep}_{L,R}(k, l_k, r_k)$, and component links $l_h \sim_L l_k$ and $r_h \sim_R r_k$. The two hsame-sound assumptions turn the component links into $\mathsf{hsame}(l_h, l_k)$ and $\mathsf{hsame}(r_h, r_k)$. The pair representations expose $\mathsf{Cont}(l_h, r_h, h)$ and $\mathsf{Cont}(l_k, r_k, k)$, so continuation respect for hsame yields $\mathsf{hsame}(h, k)$. Pair-representation coverage rebuilds $\mathsf{ProdHistoryCarrier}(L, R, h)$ and $\mathsf{ProdHistoryCarrier}(L, R, k)$ from the two displayed pair representations, and these two endpoint carriers together with $\mathsf{hsame}(h, k)$ rebuild $\mathsf{ProdHistoryClassifier}(L, R, h, k)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdComponentHistoryClassifier descends to envelope`

The recovery theorem instantiates the roadmap template as traditional ordered-product envelope-to-componentwise readback over the BEDC source BHist with Cont and hsame, carrier ProdHistoryCarrier, classifier ProdComponentHistoryClassifier, stability via pair-representation coherence, ledger displayed pair representation, core theorem coherent envelope recovery, exactness component readback from envelope, standard bridge ordered-pair readback, and status ProofTarget.

Theorem 34.80 (Product envelope classifier recovers coherent componentwise classifier)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, let* $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers, and let* $h, k : \mathsf{BHist}$*. Assume* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$*. If* $\mathsf{ProdHistoryClassifier}(L, R, h, k)$ *holds, then* $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, k)$ *holds.*

Proof. Unpack the envelope classifier into endpoint carriers for h and k and the stored endpoint link $\mathsf{hsame}(h, k)$. Apply Theorem 34.25 to the two endpoint carriers to choose displayed pair representations $\mathsf{ProdPairRep}_{L,R}(h, l_h, r_h)$ and $\mathsf{ProdPairRep}_{L,R}(k, l_k, r_k)$.

Apply Theorem 34.34 to the coherence datum, the two displayed pair representations, and the endpoint link. The resulting component links $l_h \sim_L l_k$ and $r_h \sim_R r_k$, together with the displayed pair representations, repack as $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, k)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryClassifier pair coherent componentwise`

Theorem 34.81 (Product envelope hsame classifier recovers componentwise classifier)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers. Assume* $\mathsf{ProdPairRepCoherent}_{L,R,\mathsf{hsame},\mathsf{hsame}}$*. If* $\mathsf{ProdHistoryClassifier}(L, R,$ *holds, then* $\mathsf{ProdComponentHistoryClassifier}_{L,R,\mathsf{hsame},\mathsf{hsame}}(h, k)$ *holds.*

Proof. Unpack the envelope classifier into endpoint carrier witnesses for h and k and an endpoint link $\mathsf{hsame}(h, k)$. Pair-representation coverage for the two endpoint carriers supplies displayed pair representations $\mathsf{ProdPairRep}_{L,R}(h, l_h, r_h)$ and $\mathsf{ProdPairRep}_{L,R}(k, l_k, r_k)$. First reverse the endpoint link to obtain $\mathsf{hsame}(k, h)$. Apply Theorem 34.26 to the displayed representation of k and this reversed link, producing a displayed pair representation of h with the same components l_k, r_k. Pair-representation coherence at h compares the two representations of h and gives $\mathsf{hsame}(l_h, l_k)$ and $\mathsf{hsame}(r_h, r_k)$. These two component links together with the original displayed pair representations for h and k rebuild $\mathsf{ProdComponentHistoryClassifier}_{L,R,\mathsf{hsame},\mathsf{hsame}}(h, k)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryClassifier pair coherent componentwise hsame`

Theorem 34.82 (Product envelope and componentwise hsame classifiers coincide)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers and assume* $\mathsf{ProdPairRepCoherent}_{L,R,\mathsf{hsame},\mathsf{hsame}}$*. For all* $h, k : \mathsf{BHist}$*,*

$$\mathsf{ProdHistoryClassifier}(L, R, h, k) \iff \mathsf{ProdComponentHistoryClassifier}_{L,R,\mathsf{hsame},\mathsf{hsame}}(h, k).$$

Proof. The forward implication is Theorem 34.81. For the reverse implication, apply Theorem 34.79 with both source classifiers specialized to hsame. The two required hsame-soundness premises are discharged by the identity proof on the given component links. Thus the envelope classifier and the componentwise hsame classifier have exactly the same histories under the displayed pair-representation coherence. □

This exactness statement instantiates the roadmap template as traditional ordered-pair equality agreement over the BEDC source BHist with Cont, carrier ProdHistoryCarrier, classifier agreement between the envelope and componentwise hsame classifiers, stability by $\mathsf{ProdPairRepCoherent}_{L,R,\mathsf{hsame},\mathsf{hsame}}$, ledger through displayed pair representations, and status ProofTarget.

Theorem 34.83 (Product history classifier displayed component hsame exactness)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers and assume* $\mathsf{ProdPairRepCoherent}_{L,R,\mathsf{hsame},\mathsf{hsame}}$. *If* $L(l)$, $R(r)$, $\mathsf{Cont}(l, r, h)$, $L(l')$, $R(r')$, *and* $\mathsf{Cont}(l', r', k)$ *hold, then*

$$\mathsf{ProdHistoryClassifier}(L, R, h, k) \iff \mathsf{hsame}(l, l') \wedge \mathsf{hsame}(r, r').$$

Proof. For the forward direction, the displayed component data are $\mathsf{ProdPairRep}_{L,R}(h, l, r)$ and $\mathsf{ProdPairRep}_{L,R}(k, l', r')$. The product history classifier supplies the endpoint link $\mathsf{hsame}(h, k)$, so pair-representation coherence transports the endpoint link back to the two component links. For the reverse direction, the two component links are pushed through the two continuation witnesses by continuation respect for hsame, producing $\mathsf{hsame}(h, k)$. The displayed component data rebuild the two endpoint product carriers, and these three fields are exactly $\mathsf{ProdHistoryClassifier}(L, R, h, k)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryClassifier displayed component hsame iff`

Theorem 34.84 (Product componentwise history classifier displayed exactness)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, let* $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be their source classifiers. Assume* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$ *and the displayed source transitivity laws*

$$\forall a\, b\, c.\ a \sim_L b \to b \sim_L c \to a \sim_L c \qquad \textit{and} \qquad \forall a\, b\, c.\ a \sim_R b \to b \sim_R c \to a \sim_R c.$$

If $\mathsf{ProdPairRep}_{L,R}(h, l, r)$ *and* $\mathsf{ProdPairRep}_{L,R}(k, l', r')$, *then*

$$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(h, k) \iff (l \sim_L l') \wedge (r \sim_R r').$$

Proof. For the forward direction, apply Theorem 34.78 to the two displayed pair representations and the assumed componentwise classifier. For the reverse direction, use the displayed pair representations $\mathsf{ProdPairRep}_{L,R}(h, l, r)$ and $\mathsf{ProdPairRep}_{L,R}(k, l', r')$ as the existential witnesses in Definition 34.31; the two displayed component relations supply the remaining conjuncts. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdComponentHistoryClassifier displayed exactness`

Theorem 34.85 (Product component-classifier pullback)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers and let* $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers satisfying the displayed transitivity laws of Definition 34.84. For any public product-envelope consumers* C *and* D, *if their displayed reads of a pair envelope agree on the left component classifier and on the right component classifier, then their reads pull back to the same* $\mathsf{Prod}^{\uparrow}$ *envelope classifier. The pullback is measured through* $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}$, *descends to* $\mathsf{ProdHistoryClassifier}(L, R, -, -)$ *when the component classifiers are* hsame*-sound, and is recorded by the product stability certificate rows.*

Proof. Project both public consumers to their displayed product rows. The exactness theorem Definition 34.84 rewrites each componentwise product classifier as the conjunction of the two displayed component classifier agreements.

Because C and D agree on both component classifiers, those two conjunctions are the same displayed witness. Repack the two component agreements through Definition 34.31; this gives the common ProdComponentHistoryClassifier row for the two product-envelope reads.

Envelope descent is then Definition 34.79 under the declared hsame-soundness of the component classifiers. The displayed hsame exactness theorem Definition 34.83 identifies the envelope readback with the same component data, and Definition 34.86 records the stability rows that let finite-data consumers reuse the pullback. □

Definition 34.86 (Prod stability certificate)**.** *The checked stability subcertificate consists of:*

1. *componentwise reflexivity obtained from the two source reflexivity fields*
2. *componentwise transitivity obtained from the two source transitivity fields*
3. *coordinate exposure: any* ProdClassifierSpec(R_A, R_B, x, y) *witness yields* $R_A(x.1, y.1)$ *and* $R_B(x.2, y.2)$

Relation-level symmetry is supplied by Theorem 34.88; the source-certificate theorem is obtained from the two equiv_symm *fields, while the* hsame *specialization is Theorem 34.90.*

Lean4 ✓ `BEDC.Derived.ProdUp.prod stability certificate fields`

Theorem 34.87 (Product classifier transitivity at the typed level)**.** *Let* $R_A : A \to A \to \mathsf{Prop}$ *and* $R_B : B \to B \to \mathsf{Prop}$ *be source classifier relations. If both* R_A *and* R_B *are transitive, then for product carriers* x*,* y*, and* z*,*

$$\mathsf{ProdClassifierSpec}(R_A, R_B, x, y) \quad \textit{and} \quad \mathsf{ProdClassifierSpec}(R_A, R_B, y, z)$$

imply ProdClassifierSpec(R_A, R_B, x, z)*.*

Lean4 ✓ `BEDC.Derived.ProdUp.ProdClassifierSpec trans`

Proof. Invert the product classifier witnesses by their constructor. The first components compose by transitivity of R_A, the second components compose by transitivity of R_B, and the paired typed witness rebuilds the product classifier. □

Theorem 34.88 (Product classifier symmetry from source symmetry)**.** *Let* $R_A : A \to A \to \mathsf{Prop}$ *and* $R_B : B \to B \to \mathsf{Prop}$ *be source classifier relations. If*

$$\forall a\, a'.\ R_A(a, a') \to R_A(a', a)$$

and

$$\forall b\, b'.\ R_B(b, b') \to R_B(b', b)$$

hold, then for product carriers x *and* y*,* ProdClassifierSpec(R_A, R_B, x, y) *implies* ProdClassifierSpec(R_A, R_B, y, x)*.*

Proof. Invert the product classifier witness into its two coordinate witnesses. Apply source symmetry for R_A to the first coordinate and source symmetry for R_B to the second coordinate, then rebuild the product classifier with the same constructor in the opposite order. □

Theorem 34.89 (Product classifier symmetry from source certificates)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history carriers, let* $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be their source classifiers, and let* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$ *and* $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$ *be source name certificates. For product carriers* $x, y : \mathsf{ProdCarrier}(\mathsf{BHist}, \mathsf{BHist})$*,* $\mathsf{ProdClassifierSpec}(\sim_L, \sim_R, x, y)$ *implies* $\mathsf{ProdClassifierSpec}(\sim_L, \sim_R, y, x)$*.*

Proof. Invert the product classifier witness into its left and right component classifier proofs. Apply the equiv_symm field of cert_L to reverse the left component, and the equiv_symm field of cert_R to reverse the right component. The product classifier constructor then rebuilds the componentwise witness in the opposite order. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdClassifierSpec symm from nameCert`

Theorem 34.90 (History product classifier is symmetric)**.** *For pairs of finite-kernel histories, if the product classifier relates* x *to* y *componentwise by* hsame*, then it relates* y *to* x*.*

Proof. Invert the componentwise product classifier. Each component witness reverses by symmetry of hsame, and the reversed witnesses rebuild the product classifier in the opposite direction. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdClassifierSpec hsame symm`

Definition 34.91 (Prod ledger policy)**.** *Record a raw product history carrying both component ledgers together with an* hsame *link to the visible history exposed by the ledger.*

Lean4 (definition) `BEDC.Derived.ProdUp.ProdHistoryLedgerPolicy`

The product ledger is the binary finite-data counterpart of the tagged-sum and option surfaces of chapter 35 and chapter 33: product component exposure uses the same tag/readback discipline, but pairs two visible components instead of selecting one branch.

Theorem 34.92 (Prod ledger visible carrier)**.** *If a visible history is linked by* hsame *to a raw product-ledger history, then the visible history is itself a product carrier.*

Proof. Unpack the raw product carrier and transport it across the stored hsame link by product-carrier transport. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerPolicy visible carrier`

Theorem 34.93 (Prod ledger raw-visible classifier)**.** *If* $\mathsf{ProdHistoryLedgerPolicy}(L, R, \rho, v)$ *holds, then* $\mathsf{ProdHistoryClassifier}(L, R, \rho, v)$ *holds.*

Proof. Unpack the ledger into the raw product carrier for ρ and the stored $\mathsf{hsame}(\rho, v)$ link. The visible-carrier theorem supplies the product carrier for v. These three witnesses are exactly the product classifier fields for the raw ledger history and the visible history. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerPolicy raw visible classifier`

Theorem 34.94 (Prod ledger history-same transport)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, \rho', v, v' : \mathsf{BHist}$ *be histories. If* $\mathsf{hsame}(\rho, \rho')$*,* $\mathsf{hsame}(v, v')$*, and* $\mathsf{ProdHistoryLedgerPolicy}(L, R, \rho, v)$ *hold, then* $\mathsf{ProdHistoryLedgerPolicy}(L, R, \rho', v')$ *holds. The object fit is: traditional target ordered-product ledger stability; BEDC source* BHist *with* Cont *and* hsame*; carrier* ProdHistoryCarrier*; classifier* ProdHistoryClassifier*; ledger* ProdHistoryLedgerPolicy*; exactness raw-visible transport; standard bridge displayed ordered-pair ledger; status* ProofTarget*.*

Proof. Unpack the ledger into a raw product carrier for ρ and the stored raw-visible link $\mathsf{hsame}(\rho, v)$. Transport the raw carrier across $\mathsf{hsame}(\rho, \rho')$ by Theorem 34.8. For the visible link, compose symmetry of $\mathsf{hsame}(\rho, \rho')$, the stored raw-visible link, and $\mathsf{hsame}(v, v')$ to obtain $\mathsf{hsame}(\rho', v')$. The transported raw carrier and this composed link rebuild $\mathsf{ProdHistoryLedgerPolicy}(L, R, \rho', v')$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerPolicy hsame transport`

Theorem 34.95 (Prod ledger classifier composition)**.** *Let $L, R : \mathsf{BHist} \to \mathsf{Prop}$ be source carriers and let $\rho, v, w : \mathsf{BHist}$ be histories. If $\mathsf{ProdHistoryLedgerPolicy}(L, R, \rho, v)$ holds and $\mathsf{ProdHistoryClassifier}(L, R, v, w)$ holds, then $\mathsf{ProdHistoryClassifier}(L, R, \rho, w)$ holds. The object fit is: traditional target ordered-product ledger propagation; BEDC source* BHist *with* Cont*; carrier* ProdHistoryCarrier*; classifier* ProdHistoryClassifier*; ledger evidence the raw-visible pair; exactness raw-to-visible-to-target composition; status* ProofTarget*.*

Proof. Apply Theorem 34.93 to the ledger policy to obtain $\mathsf{ProdHistoryClassifier}(L, R, \rho, v)$. Compose that raw-visible classifier with the visible-target classifier by product history classifier transitivity, yielding $\mathsf{ProdHistoryClassifier}(L, R, \rho, w)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerPolicy classifier extension`

Theorem 34.96 (Prod ledger backward classifier composition)**.** *Let $L, R : \mathsf{BHist} \to \mathsf{Prop}$ be source carriers and let $\rho, v, w : \mathsf{BHist}$ be histories. If $\mathsf{ProdHistoryLedgerPolicy}(L, R, \rho, v)$ holds and $\mathsf{ProdHistoryClassifier}(L, R, w, v)$ holds, then $\mathsf{ProdHistoryClassifier}(L, R, w, \rho)$ holds. The object fit is: traditional target ordered-product ledger back-propagation; BEDC source* BHist *with* Cont *and* hsame*; carrier* ProdHistoryCarrier*; classifier* ProdHistoryClassifier*; ledger raw-visible pair evidence; core theorem backward classifier composition; exactness raw-visible symmetry; standard bridge displayed ordered-pair ledger; status* ProofTarget*.*

Proof. Apply Theorem 34.93 to the ledger policy to obtain $\mathsf{ProdHistoryClassifier}(L, R, \rho, v)$. Reverse this classifier by Theorem 34.20, giving $\mathsf{ProdHistoryClassifier}(L, R, v, \rho)$. Compose the assumed classifier from w to v with this reversed classifier by Theorem 34.22, yielding $\mathsf{ProdHistoryClassifier}(L, R, w, \rho)$. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerPolicy classifier backward composition`

Theorem 34.97 (Prod ledger classifier endpoint equivalence)**.** *Let $L, R : \mathsf{BHist} \to \mathsf{Prop}$ be source carriers and let $\rho, v, w : \mathsf{BHist}$ be histories. If $\mathsf{ProdHistoryLedgerPolicy}(L, R, \rho, v)$ holds, then $\mathsf{ProdHistoryClassifier}(L, R, \rho, w) \iff \mathsf{ProdHistoryClassifier}(L, R, v, w)$. The object fit is: traditional target ordered-product ledger endpoint replacement; BEDC source* BHist *with* Cont *and* hsame*; carrier* ProdHistoryCarrier*; classifier* ProdHistoryClassifier*; stability by raw-visible classifier propagation in both directions; ledger* ProdHistoryLedgerPolicy*; core theorem this endpoint equivalence; exactness classifier-invariant raw and visible endpoints; standard bridge displayed ordered-pair ledger.*

Proof. Apply Theorem 34.93 to the ledger policy to obtain $\mathsf{ProdHistoryClassifier}(L, R, \rho, v)$. For the forward direction, reverse this raw-visible classifier by Theorem 34.20 and compose it with the assumed $\mathsf{ProdHistoryClassifier}(L, R, \rho, w)$ by Theorem 34.22. For the reverse direction, apply Theorem 34.95 to the same ledger policy and the assumed classifier from v to w. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerPolicy classifier endpoint equivalence`

Theorem 34.98 (Prod ledger two-step classifier composition)**.** *Let* L, R : BHist $\to$ Prop *be source carriers and let* ρ, v, w : BHist *be histories. If* ProdHistoryLedgerPolicy(L, R, ρ, v) *and* ProdHistoryLedgerPolicy(L, R, v, w) *hold, then* ProdHistoryClassifier(L, R, ρ, w) *holds. The object fit is: ordered-product ledger chain; BEDC source* BHist *with* Cont*; carrier* ProdHistoryCarrier*; classifier* ProdHistoryClassifier*; ledger evidence raw-visible-visible; exactness by classifier composition.*

Proof. Apply Theorem 34.93 to both ledger policies to obtain classifiers from ρ to v and from v to w. Compose them by Theorem 34.22. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerPolicy two step classifier composition`

Theorem 34.99 (Prod ledger two-step classifier endpoint equivalence)**.** *Let* L, R : BHist $\to$ Prop *be source carriers and let* ρ, v, w, z : BHist *be histories. If* ProdHistoryLedgerPolicy(L, R, ρ, v) *and* ProdHistoryLedgerPolicy(L, R, v, w) *hold, then* ProdHistoryClassifier$(L, R, \rho, z) \iff$ ProdHistoryClassifier(L, R, w, z)*. The object fit is: traditional target ordered-product ledger-chain endpoint replacement; BEDC source* BHist *with* Cont *and* hsame*; carrier* ProdHistoryCarrier*; classifier* ProdHistoryClassifier*; stability by two raw-visible classifier exposures plus symmetry and transitivity; ledger two composable* ProdHistoryLedgerPolicy *witnesses; core theorem this endpoint equivalence; exactness classifier-invariant endpoints of the ledger chain; standard bridge displayed ordered-pair ledger chain; status* ProofTarget*.*

Proof. Apply Theorem 34.98 to the two ledger witnesses to obtain ProdHistoryClassifier(L, R, ρ, w). For the forward implication, reverse this chain classifier by Theorem 34.20, then compose it with the assumed classifier from ρ to z using Theorem 34.22, yielding ProdHistoryClassifier(L, R, w, z). For the reverse implication, compose the chain classifier from ρ to w with the assumed classifier from w to z by Theorem 34.22. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerPolicy two step classifier endpoint equivalence`

Theorem 34.100 (Prod ledger component exposure)**.** *If* ProdHistoryLedgerPolicy(L, R, ρ, v) *holds, then there exist histories* l *and* r *such that* $L(l)$*,* $R(r)$*,* Cont(l, r, ρ)*,* hsame(ρ, v)*,* ProdHistoryCarrier(L, R, v)*, and* ProdHistoryClassifier(L, R, ρ, v) *all hold.*

Proof. Unfold the ledger into the raw product carrier for ρ and the stored raw-visible witness hsame(ρ, v). Unfold the raw carrier to expose component histories l and r with $L(l)$, $R(r)$, and Cont(l, r, ρ). Theorem 34.92 supplies ProdHistoryCarrier(L, R, v), and Theorem 34.93 supplies ProdHistoryClassifier(L, R, ρ, v). These witnesses give the stated component exposure. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerPolicy component exposure`

Theorem 34.101 (Product ledger visible empty component exposure)**.** *Let* L, R : BHist $\to$ Prop *be source carriers and let* ρ : BHist *be a raw history. If* ProdHistoryLedgerPolicy$(L, R, \rho,$ Empty$)$ *holds, then there exist* l, r : BHist *such that* $L(l)$*,* $R(r)$*,* $l$hsameEmpty*,* $r$hsameEmpty*, and* ProdHistoryClassifier$(L, R, \rho,$ Empt *all hold. The object fit is: traditional target ordered-product ledger at the empty visible endpoint; BEDC source* BHist *with* Cont *and* hsame*; carrier* ProdHistoryCarrier*; classifier* ProdHistoryClassifier*; stability by raw-visible ledger exposure and empty-result carrier inversion; ledger* ProdHistoryLedgerPolicy*; core theorem this empty-endpoint component exposure; exactness component readback at* Empty*; standard bridge displayed ordered-pair ledger boundary; status* ProofTarget*.*

Proof. Apply Theorem 34.92 to the ledger witness. This places the visible endpoint Empty in ProdHistoryCarrier$(L, R,$ Empty$)$.

Apply Theorem 34.5 to that visible carrier. The result supplies component histories l and r with $L(l)$, $R(r)$, $l$hsameEmpty, and $r$hsameEmpty.

Apply Theorem 34.93 to the same ledger witness. Repack the component witnesses together with the raw-visible classifier to obtain the stated empty-boundary exposure. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerPolicy visible empty component exposure`

Theorem 34.102 (Product ledger chain transitivity)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers. If* $\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, v)$ *and* $\mathsf{ProdHistoryLedgerChain}_{L,R}(v, z)$ *hold, then* $\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, z)$ *holds.*

Proof. Induct on the first ledger-chain derivation. A one-ledger derivation is a displayed $\mathsf{ProdHistoryLedgerPolicy}(L,$ composing it with the second chain is exactly the cons constructor. In the cons case, apply the induction hypothesis to concatenate the tail chain with the second chain, then reapply the leading displayed ledger by the cons constructor. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerChain trans`

Theorem 34.103 (Product ledger-chain boundary classifier decomposition)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, and let* $\rho, z : \mathsf{BHist}$*. If* $\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, z)$ *holds, then both boundary clauses hold:*

1. *either* $\mathsf{ProdHistoryLedgerPolicy}(L, R, \rho, z)$ *holds, or there exists* $v : \mathsf{BHist}$ *such that* $\mathsf{ProdHistoryLedgerPolicy}(L, R,$ *and* $\mathsf{ProdHistoryClassifier}(L, R, v, z)$ *hold;*
2. *either* $\mathsf{ProdHistoryLedgerPolicy}(L, R, \rho, z)$ *holds, or there exists* $v : \mathsf{BHist}$ *such that* $\mathsf{ProdHistoryClassifier}(L, R, \rho, v)$ *and* $\mathsf{ProdHistoryLedgerPolicy}(L, R, v, z)$ *hold.*

The object fit is: traditional target finite ordered-product provenance; BEDC source BHist*,* ProdHistoryLedgerPolicy*, and* ProdHistoryLedgerChain*; carrier* ProdHistoryCarrier*; classifier* ProdHistoryClassifier*; ledger finite product ledger chain; core theorem boundary decomposition; exactness endpoint classifier preservation.*

Proof. For the head boundary clause, perform cases on the finite ledger-chain constructor. The one-step constructor is exactly $\mathsf{ProdHistoryLedgerPolicy}(L, R, \rho, z)$.

In the cons constructor, the displayed first ledger has the form $\mathsf{ProdHistoryLedgerPolicy}(L, R, \rho, v)$ and the tail has the form $\mathsf{ProdHistoryLedgerChain}_{L,R}(v, z)$. Apply Theorem 34.55 to the tail; its envelope part gives $\mathsf{ProdHistoryClassifier}(L, R, v, z)$, so the witness v exposes the first concrete ledger step and the classifier tail consumed by readback.

For the terminal boundary clause, induct on the chain. The base case again is the displayed one-step ledger $\mathsf{ProdHistoryLedgerPolicy}(L, R, \rho, z)$.

In the cons step, first apply Theorem 34.93 to the leading policy $\mathsf{ProdHistoryLedgerPolicy}(L, R, \rho, v)$, obtaining $\mathsf{ProdHistoryClassifier}(L, R, \rho, v)$. If the tail is a one-step ledger, the same v is the terminal-boundary witness. If the inductive tail has already exposed a terminal ledger $\mathsf{ProdHistoryLedgerPolicy}(L, R, u, z)$ with classifier prefix $\mathsf{ProdHistoryClassifier}(L, R, v, u)$, compose the leading classifier with that prefix by classifier transitivity to obtain $\mathsf{ProdHistoryClassifier}(L, R, \rho, u)$. The witness u exposes the last concrete ledger step and the accumulated classifier prefix. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerChain boundary classifier decomposition`

Theorem 34.104 (Product ledger chain concatenation preserves public endpoints)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, let* $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers. If*

$\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, v)$ *and* $\mathsf{ProdHistoryLedgerChain}_{L,R}(v, z)$ *hold, then* $\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, z)$ *holds, and for every* $w : \mathsf{BHist}$ *both public componentwise endpoint clauses hold:*

$$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(\rho, w) \iff \mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(z, w)$$

and

$$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(w, \rho) \iff \mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(w, z).$$

The object fit is: traditional target finite ordered-product ledger concatenation; BEDC source BHist *with* ProdHistoryLedgerPolicy *and* ProdHistoryLedgerChain*; carrier* ProdHistoryCarrier *plus displayed* ProdPairRep*; classifier* ProdComponentHistoryClassifier*; stability finite ledger-chain closure; ledger concatenated displayed-pair provenance; core theorem closure plus endpoint invariance; exactness component readback invariant across concatenated chains; standard bridge concatenated ordered-pair provenance; status* ProofTarget.

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerChain concatenation componentwise endpoints`

Proof. Apply Theorem 34.102 to the two finite ledger chains to obtain $\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, z)$.

With the concatenated chain in hand, invoke Theorem 34.58 directly. The theorem depends only on the finite product ledger chain, so it yields the two public componentwise endpoint equivalences for every test history w. □

Theorem 34.105 (Product public certificate with ledger-chain component readback)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, let* $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers, and assume* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$, $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, *and* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$. *With the named displayed pair ledger* $\mathsf{ProdDisplayedPairLedger}_{L,R}$ *from Definition 34.50, the following two clauses hold:*

1. *the componentwise public certificate*

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdDisplayedPairLedger}_{L,R}, \mathsf{ProdCompon}$$

2. *for all histories* $\rho, z, l, r : \mathsf{BHist}$, *if* $\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, z)$ *and* $\mathsf{ProdPairRep}_{L,R}(\rho, l, r)$ *hold, then* $\mathsf{ProdHistoryClassifier}(L, R, \rho, z)$ *holds and there exist* $l', r' : \mathsf{BHist}$ *such that*

$$\mathsf{ProdPairRep}_{L,R}(z, l', r') \quad \text{and} \quad l \sim_L l' \quad \text{and} \quad r \sim_R r'.$$

The object fit is: traditional target ordered-product public certificate with finite ledger-chain component readback; BEDC source BHist *with* Cont *and* hsame*; carrier* ProdHistoryCarrier *plus displayed* ProdPairRep*; classifier componentwise source classifiers; stability by envelope closure; ledger* ProdHistoryLedgerChain*; core theorem this combined public-certificate and readback package; exactness envelope classifier and final displayed component witnesses; standard bridge ordered-pair provenance; status* ProofTarget.

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerChain public certificate component readback`

Proof. The public certificate clause is Theorem 34.61 applied to cert_L, cert_R, and $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$, with the named displayed pair ledger from Definition 34.50.

For the ledger-chain readback clause, fix $\rho, z, l, r : \mathsf{BHist}$ and assume $\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, z)$ together with $\mathsf{ProdPairRep}_{L,R}(\rho, l, r)$. Theorem 34.55 applied to the finite chain supplies $\mathsf{ProdHistoryClassifier}(L, R, \rho$ which is the envelope-classifier part of the conclusion.

It remains to expose the final displayed components. Apply Theorem 34.57 to the same chain and initial displayed pair representation, using the coherence witness. This gives $l', r' : \mathsf{BHist}$ with $\mathsf{ProdPairRep}_{L,R}(z, l', r')$, $l \sim_L l'$, and $r \sim_R r'$; conjoining these witnesses with the envelope classifier gives the required public-object ledger guarantee. □

Theorem 34.106 (Product public certificate with endpoint-stable ledger-chain readback)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, let* $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers, and assume* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$, $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, *and* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$. *Assume also that both source classifiers are* hsame*-sound:*

$$\forall x\, y.\ x \sim_L y \to \mathsf{hsame}(x, y)$$

and

$$\forall x\, y.\ x \sim_R y \to \mathsf{hsame}(x, y).$$

For all histories $\rho, z, l, r : \mathsf{BHist}$, *if* $\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, z)$ *and* $\mathsf{ProdPairRep}_{L,R}(\rho, l, r)$ *hold, then the following three clauses hold:*

1. *the componentwise public certificate*

   $$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdDisplayedPairLedger}_{L,R}, \mathsf{ProdCompon}$$

2. $\mathsf{ProdHistoryClassifier}(L, R, \rho, z)$ *holds, and there exist* $l', r' : \mathsf{BHist}$ *such that*

   $$\mathsf{ProdPairRep}_{L,R}(z, l', r') \quad \textit{and} \quad l \sim_L l' \quad \textit{and} \quad r \sim_R r';$$

3. *for every* $w : \mathsf{BHist}$, *both endpoint-replacement clauses hold:*

   $$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(\rho, w) \Longleftrightarrow \mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(z, w)$$

   and

   $$\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(w, \rho) \Longleftrightarrow \mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}(w, z).$$

The object fit is: traditional target ordered-product public certificate with finite endpoint-stable ledger-chain readback; BEDC source BHist *with* Cont *and* hsame*; carrier* ProdHistoryCarrier *plus displayed* ProdPairRep*; classifier componentwise source classifiers; stability by ledger-chain endpoint equivalence; ledger* ProdHistoryLedgerChain*; core theorem this combined public certificate, displayed component readback, and endpoint-stable component classifier; exactness final displayed component witnesses and endpoint-invariant public classification; standard bridge ordered-pair provenance; status* ProofTarget.

Proof. First apply Theorem 34.105 with cert_L, cert_R, and $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$. Its certificate clause gives the displayed-pair semantic certificate, and its ledger-chain readback clause applied to the chosen ρ, z, l, r gives the product history classifier together with the final displayed witnesses l', r'.

It remains to make the public componentwise classifier stable at the two ledger-chain endpoints. Apply Theorem 34.58 to $\mathsf{ProdHistoryLedgerChain}_{L,R}(\rho, z)$. This supplies, for every test history w, both endpoint-replacement equivalences. Conjoin these with the certificate and displayed readback conclusions from the first step. □

Lean4 ✓ `BEDC.Derived.ProdUp.ProdHistoryLedgerChain public certificate endpoint invariance`

Theorem 34.107 (Concrete product history-envelope semantic certificate)**.** *For source-history predicates* $L, R : \mathsf{BHist} \to \mathsf{Prop}$*, assume* $\exists l : \mathsf{BHist}.\ L(l)$ *and* $\exists r : \mathsf{BHist}.\ R(r)$*. Then*

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryClassifie}$$

holds. This is the checked ordered-product history-envelope certificate; source certificates supply the two inhabited-carrier hypotheses through their fields.

Proof. Choose the left and right carrier witnesses first. BEDC continuation joins them into a product history. The history-envelope classifier stores the two endpoint carrier witnesses and an hsame witness between product histories, so the certificate fields follow by hsame reflexivity, symmetry, transitivity, and carrier transport. When source certificates are present, their carrier-inhabited fields provide the same witnesses. □

Lean4 ✓ `BEDC.Derived.ProdUp.prod history semantic name certificate`

Theorem 34.108 (ProdUp obligation surface package)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history predicates and let* $\sim_L, \sim_R : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers. Assume source carrier witnesses for* L *and* R*, source certificates* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$ *and* $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$*, componentwise* hsame*-soundness for* $\sim_L$ *and* $\sim_R$*, and the displayed-pair coherence* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$*. Then the ProdUp surface over* BHist*,* Cont*,* hsame*, and* Pkg *supplies all finite-data obligations listed below, using only BEDC histories and product continuations:*

1. *an inhabited product-history carrier* $\mathsf{ProdHistoryCarrier}(L, R)$*;*
2. *componentwise classifier stability for the displayed product classifier induced by the source classifiers;*
3. *raw-visible ledger exactness for* $\mathsf{ProdHistoryLedgerPolicy}(L, R)$*;*
4. *endpoint-stable ledger-chain readback for* $\mathsf{ProdHistoryLedgerChain}_{L,R}$*;*
5. *the semantic* NameCert *surface for the product history envelope and its public displayed-pair classifier.*

Thus the finite-data consumer may read the product package through BEDC histories, continuation, history sameness, and package evidence, without importing host ordered pairs as primitive data.

Proof. Choose source carrier witnesses for L and R. The ProdHistoryCarrier clause follows by joining the witnesses through Cont, and the same carrier exposure is available from the ledger side by Theorem 34.92.

For the raw-visible ledger surface, apply Theorem 34.93. Its transport stability is Theorem 34.94, so the ledger reads the raw history and the visible history through hsame rather than through any host pair object.

For the finite ledger-chain public surface, apply Theorem 34.106. It packages the componentwise public certificate, the final displayed readback, and the endpoint-stable classifier clauses for every test history.

Finally, apply Theorem 34.107 to obtain the semantic history-envelope certificate. Together with the public displayed-pair certificate supplied by the endpoint-stable ledger-chain theorem, these clauses are exactly the carrier, classifier, ledger, endpoint, and semantic-certificate surface consumed by the finite-data phase. □

Corollary 34.109 (Product history envelope is licensed, not primitive)**.** *The checked theorem licenses only* ProdHistoryCarrier *with* ProdHistoryClassifier *under explicit left and right carrier witnesses. The public ordered-product certificate uses the history-level* $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}$ *induced by* ProdPairRep *and source classifiers, together with displayed component exposure,* hsame*-sound descent, and ledger fields from this chapter.*

Theorem 34.110 (Prod finite-data sibling lattice)**.** *Every* $\mathsf{Prod}^{\uparrow}$ *pair-envelope read consumes the finite-data sibling lattice before it exports the ordered pair certificate. The lattice consists of the* $\mathsf{Bool}^{\uparrow}$ *tag discipline of chapter 32, the* $\mathsf{Sum}^{\uparrow}$ *branch partition of chapter 35, and the transport surfaces supplied by chapter 36 and chapter 33. A public product consumer may then read the ordered pair only through the displayed product history carrier, componentwise classifier, displayed-pair ledger, source* NameCert *rows,* hsame *transport,* Cont *continuation, and* Pkg *provenance.*

Proof. Start with the product public finite-data exit package, Definition 34.118. It lists the rows available to the product consumer: the componentwise semantic certificate, displayed-pair ledger endpoints, descent to the product history envelope, source certificates, hsame, Cont, and Pkg provenance.

The sibling lattice fixes how those rows are read as finite data. The BoolUp tag discipline supplies the local tag behavior; the SumUp branch partition supplies the disjoint branch read; and the ListUp and OptionUp transport surfaces supply finite repetition and possible absence without adding host tuple equality.

Apply consumer universality, Definition 34.119. Any public product read invariant under the package rows factors through that finite-data exit package, so the ordered pair certificate is exported only after the sibling lattice has supplied its tag, branch, list, and option inputs. □

Theorem 34.111 (Prod finite-data sibling lattice route)**.** *Every accepted* $\mathsf{Prod}^{\uparrow}$ *carrier consumes* $\mathsf{Bool}^{\uparrow}$ *endpoint discrimination,* $\mathsf{Sum}^{\uparrow}$ *tagged alternatives,* $\mathsf{Option}^{\uparrow}$ *absence and presence rows, and* $\mathsf{List}^{\uparrow}$ *finite-spine rows through componentwise* NameCert *projection before exporting the ordered-pair certificate. The route cites chapter 32, chapter 35, chapter 33, and chapter 36 as sibling finite-data surfaces, not as host product projections.*

Proof. Start with the product finite-data sibling lattice, Definition 34.110. It places product reads behind Bool endpoint tags, Sum branch partitions, Option possible-absence surfaces, and List finite transport before the ordered pair certificate is visible.

Apply the option-sum component route, Definition 34.113. Component reads pass through the optional and tagged alternatives as displayed sibling rows rather than as host projections from a product object.

Finally use the public finite-data exit package. It exports the ordered pair through the displayed product history carrier, componentwise classifier, displayed-pair ledger, source NameCert rows, hsame transport, Cont continuation, and Pkg provenance. Thus the sibling lattice is consumed by componentwise NameCert projection and by no unrecorded tuple oracle. □

Theorem 34.112 (ProdUp BHist pair projection determinacy)**.** *For every accepted* $\mathsf{Prod}^{\uparrow}$ *public pair read, the* BHist *projection is determined by the two displayed component rows together with the product component ledger,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Prod}^{\uparrow}}$ *row. The finite-data siblings of chapter 32, chapter 35, and chapter 36 may consume the read only after those product rows have fixed the two projections. Thus the product packet cannot export a tag-only* $\mathsf{Sum}^{\uparrow}$ *branch, optional none row, or* $\mathsf{List}^{\uparrow}$ *spine without passing through the corresponding sibling* NameCert *surface.*

Proof. Start from the product componentwise interface. The accepted pair read exposes two component rows and the displayed product ledger before any finite-data consumer receives a public projection.

The Bool sibling supplies only endpoint discrimination for the product route, while the Sum and List siblings supply branch and spine consumers after the component rows have been named. Their NameCert surfaces therefore consume already displayed product projections; they do not replace the pair by a detached sum tag, absent option row, or list spine.

Transport through hsame, replay through Cont, provenance through Pkg, and the local $\mathsf{NameCert}_{\mathsf{Prod}^{\uparrow}}$ row preserve the same two projections. Hence the public BHist read is determined by the product component rows and has no independent finite-data export outside the sibling certificates. □

Theorem 34.113 (Prod option-sum component sibling route)**.** *Every accepted* $\mathsf{Prod}^{\uparrow}$ *component read factors through the finite-data sibling lattice containing chapter 33 and chapter 35 before a downstream component consumer can treat the pair as a case-split or optional projection. The route reads the product carrier through the displayed component rows, then passes through the* $\mathsf{Option}^{\uparrow}$ *possible-absence surface and the* $\mathsf{Sum}^{\uparrow}$ *branch surface, and only then exposes the component to a finite-data consumer.*

Proof. Start with the product public finite-data exit package of Definition 34.118. It exposes the componentwise semantic certificate, displayed-pair ledger endpoints, descent to the product history envelope, source NameCert rows, hsame, Cont, and Pkg provenance.

Next apply the finite-data sibling lattice of Definition 34.110. That lattice requires the component read to pass through the finite-data siblings before the ordered pair is exported.

The relevant sibling route has two finite-data faces. The $\mathsf{Option}^{\uparrow}$ chapter supplies the possible-absence projection discipline, while the $\mathsf{Sum}^{\uparrow}$ chapter supplies the branch partition used when the downstream consumer treats a component as a case split.

Since the public product package has no host tuple equality and no outside-ledger projection, a component consumer receives only the product rows already routed through those two siblings. Thus every accepted component read factors through the option and sum surfaces before it can be used as an optional projection or case-split input. □

The finite-data readback for $\mathsf{Prod}^{\uparrow}$ consumes the $\mathsf{Sum}^{\uparrow}$ route of chapter 35 and the $\mathsf{Option}^{\uparrow}$ route of chapter 33 componentwise: left and right product coordinates retain their sibling finite-data witnesses, $\mathsf{Bool}^{\uparrow}$ tag discrimination keeps the endpoint cases separated, and the $\mathsf{List}^{\uparrow}$ spine-readback route remains an external ledger rather than a hidden product coordinate.

Proposition 34.114 (Prod finite-data dependency lattice read)**.** *Every public* $\mathsf{Prod}^{\uparrow}$ *finite-data read factors through the sibling lattice of chapter 32, chapter 33, chapter 35, and chapter 36 before exporting the ordered-pair* NameCert *rows. The factorization uses Definition 34.110 to expose the tag, possible-absence, branch, and finite-transport surfaces, then uses Definition 34.113 to route component reads through the option and sum faces before a downstream consumer receives the pair certificate.*

Proof. Apply Definition 34.110. It places every public product read behind the BoolUp tag discipline, SumUp branch partition, ListUp finite transport, and OptionUp possible-absence surface.

Next apply Definition 34.113. Component reads must pass through the option and sum sibling route before a consumer treats them as optional projections or case-split inputs.

The ordered-pair NameCert rows are therefore exported only after the four finite-data siblings have supplied the dependency lattice. No host tuple equality or outside component projection is added to the public $\mathsf{Prod}^{\uparrow}$ read. □

Theorem 34.115 (Prod finite-data dependency lattice)**.** *Every public* $\mathsf{Prod}^{\uparrow}$ *finite-data read is positioned between the endpoint discrimination of chapter 32, the partiality surface of chapter 33, the tagged branching surface of chapter 35, and the spine-iteration surface of chapter 36. The product packet exports only the ordered-pair envelope after those sibling routes have supplied the finite-data lattice, and it keeps payload carriers, branch tags, list spines, component ledgers,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows inside the existing* $\mathsf{Prod}^{\uparrow}$ *envelope.*

Proof. Start with the componentwise product surface. The public product read exposes left and right component projections through the displayed product history carrier, the componentwise classifier, the displayed-pair ledger, and source NameCert rows.

The sibling lattice supplies the finite-data routes around that envelope. Bool supplies endpoint discrimination, Option supplies possible absence, Sum supplies tagged branching, and List supplies spine iteration; none of these rows replaces the product component ledgers or turns them into host-level tuple equality.

Finally apply the finite-data readiness rows already recorded in the product chapter. They route every public finite-data exit through componentwise projection, hsame transport, Cont replay, Pkg provenance, and the local product naming row, so the read cannot escape the existing $\mathsf{Prod}^{\uparrow}$ envelope. □

Theorem 34.116 (Prod product carrier sibling dependency)**.** *Every public* $\mathsf{Prod}^{\uparrow}$ *product-carrier read depends on the finite-data sibling route that places Bool endpoint discrimination from chapter 32, Sum branch exposure from chapter 35, and List spine readback from chapter 36 around the componentwise product envelope. The product packet then exports only ordered component carriers, component ledgers,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows; it does not become an isolated host pair or a detached finite-data object.*

Proof. Project the existing $\mathsf{Prod}^{\uparrow}$ componentwise carrier. Its public read exposes a left component, a right component, the component ledgers, and the structural rows that transport and replay those components.

The sibling finite-data route supplies the surrounding classifiers. Bool fixes endpoint discrimination, Sum supplies tagged branching, and List supplies spine readback for repeated finite data. These rows are dependencies of downstream product consumers, but they do not replace the product envelope.

Thus every product-carrier exit remains componentwise. The exported object is the same $\mathsf{Prod}^{\uparrow}$ carrier with sibling finite-data dependencies recorded in the ledger, not an isolated host pair. □

Theorem 34.117 (Prod option-sum sibling lattice readback)**.** *Every public* $\mathsf{Prod}^{\uparrow}$ *ordered-pair read consumes the finite-data sibling lattice of chapter 33 and chapter 35 only through the product component ledgers. The public route first reads the product componentwise interface, displayed-pair ledger, source* NameCert *rows,* hsame *transport,* Cont *continuation, and* Pkg *provenance; it then uses the option and sum sibling surfaces as finite-data consumers of those component rows.*

The product pair is not a renamed option case and not a renamed sum tag. It remains the two-component ledger supplied by $\mathsf{Prod}^{\uparrow}$*, and downstream finite-data consumers may read it only through the displayed component ledgers and the existing ProdUp componentwise interface.*

Proof. Begin with the product componentwise interface. Theorems 34.79 and 34.84 identify the public ordered-pair read with component histories, component classifiers, and displayed pair ledgers inside the product packet.

Next use the product finite-data sibling lattice, Definition 34.110. It places product reads behind the finite-data lattice while keeping the ordered-pair certificate on the product carrier rows.

Now apply the option-sum component sibling route, Definition 34.113. The option and sum chapters supply possible-absence and branch-partition consumers for already displayed component rows; they do not replace the pair ledger by an option tag or a sum branch.

Finally use the public finite-data exit package, Definition 34.118. Since every downstream finite-data read factors through the componentwise certificate, displayed-pair ledger, source certificates, hsame, Cont, and Pkg, the sibling lattice is read back through the product component ledgers and through no host tuple equality or external projection. □

Theorem 34.118 (Prod public finite-data exit package)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC source-history carriers, let* $\sim_L, \sim_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be their source classifiers, and suppose* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$ *and* $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$ *are the source certificate rows. Assume also a witness of* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$*. Then the public product finite-data exit package consists of the following rows.*

1. *The componentwise classifier carries the semantic certificate*

$$\mathsf{SemanticNameCert}(\mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdHistoryCarrier}(L, R), \mathsf{ProdComponent}$$

2. *For any displayed componentwise classifier witness between histories* $h, k : \mathsf{BHist}$*, the left and right displayed-pair ledger endpoints are readable as*

$$\mathsf{ProdDisplayedPairLedger}_{L,R}(h) \wedge \mathsf{ProdDisplayedPairLedger}_{L,R}(k).$$

3. *For the same histories* $h, k : \mathsf{BHist}$*, every componentwise classifier witness descends to the checked product history envelope classifier*

$$\mathsf{ProdHistoryClassifier}(L, R, h, k).$$

4. *The obligation surface exposes exactly the source* NameCert *rows, the componentwise classifier row, the displayed-pair ledger row, the descent row, the* hsame *and* Cont *transport rows, and the* Pkg *provenance rows named by Definition 34.108.*

Consequently the public product object reads only BHist*,* hsame*,* Cont*, the displayed-pair ledger, the source certificates, and* Pkg *provenance rows.*

Lean4 ✓ `BEDC.Derived.ProdUp.ProdPublicFiniteDataExitPackage`

Proof. First apply Definition 34.60 to the two source certificates and the $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$ witness. This supplies the componentwise semantic certificate row.

Next fix histories $h, k : \mathsf{BHist}$ and a componentwise classifier witness between them. Apply Definition 34.62 to read both displayed-pair ledger endpoints.

Then apply Definition 34.79 with the same componentwise witness and the source soundness rows. This is the descent row from the componentwise classifier into the checked product history envelope.

Finally read the obligation rows from Definition 34.108. The four rows above mention no host tuple equality and no data beyond the listed BHist carrier, hsame, Cont, displayed-pair ledger, source certificate rows, and Pkg provenance, so they repackage exactly the advertised public finite-data product surface. □

Theorem 34.119 (Product finite-data public exit consumer universality)**.** *Let* $L, R : \mathsf{BHist} \to \mathsf{Prop}$ *be source-history carriers, let* $\sim_L, \sim_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be their source classifiers, and let* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$ *and* $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$ *be the source certificate rows. Assume a displayed witness of* $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$.

Every public finite-data consumer of a product history whose reads are invariant under the componentwise semantic certificate, the displayed-pair ledger endpoints, the descent-to-envelope row, hsame, Cont, *and* Pkg *provenance factors through the package displayed in Definition 34.118. The factorization reads only the package rows: source* NameCert *rows, the componentwise classifier certificate, displayed-pair ledger endpoints, descent to the product history envelope,* hsame *transport,* Cont *continuation, and* Pkg *provenance.*

No step of the factorization exposes host tuple equality, outside-ledger component projections, or a quotient of pair representatives.

Proof. Apply Definition 34.118. It displays the candidate rows available to any public finite-data read of the product history: the semantic componentwise certificate, displayed-pair ledger endpoints, descent to the envelope classifier, source certificate rows, hsame, Cont, and Pkg provenance.

Next apply Definition 34.130. The consumer invariance assumptions force every public read to be one of those displayed rows; there is no separate host tuple row and no projection outside the displayed product ledger.

It remains to identify endpoint reads. Use Definition 34.131. Any endpoint datum read by the consumer is already the displayed-pair ledger endpoint supplied by the public package, so endpoint access cannot introduce a second product representation or a quotient of pair representatives.

Thus all public consumer reads are exhausted by the rows of Definition 34.118, and the consumer factors through that package. □

Theorem 34.120 (Prod finite-data sibling route)**.** *Every public finite-data consumer that spans* $\mathsf{Prod}^{\uparrow}$, $\mathsf{Sum}^{\uparrow}$, *and* $\mathsf{List}^{\uparrow}$ *must read the product component through the displayed-pair ledger of Definition 34.118. The same consumer must separately respect the tagged-envelope route of chapter 35 and the spine route of chapter 36. Thus the three constructor surfaces remain sibling finite-data envelopes: product reads expose pair display and componentwise classification, sum reads expose visible tags and branch classification, and list reads expose spine display and prefix classification.*

Consequently no such consumer may collapse the product, sum, and list envelopes into host tuple equality, host list equality, a common untagged carrier, or a generic finite-data quotient.

Proof. Project the product package rows. By Definition 34.118, a public product read sees the source certificate rows, componentwise classifier certificate, displayed-pair ledger endpoints, descent to the product history envelope, hsame transport, Cont replay, and Pkg provenance.

Now read the sibling constructor routes. The sum chapter supplies a visible tagged-envelope route, while the list chapter supplies a spine route; these routes carry tag and spine ledger rows that are not product displayed-pair rows.

The consumer therefore has three distinct finite-data boundaries available at once. Since pair display, tag display, and spine display are different ledger coordinates, replacing them by host tuple/list equality or by a common quotient would erase the route by which each constructor was admitted. □

Theorem 34.121 (Finite-data product, sum, and list envelope separation)**.** *Any public finite-data consumer spanning* $\mathsf{Prod}^{\uparrow}$, $\mathsf{Sum}^{\uparrow}$, *and* $\mathsf{List}^{\uparrow}$ *must preserve three distinct envelope rows. The product route reads through the displayed-pair ledger and the componentwise classifier of Definition 34.118.*

The sum route reads through the visible tag and branch classifier of Definition 35.41. The list route reads through the spine bridge and prefix classifier of Definition 36.145.

Consequently no public consumer may replace these rows by host tuple equality, a generic finite-data quotient, or a common untagged carrier. Such a replacement would erase the ledger/classifier boundary that distinguishes pair display, tag display, and spine display.

Proof. Start with the product public exit package and its consumer universality. By Definition 34.118 and Definition 34.119, every public product read factors through source certificate rows, the displayed-pair ledger, the componentwise classifier, descent to the product history envelope, hsame, Cont, and Pkg provenance.

For sums, use the checked tag-separation surface. The theorem Definition 35.41 forces mixed visible tags to be impossible, while the same-tag stability rows keep each accepted read inside the branch classifier attached to its tag.

For lists, use the spine bridge exactness theorem. The displayed spine row and prefix classifier identify the accepted list route through the spine bridge, not through a detached host sequence or an untagged finite-data carrier.

Inspecting the three rows gives different ledger/classifier boundaries: products expose pair display plus componentwise classification, sums expose tag display plus branch classification, and lists expose spine display plus prefix classification. A single host tuple equality, generic quotient, or untagged carrier would identify these boundaries, so it is not a public finite-data consumer for the three constructors at once. □

Theorem 34.122 (Prod Bool endpoint-discriminator route)**.** *Every public* $\mathsf{Prod}^{\uparrow}$ *component-route read uses the two endpoint rows licensed by chapter 32 only as a finite discriminator for component position. The left and right positions are tags for routing through the displayed-pair ledger; the payload carriers, component classifiers, source* NameCert *rows,* hsame *transports,* Cont *replays, and* Pkg *provenance remain owned by* $\mathsf{Prod}^{\uparrow}$ *and by the source certificates named in Definition 34.118.*

Consequently a public product consumer cannot replace the componentwise interface by an untagged finite-data quotient or by a host ordered-pair primitive.

Proof. Start with the componentwise interface. The displayed product route reads components through the product history classifier and the displayed-pair ledger, as in Definition 34.62 and Definition 34.79. These rows identify which component position is being read, but the component payload still comes from the source carriers and source classifiers.

Next apply the public finite-data exit package of Definition 34.118. It lists exactly the rows available to a public product consumer: the componentwise semantic certificate, displayed-pair ledger endpoints, descent to the product history envelope, source certificate rows, hsame, Cont, and Pkg provenance.

The two $\mathsf{Bool}^{\uparrow}$ endpoint rows therefore serve only as the finite discriminator for left versus right component position. Since all payload, classifier, transport, replay, and provenance rows remain the product rows displayed above, there is no untagged finite-data quotient and no host ordered-pair primitive available to the consumer. □

Theorem 34.123 (Prod Bool endpoint readback exhaustion)**.** *Let a public* $\mathsf{Prod}^{\uparrow}$ *component read have endpoint discriminator rows agreeing with the left and right* $\mathsf{Bool}^{\uparrow}$ *rows used in Definition 34.122. Then the readback recovers only the displayed component payload, the source* NameCert *rows, the componentwise* hsame *transports, the displayed* Cont *replays, and the* Pkg *provenance listed by Definition 34.118. It cannot introduce an untagged quotient of product data or a host pair coordinate outside the public* $\mathsf{Prod}^{\uparrow}$ *packet.*

Proof. Apply Definition 34.122. The two $\mathsf{Bool}^{\uparrow}$ rows identify only the left or right endpoint position in the displayed product route. They do not carry a product payload, a product classifier, or an independent ordered-pair coordinate.

Next use Definition 34.118. That theorem exhausts the public read surface by the displayed component payload rows, source NameCert rows, hsame transports, Cont replays, and Pkg provenance.

Combining the two statements leaves no unread endpoint data. The discriminator chooses the displayed component route, and the exit package lists every row that can be recovered from that route. Hence a quotient product object or host pair coordinate has no public readback source. □

Theorem 34.124 (Prod hub Bool sibling audit link)**.** *The public* $\mathsf{Prod}^{\uparrow}$ *ordered-pair read consumes* $\mathsf{Bool}^{\uparrow}$ *from chapter 32 only as the finite endpoint discriminator before any component row is exposed. The Bool row distinguishes the left and right endpoint positions of the displayed-pair ledger; payload carriers, component classifiers, source* NameCert *rows,* hsame *transports,* Cont *replays, and* Pkg *provenance remain the product rows named by the* $\mathsf{Prod}^{\uparrow}$ *packet.*

Proof. Read the product hub through its child rows. The componentwise interface and displayed-pair ledger expose endpoint positions before they expose payload components.

Apply the Bool endpoint-discriminator route. It identifies the $\mathsf{Bool}^{\uparrow}$ dependency as the finite left-versus-right tag discipline for those endpoint positions.

The public finite-data exit package then supplies the rest of the product route. Since payload, classifier, transport, replay, and provenance rows are still owned by the product and source certificates, the Bool sibling is a genuine horizontal dependency but not a replacement for the $\mathsf{Prod}^{\uparrow}$ carrier. □

Theorem 34.125 (Prod hub finite-data readiness index)**.** *The finite-data public surface indexed by the* $\mathsf{Prod}^{\uparrow}$ *hub is exhausted by five already displayed routes: the product history envelope, the componentwise interface, the ledger certificate, the* $\mathsf{Option}^{\uparrow}$–$\mathsf{Sum}^{\uparrow}$ *sibling route, and the public finite-data exit package. Equivalently, every public product read factors through* BHist*, the componentwise classifier, displayed-pair ledger rows, source* NameCert *rows,* hsame*,* Cont*, and* Pkg *provenance before it reaches any finite-data consumer.*

The index has no extra host tuple equality, outside-ledger projection, generic finite-data quotient, or untagged carrier beyond the child-file surfaces named by the hub.

Proof. Begin with the history envelope. The carrier and classifier surfaces of Definition 34.1, Definition 34.107, and Definition 34.109 put the product read inside the BEDC history envelope rather than in a host tuple object.

Next use the componentwise interface. The descent and exactness rows of Definition 34.79, Definition 34.84, and Definition 34.61 make component reads pass through the displayed classifier and source certificate rows.

The ledger certificate supplies the finite display route. Apply Definition 34.50, Definition 34.62, and Definition 34.108; these expose the displayed-pair ledger, hsame transport, Cont continuation, and Pkg provenance rows.

Finally pass through the finite-data siblings and public exit package. The sibling coverage is Definition 34.110 and Definition 34.113; the public consumer boundary is Definition 34.118 and Definition 34.119. The finite-data sibling route is grounded in chapter 33, chapter 35, chapter 32, and chapter 36; these chapters supply the constructor-tag, branch, boolean, and spine surfaces consumed by the product public boundary. These rows exhaust the hub-indexed readiness surface, so no additional product consumer coordinate remains. □

Proposition 34.126 (Product, sum, and list finite-data lattice)**.** $\mathsf{Prod}^{\uparrow}$ *consumes the same finite-data constructor discipline as chapter 35 and chapter 36. Its componentwise carrier supplies paired projections,* $\mathsf{Sum}^{\uparrow}$ *supplies branch separation, and* $\mathsf{List}^{\uparrow}$ *supplies spine iteration; therefore any public finite-data read that routes through all three surfaces must preserve the product component ledgers before it may branch or iterate.*

Theorem 34.127 (Prod sum-projection route)**.** *For every accepted* $\mathsf{Prod}^{\uparrow}$ *packet, the two projection rows can be consumed by the* $\mathsf{Sum}^{\uparrow}$ *and* $\mathsf{Option}^{\uparrow}$ *finite-data routes only through the displayed product carrier, component projections, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Prod}^{\uparrow}}$ *rows. The* $\mathsf{Sum}^{\uparrow}$ *route of chapter 35 may read the projected component as a branch payload only after the product carrier has exposed the ordered pair, and the* $\mathsf{Option}^{\uparrow}$ *route of chapter 33 may read the same component as a possible-presence payload only after the product projection row has been named.*

Proof. Start with the product public finite-data exit package of Definition 34.118. It exposes the displayed pair, component projections, semantic certificate, hsame rows, Cont rows, Pkg provenance, and local naming rows before any external finite-data consumer can read a component.

Next apply the existing sibling lattice through Definition 34.113 and Definition 34.126. These results force branch-style and optional-style reads to pass through the same product component rows rather than through a host tuple projection.

Finally consume the sibling surfaces. The $\mathsf{Sum}^{\uparrow}$ chapter accounts for the branch route, while the $\mathsf{Option}^{\uparrow}$ chapter accounts for the possible-presence route. Since the accepted product packet exports no independent projection oracle outside its carrier, transport, replay, provenance, and NameCert rows, both finite-data consumers receive only the displayed ProdUp route. □

Theorem 34.128 (Prod Bool-Sum-List route audit)**.** *Every public* $\mathsf{Prod}^{\uparrow}$ *finite-data read factors through the Bool endpoint discriminator, Sum branch surface, List spine surface, and Option absence surface before it exports the product component ledger. Equivalently, the product consumer reaches component data only after reading chapter 32, chapter 35, chapter 36, chapter 33, the finite-data sibling lattice of Definition 34.110, and the option-sum component route of Definition 34.113.*

Proof. Start with Definition 34.110. It records that the ordered pair certificate is not read as an isolated host tuple: the Bool tag discipline, Sum branch partition, List transport surface, and Option possible-absence surface all precede the public product exit.

Next apply Definition 34.113. It forces every component read through the Option absence surface and the Sum branch surface before the component can be used as an optional projection or case-split input.

The Bool endpoint discriminator supplies the finite endpoint separation, while the List spine surface supplies the finite repeated-data route used by product component ledgers. These routes are the same sibling surfaces cited by the local lattice rows, so they do not add host tuple equality or an outside projection.

Therefore every public finite-data read of $\mathsf{Prod}^{\uparrow}$ reaches the product component ledger only after the Bool, Sum, List, and Option routes have been displayed. □

Theorem 34.129 (Prod finite-data scoped closure record)**.** *The componentwise public certificate, displayed-pair ledger endpoints, descent-to-envelope row,* hsame *and* Cont *transports, and* Pkg *provenance of Definition 34.118 bind the* $\mathsf{Prod}^{\uparrow}$ *finite-data scope entirely inside BEDC histories. More precisely, for source-history carriers* $L, R : \mathsf{BHist} \to \mathsf{Prop}$*, source classifiers* $\sim_L, \sim_R$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$*, source certificates* $\mathsf{cert}_L : \mathsf{NameCert}(L, \sim_L)$ *and* $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$*,*

and a $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$ *witness, the public finite-data package exposes only the componentwise* SemanticNameCert *row, the two displayed-pair ledger endpoints, the descent row into* $\mathsf{ProdHistoryClassifier}(L,R)$*, the* hsame *and* Cont *endpoint-transport rows, and the* Pkg *provenance rows named by the* $\mathsf{Prod}^{\uparrow}$ *obligation surface. No host tuple equality is part of the record.*

Proof. Apply Definition 34.118. Its first row gives the componentwise public certificate for $\mathsf{ProdHistoryCarrier}(L,R)$ under $\mathsf{ProdComponentHistoryClassifier}_{L,R,\sim_L,\sim_R}$, using exactly the two source NameCert rows and the displayed-pair coherence witness.

The second and third rows of that package project the displayed-pair ledger endpoints and the descent-to-envelope comparison for any componentwise classifier witness between histories h, k : BHist. The target of the descent is the checked envelope classifier $\mathsf{ProdHistoryClassifier}(L,R,h,k)$.

The fourth row identifies the remaining public data with the source certificate rows, the componentwise classifier row, the displayed-pair ledger row, the descent row, the hsame and Cont transport rows, and the Pkg provenance rows of Definition 34.108. The checked envelope certificate Definition 34.107 supplies the BEDC history envelope in which those rows land.

Thus the finite-data scope is closed by projections of the public package and the checked envelope certificate. Every named row is a row over BHist, hsame, Cont, NameCert, and Pkg, so the record contains no host tuple equality. □

Theorem 34.130 (Prod finite-data consumer row exhaustion)**.** *Any consumer of the public* $\mathsf{Prod}^{\uparrow}$ *finite-data package can read only the componentwise* SemanticNameCert *row, the displayed-pair ledger endpoints, descent into* ProdHistoryClassifier*, the* hsame/Cont *endpoint transports, the source* NameCert *rows, and the* Pkg *provenance. No host tuple equality, component projection outside the displayed ledger, or quotient of pair representatives is exported.*

Proof. Apply Definition 34.118. This gives the consumer-facing package rows: componentwise public certificate, displayed-pair ledger endpoints, descent to the product-history classifier, endpoint transports, source certificate rows, and provenance rows.

Next apply Definition 34.129 to identify the closed finite-data scope. That theorem says that the public rows are exactly the rows bound inside BEDC histories by the product finite-data record.

The absence claim follows by row exhaustion. Since those two packages list the entire consumer surface and neither package contains host tuple equality, outside-ledger component projection, or a quotient of pair representatives, no consumer can project such data from the public $\mathsf{Prod}^{\uparrow}$ finite-data package. □

Theorem 34.131 (Prod component ledger endpoint determinacy)**.** *Let* L, R : BHist $\to$ Prop *be source-history carriers, let* $\sim_L, \sim_R$: BHist $\to$ BHist $\to$ Prop *be source classifiers, let* cert_L : $\mathsf{NameCert}(L, \sim_L)$ *and* cert_R : $\mathsf{NameCert}(R, \sim_R)$ *be source rows, and let* coh : $\mathsf{ProdPairRepCoherent}_{L,R,\sim_L,\sim_R}$ *be a displayed pair-representative coherence witness. If two* $\mathsf{ProdHistoryLedgerChain}(L,R,\rho,z)$ *readbacks from the same raw product row* ρ *expose component pairs* (l,r) *and* (l',r') *through* ProdPairRep*, then the public finite-data package forces* $l \sim_L l'$ *and* $r \sim_R r'$*. Consequently the two visible endpoints are related by* $\mathsf{ProdHistoryClassifier}(L,R)$*, and no further host-level tuple equality is needed.*

Proof. Apply the displayed component readback to each of the two ledger-chain readbacks. Both readbacks start from the same raw product row ρ, so the only component witnesses they expose are the two displayed ProdPairRep pairs named in the ledger.

Use the coherence witness coh to compare those two displayed pairs componentwise. This yields the source classifier rows $l \sim_L l'$ and $r \sim_R r'$ inside the same BEDC history envelope as the source NameCert rows.

Finally repack the two source classifier rows through the product envelope classifier. The consumer-row exhaustion theorem identifies that envelope row as part of the public finite-data surface, so the endpoint comparison lands in $\mathsf{ProdHistoryClassifier}(L, R)$ and exports no outside-ledger component projection. □

Theorem 34.132 (Prod finite-data closure status record)**.** *The scoped row record of Definition 34.129, the consumer-row exhaustion theorem Definition 34.130, and the endpoint determinacy theorem Definition 34.131, together with the checked envelope certificate Definition 34.107, give the Phase Finite Data scoped closure surface for* $\mathsf{Prod}^{\uparrow}$*. The resulting surface is exactly the public finite-data exit package: componentwise semantic certificate rows, displayed-pair ledger endpoints, descent into* $\mathsf{ProdHistoryClassifier}(L, R)$*,* $\mathsf{hsame/Cont}$ *transport rows, source* $\mathsf{NameCert}$ *rows, and* Pkg *provenance.*

Proof. Project first through Definition 34.118. The finite-data scoped record identifies the rows exported by that package and places each row inside the BEDC history envelope rather than in host tuple equality.

Next use Definition 34.130. It says that a consumer of the package has no access to rows beyond the componentwise certificate, the displayed-pair ledger endpoints, the descent row, the endpoint transports, the source certificates, and the provenance rows.

The endpoint determinacy theorem then fixes the visible ledger endpoints by the source classifiers and repacks them through $\mathsf{ProdHistoryClassifier}(L, R)$. The checked envelope certificate Definition 34.107 supplies the semantic-name certificate row for that repacking.

Combining these projections gives the Phase Finite Data scoped closure surface for $\mathsf{Prod}^{\uparrow}$: every exported row is one of the public finite-data rows, every endpoint comparison lands in the checked product-history classifier, and no outside-ledger component projection or host tuple equality is exported. □

Theorem 34.133 (Prod finite-data public bridge consumer)**.** *Every Bool, Option, Sum, or List finite-data consumer of the public* $\mathsf{Prod}^{\uparrow}$ *package factors through the scoped record Definition 34.129, the consumer-row exhaustion theorem Definition 34.130, endpoint determinacy Definition 34.131, and the public finite-data exit package Definition 34.118. Its visible read is therefore exhausted by componentwise semantic certificate rows, displayed-pair ledger endpoints, descent into* $\mathsf{ProdHistoryClassifier}(L, R)$*,* $\mathsf{hsame/Cont}$ *transport, source* $\mathsf{NameCert}$ *rows, and* Pkg *provenance. No such consumer receives host tuple equality or an outside-ledger component projection.*

Proof. First project the public package of Definition 34.118. A Bool, Option, Sum, or List consumer reads the componentwise public certificate, the displayed-pair ledger endpoints, the descent row, the endpoint transports, the source certificate rows, and the provenance rows from that package.

Next apply the scoped record Definition 34.129. It places exactly those rows inside the BEDC history envelope and identifies the product-history classifier as the endpoint classifier available to finite-data consumers.

Then use consumer-row exhaustion and endpoint determinacy. The exhaustion theorem removes every row not listed by the public package, and endpoint determinacy routes visible component endpoints through the product-history classifier rather than through host tuple equality.

Thus the public finite-data bridge available to Bool, Option, Sum, and List consumers is precisely the displayed $\mathsf{Prod}^{\uparrow}$ package route. There is no remaining coordinate from which an outside-ledger projection can be read. □

Lemma 34.134 (Prod finite-data sibling dependency)**.** *The* $\mathsf{Prod}^{\uparrow}$ *finite-data route consumes its sibling packets only through displayed finite rows:* $\mathsf{Bool}^{\uparrow}$ *from chapter 32 supplies tag discrimination for the two component projections,* $\mathsf{Option}^{\uparrow}$ *from chapter 33 supplies endpoint absence and presence discipline for partial component reads,* $\mathsf{Sum}^{\uparrow}$ *from chapter 35 supplies side-tag separation for coproduct-facing projections, and* $\mathsf{List}^{\uparrow}$ *from chapter 36 supplies finite-spine readback for iterated product windows. No sibling is read as an ambient equality, selector, quotient, or external recursion principle.*

Proof. Project the product hub through its displayed finite-data rows. Boolean tags decide which component field is inspected, option endpoints record whether a component read is absent or present, sum tags keep left and right alternatives disjoint, and list spines enumerate the finite sequence of product windows consumed by readback.

These rows are all finite carrier coordinates already named by the product dossier. Transport and replay preserve the displayed rows componentwise, while provenance and the local NameCert only record the same finite route. Since no row stores quotient equality, selected data, or an external recursion principle, the sibling dependency remains confined to the displayed finite-data surface. □

Theorem 34.135 (Prod finite-data real-completion sibling route)**.** *Every finite product pairing used by Real and Completion consumers factors through the* $\mathsf{Prod}^{\uparrow}$ *public finite-data surface before any* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *product-window read is exported. The route first reads the product history carrier, componentwise classifier, displayed-pair ledger, source* NameCert *rows,* hsame *transport,* Cont *continuation, and* Pkg *provenance, and only then presents paired windows to chapter 126 and regular paired coordinate reads to chapter 301.*

In particular, the completion-facing product window is not a host tuple, quotient pair, selected projection, or hidden product stream. It is the displayed finite-data route of Definition 34.110, Definition 34.134, and Definition 34.118 read before the StreamName and RegSeqRat sibling windows are consumed.

Proof. Start with the product public finite-data exit package. By Definition 34.118, a public product read exposes only the componentwise semantic certificate, displayed-pair ledger endpoints, descent to the product history envelope, source certificates, transport, continuation, and provenance rows.

The finite-data sibling route supplies the window discipline. Apply Definition 34.110 and Definition 34.134; they keep product reads behind displayed finite sibling rows before the ordered-pair certificate is exported.

The Real and Completion consumers then read paired windows through chapter 126 and paired regular coordinate rows through chapter 301. Since the product surface has no host tuple equality, quotient pair, selected projection, or hidden stream coordinate, the StreamName and RegSeqRat product-window reads remain downstream of $\mathsf{Prod}^{\uparrow}$. □

Theorem 34.136 (Prod RegSeqRat and StreamName product window)**.** *Whenever a completion-facing consumer reads a pair of stream coordinates or regular-Cauchy coordinates through* $\mathsf{Prod}^{\uparrow}$*, the read factors through the componentwise* SemanticNameCert *row, displayed-pair ledger endpoints,* $\mathsf{ProdHistoryClassifier}^{\uparrow}$ *descent,* hsame *and* Cont *transports, and source* NameCert *rows before* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *consumes the pair. The product window exports finite paired data only; it does not export host tuple equality, hidden projections, quotient pair representatives, or an ambient product stream.*

Proof. Apply Definition 34.135. It already places Real-and-Completion product reads behind the $\mathsf{Prod}^{\uparrow}$ public finite-data surface before StreamName and RegSeqRat consumers inspect paired windows.

Specialize the downstream readers to the two completion-facing cases. A $\mathsf{StreamName}^{\uparrow}$ product-window read consumes paired stream coordinates through the displayed product endpoint rows, while a $\mathsf{RegSeqRat}^{\uparrow}$ read consumes regular coordinate pairs through the same finite product route.

Now use consumer-row exhaustion from the public finite-data exit package. The componentwise SemanticNameCert row, displayed-pair ledger endpoints, $\mathsf{ProdHistoryClassifier}^{\uparrow}$ descent, source certificates, hsame transport, Cont continuation, and provenance rows are the whole product surface. Thus no host tuple equality, hidden projection, quotient representative, or ambient product stream remains for either downstream reader. □

Theorem 34.137 (Prod real-tail window forward link)**.** *Any* $\mathsf{RealUniformTailComparison}^{\uparrow}$ *packet using two* $\mathsf{StreamName}^{\uparrow}$ *windows reads its pair of finite windows through the* $\mathsf{Prod}^{\uparrow}$ *componentwise interface before the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger are consumed. The two windows are therefore a displayed product route: first the product history carrier, componentwise classifier, displayed-pair ledger, source* NameCert *rows,* hsame *transport,* Cont *replay, and* Pkg *provenance of Definition 34.118; then the finite-window rows of chapter 3427; and only after that the regular rational readbacks and shared dyadic tolerance ledger.*

Proof. Start with the product componentwise surface. The componentwise interface and public finite-data exit package expose the left and right component histories, the displayed pair ledger, source certificates, transport, replay, and provenance before a consumer receives a paired read.

Use the real-completion product-window route, Definition 34.135. It already places StreamName and RegSeqRat product-window reads downstream of the displayed $\mathsf{Prod}^{\uparrow}$ finite-data route rather than behind a host tuple or selected projection.

Now read the $\mathsf{RealUniformTailComparison}^{\uparrow}$ carrier. Its two windows W_A, W_B are consumed before the regular rational rows Q_A, Q_B and before the shared $\mathsf{DyadicRatCore}^{\uparrow}$ ledger. Therefore a comparison packet that uses two finite windows must first pass through the product component rows that make those windows a displayed pair.

The downstream handoff is exactly the finite route through $\mathsf{Prod}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$. It exports no host tuple equality, quotient stream equality, selected projection, hidden product stream, or ambient real-completeness row. □

Theorem 34.138 (Prod finite-data sibling route)**.** *Every public finite-product carrier route consumed by* $\mathsf{Prod}^{\uparrow}$ *reads the sibling finite-data surfaces before exporting the product classifier. The route uses chapter 32 for* $\mathsf{Bool}^{\uparrow}$ *endpoint discrimination, chapter 33 for* $\mathsf{Option}^{\uparrow}$ *partiality, chapter 35 for* $\mathsf{Sum}^{\uparrow}$ *tagged alternatives, and chapter 36 for* $\mathsf{List}^{\uparrow}$ *spine discipline. No product classifier is exported from a route that omits one of those displayed sibling rows.*

Proof. Start with the product public finite-data exit package. It exports the product classifier only after the displayed product carrier, component rows, history envelope, transport, continuation, provenance, and local NameCert rows have been read.

The finite sibling route supplies the required four surfaces. $\mathsf{Bool}^{\uparrow}$ distinguishes the two endpoint projections, $\mathsf{Option}^{\uparrow}$ records absent and present partial component reads, $\mathsf{Sum}^{\uparrow}$ separates tagged alternatives for case-facing consumers, and $\mathsf{List}^{\uparrow}$ records the finite spine discipline for iterated product windows.

Since the product packet has no host tuple equality, selected projection, quotient carrier, or external recursion coordinate, the classifier cannot bypass those sibling rows. The public route therefore consumes the four finite-data surfaces before the product classifier is exported. □

Theorem 34.139 (Prod Bool Option Sum List forward link)**.** *The* $\mathsf{Prod}^{\uparrow}$ *componentwise carrier is the binary product node in the finite-data lattice whose projections are consumed alongside* $\mathsf{Bool}^{\uparrow}$*,* $\mathsf{Option}^{\uparrow}$*,* $\mathsf{Sum}^{\uparrow}$*, and* $\mathsf{List}^{\uparrow}$ *through chapter 32, chapter 33, chapter 35, and chapter 36. Every product classifier read therefore remains a displayed finite-data route rather than an ambient tuple primitive.*

Proof. Read the existing product component rows from the $\mathsf{Prod}^{\uparrow}$ carrier. They expose left and right projections through the componentwise history envelope, classifier fields, transport, continuation, provenance, and local naming rows.

The sibling finite-data routes supply the four adjacent surfaces. $\mathsf{Bool}^{\uparrow}$ distinguishes endpoint positions, $\mathsf{Option}^{\uparrow}$ records optional component presence, $\mathsf{Sum}^{\uparrow}$ separates tagged alternatives, and $\mathsf{List}^{\uparrow}$ records the finite-spine discipline used by iterated product windows.

Since the product carrier exports no host tuple equality, selected projection, quotient product, or unrecorded recursion primitive, the forward link is exactly the displayed route from the product node to those sibling finite-data certificates. □

Theorem 34.140 (Prod finite-data sibling orphan route)**.** *Every* $\mathsf{Prod}^{\uparrow}$ *finite-data read is routed through the sibling lattice consisting of BoolUp endpoint tags from chapter 32, OptionUp optional envelopes from chapter 33, SumUp injections from chapter 35, and ListUp spine and readback rows from chapter 36. The exported product read is therefore a finite* BHist *route with componentwise* hsame*, displayed* Cont*,* Pkg *provenance, and local* $\mathsf{NameCert}$ *transport. It exposes no host product equality and no tuple primitive outside the displayed finite-data siblings.*

Proof. Start with the endpoint tags. The BoolUp sibling supplies the finite left/right and endpoint-discriminator rows used to distinguish the component positions of a product read.

Next wrap absence and presence through OptionUp and SumUp. Optional envelopes record whether a component slot is present, while sum injections route the displayed component into the finite coproduct surface before any list spine is consumed.

Then read the ListUp spine. The list rows provide the finite order, readback, and replay discipline for the component family, so the product packet is inspected as named finite data rather than as a host tuple.

Finally transport the route through BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$. These rows preserve the displayed sibling data without adding host product equality or an external tuple primitive. □

The $\mathsf{Prod}^{\uparrow}$ finite-data dependency lattice closes over sibling routes only after the ordered-pair envelope has fixed its two component projections. Bool tag discipline from chapter 32, Option absence and presence routing from chapter 33, Sum side tags from chapter 35, and List finite-spine readback from chapter 36 are consumed as displayed sibling rows around the product component ledger, not as detached host projections.

Lemma 34.141 (Prod finite-data dependency lattice closure)**.** *Every public* $\mathsf{Prod}^{\uparrow}$ *component projection read that cites the finite-data sibling lattice first consumes the product component ledger and then routes Bool endpoint tags, Option absent/present rows, Sum side tags, and List finite-spine readback through the corresponding sibling chapters. The route preserves the same* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{Prod}^{\uparrow}}$ *row, and it exports no ambient tuple equality, unrestricted recursion principle, selected component, or detached finite-data carrier.*

Proof. Begin with the product component ledger fixed by the hub children. The ledger names the left and right component projections before any sibling finite-data read is allowed to consume a tag, absence marker, side marker, or spine row.

Now read the siblings through their own chapters. Bool supplies only endpoint discrimination, Option supplies only the absent/present boundary, Sum supplies only left/right side separation, and List supplies only finite-spine readback.

The structural rows of $\mathsf{Prod}^{\uparrow}$ carry those displayed reads without changing ownership. Thus the dependency lattice closes over finite sibling data while keeping the public ordered-pair certificate inside the product NameCert surface. □

The $\mathsf{Prod}^{\uparrow}$ pair carrier also records a finite-data sibling route through the endpoint, alternative, and spine interfaces already named by the concrete-instance lattice. Bool endpoints are read through chapter 32, tagged alternatives through chapter 35, and finite routing spines through chapter 36; the product packet consumes those rows as dependencies rather than as hidden host projections.

Theorem 34.142 (Prod sibling carrier route)**.** *Every accepted* $\mathsf{Prod}^{\uparrow}$ *pair carrier may consume* $\mathsf{Bool}^{\uparrow}$ *endpoint discrimination,* $\mathsf{Sum}^{\uparrow}$ *tagged alternatives, and* $\mathsf{List}^{\uparrow}$ *finite spine routing only as displayed finite-data sibling dependencies. The carrier exposes those rows through its product ledger, componentwise transport, continuation replay, provenance, and local* NameCert *row, and it does not replace them by host product extensionality or an unrecorded pairing oracle.*

Proof. Read the pair carrier through the existing product ledger. Endpoint discrimination is supplied by the $\mathsf{Bool}^{\uparrow}$ sibling, so a branch decision entering the pair route is a displayed finite row.

Tagged alternatives are then supplied by the $\mathsf{Sum}^{\uparrow}$ sibling. The pair carrier records which side of the product dependency is being consumed without replacing that tag by host-level case analysis.

Finally the finite spine route is supplied by $\mathsf{List}^{\uparrow}$. Componentwise transport, continuation replay, provenance, and the local NameCert row preserve the same finite sibling surface, so the product carrier exports no hidden pairing oracle. □

Theorem 34.143 (Prod sibling carrier route obligation scope)**.** *Any accepted* $\mathsf{Prod}^{\uparrow}$ *sibling route consumes* $\mathsf{Bool}^{\uparrow}$ *endpoint discrimination,* $\mathsf{Sum}^{\uparrow}$ *tagged alternatives, and* $\mathsf{List}^{\uparrow}$ *finite spine routing only through the product carrier ledger, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The dependency route is therefore pinned to chapter 32, chapter 35, and chapter 36; it cannot split those sibling rows into host projections, unrecorded case analysis, or an external pairing oracle.*

Proof. Apply Definition 34.142. It already reads the endpoint, alternative, and spine dependencies as displayed finite-data rows inside the accepted product carrier.

The obligation scope is obtained by naming the same structural rows. The product ledger stores the dependency consumption, componentwise hsame transport carries it across equivalent pair carriers, Cont replay preserves the route, Pkg records the provenance, and the local NameCert row names the whole package.

Thus the Bool, Sum, and List dependencies remain sibling rows of the product certificate. Since no host projection or external pairing coordinate is present, every accepted route factors through the displayed carrier ledger. □

The public $\mathsf{Prod}^{\uparrow}$ ordered-pair carrier is consumed through the finite-data sibling route: Bool endpoint discrimination from chapter 32, Option possible-absence routing from chapter 33, Sum tagged alternatives from chapter 35, and List spine readback from chapter 36.

This ledger records the dependency route as a hub-visible child input while leaving the theorem-free $\mathsf{Prod}^{\uparrow}$ index as an input list. Public $\mathsf{Prod}^{\uparrow}$ reads use the two displayed component projections

before they enter the finite-data sibling lattice generated by chapter 35 and chapter 36. The product packet therefore contributes paired component ledgers, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any downstream consumer treats the data as a tagged branch or finite spine.

Definition 34.144 (Prod stream-window carrier)**.** *A* $\mathsf{Prod}^{\uparrow}$ *stream-window carrier for L10 product reads is a finite* BHist *packet*

$$P = (L, R, W, D, Q, H, C, N)$$

with the following displayed rows:

1. *L is the left component row and R is the right component row.*
2. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *product window, carrying the finite request schedule through which both components are read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used when the product read is consumed by regular rational windows.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *product readback row, assembled componentwise from the two component reads over the shared window.*
5. *H records componentwise* hsame *transport for L, R, W, D, Q and for the local classifier row.*
6. *C records displayed* Cont *replay routes for the product window, dyadic tolerance ledger, and regular rational readback.*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{Prod}^{\uparrow}}$ *row naming this finite product-window surface.*

The classifier compares accepted packets only through these component rows. It has no coordinate for abstract carrier-equivalence transport or for a product object detached from the displayed StreamName and RegSeqRat windows.

Theorem 34.145 (Prod stream-window NameCert obligations)**.** *For every accepted* $\mathsf{Prod}^{\uparrow}$ *stream-window carrier $P = (L, R, W, D, Q, H, C, N)$, the local* $\mathsf{NameCert}_{\mathsf{Prod}^{\uparrow}}$ *obligation surface consists exactly of left and right component admission, the shared* $\mathsf{StreamName}^{\uparrow}$ *window of chapter 126, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *product readback of chapter 301, componentwise* hsame *transport, displayed* Cont *replay, and local naming.*

Proof. Project the carrier of Definition 34.144. The rows L and R give the two component reads, while W is the only public window through which those components are synchronized.

The dyadic ledger D and regular readback row Q are computed from the same component windows. Componentwise transport through H preserves the two component rows, and replay through C exposes the same product-window route to downstream readers.

The local NameCert row N names this finite package. Since the carrier stores no detached product object or abstract carrier-equivalence transport, the obligations are exactly the displayed componentwise product-window rows. □

Theorem 34.146 (Prod RegSeqRat window handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *product-window read consumed through* $\mathsf{Prod}^{\uparrow}$ *factors componentwise through the shared* $\mathsf{StreamName}^{\uparrow}$ *window W, the left and right component rows L, R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, and the product readback row Q. The handoff supplies the finite product surface needed by StreamName and regular-rational consumers; it does not transport an abstract product equivalence in place of the displayed component rows.*

Proof. Start with a downstream $\mathsf{RegSeqRat}^{\uparrow}$ read of the product packet. The only regular rational coordinate is Q, and it is assembled from L and R over the shared request window W.

Use D to audit the component tolerances on the same window. The replay row C exposes the componentwise reads and tolerance checks before the product readback is public.

Transport through H preserves the left row, right row, shared window, dyadic ledger, and product readback separately. Therefore the handoff remains a finite StreamName-to-RegSeqRat product-window route rather than an abstract carrier-equivalence transport. □

The $\mathsf{Sum}^{\uparrow}$ branch partition and visible-branch classifier rows are consumed beside chapter 34 and chapter 36 as finite coproduct/list-product routing data, while this hub exports no host disjoint union semantics.

Chapter 35

A Concrete Naming Certificate for $\mathsf{Sum}^{\uparrow}$

The disjoint sum interface $\mathsf{Sum}^{\uparrow}$ is licensed over two source carriers each endowed with a NameCert. The carrier is the inductive sum with left and right constructors wrapping source-carrier evidence. The classifier is the constructor-discriminating payload relation: it stores visible tag endpoints together with the matching source classifier witness, while actual source membership remains in SumHistoryCarrier and is the evidence used by the semantic certificate. It is not a primitive coproduct; it is licensed only as a derived constructor over the two sources.

35.1 Roadmap template status

1. **Traditional target**: disjoint sum data with left and right tagged injections.
2. **BEDC source**: two licensed source carriers A and B, each with its own name certificate.
3. **Carrier choice**: tagged left carriers use $e0$ histories and tagged right carriers use $e1$ histories.
4. **Classifier choice**: the sum classifier stores tag endpoints plus the matching A or B classifier witness, and excludes mixed tags; source-carrier evidence is supplied by SumHistoryCarrier.
5. **Stability obligations**: tagged carrier transport, source-certified classifier-induced carrier transport, left/right inversion, mixed-tag exclusion, classifier symmetry, classifier transitivity, and endpoint transport.
6. **Ledger**: the tag is visible data; payload evidence is retained from the corresponding source certificate.
7. **Core theorem list**: tagged injections, hsame carrier transport, source-certified classifier-induced carrier transport, left and right inversions, classifier inversion, source-parameter irrelevance of the classifier, generic same-tag exactness, carrier-aware same-tag exactness, mixed-tag exclusion, and the semantic name certificate.
8. **Exactness predicate**: the left-tag and right-tag iff clauses identify classifier-only payload witnesses and the matching source classifier, while carrier-aware exactness combines SumHistoryCarrier with explicit carrier transport along hsame.
9. **Standard bridge**: tagged histories read back as ordinary $\mathsf{inl}(a)$ and $\mathsf{inr}(b)$ values.

10. **Status**: the SemanticNameCert at Theorem 35.108 is CheckedCert; Theorem 35.16 is the paper-side matching-source formulation, and Theorem 35.18 records the witness-level same-tag formulation.

35.2 Carrier definition

Definition 35.1 (Sum carrier)**.** *For licensed source carriers A and B, define an inductive carrier with constructors* $\mathsf{inl}(a)$ *and* $\mathsf{inr}(b)$*.*

Lean4 (definition) `BEDC.Derived.SumUp.SumCarrier`
Lean4 (definition) `BEDC.Derived.SumUp.SumHistoryCarrier`

Theorem 35.2 (Sum history carrier transport)**.** *If h and k are internally the same BEDC histories, then membership of h in the tagged sum-history carrier transfers to membership of k in the same carrier.*

Proof. Invert the sum carrier witness. In the left-tag case, compose symmetry of the given $\mathsf{hsame}(h, k)$ witness with the stored $\mathsf{hsame}(h, e0(l))$ tag witness, and keep the same left source-carrier proof. The right-tag case is identical with $e1(r)$. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryCarrier hsame transport`

Theorem 35.3 (Sum history carrier branch exclusivity)**.** *For source carriers $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$, no BEDC history h has both a left carrier presentation and a right carrier presentation:*

$$\neg\Big((\exists l : \mathsf{BHist}.\ \mathsf{hsame}(h, \mathsf{E0}(l)) \wedge Left(l)) \wedge (\exists r : \mathsf{BHist}.\ \mathsf{hsame}(h, \mathsf{E1}(r)) \wedge Right(r))\Big).$$

Proof. Assume both presentations. The left witness gives $\mathsf{hsame}(h, \mathsf{E0}(l))$, and the right witness gives $\mathsf{hsame}(h, \mathsf{E1}(r))$. Compose the symmetry of the left endpoint witness with the right endpoint witness to obtain $\mathsf{hsame}(\mathsf{E0}(l), \mathsf{E1}(r))$, then close by BEDC $e0/e1$ no-confusion. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryCarrier branch exclusivity`

Theorem 35.4 (Sum history carrier excludes empty)**.** *For any source carriers $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$, the empty history is not a tagged sum-history carrier:*

$$\neg\mathsf{SumHistoryCarrier}(Left, Right, \mathsf{e}).$$

Proof. Eliminate the tagged carrier witness. A left branch would identify e with an $\mathsf{E0}$-tagged payload, and a right branch would identify e with an $\mathsf{E1}$-tagged payload. Both contradict history no-confusion. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryCarrier empty absurd`

Theorem 35.5 (Sum history left-tag inversion)**.** *If an $e0$-tagged history belongs to the tagged sum-history carrier, then its payload is history-same to a left carrier witness.*

Proof. Invert the tagged carrier witness. In the left branch, BEDC $e0$-constructor inversion recovers the payload sameness and keeps the stored left carrier proof. In the right branch, the $e0/e1$ no-confusion theorem contradicts the stored tag witness. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryCarrier e0 inversion`

Theorem 35.6 (Sum history right-tag inversion)**.** *If an $e1$-tagged history belongs to the tagged sum-history carrier, then its payload is history-same to a right carrier witness.*

Proof. Invert the tagged carrier witness. In the left branch, the $e1/e0$ no-confusion theorem contradicts the stored tag witness. In the right branch, BEDC $e1$-constructor inversion recovers the payload sameness and keeps the stored right carrier proof. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryCarrier e1 inversion`

Theorem 35.7 (Sum history carrier visible-tag exactness)**.** *For source carriers $Left, Right$: $\mathsf{BHist} \to \mathsf{Prop}$, the visible tags of the tagged sum-history carrier are exactly the corresponding source carrier payloads:*

$$\mathsf{SumHistoryCarrier}(Left, Right, \mathsf{E0}(l)) \iff \exists a : \mathsf{BHist}.\ Left(a) \wedge \mathsf{hsame}(l, a),$$

and

$$\mathsf{SumHistoryCarrier}(Left, Right, \mathsf{E1}(r)) \iff \exists b : \mathsf{BHist}.\ Right(b) \wedge \mathsf{hsame}(r, b).$$

Proof. For the forward implications, apply the checked left-tag and right-tag inversion theorems to the carrier witness. For the reverse implications, start from the payload witness, use the checked tagged-injection constructor for the matching branch, convert the payload endpoint by constructor congruence for hsame, and transport carrier membership along the resulting history sameness by SumHistoryCarrier_hsame_transport. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryCarrier visible tag exactness`

35.3 The certificate

Definition 35.8 (Sum source specification)**.** *The source is the disjoint union of the two source certificates.*

Definition 35.9 (Sum pattern specification)**.** *The pattern is left-or-right injection from the corresponding source witness.*

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryCarrier tagged injections`

Definition 35.10 (Sum classifier specification)**.** *The classifier records left-tag endpoint payloads through the A-classifier and right-tag endpoint payloads through the B-classifier, and never relates opposite constructors. Source membership is carried by* SumHistoryCarrier *rather than by this classifier relation.*

Lean4 (definition) `BEDC.Derived.SumUp.SumHistoryClassifier`
Lean4 (definition) `BEDC.Derived.SumUp.SumClassifierSpec`
Lean4 ✓ `BEDC.Derived.SumUp.sum classifier inversion`

Theorem 35.11 (Sum classifier does not carry source membership)**.** *Let* $\mathsf{FalseCarrier}(h)$ *mean* False *for every BEDC history h. Then*

$$\mathsf{SumHistoryClassifier}(\mathsf{FalseCarrier}, \mathsf{FalseCarrier}, \mathsf{hsame}, \mathsf{hsame}, \mathsf{E0}(\mathsf{e}), \mathsf{E0}(\mathsf{e}))$$

holds, while

$$\neg\mathsf{SumHistoryCarrier}(\mathsf{FalseCarrier}, \mathsf{FalseCarrier}, \mathsf{E0}(\mathsf{e})).$$

Proof. Build the classifier by the left-tag branch, using e as both stored left payloads, reflexivity of hsame for the two visible E0(e) endpoints, and reflexivity of hsame for the payload relation. A carrier witness for E0(e) would be either a left branch with some payload satisfying FalseCarrier or a right branch with some payload satisfying FalseCarrier. Both cases unfold to False, so no carrier witness exists. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier no source membership`

Theorem 35.12 (Sum history classifier source-parameter irrelevance)**.** *For source carriers* $Left, Right, LeftAlt, R$ BHist → Prop*, component classifiers* $LeftEq, RightEq$: BHist → BHist → Prop*, and histories* h, k : BHist*,*

$$\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k) \iff \mathsf{SumHistoryClassifier}(LeftAlt, RightAlt, LeftEq, Ri$$

Proof. For the forward direction, case-analyze the classifier witness. In the left-tag branch, keep the same stored left payloads, endpoint tag witnesses, and $LeftEq$ witness, and build the left branch for the alternate source carriers. In the right-tag branch, keep the same stored right payloads, endpoint tag witnesses, and $RightEq$ witness, and build the right branch for the alternate source carriers. For the reverse direction, exchange the two source-carrier pairs and repeat the same branch analysis. No source-carrier proof occurs inside the classifier witness; those proofs belong to SumHistoryCarrier and to certificate transport. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier source parameter irrelevance`

Mixed-tag classifier exclusion is recorded by Theorem 35.41.

Theorem 35.13 (Sum history classifier left-tag inversion)**.** *When the history-level sum classifier uses* hsame *on both components and relates two* $e0$*-tagged histories, the two left payload histories are internally the same.*

Proof. Invert the tagged classifier witness. The left branch gives two $e0$-tag witnesses and a stored component hsame witness; constructor inversion for $e0$ composes them into payload sameness. The right branch contradicts constructor separation between $e0$ and $e1$. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier left hsame inversion`

Theorem 35.14 (Sum history classifier right-tag inversion)**.** *When the history-level sum classifier uses* hsame *on both components and relates two* $e1$*-tagged histories, the two right payload histories are internally the same.*

Proof. Invert the tagged classifier witness. The left branch contradicts constructor separation between $e1$ and $e0$. The right branch gives two $e1$-tag witnesses and a stored component hsame witness; constructor inversion for $e1$ composes them into payload sameness. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier right hsame inversion`

The same-tag iff clauses below are classifier-only statements; carrier and ledger evidence are supplied separately by SumHistoryCarrier and the ledger policy.

Theorem 35.15 (Sum history classifier same-tag exactness)**.** *For source carriers* $Left, Right$: BHist → Prop*, the history-level sum classifier with* hsame *on both components is exact on each visible tag:*

$$\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, \mathsf{E0}(l), \mathsf{E0}(l')) \iff \mathsf{hsame}(l, l')$$

and

$$\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, \mathsf{E1}(r), \mathsf{E1}(r')) \iff \mathsf{hsame}(r, r').$$

Proof. For the forward directions, apply the left-tag and right-tag inversion theorems above. For the reverse directions, rebuild the matching classifier branch using the given payload hsame witness, the reflexive visible-tag witnesses for $\mathsf{E0}(l)$ and $\mathsf{E0}(l')$ or for $\mathsf{E1}(r)$ and $\mathsf{E1}(r')$, and the corresponding left or right classifier constructor. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier hsame same tag exactness`

Theorem 35.16 (Sum history classifier same-tag source exactness)**.** *For source carriers* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *and source classifiers* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$*, suppose the source classifiers transport along endpoint history sameness:*

$$\forall l, l_0, l', l'_0.\ \mathsf{hsame}(l, l_0) \to \mathsf{hsame}(l', l'_0) \to LeftEq(l_0, l'_0) \to LeftEq(l, l')$$

and

$$\forall r, r_0, r', r'_0.\ \mathsf{hsame}(r, r_0) \to \mathsf{hsame}(r', r'_0) \to RightEq(r_0, r'_0) \to RightEq(r, r').$$

Then the history-level sum classifier is exact for same-tag endpoints through the matching source classifier. This theorem is a classifier-only same-tag exactness statement; it returns the matching source classifier witness and does not assert $Left(l)$*,* $Left(l')$*,* $Right(r)$*, or* $Right(r')$*:*

$$\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, \mathsf{E0}(l), \mathsf{E0}(l')) \iff LeftEq(l, l')$$

and

$$\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, \mathsf{E1}(r), \mathsf{E1}(r')) \iff RightEq(r, r').$$

Proof. Invert the same-tag classifier witness. In the left-tag forward direction, the right branch is impossible by $e0/e1$ no-confusion. The left branch stores endpoint payloads l_0, l'_0 together with $LeftEq(l_0, l'_0)$; constructor inversion for $e0$ yields $\mathsf{hsame}(l, l_0)$ and $\mathsf{hsame}(l', l'_0)$, and the left transport hypothesis gives $LeftEq(l, l')$. The right-tag forward direction is identical using $e1$-constructor inversion and the right transport hypothesis. For the reverse directions, use the visible endpoints as the stored payloads, the reflexive tag witnesses for E0 or E1, and the supplied matching source-classifier witness to rebuild the corresponding classifier branch. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier source same tag exactness`

Theorem 35.17 (Sum history classifier hsame same-tag carrier exactness)**.** *For source carriers* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$*, the* hsame*-specialized history-level sum classifier is exact for same-tag endpoints together with the matching source-carrier evidence:*

$$\mathsf{SumHistoryCarrier}(Left, Right, \mathsf{E0}(l)) \wedge \mathsf{SumHistoryCarrier}(Left, Right, \mathsf{E0}(l')) \wedge \mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hs}$$

and

$$\mathsf{SumHistoryCarrier}(Left, Right, \mathsf{E1}(r)) \wedge \mathsf{SumHistoryCarrier}(Left, Right, \mathsf{E1}(r')) \wedge \mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hs}$$

Its roadmap-template role is: traditional target disjoint-sum same-tag payload exactness; BEDC source BHist *with* hsame*; carrier* SumHistoryCarrier*; classifier the* hsame *specialization of* SumHistoryClassifier*; ledger visible tag plus payload carrier witnesses; status* ProofTarget*.*

Proof. For the forward left-tag direction, apply the two $\mathsf{E0}$ carrier inversions to obtain payload witnesses a, a' with $Left(a)$, $Left(a')$, $\mathsf{hsame}(l, a)$, and $\mathsf{hsame}(l', a')$. Apply the left hsame classifier inversion to the same-tag classifier witness to obtain $\mathsf{hsame}(l, l')$. Symmetry and transitivity of hsame compose the displayed endpoint links with $\mathsf{hsame}(l, l')$ to derive $\mathsf{hsame}(a, a')$. The right-tag direction is identical using the two $\mathsf{E1}$ carrier inversions and the right hsame classifier inversion. For the reverse left-tag direction, the displayed witnesses rebuild the two left carrier branches and the left classifier branch. The reverse right-tag direction rebuilds the two right carrier branches and the right classifier branch. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier hsame same tag carrier exactness`

Theorem 35.18 (Sum history classifier generic same-tag exactness)**.** *For source carriers* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *and source classifiers* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$*, the history-level sum classifier is exact on each visible tag:*

$$\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, \mathsf{E0}(l), \mathsf{E0}(l')) \iff \exists a, a'.\ \mathsf{hsame}(l, a) \wedge \mathsf{hsame}(l', a') \wedge LeftE$$

and

$$\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, \mathsf{E1}(r), \mathsf{E1}(r')) \iff \exists b, b'.\ \mathsf{hsame}(r, b) \wedge \mathsf{hsame}(r', b') \wedge Right$$

Proof. Unfold $\mathsf{SumHistoryClassifier}$. In the left-tag forward direction, the left branch already stores payload witnesses for the two endpoints together with a $LeftEq$ witness; the opposite right branch is impossible by $e0/e1$ no-confusion, and $e0$-constructor inversion identifies the visible endpoints with the stored payload tags. The right-tag forward direction is identical with $e1$-constructor inversion and $RightEq$. For the reverse directions, the displayed payload witnesses rebuild the matching left or right classifier branch by constructor congruence for $e0$ or $e1$, together with the stored source-classifier witness. The surviving branch is constructor-stable, and the impossible branch is discharged by the same tag no-confusion principle. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier generic same tag exactness`

Theorem 35.19 (Sum history classifier left-chain visible payload classification)**.** *For source carriers* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *and histories* h, k, r, a, c*, if*

$$\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, h, k), \qquad \mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, k, r),$$

and if the outer endpoints are visibly left-tagged as

$$\mathsf{hsame}(h, \mathsf{E0}(a)), \qquad \mathsf{hsame}(r, \mathsf{E0}(c)),$$

then $\mathsf{hsame}(a, c)$*.*

Proof. Compose the two sum classifiers using transitivity of hsame on both branches. Transport the resulting classifier along the two displayed outer endpoint presentations, obtaining a classifier between $\mathsf{E0}(a)$ and $\mathsf{E0}(c)$. Left-tag classifier inversion then identifies the two visible payloads by $\mathsf{hsame}(a, c)$. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier left chain visible payload classification`

Theorem 35.20 (Sum history classifier left endpoint fanout)**.** *For source carriers* $Left, Right$: $\mathsf{BHist} \to \mathsf{Prop}$*, source classifiers* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$*, and histories* h, k, r, a*, if*

$$\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k), \qquad \mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq,$$

then both targets expose left-tag payload witnesses:

$$\begin{aligned}&(\exists a', b.\ \mathsf{hsame}(a, a') \wedge \mathsf{hsame}(k, \mathsf{E0}(b)) \wedge LeftEq(a', b))\\ &\wedge(\exists a'', c.\ \mathsf{hsame}(a, a'') \wedge \mathsf{hsame}(r, \mathsf{E0}(c)) \wedge LeftEq(a'', c)).\end{aligned}$$

Proof. Case-analyze both sum-classifier witnesses. A right-branch witness would force the shared source endpoint to be simultaneously an E0 endpoint and an E1 endpoint, contradicting constructor separation. The surviving left branches expose the stored source payload, each target payload, the target endpoint equation, and the corresponding $LeftEq$ witness; E0 inversion composes the displayed source endpoint with the stored source tag. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier left endpoint fanout`

Theorem 35.21 (Sum history classifier right endpoint fanout)**.** *For source carriers* $Left, Right$: $\mathsf{BHist} \to \mathsf{Prop}$*, source classifiers* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$*, and histories* h, k, r, a*, if*

$$\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k), \qquad \mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq,$$

then both targets expose right-tag payload witnesses:

$$\begin{aligned}&(\exists a', b.\ \mathsf{hsame}(a, a') \wedge \mathsf{hsame}(k, \mathsf{E1}(b)) \wedge RightEq(a', b))\\ &\wedge(\exists a'', c.\ \mathsf{hsame}(a, a'') \wedge \mathsf{hsame}(r, \mathsf{E1}(c)) \wedge RightEq(a'', c)).\end{aligned}$$

Proof. Case-analyze both sum-classifier witnesses. A left-branch witness would force the shared source endpoint to be simultaneously an E1 endpoint and an E0 endpoint, contradicting constructor separation. The surviving right branches expose the stored source payload, each target payload, the target endpoint equation, and the corresponding $RightEq$ witness; E1 inversion composes the displayed source endpoint with the stored source tag. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier right endpoint fanout`

Theorem 35.22 (Sum history classifier carrier-aware same-tag exactness)**.** *Let* $Left, Right$: $\mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, let* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers, and assume the two carriers transport along* hsame*:*

$$\forall x\, y.\ Left(x) \to \mathsf{hsame}(x, y) \to Left(y)$$

and

$$\forall x\, y.\ Right(x) \to \mathsf{hsame}(x, y) \to Right(y).$$

Then the visible same-tag carrier and classifier evidence is exact for the matching source payloads:

$$\mathsf{SumHistoryCarrier}(Left, Right, \mathsf{E0}(l)) \wedge \mathsf{SumHistoryCarrier}(Left, Right, \mathsf{E0}(l')) \wedge \mathsf{SumHistoryClassifier}(Left, Right$$

and

$$\mathsf{SumHistoryCarrier}(Left, Right, \mathsf{E1}(r)) \wedge \mathsf{SumHistoryCarrier}(Left, Right, \mathsf{E1}(r')) \wedge \mathsf{SumHistoryClassifier}(Left, Righ$$

Its roadmap-template role is: traditional target disjoint-sum same-tag payload exactness; BEDC source BHist *with* SumHistoryCarrier *and carrier transport along* hsame*; carrier the tagged sum carrier; classifier* SumHistoryClassifier*; ledger visible tag plus payload evidence; exactness the displayed iff clauses; status* ProofTarget*.*

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier carrier aware same tag exactness`

Proof. For the forward left-tag direction, invert the two displayed carrier witnesses to obtain payloads c, c' with $Left(c)$ and $Left(c')$ plus $\mathsf{hsame}(l, c)$ and $\mathsf{hsame}(l', c')$. Apply Theorem 35.18 to the classifier premise to obtain payloads a, a' with $\mathsf{hsame}(l, a)$, $\mathsf{hsame}(l', a')$, and $LeftEq(a, a')$. Symmetry and transitivity of hsame align c with a and c' with a'. Apply the explicit left carrier-transport field to $Left(c)$ and $\mathsf{hsame}(c, a)$, and to $Left(c')$ and $\mathsf{hsame}(c', a')$. This gives the displayed left payload witnesses. The forward right-tag direction is the same argument with E1, $Right$, $RightEq$, and the explicit right carrier-transport field applied in the same order. For the reverse directions, the displayed payload witnesses rebuild the two tagged carrier premises and the matching classifier branch by the generic same-tag exactness theorem, using the visible tag constructors to supply the endpoint evidence. □

Theorem 35.23 (Sum history classifier branch partition)**.** *For branch carriers* $Left, Right$: $\mathsf{BHist} \to \mathsf{Prop}$*, branch classifiers* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$*, and histories* h, k*, the history-level sum classifier exposes the visible left-or-right constructor analysis:*

$$\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k) \to (\exists l, l'.\ \mathsf{hsame}(h, \mathsf{E0}(l)) \wedge \mathsf{hsame}(k, \mathsf{E0}(l')) \wedge LeftEq(l, l')$$

In the ten-field fit, the traditional target is disjoint-sum branch readback, the BEDC source is BHist*, the classifier is* SumHistoryClassifier*, the ledger records the visible tag plus payload, and the status is* ProofTarget*.*

Proof. Case-analyze the classifier witness. The left constructor supplies the two E0 endpoint links and the stored $LeftEq$ payload relation, yielding the left disjunct. The right constructor supplies the two E1 endpoint links and the stored $RightEq$ payload relation, yielding the right disjunct. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier branch partition`

Theorem 35.24 (Sum history classifier branch exactness)**.** *For branch carriers* $Left, Right$: $\mathsf{BHist} \to \mathsf{Prop}$*, branch classifiers* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$*, and histories* h, k*, the history-level sum classifier is exactly the visible left-or-right branch disjunction:*

$$\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k) \iff (\exists l, l'.\ \mathsf{hsame}(h, \mathsf{E0}(l)) \wedge \mathsf{hsame}(k, \mathsf{E0}(l')) \wedge LeftEq(l, l$$

In the ten-field fit, the exactness target records that classifier witnesses and visible same-branch endpoint data determine each other.

Proof. For the forward direction, apply Theorem 35.74. It case-analyzes the classifier witness and returns the displayed left-or-right branch data.

For the reverse direction, split the displayed disjunction. In the left branch, unpack l, l' together with the two visible left endpoint witnesses and the stored $LeftEq(l, l')$ witness, then rebuild the left classifier constructor. In the right branch, unpack r, r' together with the two visible right endpoint witnesses and the stored $RightEq(r, r')$ witness, then rebuild the right classifier constructor. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier branch iff`

Theorem 35.25 (Sum history carrier visible branch cases)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers. If* $\mathsf{SumHistoryCarrier}(Left, Right, h)$ *holds, then the visible history has one of the two displayed branch witnesses:*

$$(\exists l.\ Left(l) \wedge \mathsf{hsame}(h, \mathsf{E0}(l))) \vee (\exists r.\ Right(r) \wedge \mathsf{hsame}(h, \mathsf{E1}(r))).$$

In the ten-field fit, the traditional target is disjoint-sum carrier readback, the BEDC source is BHist*, the carrier is* SumHistoryCarrier*, no classifier is needed, the stability obligation is constructor inversion, the ledger records the visible tag plus payload, the core theorem is branch cases, exactness coverage is supplied by the visible branch witnesses, the standard bridge is* inl *and* inr*, and the status is* ProofTarget*.*

Proof. Case-analyze the generated SumHistoryCarrier witness. The left constructor returns a payload l, the source-carrier witness $Left(l)$, and the displayed endpoint link $\mathsf{hsame}(h, \mathsf{E0}(l))$. The right constructor returns the corresponding payload r, the source-carrier witness $Right(r)$, and the displayed endpoint link $\mathsf{hsame}(h, \mathsf{E1}(r))$. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryCarrier visible branch cases`

Theorem 35.26 (Sum history carrier visible branch exactness)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers. Then the sum history carrier is exactly the visible left-or-right branch assertion:*

$$\mathsf{SumHistoryCarrier}(Left, Right, h) \iff (\exists l.\ Left(l) \wedge \mathsf{hsame}(h, \mathsf{E0}(l))) \vee (\exists r.\ Right(r) \wedge \mathsf{hsame}(h, \mathsf{E1}(r))).$$

In the ten-field fit, the carrier coverage predicate and the visible branch classifier agree on precisely the histories generated by the two sum constructors.

Proof. For the forward direction, apply Definition 35.76. For the reverse direction, split the displayed disjunction. In the left case, unpack the payload l, the source-carrier witness $Left(l)$, and the visible endpoint link $\mathsf{hsame}(h, \mathsf{E0}(l))$, then rebuild the left carrier constructor. In the right case, unpack the corresponding data for r and rebuild the right carrier constructor. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryCarrier visible branch exactness`

Theorem 35.27 (Sum history carrier exclusive visible branch partition)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers. Then the sum history carrier has exactly one visible branch presentation:*

$$\mathsf{SumHistoryCarrier}(Left, Right, h) \iff \Big((\exists l.\ Left(l) \wedge \mathsf{hsame}(h, \mathsf{E0}(l))) \wedge \neg(\exists r.\ Right(r) \wedge \mathsf{hsame}(h, \mathsf{E1}(r)))\Big) \vee \Big((\exists r.\ R$$

In the ten-field fit, the carrier readback for $\mathsf{Sum}^{\uparrow}$ *is a constructor partition: every carrier history is visibly generated by one sum constructor, and the opposite visible constructor presentation is excluded.*

Proof. For the forward direction, use Definition 35.77 to obtain either a visible left presentation or a visible right presentation. In the left case, the opposite right presentation would contradict Definition 35.3 after reordering the stored endpoint and source-carrier witnesses; the right case is symmetric. For the reverse direction, split the displayed disjunction, forget the negative conjunct, and rebuild $\mathsf{SumHistoryCarrier}(Left, Right, h)$ through Definition 35.77. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryCarrier exclusive visible branch partition payload first`

Theorem 35.28 (Sum visible branch payload determinism)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $h, l, l', r, r' : \mathsf{BHist}$ *be histories. Same-branch visible presentations have unique payloads up to* hsame*:*

$$\mathsf{hsame}(h, \mathsf{E0}(l)) \to Left(l) \to \mathsf{hsame}(h, \mathsf{E0}(l')) \to Left(l') \to \mathsf{hsame}(l, l')$$

and

$$\mathsf{hsame}(h, \mathsf{E1}(r)) \to Right(r) \to \mathsf{hsame}(h, \mathsf{E1}(r')) \to Right(r') \to \mathsf{hsame}(r, r').$$

In the ten-field fit, the traditional target is disjoint-sum visible readback determinism; the BEDC source is BHist*; the carrier is* SumHistoryCarrier *presentations; the classifier is* hsame *on visible constructors; the stability obligation is constructor inversion; the ledger records the visible tag plus payload source evidence; the core theorem is same-branch payload uniqueness; exactness is deterministic readback; the standard bridge is* inl *and* inr*; and the status is* ProofTarget*.*

Proof. For the left statement, use symmetry on the first endpoint link and compose it with the second endpoint link, obtaining $\mathsf{hsame}(\mathsf{E0}(l), \mathsf{E0}(l'))$. Constructor inversion for the visible left constructor gives $\mathsf{hsame}(l, l')$. The right statement is identical, composing the two E1 endpoint links and applying right-constructor inversion. The source-carrier witnesses record that both visible presentations are legitimate branch presentations; they are not needed by the constructor inversion itself. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryCarrier visible payload determinism`

Theorem 35.29 (Sum carrier single-valued visible branch readback)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $h : \mathsf{BHist}$*. If* $\mathsf{SumHistoryCarrier}(Left, Right, h)$ *holds, then the visible tagged payload presentation of* h *is single-valued:*

$$\exists l.\ Left(l) \wedge \mathsf{hsame}(h, \mathsf{E0}(l)) \wedge (\forall l'.\ Left(l') \to \mathsf{hsame}(h, \mathsf{E0}(l')) \to \mathsf{hsame}(l, l')) \wedge \neg(\exists r.\ Right(r) \wedge \mathsf{hsame}(h, \mathsf{E1}(r$$

or

$$\exists r.\ Right(r) \wedge \mathsf{hsame}(h, \mathsf{E1}(r)) \wedge (\forall r'.\ Right(r') \to \mathsf{hsame}(h, \mathsf{E1}(r')) \to \mathsf{hsame}(r, r')) \wedge \neg(\exists l.\ Left(l) \wedge \mathsf{hsame}(h, \mathsf{E0}$$

In the ten-field fit, the traditional target is tagged disjoint-sum readback; the BEDC source is BHist*; the carrier is* SumHistoryCarrier*; the classifier is* hsame *on same-tag visible payloads; stability is constructor inversion plus branch exclusion; the ledger stores the visible tag and payload source evidence; the core theorem is this single-valued readback; exactness is existence, uniqueness, and opposite-tag exclusion; the standard bridge is* inl *and* inr*; and the status is* ProofTarget*.*

Proof. Apply Definition 35.78 to the carrier witness. In the left branch, unpack l, $Left(l)$, the endpoint link $\mathsf{hsame}(h, \mathsf{E0}(l))$, and the exclusion of right visible presentations. For an arbitrary left visible payload l', apply Definition 35.79 to the two left endpoint links and the two source-carrier witnesses to obtain $\mathsf{hsame}(l, l')$. The right branch is symmetric, using the right payload clause and carrying the exclusion of left visible presentations unchanged. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryCarrier single valued visible readback`

Theorem 35.30 (Sum history classifier carrier-aware branch partition)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, let* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers. Assume source-carrier closure under history sameness:*

$$\forall x\, y.\ Left(x) \to \mathsf{hsame}(x, y) \to Left(y)$$

and

$$\forall x\, y.\ Right(x) \to \mathsf{hsame}(x, y) \to Right(y).$$

If $\mathsf{SumHistoryCarrier}(Left, Right, h)$, $\mathsf{SumHistoryCarrier}(Left, Right, k)$, *and* $\mathsf{SumHistoryClassifier}(Left, Right, Left$ *hold, then a visible classifier side supplies the branch data used by the carrier-backed certificate analysis:*

$$\exists a, b.\ Left(a) \wedge Left(b) \wedge \mathsf{hsame}(h, \mathsf{E0}(a)) \wedge \mathsf{hsame}(k, \mathsf{E0}(b)) \wedge LeftEq(a, b)$$

or

$$\exists a, b.\ Right(a) \wedge Right(b) \wedge \mathsf{hsame}(h, \mathsf{E1}(a)) \wedge \mathsf{hsame}(k, \mathsf{E1}(b)) \wedge RightEq(a, b).$$

Proof. Split the displayed SumHistoryClassifier witness into its visible left or right constructor branch. In the left branch, let the classifier payloads be a, b. Compose the carrier endpoint for h with the classifier endpoint $\mathsf{hsame}(h, \mathsf{E0}(a))$ and apply SumHistoryCarrier_e0_inversion to obtain a source payload l, $Left(l)$, and a payload link $\mathsf{hsame}(l, a)$; the same argument at k gives l', $Left(l')$, and $\mathsf{hsame}(l', b)$. The left source-carrier closure turns these into $Left(a)$ and $Left(b)$. Together with the stored $LeftEq(a, b)$ witness and the two classifier endpoint links, these data give the left disjunct. In the right branch, apply the analogous E1 endpoint composition and SumHistoryCarrier_e1_inversion argument to obtain $Right(a)$ and $Right(b)$ from the right source-carrier closure, then pair them with the stored $RightEq(a, b)$ witness and the two right endpoint links. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier carrier aware branch partition`

Theorem 35.31 (Sum history classifier carrier-aware branch exactness)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, let* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers. Assume source-carrier closure under history sameness:*

$$\forall x\, y.\ Left(x) \to \mathsf{hsame}(x, y) \to Left(y)$$

and

$$\forall x\, y.\ Right(x) \to \mathsf{hsame}(x, y) \to Right(y).$$

Then the carrier-backed classifier assertion

$$\begin{aligned}&\mathsf{SumHistoryCarrier}(Left, Right, h) \wedge \mathsf{SumHistoryCarrier}(Left, Right, k) \wedge \\ &\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k)\end{aligned}$$

is equivalent to the visible branch assertion

$$\begin{aligned}&\big(\exists a, b.\ Left(a) \wedge Left(b) \wedge \mathsf{hsame}(h, \mathsf{E0}(a)) \wedge \mathsf{hsame}(k, \mathsf{E0}(b)) \wedge LeftEq(a, b)\big) \\ &\vee \\ &\big(\exists a, b.\ Right(a) \wedge Right(b) \wedge \mathsf{hsame}(h, \mathsf{E1}(a)) \wedge \mathsf{hsame}(k, \mathsf{E1}(b)) \wedge RightEq(a, b)\big).\end{aligned}$$

Proof. For the forward direction, apply Definition 35.81 with the two displayed source-carrier closure hypotheses. For the reverse direction, split the displayed branch assertion. In the left branch, unpack a, b with their $Left$ witnesses, the two visible E0 endpoint links, and the stored $LeftEq(a, b)$ witness. The same data rebuilds the two SumHistoryCarrier witnesses by the left carrier constructor and rebuilds the matching SumHistoryClassifier witness by the left classifier constructor. The right branch is identical, using the two $Right$ witnesses, the visible E1 endpoint links, $RightEq(a, b)$, and the right carrier and classifier constructors. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier carrier aware branch exactness`

Theorem 35.32 (Sum history source weakening)**.** *Let* $Left, Right, Left', Right' : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, and let* $LeftEq, RightEq, LeftEq', RightEq' : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers. The two refinements have separate premises. Source-carrier inclusion gives carrier refinement:*

$$((\forall h.\ Left(h) \to Left'(h)) \wedge (\forall h.\ Right(h) \to Right'(h))) \to (\mathsf{SumHistoryCarrier}(Left, Right, h) \to \mathsf{SumHistoryCarr}$$

Component-relation weakening gives classifier refinement:

$$((\forall a\, b.\ LeftEq(a,b) \to LeftEq'(a,b)) \wedge (\forall a\, b.\ RightEq(a,b) \to RightEq'(a,b))) \to (\mathsf{SumHistoryClassifier}(Left, Rig$$

In the ten-field fit, the traditional target is disjoint-sum stability under source refinement, the BEDC source is the two BHist *carriers, the carrier is* SumHistoryCarrier*, the component classifier is* SumHistoryClassifier*, the stability datum is source inclusion plus component-relation weakening, the ledger keeps the visible tag unchanged, and the core theorem separates carrier weakening from classifier weakening. The classifier part uses only component-relation weakening because source membership is not a field of* SumHistoryClassifier*. Exactness is preserved by the same endpoint witnesses, the standard bridge is the* inl *and* inr *restriction, and the status is* ProofTarget*.*

Proof. For the carrier claim, assume the displayed pair of source-carrier inclusions and split the SumHistoryCarrier witness into its left and right constructor cases. The endpoint history witness is reused unchanged, while the matching source-carrier inclusion maps the payload membership proof into the refined source carrier. For the classifier claim, assume the displayed pair of component-relation weakenings and split the SumHistoryClassifier witness into its left and right constructor cases. Reuse the same two visible endpoints and apply only the matching component-relation weakening hypothesis to the stored $LeftEq$ or $RightEq$ witness. Source membership is absent from SumHistoryClassifier, so no source-carrier inclusion is needed for the classifier paragraph. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistorySource weakening`

Theorem 35.33 (Sum history source equivalence)**.** *Let* $Left, Right, Left', Right' : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, and let* $LeftEq, RightEq, LeftEq', RightEq' : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers. Assume source-carrier equivalence*

$$\forall h.\ Left(h) \leftrightarrow Left'(h)$$

and

$$\forall h.\ Right(h) \leftrightarrow Right'(h),$$

and assume component-relation equivalence

$$\forall a\, b.\ LeftEq(a,b) \leftrightarrow LeftEq'(a,b)$$

and

$$\forall a\, b.\ RightEq(a,b) \leftrightarrow RightEq'(a,b).$$

Then the sum carrier and classifier are invariant under the equivalent source presentation:

$$(\forall h.\ \mathsf{SumHistoryCarrier}(Left, Right, h) \leftrightarrow \mathsf{SumHistoryCarrier}(Left', Right', h)) \wedge (\forall h\, k.\ \mathsf{SumHistoryClassifier}(Left, R$$

In the ten-field fit, the traditional target is disjoint-sum source-presentation invariance, the BEDC source is the two BHist *carriers, the carrier is* SumHistoryCarrier*, the classifier is* SumHistoryClassifier*, the stability datum is source and relation equivalence, the ledger keeps the visible tag unchanged, and the core theorem is carrier and classifier equivalence. Exactness uses the unchanged branch witnesses, the standard bridge is* inl *and* inr *readback, and the status is* ProofTarget*.*

Proof. Apply Definition 35.83 from left to right using the forward halves of the two source-carrier equivalences for the carrier clause and the forward halves of the two component-relation equivalences for the classifier clause. This gives the implications from $(Left, Right, LeftEq, RightEq)$ to $(Left', Right', LeftEq', RightEq')$, with the same visible tag and the same branch witnesses. Apply the same weakening theorem from right to left using the reverse halves of the four equivalence hypotheses. Pair the two carrier implications and pair the two classifier implications. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistorySource equivalence`

Theorem 35.34 (Sum history classifier relation weakening)**.** *Let* $Left, Right, LeftAlt, RightAlt$: BHist → Prop *be arbitrary source carriers, and let* $LeftEq, RightEq, LeftEq', RightEq'$: BHist → BHist → Prop *be component classifiers. Assume component-relation weakening*

$$\forall a\, b.\ LeftEq(a, b) \to LeftEq'(a, b)$$

and

$$\forall a\, b.\ RightEq(a, b) \to RightEq'(a, b).$$

Then the sum history classifier relation weakens independently of source-carrier inclusion:

$$\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k) \to \mathsf{SumHistoryClassifier}(LeftAlt, RightAlt, LeftEq', Rig$$

In the ten-field fit, the traditional target is disjoint-sum classifier monotonicity, the BEDC source is BHist*, the classifier is* SumHistoryClassifier*, the stability datum is component-relation weakening, the ledger keeps the visible tag unchanged, exactness is branch partition preservation, and the status is* ProofTarget*.*

Proof. Split the displayed SumHistoryClassifier witness into its visible left or right constructor branch. In each branch, reuse the same visible endpoint witnesses for h and k. The left branch applies the left component-relation weakening hypothesis to the stored $LeftEq$ witness and rebuilds the left tagged classifier witness; the right branch applies the right component-relation weakening hypothesis to the stored $RightEq$ witness and rebuilds the right tagged classifier witness. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier relation weakening`

Theorem 35.35 (Sum ledger raw-visible branch partition)**.** *Let* $Left, Right$: BHist → Prop *be source carriers and let* ρ, v : BHist *be histories. If* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$ *holds, then the same visible branch and payload appear on both ends of the ledger link:*

$$\big(\exists l.\ Left(l) \wedge \mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(v, \mathsf{E0}(l))\big) \vee \big(\exists r.\ Right(r) \wedge \mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(v, \mathsf{E1}(r))\big).$$

In the ten-field fit, the traditional target is disjoint-sum ledger branch readback; the BEDC source is BHist *with* hsame*; the carrier is* SumHistoryCarrier*; no classifier is needed for the direct branch exposure; the ledger is* SumHistoryLedgerPolicy*; exactness is the same raw-visible branch and payload on both endpoints; and the status is* ProofTarget*.*

Proof. Unpack the ledger into the raw SumHistoryCarrier witness and the stored raw-visible $\mathsf{hsame}(\rho, v)$ link. Split the raw carrier. In the left branch, keep the raw payload l and its $Left(l)$ witness, retain the stored raw tag witness $\mathsf{hsame}(\rho, \mathsf{E0}(l))$, and compose symmetry of $\mathsf{hsame}(\rho, v)$ with that raw tag witness to obtain $\mathsf{hsame}(v, \mathsf{E0}(l))$. The right branch uses the same argument with the raw payload r, the $Right(r)$ witness, and the E1 tag. □

Theorem 35.36 (Sum history classifier symmetry under history sameness)**.** *When both component classifiers are* hsame*, the history-level sum classifier is symmetric.*

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier hsame symm`

Proof. Invert the classifier witness. In the left-tagged case, swap the two tagged witnesses and use symmetry of hsame on the left component. The right-tagged case is identical with the right component. □

Theorem 35.37 (Sum history classifier history transport)**.** *If both endpoints of a history-level* $\mathsf{Sum}^{\uparrow}$ *classifier are transported by* hsame*, then the same classifier witness transports to the transported endpoints.*

Proof. Invert the tagged classifier witness. In the left branch, keep the same left component witnesses and compose the reversed endpoint transports with the two stored $e0$-tag witnesses. The right branch is identical using the $e1$-tag witnesses. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier hsame transport`

Theorem 35.38 (Sum history classifier source-certified carrier transport)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, let* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers, and assume source certificates* $\mathsf{NameCert}(Left, LeftEq)$ *and* $\mathsf{NameCert}(Right, RightEq)$*. If* $\mathsf{SumHistoryCarrier}(Left, Right, h)$ *and* $\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k)$ *hold, then* $\mathsf{SumHistoryCarrier}(Left, Right, k)$ *holds.*

Proof. Case-analyze the displayed carrier witness and the tagged classifier witness. Mixed source tags are impossible by BEDC $e0/e1$ no-confusion. In the left-left case, let c be the payload supplied by the carrier witness, and let a, a' be the source payloads supplied by the classifier witness. The carrier branch stores $\mathsf{hsame}(h, \mathsf{E0}(c))$ and $Left(c)$, while the classifier branch stores $\mathsf{hsame}(h, \mathsf{E0}(a))$, $\mathsf{hsame}(k, \mathsf{E0}(a'))$, and $LeftEq(a, a')$. Composing the symmetric carrier endpoint witness with the classifier endpoint witness gives $\mathsf{hsame}(\mathsf{E0}(c), \mathsf{E0}(a))$; $e0$ constructor inversion gives $\mathsf{hsame}(c, a)$. The only source-carrier rewrite in this proof is the checked finite-kernel history-sameness identity target BEDC.FKernel.Hist.hsame_iff_eq recorded at Definition 3.2; it turns the payload witness into kernel equality and transports $Left(c)$ to $Left(a)$. After that kernel transport, NameCert.carrier_respects_equiv applies from the left source certificate along the displayed source classifier $LeftEq(a, a')$ to obtain $Left(a')$, before rebuilding the target left tagged carrier using the stored endpoint witness $\mathsf{hsame}(k, \mathsf{E0}(a'))$. The right-right case is identical with payloads aligned through $e1$ constructor inversion and the right source certificate applied along the displayed source classifier $RightEq$. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier carrier transport from nameCert`

Theorem 35.39 (Sum classifier endpoint readback under source certificates)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, let* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers, let* $h, k : \mathsf{BHist}$*, and assume source certificates* $cert_L : \mathsf{NameCert}(Left, LeftEq)$ *and* $cert_R :$

$\mathsf{NameCert}(Right, RightEq)$. *If* $\mathsf{SumHistoryCarrier}(Left, Right, h)$ *and* $\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, R$
hold, then all of the following assertions hold:

1. $\mathsf{SumHistoryCarrier}(Left, Right, k)$.
2. *The source endpoint h satisfies the visible readback assertion*

$$(\exists l.\ Left(l) \wedge \mathsf{hsame}(h, \mathsf{E0}(l)) \wedge (\forall l'.\ Left(l') \to \mathsf{hsame}(h, \mathsf{E0}(l')) \to \mathsf{hsame}(l, l')) \wedge \neg(\exists r.\ Right(r) \wedge \mathsf{hsame}(h, \mathsf{E}$$
$$\vee$$
$$(\exists r.\ Right(r) \wedge \mathsf{hsame}(h, \mathsf{E1}(r)) \wedge (\forall r'.\ Right(r') \to \mathsf{hsame}(h, \mathsf{E1}(r')) \to \mathsf{hsame}(r, r')) \wedge \neg(\exists l.\ Left(l) \wedge \mathsf{hsame}($$

3. *The target endpoint k satisfies the visible readback assertion*

$$(\exists l.\ Left(l) \wedge \mathsf{hsame}(k, \mathsf{E0}(l)) \wedge (\forall l'.\ Left(l') \to \mathsf{hsame}(k, \mathsf{E0}(l')) \to \mathsf{hsame}(l, l')) \wedge \neg(\exists r.\ Right(r) \wedge \mathsf{hsame}(k, \mathsf{E}$$
$$\vee$$
$$(\exists r.\ Right(r) \wedge \mathsf{hsame}(k, \mathsf{E1}(r)) \wedge (\forall r'.\ Right(r') \to \mathsf{hsame}(k, \mathsf{E1}(r')) \to \mathsf{hsame}(r, r')) \wedge \neg(\exists l.\ Left(l) \wedge \mathsf{hsame}($$

4. *The classifier pair satisfies the visible branch assertion*

$$(\exists a, b.\ Left(a) \wedge Left(b) \wedge \mathsf{hsame}(h, \mathsf{E0}(a)) \wedge \mathsf{hsame}(k, \mathsf{E0}(b)) \wedge LeftEq(a, b))$$
$$\vee$$
$$(\exists a, b.\ Right(a) \wedge Right(b) \wedge \mathsf{hsame}(h, \mathsf{E1}(a)) \wedge \mathsf{hsame}(k, \mathsf{E1}(b)) \wedge RightEq(a, b)).$$

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier source certified endpoint readback`

Proof. First obtain the target carrier. Apply Definition 35.38 to the given source carrier witness, the classifier witness, and the two certificates.

The branch-exactness theorem requires closure of $Left$ and $Right$ under hsame. For $Left$, suppose $Left(x)$ and $\mathsf{hsame}(x, y)$. The checked identity BEDC.FKernel.Hist.hsame_iff_eq turns the history-sameness witness into kernel equality, and transport along that equality gives $Left(y)$. The right closure is identical with $Right$.

Apply Definition 35.80 once to the given carrier witness for h and once to the target carrier witness for k. These are exactly the two displayed endpoint readback assertions.

Finally apply the forward direction of Definition 35.82 with the two closure hypotheses to the triple consisting of the source carrier, the target carrier, and the displayed classifier witness. The forward projection gives the displayed branch assertion, and the four components are conjoined in the listed order. □

Theorem 35.40 (Sum history classifier source-certified symmetry)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, let* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers, and assume source certificates* $\mathsf{NameCert}(Left, LeftEq)$ *and* $\mathsf{NameCert}(Right, RightEq)$. *If* $\mathsf{SumHistoryClassifier}(Left, R$
holds, then $\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, k, h)$ *holds.*

Proof. Invert the tagged classifier witness. In the left branch, swap the two visible $e0$ endpoint witnesses and apply the left source certificate field equiv_symm to the stored $LeftEq$ witness. In the right branch, swap the two visible $e1$ endpoint witnesses and apply the right source certificate field equiv_symm to the stored $RightEq$ witness. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier symm from nameCert`

Theorem 35.41 (Sum history classifier tag separation)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, let* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers, and let* $h, k, l, r : \mathsf{BHist}$*. Then*

$$\mathsf{hsame}(h, \mathsf{E0}(l)) \to \mathsf{hsame}(k, \mathsf{E1}(r)) \to \mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k) \to \bot.$$

Proof. Invert the classifier witness. In the left branch k is also E0-tagged, contradicting the displayed E1 endpoint witness. In the right branch h is E1-tagged, contradicting the displayed E0 endpoint witness. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier mixed tags absurd`

Theorem 35.42 (Sum history classifier reverse tag separation)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, let* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers, and let* $h, k, l, r : \mathsf{BHist}$*. Then*

$$\mathsf{hsame}(h, \mathsf{E1}(r)) \to \mathsf{hsame}(k, \mathsf{E0}(l)) \to \mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k) \to \bot.$$

Proof. Invert the classifier witness. In the left branch, the classifier forces h to be E0-tagged, contradicting the displayed E1 endpoint witness by E0/E1 no-confusion. In the right branch, the classifier forces k to be E1-tagged, contradicting the displayed E0 endpoint witness by E0/E1 no-confusion. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier reverse tag separation`

Theorem 35.43 (Sum history classifier transitivity)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, let* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers, and let* $h, k, u : \mathsf{BHist}$*. Assume*

$$\forall a\, b\, c : \mathsf{BHist}.\ LeftEq(a, b) \to LeftEq(b, c) \to LeftEq(a, c)$$

and

$$\forall a\, b\, c : \mathsf{BHist}.\ RightEq(a, b) \to RightEq(b, c) \to RightEq(a, c).$$

Then

$$\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k) \to \mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, k,$$

Proof. Invert both classifier witnesses. Matching left–left and right–right branches identify the shared tagged middle history by BEDC constructor inversion and compose the corresponding source-classifier witnesses. Mixed branches contradict the $e0/e1$ no-confusion rule. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier trans`

Theorem 35.44 (Sum history classifier source-certified stability fields)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, let* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers, and assume source certificates* $\mathsf{NameCert}(Left, LeftEq)$ *and* $\mathsf{NameCert}(Right, RightEq)$*. For the carrier* $\mathsf{SumHistoryCarrier}(Left, Right)$ *and classifier* $\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq)$*, the following stability fields hold:*

1. *carrier-relative reflexivity:*

$$\forall h.\ \mathsf{SumHistoryCarrier}(Left, Right, h) \to \mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, h);$$

2. *source-certified symmetry:*

$$\forall h\, k.\ \mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k) \to \mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, k, h);$$

3. *source-certified transitivity:*

$$\forall h\, k\, u.\ \mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k) \to \mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, k, u) \to \mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, u);$$

4. *classifier-induced carrier transport:*

$$\forall h\, k.\ \mathsf{SumHistoryCarrier}(Left, Right, h) \to \mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k) \to \mathsf{SumHistoryCarrier}(Left, Right, k).$$

Proof. For reflexivity, invert the displayed sum carrier witness. In the left branch, use the left source certificate reflexivity field on the source payload and rebuild the $e0$-tagged classifier witness with the same endpoint evidence; the right branch is the same with the right source certificate and $e1$ tag. The symmetry field is Theorem 35.40. The transitivity field is Theorem 35.43 applied with the transitivity fields of the two source certificates. The carrier transport field is Theorem 35.38. □

Lean4 ✓ `BEDC.Derived.SumUp.SumUp StdBridge`

Definition 35.45 (Sum stability certificate)**.** *The displayed checked theorem records the typed structural stability subcertificate:*

1. inl *and* inr *reflexivity*
2. *typed classifier transitivity*
3. *mixed* inl/inr *separation in both directions*

Carrier transport, endpoint transport, and history-level transitivity are supplied by Theorems 35.2, 35.37, and 35.43. Theorem 35.36 is the hsame *specialization of classifier symmetry. For the arbitrary source classifiers used by the concrete semantic certificate, Theorem 35.44 packages carrier-relative reflexivity, symmetry, transitivity, and classifier-induced carrier transport from the two source certificates. For the arbitrary source classifiers used by Theorem 35.108, Theorem 35.2 transports only a displayed carrier witness along* hsame.

Lean4 ✓ `BEDC.Derived.SumUp.sum stability certificate fields`

Theorem 35.46 (Sum classifier transitivity at the typed level)**.** *Let* $R_A : A \to A \to \mathsf{Prop}$ *and* $R_B : B \to B \to \mathsf{Prop}$ *be source classifier relations. If both* R_A *and* R_B *are transitive, then for sum carriers* x*,* y*, and* z*,*

$$\mathsf{SumClassifierSpec}(R_A, R_B, x, y) \quad \textit{and} \quad \mathsf{SumClassifierSpec}(R_A, R_B, y, z)$$

imply $\mathsf{SumClassifierSpec}(R_A, R_B, x, z)$*.*

Lean4 ✓ `BEDC.Derived.SumUp.SumClassifierSpec trans`

Proof. Invert the sum classifier witnesses by their constructors. Matching left and right branches compose through the corresponding source transitivity assumption, while mixed tags are impossible by the classifier clauses. □

Definition 35.47 (Sum ledger policy)**.** *Record a raw sum history carrying the selected injection tag and source ledger together with an* hsame *link to the visible history exposed by the ledger.*

Lean4 (definition) `BEDC.Derived.SumUp.SumHistoryLedgerPolicy`

Theorem 35.48 (Sum ledger visible carrier)**.** *If a visible history is linked by* hsame *to a raw sum-ledger history, then the visible history is itself a sum carrier.*

Proof. Unpack the raw sum carrier and transport it across the stored hsame link by sum-carrier transport. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy visible carrier`

Theorem 35.49 (Sum ledger raw-visible classifier)**.** *If* $\mathsf{SumHistoryLedgerPolicy}(L, R, \rho, v)$ *holds, then* $\mathsf{SumHistoryClassifier}(L, R, \mathsf{hsame}, \mathsf{hsame}, \rho, v)$ *holds.*

Proof. Unpack the ledger into its raw sum carrier and the stored $\mathsf{hsame}(\rho, v)$ link. The raw carrier determines whether ρ is left-tagged or right-tagged; transport the tag witness across the stored link and use reflexivity of hsame on the selected component to build the matching classifier branch. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy raw visible classifier`

Theorem 35.50 (Sum ledger history-same transport)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $raw, raw', visible, visible' : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, raw, visible)$ $\mathsf{hsame}(raw, raw')$*, and* $\mathsf{hsame}(visible, visible')$ *hold, then*

$$\mathsf{SumHistoryLedgerPolicy}(Left, Right, raw', visible')$$

holds.

Proof. Unpack the ledger into the raw SumHistoryCarrier witness and the stored link $\mathsf{hsame}(raw, visible)$. Transport the raw carrier along $\mathsf{hsame}(raw, raw')$ by Theorem 35.2. For the raw-visible link of the transported ledger, compose symmetry of $\mathsf{hsame}(raw, raw')$, the stored $\mathsf{hsame}(raw, visible)$ link, and $\mathsf{hsame}(visible, visible')$ to obtain $\mathsf{hsame}(raw', visible')$. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy hsame transport`

Theorem 35.51 (Sum ledger classifier composition)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, v, w : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$ *holds and* $\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, v, w)$ *holds, then*

$$\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, \rho, w)$$

holds.

Proof. First apply the raw-visible classifier theorem to the ledger policy, obtaining

$$\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, \rho, v).$$

Then compose this classifier witness with the given visible-target classifier witness using sum-history classifier transitivity. The branch classifiers are both hsame, so their required transitivity inputs are the left and right instances of BEDC history equality transitivity. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy classifier composition`

Theorem 35.52 (Sum ledger two-step classifier composition)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, v, w : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$ *and* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, v, w)$ *hold, then*

$$\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, \rho, w)$$

holds. The roadmap fit is: traditional target disjoint-sum ledger-chain closure; BEDC source BHist *with tagged sum carrier; carrier* SumHistoryCarrier*; classifier* SumHistoryClassifier$(Left, Right, \mathsf{hsame}, \mathsf{hsame})$*; stability by two raw-visible ledger exposures and classifier transitivity; ledger two composable* SumHistoryLedgerPolicy *witnesses; core theorem this closure; exactness raw-to-middle-to-visible; standard bridge tagged sum ledger chain; status* ProofTarget*.*

Proof. Apply Theorem 35.89 to the two ledger witnesses, obtaining classifiers from ρ to v and from v to w. Compose them by Theorem 35.43; the branch classifiers are both hsame, so the required transitivity inputs are the left and right instances of BEDC history equality transitivity. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy two step classifier composition`

Theorem 35.53 (Sum ledger raw-visible branch exactness)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $raw, visible : \mathsf{BHist}$ *be histories. Then*

$$\mathsf{SumHistoryLedgerPolicy}(Left, Right, raw, visible) \iff (\exists l : \mathsf{BHist}.\ Left(l) \wedge \mathsf{hsame}(raw, \mathsf{E0}(l)) \wedge \mathsf{hsame}(visible, \mathsf{E0}(l$$

Proof. For the forward direction, unpack the ledger into its raw sum carrier and the stored raw-visible link. Split the raw carrier branch.

In the left branch, the carrier supplies $Left(l)$ and $\mathsf{hsame}(raw, \mathsf{E0}(l))$. Compose symmetry of the stored raw-visible link with this raw endpoint witness to obtain $\mathsf{hsame}(visible, \mathsf{E0}(l))$, and assemble the left disjunct.

In the right branch, the same argument uses the witness $Right(r)$ and $\mathsf{hsame}(raw, \mathsf{E1}(r))$ to obtain $\mathsf{hsame}(visible, \mathsf{E1}(r))$ and assemble the right disjunct.

For the reverse direction, split the displayed branch evidence. In the left branch, rebuild the raw sum carrier from $Left(l)$ and $\mathsf{hsame}(raw, \mathsf{E0}(l))$. Compose $\mathsf{hsame}(raw, \mathsf{E0}(l))$ with symmetry of $\mathsf{hsame}(visible, \mathsf{E0}(l))$ to recover the raw-visible ledger link.

The right branch is identical, rebuilding the raw carrier from $Right(r)$ and $\mathsf{hsame}(raw, \mathsf{E1}(r))$, then composing the two endpoint witnesses to recover the stored raw-visible link. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy raw visible branch exactness`

Theorem 35.54 (Sum ledger two-step branch exactness)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, v, w : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$ *and* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, v, w)$ *hold, then the whole two-step chain has a visible same-branch payload readback:*

$$(\exists l\, l' : \mathsf{BHist}.\ Left(l) \wedge Left(l') \wedge \mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(w, \mathsf{E0}(l')) \wedge \mathsf{hsame}(l, l')) \vee (\exists r\, r' : \mathsf{BHist}.\ Right(r) \wedge Right(r')$$

The ten-field fit is: traditional target disjoint-sum ledger-chain readback; BEDC source BHist *with* hsame*; carrier* SumHistoryCarrier*; classifier unused in the final exactness statement but supplied by Theorem 35.92; ledger two composable* SumHistoryLedgerPolicy *witnesses; core theorem this branch exactness statement; exactness raw-to-visible same-branch payload readback; standard bridge tagged sum ledger chains; status* ProofTarget*.*

Proof. Apply Theorem 35.93 to each ledger witness. The first application exposes either a left payload visible at ρ and v, or a right payload visible at ρ and v; the second exposes the corresponding alternatives at v and w. Split the four branch cases. In the left-left case, use Theorem 35.79 at the shared middle endpoint v to identify the two left payloads and assemble the left disjunct. The right-right case is identical with the right branch. The mixed left-right and right-left cases contradict generated-history no-confusion between $\mathsf{E0}$ and $\mathsf{E1}$ at the shared middle endpoint v. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy two step branch exactness`

Theorem 35.55 (Sum ledger two-step endpoint exactness)**.** *Let $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ be source carriers and let $\rho, v, w, l, l', r, r' : \mathsf{BHist}$ be histories. If $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$ and $\mathsf{SumHistoryLedgerPolicy}(Left, Right, v, w)$ hold, then the two-ledger chain has endpoint exactness from ρ to w. First, both mixed endpoint pairs are impossible:*

$$(\mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(w, \mathsf{E1}(r'))) \to \bot$$

and

$$(\mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(w, \mathsf{E0}(l'))) \to \bot.$$

Second, same-tag endpoint pairs determine their payloads:

$$(\mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(w, \mathsf{E0}(l'))) \to \mathsf{hsame}(l, l')$$

and

$$(\mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(w, \mathsf{E1}(r'))) \to \mathsf{hsame}(r, r').$$

Third, final visible endpoints of w read back source payload evidence:

$$(\mathsf{hsame}(w, \mathsf{E0}(l')) \to \exists a : \mathsf{BHist}.\ Left(a) \wedge \mathsf{hsame}(l', a))$$

and

$$(\mathsf{hsame}(w, \mathsf{E1}(r')) \to \exists b : \mathsf{BHist}.\ Right(b) \wedge \mathsf{hsame}(r', b)).$$

Proof. Apply Theorem 35.92 to the two ledger witnesses and obtain $\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame},$ The two mixed endpoint conclusions follow from Theorem 35.41; for the reversed displayed order, use classifier symmetry from Theorem 35.36 before applying the same tag-separation theorem. The left same-tag conclusion is exactly the left endpoint inversion supplied by Theorem 35.13, and the right same-tag conclusion is the corresponding right inversion from Theorem 35.14. For the final visible readback, apply Theorem 35.88 to the second ledger witness, obtaining a visible carrier for w; then apply Theorem 35.7 to the displayed $\mathsf{E0}$ or $\mathsf{E1}$ endpoint of w to extract the matching source payload evidence. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy two step endpoint exactness`

Definition 35.56 (Sum ledger finite provenance chain)**.** *For source carriers $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$, define $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$ as the finite provenance relation generated by the following two clauses. A displayed one-ledger witness $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, z)$ gives $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$. If there is a history $v : \mathsf{BHist}$ such that $\mathsf{SumHistoryLedgerPolicy}(Left, R$ and $\mathsf{SumHistoryLedgerChain}_{Left,Right}(v, z)$ hold, then $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$ also holds.*

Lean4 (definition) `BEDC.Derived.SumUp.SumHistoryLedgerChain`

Theorem 35.57 (Sum ledger chain transitivity)**.** *Let* $Left, Right$: BHist → Prop *be source carriers and let* ρ, m, z : BHist *be histories. If* $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, m)$ *and* $\mathsf{SumHistoryLedgerChain}_{Left,Righ}$ *hold, then* $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$ *holds. The ten-field fit is: traditional target finite tagged-sum ledger provenance composition; BEDC source* BHist *with tagged sum carrier; carrier* SumHistoryCarrier*; classifier supplied downstream by Theorem 35.98; ledger* $\mathsf{SumHistoryLedgerChain}_{Left,Right}$*; core theorem finite-chain composition; exactness concatenated raw-to-visible provenance; standard bridge tagged sum ledger audit composition; status* ProofTarget*.*

Proof. Induct on the first displayed $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, m)$ witness.

In the one-ledger case, the displayed $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, m)$ is the first finite ledger step. Rebuild the target chain by the cons constructor, using that ledger step as the head and the second displayed chain from m to z as the tail.

In the cons case, the first chain consists of a head ledger from ρ to an intermediate history and a tail chain from that intermediate history to m. Apply the induction hypothesis to compose the tail chain with the second displayed chain from m to z, then rebuild the full chain by the cons constructor with the original head ledger. □

Theorem 35.58 (Sum ledger chain classifier composition)**.** *Let* $Left, Right$: BHist → Prop *be source carriers and let* $raw, visible$: BHist *be histories. If* $\mathsf{SumHistoryLedgerChain}_{Left,Right}(raw, visible)$ *holds, then*

$$\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, raw, visible)$$

holds. The ten-field fit is: traditional target disjoint-sum finite ledger classifier closure; BEDC source BHist *with* hsame*; source carriers* $Left$ *and* $Right$*; carrier* SumHistoryCarrier*; classifier* $\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame})$*; stability by raw-visible classification plus classifier transitivity; ledger* $\mathsf{SumHistoryLedgerChain}_{Left,Right}$*; core theorem this finite-chain classifier closure; exactness finite raw-to-visible classifier reachability; standard bridge tagged sum finite ledger provenance; status* ProofTarget*.*

Proof. Induct on the displayed $\mathsf{SumHistoryLedgerChain}_{Left,Right}(raw, visible)$ witness. In the one-ledger case, apply Theorem 35.89. In the cons case, apply the induction hypothesis to the tail chain to obtain the classifier from the middle history to *visible*, then compose it with the first ledger by Theorem 35.91. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerChain classifier composition`

Theorem 35.59 (Sum ledger chain visible carrier)**.** *Let* $Left, Right$: BHist → Prop *be source carriers and let* ρ, z : BHist *be histories. If* $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$ *holds, then*

$$\mathsf{SumHistoryCarrier}(Left, Right, z)$$

holds. The ten-field fit is: traditional target disjoint-sum finite ledger visible-carrier closure; BEDC source BHist *with* hsame*; source carriers* $Left$ *and* $Right$*; carrier* SumHistoryCarrier*; classifier not needed for this unary closure; ledger* $\mathsf{SumHistoryLedgerChain}_{Left,Right}$*; core theorem this carrier closure; exactness final visible endpoint remains in the sum carrier; standard bridge tagged sum finite ledger provenance; status* ProofTarget*.*

Proof. Induct on the displayed $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$ witness. In the one-ledger case, apply Theorem 35.88. In the cons case, use the carrier supplied by the tail induction hypothesis. □

Theorem 35.60 (Sum ledger chain endpoint exactness)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, z, l, l', r, r' : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$ *holds, then the whole finite ledger provenance from* ρ *to* z *has endpoint exactness. First, both mixed endpoint pairs are impossible:*

$$(\mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(z, \mathsf{E1}(r'))) \to \bot$$

and

$$(\mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(z, \mathsf{E0}(l'))) \to \bot.$$

Second, same-tag endpoint pairs determine their payloads:

$$(\mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(z, \mathsf{E0}(l'))) \to \mathsf{hsame}(l, l')$$

and

$$(\mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(z, \mathsf{E1}(r'))) \to \mathsf{hsame}(r, r').$$

Third, final visible endpoints of z *read back matching source payload evidence:*

$$(\mathsf{hsame}(z, \mathsf{E0}(l')) \to \exists a : \mathsf{BHist}.\ Left(a) \wedge \mathsf{hsame}(l', a))$$

and

$$(\mathsf{hsame}(z, \mathsf{E1}(r')) \to \exists b : \mathsf{BHist}.\ Right(b) \wedge \mathsf{hsame}(r', b)).$$

The ten-field fit is: traditional target disjoint-sum finite ledger provenance; BEDC source BHist *with* hsame*; source carriers* $Left$ *and* $Right$*; carrier* SumHistoryCarrier*; classifier* SumHistoryClassifier$(Left, Right,$ hsame *supplied one ledger at a time by raw-visible classification; ledger* $\mathsf{SumHistoryLedgerChain}_{Left,Right}$ *generated by* SumHistoryLedgerPolicy*; core theorem this chain endpoint exactness package; exactness mixed-tag separation, same-tag payload determinacy, and final visible source readback; standard bridge tagged sum finite ledger provenance; status* ProofTarget*.*

Proof. First apply Theorem 35.98 to the displayed chain, obtaining SumHistoryClassifier$(Left, Right,$ hsame, hsame, The two mixed endpoint clauses follow from Theorem 35.41; for the reversed displayed order, first use classifier symmetry from Theorem 35.36. The same-tag endpoint clauses follow by transporting the classifier along the displayed endpoint hsame links and applying Theorem 35.13 or Theorem 35.14. For the final visible readback, apply Theorem 35.99 to the displayed chain to obtain SumHistoryCarrier$(Left, Right, z)$. Transport this carrier along the displayed hsame endpoint at z and apply the left or right carrier inversion theorem to extract the matching source payload evidence. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerChain endpoint exactness`

Theorem 35.61 (Sum ledger chain branch readback soundness)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, z : \mathsf{BHist}$ *be histories. The finite ledger-chain relation forces exact same-branch payload readback:*

$$\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z) \to (\exists l\, l' : \mathsf{BHist}.\ Left(l) \wedge Left(l') \wedge \mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(z, \mathsf{E0}(l')) \wedge \mathsf{hsame}(l$$

The ten-field fit is: traditional target disjoint-sum finite ledger branch readback; BEDC source BHist *with* hsame*; source carriers* $Left$ *and* $Right$*; carrier* SumHistoryCarrier*; classifier supplied by Theorem 35.98; ledger* $\mathsf{SumHistoryLedgerChain}_{Left,Right}$*; core theorem this branch readback soundness; finite ledger-chain witnesses map into same-branch payload readback; standard bridge tagged sum finite ledger provenance; status* ProofTarget*.*

Proof. Induct on the displayed $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$ witness. In the one-ledger case, apply Theorem 35.93 and choose the same payload at the raw and visible endpoints, with hsame reflexivity for the payload link.

In the cons case, combine the raw-visible branch exactness of the first ledger with the induction hypothesis for the tail chain. The mixed left-right and right-left cases contradict generated-history no-confusion between E0 and E1 at the shared middle endpoint. In the same-branch cases, use Theorem 35.79 at the middle endpoint and hsame transitivity to compose the first payload with the final payload. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerChain branch exactness`

Theorem 35.62 (Sum ledger chain branch exactness)**.** *Let $Left, Right$: BHist → Prop be source carriers and let ρ, z : BHist be histories. The finite ledger-chain relation is equivalent to exact same-branch payload readback:*

$$\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z) \iff (\exists l\, l' : \mathsf{BHist}.\ Left(l) \wedge Left(l') \wedge \mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(z, \mathsf{E0}(l')) \wedge \mathsf{hsame}$$

The ten-field fit is: traditional target disjoint-sum finite ledger branch readback; BEDC source BHist *with* hsame*; source carriers $Left$ and $Right$; carrier* SumHistoryCarrier*; classifier supplied by Theorem 35.98; ledger* $\mathsf{SumHistoryLedgerChain}_{Left,Right}$*; core theorem this branch exactness; exactness coverage and completeness of the finite ledger-chain relation by same-branch payload readback; standard bridge tagged sum finite ledger provenance; status* ProofTarget*.*

Proof. For the forward direction, apply Theorem 35.101.

For the reverse direction, split the displayed disjunction. In the left branch, the witnesses $Left(l)$, $\mathsf{hsame}(\rho, \mathsf{E0}(l))$, $\mathsf{hsame}(z, \mathsf{E0}(l'))$, and $\mathsf{hsame}(l, l')$ determine a one-ledger left readback. Use symmetry of $\mathsf{hsame}(l, l')$ and constructor congruence for E0 to transport $\mathsf{hsame}(z, \mathsf{E0}(l'))$ into $\mathsf{hsame}(z, \mathsf{E0}(l))$.

Apply the reverse direction of Theorem 35.93 to obtain $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, z)$, then use the one-ledger constructor of $\mathsf{SumHistoryLedgerChain}_{Left,Right}$.

The right branch is identical, using the witnesses $Right(r)$, $\mathsf{hsame}(\rho, \mathsf{E1}(r))$, $\mathsf{hsame}(z, \mathsf{E1}(r'))$, and $\mathsf{hsame}(r, r')$, with constructor congruence for E1 before applying the same raw-visible branch exactness theorem and the one-ledger chain constructor. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerChain branch exactness iff`

Theorem 35.63 (Sum ledger chain raw branch forces final branch readback)**.** *Let $Left, Right$: BHist → Prop be source carriers and let ρ, z, l, r : BHist be histories. If* $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$ *holds, then raw visible branch evidence forces the matching final visible branch. The left clause is*

$$Left(l) \to \mathsf{hsame}(\rho, \mathsf{E0}(l)) \to \exists l' : \mathsf{BHist}.\ Left(l') \wedge \mathsf{hsame}(z, \mathsf{E0}(l')) \wedge \mathsf{hsame}(l, l') \wedge \neg(\exists r' : \mathsf{BHist}.\ Right(r') \wedge \mathsf{hsa}$$

and the right clause is

$$Right(r) \to \mathsf{hsame}(\rho, \mathsf{E1}(r)) \to \exists r' : \mathsf{BHist}.\ Right(r') \wedge \mathsf{hsame}(z, \mathsf{E1}(r')) \wedge \mathsf{hsame}(r, r') \wedge \neg(\exists l' : \mathsf{BHist}.\ Left(l') \wedge \mathsf{h}$$

The ten-field fit is: traditional target disjoint-sum finite ledger branch forcing; BEDC source BHist *with* hsame*; carrier final* SumHistoryCarrier*; classifier supplied by the chain classifier composition theorem; ledger* $\mathsf{SumHistoryLedgerChain}_{Left,Right}$*; core theorem this raw-branch forcing readback; exactness same-tag payload determinacy plus mixed-tag exclusion; standard bridge tagged sum finite ledger provenance; status* ProofTarget*.*

Proof. Apply Theorem 35.99 to the chain and then Theorem 35.80 to the final carrier. This splits the endpoint z into a left visible presentation with right-presentation exclusion, or a right visible presentation with left-presentation exclusion.

For the left raw premise, keep the left final presentation from the split. The same-tag payload clause of Theorem 35.100, applied to $\mathsf{hsame}(\rho, \mathsf{E0}(l))$ and the displayed $\mathsf{hsame}(z, \mathsf{E0}(l'))$, gives $\mathsf{hsame}(l, l')$; combine it with the source witness for l' and the carried right-presentation exclusion.

The right final presentation cannot occur under the left raw premise, because the mixed endpoint clause of Theorem 35.100 contradicts $\mathsf{hsame}(\rho, \mathsf{E0}(l))$ and $\mathsf{hsame}(z, \mathsf{E1}(r'))$. The right raw premise is symmetric: the right final presentation supplies the witness and the left-presentation exclusion, while the mixed endpoint clause excludes any left final presentation. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerChain raw branch final readback`

Theorem 35.64 (Sum ledger preserves visible tag separation)**.** *Let $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ be source carriers and let $\rho, v, l, r : \mathsf{BHist}$ be histories. If $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$ holds, then both visible mixed-tag endpoint pairs are impossible:*

$$(\mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(v, \mathsf{E1}(r))) \to \bot$$

and

$$(\mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(v, \mathsf{E0}(l))) \to \bot.$$

Proof. Apply Theorem 35.89 to the ledger policy to obtain $\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, \rho, v)$. The left-to-right mixed endpoint pair is then discharged by $\mathsf{SumHistoryClassifier_mixed_tags_absurd}$ with the displayed $\mathsf{hsame}(\rho, \mathsf{E0}(l))$ and $\mathsf{hsame}(v, \mathsf{E1}(r))$ witnesses. For the symmetric right-to-left pair, use classifier symmetry from Theorem 35.36 and apply the same mixed-tag separation theorem to the exchanged endpoints. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy visible tag separation`

Theorem 35.65 (Sum ledger same-tag payload exactness)**.** *Let $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ be source carriers and let $\rho, v, l, l', r, r' : \mathsf{BHist}$ be histories. If $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$ holds, then the visible same-tag endpoint pairs determine their payloads:*

$$(\mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(v, \mathsf{E0}(l'))) \to \mathsf{hsame}(l, l')$$

and

$$(\mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(v, \mathsf{E1}(r'))) \to \mathsf{hsame}(r, r').$$

Proof. Apply Theorem 35.89 to obtain the raw-visible $\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, \rho, v)$ witness. For the left-tagged endpoint pair, transport this witness along the displayed $\mathsf{hsame}(\rho, \mathsf{E0}(l))$ and $\mathsf{hsame}(v, \mathsf{E0}(l'))$ links by Theorem 35.37, then apply the left inversion Theorem 35.13 to extract $\mathsf{hsame}(l, l')$. The right-tagged case is identical with Theorem 35.14. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy same tag payload exactness`

Theorem 35.66 (Sum ledger visible payload readback)**.** *Let $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ be source carriers and let $\rho, v, l, r : \mathsf{BHist}$ be histories. If $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$ holds, then visible tagged endpoints read back source payload evidence:*

$$(\mathsf{hsame}(v, \mathsf{E0}(l)) \to \exists a : \mathsf{BHist}.\ Left(a) \wedge \mathsf{hsame}(l, a))$$

and

$$(\mathsf{hsame}(v, \mathsf{E1}(r)) \to \exists b : \mathsf{BHist}.\ Right(b) \wedge \mathsf{hsame}(r, b)).$$

Proof. The traditional target is disjoint-sum ledger readback; the BEDC source is BHist; the carrier is SumHistoryCarrier; no classifier is needed for this carrier-readback obligation; the ledger is SumHistoryLedgerPolicy; the exactness principle is visible-tag carrier readback; the status is ProofTarget. Apply Theorem 35.88 to the ledger, transport the visible carrier witness along the displayed $\mathsf{hsame}(v, \mathsf{E0}(l))$ or $\mathsf{hsame}(v, \mathsf{E1}(r))$ endpoint equality, and then apply Theorem 35.7 to extract the left or right source payload witness. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy visible payload readback`

Theorem 35.67 (Sum ledger one-step endpoint exactness)**.** *Let $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ be source carriers and let $\rho, v, l, l', r, r' : \mathsf{BHist}$ be histories. If $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$ holds, then the one-ledger link has endpoint exactness from ρ to v. First, both mixed endpoint pairs are impossible:*

$$(\mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(v, \mathsf{E1}(r'))) \to \bot$$

and

$$(\mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(v, \mathsf{E0}(l'))) \to \bot.$$

Second, same-tag endpoint pairs determine their payloads:

$$(\mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(v, \mathsf{E0}(l'))) \to \mathsf{hsame}(l, l')$$

and

$$(\mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(v, \mathsf{E1}(r'))) \to \mathsf{hsame}(r, r').$$

Third, final visible endpoints read back source payload evidence:

$$(\mathsf{hsame}(v, \mathsf{E0}(l')) \to \exists a : \mathsf{BHist}.\ Left(a) \wedge \mathsf{hsame}(l', a))$$

and

$$(\mathsf{hsame}(v, \mathsf{E1}(r')) \to \exists b : \mathsf{BHist}.\ Right(b) \wedge \mathsf{hsame}(r', b)).$$

The roadmap ten-field fit is: traditional target disjoint-sum one-ledger endpoint audit; BEDC source BHist *with* hsame*; source carriers $Left$ and $Right$; carrier* SumHistoryCarrier*; classifier* $\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame})$*; ledger* SumHistoryLedgerPolicy*; core theorem this endpoint exactness package; exactness raw-to-visible tag separation, same-tag payload determinacy, and visible source readback; standard bridge tagged sum ledger readback; status* ProofTarget*.*

Proof. Apply Theorem 35.104 to the ledger witness for the two mixed clauses. Apply Theorem 35.105 to the same ledger witness for the two same-tag payload clauses. Apply Theorem 35.106 to the ledger witness for the two final visible readback clauses. □

Theorem 35.68 (Concrete $\mathsf{Sum}^{\uparrow}$ semantic name certificate)**.** *Let $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ be source carriers with classifiers $LeftEq$ and $RightEq$. If $\mathsf{NameCert}(Left, LeftEq)$ and $\mathsf{NameCert}(Right, RightEq)$ are supplied, then the tagged sum carrier, the tagged sum classifier, and the carrier-as-pattern and carrier-as-ledger tuple form*

$$\begin{aligned}
&\mathsf{SemanticNameCert}(\\
&\quad \mathsf{SumHistoryCarrier}(Left, Right),\\
&\quad \mathsf{SumHistoryCarrier}(Left, Right),\\
&\quad \mathsf{SumHistoryCarrier}(Left, Right),\\
&\quad \mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq)).
\end{aligned}$$

Proof. The carrier is represented by $e0$-tagged left histories and $e1$-tagged right histories. Theorem 35.11 marks the split: the classifier delegates within matching tags to the corresponding source certificate, while source-carrier evidence is taken from SumHistoryCarrier when certificate fields require it. Reflexivity is built by tagging the source certificate reflexivity field on the selected component. Symmetry and transitivity invert the tagged classifier witnesses, use the matching source certificate fields inside a left–left or right–right branch, and discharge mixed tags by constructor no-confusion.

The core certificate fields are assembled from Theorem 35.44. That theorem supplies carrier-relative reflexivity, source-certified symmetry, source-certified transitivity, and classifier-induced carrier transport for the tagged carrier and tagged classifier. The inhabited field is separate: take the inhabited witness l from the left source certificate, choose the visible endpoint $\mathsf{E0}(l)$, and rebuild $\mathsf{SumHistoryCarrier}(Left, Right, \mathsf{E0}(l))$ by the left tagged constructor with the reflexive endpoint witness and the stored $Left(l)$ evidence.

Inside the carrier-transport field supplied by the cited theorem, source-carrier membership is not transported along an arbitrary source NameCert merely from $\mathsf{hsame}(l, a)$. In the left branch, constructor inversion first aligns the tagged payloads and obtains $\mathsf{hsame}(l, a)$; the checked finite-kernel identity BEDC.FKernel.Hist.hsame_iff_eq converts that history-sameness witness to kernel equality before the stored $Left(l)$ evidence is rewritten as $Left(a)$. Only after this equality rewrite does NameCert.*carrier_respects_equiv* from the left source certificate apply along the displayed source classifier witness $LeftEq(a, b)$, yielding $Left(b)$ and hence the target left tagged carrier. The right branch is the same with $RightEq(a, b)$ and the right source certificate. Pattern soundness and ledger soundness are identity implications, since both semantic fields are the same predicate $\mathsf{SumHistoryCarrier}(Left, Right)$. □

Lean4 ✓ `BEDC.Derived.SumUp.sum history semantic name certificate`

Corollary 35.69 ($\mathsf{Sum}^{\uparrow}$ is licensed, not primitive)**.** $\mathsf{Sum}^{\uparrow}$ *is licensed as a derived disjoint sum, not as a primitive coproduct.*

Theorem 35.70 (Sum public tagged-payload standard bridge)**.** *For source carriers* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *equipped with source classifiers and source* NameCert *rows, the public* $\mathsf{Sum}^{\uparrow}$ *semantic certificate presents exactly the standard finite disjoint-sum interface with two visible injections. A public endpoint is either an* E0*-tagged left payload or an* E1*-tagged right payload. Endpoints with the same tag compare by the corresponding source classifier, and endpoints with mixed tags are separated by constructor no-confusion.*

The exported ledger surface is precisely the visible tag, payload readback, raw-visible branch exactness, and endpoint exactness already recorded by the $\mathsf{Sum}^{\uparrow}$ *rows. No consumer receives an additional coproduct eliminator, hidden branch coordinate, host disjoint-union type, or classifier other than the branchwise tagged classifier.*

Lean4 ✓ `BEDC.Derived.SumUp.SumUp concrete to schema`

Proof. The public certificate is the one supplied by Definition 35.108. Its carrier consists of histories built by the two visible constructors, so constructor inversion gives the two alternatives $\mathsf{E0}(l)$ and $\mathsf{E1}(r)$ and gives no third endpoint form.

Within a left–left comparison, the tagged classifier in Definition 35.108 projects to the left source classifier; within a right–right comparison, it projects to the right source classifier. The branch exactness statement in Definition 35.93 identifies those projections with the raw visible branch rows exported by the ledger.

For mixed tags, Definition 35.104 applies to the visible ledger row and reduces equality or classifier compatibility of opposite tags to constructor no-confusion. Thus a left endpoint and a right endpoint remain separated in the public reading.

Finally, Definition 35.106 recovers the displayed source payload from each visible endpoint, and Definition 35.100 states that the endpoint readback is exact along the public chain. These rows are exactly the finite two-injection interface described above, so the tagged-payload certificate is a paper bridge to the standard disjoint-sum reading. □

Theorem 35.71 (Sum mature finite consumer boundary)**.** *Every finite consumer of the public* $\mathsf{Sum}^{\uparrow}$ *package factors through the tagged payload carrier, visible tag separation, branch exactness, payload readback, endpoint chain exactness, and the public tagged-payload standard bridge. Such a consumer can inspect only whether the exposed endpoint is an* $\mathsf{E0}$*-tagged left payload or an* $\mathsf{E1}$*-tagged right payload, can read the corresponding source evidence through the ledger rows, and can compare same-tag payloads only through the branch classifier exactness already exported by the certificate.*

This finite boundary excludes eliminators into arbitrary certified targets, dependent sums, and categorical coproduct universal properties. Those structures are not consequences of the tagged-payload package surface; they require additional consumer principles beyond the public $\mathsf{Sum}^{\uparrow}$ *certificate.*

Proof. Start with the public tagged-payload bridge in Theorem 35.110. It identifies the public surface with the two visible injections and rules out any hidden carrier coordinate outside the tagged history endpoint.

The finite consumer's branch observation is then forced by Theorem 35.104; mixed visible tags cannot be read as the same public branch. Same-branch comparisons are governed by Theorem 35.93, which is the raw-visible branch exactness row for the ledger.

Payload access is supplied by Theorem 35.106. Chain-level endpoint soundness is supplied by Theorem 35.100, so repeated finite ledger reads still factor through the same tagged endpoint and its source payload evidence.

Combining these rows leaves exactly the finite tagged-payload consumer surface. Since none of the cited rows constructs an arbitrary-target eliminator, dependent sum, or coproduct universal arrow, those stronger interfaces remain outside the mature finite boundary stated here. □

Theorem 35.72 (Sum finite-data scoped-exit package)**.** *The scoped finite-data exit surface of* $\mathsf{Sum}^{\uparrow}$ *is exactly the package consisting of the tagged semantic certificate of Definition 35.108, the selected visible injection tag, left and right branch exactness, the source ledger rows, visible-history descent through endpoint readback, and the mature finite consumer boundary of Definition 35.111. The selected injection tag is the two-branch finite-choice row already licensed by chapter 32;* $\mathsf{Sum}^{\uparrow}$ *consumes that sibling only as visible tag discipline, while the left and right payload rows remain governed by the local sum carrier and classifier. A consumer exiting the* $\mathsf{Sum}^{\uparrow}$ *chapter through this surface may inspect the selected tag, recover the corresponding source payload and source ledger evidence, compare same-tag endpoints through the displayed branch classifier, and replay the visible history descent. It receives no hidden coproduct eliminator, no dependent target recursion, and no classifier beyond the tagged finite-data rows already exported by the semantic certificate.*

Proof. Start with the semantic certificate in Definition 35.108. Its carrier is the tagged finite packet, so each public endpoint enters through an $\mathsf{E0}$ or $\mathsf{E1}$ injection rather than through a host coproduct object.

The selected tag is governed by Definition 35.104. The $\mathsf{Bool}^{\uparrow}$ reference supplies only the finite $b0/b1$ tag reading for this visible branch choice; it does not introduce a host coproduct, an eliminator, or an external Boolean equality. The same-tag clauses are governed by Definition 35.93, while visible payload recovery is governed by Definition 35.106 and endpoint descent by Definition 35.100.

Finally apply the consumer boundary in Definition 35.111. It states that every finite consumer factors through exactly these tagged payload, branch exactness, source ledger, and visible-history rows. Therefore the package is a scoped exit surface for finite data rather than a generic coproduct interface. □

Theorem 35.73 (Sum classifier transitivity at the typed level)**.** *Let $R_A : A \to A \to \mathsf{Prop}$ and $R_B : B \to B \to \mathsf{Prop}$ be source classifier relations. If both R_A and R_B are transitive, then for sum carriers x, y, and z,*

$$\mathsf{SumClassifierSpec}(R_A, R_B, x, y) \quad \textit{and} \quad \mathsf{SumClassifierSpec}(R_A, R_B, y, z)$$

imply $\mathsf{SumClassifierSpec}(R_A, R_B, x, z)$.

Lean4 ✓ `BEDC.Derived.SumUp.SumClassifierSpec trans`

Proof. Invert the sum classifier witnesses by their constructors. Matching left and right branches compose through the corresponding source transitivity assumption, while mixed tags are impossible by the classifier clauses. □

Theorem 35.74 (Sum history classifier branch partition)**.** *For branch carriers $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$, branch classifiers $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$, and histories h, k, the history-level sum classifier exposes the visible left-or-right constructor analysis:*

$$\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k) \to (\exists l, l'.\ \mathsf{hsame}(h, \mathsf{E0}(l)) \wedge \mathsf{hsame}(k, \mathsf{E0}(l')) \wedge LeftEq(l, l')$$

In the ten-field fit, the traditional target is disjoint-sum branch readback, the BEDC source is BHist*, the classifier is* $\mathsf{SumHistoryClassifier}$*, the ledger records the visible tag plus payload, and the status is* $\mathsf{ProofTarget}$.

Proof. Case-analyze the classifier witness. The left constructor supplies the two $\mathsf{E0}$ endpoint links and the stored $LeftEq$ payload relation, yielding the left disjunct. The right constructor supplies the two $\mathsf{E1}$ endpoint links and the stored $RightEq$ payload relation, yielding the right disjunct. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier branch partition`

Theorem 35.75 (Sum history classifier branch exactness)**.** *For branch carriers $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$, branch classifiers $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$, and histories h, k, the history-level sum classifier is exactly the visible left-or-right branch disjunction:*

$$\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k) \iff (\exists l, l'.\ \mathsf{hsame}(h, \mathsf{E0}(l)) \wedge \mathsf{hsame}(k, \mathsf{E0}(l')) \wedge LeftEq(l, l$$

In the ten-field fit, the exactness target records that classifier witnesses and visible same-branch endpoint data determine each other.

Proof. For the forward direction, apply Theorem 35.74. It case-analyzes the classifier witness and returns the displayed left-or-right branch data.

For the reverse direction, split the displayed disjunction. In the left branch, unpack l, l' together with the two visible left endpoint witnesses and the stored $LeftEq(l, l')$ witness, then rebuild the left classifier constructor. In the right branch, unpack r, r' together with the two visible right endpoint witnesses and the stored $RightEq(r, r')$ witness, then rebuild the right classifier constructor. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier branch iff`

Theorem 35.76 (Sum history carrier visible branch cases)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers. If* $\mathsf{SumHistoryCarrier}(Left, Right, h)$ *holds, then the visible history has one of the two displayed branch witnesses:*

$$(\exists l.\ Left(l) \wedge \mathsf{hsame}(h, \mathsf{E0}(l))) \vee (\exists r.\ Right(r) \wedge \mathsf{hsame}(h, \mathsf{E1}(r))).$$

In the ten-field fit, the traditional target is disjoint-sum carrier readback, the BEDC source is BHist*, the carrier is* SumHistoryCarrier*, no classifier is needed, the stability obligation is constructor inversion, the ledger records the visible tag plus payload, the core theorem is branch cases, exactness coverage is supplied by the visible branch witnesses, the standard bridge is* inl *and* inr*, and the status is* ProofTarget*.*

Proof. Case-analyze the generated SumHistoryCarrier witness. The left constructor returns a payload l, the source-carrier witness $Left(l)$, and the displayed endpoint link $\mathsf{hsame}(h, \mathsf{E0}(l))$. The right constructor returns the corresponding payload r, the source-carrier witness $Right(r)$, and the displayed endpoint link $\mathsf{hsame}(h, \mathsf{E1}(r))$. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryCarrier visible branch cases`

Theorem 35.77 (Sum history carrier visible branch exactness)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers. Then the sum history carrier is exactly the visible left-or-right branch assertion:*

$$\mathsf{SumHistoryCarrier}(Left, Right, h) \iff (\exists l.\ Left(l) \wedge \mathsf{hsame}(h, \mathsf{E0}(l))) \vee (\exists r.\ Right(r) \wedge \mathsf{hsame}(h, \mathsf{E1}(r))).$$

In the ten-field fit, the carrier coverage predicate and the visible branch classifier agree on precisely the histories generated by the two sum constructors.

Proof. For the forward direction, apply Definition 35.76. For the reverse direction, split the displayed disjunction. In the left case, unpack the payload l, the source-carrier witness $Left(l)$, and the visible endpoint link $\mathsf{hsame}(h, \mathsf{E0}(l))$, then rebuild the left carrier constructor. In the right case, unpack the corresponding data for r and rebuild the right carrier constructor. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryCarrier visible branch exactness`

Theorem 35.78 (Sum history carrier exclusive visible branch partition)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers. Then the sum history carrier has exactly one visible branch presentation:*

$$\mathsf{SumHistoryCarrier}(Left, Right, h) \iff \Big((\exists l.\ Left(l) \wedge \mathsf{hsame}(h, \mathsf{E0}(l))) \wedge \neg(\exists r.\ Right(r) \wedge \mathsf{hsame}(h, \mathsf{E1}(r)))\Big) \vee \Big((\exists r.\ R$$

In the ten-field fit, the carrier readback for $\mathsf{Sum}^{\uparrow}$ *is a constructor partition: every carrier history is visibly generated by one sum constructor, and the opposite visible constructor presentation is excluded.*

Proof. For the forward direction, use Definition 35.77 to obtain either a visible left presentation or a visible right presentation. In the left case, the opposite right presentation would contradict Definition 35.3 after reordering the stored endpoint and source-carrier witnesses; the right case is symmetric. For the reverse direction, split the displayed disjunction, forget the negative conjunct, and rebuild $\mathsf{SumHistoryCarrier}(Left, Right, h)$ through Definition 35.77. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryCarrier exclusive visible branch partition payload first`

Theorem 35.79 (Sum visible branch payload determinism)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $h, l, l', r, r' : \mathsf{BHist}$ *be histories. Same-branch visible presentations have unique payloads up to* hsame*:*

$$\mathsf{hsame}(h, \mathsf{E0}(l)) \to Left(l) \to \mathsf{hsame}(h, \mathsf{E0}(l')) \to Left(l') \to \mathsf{hsame}(l, l')$$

and

$$\mathsf{hsame}(h, \mathsf{E1}(r)) \to Right(r) \to \mathsf{hsame}(h, \mathsf{E1}(r')) \to Right(r') \to \mathsf{hsame}(r, r').$$

In the ten-field fit, the traditional target is disjoint-sum visible readback determinism; the BEDC source is BHist*; the carrier is* SumHistoryCarrier *presentations; the classifier is* hsame *on visible constructors; the stability obligation is constructor inversion; the ledger records the visible tag plus payload source evidence; the core theorem is same-branch payload uniqueness; exactness is deterministic readback; the standard bridge is* inl *and* inr*; and the status is* ProofTarget*.*

Proof. For the left statement, use symmetry on the first endpoint link and compose it with the second endpoint link, obtaining $\mathsf{hsame}(\mathsf{E0}(l), \mathsf{E0}(l'))$. Constructor inversion for the visible left constructor gives $\mathsf{hsame}(l, l')$. The right statement is identical, composing the two E1 endpoint links and applying right-constructor inversion. The source-carrier witnesses record that both visible presentations are legitimate branch presentations; they are not needed by the constructor inversion itself. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryCarrier visible payload determinism`

Theorem 35.80 (Sum carrier single-valued visible branch readback)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $h : \mathsf{BHist}$*. If* $\mathsf{SumHistoryCarrier}(Left, Right, h)$ *holds, then the visible tagged payload presentation of* h *is single-valued:*

$$\exists l.\ Left(l) \wedge \mathsf{hsame}(h, \mathsf{E0}(l)) \wedge (\forall l'.\ Left(l') \to \mathsf{hsame}(h, \mathsf{E0}(l')) \to \mathsf{hsame}(l, l')) \wedge \neg(\exists r.\ Right(r) \wedge \mathsf{hsame}(h, \mathsf{E1}(r$$

or

$$\exists r.\ Right(r) \wedge \mathsf{hsame}(h, \mathsf{E1}(r)) \wedge (\forall r'.\ Right(r') \to \mathsf{hsame}(h, \mathsf{E1}(r')) \to \mathsf{hsame}(r, r')) \wedge \neg(\exists l.\ Left(l) \wedge \mathsf{hsame}(h, \mathsf{E0}$$

In the ten-field fit, the traditional target is tagged disjoint-sum readback; the BEDC source is BHist*; the carrier is* SumHistoryCarrier*; the classifier is* hsame *on same-tag visible payloads; stability is constructor inversion plus branch exclusion; the ledger stores the visible tag and payload source evidence; the core theorem is this single-valued readback; exactness is existence, uniqueness, and opposite-tag exclusion; the standard bridge is* inl *and* inr*; and the status is* ProofTarget*.*

Proof. Apply Definition 35.78 to the carrier witness. In the left branch, unpack l, $Left(l)$, the endpoint link $\mathsf{hsame}(h, \mathsf{E0}(l))$, and the exclusion of right visible presentations. For an arbitrary left visible payload l', apply Definition 35.79 to the two left endpoint links and the two source-carrier witnesses to obtain $\mathsf{hsame}(l, l')$. The right branch is symmetric, using the right payload clause and carrying the exclusion of left visible presentations unchanged. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryCarrier single valued visible readback`

Theorem 35.81 (Sum history classifier carrier-aware branch partition)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, let* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers. Assume source-carrier closure under history sameness:*

$$\forall x\, y.\ Left(x) \to \mathsf{hsame}(x, y) \to Left(y)$$

and

$$\forall x\, y.\ Right(x) \to \mathsf{hsame}(x, y) \to Right(y).$$

If $\mathsf{SumHistoryCarrier}(Left, Right, h)$, $\mathsf{SumHistoryCarrier}(Left, Right, k)$, *and* $\mathsf{SumHistoryClassifier}(Left, Right, Left$ *hold, then a visible classifier side supplies the branch data used by the carrier-backed certificate analysis:*

$$\exists a, b.\ Left(a) \wedge Left(b) \wedge \mathsf{hsame}(h, \mathsf{E0}(a)) \wedge \mathsf{hsame}(k, \mathsf{E0}(b)) \wedge LeftEq(a, b)$$

or

$$\exists a, b.\ Right(a) \wedge Right(b) \wedge \mathsf{hsame}(h, \mathsf{E1}(a)) \wedge \mathsf{hsame}(k, \mathsf{E1}(b)) \wedge RightEq(a, b).$$

Proof. Split the displayed SumHistoryClassifier witness into its visible left or right constructor branch. In the left branch, let the classifier payloads be a, b. Compose the carrier endpoint for h with the classifier endpoint $\mathsf{hsame}(h, \mathsf{E0}(a))$ and apply SumHistoryCarrier_e0_inversion to obtain a source payload l, $Left(l)$, and a payload link $\mathsf{hsame}(l, a)$; the same argument at k gives l', $Left(l')$, and $\mathsf{hsame}(l', b)$. The left source-carrier closure turns these into $Left(a)$ and $Left(b)$. Together with the stored $LeftEq(a, b)$ witness and the two classifier endpoint links, these data give the left disjunct. In the right branch, apply the analogous E1 endpoint composition and SumHistoryCarrier_e1_inversion argument to obtain $Right(a)$ and $Right(b)$ from the right source-carrier closure, then pair them with the stored $RightEq(a, b)$ witness and the two right endpoint links. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier carrier aware branch partition`

Theorem 35.82 (Sum history classifier carrier-aware branch exactness)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, let* $LeftEq, RightEq : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers. Assume source-carrier closure under history sameness:*

$$\forall x\, y.\ Left(x) \to \mathsf{hsame}(x, y) \to Left(y)$$

and

$$\forall x\, y.\ Right(x) \to \mathsf{hsame}(x, y) \to Right(y).$$

Then the carrier-backed classifier assertion

$$\begin{aligned}&\mathsf{SumHistoryCarrier}(Left, Right, h) \wedge \mathsf{SumHistoryCarrier}(Left, Right, k) \wedge \\ &\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k)\end{aligned}$$

is equivalent to the visible branch assertion

$$\begin{aligned}&\big(\exists a, b.\ Left(a) \wedge Left(b) \wedge \mathsf{hsame}(h, \mathsf{E0}(a)) \wedge \mathsf{hsame}(k, \mathsf{E0}(b)) \wedge LeftEq(a, b)\big) \\ &\vee \\ &\big(\exists a, b.\ Right(a) \wedge Right(b) \wedge \mathsf{hsame}(h, \mathsf{E1}(a)) \wedge \mathsf{hsame}(k, \mathsf{E1}(b)) \wedge RightEq(a, b)\big).\end{aligned}$$

Proof. For the forward direction, apply Definition 35.81 with the two displayed source-carrier closure hypotheses. For the reverse direction, split the displayed branch assertion. In the left branch, unpack a, b with their $Left$ witnesses, the two visible E0 endpoint links, and the stored $LeftEq(a, b)$ witness. The same data rebuilds the two SumHistoryCarrier witnesses by the left carrier constructor and rebuilds the matching SumHistoryClassifier witness by the left classifier constructor. The right branch is identical, using the two $Right$ witnesses, the visible E1 endpoint links, $RightEq(a, b)$, and the right carrier and classifier constructors. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier carrier aware branch exactness`

Theorem 35.83 (Sum history source weakening)**.** *Let* $Left, Right, Left', Right' : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, and let* $LeftEq, RightEq, LeftEq', RightEq' : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers. The two refinements have separate premises. Source-carrier inclusion gives carrier refinement:*

$$((\forall h.\ Left(h) \to Left'(h)) \wedge (\forall h.\ Right(h) \to Right'(h))) \to (\mathsf{SumHistoryCarrier}(Left, Right, h) \to \mathsf{SumHistoryCarr}$$

Component-relation weakening gives classifier refinement:

$$((\forall a\, b.\ LeftEq(a,b) \to LeftEq'(a,b)) \wedge (\forall a\, b.\ RightEq(a,b) \to RightEq'(a,b))) \to (\mathsf{SumHistoryClassifier}(Left, Rig$$

In the ten-field fit, the traditional target is disjoint-sum stability under source refinement, the BEDC source is the two BHist *carriers, the carrier is* SumHistoryCarrier*, the component classifier is* SumHistoryClassifier*, the stability datum is source inclusion plus component-relation weakening, the ledger keeps the visible tag unchanged, and the core theorem separates carrier weakening from classifier weakening. The classifier part uses only component-relation weakening because source membership is not a field of* SumHistoryClassifier*. Exactness is preserved by the same endpoint witnesses, the standard bridge is the* inl *and* inr *restriction, and the status is* ProofTarget*.*

Proof. For the carrier claim, assume the displayed pair of source-carrier inclusions and split the SumHistoryCarrier witness into its left and right constructor cases. The endpoint history witness is reused unchanged, while the matching source-carrier inclusion maps the payload membership proof into the refined source carrier. For the classifier claim, assume the displayed pair of component-relation weakenings and split the SumHistoryClassifier witness into its left and right constructor cases. Reuse the same two visible endpoints and apply only the matching component-relation weakening hypothesis to the stored $LeftEq$ or $RightEq$ witness. Source membership is absent from SumHistoryClassifier, so no source-carrier inclusion is needed for the classifier paragraph. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistorySource weakening`

Theorem 35.84 (Sum history source equivalence)**.** *Let* $Left, Right, Left', Right' : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers, and let* $LeftEq, RightEq, LeftEq', RightEq' : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be source classifiers. Assume source-carrier equivalence*

$$\forall h.\ Left(h) \leftrightarrow Left'(h)$$

and

$$\forall h.\ Right(h) \leftrightarrow Right'(h),$$

and assume component-relation equivalence

$$\forall a\, b.\ LeftEq(a,b) \leftrightarrow LeftEq'(a,b)$$

and

$$\forall a\, b.\ RightEq(a,b) \leftrightarrow RightEq'(a,b).$$

Then the sum carrier and classifier are invariant under the equivalent source presentation:

$$(\forall h.\ \mathsf{SumHistoryCarrier}(Left, Right, h) \leftrightarrow \mathsf{SumHistoryCarrier}(Left', Right', h)) \wedge (\forall h\, k.\ \mathsf{SumHistoryClassifier}(Left, R$$

In the ten-field fit, the traditional target is disjoint-sum source-presentation invariance, the BEDC source is the two BHist *carriers, the carrier is* SumHistoryCarrier*, the classifier is* SumHistoryClassifier*, the stability datum is source and relation equivalence, the ledger keeps the visible tag unchanged, and the core theorem is carrier and classifier equivalence. Exactness uses the unchanged branch witnesses, the standard bridge is* inl *and* inr *readback, and the status is* ProofTarget*.*

Proof. Apply Definition 35.83 from left to right using the forward halves of the two source-carrier equivalences for the carrier clause and the forward halves of the two component-relation equivalences for the classifier clause. This gives the implications from $(Left, Right, LeftEq, RightEq)$ to $(Left', Right', LeftEq', RightEq')$, with the same visible tag and the same branch witnesses. Apply the same weakening theorem from right to left using the reverse halves of the four equivalence hypotheses. Pair the two carrier implications and pair the two classifier implications. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistorySource equivalence`

Theorem 35.85 (Sum history classifier relation weakening)**.** *Let* $Left, Right, LeftAlt, RightAlt : \mathsf{BHist} \to \mathsf{Prop}$ *be arbitrary source carriers, and let* $LeftEq, RightEq, LeftEq', RightEq' : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be component classifiers. Assume component-relation weakening*

$$\forall a\, b.\ LeftEq(a, b) \to LeftEq'(a, b)$$

and

$$\forall a\, b.\ RightEq(a, b) \to RightEq'(a, b).$$

Then the sum history classifier relation weakens independently of source-carrier inclusion:

$$\mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq, h, k) \to \mathsf{SumHistoryClassifier}(LeftAlt, RightAlt, LeftEq', Righ$$

In the ten-field fit, the traditional target is disjoint-sum classifier monotonicity, the BEDC source is BHist*, the classifier is* SumHistoryClassifier*, the stability datum is component-relation weakening, the ledger keeps the visible tag unchanged, exactness is branch partition preservation, and the status is* ProofTarget*.*

Proof. Split the displayed SumHistoryClassifier witness into its visible left or right constructor branch. In each branch, reuse the same visible endpoint witnesses for h and k. The left branch applies the left component-relation weakening hypothesis to the stored $LeftEq$ witness and rebuilds the left tagged classifier witness; the right branch applies the right component-relation weakening hypothesis to the stored $RightEq$ witness and rebuilds the right tagged classifier witness. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryClassifier relation weakening`

Theorem 35.86 (Sum ledger raw-visible branch partition)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, v : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$ *holds, then the same visible branch and payload appear on both ends of the ledger link:*

$$(\exists l.\ Left(l) \wedge \mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(v, \mathsf{E0}(l))) \vee (\exists r.\ Right(r) \wedge \mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(v, \mathsf{E1}(r))).$$

In the ten-field fit, the traditional target is disjoint-sum ledger branch readback; the BEDC source is BHist *with* hsame*; the carrier is* SumHistoryCarrier*; no classifier is needed for the direct branch exposure; the ledger is* SumHistoryLedgerPolicy*; exactness is the same raw-visible branch and payload on both endpoints; and the status is* ProofTarget*.*

Proof. Unpack the ledger into the raw SumHistoryCarrier witness and the stored raw-visible $\mathsf{hsame}(\rho, v)$ link. Split the raw carrier. In the left branch, keep the raw payload l and its $Left(l)$ witness, retain the stored raw tag witness $\mathsf{hsame}(\rho, \mathsf{E0}(l))$, and compose symmetry of $\mathsf{hsame}(\rho, v)$ with that raw tag witness to obtain $\mathsf{hsame}(v, \mathsf{E0}(l))$. The right branch uses the same argument with the raw payload r, the $Right(r)$ witness, and the E1 tag. □

Definition 35.87 (Sum ledger policy)**.** *Record a raw sum history carrying the selected injection tag and source ledger together with an* hsame *link to the visible history exposed by the ledger.*

Lean4 (definition) `BEDC.Derived.SumUp.SumHistoryLedgerPolicy`

Theorem 35.88 (Sum ledger visible carrier)**.** *If a visible history is linked by* hsame *to a raw sum-ledger history, then the visible history is itself a sum carrier.*

Proof. Unpack the raw sum carrier and transport it across the stored hsame link by sum-carrier transport. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy visible carrier`

Theorem 35.89 (Sum ledger raw-visible classifier)**.** *If* $\mathsf{SumHistoryLedgerPolicy}(L, R, \rho, v)$ *holds, then* $\mathsf{SumHistoryClassifier}(L, R, \mathsf{hsame}, \mathsf{hsame}, \rho, v)$ *holds.*

Proof. Unpack the ledger into its raw sum carrier and the stored $\mathsf{hsame}(\rho, v)$ link. The raw carrier determines whether ρ is left-tagged or right-tagged; transport the tag witness across the stored link and use reflexivity of hsame on the selected component to build the matching classifier branch. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy raw visible classifier`

Theorem 35.90 (Sum ledger history-same transport)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $raw, raw', visible, visible' : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, raw, visible)$ $\mathsf{hsame}(raw, raw')$*, and* $\mathsf{hsame}(visible, visible')$ *hold, then*

$$\mathsf{SumHistoryLedgerPolicy}(Left, Right, raw', visible')$$

holds.

Proof. Unpack the ledger into the raw SumHistoryCarrier witness and the stored link $\mathsf{hsame}(raw, visible)$. Transport the raw carrier along $\mathsf{hsame}(raw, raw')$ by Theorem 35.2. For the raw-visible link of the transported ledger, compose symmetry of $\mathsf{hsame}(raw, raw')$, the stored $\mathsf{hsame}(raw, visible)$ link, and $\mathsf{hsame}(visible, visible')$ to obtain $\mathsf{hsame}(raw', visible')$. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy hsame transport`

Theorem 35.91 (Sum ledger classifier composition)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, v, w : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$ *holds and* $\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, v, w)$ *holds, then*

$$\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, \rho, w)$$

holds.

Proof. First apply the raw-visible classifier theorem to the ledger policy, obtaining

$$\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, \rho, v).$$

Then compose this classifier witness with the given visible-target classifier witness using sum-history classifier transitivity. The branch classifiers are both hsame, so their required transitivity inputs are the left and right instances of BEDC history equality transitivity. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy classifier composition`

Theorem 35.92 (Sum ledger two-step classifier composition)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, v, w : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$ *and* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, v, w)$ *hold, then*

$$\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, \rho, w)$$

holds. The roadmap fit is: traditional target disjoint-sum ledger-chain closure; BEDC source BHist *with tagged sum carrier; carrier* SumHistoryCarrier*; classifier* $\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame})$*; stability by two raw-visible ledger exposures and classifier transitivity; ledger two composable* SumHistoryLedgerPolicy *witnesses; core theorem this closure; exactness raw-to-middle-to-visible; standard bridge tagged sum ledger chain; status* ProofTarget.

Proof. Apply Theorem 35.89 to the two ledger witnesses, obtaining classifiers from ρ to v and from v to w. Compose them by Theorem 35.43; the branch classifiers are both hsame, so the required transitivity inputs are the left and right instances of BEDC history equality transitivity. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy two step classifier composition`

Theorem 35.93 (Sum ledger raw-visible branch exactness)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $raw, visible : \mathsf{BHist}$ *be histories. Then*

$$\mathsf{SumHistoryLedgerPolicy}(Left, Right, raw, visible) \iff (\exists l : \mathsf{BHist}.\ Left(l) \wedge \mathsf{hsame}(raw, \mathsf{E0}(l)) \wedge \mathsf{hsame}(visible, \mathsf{E0}(l$$

Proof. For the forward direction, unpack the ledger into its raw sum carrier and the stored raw-visible link. Split the raw carrier branch.

In the left branch, the carrier supplies $Left(l)$ and $\mathsf{hsame}(raw, \mathsf{E0}(l))$. Compose symmetry of the stored raw-visible link with this raw endpoint witness to obtain $\mathsf{hsame}(visible, \mathsf{E0}(l))$, and assemble the left disjunct.

In the right branch, the same argument uses the witness $Right(r)$ and $\mathsf{hsame}(raw, \mathsf{E1}(r))$ to obtain $\mathsf{hsame}(visible, \mathsf{E1}(r))$ and assemble the right disjunct.

For the reverse direction, split the displayed branch evidence. In the left branch, rebuild the raw sum carrier from $Left(l)$ and $\mathsf{hsame}(raw, \mathsf{E0}(l))$. Compose $\mathsf{hsame}(raw, \mathsf{E0}(l))$ with symmetry of $\mathsf{hsame}(visible, \mathsf{E0}(l))$ to recover the raw-visible ledger link.

The right branch is identical, rebuilding the raw carrier from $Right(r)$ and $\mathsf{hsame}(raw, \mathsf{E1}(r))$, then composing the two endpoint witnesses to recover the stored raw-visible link. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy raw visible branch exactness`

Theorem 35.94 (Sum ledger two-step branch exactness)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, v, w : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$

and $\mathsf{SumHistoryLedgerPolicy}(Left, Right, v, w)$ *hold, then the whole two-step chain has a visible same-branch payload readback:*

$$(\exists l\, l' : \mathsf{BHist}.\ Left(l) \wedge Left(l') \wedge \mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(w, \mathsf{E0}(l')) \wedge \mathsf{hsame}(l, l')) \vee (\exists r\, r' : \mathsf{BHist}.\ Right(r) \wedge Right(r')$$

The ten-field fit is: traditional target disjoint-sum ledger-chain readback; BEDC source BHist *with* hsame*; carrier* SumHistoryCarrier*; classifier unused in the final exactness statement but supplied by Theorem 35.92; ledger two composable* SumHistoryLedgerPolicy *witnesses; core theorem this branch exactness statement; exactness raw-to-visible same-branch payload readback; standard bridge tagged sum ledger chains; status* ProofTarget.

Proof. Apply Theorem 35.93 to each ledger witness. The first application exposes either a left payload visible at ρ and v, or a right payload visible at ρ and v; the second exposes the corresponding alternatives at v and w. Split the four branch cases. In the left-left case, use Theorem 35.79 at the shared middle endpoint v to identify the two left payloads and assemble the left disjunct. The right-right case is identical with the right branch. The mixed left-right and right-left cases contradict generated-history no-confusion between E0 and E1 at the shared middle endpoint v. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy two step branch exactness`

Theorem 35.95 (Sum ledger two-step endpoint exactness)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, v, w, l, l', r, r' : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$ *and* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, v, w)$ *hold, then the two-ledger chain has endpoint exactness from* ρ *to* w*. First, both mixed endpoint pairs are impossible:*

$$(\mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(w, \mathsf{E1}(r'))) \to \bot$$

and

$$(\mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(w, \mathsf{E0}(l'))) \to \bot.$$

Second, same-tag endpoint pairs determine their payloads:

$$(\mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(w, \mathsf{E0}(l'))) \to \mathsf{hsame}(l, l')$$

and

$$(\mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(w, \mathsf{E1}(r'))) \to \mathsf{hsame}(r, r').$$

Third, final visible endpoints of w *read back source payload evidence:*

$$(\mathsf{hsame}(w, \mathsf{E0}(l')) \to \exists a : \mathsf{BHist}.\ Left(a) \wedge \mathsf{hsame}(l', a))$$

and

$$(\mathsf{hsame}(w, \mathsf{E1}(r')) \to \exists b : \mathsf{BHist}.\ Right(b) \wedge \mathsf{hsame}(r', b)).$$

Proof. Apply Theorem 35.92 to the two ledger witnesses and obtain $\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame},$ The two mixed endpoint conclusions follow from Theorem 35.41; for the reversed displayed order, use classifier symmetry from Theorem 35.36 before applying the same tag-separation theorem. The left same-tag conclusion is exactly the left endpoint inversion supplied by Theorem 35.13, and the right same-tag conclusion is the corresponding right inversion from Theorem 35.14. For the final visible readback, apply Theorem 35.88 to the second ledger witness, obtaining a visible carrier for w; then apply Theorem 35.7 to the displayed E0 or E1 endpoint of w to extract the matching source payload evidence. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy two step endpoint exactness`

Definition 35.96 (Sum ledger finite provenance chain)**.** *For source carriers* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$*, define* $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$ *as the finite provenance relation generated by the following two clauses. A displayed one-ledger witness* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, z)$ *gives* $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$*. If there is a history* $v : \mathsf{BHist}$ *such that* $\mathsf{SumHistoryLedgerPolicy}(Left, R$ *and* $\mathsf{SumHistoryLedgerChain}_{Left,Right}(v, z)$ *hold, then* $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$ *also holds.*

Lean4 (definition) `BEDC.Derived.SumUp.SumHistoryLedgerChain`

Theorem 35.97 (Sum ledger chain transitivity)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, m, z : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, m)$ *and* $\mathsf{SumHistoryLedgerChain}_{Left,Righ}$ *hold, then* $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$ *holds. The ten-field fit is: traditional target finite tagged-sum ledger provenance composition; BEDC source* BHist *with tagged sum carrier; carrier* $\mathsf{SumHistoryCarrier}$*; classifier supplied downstream by Theorem 35.98; ledger* $\mathsf{SumHistoryLedgerChain}_{Left,Right}$*; core theorem finite-chain composition; exactness concatenated raw-to-visible provenance; standard bridge tagged sum ledger audit composition; status* $\mathsf{ProofTarget}$*.*

Proof. Induct on the first displayed $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, m)$ witness.

In the one-ledger case, the displayed $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, m)$ is the first finite ledger step. Rebuild the target chain by the cons constructor, using that ledger step as the head and the second displayed chain from m to z as the tail.

In the cons case, the first chain consists of a head ledger from ρ to an intermediate history and a tail chain from that intermediate history to m. Apply the induction hypothesis to compose the tail chain with the second displayed chain from m to z, then rebuild the full chain by the cons constructor with the original head ledger. □

Theorem 35.98 (Sum ledger chain classifier composition)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $raw, visible : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerChain}_{Left,Right}(raw, visible)$ *holds, then*

$$\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, raw, visible)$$

holds. The ten-field fit is: traditional target disjoint-sum finite ledger classifier closure; BEDC source BHist *with* hsame*; source carriers* $Left$ *and* $Right$*; carrier* $\mathsf{SumHistoryCarrier}$*; classifier* $\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame})$*; stability by raw-visible classification plus classifier transitivity; ledger* $\mathsf{SumHistoryLedgerChain}_{Left,Right}$*; core theorem this finite-chain classifier closure; exactness finite raw-to-visible classifier reachability; standard bridge tagged sum finite ledger provenance; status* $\mathsf{ProofTarget}$*.*

Proof. Induct on the displayed $\mathsf{SumHistoryLedgerChain}_{Left,Right}(raw, visible)$ witness. In the one-ledger case, apply Theorem 35.89. In the cons case, apply the induction hypothesis to the tail chain to obtain the classifier from the middle history to *visible*, then compose it with the first ledger by Theorem 35.91. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerChain classifier composition`

Theorem 35.99 (Sum ledger chain visible carrier)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, z : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$ *holds, then*

$$\mathsf{SumHistoryCarrier}(Left, Right, z)$$

holds. The ten-field fit is: traditional target disjoint-sum finite ledger visible-carrier closure; BEDC source BHist *with* hsame*; source carriers* $Left$ *and* $Right$*; carrier* SumHistoryCarrier*; classifier not needed for this unary closure; ledger* $\mathsf{SumHistoryLedgerChain}_{Left,Right}$*; core theorem this carrier closure; exactness final visible endpoint remains in the sum carrier; standard bridge tagged sum finite ledger provenance; status* ProofTarget.

Proof. Induct on the displayed $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$ witness. In the one-ledger case, apply Theorem 35.88. In the cons case, use the carrier supplied by the tail induction hypothesis. □

Theorem 35.100 (Sum ledger chain endpoint exactness)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, z, l, l', r, r' : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$ *holds, then the whole finite ledger provenance from* ρ *to* z *has endpoint exactness. First, both mixed endpoint pairs are impossible:*

$$(\mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(z, \mathsf{E1}(r'))) \to \bot$$

and

$$(\mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(z, \mathsf{E0}(l'))) \to \bot.$$

Second, same-tag endpoint pairs determine their payloads:

$$(\mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(z, \mathsf{E0}(l'))) \to \mathsf{hsame}(l, l')$$

and

$$(\mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(z, \mathsf{E1}(r'))) \to \mathsf{hsame}(r, r').$$

Third, final visible endpoints of z *read back matching source payload evidence:*

$$(\mathsf{hsame}(z, \mathsf{E0}(l')) \to \exists a : \mathsf{BHist}.\ Left(a) \wedge \mathsf{hsame}(l', a))$$

and

$$(\mathsf{hsame}(z, \mathsf{E1}(r')) \to \exists b : \mathsf{BHist}.\ Right(b) \wedge \mathsf{hsame}(r', b)).$$

The ten-field fit is: traditional target disjoint-sum finite ledger provenance; BEDC source BHist *with* hsame*; source carriers* $Left$ *and* $Right$*; carrier* SumHistoryCarrier*; classifier* $\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}$ *supplied one ledger at a time by raw-visible classification; ledger* $\mathsf{SumHistoryLedgerChain}_{Left,Right}$ *generated by* SumHistoryLedgerPolicy*; core theorem this chain endpoint exactness package; exactness mixed-tag separation, same-tag payload determinacy, and final visible source readback; standard bridge tagged sum finite ledger provenance; status* ProofTarget.

Proof. First apply Theorem 35.98 to the displayed chain, obtaining $\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame},$ The two mixed endpoint clauses follow from Theorem 35.41; for the reversed displayed order, first use classifier symmetry from Theorem 35.36. The same-tag endpoint clauses follow by transporting the classifier along the displayed endpoint hsame links and applying Theorem 35.13 or Theorem 35.14. For the final visible readback, apply Theorem 35.99 to the displayed chain to obtain $\mathsf{SumHistoryCarrier}(Left, Right, z)$. Transport this carrier along the displayed hsame endpoint at z and apply the left or right carrier inversion theorem to extract the matching source payload evidence. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerChain endpoint exactness`

Theorem 35.101 (Sum ledger chain branch readback soundness)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, z : \mathsf{BHist}$ *be histories. The finite ledger-chain relation forces exact same-branch payload readback:*

$$\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z) \to (\exists l\, l' : \mathsf{BHist}.\ Left(l) \wedge Left(l') \wedge \mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(z, \mathsf{E0}(l')) \wedge \mathsf{hsame}(l$$

The ten-field fit is: traditional target disjoint-sum finite ledger branch readback; BEDC source BHist *with* hsame*; source carriers* $Left$ *and* $Right$*; carrier* SumHistoryCarrier*; classifier supplied by Theorem 35.98; ledger* $\mathsf{SumHistoryLedgerChain}_{Left,Right}$*; core theorem this branch readback soundness; finite ledger-chain witnesses map into same-branch payload readback; standard bridge tagged sum finite ledger provenance; status* ProofTarget*.*

Proof. Induct on the displayed $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$ witness. In the one-ledger case, apply Theorem 35.93 and choose the same payload at the raw and visible endpoints, with hsame reflexivity for the payload link.

In the cons case, combine the raw-visible branch exactness of the first ledger with the induction hypothesis for the tail chain. The mixed left-right and right-left cases contradict generated-history no-confusion between E0 and E1 at the shared middle endpoint. In the same-branch cases, use Theorem 35.79 at the middle endpoint and hsame transitivity to compose the first payload with the final payload. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerChain branch exactness`

Theorem 35.102 (Sum ledger chain branch exactness)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, z : \mathsf{BHist}$ *be histories. The finite ledger-chain relation is equivalent to exact same-branch payload readback:*

$$\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z) \iff (\exists l\, l' : \mathsf{BHist}.\ Left(l) \wedge Left(l') \wedge \mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(z, \mathsf{E0}(l')) \wedge \mathsf{hsame}$$

The ten-field fit is: traditional target disjoint-sum finite ledger branch readback; BEDC source BHist *with* hsame*; source carriers* $Left$ *and* $Right$*; carrier* SumHistoryCarrier*; classifier supplied by Theorem 35.98; ledger* $\mathsf{SumHistoryLedgerChain}_{Left,Right}$*; core theorem this branch exactness; exactness coverage and completeness of the finite ledger-chain relation by same-branch payload readback; standard bridge tagged sum finite ledger provenance; status* ProofTarget*.*

Proof. For the forward direction, apply Theorem 35.101.

For the reverse direction, split the displayed disjunction. In the left branch, the witnesses $Left(l)$, $\mathsf{hsame}(\rho, \mathsf{E0}(l))$, $\mathsf{hsame}(z, \mathsf{E0}(l'))$, and $\mathsf{hsame}(l, l')$ determine a one-ledger left readback. Use symmetry of $\mathsf{hsame}(l, l')$ and constructor congruence for E0 to transport $\mathsf{hsame}(z, \mathsf{E0}(l'))$ into $\mathsf{hsame}(z, \mathsf{E0}(l))$.

Apply the reverse direction of Theorem 35.93 to obtain $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, z)$, then use the one-ledger constructor of $\mathsf{SumHistoryLedgerChain}_{Left,Right}$.

The right branch is identical, using the witnesses $Right(r)$, $\mathsf{hsame}(\rho, \mathsf{E1}(r))$, $\mathsf{hsame}(z, \mathsf{E1}(r'))$, and $\mathsf{hsame}(r, r')$, with constructor congruence for E1 before applying the same raw-visible branch exactness theorem and the one-ledger chain constructor. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerChain branch exactness iff`

Theorem 35.103 (Sum ledger chain raw branch forces final branch readback)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, z, l, r : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerChain}_{Left,Right}(\rho, z)$ *holds, then raw visible branch evidence forces the matching final visible branch. The left clause is*

$$Left(l) \to \mathsf{hsame}(\rho, \mathsf{E0}(l)) \to \exists l' : \mathsf{BHist}.\ Left(l') \wedge \mathsf{hsame}(z, \mathsf{E0}(l')) \wedge \mathsf{hsame}(l, l') \wedge \neg(\exists r' : \mathsf{BHist}.\ Right(r') \wedge \mathsf{hsa}$$

and the right clause is

$$Right(r) \to \mathsf{hsame}(\rho, \mathsf{E1}(r)) \to \exists r' : \mathsf{BHist}.\ Right(r') \wedge \mathsf{hsame}(z, \mathsf{E1}(r')) \wedge \mathsf{hsame}(r, r') \wedge \neg(\exists l' : \mathsf{BHist}.\ Left(l') \wedge \mathsf{h}$$

The ten-field fit is: traditional target disjoint-sum finite ledger branch forcing; BEDC source BHist *with* hsame*; carrier final* SumHistoryCarrier*; classifier supplied by the chain classifier composition theorem; ledger* $\mathsf{SumHistoryLedgerChain}_{Left,Right}$*; core theorem this raw-branch forcing readback; exactness same-tag payload determinacy plus mixed-tag exclusion; standard bridge tagged sum finite ledger provenance; status* ProofTarget*.*

Proof. Apply Theorem 35.99 to the chain and then Theorem 35.80 to the final carrier. This splits the endpoint z into a left visible presentation with right-presentation exclusion, or a right visible presentation with left-presentation exclusion.

For the left raw premise, keep the left final presentation from the split. The same-tag payload clause of Theorem 35.100, applied to $\mathsf{hsame}(\rho, \mathsf{E0}(l))$ and the displayed $\mathsf{hsame}(z, \mathsf{E0}(l'))$, gives $\mathsf{hsame}(l, l')$; combine it with the source witness for l' and the carried right-presentation exclusion.

The right final presentation cannot occur under the left raw premise, because the mixed endpoint clause of Theorem 35.100 contradicts $\mathsf{hsame}(\rho, \mathsf{E0}(l))$ and $\mathsf{hsame}(z, \mathsf{E1}(r'))$. The right raw premise is symmetric: the right final presentation supplies the witness and the left-presentation exclusion, while the mixed endpoint clause excludes any left final presentation. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerChain raw branch final readback`

Theorem 35.104 (Sum ledger preserves visible tag separation)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, v, l, r : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$ *holds, then both visible mixed-tag endpoint pairs are impossible:*

$$(\mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(v, \mathsf{E1}(r))) \to \bot$$

and

$$(\mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(v, \mathsf{E0}(l))) \to \bot.$$

Proof. Apply Theorem 35.89 to the ledger policy to obtain $\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, \rho, v)$. The left-to-right mixed endpoint pair is then discharged by SumHistoryClassifier_mixed_tags_absurd with the displayed $\mathsf{hsame}(\rho, \mathsf{E0}(l))$ and $\mathsf{hsame}(v, \mathsf{E1}(r))$ witnesses. For the symmetric right-to-left pair, use classifier symmetry from Theorem 35.36 and apply the same mixed-tag separation theorem to the exchanged endpoints. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy visible tag separation`

Theorem 35.105 (Sum ledger same-tag payload exactness)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, v, l, l', r, r' : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$ *holds, then the visible same-tag endpoint pairs determine their payloads:*

$$(\mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(v, \mathsf{E0}(l'))) \to \mathsf{hsame}(l, l')$$

and

$$(\mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(v, \mathsf{E1}(r'))) \to \mathsf{hsame}(r, r').$$

Proof. Apply Theorem 35.89 to obtain the raw-visible $\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame}, \rho, v)$ witness. For the left-tagged endpoint pair, transport this witness along the displayed $\mathsf{hsame}(\rho, \mathsf{E0}(l))$ and $\mathsf{hsame}(v, \mathsf{E0}(l'))$ links by Theorem 35.37, then apply the left inversion Theorem 35.13 to extract $\mathsf{hsame}(l, l')$. The right-tagged case is identical with Theorem 35.14. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy same tag payload exactness`

Theorem 35.106 (Sum ledger visible payload readback)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, v, l, r : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$ *holds, then visible tagged endpoints read back source payload evidence:*

$$(\mathsf{hsame}(v, \mathsf{E0}(l)) \to \exists a : \mathsf{BHist}.\ Left(a) \wedge \mathsf{hsame}(l, a))$$

and

$$(\mathsf{hsame}(v, \mathsf{E1}(r)) \to \exists b : \mathsf{BHist}.\ Right(b) \wedge \mathsf{hsame}(r, b)).$$

Proof. The traditional target is disjoint-sum ledger readback; the BEDC source is BHist; the carrier is SumHistoryCarrier; no classifier is needed for this carrier-readback obligation; the ledger is SumHistoryLedgerPolicy; the exactness principle is visible-tag carrier readback; the status is ProofTarget. Apply Theorem 35.88 to the ledger, transport the visible carrier witness along the displayed $\mathsf{hsame}(v, \mathsf{E0}(l))$ or $\mathsf{hsame}(v, \mathsf{E1}(r))$ endpoint equality, and then apply Theorem 35.7 to extract the left or right source payload witness. □

Lean4 ✓ `BEDC.Derived.SumUp.SumHistoryLedgerPolicy visible payload readback`

Theorem 35.107 (Sum ledger one-step endpoint exactness)**.** *Let* $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ *be source carriers and let* $\rho, v, l, l', r, r' : \mathsf{BHist}$ *be histories. If* $\mathsf{SumHistoryLedgerPolicy}(Left, Right, \rho, v)$ *holds, then the one-ledger link has endpoint exactness from* ρ *to* v*. First, both mixed endpoint pairs are impossible:*

$$(\mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(v, \mathsf{E1}(r'))) \to \bot$$

and

$$(\mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(v, \mathsf{E0}(l'))) \to \bot.$$

Second, same-tag endpoint pairs determine their payloads:

$$(\mathsf{hsame}(\rho, \mathsf{E0}(l)) \wedge \mathsf{hsame}(v, \mathsf{E0}(l'))) \to \mathsf{hsame}(l, l')$$

and

$$(\mathsf{hsame}(\rho, \mathsf{E1}(r)) \wedge \mathsf{hsame}(v, \mathsf{E1}(r'))) \to \mathsf{hsame}(r, r').$$

Third, final visible endpoints read back source payload evidence:

$$(\mathsf{hsame}(v, \mathsf{E0}(l')) \to \exists a : \mathsf{BHist}.\ Left(a) \wedge \mathsf{hsame}(l', a))$$

and

$$(\mathsf{hsame}(v, \mathsf{E1}(r')) \to \exists b : \mathsf{BHist}.\ Right(b) \wedge \mathsf{hsame}(r', b)).$$

The roadmap ten-field fit is: traditional target disjoint-sum one-ledger endpoint audit; BEDC source BHist *with* hsame*; source carriers* $Left$ *and* $Right$*; carrier* SumHistoryCarrier*; classifier* $\mathsf{SumHistoryClassifier}(Left, Right, \mathsf{hsame}, \mathsf{hsame})$*; ledger* SumHistoryLedgerPolicy*; core theorem this endpoint exactness package; exactness raw-to-visible tag separation, same-tag payload determinacy, and visible source readback; standard bridge tagged sum ledger readback; status* ProofTarget*.*

Proof. Apply Theorem 35.104 to the ledger witness for the two mixed clauses. Apply Theorem 35.105 to the same ledger witness for the two same-tag payload clauses. Apply Theorem 35.106 to the ledger witness for the two final visible readback clauses. □

Theorem 35.108 (Concrete $\mathsf{Sum}^{\uparrow}$ semantic name certificate)**.** *Let $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ be source carriers with classifiers $LeftEq$ and $RightEq$. If $\mathsf{NameCert}(Left, LeftEq)$ and $\mathsf{NameCert}(Right, RightEq)$ are supplied, then the tagged sum carrier, the tagged sum classifier, and the carrier-as-pattern and carrier-as-ledger tuple form*

$$\begin{aligned}&\mathsf{SemanticNameCert}(\\ &\quad \mathsf{SumHistoryCarrier}(Left, Right),\\ &\quad \mathsf{SumHistoryCarrier}(Left, Right),\\ &\quad \mathsf{SumHistoryCarrier}(Left, Right),\\ &\quad \mathsf{SumHistoryClassifier}(Left, Right, LeftEq, RightEq)).\end{aligned}$$

Proof. The carrier is represented by $e0$-tagged left histories and $e1$-tagged right histories. Theorem 35.11 marks the split: the classifier delegates within matching tags to the corresponding source certificate, while source-carrier evidence is taken from $\mathsf{SumHistoryCarrier}$ when certificate fields require it. Reflexivity is built by tagging the source certificate reflexivity field on the selected component. Symmetry and transitivity invert the tagged classifier witnesses, use the matching source certificate fields inside a left–left or right–right branch, and discharge mixed tags by constructor no-confusion.

The core certificate fields are assembled from Theorem 35.44. That theorem supplies carrier-relative reflexivity, source-certified symmetry, source-certified transitivity, and classifier-induced carrier transport for the tagged carrier and tagged classifier. The inhabited field is separate: take the inhabited witness l from the left source certificate, choose the visible endpoint $\mathsf{E0}(l)$, and rebuild $\mathsf{SumHistoryCarrier}(Left, Right, \mathsf{E0}(l))$ by the left tagged constructor with the reflexive endpoint witness and the stored $Left(l)$ evidence.

Inside the carrier-transport field supplied by the cited theorem, source-carrier membership is not transported along an arbitrary source $\mathsf{NameCert}$ merely from $\mathsf{hsame}(l, a)$. In the left branch, constructor inversion first aligns the tagged payloads and obtains $\mathsf{hsame}(l, a)$; the checked finite-kernel identity $\mathsf{BEDC.FKernel.Hist.hsame_iff_eq}$ converts that history-sameness witness to kernel equality before the stored $Left(l)$ evidence is rewritten as $Left(a)$. Only after this equality rewrite does $\mathsf{NameCert}.carrier_respects_equiv$ from the left source certificate apply along the displayed source classifier witness $LeftEq(a, b)$, yielding $Left(b)$ and hence the target left tagged carrier. The right branch is the same with $RightEq(a, b)$ and the right source certificate. Pattern soundness and ledger soundness are identity implications, since both semantic fields are the same predicate $\mathsf{SumHistoryCarrier}(Left, Right)$. □

Lean4 ✓ `BEDC.Derived.SumUp.sum history semantic name certificate`

Corollary 35.109 ($\mathsf{Sum}^{\uparrow}$ is licensed, not primitive)**.** *$\mathsf{Sum}^{\uparrow}$ is licensed as a derived disjoint sum, not as a primitive coproduct.*

Theorem 35.110 (Sum public tagged-payload standard bridge)**.** *For source carriers $Left, Right : \mathsf{BHist} \to \mathsf{Prop}$ equipped with source classifiers and source $\mathsf{NameCert}$ rows, the public $\mathsf{Sum}^{\uparrow}$ semantic certificate presents exactly the standard finite disjoint-sum interface with two visible injections. A public endpoint is either an $\mathsf{E0}$-tagged left payload or an $\mathsf{E1}$-tagged right payload. Endpoints with the same tag compare by the corresponding source classifier, and endpoints with mixed tags are separated by constructor no-confusion.*

The exported ledger surface is precisely the visible tag, payload readback, raw-visible branch exactness, and endpoint exactness already recorded by the $\mathsf{Sum}^{\uparrow}$ rows. No consumer receives an additional coproduct eliminator, hidden branch coordinate, host disjoint-union type, or classifier other than the branchwise tagged classifier.

Lean4 ✓ `BEDC.Derived.SumUp.SumUp concrete to schema`

Proof. The public certificate is the one supplied by Definition 35.108. Its carrier consists of histories built by the two visible constructors, so constructor inversion gives the two alternatives $\mathsf{E0}(l)$ and $\mathsf{E1}(r)$ and gives no third endpoint form.

Within a left–left comparison, the tagged classifier in Definition 35.108 projects to the left source classifier; within a right–right comparison, it projects to the right source classifier. The branch exactness statement in Definition 35.93 identifies those projections with the raw visible branch rows exported by the ledger.

For mixed tags, Definition 35.104 applies to the visible ledger row and reduces equality or classifier compatibility of opposite tags to constructor no-confusion. Thus a left endpoint and a right endpoint remain separated in the public reading.

Finally, Definition 35.106 recovers the displayed source payload from each visible endpoint, and Definition 35.100 states that the endpoint readback is exact along the public chain. These rows are exactly the finite two-injection interface described above, so the tagged-payload certificate is a paper bridge to the standard disjoint-sum reading. □

Theorem 35.111 (Sum mature finite consumer boundary)**.** *Every finite consumer of the public* $\mathsf{Sum}^{\uparrow}$ *package factors through the tagged payload carrier, visible tag separation, branch exactness, payload readback, endpoint chain exactness, and the public tagged-payload standard bridge. Such a consumer can inspect only whether the exposed endpoint is an* $\mathsf{E0}$*-tagged left payload or an* $\mathsf{E1}$*-tagged right payload, can read the corresponding source evidence through the ledger rows, and can compare same-tag payloads only through the branch classifier exactness already exported by the certificate.*

This finite boundary excludes eliminators into arbitrary certified targets, dependent sums, and categorical coproduct universal properties. Those structures are not consequences of the tagged-payload package surface; they require additional consumer principles beyond the public $\mathsf{Sum}^{\uparrow}$ *certificate.*

Proof. Start with the public tagged-payload bridge in Theorem 35.110. It identifies the public surface with the two visible injections and rules out any hidden carrier coordinate outside the tagged history endpoint.

The finite consumer's branch observation is then forced by Theorem 35.104; mixed visible tags cannot be read as the same public branch. Same-branch comparisons are governed by Theorem 35.93, which is the raw-visible branch exactness row for the ledger.

Payload access is supplied by Theorem 35.106. Chain-level endpoint soundness is supplied by Theorem 35.100, so repeated finite ledger reads still factor through the same tagged endpoint and its source payload evidence.

Combining these rows leaves exactly the finite tagged-payload consumer surface. Since none of the cited rows constructs an arbitrary-target eliminator, dependent sum, or coproduct universal arrow, those stronger interfaces remain outside the mature finite boundary stated here. □

Theorem 35.112 (Sum finite-data scoped-exit package)**.** *The scoped finite-data exit surface of* $\mathsf{Sum}^{\uparrow}$ *is exactly the package consisting of the tagged semantic certificate of Definition 35.108, the selected visible injection tag, left and right branch exactness, the source ledger rows, visible-history descent through endpoint readback, and the mature finite consumer boundary of Definition 35.111. The selected injection tag is the two-branch finite-choice row already licensed by chapter 32;* $\mathsf{Sum}^{\uparrow}$ *consumes that sibling only as visible tag discipline, while the left and right payload rows remain governed by the local sum carrier and classifier. A consumer exiting the* $\mathsf{Sum}^{\uparrow}$ *chapter through this*

surface may inspect the selected tag, recover the corresponding source payload and source ledger evidence, compare same-tag endpoints through the displayed branch classifier, and replay the visible history descent. It receives no hidden coproduct eliminator, no dependent target recursion, and no classifier beyond the tagged finite-data rows already exported by the semantic certificate.

Proof. Start with the semantic certificate in Definition 35.108. Its carrier is the tagged finite packet, so each public endpoint enters through an $\mathsf{E0}$ or $\mathsf{E1}$ injection rather than through a host coproduct object.

The selected tag is governed by Definition 35.104. The $\mathsf{Bool}^{\uparrow}$ reference supplies only the finite $b0/b1$ tag reading for this visible branch choice; it does not introduce a host coproduct, an eliminator, or an external Boolean equality. The same-tag clauses are governed by Definition 35.93, while visible payload recovery is governed by Definition 35.106 and endpoint descent by Definition 35.100.

Finally apply the consumer boundary in Definition 35.111. It states that every finite consumer factors through exactly these tagged payload, branch exactness, source ledger, and visible-history rows. Therefore the package is a scoped exit surface for finite data rather than a generic coproduct interface. □

Theorem 35.113 (Sum finite-data scoped-exit package)**.** *The scoped finite-data exit surface of* $\mathsf{Sum}^{\uparrow}$ *is exactly the package consisting of the tagged semantic certificate of Definition 35.108, the selected visible injection tag, left and right branch exactness, the source ledger rows, visible-history descent through endpoint readback, and the mature finite consumer boundary of Definition 35.111. The selected injection tag is the two-branch finite-choice row already licensed by chapter 32;* $\mathsf{Sum}^{\uparrow}$ *consumes that sibling only as visible tag discipline, while the left and right payload rows remain governed by the local sum carrier and classifier. A consumer exiting the* $\mathsf{Sum}^{\uparrow}$ *chapter through this surface may inspect the selected tag, recover the corresponding source payload and source ledger evidence, compare same-tag endpoints through the displayed branch classifier, and replay the visible history descent. It receives no hidden coproduct eliminator, no dependent target recursion, and no classifier beyond the tagged finite-data rows already exported by the semantic certificate.*

Proof. Start with the semantic certificate in Definition 35.108. Its carrier is the tagged finite packet, so each public endpoint enters through an $\mathsf{E0}$ or $\mathsf{E1}$ injection rather than through a host coproduct object.

The selected tag is governed by Definition 35.104. The $\mathsf{Bool}^{\uparrow}$ reference supplies only the finite $b0/b1$ tag reading for this visible branch choice; it does not introduce a host coproduct, an eliminator, or an external Boolean equality. The same-tag clauses are governed by Definition 35.93, while visible payload recovery is governed by Definition 35.106 and endpoint descent by Definition 35.100.

Finally apply the consumer boundary in Definition 35.111. It states that every finite consumer factors through exactly these tagged payload, branch exactness, source ledger, and visible-history rows. Therefore the package is a scoped exit surface for finite data rather than a generic coproduct interface. □

Theorem 35.114 (Sum finite-data sibling route)**.** *The scoped finite-data exit surface of* $\mathsf{Sum}^{\uparrow}$ *reads its visible branch tag through the same* $b0/b1$ *discipline licensed by chapter 32. Once that visible tag has selected the left or right branch, the selected payload is carried only through the* $\mathsf{Sum}^{\uparrow}$ *semantic certificate of Definition 35.108 and through the existing branch exactness rows, including the single-valued visible readback of Definition 35.80. Thus the sibling route identifies the finite tag surface consumed by* $\mathsf{Sum}^{\uparrow}$ *without adding a host coproduct eliminator, a hidden branch coordinate, or any classifier beyond the displayed tagged finite-data rows.*

Proof. The semantic certificate of Definition 35.108 supplies the carrier and classifier for the tagged sum packet. Its two public entry forms are the displayed injections $\mathsf{E0}(l)$ and $\mathsf{E1}(r)$, so the branch decision is already a visible finite tag rather than an ambient coproduct object.

The tag discipline is the same two-row $b0/b1$ surface recorded by chapter 32. In the $\mathsf{Sum}^{\uparrow}$ chapter this discipline is consumed only as the selected visible branch. The payload itself remains governed by the left or right source classifier inside the local sum certificate.

Apply the visible readback theorem Definition 35.80. It says that the public history carrier has a single visible branch presentation, so the tag that selects the branch also selects the payload row used downstream. The branch exactness rows then compare only same-tag endpoints through the displayed branch classifier.

Therefore the route from finite tag to payload is a sibling finite-data route: it reads the branch through the BoolUp tag surface and then stays inside the SumUp semantic certificate and ledger rows. No hidden branch coordinate, host eliminator, or additional classifier is supplied. □

Theorem 35.115 (Sum finite-data Option route)**.** *The optional value surface of chapter 33 is the one-sided specialization of the same visible $b0/b1$ tag discipline used by $\mathsf{Sum}^{\uparrow}$. $\mathsf{Option}^{\uparrow}$ contributes the none/some finite tag route, while $\mathsf{Sum}^{\uparrow}$ contributes the two-payload branch classifier through Definition 35.114; neither route exports a host coproduct eliminator or hidden branch coordinate.*

Proof. Project the $\mathsf{Sum}^{\uparrow}$ semantic certificate of Definition 35.108. Its visible branch surface is the pair of displayed tags $\mathsf{E0}(l)$ and $\mathsf{E1}(r)$, and the payload is read only after the tag selects the left or right source classifier.

Compare this with the $\mathsf{Option}^{\uparrow}$ surface of chapter 33. The none/some distinction is a one-sided finite tag route: the none case carries no payload, while the some case carries the single payload behind its visible tag.

Use Definition 35.114. The existing BoolUp $b0/b1$ discipline identifies the shared visible tag layer, so the Option route is a sibling finite-data route rather than a new classifier or hidden branch coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{Sum}^{\uparrow}}$**.**

Constructive story: A sum value is made by choosing one side and marking that choice directly on the payload: a left payload l from L becomes $\mathsf{E0}(l)$, while a right payload r from R becomes $\mathsf{E1}(r)$. Those two tags are part of the history itself, so the classifier first checks that the tags land on the same branch and only then compares the payloads by the left or right source classifier; a b0-tagged left value and a b1-tagged right value never meet. The same tagged-history predicate is the source, the pattern records the left-versus-right split, the two tag forms, and the no-confusion rows, and the ledger keeps each visible sum history aligned with the raw tagged payload that produced it. Because history-equality and the two source-side classifiers are equivalences, the injected witnesses supply the carrier, the branchwise classifier is reflexive, symmetric, and transitive, and classifier-recognized representatives stay inside the same tagged carrier. A history h lies in the signature gap of a $\mathsf{Sum}^{\uparrow}$ token p when the source-domain accepts the tagged history, the signature relation pairs it with an answer history and evidence ledger, and the token-introduction relation names that answer as p; after the tags are inspected, h is either a left injection whose payload matches the left side encoded by p, or a right injection whose payload matches the right side encoded by p. The chapter registers this tagged-payload construction under the name $\mathsf{Sum}^{\uparrow}$; disjoint union is the same b0/b1 choice used at the kernel level, now carrying a payload, with no separate coproduct type, eliminator, or host disjoint-union construct introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Sum}^{\uparrow}}$, maturePackageClosed)

Scope closed: The public paper scope binds the tagged sum semantic certificate, selected injection tag, left and right branch classifier exactness, source ledger, visible-history descent, licensed public surface, mature finite consumer boundary, scoped finite-data exit package, and finite-data sibling route in Definition 35.114.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Sum}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.SumUp.sum\_history\_semantic\_name\_certificate`

Bridge status: bridgeChecked

Not claimed: Full sum or coproduct theory: eliminators into arbitrary certified targets, dependent sums, categorical coproduct universal property, distributivity laws, or generic case recursion.

Upgrade path: No further upgrade: chapter is at the top of the formal bridge axis.

Theorem 35.116 (Sum finite-data sibling dependency route)**.** *Every scoped finite-data consumer of* $\mathsf{Sum}^{\uparrow}$ *first reads the visible branch tag through the* $b0/b1$ *branch-mark surface of chapter 32, and only then reads the selected payload from the local* $\mathsf{Sum}^{\uparrow}$ *branch ledger. Its payload packaging is compared with the paired-carrier route of chapter 34:* $\mathsf{Prod}^{\uparrow}$ *keeps both coordinates simultaneously, while* $\mathsf{Sum}^{\uparrow}$ *exposes exactly one branch after the Boolean tag has selected it.*

Proof. Project the accepted $\mathsf{Sum}^{\uparrow}$ certificate. The carrier visible at Definition 35.108 contains a tag row and one payload row, so the consumer cannot inspect a left or right payload before the tag has been read.

The tag is the same finite branch surface used by $\mathsf{Bool}^{\uparrow}$. It contributes only the two visible marks $b0$ and $b1$; it does not add a host eliminator, ambient Boolean equality, or hidden branch coordinate.

Compare this with $\mathsf{Prod}^{\uparrow}$. The product route keeps both payload coordinates under one paired carrier, while the sum route keeps one payload behind a visible tag. Thus the sibling dependency is finite and explicit: $\mathsf{Bool}^{\uparrow}$ supplies the branch mark, $\mathsf{Prod}^{\uparrow}$ supplies the paired-carrier comparison, and $\mathsf{Sum}^{\uparrow}$ retains its own tagged payload certificate. □

Theorem 35.117 (Sum public branch-disjointness route)**.** *Every public* $\mathsf{Sum}^{\uparrow}$ *branch read factors through the visible tag exactness, branch exclusivity, left and right tag inversion, same-tag exactness, and the* $\mathsf{Bool}^{\uparrow}$ *finite discriminator route. A left-branch read exposes only a displayed* $\mathsf{E0}$ *tag together with its left payload classifier row; a right-branch read exposes only a displayed* $\mathsf{E1}$ *tag together with its right payload classifier row. No public consumer can read a left payload as a right payload or read a right payload as a left payload.*

Proof. Start with carrier branch exclusivity from Definition 35.3. It prevents a single displayed sum history from carrying both a left presentation and a right presentation, so a public branch read must choose one visible tag surface.

For same-tag reads, apply the left and right tag inversion theorems Definition 35.13 and Definition 35.14, together with Definition 35.15. These identify the payload classifier only inside the branch selected by the visible tag.

For mixed-tag reads, use Definition 35.41 and Definition 35.42. The finite discriminator supplied by $\mathsf{Bool}^{\uparrow}$ in Definition 32.63 and Definition 32.83 is therefore only a displayed left/right endpoint row; it cannot export the opposite payload carrier or classifier. Thus the public route is branch-disjoint. □

Chapter 36

A Concrete Naming Certificate for $\mathsf{List}^{\uparrow}$

The list interface $\mathsf{List}^{\uparrow}$ is licensed over a source carrier endowed with a $\mathsf{NameCert}$ and a spine-representation coherence witness. The carrier is the inductive sequence built from a nil constructor and a cons constructor consuming one source witness and one shorter list. The classifier is structural sameness lifted from the source classifier through finite spines: nil-with-nil and cons-with-cons under componentwise sameness. It is not a primitive sequence type; it is licensed only as a derived inductive over the source under this coherence datum.

The $\mathsf{List}^{\uparrow}$ spine consumes the constructor-tag and product-envelope surfaces of chapter 32, chapter 33, chapter 35, and chapter 34 before exporting the finite list carrier.

36.1 Roadmap template status

1. **Traditional target**: finite lists over a source object.
2. **BEDC source**: one licensed source carrier A with its name certificate.
3. **Carrier choice**: the carrier is generated by nil and $\mathsf{cons}(a, xs)$.
4. **Classifier choice**: $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{S,\sim_S}$ is the paper-side generated relation on BEDC histories, relating nil endpoints to nil endpoints and cons endpoints to cons endpoints by source head classification, recursive tail classification, and continuation witnesses. The certificate classifier is the spine-representation classifier from Definition 36.57, linked to the generated relation by Theorem 36.61 and used for the semantic certificate under $\mathsf{ListSpineRepCoherent}_{S,\sim_S}$; the finite-spine helper $\mathsf{ListClassifierSpec}$ remains the checked structural model.
5. **Stability obligations**: structural symmetry from the source $\mathsf{NameCert}$, structural transitivity, list-carrier transport, nil/cons separation, map stability, append stability, reverse stability, and cancellation facts.
6. **Ledger**: list length and constructor shape remain visible; payload classification is delegated to the source certificate.
7. **Core theorem list**: history carrier case analysis, history classifier constructor exactness, list spine representation coverage, classifier transitivity, classifier symmetry from the source $\mathsf{NameCert}$, cons inversion, singleton equivalence, map stability, append stability, source-parametric

left, right, and context cancellation, reverse stability, checked hsame length preservation, represented-spine classifier alignment of Theorem 36.144, and the paper-side source-parametric length preservation of Theorem 36.31.

8. **Exactness predicate**: classification holds exactly when there exist finite spines xs, ys such that $\mathsf{ListSpineRep}_A(h, xs)$, $\mathsf{ListSpineRep}_A(k, ys)$, and $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$ hold; $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$ makes alternate presentations of the same endpoint compatible for certificate use.

9. **Standard bridge**: the generated carrier reads back through $\mathsf{ListSpineRep}_A$ under $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$; ordinary finite list syntax is the finite-spine presentation witness, not exported carrier equality or a quotient.

10. **Status**: three certificate scopes are kept separate. Theorem 36.68 is the Phase Finite Data unframed public-object ProofTarget for $\mathsf{List}^{\uparrow}$ under $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$. Theorem 36.163 is the cons-boundary route to that same public ProofTarget when $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$ is supplied. Corollary 36.128 is a separate framed carrier certificate under source-carrier hsame compatibility and does not close the unframed public $\mathsf{List}^{\uparrow}$ scope. The finite-spine classifier field inventory is recorded in Definition 36.32, while Theorem 36.31 records only source-parametric length preservation.

36.2 Carrier definition

Definition 36.1 (List finite-spine carrier)**.** *For a source type A,* $\mathsf{ListCarrier}(A)$ *denotes the finite-spine helper with entries of type A;* ListClassifierSpec *uses this helper for structural nil/cons reasoning. The exported BEDC public history carrier is* $\mathsf{ListHistoryCarrier}_S$ *in Definition 36.3.*

36.3 The certificate

Definition 36.2 (List source specification)**.** *The source is finite generated sequencing over the source certificate for A.*

Definition 36.3 (List history carrier)**.** *For a source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$, define* $\mathsf{ListHistoryCarrier}_S(h)$ *as the least history predicate generated by two clauses:*

1. *nil: if* $\mathsf{hsame}(h, \mathsf{e})$*, then* $\mathsf{ListHistoryCarrier}_S(h)$*;*
2. *cons: if there are histories a, t, p with $S(a)$,* $\mathsf{ListHistoryCarrier}_S(t)$*,* $\mathsf{Cont}(a, t, p)$*, and* $\mathsf{hsame}(h, \mathsf{E1}(p))$*, then* $\mathsf{ListHistoryCarrier}_S(h)$*.*

Lean4 (definition) `BEDC.Derived.ListUp.ListHistoryCarrier`

Definition 36.4 (List recursive history classifier)**.** *For a source carrier $S : \mathsf{BHist} \to \mathsf{Prop}$ and source classifier $\sim_S : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$, define* $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{S,\sim_S}(h, k)$ *as the least relation generated by two clauses:*

1. *nil-nil: if* $\mathsf{hsame}(h, \mathsf{e})$ *and* $\mathsf{hsame}(k, \mathsf{e})$*, then* $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{S,\sim_S}(h, k)$*;*
2. *cons-cons: if there are histories a, b, t, u, p, q such that $S(a)$, $S(b)$, $a \sim_S b$,* $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{S,\sim_S}(t, u)$*,* $\mathsf{Cont}(a, t, p)$*,* $\mathsf{Cont}(b, u, q)$*,* $\mathsf{hsame}(h, \mathsf{E1}(p))$*, and* $\mathsf{hsame}(k, \mathsf{E1}(q))$*, then* $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{S,\sim_S}(h, k)$*.*

Lean4 (definition) `BEDC.Derived.ListUp.ListHistoryClassifierRec`
Lean4 (definition) `BEDC.Derived.ListUp.ListHistoryClassifier`

Theorem 36.5 (List recursive history classifier carrier endpoints)**.** *For any source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and source classifier* $\sim_S$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$*, if* $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{S,\sim_S}(h,k)$ *holds, then both* $\mathsf{ListHistoryCarrier}_S(h)$ *and* $\mathsf{ListHistoryCarrier}_S(k)$ *hold.*

Proof. Induct on the displayed classifier witness. In the nil-nil clause, the two endpoint witnesses rebuild the nil clause of $\mathsf{ListHistoryCarrier}_S$ on both sides. In the cons-cons clause, the induction hypothesis gives carrier witnesses for the two tails t and u; combine those with the source carrier witnesses $S(a)$ and $S(b)$, the continuation witnesses $\mathsf{Cont}(a,t,p)$ and $\mathsf{Cont}(b,u,q)$, and the endpoint witnesses $\mathsf{hsame}(h,\mathsf{E1}(p))$ and $\mathsf{hsame}(k,\mathsf{E1}(q))$ to rebuild the two cons carrier clauses. □

Lean4 ✓ `BEDC.Derived.ListUp.ListHistoryClassifierRec carrier endpoints`
Lean4 ✓ `BEDC.Derived.ListUp.ListHistoryClassifier carrier endpoints`

Theorem 36.6 (List recursive history classifier constructor exactness)**.** *For any source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, source classifier* $\sim_S$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$*, and histories* h, k*, the recursive classifier is exactly the constructor disjunction*

$$\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{S,\sim_S}(h,k) \iff (\mathsf{hsame}(h,\mathsf{e}) \wedge \mathsf{hsame}(k,\mathsf{e})) \vee \exists a\, b\, t\, u\, p\, q.\ S(a) \wedge S(b) \wedge a \sim_S b \wedge \mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{S,\sim}$$

Proof. For the forward implication, induct on the generated classifier witness. The nil-nil constructor gives the left disjunct, and the cons-cons constructor gives the right disjunct with its source head witnesses, recursive tail-classifier witness, continuation witnesses, and visible $e1$ endpoint witnesses. For the reverse implication, the left disjunct is exactly the nil-nil generation clause, and the right disjunct is exactly the cons-cons generation clause. Mixed nil/cons endpoint claims reduce to BEDC history no-confusion: `not_hsame_emp_e1` eliminates nil against cons, and `not_hsame_e1_empty` eliminates cons against nil. □

Theorem 36.7 (List history carrier generated cases)**.** *For any source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and any history* h*, if* $\mathsf{ListHistoryCarrier}_S(h)$*, then either* $\mathsf{hsame}(h,\mathsf{e})$*, or there exist histories* a, t, p *such that* $S(a)$*,* $\mathsf{ListHistoryCarrier}_S(t)$*,* $\mathsf{Cont}(a,t,p)$*, and* $\mathsf{hsame}(h,\mathsf{E1}(p))$*.*

Proof. Apply the induction principle for the least predicate displayed in the preceding definition. The nil constructor gives the left disjunct directly. The cons constructor exposes its witnesses a, t, p together with $S(a)$, the recursive carrier witness for t, the continuation witness $\mathsf{Cont}(a,t,p)$, and the endpoint witness $\mathsf{hsame}(h,\mathsf{E1}(p))$, which are exactly the data required for the right disjunct. □

Lean4 ✓ `BEDC.Derived.ListUp.ListHistoryCarrier generated cases`

Theorem 36.8 (List history carrier transport)**.** *For any source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, if* $\mathsf{hsame}(h,k)$ *and* $\mathsf{ListHistoryCarrier}_S(h)$*, then* $\mathsf{ListHistoryCarrier}_S(k)$*.*

Proof. Proceed by cases on the displayed generation of $\mathsf{ListHistoryCarrier}_S(h)$. In the nil case, compose the symmetry of $\mathsf{hsame}(h,k)$ with the endpoint witness $\mathsf{hsame}(h,\mathsf{e})$ to obtain $\mathsf{hsame}(k,\mathsf{e})$, then use the nil clause. In the cons case, keep the witnesses a, t, p, the source witness $S(a)$, the recursive carrier witness for t, and the continuation witness $\mathsf{Cont}(a,t,p)$. Compose the symmetry of $\mathsf{hsame}(h,k)$ with the endpoint witness $\mathsf{hsame}(h,\mathsf{E1}(p))$ to obtain $\mathsf{hsame}(k,\mathsf{E1}(p))$, then rebuild the cons clause for k. □

Theorem 36.9 (List recursive history classifier reflexivity, symmetry, and endpoint exposure from a source certificate)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*. The generated classifier* $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}$ *records the following recursive classifier fields here, rather than the entire certificate stability block:*

1. *if* $\mathsf{ListHistoryCarrier}_A(h)$ *holds, then* $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}(h,h)$ *holds;*
2. *if* $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}(h,k)$ *holds, then* $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}(k,h)$ *holds;*
3. *if* $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}(h,k)$ *holds, then both* $\mathsf{ListHistoryCarrier}_A(h)$ *and* $\mathsf{ListHistoryCarrier}_A(k)$ *hold.*

Lean4 ✓ `BEDC.Derived.ListUp.ListHistoryClassifierRec equivalence fields`

Proof. For reflexivity, induct on the displayed generation of $\mathsf{ListHistoryCarrier}_A(h)$. The nil clause is rebuilt from hsame reflexivity and the given endpoint link. In the cons clause, the source certificate supplies head reflexivity from the head carrier witness, the induction hypothesis supplies tail reflexivity, and the stored Cont witness and endpoint hsame link rebuild the cons-cons classifier clause. For endpoint membership, induct on the displayed generation of $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}(h,k)$. The nil-nil clause rebuilds two nil carrier witnesses. The cons-cons clause combines the two source carrier witnesses, the induction hypotheses for the two tails, the two Cont witnesses, and the two endpoint hsame links to rebuild both cons carrier witnesses. For symmetry, induct on the classifier generation. The nil-nil case swaps the two endpoint hsame witnesses. The cons-cons case uses the symmetry field of cert on the head classifier witness, applies the induction hypothesis to the tail classifier witness, swaps the two Cont witnesses and endpoint links, and rebuilds the cons-cons clause. □

Transitivity for the certificate classifier is the separate spine-coherent result Theorem 36.63.

Definition 36.10 (List pattern specification)**.** *The pattern is nil-or-cons generation with structurally smaller tail.*

Definition 36.11 (List history pattern)**.** *For a source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*, the predicate* $\mathsf{ListHistoryPattern}_S(h)$ *holds when* h *has the visible BEDC shape of a list endpoint: either* $\mathsf{hsame}(h,\mathsf{e})$*, or there are histories* a,t,p *with* $S(a)$*,* $\mathsf{ListHistoryCarrier}_S(t)$*,* $\mathsf{Cont}(a,t,p)$*, and* $\mathsf{hsame}(h,\mathsf{E1}(p))$*.*

Definition 36.12 (List classifier specification)**.** *The finite-spine helper classifier relates nil with nil and cons with cons when heads are source-classified the same and tails are list-classified the same.*

Lean4 (definition) `BEDC.Derived.ListUp.ListClassifierSpec`

Theorem 36.13 (List classifier case exactness)**.** *For any source relation* sameA *on* A *and any finite spines* $xs, ys : \mathsf{ListCarrier}(A)$*,* $\mathsf{ListClassifierSpec}(\mathsf{sameA}, xs, ys)$ *holds exactly in the matching constructor cases: both spines are* nil*, or both spines are* cons *spines with a source-head witness* $\mathsf{sameA}(a,b)$ *and a recursive tail witness* $\mathsf{ListClassifierSpec}(\mathsf{sameA}, xs', ys')$*. It is false for the mixed shapes* nil *against* $\mathsf{cons}(b, ys')$ *and* $\mathsf{cons}(a, xs')$ *against* nil*.*

Proof. Case-analyze the two finite-spine constructors. In the nil-nil case the classifier is the nil clause. In the cons-cons case the classifier unfolds to its head source witness together with the recursive tail classifier witness, and conversely those two witnesses rebuild the cons classifier clause. The nil-cons and cons-nil cases have no classifier clause, so any assumed witness is eliminated by constructor case analysis. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec case exactness`

Lemma 36.14 (List classifier nil-cons no-confusion)**.** *For any source classifier on A,* ListClassifierSpec *never relates* nil *to* $\mathsf{cons}(a, xs)$*, and never relates* $\mathsf{cons}(a, xs)$ *to* nil*.*

Proof. Unfold the structural classifier by list constructors. The only nil clause is the nil-nil clause, and the only cons clause is the cons-cons clause. The two mixed constructor shapes therefore have no classifier constructor, so both directions are discharged directly by case analysis on the impossible witness. □

Theorem 36.15 (List classifier is transitive)**.** *For any source type A, relation $R : A \to A \to \mathsf{Prop}$, and finite spines $xs, ys, zs : \mathsf{ListCarrier}(A)$, if $\forall a\, b\, c.\ R(a, b) \to R(b, c) \to R(a, c)$,* $\mathsf{ListClassifierSpec}(R, xs, ys)$*, and* $\mathsf{ListClassifierSpec}(R, ys, zs)$ *hold, then* $\mathsf{ListClassifierSpec}(R, xs, zs)$ *holds.*

Proof. Induct on the first finite spine. Shape mismatches are impossible by the classifier clauses. In the cons-cons-cons case, the head witnesses compose by source transitivity and the tail witnesses compose by the induction hypothesis. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec trans`

Theorem 36.16 (History list classifier is transitive)**.** *For lists of finite-kernel histories, if the structural list classifier relates x to y and y to z using* hsame *on heads, then it relates x to z.*

Proof. Induct on the first list. The nil and cons shape mismatches are impossible by the classifier clauses. In the cons-cons-cons case, head witnesses compose by transitivity of hsame, and the tail witnesses compose by the induction hypothesis. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame trans`

Theorem 36.17 (History list classifier is symmetric)**.** *For lists of finite-kernel histories, if the structural list classifier relates x to y using* hsame *on heads, then it relates y to x.*

Proof. Induct on the first list. Shape mismatches are impossible by the classifier clauses. In the cons-cons case, head witnesses reverse by symmetry of hsame, and tail witnesses reverse by the induction hypothesis. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame symm`

Theorem 36.18 (History list classifier cons inversion)**.** *For BEDC histories x, y and history-list tails xs, ys, if* $\mathsf{ListClassifierSpec}(\mathsf{hsame}, x :: xs, y :: ys)$ *holds, then* $\mathsf{hsame}(x, y)$ *and* $\mathsf{ListClassifierSpec}(\mathsf{hsame}, xs, ys)$ *hold.*

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame cons inversion`

Proof. Unfold the cons-cons classifier clause and read off its source-head and recursive-tail components. □

Theorem 36.19 (History list classifier one-headed tail transport)**.** *For BEDC histories x, y and history-list tails xs, ys, zs, if* $\mathsf{ListClassifierSpec}(\mathsf{hsame}, xs, zs)$ *and* $\mathsf{ListClassifierSpec}(\mathsf{hsame}, \mathsf{E1}(x) :: xs, \mathsf{E1}(y) :: ys)$ *hold, then*

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, \mathsf{E1}(x) :: zs, \mathsf{E1}(y) :: ys)$$

holds.

Proof. Invert the one-headed cons classifier to read off the head comparison $\mathsf{hsame}(\mathsf{E1}(x), \mathsf{E1}(y))$ and the tail classifier from xs to ys. Reverse the classifier from xs to zs and compose it with the tail classifier by history-list transitivity. Reattach the unchanged head comparison by the cons clause. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame e1 cons tail transport`

Theorem 36.20 (Bool-sourced list classifier cons mark readback)**.** *For histories h, k : BHist and finite spines xs, ys, if* $\mathsf{ListClassifierSpec}(\mathsf{BoolHistoryClassifier}, h :: xs, k :: ys)$ *holds, then*

$$(\exists v, w : \mathsf{BMark}.\ \mathsf{hsame}(h, \mathsf{BoolEndpoint}(v)) \wedge \mathsf{hsame}(k, \mathsf{BoolEndpoint}(w)) \wedge \mathsf{msame}(v, w)) \wedge \mathsf{ListClassifierSpec}(\mathsf{BoolHisto}$$

Proof. Invert the cons clause of ListClassifierSpec to obtain the head classifier $\mathsf{BoolHistoryClassifier}(h, k)$ and the recursive tail classifier $\mathsf{ListClassifierSpec}(\mathsf{BoolHistoryClassifier}, xs, ys)$.

Apply Theorem 32.12 to the head classifier. The forward direction supplies endpoints v, w with the two hsame readbacks and $\mathsf{msame}(v, w)$.

Package these endpoint readbacks, mark sameness, and the tail classifier into the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec BoolHistoryClassifier cons mark readback`

Theorem 36.21 (History list classifier singleton equivalence)**.** *For BEDC history singleton lists, structural classification by* hsame *is equivalent to* hsame *of the two displayed histories.*

Proof. Unfold the singleton cons-cons classifier shape. The forward direction keeps the head hsame witness; the reverse direction pairs that head witness with the nil-tail classifier clause. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame singleton iff`

Theorem 36.22 (History list classifier head transport)**.** *For BEDC history lists, if y is internally the same history as z and the structural classifier relates $x :: xs$ to $y :: ys$, then the structural classifier also relates $x :: xs$ to $z :: ys$.*

Proof. Eliminate the cons-cons classifier witness. Compose its head witness $\mathsf{hsame}(x, y)$ with the replacement witness $\mathsf{hsame}(y, z)$, and keep the tail classifier witness unchanged. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame cons head transport`

Theorem 36.23 (List classifier stability under certified entry descent)**.** *Let R, T : BHist $\to$ BHist $\to$ Prop be BEDC history classifiers, and let* cert : $\mathsf{DescentCertificate}(\mathsf{BHist}, \mathsf{BHist}, R, T)$. *If* $\mathsf{ListClassifierSpec}(R, xs, ys)$ *holds, then* $\mathsf{ListClassifierSpec}(T, \mathsf{map}(\mathsf{cert.map}, xs), \mathsf{map}(\mathsf{cert.map}, ys))$ *holds.*

Proof. Induct on the finite list-classifier witness. The nil witness maps to the nil classifier clause. In the cons-cons case, apply descentCertificate_respects to the head witness for cert.map and use the induction hypothesis on the tail witness, then rebuild the cons-cons ListClassifierSpec clause for the mapped lists. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec descentCertificate map`

Theorem 36.24 (History list classifier is stable under $e0$-mapping)**.** *For BEDC history lists, structural classification by* hsame *is preserved when every entry of both lists is mapped through the $e0$ history constructor.*

Proof. Induct on the first list. Nil and cons shape mismatches are impossible by the classifier clauses. In the cons-cons case, apply $e0$-congruence of hsame to the heads and apply the induction hypothesis to the classified tails. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame map e0`

Theorem 36.25 (History list classifier reflects $e0$-mapping)**.** *For BEDC history lists, if the lists obtained by mapping every entry through the $e0$ history constructor are structurally classified by* hsame*, then the original lists are structurally classified by* hsame*.*

Proof. Induct on the first list. Nil and cons shape mismatches are impossible by the classifier clauses. In the cons-cons case, invert the mapped head witness using the $e0$ constructor characterization for hsame, then apply the induction hypothesis to the mapped-tail classifier witness. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame map e0 inversion`

Theorem 36.26 (History list classifier is stable under $e1$-mapping)**.** *For BEDC history lists, structural classification by* hsame *is preserved when every entry of both lists is mapped through the $e1$ history constructor.*

Proof. Induct on the first list. Nil and cons shape mismatches are impossible by the classifier clauses. In the cons-cons case, apply $e1$-congruence of hsame to the heads and apply the induction hypothesis to the classified tails. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame map e1`

Theorem 36.27 (History list classifier reflects $e1$-mapping)**.** *For BEDC history lists, if the lists obtained by mapping every entry through the $e1$ history constructor are structurally classified by* hsame*, then the original lists are structurally classified by* hsame*.*

Proof. Induct on the first list. Nil and cons shape mismatches are impossible by the classifier clauses. In the cons-cons case, invert the mapped head witness using the $e1$ constructor characterization for hsame, then apply the induction hypothesis to the mapped-tail classifier witness. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame map e1 inversion`

Theorem 36.28 (History list classifier constructor-map embeddings)**.** *For BEDC history lists xs and ys, structural classification by* hsame *is equivalent to structural classification after mapping both lists through the $e0$ history constructor, and likewise equivalent to structural classification after mapping both lists through the $e1$ history constructor.*

Proof. For the $e0$ equivalence, the forward implication is exactly the checked preservation theorem for $e0$-mapping, and the reverse implication is exactly the checked $e0$-mapping inversion theorem. The $e1$ equivalence is obtained in the same way from the checked preservation theorem for $e1$-mapping and the checked $e1$-mapping inversion theorem. Thus each BEDC history constructor preserves and reflects the list classifier, giving a classifier embedding in both constructor-map cases. □

Theorem 36.29 (History list classifier separates mixed mapped tags)**.** *For BEDC history lists, if the list obtained by mapping every entry of x through $e0$ is structurally classified by* hsame *with the list obtained by mapping every entry of y through $e1$, then x and y are both empty.*

Proof. Split both lists by constructors. The nil-nil case is immediate. Nil-cons and cons-nil cases contradict the structural classifier clauses. In the cons-cons case, the head witness would relate an $e0$-tagged history to an $e1$-tagged history, contradicting BEDC history constructor separation. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame map e0 map e1 empty`

Theorem 36.30 (History list classifier preserves length)**.** *For lists of finite-kernel histories, structural classification by* hsame *can only relate lists with equal length.*

Proof. Induct on the first list. Nil can only classify with nil. In the cons case, classifier inversion forces the second list to be cons, and the induction hypothesis gives equality of the tail lengths. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame length eq`

Theorem 36.31 (List classifier preserves length)**.** *For finite-spine presentation witnesses only, write $\ell(xs)$ for their meta-level finite length; this notation is neither a* $\mathsf{Nat}^{\uparrow}$ *operation nor a certificate field. For any source type A, any source relation $sameA : A \to A \to \mathsf{Prop}$, and finite spines $xs, ys : \mathsf{ListCarrier}(A)$, if* $\mathsf{ListClassifierSpec}(sameA, xs, ys)$ *holds, then*

$$\ell(xs) = \ell(ys).$$

Proof. Induct on the first list spine. The nil case can classify only against nil by the mixed-shape clauses of ListClassifierSpec. In the cons case, the classifier can classify only against a cons spine; its tail witness is again a ListClassifierSpec witness for entries related by $sameA$. The induction hypothesis gives equality of tail lengths, and the two cons lengths are equal. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec length eq`

Definition 36.32 (Finite-spine helper stability certificate)**.** *The checked finite-spine fields recorded in this chapter are the marked* ListClassifierSpec *facts: reflexivity, symmetry, source-certificate transitivity, nil/cons separation with cons inversion, constructor-map preservation/reflection with mixed-tag separation, append stability, checked* hsame *left and right cancellation, reverse stability with reverse inversion, and checked* hsame *length preservation. Reverse equivalence, source-parametric left, right, and context cancellation, source-certificate symmetry, source-certificate carrier transport, and source-parametric length preservation are paper-side composite targets built from these checked fields. The public generated-history* $\mathsf{List}^{\uparrow}$ *certificate is obtained only through* ListSpineRep*,* ListSpineBridgeClassifier*,* ListSpineRepCoherent*, and Theorem 36.68.*

Theorem 36.33 (List classifier reflexivity)**.** *If the source classifier is reflexive on A, then* ListClassifierSpec *is reflexive on finite list spines over A.*

Lean4 ✓ `BEDC.Derived.ListUp.list stability reflexive by induction`

Proof. Induct on the finite list spine. The nil spine is classified by the nil clause. In the cons spine, source reflexivity classifies the head and the induction hypothesis classifies the tail. □

Theorem 36.34 (List classifier stability under append)**.** *For any source entry type A, source classifier $sameA : A \to A \to \mathsf{Prop}$, and finite list spines xs, ys, zs, and ws, if* $\mathsf{ListClassifierSpec}(sameA, xs, ys)$ *and* $\mathsf{ListClassifierSpec}(sameA, zs, ws)$ *hold, then* $\mathsf{ListClassifierSpec}(sameA, xs{+}{+}zs, ys{+}{+}ws)$ *holds.*

Proof. Induct on the first classifier witness. The nil clause returns the second classifier witness. In the cons clause, keep the head classifier witness and apply the induction hypothesis to the tail classifier witness and the second classifier witness, then rebuild the cons classifier clause. □

Theorem 36.35 (List classifier stability under append for histories)**.** *For BEDC histories, if two list pairs are structurally classified by* hsame*, then appending the first components and appending the second components preserves structural classification.*

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec append hsame`

Proof. This is the BEDC-history specialization of Theorem 36.34, with the source entry type specialized to BHist and *sameA* specialized to hsame. The empty and cons clauses are exactly the two clauses of the source-parametric append proof. □

Theorem 36.36 (History list classifier left append cancellation)**.** *For BEDC history lists, structural classification of $p{+}{+}x$ with $p{+}{+}y$ using* hsame *on heads determines structural classification of x with y.*

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame append left cancel`

Proof. Induct on the common prefix p. The empty-prefix case is the given classification. In the cons-prefix case, invert the structural classifier and apply the induction hypothesis to the classified tails. □

Theorem 36.37 (Classified list prefix cancellation)**.** *For BEDC history lists, if p and p' are structurally classified by* hsame*, and $p{+}{+}x$ is structurally classified with $p'{+}{+}y$, then x is structurally classified with y.*

Proof. Induct on p. The empty case forces p' to be empty by the prefix classifier, leaving the appended classifier. In the cons case, the prefix classifier and appended classifier both expose matching classified tails, and the induction hypothesis applies to those tails. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame append left cancel classified`

Theorem 36.38 (List classifier stability under reverse)**.** *For BEDC history lists, structural classification by* hsame *is preserved when both lists are reversed.*

Proof. Induct on the first list. Shape mismatches are impossible by the classifier clauses. In the cons-cons case, reverse turns each list into the reversed tail followed by a singleton head; the induction hypothesis handles the tails and append stability combines it with the head witness. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec reverse hsame`

Theorem 36.39 (Source-parametric list classifier stability under reverse)**.** *For any source type A, source relation $\sim_A : A \to A \to \mathsf{Prop}$, and finite spines $xs, ys : \mathsf{ListCarrier}(A)$, $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$ implies $\mathsf{ListClassifierSpec}(\sim_A, \mathsf{reverse}(xs), \mathsf{reverse}(ys))$.*

Proof. Induct on the first spine and case-analyze the second. Mixed shapes are impossible by the classifier clauses. In the cons-cons case, reverse writes both spines as reversed tails followed by singleton heads; the induction hypothesis classifies the reversed tails, and append stability combines that tail witness with the singleton head classifier witness. □

Theorem 36.40 (List classifier reverse inversion)**.** *For BEDC history lists, if the reversed lists are structurally classified by* hsame*, then the original lists are structurally classified by* hsame*.*

Proof. Apply reverse stability to the classified reversed lists, obtaining a classifier on $\mathsf{reverse}(\mathsf{reverse}(xs))$ and $\mathsf{reverse}(\mathsf{reverse}(ys))$. For each finite spine, prove the reverse-reverse identity by induction, using append associativity and append-nil at the cons step. Rewrite both endpoints along those two identities to recover $\mathsf{ListClassifierSpec}(\mathsf{hsame}, xs, ys)$. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec reverse hsame inversion`

Theorem 36.41 (Source-parametric list classifier reverse equivalence)**.** *For any source type A, source relation $\sim_A : A \to A \to \mathsf{Prop}$, and finite spines $xs, ys : \mathsf{ListCarrier}(A)$, list classification by $\sim_A$ is equivalent before and after reversing both spines:*

$$\mathsf{ListClassifierSpec}(\sim_A, xs, ys) \iff \mathsf{ListClassifierSpec}(\sim_A, \mathsf{reverse}(xs), \mathsf{reverse}(ys)).$$

Proof. The forward direction is Theorem 36.39.

For the reverse direction, apply the same source-parametric reverse stability to the classified reversed spines. This gives a classifier on $\mathsf{reverse}(\mathsf{reverse}(xs))$ and $\mathsf{reverse}(\mathsf{reverse}(ys))$. Reverse-involutivity of finite spines identifies these endpoints with xs and ys, yielding $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec reverse iff`

Theorem 36.42 (List classifier append right cancellation)**.** *For BEDC history lists, if adding the same right suffix to two lists gives a structural* hsame*-classification, then the original lists are structurally classified.*

Proof. Reverse the classified append witnesses. The common right suffix becomes a common left prefix, so left-append cancellation removes it. Reversing the remaining classifier witness returns the original list order. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec append right cancel hsame`

Theorem 36.43 (List classifier right cancellation with equivalent suffixes)**.** *For BEDC history lists, if two right suffixes are structurally classified by* hsame*, and appending those suffixes to x and y gives a structural* hsame*-classification, then x and y are structurally classified.*

Proof. Use symmetry on the suffix classifier and append stability with reflexivity on the left list y to classify $y{+}{+}suffix'$ with $y{+}{+}suffix$. Transitivity aligns the appended classification to a common right suffix, and ordinary right-append cancellation removes it. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec append right cancel with hsame suffix`

Theorem 36.44 (List classifier two-sided cancellation with classified boundaries)**.** *For BEDC history lists p, p', x, y, s, and s', if*

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p, p'), \quad \mathsf{ListClassifierSpec}(\mathsf{hsame}, s, s'), \quad \mathsf{ListClassifierSpec}(\mathsf{hsame}, p{+}{+}x{+}{+}s, p'{+}{+}y{+}{+}s')$$

hold, then $\mathsf{ListClassifierSpec}(\mathsf{hsame}, x, y)$ *holds.*

Proof. Reassociate both appended histories as $(p{+}{+}x){+}{+}s$ and $(p'{+}{+}y){+}{+}s'$. Apply right cancellation with the classified suffixes to obtain $\mathsf{ListClassifierSpec}(\mathsf{hsame}, p{+}{+}x, p'{+}{+}y)$. Then apply classified left cancellation with the classified prefixes p and p' to obtain $\mathsf{ListClassifierSpec}(\mathsf{hsame}, x, y)$. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame append boundary cancel`

Theorem 36.45 (List classifier classified append context equivalence)**.** *For BEDC history lists p, p', x, y, s, and s', if the prefix contexts p and p' are structurally classified by* hsame *and the suffix contexts s and s' are structurally classified by* hsame*, then*

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, x, y) \quad \textit{if and only if} \quad \mathsf{ListClassifierSpec}(\mathsf{hsame}, p{+}{+}x{+}{+}s, p'{+}{+}y{+}{+}s')$$

holds.

Proof. For the forward direction, apply append stability first to the classified prefixes and middle lists, obtaining a classification of $p{+}{+}x$ with $p'{+}{+}y$, and then apply append stability again with the classified suffixes. For the reverse direction, apply the preceding two-sided cancellation theorem to the classified bordered histories, the classified prefixes, and the classified suffixes. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame append context iff`

Theorem 36.46 (List classifier transitivity from a source certificate)**.** *If the source classifier is supplied by a* NameCert*, then the lifted list classifier is transitive on finite list spines.*

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec trans from nameCert`

Proof. Proceed by induction on the first list. The nil case forces the middle list to be nil, then the final list is nil. In the cons case, nil/cons mismatches are impossible by classifier inversion. For matching cons constructors, transitivity of the source certificate handles the heads and the induction hypothesis handles the tails. □

Theorem 36.47 (List classifier symmetry from a source certificate)**.** *For a BEDC history carrier A : $\mathsf{BHist} \to \mathsf{Prop}$, source classifier $\sim_A$, and source certificate* cert : $\mathsf{NameCert}(A, \sim_A)$*, if* $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$ *holds for finite list spines xs and ys, then* $\mathsf{ListClassifierSpec}(\sim_A, ys, xs)$ *holds.*

Proof. Induct on the structural list-classifier witness. The nil clause reverses to nil. In the cons clause, apply cert.equiv_symm to the head witness and apply the induction hypothesis to the tail witness; the cons constructor of the lifted classifier rebuilds the reversed structural witness. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec symm from nameCert`

Theorem 36.48 (List carrier transport from a source certificate)**.** *Let C : $\mathsf{BHist} \to \mathsf{Prop}$ be a source carrier predicate, let $\sim_C$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ be a source classifier, and assume* cert : $\mathsf{NameCert}(C, \sim_C)$*. For finite BEDC-history spines xs, ys :* $\mathsf{ListCarrier}(\mathsf{BHist})$*, if every entry of xs satisfies C and* $\mathsf{ListClassifierSpec}(\sim_C, xs, ys)$ *holds, then every entry of ys satisfies C.*

Proof. Induct on the structural classifier derivation. The nil clause has no entries to transport. In the cons clause, the source certificate field NameCert.carrier_respects_equiv transports the head carrier witness across the head classifier witness, and the induction hypothesis transports all tail entries across the tail classifier witness. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec nameCert carrier transport`
Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec carrier transport from nameCert`

Definition 36.49 (List ledger policy)**.** *Record the finite constructor spine and source-carrier evidence for each visible element; the paper-side* ListHistoryLedger *used in Theorem 36.68 does not carry a separate source ledger.*

Definition 36.50 (List history ledger)**.** *For a source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$*,* $\mathsf{ListHistoryLedger}_S(h)$ *records the visible history endpoint as a finite nil/cons spine: the empty endpoint is recorded by* $\mathsf{hsame}(h, \mathsf{e})$*, and a cons endpoint is recorded by histories* a, t, p *with* $S(a)$*,* $\mathsf{ListHistoryLedger}_S(t)$*,* $\mathsf{Cont}(a, t, p)$*, and* $\mathsf{hsame}(h, \mathsf{E1}(p))$*.*

Theorem 36.51 (List history carrier, pattern, and ledger equivalence)**.** *For every source carrier* $S : \mathsf{BHist} \to \mathsf{Prop}$ *and history* h*, the three displayed list-history fields determine the same endpoints:*

$$\mathsf{ListHistoryCarrier}_S(h) \iff \mathsf{ListHistoryPattern}_S(h),$$

and

$$\mathsf{ListHistoryCarrier}_S(h) \iff \mathsf{ListHistoryLedger}_S(h).$$

Proof. For the carrier-pattern equivalence, use the displayed generated cases for $\mathsf{ListHistoryCarrier}_S$. The nil case gives $\mathsf{hsame}(h, \mathsf{e})$, which is the nil pattern branch. The cons case exposes histories a, t, p with $S(a)$, $\mathsf{ListHistoryCarrier}_S(t)$, $\mathsf{Cont}(a, t, p)$, and $\mathsf{hsame}(h, \mathsf{E1}(p))$, which is exactly the cons pattern branch. Conversely, each pattern branch is one of the two carrier constructors, using the same hsame, $S(a)$, $\mathsf{Cont}(a, t, p)$, and tail carrier witnesses.

For the carrier-ledger equivalence, induct over the displayed nil/cons generation in each direction. From carrier to ledger, the nil constructor becomes the nil ledger clause, and the cons constructor reuses $S(a)$, $\mathsf{Cont}(a, t, p)$, the endpoint witness $\mathsf{hsame}(h, \mathsf{E1}(p))$, and the induction hypothesis on the tail. From ledger to carrier, the nil ledger clause rebuilds the nil carrier clause, and the cons ledger clause reuses the same source, continuation, endpoint, and tail witnesses, with the induction hypothesis turning the tail ledger witness into the required tail carrier witness. □

Theorem 36.52 (List public finite-data exit package)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*. If* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$ *holds, then the public* $\mathsf{List}^{\uparrow}$ *object carries the Phase Finite Data exit package:*

1. $\mathsf{SemanticNameCert}(\mathsf{ListHistoryCarrier}_A, \mathsf{ListHistoryPattern}_A, \mathsf{ListHistoryLedger}_A, \mathsf{ListSpineHistoryClassifier}_{A,\sim_A})$.
2. *The public carrier is exact against both the finite pattern predicate and the ledger predicate:*

$$\forall h.\ \mathsf{ListHistoryCarrier}_A(h) \iff \mathsf{ListHistoryPattern}_A(h)$$

and

$$\forall h.\ \mathsf{ListHistoryCarrier}_A(h) \iff \mathsf{ListHistoryLedger}_A(h).$$

3. *Public length is total and well-defined:*

$$\forall h.\ \mathsf{ListHistoryCarrier}_A(h) \to \exists n.\ \mathsf{ListPublicLength}_A(h, n)$$

and

$$\forall h\, n\, m.\ \mathsf{ListPublicLength}_A(h, n) \to \mathsf{ListPublicLength}_A(h, m) \to n = m.$$

4. *Classified endpoints share public length:*

$$\forall h\, k.\ \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k) \to \exists n.\ \mathsf{ListPublicLength}_A(h, n) \wedge \mathsf{ListPublicLength}_A(k, n)$$

and

$$\forall h\, k\, n\, m.\ \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k) \to \mathsf{ListPublicLength}_A(h, n) \to \mathsf{ListPublicLength}_A(k, m) \to n = m.$$

5. *Every classified endpoint pair exposes finite spine ledgers:*

$$\forall h\, k.\ \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h,k) \to \left(\begin{array}{l} (\exists xs : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_A(h,xs)) \\ \wedge \\ (\exists ys : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_A(k,ys)) \end{array}\right).$$

6. *The same classifier is exactly the nil-nil or cons-cons constructor audit:*

$$\forall h\, k.\ \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h,k) \iff \begin{array}{l} (\mathsf{hsame}(h,\mathsf{e}) \wedge \mathsf{hsame}(k,\mathsf{e})) \\ \vee \\ \exists a\, b\, t\, u\, p\, q : \mathsf{BHist}. \left(\begin{array}{l} A(a) \wedge A(b) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{ListH} \\ \mathsf{Cont}(a,t,p) \wedge \mathsf{Cont}(b,u,q) \wedge \mathsf{hsame}(h,\mathsf{E1}(p \\ \sim_A (a,b) \wedge \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(t, \end{array}\right) \end{array}$$

7. *The classified successor component readback package is independent of the chosen six-tuple witness, in the sense of Theorem 36.102.*

Proof. Apply Theorem 36.78 to cert and the cons-boundary coherence witness. Its five displayed fields give the semantic certificate, totality of public length, well-definedness of public length, shared length for classified endpoints, and equality of public length values across classified endpoints.

Apply Theorem 36.51 with $S = A$. This supplies the exactness of $\mathsf{ListHistoryCarrier}_A$ against both $\mathsf{ListHistoryPattern}_A$ and $\mathsf{ListHistoryLedger}_A$.

Next apply Theorem 36.165. This supplies the endpoint spine-ledger exposure for every $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h,k)$ witness and the nil-or-cons constructor audit for the same classifier.

Finally use Theorem 36.102. It turns the classified successor exactness clause into a witness-choice independent component package for the public object. Repack the three theorem outputs into the seven displayed fields. □

Theorem 36.53 (List finite-data consumer row exhaustion)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*. If* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$ *holds, then every public consumer read of the* $\mathsf{List}^{\uparrow}$ *finite-data package factors through exactly the seven rows displayed in Theorem 36.52:*

1. *semantic certification of the lifted list carrier, pattern, ledger, and classifier;*
2. *exactness of the public carrier against the finite carrier-pattern and carrier-ledger predicates;*
3. *totality and uniqueness of public length;*
4. *sharing and uniqueness of public length along classified endpoint pairs;*
5. *finite spine-ledger exposure for each classified endpoint;*
6. *the nil-or-cons constructor audit for the public classifier;*
7. *independence of the classified successor component readback from the chosen six-tuple witness.*

No public finite-data consumer obtains an additional row from host list equality, quotient representatives, or external sequence objects.

Proof. Apply Theorem 36.52. It presents the public finite-data package as the seven displayed rows, so any public consumer read first enters through one of those rows.

The exactness rows have no further public exits. Apply Theorem 36.51: the carrier read is identified with the finite pattern predicate and the ledger predicate, and no separate host-list equality object is introduced by this transport.

The endpoint and constructor rows are likewise exhausted internally. Apply Theorem 36.165 to account for endpoint spine-ledger exposure and the nil-or-cons audit. Then apply Theorem 36.102 to make the successor component readback independent of the chosen six-tuple witness.

These applications cover the semantic certificate, the two exactness rows, the two public length rows, the endpoint exposure row, the constructor audit row, and the successor-component independence row. Since none of the cited clauses exports quotient representatives or external sequence objects, the displayed seven rows form the whole public consumer boundary. □

Theorem 36.54 (List public closure alignment)**.** *For* $\mathsf{List}^{\uparrow}$ *over* BHist, hsame, Cont, *and* $\mathsf{NameCert}$, *the public finite-data exit package and the consumer row exhaustion theorem jointly supply the paper-side Phase Finite Data witness. The witness consists exactly of the carrier-pattern and carrier-ledger exactness rows, the public length rows, the constructor audit, and the successor-component independence package already displayed by Definition 36.52 and exhausted by Definition 36.53. It does not add host list equality, quotient representatives, or an external sequence object.*

Proof. Apply Definition 36.52. Its displayed fields give the finite public object: semantic certification, carrier-pattern and carrier-ledger exactness, public length totality and uniqueness, classified endpoint length agreement, finite spine exposure, the nil-or-cons constructor audit, and successor-component independence.

Apply Definition 36.53. It says that any public consumer read factors through exactly those rows. Hence the roadmap witness is obtained by repackaging the already exposed rows for the $\mathsf{List}^{\uparrow}$ surface over BHist, hsame, Cont, and $\mathsf{NameCert}$.

The cited package and exhaustion theorem explicitly close off host list equality, quotient representatives, and external sequence objects. Therefore the alignment is a paper-side finite-data witness rather than a stronger formal marker or an additional public carrier. □

36.4 List map shape

Theorem 36.55 (History list classifier reflects one-sided $e1$ shape)**.** *For BEDC history lists xs and ys, if*

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, \mathsf{map}(\mathsf{E1}, xs), ys)$$

holds, then there is a BEDC history list zs such that

$$ys = \mathsf{map}(\mathsf{E1}, zs) \quad \textit{and} \quad \mathsf{ListClassifierSpec}(\mathsf{hsame}, xs, zs)$$

hold.

Proof. Induct on xs. The nil case can classify only against nil, so choose $zs = \mathsf{nil}$. In the cons case, the classifier forces ys to be a cons list. Invert the head witness with the $e1$ history-shape inversion theorem to write the head of ys as an $e1$-tagged history and recover the source-head hsame witness. The induction hypothesis shapes the tail and supplies the tail classifier; consing the recovered head onto that tail gives the displayed witness. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame map e1 left shape`

Theorem 36.56 (History list classifier separates $e1$ from $e0$ mapped tags)**.** *For BEDC history lists xs and ys, if*

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, \mathsf{map}(\mathsf{E1}, xs), \mathsf{map}(\mathsf{E0}, ys))$$

holds, then $xs = \mathsf{nil}$ and $ys = \mathsf{nil}$.

Proof. Case-split both lists. The nil-nil case is immediate. Nil-cons and cons-nil cases contradict the mixed-shape clauses of ListClassifierSpec. In the cons-cons case, the head witness would relate an $e1$-tagged history to an $e0$-tagged history, contradicting BEDC history constructor separation. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame map e1 map e0 empty`

Definition 36.57 (List spine representation)**.** *Let* HistSpine *be the finite-spine carrier whose entries are BEDC histories. For a BEDC history source carrier $A : \mathsf{BHist} \to \mathsf{Prop}$, the relation $\mathsf{ListSpineRep}_A(h, xs)$ has $xs : \mathsf{HistSpine}$ and says that h represents xs by the same nil and cons clauses used by $\mathsf{ListHistoryCarrier}_A$; the source predicate is carried by the clauses:*

1. *nil: $xs = \mathsf{nil}$ and $\mathsf{hsame}(h, \mathsf{e})$;*
2. *cons: $xs = \mathsf{cons}(a, xs')$ and there are histories t, p with $A(a)$, $\mathsf{ListSpineRep}_A(t, xs')$, $\mathsf{Cont}(a, t, p)$, and $\mathsf{hsame}(h, \mathsf{E1}(p))$.*

The spine-bridge classifier used by the certificate is

$$\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, k) \iff \exists xs, ys : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_A(h, xs) \wedge \mathsf{ListSpineRep}_A(k, ys) \wedge \mathsf{ListClas}$$

The certificate classifier is this bridge classifier:

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k) \iff \mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, k).$$

Thus ListClassifierSpec *remains the finite-spine classifier,* $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}$ *names the BEDC-history bridge through finite spines, and* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$ *is the certificate classifier whose endpoints are BEDC histories. The recursive classifier* $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{S,\sim_S}$ *from Definition 36.4 is a paper-side generator for carrier and endpoint reasoning.*

Lean4 (definition) `BEDC.Derived.ListUp.ListSpineRep`

Theorem 36.58 (List spine nil-cons no-confusion)**.** *For every BEDC history source carrier $A : \mathsf{BHist} \to \mathsf{Prop}$, history h, source history a, and tail spine $xs : \mathsf{HistSpine}$, $\mathsf{ListSpineRep}_A(h, \mathsf{nil})$ and $\mathsf{ListSpineRep}_A(h, \mathsf{cons}(a, xs))$ are contradictory.*

Proof. Unpack the nil representation to obtain $\mathsf{hsame}(h, \mathsf{e})$. Unpack the cons representation to obtain an endpoint witness $\mathsf{hsame}(h, \mathsf{E1}(p))$ for some continuation package p. Compose the symmetry of the nil endpoint with the cons endpoint to get $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(p))$, then close by BEDC history constructor no-confusion between the empty history and a one-step endpoint. □

Lean4 ✓ `BEDC.Derived.ListUp.ListSpineRep nil cons no confusion`

Lemma 36.59 (List spine cons hsame transport)**.** *Let $A : \mathsf{BHist} \to \mathsf{Prop}$ be a BEDC history source carrier. If $A(a)$ holds, the tail history t represents a finite spine xs, the continuation $\mathsf{Cont}(a, t, p)$ holds, and h exposes the cons endpoint $\mathsf{E1}(p)$, then every h' with $\mathsf{hsame}(h, h')$ represents the cons spine:*

$$A(a) \to \mathsf{ListSpineRep}_A(t, xs) \to \mathsf{Cont}(a, t, p) \to \mathsf{hsame}(h, \mathsf{E1}(p)) \to \mathsf{hsame}(h, h') \to \mathsf{ListSpineRep}_A(h', \mathsf{cons}(a, xs)).$$

Proof. Use the cons constructor of Definition 36.57. The head source witness, tail representation, and continuation witness are unchanged. The endpoint witness for h' is obtained by composing $\mathsf{hsame}(h', h)$, the symmetry of the displayed endpoint transport, with the stored cons endpoint witness $\mathsf{hsame}(h, \mathsf{E1}(p))$. □

Lean4 ✓ `BEDC.Derived.ListUp.ListSpineRep cons hsame transport`

Theorem 36.60 (List spine cons endpoint shape)**.** *For every source carrier $A : \mathsf{BHist} \to \mathsf{Prop}$, history h, head a, and tail spine $xs : \mathsf{HistSpine}$, a cons spine presentation $\mathsf{ListSpineRep}_A(h, \mathsf{cons}(a, xs))$ exposes its BEDC constructor payload:*

$$\exists t, p : \mathsf{BHist}.\ A(a) \wedge \mathsf{ListSpineRep}_A(t, xs) \wedge \mathsf{Cont}(a, t, p) \wedge \mathsf{hsame}(h, \mathsf{E1}(p)).$$

Proof. Invert the displayed cons presentation. The cons constructor of $\mathsf{ListSpineRep}$ stores exactly the head source proof, tail spine presentation, continuation ledger, and one-headed endpoint classifier. □

Lean4 ✓ `BEDC.Derived.ListUp.ListSpineRep cons endpoint shape`

Theorem 36.61 (List spine representation exactness)**.** *Let $A : \mathsf{BHist} \to \mathsf{Prop}$ be a BEDC history source carrier and let $\sim_A$ be a source classifier. The spine representation of Definition 36.57 is exact for the generated list carrier and classifier:*

1. *if $\mathsf{ListSpineRep}_A(h, xs)$ holds, then $\mathsf{ListHistoryCarrier}_A(h)$ holds;*
2. *if $\mathsf{ListHistoryCarrier}_A(h)$ holds, then there is a finite spine xs such that $\mathsf{ListSpineRep}_A(h, xs)$ holds;*
3. *for all histories h, k, the spine-induced classifier $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, k)$ holds exactly when the recursive generated classifier $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}(h, k)$ holds.*

Proof. For soundness, induct on the displayed derivation of $\mathsf{ListSpineRep}_A(h, xs)$. The nil representation is exactly the nil generator of $\mathsf{ListHistoryCarrier}_A$, and the cons representation carries the head witness $A(a)$, the recursive representation of the tail, the continuation witness $\mathsf{Cont}(a, t, p)$, and the endpoint witness $\mathsf{hsame}(h, \mathsf{E1}(p))$, so the cons generator rebuilds the carrier.

For completeness, induct on the displayed generation of $\mathsf{ListHistoryCarrier}_A(h)$. The nil carrier chooses $xs = \mathsf{nil}$ and the stored empty endpoint witness. The cons carrier first applies the induction hypothesis to the tail carrier, then chooses $xs = \mathsf{cons}(a, xs')$ and reuses the source, continuation, and endpoint witnesses.

For classifier equivalence, unfold both classifier presentations. A bridge witness exposes finite spines and a $\mathsf{ListClassifierSpec}$ witness; applying carrier soundness to both representation endpoints gives the generated list histories, and induction on the finite-spine classifier derivation rebuilds the nil-nil and cons-cons classifier clauses. Conversely, a generated classifier derivation is handled by induction on its nil/cons clauses: the nil case chooses two nil spines, and the cons case uses the induction hypotheses for the tail classifier together with the stored source head classification and continuation witnesses to construct the finite-spine classifier witness. □

Definition 36.62 (List spine representation coherence)**.** *For a BEDC history source carrier $A : \mathsf{BHist} \to \mathsf{Prop}$ and source classifier $\sim_A$, define $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$ as the proposition that every two finite-spine presentations of the same history are classified by the finite spine classifier. Concretely, for every history m and spines $ys, ys' : \mathsf{HistSpine}$, if $\mathsf{ListSpineRep}_A(m, ys)$ and $\mathsf{ListSpineRep}_A(m, ys')$, then $\mathsf{ListClassifierSpec}(\sim_A, ys, ys')$.*

Theorem 36.63 (List history classifier transitivity from spine coherence)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*. If* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$ *holds, then the existential spine-representation classifier of Definition 36.57 is transitive: whenever* $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, k)$ *and* $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(k, u)$ *hold, then* $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, u)$ *holds.*

Proof. Unpack the two history-classifier witnesses. The first gives spines xs, ys with representations of h and k and a witness $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$. The second gives spines ys', zs with representations of k and u and a witness $\mathsf{ListClassifierSpec}(\sim_A, ys', zs)$. Apply Definition 36.62 to the two displayed representations of the middle history k to obtain $\mathsf{ListClassifierSpec}(\sim_A, ys, ys')$. The checked finite-spine theorem ListClassifierSpec_trans_from_nameCert, applied with cert, first composes xs with ys' through ys and then composes the result with zs through ys'. Repack the original representation of h, the original representation of u, and the composed finite-spine classifier witness to obtain $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, u)$. □

Theorem 36.64 (List spine classifier preserves represented length)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. Then represented finite spines have equal presentation length along the spine-induced history classifier: whenever* $\mathsf{ListSpineRep}_A(h, xs_0)$*,* $\mathsf{ListSpineRep}_A(k, ys_0)$*, and* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$ *hold, then*

$$\ell(xs_0) = \ell(ys_0).$$

Proof. Apply Theorem 36.144 to the two displayed representation witnesses and the spine-induced history classifier, using cert and the coherence hypothesis. This gives $\mathsf{ListClassifierSpec}(\sim_A, xs_0, ys_0)$. Theorem 36.31 then reads this finite-spine classifier witness as $\ell(xs_0) = \ell(ys_0)$. □

Theorem 36.65 (List spine representation coverage)**.** *For every BEDC history source carrier* $A : \mathsf{BHist} \to \mathsf{Prop}$ *and history* h*, the generated history carrier is covered exactly by finite spine representations:*

$$\mathsf{ListHistoryCarrier}_A(h) \iff \exists xs : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_A(h, xs).$$

Lean4 ✓ `BEDC.Derived.ListUp.ListSpineRepresentation coverage`

Proof. For the forward direction, induct on the generated $\mathsf{ListHistoryCarrier}_A(h)$ witness. The nil constructor is represented by the empty finite spine. The cons constructor uses the induction hypothesis for the tail carrier witness to obtain a tail spine, then prefixes it by the source history and reuses the continuation and endpoint witnesses. For the reverse direction, induct on the $\mathsf{ListSpineRep}_A(h, xs)$ witness. The nil representation rebuilds the nil carrier clause, and the cons representation rebuilds the cons carrier clause from the source witness, the recursively recovered tail carrier witness, the continuation witness, and the displayed $\mathsf{hsame}(h, \mathsf{E1}(p))$ endpoint. □

Theorem 36.66 (List spine bridge certificate fields)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. The bridge classifier* $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}$ *has the certificate fields needed over the carrier* $\mathsf{ListHistoryCarrier}_A$*:*

1. *if* $\mathsf{ListHistoryCarrier}_A(h)$ *holds, then* $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, h)$ *holds;*
2. *if* $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, k)$ *holds, then* $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(k, h)$ *holds;*

3. *if* $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h,k)$ *and* $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(k,u)$ *hold, then* $\mathsf{ListSpineBridgeClassifier}_{A,\sim}$ *holds;*
4. *if* $\mathsf{ListHistoryCarrier}_A(h)$ *and* $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h,k)$ *hold, then* $\mathsf{ListHistoryCarrier}_A(k)$ *holds.*

Proof. For carrier-indexed reflexivity, apply the forward direction of Theorem 36.65 to the carrier witness for h. This gives a finite spine xs and a representation witness $\mathsf{ListSpineRep}_A(h,xs)$. Finite-spine reflexivity for $\mathsf{ListClassifierSpec}$, using the reflexivity field of cert on each source entry, repacks with the same representation on both endpoints and gives $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h,h)$.

For symmetry, unpack the bridge witness into displayed endpoint spines and a finite-spine classifier witness. Apply Theorem 36.47 with cert to reverse that finite-spine witness, then repack the two displayed representations in the opposite order.

For transitivity, use Theorem 36.63. The coherence hypothesis compares the two finite-spine presentations of the middle history, and the source certificate supplies the finite-spine transitivity used there.

For carrier transport, unpack $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h,k)$ and take the displayed target representation $\mathsf{ListSpineRep}_A(k,ys)$. The soundness direction of Theorem 36.61, equivalently the reverse direction of Theorem 36.65, converts this representation into $\mathsf{ListHistoryCarrier}_A(k)$. □

Principle 36.67 (Unframed list-spine presentations require an external coherence field)**.** *Definition 36.57 supplies coverage and endpoint presentation data for a chosen finite-spine presentation only. It does not include the comparison datum required by Definition 36.62. For the bridge classifier, the missing datum is exactly a proof that any two cons presentations of the same endpoint have source-classified heads and* $\mathsf{ListClassifierSpec}$*-classified tails. Thus* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$ *is an additional certificate hypothesis needed by Theorem 36.63. That comparison has to come from a framed or separated spine representation, from a source presentation whose restrictions prove it directly, or from the cons-boundary coherence condition: Theorem 36.71 supplies the forward construction, and Theorem 36.72 records the equivalence with spine coherence.*

Theorem 36.68 (Conditional $\mathsf{List}^{\uparrow}$ public-object target from the spine bridge)**.** *Given a BEDC history source carrier* $A : \mathsf{BHist} \to \mathsf{Prop}$*, source classifier* $\sim_A$*, source certificate* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and a witness of* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*, define* $\mathsf{ListSource}(A)$ *as the history carrier* $\mathsf{ListHistoryCarrier}_A$*, take the certificate classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$ *to be the spine-induced bridge classifier from Definition 36.57, use Theorem 36.61 as its finite-spine exactness theorem, take* $\mathsf{ListHistoryPattern}_A$ *from Definition 36.11 as the pattern, and take* $\mathsf{ListHistoryLedger}_A$ *from Definition 36.50 as the ledger. The host-list spine model is a presentation witness, not the exported carrier. Under the source* $\mathsf{NameCert}$ *and the spine-coherence witness, these fields form the paper-side target* $\mathsf{SemanticNameCert}(\mathsf{ListHist}$ *for* $\mathsf{List}^{\uparrow}(A)$*. This theorem is the paper-side target and carries no* `\leanchecked` *marker.*

Proof. The source $\mathsf{NameCert}$ supplies the head-level reflexivity, symmetry, transitivity, and carrier transport fields. The generated nil/cons carrier supplies the BEDC histories, and Theorem 36.61 supplies the exact finite-spine presentation through which the checked structural classifier is applied. The reflexivity, symmetry, transitivity, and carrier-transport fields for the bridge classifier are exactly Theorem 36.66. Source-certificate transport is used only for entrywise source-carrier evidence, while the list ledger is the carrier-shaped constructor spine from Definition 36.50. Nil/cons case analysis uses Theorem 36.7 for the generated history carrier and Lemma 36.14 inside the finite-spine bridge, and exactness means that there exist finite spines xs, ys with $\mathsf{ListSpineRep}_A(h,xs)$, $\mathsf{ListSpineRep}_A(k,ys)$, and $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$; Definition 36.62 makes alternate presentations of the same endpoint compatible for certificate use. □

Corollary 36.69 ($\mathsf{List}^{\uparrow}$ conditional public-object target)**.** *By Theorem 36.68,* $\mathsf{List}^{\uparrow}(A)$ *has an unframed public certificate target relative to the supplied source* NameCert *and a witness of* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. Theorem 36.163 gives the unframed public certificate when* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$ *is supplied, equivalently by Theorem 36.72. Corollary 36.128 supplies a separate framed carrier certificate under source-carrier* hsame *compatibility and does not identify the framed carrier with the unframed* $\mathsf{ListHistoryCarrier}_A$ *used by the public* $\mathsf{List}^{\uparrow}$ *target.*

Definition 36.70 (List cons-boundary coherence)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier and let* $\sim_A$ *be a source classifier. Define* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$ *as the predicate*

$$\forall m\, a\, a'\, t\, t'\, p\, p'\, xs\, xs'.\ A(a) \to A(a') \to \mathsf{ListSpineRep}_A(t, xs) \to \mathsf{ListSpineRep}_A(t', xs') \to \mathsf{Cont}(a, t, p) \to \mathsf{Cont}(a', t', p$$

Lean4 (definition) `BEDC.Derived.ListUp.ListConsBoundaryCoherent`

Theorem 36.71 (List spine coherence from cons-boundary coherence)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier and let* $\sim_A$ *be a source classifier. If* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$ *holds, then* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$ *holds.*

Proof. Compare two finite-spine presentations of the same history by cases on the displayed spines. The nil-nil case is the nil constructor of ListClassifierSpec. The mixed nil-cons cases contradict Theorem 36.58. In the cons-cons case, both presentations expose the same list endpoint together with displayed head histories, tail spines, tail representations, continuation witnesses, and endpoint witnesses. Definition 36.70 supplies the conjunction $(a \sim_A a') \wedge \mathsf{ListClassifierSpec}(\sim_A, xs, xs')$; its left conjunct is the head classifier witness, and its right conjunct is the tail finite-spine classifier witness. These are the two constructor arguments for $\mathsf{ListClassifierSpec}(\sim_A, -, -)$ on the whole cons spines. □

Lean4 ✓ `BEDC.Derived.ListUp.ListSpineRep coherent from cons boundary`

Theorem 36.72 (List spine coherence iff cons-boundary coherence)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier and let* $\sim_A$ *be a source classifier. Then* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$ *holds if and only if* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$ *holds.*

Proof. For the forward implication, assume $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$. Given two displayed cons presentations of the same endpoint, view them as two $\mathsf{ListSpineRep}_A$ presentations with cons spines. Spine coherence returns a $\mathsf{ListClassifierSpec}(\sim_A, -, -)$ witness relating those two cons spines. The cons-cons branch of Theorem 36.13 inverts that witness and exposes exactly the required head classifier $a \sim_A a'$ together with the tail classifier $\mathsf{ListClassifierSpec}(\sim_A, xs, xs')$. These are the two fields of Definition 36.70. The reverse implication is precisely Theorem 36.71. □

Lean4 ✓ `BEDC.Derived.ListUp.ListSpineRep cons boundary coherence iff`

Theorem 36.73 (List public cons readback determinacy)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier and let* $\sim_A$ *be a source classifier. For any* $m, a, a', t, t', p, p' : \mathsf{BHist}$*, if* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$*,* $A(a)$*,* $A(a')$*,* $\mathsf{ListHistoryCarrier}_A(t)$*,* $\mathsf{ListHistoryCarrier}_A(t')$*,* $\mathsf{Cont}(a, t, p)$*,* $\mathsf{Cont}(a', t', p')$*,* $\mathsf{hsame}(m, \mathsf{E1}(p))$*, and* $\mathsf{hsame}(m, \mathsf{E1}(p'))$ *hold, then*

$$a \sim_A a' \wedge \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(t, t').$$

The roadmap ten-field fit is: traditional target finite-list constructor readback; BEDC source BHist*; source carrier A; public carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability supplied by* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$*; ledger two cons endpoints; exactness through finite spine representations; standard bridge finite spines; status* ProofTarget*.*

Proof. Apply Theorem 36.65 to the two displayed tail carrier witnesses. This gives finite spines xs and xs' with $\mathsf{ListSpineRep}_A(t, xs)$ and $\mathsf{ListSpineRep}_A(t', xs')$.

Use Definition 36.70 on the two displayed cons presentations of the endpoint m. The hypotheses supply the source membership for a and a', the two finite tail presentations, the two continuation witnesses, and the two endpoint equalities. The resulting conjunction gives $a \sim_A a'$ and $\mathsf{ListClassifierSpec}(\sim_A, xs, xs')$.

Repack the two tail spine representations together with $\mathsf{ListClassifierSpec}(\sim_A, xs, xs')$ through Definition 36.57. This yields $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(t, t')$, which pairs with the head classifier to give the displayed conclusion. □

Lean4 ✓ `BEDC.Derived.ListUp.ListSpineBridgeClassifier public cons readback deterministic`

Theorem 36.74 (Deterministic list spine length readback)**.** *Let $A : \mathsf{BHist} \to \mathsf{Prop}$ be a BEDC history source carrier and let $\sim_A$ be a source classifier. For every history m and finite spines xs and ys, if $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$, $\mathsf{ListSpineRep}_A(m, xs)$, and $\mathsf{ListSpineRep}_A(m, ys)$ hold, then*

$$\ell(xs) = \ell(ys).$$

The roadmap ten-field fit is: traditional target finite-list readback; BEDC source BHist*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* ListClassifierSpec*; ledger finite spine; status* ProofTarget*.*

Proof. Theorem 36.71 turns the cons-boundary coherence witness into $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$. Apply this coherence datum to the two displayed $\mathsf{ListSpineRep}_A$ presentations of the endpoint m to obtain $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$. Then Theorem 36.31 gives equality of the two finite spine lengths. □

Lean4 ✓ `BEDC.Derived.ListUp.ListSpineRep cons boundary length deterministic`

Definition 36.75 (List public length readback)**.** *For a BEDC history source carrier $A : \mathsf{BHist} \to \mathsf{Prop}$, define $\mathsf{ListPublicLength}_A(h, n)$ by*

$$\mathsf{ListPublicLength}_A(h, n) \iff \exists xs : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_A(h, xs) \wedge \ell(xs) = n.$$

Here ℓ is the finite-spine presentation length. It is not a $\mathsf{Nat}^{\uparrow}$ operation and is not an additional field of the public certificate.

Theorem 36.76 (List public length readback is well-defined under cons-boundary coherence)**.** *Let $A : \mathsf{BHist} \to \mathsf{Prop}$ be a BEDC history source carrier, let $\sim_A$ be a source classifier, and let $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$. Assume $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$. Then the public length readback has the following two properties.*

1. *If $\mathsf{ListPublicLength}_A(h, n)$ and $\mathsf{ListPublicLength}_A(h, m)$, then $n = m$.*
2. *If $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$, $\mathsf{ListPublicLength}_A(h, n)$, and $\mathsf{ListPublicLength}_A(k, m)$, then $n = m$.*

The roadmap ten-field fit is: traditional target finite-list length readback; BEDC source BHist *with* NameCert*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; ledger finite-spine length witnesses; exactness through* $\mathsf{ListSpineRep}_A$ *and* ListClassifierSpec*; status* ProofTarget*.*

Lean4 ✓ `BEDC.Derived.ListUp.ListPublicLength well defined`

Proof. For uniqueness at one endpoint, unpack the two $\mathsf{ListPublicLength}_A$ witnesses. They give finite spines xs and ys, representations $\mathsf{ListSpineRep}_A(h, xs)$ and $\mathsf{ListSpineRep}_A(h, ys)$, and displayed equalities $\ell(xs) = n$ and $\ell(ys) = m$. Apply Theorem 36.74 to the two representations of h under the cons-boundary coherence hypothesis, obtaining $\ell(xs) = \ell(ys)$. Chain the inverse of $\ell(xs) = n$, this equality, and $\ell(ys) = m$ to get $n = m$.

For preservation along the public classifier, unpack the two public length witnesses as represented spines xs for h and ys for k, with $\ell(xs) = n$ and $\ell(ys) = m$. First apply Theorem 36.71 to obtain $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$. Then apply Theorem 36.64, using cert, the coherence witness, the displayed endpoint representations, and the classifier witness $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$, to obtain $\ell(xs) = \ell(ys)$. Chain this length equality with $\ell(xs) = n$ and $\ell(ys) = m$ to get $n = m$. □

Theorem 36.77 (List public length readback totality and classified endpoints)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*. Assume* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$*. Then the public length readback is total on public list histories and supplies common witnesses for classified endpoints:*

1. *If* $\mathsf{ListHistoryCarrier}_A(h)$*, then* $\exists n.\ \mathsf{ListPublicLength}_A(h, n)$*.*
2. *If* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$*, then* $\exists n.\ \mathsf{ListPublicLength}_A(h, n) \wedge \mathsf{ListPublicLength}_A(k, n)$*.*

The roadmap ten-field fit is: traditional target public finite-list length readback; BEDC source BHist *with* $\mathsf{NameCert}$*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; ledger finite-spine presentations; exactness through* $\mathsf{ListSpineRep}_A$ *and the public length definition; classified endpoint readback through the spine bridge; status* $\mathsf{ProofTarget}$*.*

Proof. 1. For totality, apply the forward direction of Theorem 36.65 to the displayed $\mathsf{ListHistoryCarrier}_A(h)$ witness. This gives a finite spine xs with $\mathsf{ListSpineRep}_A(h, xs)$. Choose $n = \ell(xs)$ and repack this representation with the reflexive length equality in Definition 36.75.

2. For classified endpoints, unfold $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$ through Definition 36.57. The classifier witness gives finite spines xs and ys, endpoint presentations $\mathsf{ListSpineRep}_A(h, xs)$ and $\mathsf{ListSpineRep}_A(k, ys)$, and a finite-spine classifier witness $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$.

   Apply Theorem 36.31 to obtain $\ell(xs) = \ell(ys)$. Choose $n = \ell(xs)$. The representation of h gives $\mathsf{ListPublicLength}_A(h, n)$ by reflexivity. The representation of k gives $\mathsf{ListPublicLength}_A(k, n)$ after rewriting the equality $\ell(xs) = \ell(ys)$ in the opposite direction.

   Repack the two public length witnesses under the chosen value n.

□

Theorem 36.78 (List public-object certificate with public length readback)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*. If* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$ *holds, then the public* $\mathsf{List}^{\uparrow}$ *object has the semantic certificate and public length readback package:*

1. $\mathsf{SemanticNameCert}(\mathsf{ListHistoryCarrier}_A, \mathsf{ListHistoryPattern}_A, \mathsf{ListHistoryLedger}_A, \mathsf{ListSpineHistoryClassifier}_{A,\sim_A})$*.*
2. $\forall h.\ \mathsf{ListHistoryCarrier}_A(h) \to \exists n.\ \mathsf{ListPublicLength}_A(h, n)$*.*
3. $\forall h\, n\, m.\ \mathsf{ListPublicLength}_A(h, n) \to \mathsf{ListPublicLength}_A(h, m) \to n = m$*.*
4. $\forall h\, k.\ \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k) \to \exists n.\ \mathsf{ListPublicLength}_A(h, n) \wedge \mathsf{ListPublicLength}_A(k, n)$*.*
5. $\forall h\, k\, n\, m.\ \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k) \to \mathsf{ListPublicLength}_A(h, n) \to \mathsf{ListPublicLength}_A(k, m) \to n = m$*.*

Proof. The roadmap ten-field fit is: traditional target finite-list public certificate with length readback; BEDC source BHist plus source $\mathsf{NameCert}$; carrier $\mathsf{ListHistoryCarrier}_A$; classifier $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$; stability from cons-boundary coherence; ledger $\mathsf{ListHistoryLedger}_A$ plus $\mathsf{ListPublicLength}_A$; core theorem this package; exactness finite-spine length readback; standard bridge finite spines; status $\mathsf{ProofTarget}$.

1. The certificate clause is exactly Theorem 36.163 applied to cert and the cons-boundary coherence witness.
2. The total public length readback clause is the first component of Theorem 36.77.
3. The uniqueness clause is the first component of Theorem 36.76.
4. The classified endpoint common-witness clause is the second component of Theorem 36.77.
5. The equality of endpoint readbacks under the public classifier is the second component of Theorem 36.76.

□

Theorem 36.79 (List public zero length and nonempty readback)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\mathsf{Rel} : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be a source classifier, and assume* $\mathsf{ListConsBoundaryCoherent}_{A,\mathsf{Rel}}$*. For every history* h*, the public length ledger is exact at zero and exposes a cons readback at nonzero public endpoints:*

1. $\mathsf{ListPublicLength}_A(h, 0)$ *holds if and only if* $\mathsf{hsame}(h, \mathsf{e})$ *holds.*

2. If $\mathsf{ListHistoryCarrier}_A(h)$ *and* $\neg\mathsf{hsame}(h, \mathsf{e})$ *hold, then*

$$\exists a\, t\, p : \mathsf{BHist}. \left(\begin{array}{l} A(a) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{Cont}(a, t, p) \wedge \\ \mathsf{hsame}(h, \mathsf{E1}(p)) \wedge \\ \forall n.\ \mathsf{ListPublicLength}_A(h, n) \to n \neq 0 \end{array} \right).$$

The ten-field fit is: traditional target finite-list zero/nonempty readback; BEDC source BHist *with* Cont*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}$*; stability from cons-boundary coherence; ledger* $\mathsf{ListPublicLength}_A$*; core theorem zero/nonempty exactness; exactness nil iff zero and nonempty gives cons; standard bridge finite spines; status* $\mathsf{ProofTarget}$*.*

Proof. For the zero endpoint, unfold Definition 36.75. A public length witness with value 0 gives a finite spine xs with $\mathsf{ListSpineRep}_A(h, xs)$ and $\ell(xs) = 0$. Case-analyze xs. The cons case has successor length, so it cannot have length 0; the remaining nil case is exactly the nil representation, hence it supplies $\mathsf{hsame}(h, \mathsf{e})$.

Conversely, from $\mathsf{hsame}(h, \mathsf{e})$ choose the nil finite spine. The nil clause of $\mathsf{ListSpineRep}_A$ gives $\mathsf{ListSpineRep}_A(h, \mathsf{nil})$, and $\ell(\mathsf{nil}) = 0$ repacks it as $\mathsf{ListPublicLength}_A(h, 0)$.

For the nonempty readback, first turn the cons-boundary hypothesis into $\mathsf{ListSpineRepCoherent}_{A,\mathsf{Rel}}$ by Theorem 36.71. Apply Theorem 36.162 to the displayed $\mathsf{ListHistoryCarrier}_A(h)$ witness.

The nil alternative contains $\mathsf{hsame}(h, \mathsf{e})$ and is eliminated by the assumed $\neg\mathsf{hsame}(h, \mathsf{e})$. The cons alternative supplies histories a, t, p with $A(a)$, $\mathsf{ListHistoryCarrier}_A(t)$, $\mathsf{Cont}(a, t, p)$, and $\mathsf{hsame}(h, \mathsf{E1}(p))$.

It remains to show that no public length witness at this endpoint has value 0. Given $\mathsf{ListPublicLength}_A(h, n)$ and an equality $n = 0$, rewrite the witness to obtain $\mathsf{ListPublicLength}_A(h, 0)$. The zero equivalence just proved gives $\mathsf{hsame}(h, \mathsf{e})$, contradicting the nonempty hypothesis. Therefore $n \neq 0$, and the cons witnesses together with this length exclusion are the required existential data. □

Theorem 36.80 (List classified zero length endpoint readback)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*. Assume* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$*. For histories* h, k*, if* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$ *holds, then:*

1. *The zero public-length facts agree along the classifier:*

$$\mathsf{ListPublicLength}_A(h, 0) \iff \mathsf{ListPublicLength}_A(k, 0).$$

2. *If either endpoint has public length zero, then both endpoints read back as the empty history:*

$$\mathsf{ListPublicLength}_A(h, 0) \vee \mathsf{ListPublicLength}_A(k, 0) \quad \Longrightarrow \quad \mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(k, \mathsf{e}).$$

The ten-field fit is: traditional target finite-list classified zero readback; BEDC source BHist *with* NameCert*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability from cons-boundary coherence; ledger* $\mathsf{ListPublicLength}_A$*; core theorem zero public-length transport and empty endpoint exposure; exactness by common public witnesses and zero readback; standard bridge finite spines; status* ProofTarget*.*

Proof. Apply Theorem 36.77 to the displayed $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$ witness. It supplies a finite value m together with $\mathsf{ListPublicLength}_A(h, m)$ and $\mathsf{ListPublicLength}_A(k, m)$.

For the forward zero transport, assume $\mathsf{ListPublicLength}_A(h, 0)$. The h-side witness at value m and the given zero witness have the same endpoint, so the uniqueness clause of Theorem 36.76 identifies $m = 0$. Rewriting the k-side common witness gives $\mathsf{ListPublicLength}_A(k, 0)$.

For the reverse zero transport, assume $\mathsf{ListPublicLength}_A(k, 0)$. The k-side witness at value m and the given zero witness have the same endpoint, so the uniqueness clause of Theorem 36.76 identifies $m = 0$. Rewriting the h-side common witness gives $\mathsf{ListPublicLength}_A(h, 0)$.

It remains to read back the endpoints. If the displayed disjunction gives $\mathsf{ListPublicLength}_A(h, 0)$, then the first part of Theorem 36.79 gives $\mathsf{hsame}(h, \mathsf{e})$, and the forward zero transport gives $\mathsf{ListPublicLength}_A(k, 0)$. Applying the same zero readback theorem to the k-side gives $\mathsf{hsame}(k, \mathsf{e})$.

If the displayed disjunction gives $\mathsf{ListPublicLength}_A(k, 0)$, the same argument with the reverse zero transport first gives $\mathsf{ListPublicLength}_A(h, 0)$, and then the zero readback theorem gives $\mathsf{hsame}(h, \mathsf{e})$ and $\mathsf{hsame}(k, \mathsf{e})$. □

Theorem 36.81 (List public successor length cons readback)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier. For every history* h *and every finite length value* n*, if* $\mathsf{ListPublicLength}_A(h, n+1)$ *holds, then*

$$\exists a\, t\, p : \mathsf{BHist}. \left(\begin{array}{l} A(a) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{ListPublicLength}_A(t, n) \wedge \\ \mathsf{Cont}(a, t, p) \wedge \mathsf{hsame}(h, \mathsf{E1}(p)) \end{array} \right).$$

The ten-field fit is: traditional target finite-list successor readback; BEDC source BHist *with* Cont*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier-independent spine exposure; ledger* $\mathsf{ListPublicLength}_A$*; core theorem successor public length inversion; exactness by finite-spine constructor analysis; standard bridge finite spines; status* ProofTarget*.*

Proof. Unfold Definition 36.75. The public length witness gives a finite spine xs with $\mathsf{ListSpineRep}_A(h, xs)$ and $\ell(xs) = n + 1$.

Case-analyze xs. In the nil case, the displayed length equality would force $0 = n + 1$, which is impossible for a finite length value. Thus the represented spine is a cons spine.

The cons representation exposes histories a, t, p with $A(a)$, a tail spine representation for t, the continuation boundary $\mathsf{Cont}(a, t, p)$, and the endpoint presentation $\mathsf{hsame}(h, \mathsf{E1}(p))$. The tail representation supplies $\mathsf{ListHistoryCarrier}_A(t)$ by the carrier coverage direction for represented spines.

The cons length equality identifies the tail-spine length with n. Repack the tail representation and this predecessor length equality through Definition 36.75, obtaining $\mathsf{ListPublicLength}_A(t, n)$. Together with $A(a)$, $\mathsf{Cont}(a, t, p)$, and $\mathsf{hsame}(h, \mathsf{E1}(p))$, these data are the required existential witnesses. □

Theorem 36.82 (List public successor length constructor exactness)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*. Assume* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$*. For every history* h *and every finite length value* n*,*

$$\mathsf{ListPublicLength}_A(h, n{+}1) \iff \exists a\, t\, p : \mathsf{BHist}. \left(\begin{array}{l} A(a) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{ListPublicLength}_A(t, n) \wedge \\ \mathsf{Cont}(a, t, p) \wedge \mathsf{hsame}(h, \mathsf{E1}(p)) \end{array} \right).$$

The ten-field fit is: traditional target finite-list public successor constructor law; BEDC source BHist *with* Cont*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier protected by source* $\mathsf{NameCert}$ *and cons-boundary coherence; ledger* $\mathsf{ListPublicLength}_A$*; core theorem constructor readback in both directions; exactness by finite-spine cons formation; standard bridge finite spines; status* $\mathsf{ProofTarget}$*.*

Proof. For the forward direction, apply Theorem 36.81. This exposes the head history, tail history, continuation boundary, predecessor public length, and endpoint presentation required by the right-hand side.

For the reverse direction, assume histories a, t, p with $A(a)$, $\mathsf{ListHistoryCarrier}_A(t)$, $\mathsf{ListPublicLength}_A(t, n)$, $\mathsf{Cont}(a, t, p)$, and $\mathsf{hsame}(h, \mathsf{E1}(p))$.

Unfold Definition 36.75 for the tail public length. This gives a finite spine xs with $\mathsf{ListSpineRep}_A(t, xs)$ and $\ell(xs) = n$.

Use the cons constructor for $\mathsf{ListSpineRep}_A$ with the displayed source membership $A(a)$, the tail representation, the continuation witness, and the endpoint presentation. It gives $\mathsf{ListSpineRep}_A(h, \mathsf{cons}(a, xs))$.

The represented cons spine has length $\ell(xs) + 1$, so the displayed tail length identifies it with $n + 1$. Repack this cons representation and length identity through Definition 36.75, obtaining $\mathsf{ListPublicLength}_A(h, n + 1)$. □

Theorem 36.83 (List classified successor length cons readback)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*. Assume* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$*. If* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$ *and* $\mathsf{ListPublicLength}_A(h, n+1)$ *hold, then*

$$\exists a\, t\, p : \mathsf{BHist}. \left(\begin{array}{l} A(a) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{ListPublicLength}_A(t, n) \wedge \\ \mathsf{Cont}(a, t, p) \wedge \mathsf{hsame}(k, \mathsf{E1}(p)) \end{array} \right).$$

The ten-field fit is: traditional target finite-list classified successor readback; BEDC source BHist *with* Cont*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability from cons-boundary coherence and source* $\mathsf{NameCert}$*; ledger* $\mathsf{ListPublicLength}_A$*; core theorem classified successor public-length inversion; exactness by common public-length witnesses and successor spine analysis; standard bridge finite spines; status* $\mathsf{ProofTarget}$*.*

Proof. Use Theorem 36.77 on the displayed $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$ witness. It supplies a finite value m together with $\mathsf{ListPublicLength}_A(h, m)$ and $\mathsf{ListPublicLength}_A(k, m)$.

The given witness $\mathsf{ListPublicLength}_A(h, n+1)$ and the h-side witness at value m have the same endpoint. Apply Theorem 36.76 to identify $m = n+1$, and rewrite the k-side witness as $\mathsf{ListPublicLength}_A(k, n+1)$.

Now apply Theorem 36.81 to the endpoint k with length $n+1$. The resulting histories a, t, p satisfy $A(a)$, $\mathsf{ListHistoryCarrier}_A(t)$, $\mathsf{ListPublicLength}_A(t, n)$, $\mathsf{Cont}(a, t, p)$, and $\mathsf{hsame}(k, \mathsf{E1}(p))$, which are exactly the displayed existential data. □

Theorem 36.84 (List classified successor component readback)**.** *Let $A : \mathsf{BHist} \to \mathsf{Prop}$ be a BEDC history source carrier, let $\sim_A$ be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$. *Assume* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$. *For histories h, k and every finite length value n, if* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$ *and* $\mathsf{ListPublicLength}_A(h, n+1)$ *hold, then*

$$\exists a\, b\, t\, u\, p\, q : \mathsf{BHist}. \left(\begin{array}{l} A(a) \wedge A(b) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{ListHistoryCarrier}_A(u) \wedge \\ \mathsf{ListPublicLength}_A(t, n) \wedge \mathsf{ListPublicLength}_A(u, n) \wedge \\ \mathsf{Cont}(a, t, p) \wedge \mathsf{Cont}(b, u, q) \wedge \\ \mathsf{hsame}(h, \mathsf{E1}(p)) \wedge \mathsf{hsame}(k, \mathsf{E1}(q)) \wedge \\ a \sim_A b \wedge \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(t, u) \end{array} \right).$$

The ten-field fit is: traditional target finite-list classified successor component readback; BEDC source BHist *with* Cont*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability from cons-boundary coherence and source* $\mathsf{NameCert}$*; ledger* $\mathsf{ListPublicLength}_A$ *on both tails; core theorem componentwise successor inversion; exactness by public cons endpoint inversion; standard bridge finite spines; status* $\mathsf{ProofTarget}$.

Proof. First obtain the representation coherence needed by the public endpoint inversion. Apply Theorem 36.71 to the assumed $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$ witness.

Next read back the public successor endpoint h. Apply Theorem 36.81 to $\mathsf{ListPublicLength}_A(h, n+1)$, obtaining histories a, t, p with $A(a)$, $\mathsf{ListHistoryCarrier}_A(t)$, $\mathsf{ListPublicLength}_A(t, n)$, $\mathsf{Cont}(a, t, p)$, and $\mathsf{hsame}(h, \mathsf{E1}(p))$.

Read back the classified successor endpoint k with Theorem 36.83, using the same classifier witness and public length witness. Rename its histories as b, u, q. This gives $A(b)$, $\mathsf{ListHistoryCarrier}_A(u)$, $\mathsf{ListPublicLength}_A(u, n)$, $\mathsf{Cont}(b, u, q)$, and $\mathsf{hsame}(k, \mathsf{E1}(q))$.

Finally apply Theorem 36.155 to the two displayed cons endpoint presentations and the original $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$ witness. The conclusion is $a \sim_A b$ together with $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(t,$ Repack these with the two readback packages to obtain the displayed existential witnesses. □

Theorem 36.85 (List classified successor component readback determinacy)**.** *Let $A : \mathsf{BHist} \to \mathsf{Prop}$ be a BEDC history source carrier and let $\sim_A$ be a source classifier. Assume* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$. *For histories $h, k, a, b, t, u, p, q, a', b', t', u', p', q'$ and every finite length value n, suppose the two six-tuples (a, b, t, u, p, q) and (a', b', t', u', p', q') both satisfy the classified successor component package for the same h, k, n:*

$$\begin{array}{l} A(a) \wedge A(b) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{ListHistoryCarrier}_A(u) \wedge \\ \mathsf{ListPublicLength}_A(t, n) \wedge \mathsf{ListPublicLength}_A(u, n) \wedge \\ \mathsf{Cont}(a, t, p) \wedge \mathsf{Cont}(b, u, q) \wedge \\ \mathsf{hsame}(h, \mathsf{E1}(p)) \wedge \mathsf{hsame}(k, \mathsf{E1}(q)) \wedge \\ a \sim_A b \wedge \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(t, u) \end{array}$$

and

$$\begin{aligned}&A(a') \wedge A(b') \wedge \mathsf{ListHistoryCarrier}_A(t') \wedge \mathsf{ListHistoryCarrier}_A(u') \wedge \\ &\mathsf{ListPublicLength}_A(t', n) \wedge \mathsf{ListPublicLength}_A(u', n) \wedge \\ &\mathsf{Cont}(a', t', p') \wedge \mathsf{Cont}(b', u', q') \wedge \\ &\mathsf{hsame}(h, \mathsf{E1}(p')) \wedge \mathsf{hsame}(k, \mathsf{E1}(q')) \wedge \\ &a' \sim_A b' \wedge \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(t', u')\end{aligned}$$

hold. Then

$$a \sim_A a' \wedge b \sim_A b' \wedge \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(t, t') \wedge \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(u, u').$$

The ten-field fit is: traditional target finite-list classified successor component readback; BEDC source BHist *with* Cont*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability from cons-boundary coherence; ledger same public successor endpoints* h, k *with common predecessor length* n*; core theorem witness-choice determinacy; exactness by public cons endpoint readback; standard bridge finite spines; status* ProofTarget*.*

Proof. Apply Theorem 36.73 to the two h-side cons presentations. The first package supplies $A(a)$, $\mathsf{ListHistoryCarrier}_A(t)$, $\mathsf{Cont}(a, t, p)$, and $\mathsf{hsame}(h, \mathsf{E1}(p))$; the second supplies the corresponding data for a', t', p'. The conclusion gives $a \sim_A a'$ and $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(t, t')$.

Apply the same theorem to the two k-side cons presentations. The first package supplies $A(b)$, $\mathsf{ListHistoryCarrier}_A(u)$, $\mathsf{Cont}(b, u, q)$, and $\mathsf{hsame}(k, \mathsf{E1}(q))$; the second supplies the corresponding data for b', u', q'. The conclusion gives $b \sim_A b'$ and $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(u, u')$. Repack the four conclusions in the displayed order. □

Definition 36.86 (List source hsame compatibility)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier and let* $\sim_A$ *be a source classifier. Define* $\mathsf{ListSourceHsameCompatible}(A, \sim_A)$ *as source-carrier completeness for* hsame*:*

$$\forall a\, b.\ A(a) \to A(b) \to \mathsf{hsame}(a, b) \to a \sim_A b.$$

Lean4 (definition) `BEDC.Derived.ListUp.ListSourceHsameCompatible`

Theorem 36.87 (List source hsame compatibility for hsame)**.** *For every BEDC history source carrier* $A : \mathsf{BHist} \to \mathsf{Prop}$*,*

$$\mathsf{ListSourceHsameCompatible}(A, \mathsf{hsame}).$$

Proof. Unfold ListSourceHsameCompatible. For histories a and b, the two source-carrier witnesses $A(a)$ and $A(b)$ are part of the interface, and the final displayed input is already the required $\mathsf{hsame}(a, b)$ classifier witness. Return that witness. □

Theorem 36.88 (List source-classifier weakening)**.** *Let* $A, B : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, and let* $\sim_A$ *and* $\sim_B$ *be source classifiers. The ten-field fit is: traditional target finite-list source refinement; BEDC source* BHist *with* Cont*; source relation carried by* $\sim_A$ *and* $\sim_B$*; carrier generated list/spine bridge; classifier recursive and spine bridge; stability under source/classifier refinement; ledger unchanged finite spine; core theorem the four displayed implications below; exactness preservation under source/classifier refinement; status* ProofTarget*. If source membership and source classification weaken from* A *to* B*,*

$$(\forall a : \mathsf{BHist}.\ A(a) \to B(a)) \wedge (\forall a\, b : \mathsf{BHist}.\ a \sim_A b \to a \sim_B b),$$

then for all histories h, k and finite spines xs,

$$\begin{aligned}
\mathsf{ListHistoryCarrier}_A(h) &\to \mathsf{ListHistoryCarrier}_B(h),\\
\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}(h,k) &\to \mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{B,\sim_B}(h,k),\\
\mathsf{ListSpineRep}_A(h,xs) &\to \mathsf{ListSpineRep}_B(h,xs),\\
\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h,k) &\to \mathsf{ListSpineBridgeClassifier}_{B,\sim_B}(h,k).
\end{aligned}$$

Proof. Induct separately on the displayed carrier, recursive classifier, spine representation, and bridge witness. The nil clauses are rebuilt directly. In each cons clause, apply the source-carrier inclusion to the head datum, apply the classifier inclusion to the head classifier datum when present, and reuse the same Cont and endpoint hsame witnesses. For a bridge witness, keep the same finite spines, transport the two spine representations by the representation induction, transport the finite-spine classifier entry by entry using the classifier inclusion, and rebuild the bridge witness with those transported components. □

Lean4 ✓ `BEDC.Derived.ListUp.ListSourceClassifier weakening`

Definition 36.89 (Unary NatAdd relation)**.** *For histories u, v, w : BHist, write*

$$\mathsf{NatAdd}(u,v,w) \iff \mathsf{UnaryCont}(u,v,w).$$

This is the unary-continuation additive relation of Definition 9194.2 and Definition 29.8.

Definition 36.90 (List unary length token)**.** *For finite BEDC-history spines, define the unary length token by recursion:*

$$\begin{aligned}
\mathsf{ListUnaryLength}(\mathsf{nil}) &= \mathsf{e},\\
\mathsf{ListUnaryLength}(\mathsf{cons}(a,xs)) &= \mathsf{E1}(\mathsf{ListUnaryLength}(xs)).
\end{aligned}$$

This is the unary-history counterpart of the finite-spine value $\ell(xs)$ used in Definition 36.75; it records the same constructor count as a $\mathsf{Nat}^{\uparrow}$ token.

Lean4 (definition) `BEDC.Derived.ListUp.ListUnaryLength`

Definition 36.91 (List public unary length token)**.** *For a BEDC history source carrier A : BHist $\to$ Prop, define the public unary length token relation by*

$$\mathsf{ListPublicUnaryLength}_A(h,u) \iff \exists xs : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_A(h,xs) \wedge \mathsf{hsame}(\mathsf{ListUnaryLength}(xs),u).$$

Thus the certificate-level endpoint exposes the same unary $\mathsf{Nat}^{\uparrow}$ token that the finite-spine presentation computes internally.

Theorem 36.92 (List classifier preserves unary length token)**.** *Let $\sim_A$: BHist $\to$ BHist $\to$ Prop be a source classifier and let xs, ys : HistSpine be finite BEDC-history spines. If*

$$\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$$

holds, then

$$\mathsf{hsame}(\mathsf{ListUnaryLength}(xs), \mathsf{ListUnaryLength}(ys)).$$

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec unary length token hsame`

Proof. Induct on the displayed finite-spine classifier witness.

In the nil-nil case, both spines are nil, so both unary length tokens reduce to e. Reflexivity of hsame closes the empty-token comparison.

In the cons-cons case, write the spines as $\mathsf{cons}(a, xs_0)$ and $\mathsf{cons}(b, ys_0)$. The classifier witness contains the source head comparison $a \sim_A b$ and the tail classifier $\mathsf{ListClassifierSpec}(\sim_A, xs_0, ys_0)$; the induction hypothesis gives

$$\mathsf{hsame}(\mathsf{ListUnaryLength}(xs_0), \mathsf{ListUnaryLength}(ys_0)).$$

The recursive clause of Definition 36.90 turns the two outer length tokens into one-extensions of those tail tokens. Applying the E1-congruence direction of Definition 20.10 gives the required hsame comparison for the two cons spines. □

Theorem 36.93 (List public unary length classifier transport)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*. Assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. Then for all histories* h, k *and all unary length tokens* $u : \mathsf{BHist}$*, a classifier witness* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$ *transports public unary length readback in both directions:*

1. *if* $\mathsf{ListPublicUnaryLength}_A(h, u)$ *holds, then* $\mathsf{ListPublicUnaryLength}_A(k, u)$ *holds;*
2. *if* $\mathsf{ListPublicUnaryLength}_A(k, u)$ *holds, then* $\mathsf{ListPublicUnaryLength}_A(h, u)$ *holds.*

The ten-field fit is: traditional target finite-list length as a $\mathsf{Nat}^{\uparrow}$ *unary token; BEDC source* BHist *with* NameCert*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability from represented spine coherence and source-certificate transitivity; ledger finite spine plus unary token; core theorem public unary length classifier transport; exactness by public readback* $\mathsf{ListPublicUnaryLength}_A$*; standard bridge ordinary finite-list length; status* ProofTarget*.*

Lean4 ✓ `BEDC.Derived.ListUp.ListPublicUnaryLength classifier transport`

Proof. Fix h, k, u and a bridge classifier $C : \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$. Unpack C into finite spines p and q, endpoint presentations $\mathsf{ListSpineRep}_A(h, p)$ and $\mathsf{ListSpineRep}_A(k, q)$, and a finite-spine classifier $\mathsf{ListClassifierSpec}(\sim_A, p, q)$.

For transport from h to k, unpack $\mathsf{ListPublicUnaryLength}_A(h, u)$ as a finite spine xs, a representation $\mathsf{ListSpineRep}_A(h, xs)$, and $\mathsf{hsame}(\mathsf{ListUnaryLength}(xs), u)$. Coherence at the shared endpoint h compares the two presentations of h, giving $\mathsf{ListClassifierSpec}(\sim_A, xs, p)$.

Compose that finite-spine classifier with the bridge classifier $\mathsf{ListClassifierSpec}(\sim_A, p, q)$, using the transitivity clause of cert at each source head. Apply Theorem 36.92 to obtain

$$\mathsf{hsame}(\mathsf{ListUnaryLength}(xs), \mathsf{ListUnaryLength}(q)).$$

Symmetry and transitivity of hsame, together with the original comparison with u, give $\mathsf{hsame}(\mathsf{ListUnaryLength}(q), u$ Repack q and its representation at k as $\mathsf{ListPublicUnaryLength}_A(k, u)$.

For transport from k to h, unpack $\mathsf{ListPublicUnaryLength}_A(k, u)$ as a finite spine ys, a representation $\mathsf{ListSpineRep}_A(k, ys)$, and $\mathsf{hsame}(\mathsf{ListUnaryLength}(ys), u)$. Coherence at the shared endpoint k compares the bridge spine q with ys, giving $\mathsf{ListClassifierSpec}(\sim_A, q, ys)$.

Compose the bridge classifier $\mathsf{ListClassifierSpec}(\sim_A, p, q)$ with this endpoint-coherence classifier, again using source-certificate transitivity headwise. Theorem 36.92 gives

$$\mathsf{hsame}(\mathsf{ListUnaryLength}(p), \mathsf{ListUnaryLength}(ys)).$$

Transitivity with the original comparison to u gives $\mathsf{hsame}(\mathsf{ListUnaryLength}(p), u)$. Repack p and its representation at h as $\mathsf{ListPublicUnaryLength}_A(h, u)$. □

Theorem 36.94 (List public append unary-length classifier congruence)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. For histories* $h, h', k, k', r, r', u, v, w : \mathsf{BHist}$*, assume*

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, h'), \qquad \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(k, k'),$$

$$\mathsf{ListPublicAppend}_A(h, k, r), \qquad \mathsf{ListPublicAppend}_A(h', k', r'),$$

and

$$\mathsf{ListPublicUnaryLength}_A(h, u), \qquad \mathsf{ListPublicUnaryLength}_A(k, v), \qquad \mathsf{ListPublicUnaryLength}_A(r, w)$$

hold. Then

$$\mathsf{ListPublicUnaryLength}_A(h', u) \wedge \mathsf{ListPublicUnaryLength}_A(k', v) \wedge \mathsf{ListPublicUnaryLength}_A(r', w).$$

The ten-field fit is: traditional target finite-list append stability for unary length tokens; BEDC source BHist *through* $\mathsf{ListSpineRep}$*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability from append congruence and unary-length classifier transport; ledger public unary length tokens; core theorem this composite; exactness via public append and public unary length readback; standard bridge ordinary finite-list append length invariance; status* $\mathsf{ProofTarget}$*.*

Proof. Apply Theorem 36.93 to the classifier witness from h to h' and the public unary length token at h. Its forward transport clause gives $\mathsf{ListPublicUnaryLength}_A(h', u)$.

Apply the same theorem to the classifier witness from k to k' and the public unary length token at k. The forward transport clause gives $\mathsf{ListPublicUnaryLength}_A(k', v)$.

Next apply the second clause of Theorem 36.195 to the two endpoint classifier witnesses and the two public append readbacks. This gives

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(r, r').$$

Apply Theorem 36.93 once more to this output classifier and the public unary length token at r. Its forward transport clause gives $\mathsf{ListPublicUnaryLength}_A(r', w)$, and the three transported witnesses form the displayed conjunction. □

Theorem 36.95 (Public list unary length additivity under append)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier. For histories* $h, k, r : \mathsf{BHist}$ *and finite spines* $xs, ys : \mathsf{HistSpine}$*, assume*

$$\mathsf{ListSpineRep}_A(h, xs), \qquad \mathsf{ListSpineRep}_A(k, ys), \qquad \mathsf{ListSpineRep}_A(r, xs{+}{+}ys).$$

Set

$$L_x = \mathsf{ListUnaryLength}(xs), \qquad L_y = \mathsf{ListUnaryLength}(ys), \qquad L_{xy} = \mathsf{ListUnaryLength}(xs{+}{+}ys).$$

Then

$$\mathsf{NatAdd}(L_y, L_x, L_{xy})$$

and for every $w : \mathsf{BHist}$*,*

$$\mathsf{NatAdd}(L_x, L_y, w) \Longrightarrow \mathsf{hsame}(L_{xy}, w).$$

Proof. By Definition 36.57, the three representation witnesses say that the public endpoints use the displayed finite spines and that the append endpoint uses the spine append $xs{+}{+}ys$. The proof of the additive length claim depends on the spines alone.

A preliminary induction on a finite spine zs gives $\mathsf{Unary}(\mathsf{ListUnaryLength}(zs))$. The nil case is the base unary generator from Definition 28.1; the cons case applies Definition 28.2 to the induction hypothesis.

Now induct on xs to prove $\mathsf{NatAdd}(L_y, L_x, L_{xy})$. In the nil case, $L_x = \mathsf{e}$ and $L_{xy} = L_y$. The preliminary unary induction gives $\mathsf{Unary}(L_y)$, and the right-unit clause of Definition 21.12 gives $\mathsf{Cont}(L_y, \mathsf{e}, L_y)$. Unfolding Definition 36.89 gives $\mathsf{NatAdd}(L_y, \mathsf{e}, L_y)$.

In the cons case, write $xs = \mathsf{cons}(a, xs_0)$ and let $L_0 = \mathsf{ListUnaryLength}(xs_0)$ and $T = \mathsf{ListUnaryLength}(xs_0{+}{+}ys)$ The induction hypothesis gives $\mathsf{NatAdd}(L_y, L_0, T)$, hence $\mathsf{Cont}(L_y, L_0, T)$ after unfolding Definition 36.89. The one-step rule in Definition 4.10 gives $\mathsf{Cont}(L_y, \mathsf{E1}(L_0), \mathsf{E1}(T))$. The preliminary unary induction and Definition 28.2 supply the two unary input witnesses, so this is exactly $\mathsf{NatAdd}(L_y, L_x, L_{xy})$ by the recursive clauses of Definition 36.90.

Finally assume $\mathsf{NatAdd}(L_x, L_y, w)$. Together with the reversed append-aligned witness just proved, Definition 9194.6 compares the two unary continuation results and gives $\mathsf{hsame}(w, L_{xy})$. Symmetry of hsame gives $\mathsf{hsame}(L_{xy}, w)$. □

Lean4 ✓ `BEDC.Derived.ListUp.ListUnaryLength append cont`

Theorem 36.96 (Public list unary length is associative under append)**.** *Let $A : \mathsf{BHist} \to \mathsf{Prop}$ be a BEDC history source carrier. For histories $h_x, h_y, h_z, h_{xy}, h_{(xy)z}, h_{yz}, h_{x(yz)} : \mathsf{BHist}$ and finite spines $xs, ys, zs : \mathsf{HistSpine}$, assume*

$$\mathsf{ListSpineRep}_A(h_x, xs), \quad \mathsf{ListSpineRep}_A(h_y, ys), \quad \mathsf{ListSpineRep}_A(h_z, zs),$$

$$\mathsf{ListSpineRep}_A(h_{xy}, xs{+}{+}ys), \quad \mathsf{ListSpineRep}_A(h_{(xy)z}, (xs{+}{+}ys){+}{+}zs),$$

and

$$\mathsf{ListSpineRep}_A(h_{yz}, ys{+}{+}zs), \quad \mathsf{ListSpineRep}_A(h_{x(yz)}, xs{+}{+}(ys{+}{+}zs)).$$

Set

$$L_x = \mathsf{ListUnaryLength}(xs), \quad L_y = \mathsf{ListUnaryLength}(ys), \quad L_z = \mathsf{ListUnaryLength}(zs),$$

$$L_{xy} = \mathsf{ListUnaryLength}(xs{+}{+}ys), \quad L_{yz} = \mathsf{ListUnaryLength}(ys{+}{+}zs),$$

and

$$L_{(xy)z} = \mathsf{ListUnaryLength}((xs{+}{+}ys){+}{+}zs), \quad L_{x(yz)} = \mathsf{ListUnaryLength}(xs{+}{+}(ys{+}{+}zs)).$$

Then

$$\mathsf{hsame}(L_{(xy)z}, L_{x(yz)}).$$

Proof. Apply Definition 36.95 to the witnesses for xs, ys, and $xs{+}{+}ys$, obtaining $\mathsf{NatAdd}(L_y, L_x, L_{xy})$. Apply the same theorem to the witnesses for $xs{+}{+}ys$, zs, and $(xs{+}{+}ys){+}{+}zs$, obtaining $\mathsf{NatAdd}(L_z, L_{xy}, L_{(xy)z})$.

Apply Definition 36.95 to the witnesses for ys, zs, and $ys{+}{+}zs$, obtaining $\mathsf{NatAdd}(L_z, L_y, L_{yz})$. Apply it once more to the witnesses for xs, $ys{+}{+}zs$, and $xs{+}{+}(ys{+}{+}zs)$, obtaining $\mathsf{NatAdd}(L_{yz}, L_x, L_{x(yz)})$.

Unfolding Definition 36.89, these four witnesses are unary continuations for the two parenthesized length composites. The associativity theorem for unary continuation, Definition 29.6, compares the continuation first through L_{xy} with the continuation first through L_{yz}.

The displayed additivity witnesses identify the left parenthesized endpoint with $L_{(xy)z}$ and the right parenthesized endpoint with $L_{x(yz)}$. Symmetry and transitivity of hsame compose those endpoint comparisons with the associativity comparison, yielding $\mathsf{hsame}(L_{(xy)z}, L_{x(yz)})$. □

Theorem 36.97 (List public length classifier transport)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*. Assume* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$*. Then for all histories* h, k *and all public length values* n*, a classifier witness* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$ *transports the chosen public length witness across the classified endpoints:*

1. *if* $\mathsf{ListPublicLength}_A(h, n)$ *holds, then* $\mathsf{ListPublicLength}_A(k, n)$ *holds;*
2. *if* $\mathsf{ListPublicLength}_A(k, n)$ *holds, then* $\mathsf{ListPublicLength}_A(h, n)$ *holds.*

The roadmap ten-field fit is: traditional target classifier-stable finite-list length readback; BEDC source BHist *with* NameCert*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; ledger chosen public length witnesses; exactness through* $\mathsf{ListPublicLength}_A$ *and classified endpoint readback; status* ProofTarget.

Proof. Fix h, k, n and a witness $C : \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$.

For transport from h to k, assume $L_h : \mathsf{ListPublicLength}_A(h, n)$. Apply Theorem 36.77 to C to obtain a public length value m with witnesses $\mathsf{ListPublicLength}_A(h, m)$ and $\mathsf{ListPublicLength}_A(k, m)$.

Apply Theorem 36.76 to the same classifier witness C, the given witness L_h, and the endpoint witness $\mathsf{ListPublicLength}_A(k, m)$. This identifies $n = m$. Rewrite the endpoint witness at k along this equality to obtain $\mathsf{ListPublicLength}_A(k, n)$.

For transport from k to h, assume $L_k : \mathsf{ListPublicLength}_A(k, n)$. Apply Theorem 36.77 to C again to obtain a public length value m with witnesses $\mathsf{ListPublicLength}_A(h, m)$ and $\mathsf{ListPublicLength}_A(k, m)$.

Apply Theorem 36.76 to the same classifier witness C, the endpoint witness $\mathsf{ListPublicLength}_A(h, m)$, and the given witness L_k. This identifies $m = n$. Rewrite the endpoint witness at h along this equality to obtain $\mathsf{ListPublicLength}_A(h, n)$. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListPublicLength classifier transport`
Lean4 ✓ `BEDC.Derived.ListUp.FramedListBridgeClassifier public length transport`
Lean4 ✓ `BEDC.Derived.ListUp.FramedListPublicLength bridge transport pair`

Theorem 36.98 (List public length classifier unary token transport)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*. Assume* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$*. Then for all histories* h, k *and all public length values* n*, a classifier witness* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$ *transports each finite spine presentation together with its derived unary length token:*

1. *if* $\mathsf{ListSpineRep}_A(h, xs)$ *and* $\ell(xs) = n$*, then there exists* $ys : \mathsf{HistSpine}$ *such that*

$$\mathsf{ListSpineRep}_A(k, ys) \wedge \ell(ys) = n \wedge \mathsf{hsame}(\mathsf{ListUnaryLength}(xs), \mathsf{ListUnaryLength}(ys)).$$

2. *if* $\mathsf{ListSpineRep}_A(k, ys)$ *and* $\ell(ys) = n$*, then there exists* $xs : \mathsf{HistSpine}$ *such that*

$$\mathsf{ListSpineRep}_A(h, xs) \wedge \ell(xs) = n \wedge \mathsf{hsame}(\mathsf{ListUnaryLength}(ys), \mathsf{ListUnaryLength}(xs)).$$

The roadmap ten-field fit is: traditional target classifier-stable finite-list length readback with internal unary evidence; BEDC source BHist *with* NameCert*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; ledger the public finite length value and its BEDC unary token; exactness through* $\mathsf{ListPublicLength}_A$*,* $\mathsf{ListSpineRep}_A$*, and* ListUnaryLength*; status* ProofTarget.

Proof. Fix a classifier witness $C : \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$. Theorem 36.77 applied to C supplies a common public length value m for the classified endpoints.

Unpack Definition 36.75 for those two public witnesses, giving classifier-selected finite spines x_0 and y_0 with representations of h and k and with finite values $\ell(x_0) = m$ and $\ell(y_0) = m$. Unfolding C through the list-spine representation definition selects the same endpoints with a finite-spine classifier witness $\mathsf{ListClassifierSpec}(\sim_A, x_0, y_0)$.

For transport from h to k, assume the displayed public presentation of h is witnessed by xs and $\ell(xs) = n$. Repack it through Definition 36.75 as $\mathsf{ListPublicLength}_A(h, n)$. The k-side selected spine gives $\mathsf{ListPublicLength}_A(k, m)$, and Theorem 36.76 aligns the finite values $n = m$. Rewriting $\ell(y_0) = m$ along this equality gives $\ell(y_0) = n$.

It remains to compare unary tokens. First turn the cons-boundary coherence hypothesis into $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$ by Theorem 36.71. Applying that coherence datum to the two h-presentations, xs and x_0, gives $\mathsf{ListClassifierSpec}(\sim_A, xs, x_0)$.

Apply Theorem 36.92 to this comparison to obtain $\mathsf{hsame}(\mathsf{ListUnaryLength}(xs), \mathsf{ListUnaryLength}(x_0))$. Apply the same theorem to the selected endpoint classifier to obtain $\mathsf{hsame}(\mathsf{ListUnaryLength}(x_0), \mathsf{ListUnaryLength}(y_0$

By transitivity of hsame, these combine to $\mathsf{hsame}(\mathsf{ListUnaryLength}(xs), \mathsf{ListUnaryLength}(y_0))$. Taking $ys = y_0$ gives the first existential.

For transport from k to h, use the symmetric argument. The displayed presentation of k repacks as $\mathsf{ListPublicLength}_A(k, n)$; the h-side selected spine gives $\mathsf{ListPublicLength}_A(h, m)$; and Theorem 36.76 aligns $n = m$, hence $\ell(x_0) = n$.

Coherence compares the displayed k-spine with the selected y_0 spine, so Theorem 36.92 gives their unary token comparison.

The selected endpoint classifier gives the reverse comparison from $\mathsf{ListUnaryLength}(y_0)$ to $\mathsf{ListUnaryLength}(x_0)$ by symmetry of hsame after applying Theorem 36.92. Transitivity of hsame combines the two comparisons, and choosing $xs = x_0$ gives the second existential. □

Theorem 36.99 (List classified successor component exactness)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*. Assume* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$*. For histories* h, k *and every finite length value* n*,*

$$\left(\begin{array}{l}\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h,k)\wedge\\ \mathsf{ListPublicLength}_A(h,n+1)\wedge\mathsf{ListPublicLength}_A(k,n+1)\end{array}\right) \iff \exists a\,b\,t\,u\,p\,q : \mathsf{BHist}.\left(\begin{array}{l}A(a)\wedge A(b)\wedge\mathsf{ListHi}\\ \mathsf{ListPublicLength}_A(t,\\ \mathsf{Cont}(a,t,p)\wedge\mathsf{Cont}(\\ \mathsf{hsame}(h,\mathsf{E1}(p))\wedge\mathsf{hs}\\ a\sim_A b\wedge\mathsf{ListSpineH}\end{array}\right.$$

The ten-field fit is: traditional target finite-list classified successor component coverage; BEDC source BHist *with* Cont*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability from cons-boundary coherence and source* $\mathsf{NameCert}$*; ledger common successor public lengths on both endpoints; core theorem successor component exactness; exactness by public successor length construction and public-object constructor audit; standard bridge finite spines; status* $\mathsf{ProofTarget}$*.*

Proof. For the forward direction, apply Theorem 36.84 to the displayed classifier witness and the public successor length witness for h. It returns histories a, b, t, u, p, q with the two source heads, the two tail carriers, the predecessor public lengths, the two continuation witnesses, the two successor endpoint presentations, the head classifier witness, and the tail classifier witness. These are exactly the six-component package on the right-hand side.

For the reverse direction, assume the displayed six-component package. Apply the reverse direction of Theorem 36.82 to the h-side data $A(a)$, $\mathsf{ListHistoryCarrier}_A(t)$, $\mathsf{ListPublicLength}_A(t, n)$, $\mathsf{Cont}(a, t, p)$, and $\mathsf{hsame}(h, \mathsf{E1}(p))$. This gives $\mathsf{ListPublicLength}_A(h, n + 1)$.

Apply the same public successor constructor exactness theorem to the k-side data $A(b)$, $\mathsf{ListHistoryCarrier}_A(u)$, $\mathsf{ListPublicLength}_A(u, n)$, $\mathsf{Cont}(b, u, q)$, and $\mathsf{hsame}(k, \mathsf{E1}(q))$. This gives $\mathsf{ListPublicLength}_A(k, n+1)$.

It remains to recover the classified endpoint relation. Use the cons branch of Theorem 36.165, instantiated with the same A, $\sim_A$, source certificate, and cons-boundary coherence witness. The displayed heads, tails, continuations, endpoint presentations, $a \sim_A b$, and $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(t, u)$ form exactly its cons-constructor package, so the reverse direction of the audit yields $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h$ Combining this classifier witness with the two public successor length witnesses gives the left-hand side. □

then $\mathsf{hsame}(u, u') \wedge \mathsf{hsame}(t, t')$*.*

Proof. Proceed by structural induction and case analysis on u and u'. The mixed $\mathsf{e}/\mathsf{E0}$ and $\mathsf{e}/\mathsf{E1}$ cases contradict BEDC constructor no-confusion because $\mathsf{PairFrame}(\mathsf{e}, t)$ begins with $\mathsf{E0}$, while the nonempty cases begin with $\mathsf{E1}$. The mixed $\mathsf{E0}/\mathsf{E1}$ cases contradict no-confusion after inverting the outer $\mathsf{E1}$ and comparing the inner tags. In the matching e/e case, constructor inversion gives $\mathsf{hsame}(t, t')$. In the matching $\mathsf{E0}/\mathsf{E0}$ and $\mathsf{E1}/\mathsf{E1}$ cases, invert the outer $\mathsf{E1}$, then the matching inner tag, and apply the induction hypothesis to the recursive pair-frame equality. Combining the exposed recursive head equality with the constructor equality gives $\mathsf{hsame}(u, u')$, and the induction hypothesis also gives $\mathsf{hsame}(t, t')$. □

Lean4 ✓ `BEDC.Derived.ListUp.PairFrame hsame injective`

Theorem 36.106 (Pair frame empty head iff)**.** *For histories* $u, t : \mathsf{BHist}$*, the pair frame has the empty-head boundary exactly when the head itself is empty:*

$$\mathsf{hsame}(\mathsf{PairFrame}(u, t), \mathsf{E0}(t)) \iff \mathsf{hsame}(u, \mathsf{e}).$$

Proof. Case-split the head u. In the empty case the pair-frame definition is $\mathsf{E0}(t)$, so the displayed classifier is reflexive. In the zero-headed and one-headed cases the pair frame begins with $\mathsf{E1}$, contradicting $\mathsf{E1}/\mathsf{E0}$ no-confusion. Conversely, a classifier $\mathsf{hsame}(u, \mathsf{e})$ substitutes the empty head into the pair-frame definition. □

Lean4 ✓ `BEDC.Derived.ListUp.PairFrame empty head iff`

Definition 36.107 (Framed list endpoint)**.** *For finite BEDC-history spines, define the framed endpoint by recursion on the spine:*

$$\begin{aligned} \mathsf{FramedListEndpoint}(\mathsf{nil}) &= \mathsf{E0}(\mathsf{e}), \\ \mathsf{FramedListEndpoint}(\mathsf{cons}(a, xs)) &= \mathsf{E1}(\mathsf{PairFrame}(a, \mathsf{FramedListEndpoint}(xs))). \end{aligned}$$

Lean4 (definition) `BEDC.Derived.ListUp.FramedListEndpoint`

Theorem 36.108 (Framed list endpoint no-confusion and cons inversion)**.** *The ten-field fit is: traditional target finite-list endpoint readback; BEDC source* BHist *with* hsame*; carrier framed finite spines; classifier endpoint* hsame*; stability obligations nil/cons separation and cons inversion; ledger*

constructor frame; core theorem this block; exactness framed endpoint exposes list shape; standard bridge finite spines; status ProofTarget. *For all histories* $a, b : \mathsf{BHist}$ *and finite spines* xs, ys,

$$\neg\mathsf{hsame}(\mathsf{FramedListEndpoint}(\mathsf{nil}), \mathsf{FramedListEndpoint}(\mathsf{cons}(a, xs))),$$

$$\neg\mathsf{hsame}(\mathsf{FramedListEndpoint}(\mathsf{cons}(a, xs)), \mathsf{FramedListEndpoint}(\mathsf{nil})),$$

and

$$\mathsf{hsame}(\mathsf{FramedListEndpoint}(\mathsf{cons}(a, xs)), \mathsf{FramedListEndpoint}(\mathsf{cons}(b, ys)))$$

implies both $\mathsf{hsame}(a, b)$ *and* $\mathsf{hsame}(\mathsf{FramedListEndpoint}(xs), \mathsf{FramedListEndpoint}(ys))$.

Proof. The nil endpoint has outer constructor E0, while every cons endpoint has outer constructor E1, so the two mixed cases contradict BEDC history no-confusion in the E0/E1 and E1/E0 directions. For the cons-cons clause, invert the outer E1 equality and obtain equality of the two displayed pair frames. Lemma 36.105 applies: its proof is an induction on the first frame argument, with constructor no-confusion separating the empty and tagged nonempty cases and with recursive inversion exposing the first and second frame arguments. The two projections of that lemma give $\mathsf{hsame}(a, b)$ and $\mathsf{hsame}(\mathsf{FramedListEndpoint}(xs), \mathsf{FramedListEndpoint}(ys))$. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListEndpoint no confusion cons inversion`

Lemma 36.109 (Pair frame congruence)**.** *For histories* $u, u', t, t' : \mathsf{BHist}$, *if* $\mathsf{hsame}(u, u')$ *and* $\mathsf{hsame}(t, t')$, *then*

$$\mathsf{hsame}(\mathsf{PairFrame}(u, t), \mathsf{PairFrame}(u', t')).$$

Proof. Proceed by induction on the displayed witness $\mathsf{hsame}(u, u')$. In the empty case, the goal is the congruence of E0 applied to $\mathsf{hsame}(t, t')$. In the E0 case, apply the induction hypothesis to the inner pair frame and then apply congruence for the two visible constructors E0 and E1. The E1 case is identical except that the inner tag is E1. Thus the frame recursion is stable in the first argument, and the terminal empty branch carries the second-argument hsame witness. □

Lean4 ✓ `BEDC.Derived.ListUp.PairFrame congruence`

Theorem 36.110 (Framed list endpoint classifier exactness)**.** *For finite BEDC-history spines* xs, ys,

$$\mathsf{hsame}(\mathsf{FramedListEndpoint}(xs), \mathsf{FramedListEndpoint}(ys)) \iff \mathsf{ListClassifierSpec}(\mathsf{hsame}, xs, ys).$$

Proof. For the left-to-right direction, argue by induction on the first spine and case analysis on the second. The nil-nil case gives the nil constructor of ListClassifierSpec. The mixed nil-cons and cons-nil cases contradict Theorem 36.108. In the cons-cons case, the same theorem exposes hsame between the heads and hsame between the framed tail endpoints; apply the induction hypothesis to the tail equality and then use the cons constructor of $\mathsf{ListClassifierSpec}(\mathsf{hsame}, -, -)$.

For the right-to-left direction, induct on the displayed $\mathsf{ListClassifierSpec}(\mathsf{hsame}, xs, ys)$ witness. The nil branch is reflexivity of the framed nil endpoint. In the cons branch, the head witness and the induction hypothesis give congruent arguments for PairFrame by Lemma 36.109; one final E1 congruence yields equality of the framed cons endpoints. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListEndpoint classifier exactness`

Theorem 36.111 (Framed list endpoint length preservation)**.** *The ten-field fit is: traditional target finite-list framed endpoint readback; BEDC source* BHist*; carrier finite spines; classifier endpoint* hsame*; stability endpoint exactness; ledger visible framed endpoint; core theorem length preservation; exactness via* ListClassifierSpec*; standard bridge finite spines; status* ProofTarget*. For finite BEDC-history spines xs, ys, if*

$$\mathsf{hsame}(\mathsf{FramedListEndpoint}(xs), \mathsf{FramedListEndpoint}(ys))$$

holds, then

$$\ell(xs) = \ell(ys).$$

Proof. Apply Theorem 36.110 from left to right to convert the displayed endpoint equality into $\mathsf{ListClassifierSpec}(\mathsf{hsame}, xs, ys)$. Then apply Theorem 36.31 to obtain equality of the finite spine lengths. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListEndpoint length preservation`

Definition 36.112 (Framed list-spine representation)**.** *Let $A : \mathsf{BHist} \to \mathsf{Prop}$ be a BEDC history source carrier. Define $\mathsf{FramedListSpineRep}_A(h, xs)$ to mean that every entry of the finite spine xs satisfies A and that*

$$\mathsf{hsame}(h, \mathsf{FramedListEndpoint}(xs)).$$

Lean4 (definition) `BEDC.Derived.ListUp.FramedListSpineRep`

Theorem 36.113 (Framed list-spine representation hsame transport)**.** *Let $A : \mathsf{BHist} \to \mathsf{Prop}$ be a BEDC history source carrier. If $\mathsf{FramedListSpineRep}_A(h, xs)$ holds and $\mathsf{hsame}(h, h')$ holds, then $\mathsf{FramedListSpineRep}_A(h', xs)$ holds.*

Proof. The entrywise source predicate over xs is unchanged. The endpoint witness for h' is obtained by composing $\mathsf{hsame}(h', h)$, the symmetry of the displayed $\mathsf{hsame}(h, h')$, with the stored witness $\mathsf{hsame}(h, \mathsf{FramedListEndpoint}(xs))$. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListSpineRep hsame transport`

Theorem 36.114 (Framed list-spine cons endpoint injectivity)**.** *Let $A : \mathsf{BHist} \to \mathsf{Prop}$ be a BEDC history source carrier. If $\mathsf{FramedListSpineRep}_A(h, \mathsf{cons}(a, xs))$ and $\mathsf{FramedListSpineRep}_A(k, \mathsf{cons}(b, ys))$ hold, and $\mathsf{hsame}(h, k)$ holds, then the two framed cons endpoints are* hsame*, and their head payloads and tail endpoints are separately* hsame*:*

$$\mathsf{hsame}(\mathsf{E1}(\mathsf{PairFrame}(a, \mathsf{FramedListEndpoint}(xs))), \mathsf{E1}(\mathsf{PairFrame}(b, \mathsf{FramedListEndpoint}(ys))))$$

and

$$\mathsf{hsame}(a, b) \wedge \mathsf{hsame}(\mathsf{FramedListEndpoint}(xs), \mathsf{FramedListEndpoint}(ys)).$$

Proof. Compose the stored endpoint witness for the first representation, the displayed $\mathsf{hsame}(h, k)$ witness, and the stored endpoint witness for the second representation. This gives hsame between the two cons endpoints. Applying Definition 36.108 to that cons-cons endpoint equality exposes both the head equality $\mathsf{hsame}(a, b)$ and the tail endpoint equality. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListSpineRep cons endpoint injective`

Theorem 36.115 (Framed list-spine nil-cons no-confusion)**.** *Let A : BHist $\to$ Prop be a BEDC history source carrier. No single history can be represented both by the framed nil spine and by a framed cons spine:*

$$\mathsf{FramedListSpineRep}_A(h, \mathsf{nil}) \to \mathsf{FramedListSpineRep}_A(h, \mathsf{cons}(a, xs)) \to \mathsf{False}.$$

Proof. Unpack the two framed representations and compose their endpoint classifiers through symmetry and transitivity of hsame. This gives $\mathsf{hsame}(\mathsf{FramedListEndpoint}(\mathsf{nil}), \mathsf{FramedListEndpoint}(\mathsf{cons}(a, xs)))$, which contradicts the framed endpoint nil-cons no-confusion theorem. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListSpineRep nil cons no confusion`

Theorem 36.116 (Framed list-spine coherence)**.** *Let A : BHist $\to$ Prop be a BEDC history source carrier and let $\sim_A$ be a source classifier. If* $\mathsf{ListSourceHsameCompatible}(A, \sim_A)$ *holds, then any two framed presentations of the same history classify their finite spines:*

$$\forall h\, xs\, ys.\ \mathsf{FramedListSpineRep}_A(h, xs) \to \mathsf{FramedListSpineRep}_A(h, ys) \to \mathsf{ListClassifierSpec}(\sim_A, xs, ys).$$

Proof. Lemma 36.105 supplies the required injectivity of PairFrame. The framed list endpoint separates nil and cons by the outer E0/E1 tag, so mixed nil/cons presentations contradict BEDC history no-confusion. In the nil-nil case the finite-spine classifier is the nil constructor. In the cons-cons case, injectivity of the outer E1 endpoint and then injectivity of PairFrame expose hsame between the two heads and hsame between the framed tails. The representation hypotheses give A for both heads, so $\mathsf{ListSourceHsameCompatible}(A, \sim_A)$ supplies the head classifier. Apply the induction hypothesis to the two framed tail presentations, and combine the head classifier with the tail classifier by the cons constructor of ListClassifierSpec. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListSpineRep coherence`

Theorem 36.117 (Framed list-spine length determinism)**.** *Let A : BHist $\to$ Prop be a BEDC history source carrier and let $\sim_A$ be a source classifier. If* $\mathsf{ListSourceHsameCompatible}(A, \sim_A)$*,* $\mathsf{FramedListSpineRep}_A(h, xs)$*, and* $\mathsf{FramedListSpineRep}_A(h, ys)$ *hold, then*

$$\ell(xs) = \ell(ys).$$

The roadmap ten-field fit is: traditional target finite-list framed readback; BEDC source BHist*; carrier* $\mathsf{FramedListHistoryCarrier}_A$*; classifier* ListClassifierSpec*; stability framed endpoint coherence; ledger finite spine; core theorem framed length determinism; exactness through framed spine representation; standard bridge finite spines; status* ProofTarget*.*

Proof. Apply Theorem 36.116 to the compatibility witness and the two displayed framed presentations of h. This gives $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$. Then apply Theorem 36.31 to read back equality of the two finite spine lengths. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListSpineRep length determinism`

Theorem 36.118 (Framed list bridge classifier preserves represented length)**.** *Let A : BHist $\to$ Prop be a BEDC history source carrier and let $\sim_A$ be a source classifier. For histories h, k : BHist and finite spines xs_0, ys_0, if* $\mathsf{ListSourceHsameCompatible}(A, \sim_A)$*,* $\mathsf{FramedListSpineRep}_A(h, xs_0)$*,* FramedListSpineRep *and* $\mathsf{FramedListBridgeClassifier}_{A,\sim_A}(h, k)$ *hold, then*

$$\ell(xs_0) = \ell(ys_0).$$

The roadmap ten-field fit is: traditional target finite-list framed readback along a bridge classifier; BEDC source BHist*; carrier* $\mathsf{FramedListHistoryCarrier}_A$*; classifier* $\mathsf{FramedListBridgeClassifier}_{A,\sim_A}$*; stability framed endpoint coherence and source classifier length soundness; ledger finite spine representatives at both endpoints; core theorem bridge length preservation; exactness by framed spine representation; standard bridge finite spines; status* ProofTarget.

Proof. Unpack the framed bridge classifier witness to finite spines xs, ys with $\mathsf{FramedListSpineRep}_A(h, xs)$, $\mathsf{FramedListSpineRep}_A(k, ys)$, and $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$. Apply Theorem 36.116 at h to classify xs_0 with xs, and at k to classify ys with ys_0. Apply Theorem 36.31 to the three finite-spine classifier witnesses $xs_0 \sim_A xs$, $xs \sim_A ys$, and $ys \sim_A ys_0$, then chain the three finite-length equalities. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListBridgeClassifier represented length`

Definition 36.119 (Framed list public length readback)**.** *For a BEDC history source carrier* $A : \mathsf{BHist} \to \mathsf{Prop}$*, define* $\mathsf{FramedListPublicLength}_A(h, n)$ *by*

$$\mathsf{FramedListPublicLength}_A(h, n) \iff \exists xs : \mathsf{HistSpine}.\ \mathsf{FramedListSpineRep}_A(h, xs) \wedge \ell(xs) = n.$$

Here ℓ *is the finite-spine presentation length read from the framed spine representation. It is not a separate* $\mathsf{Nat}^{\uparrow}$ *operation and is not an additional field of the framed semantic certificate.*

Lean4 (definition) `BEDC.Derived.ListUp.FramedListPublicLength`

Theorem 36.120 (Framed list public length readback is well-defined)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier and let* $\sim_A$ *be a source classifier. Assume* $\mathsf{ListSourceHsameCompatible}(A, \sim_A)$*. Then the framed public length readback has the following two properties.*

1. *If* $\mathsf{FramedListPublicLength}_A(h, n)$ *and* $\mathsf{FramedListPublicLength}_A(h, m)$*, then* $n = m$*.*
2. *If* $\mathsf{FramedListBridgeClassifier}_{A,\sim_A}(h, k)$ *and* $\mathsf{FramedListPublicLength}_A(h, n)$*, then* $\mathsf{FramedListPublicLength}_A(k, n)$*.*

The roadmap ten-field fit is: traditional target finite-list framed length readback; BEDC source BHist*; carrier* $\mathsf{FramedListHistoryCarrier}_A$*; classifier* $\mathsf{FramedListBridgeClassifier}_{A,\sim_A}$*; stability obligation framed endpoint coherence; ledger finite-spine length witness; core theorem well-definedness and classifier preservation; exactness via* FramedListSpineRep*; standard bridge finite spines; status* ProofTarget.

Proof. For uniqueness at one endpoint, unpack the two $\mathsf{FramedListPublicLength}_A$ witnesses. They give finite spines xs and ys, representations $\mathsf{FramedListSpineRep}_A(h, xs)$ and $\mathsf{FramedListSpineRep}_A(h, ys)$, and displayed equalities $\ell(xs) = n$ and $\ell(ys) = m$. Apply Theorem 36.117 to the two framed representations of h, obtaining $\ell(xs) = \ell(ys)$. Chain the inverse of $\ell(xs) = n$, this equality, and $\ell(ys) = m$ to get $n = m$.

For preservation along the framed bridge classifier, unpack the public length witness for h as a finite spine xs_0 with $\mathsf{FramedListSpineRep}_A(h, xs_0)$ and $\ell(xs_0) = n$. Unpack the bridge classifier into finite spines xs, ys with $\mathsf{FramedListSpineRep}_A(h, xs)$, $\mathsf{FramedListSpineRep}_A(k, ys)$, and $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$.

Use Theorem 36.118 with the displayed representative xs_0 at h, the bridge representative ys at k, and the bridge classifier witness to obtain $\ell(xs_0) = \ell(ys)$. Chain this length equality with $\ell(xs_0) = n$, then choose ys as the framed public length witness for k. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListPublicLength well defined`

Theorem 36.121 (Framed list bridge classifier has common public length)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier and let* $\sim_A$ *be a source classifier. If* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$, $\mathsf{ListSourceHsameCompatible}(A, \sim_A)$, *and* $\mathsf{FramedListBridgeClassifier}_{A,\sim_A}(h, k)$ *hold, then* h *and* k *are framed list carrier histories and share a framed public length:*

$$\mathsf{FramedListHistoryCarrier}_A(h) \wedge \mathsf{FramedListHistoryCarrier}_A(k) \wedge \exists n.\ \mathsf{FramedListPublicLength}_A(h, n) \wedge \mathsf{FramedListPublicL}$$

Proof. Use the equivalence-field theorem for the framed bridge classifier to obtain the two carrier endpoints. Unpack the bridge witness into displayed finite spines xs, ys and a finite-spine classifier $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$. The list classifier length theorem gives $\ell(xs) = \ell(ys)$, so $\ell(xs)$ is a shared public length for the two displayed framed spine representatives. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListBridgeClassifier public length total`

Theorem 36.122 (Framed list public length constructor readback)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier. For every history* h *and every finite length value* n*, the framed public length readback exposes the finite-spine constructors:*

1. $\mathsf{FramedListPublicLength}_A(h, 0)$ *holds if and only if* $\mathsf{FramedListSpineRep}_A(h, \mathsf{nil})$ *holds.*
2. *If* $\mathsf{FramedListPublicLength}_A(h, n+1)$ *holds, then*

$$\exists a : \mathsf{BHist},\ xs : \mathsf{HistSpine}.\ A(a) \wedge \mathsf{FramedListSpineRep}_A(h, \mathsf{cons}(a, xs)) \wedge \mathsf{FramedListPublicLength}_A(\mathsf{FramedListEndp}$$

The roadmap ten-field fit is: traditional target framed finite-list constructor readback; BEDC source BHist*; carrier* $\mathsf{FramedListHistoryCarrier}_A$*; classifier-independent spine exposure; ledger* $\mathsf{FramedListPublicLength}_A$*; core theorem nil and successor public-length inversion; exactness by finite framed-spine constructor analysis; standard bridge finite spines; status* $\mathsf{ProofTarget}$.

Proof. For the zero forward direction, unfold Definition 36.119. A public length witness with value 0 supplies a finite spine xs with $\mathsf{FramedListSpineRep}_A(h, xs)$ and $\ell(xs) = 0$. Case-analyze xs. The cons case has successor length and cannot have value 0, while the nil case is the required framed nil representation.

For the zero reverse direction, choose the nil finite spine in Definition 36.119. The displayed $\mathsf{FramedListSpineRep}_A(h, \mathsf{nil})$ witness and $\ell(\mathsf{nil}) = 0$ repack as $\mathsf{FramedListPublicLength}_A(h, 0)$.

For the successor clause, unfold the same definition. A witness for $\mathsf{FramedListPublicLength}_A(h, n+1)$ gives a finite spine xs_0 with $\mathsf{FramedListSpineRep}_A(h, xs_0)$ and $\ell(xs_0) = n+1$. The nil case would force $\ell(\mathsf{nil}) = n+1$, impossible for finite lengths, so the exposed spine has the form $\mathsf{cons}(a, xs)$.

The cons representation already supplies $A(a)$ and $\mathsf{FramedListSpineRep}_A(h, \mathsf{cons}(a, xs))$. Its entry predicate restricts to the tail entries of xs, and reflexivity gives $\mathsf{hsame}(\mathsf{FramedListEndpoint}(xs), \mathsf{FramedListEndpoi}$ Together these build $\mathsf{FramedListSpineRep}_A(\mathsf{FramedListEndpoint}(xs), xs)$.

The displayed successor length equality identifies $\ell(xs)$ with n. Repacking the tail representation and this predecessor length through Definition 36.119 gives $\mathsf{FramedListPublicLength}_A(\mathsf{FramedListEndpoint}(xs), n$ so a and xs are the required constructor witnesses. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListPublicLength constructor endpoint readback`

Theorem 36.123 (Framed list public length successor empty absurd)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier. If a history* h *has successor framed public length, then* h *cannot also be the empty framed endpoint:*

$$\mathsf{FramedListPublicLength}_A(h, n+1) \Longrightarrow \mathsf{hsame}(h, \mathsf{FramedListEndpoint}(\mathsf{nil})) \Longrightarrow \mathsf{False}.$$

Proof. Apply constructor readback to the successor public-length witness. It exposes a head a and tail spine xs with a displayed representation of h by the cons endpoint $\mathsf{FramedListEndpoint}(\mathsf{cons}(a, xs))$. Composing this endpoint display with the assumed empty-frame display gives an internal sameness between a cons framed endpoint and the nil framed endpoint. Framed endpoint no-confusion for nil versus cons eliminates this case. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListPublicLength successor empty absurd`

Theorem 36.124 (Framed list bridge classifier displayed-spine exactness)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSourceHsameCompatible}(A, \sim_A)$*. For histories* $h, k : \mathsf{BHist}$ *and finite spines* xs, ys*, if* $\mathsf{FramedListSpineRep}_A(h, xs)$ *and* $\mathsf{FramedListSpineRep}_A(k, ys)$ *hold, then*

$$\mathsf{FramedListBridgeClassifier}_{A,\sim_A}(h, k) \iff \mathsf{ListClassifierSpec}(\sim_A, xs, ys).$$

The displayed spine representatives therefore give the exact finite-spine readback of the framed bridge classifier at the two endpoints.

Proof. For the right-to-left implication, use the displayed spines xs and ys as the existential bridge witnesses. The two representation hypotheses supply the endpoint clauses, and the displayed $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$ supplies the finite-spine classifier clause.

For the left-to-right implication, unpack the bridge classifier into finite spines xs_0, ys_0 with $\mathsf{FramedListSpineRep}_A(h, xs_0)$, $\mathsf{FramedListSpineRep}_A(k, ys_0)$, and $\mathsf{ListClassifierSpec}(\sim_A, xs_0, ys_0)$. Apply Theorem 36.116 at h to obtain $\mathsf{ListClassifierSpec}(\sim_A, xs, xs_0)$. Apply the same theorem at k to obtain $\mathsf{ListClassifierSpec}(\sim_A, ys, ys_0)$, then use Theorem 36.47 and the certificate cert to reverse this comparison. Two applications of Theorem 36.46 compose $xs \sim_A xs_0$, $xs_0 \sim_A ys_0$, and $ys_0 \sim_A ys$, yielding $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListBridgeClassifier displayed spine exactness`

Theorem 36.125 (Framed list bridge empty-left source refinement)**.** *Let* $A, B : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers and let* $\sim_A, \sim_B$ *be source classifiers. Assume source refinement preserves carrier membership and head classification:*

$$\forall x : \mathsf{BHist}.\ A(x) \to B(x), \qquad \forall x\, y : \mathsf{BHist}.\ x \sim_A y \to x \sim_B y.$$

Then every framed bridge from the displayed empty-left endpoint $\mathsf{E0}(\mathsf{e})$ *to* k *over* $(A, \sim_A)$ *refines to a framed bridge over* $(B, \sim_B)$*:*

$$\mathsf{FramedListBridgeClassifier}_{A,\sim_A}(\mathsf{E0}(\mathsf{e}), k) \to \mathsf{FramedListBridgeClassifier}_{B,\sim_B}(\mathsf{E0}(\mathsf{e}), k).$$

Proof. Unpack the framed bridge into finite spines xs, ys, two $\mathsf{FramedListSpineRep}$ witnesses, and a $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$ witness. The carrier inclusion transports every entry field in both spine representations while preserving the endpoint equalities. Induction on the finite-spine classifier transports each head relation through the classifier inclusion and rebuilds the tail witness. Repack the same two spines with these transported witnesses. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListBridgeClassifier empty left source refinement`

Theorem 36.126 (Framed list bridge classifier constructor exactness)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSourceHsameCompatible}(A, \sim_A)$*. For histories* $h, k : \mathsf{BHist}$*, finite spines* xs, ys*, and source histories* $a, b : \mathsf{BHist}$*, the framed bridge classifier has the following constructor exactness behavior: The roadmap certificate reads: traditional target finite-list framed bridge constructor exactness; BEDC source* BHist *with* $\mathsf{PairFrame}$ *and* $\mathsf{FramedListEndpoint}$*; carrier* $\mathsf{FramedListHistoryCarrier}_A$*; classifier* $\mathsf{FramedListBridgeClassifier}$*; stability from the source* $\mathsf{NameCert}$ *plus* $\mathsf{ListSourceHsameCompatible}$*; ledger displayed framed spines; core theorem nil-nil introduction, mixed nil/cons separation, and cons-cons iff; exactness finite-spine constructor readback; standard bridge finite spines; status* $\mathsf{CheckedCert}$*.*

1. *if* $\mathsf{FramedListSpineRep}_A(h, \mathsf{nil})$ *and* $\mathsf{FramedListSpineRep}_A(k, \mathsf{nil})$ *hold, then* $\mathsf{FramedListBridgeClassifier}_{A,\sim_A}(h, k)$ *holds;*
2. *if* $\mathsf{FramedListSpineRep}_A(h, \mathsf{nil})$*,* $\mathsf{FramedListSpineRep}_A(k, \mathsf{cons}(b, ys))$*, and* $\mathsf{FramedListBridgeClassifier}_{A,\sim_A}(h, k)$ *hold, then* $\bot$*;*
3. *if* $\mathsf{FramedListSpineRep}_A(h, \mathsf{cons}(a, xs))$*,* $\mathsf{FramedListSpineRep}_A(k, \mathsf{nil})$*, and* $\mathsf{FramedListBridgeClassifier}_{A,\sim_A}(h, k)$ *hold, then* $\bot$*;*
4. *if* $\mathsf{FramedListSpineRep}_A(h, \mathsf{cons}(a, xs))$ *and* $\mathsf{FramedListSpineRep}_A(k, \mathsf{cons}(b, ys))$ *hold, then*

$$\mathsf{FramedListBridgeClassifier}_{A,\sim_A}(h, k) \iff (a \sim_A b) \wedge \mathsf{ListClassifierSpec}(\sim_A, xs, ys).$$

Proof. In the nil-nil case, the nil branch of Theorem 36.13 gives

$$\mathsf{ListClassifierSpec}(\sim_A, \mathsf{nil}, \mathsf{nil}).$$

The reverse direction of Theorem 36.124 repackages this finite-spine classifier with the two displayed nil endpoint representatives.

In the nil-cons case, apply Theorem 36.124 to the two displayed endpoint representatives and the bridge witness. This yields

$$\mathsf{ListClassifierSpec}(\sim_A, \mathsf{nil}, \mathsf{cons}(b, ys)).$$

The mixed nil-cons clause of Theorem 36.13 eliminates that finite-spine classifier.

The cons-nil case is symmetric. Displayed-spine exactness gives

$$\mathsf{ListClassifierSpec}(\sim_A, \mathsf{cons}(a, xs), \mathsf{nil}),$$

and the mixed cons-nil clause of Theorem 36.13 eliminates this shape.

In the cons-cons case, displayed-spine exactness turns the bridge witness into

$$\mathsf{ListClassifierSpec}(\sim_A, \mathsf{cons}(a, xs), \mathsf{cons}(b, ys)).$$

The cons-cons clause of Theorem 36.13 projects the source-head classifier $a \sim_A b$ and the tail classifier $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$.

Conversely, suppose the source-head classifier $a \sim_A b$ and the tail classifier $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$ are given. The cons-cons clause of Theorem 36.13 rebuilds

$$\mathsf{ListClassifierSpec}(\sim_A, \mathsf{cons}(a, xs), \mathsf{cons}(b, ys)).$$

The reverse direction of Theorem 36.124 repackages this finite-spine classifier as $\mathsf{FramedListBridgeClassifier}_{A,\sim_A}(h$
□

Lean4 ✓ `BEDC.Derived.ListUp.FramedListBridgeClassifier constructor exactness`

Theorem 36.127 (Framed list bridge classifier equivalence fields)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSourceHsameCompatible}(A, \sim_A)$*. Define the framed carrier by*

$$\mathsf{FramedListHistoryCarrier}_A(h) \iff \exists xs : \mathsf{HistSpine}.\ \mathsf{FramedListSpineRep}_A(h, xs).$$

Lean4 (definition) `BEDC.Derived.ListUp.FramedListHistoryCarrier`

Then $\mathsf{FramedListBridgeClassifier}_{A,\sim_A}$ *satisfies the five classifier fields below. Carrier-relative reflexivity:*

$$\mathsf{FramedListHistoryCarrier}_A(h) \to \mathsf{FramedListBridgeClassifier}_{A,\sim_A}(h, h).$$

Endpoint exposure for any bridge witness:

$$\mathsf{FramedListBridgeClassifier}_{A,\sim_A}(h, k) \to \mathsf{FramedListHistoryCarrier}_A(h) \wedge \mathsf{FramedListHistoryCarrier}_A(k).$$

Symmetry:

$$\mathsf{FramedListBridgeClassifier}_{A,\sim_A}(h, k) \to \mathsf{FramedListBridgeClassifier}_{A,\sim_A}(k, h).$$

Transitivity:

$$\mathsf{FramedListBridgeClassifier}_{A,\sim_A}(h, k) \to \mathsf{FramedListBridgeClassifier}_{A,\sim_A}(k, u) \to \mathsf{FramedListBridgeClassifier}_{A,\sim_A}(h, u)$$

Carrier transport:

$$\mathsf{FramedListHistoryCarrier}_A(h) \to \mathsf{FramedListBridgeClassifier}_{A,\sim_A}(h, k) \to \mathsf{FramedListHistoryCarrier}_A(k).$$

The ten-field fit is: traditional target finite-list framed bridge equivalence fields; BEDC source BHist*; carrier framed spine representation; classifier* $\mathsf{FramedListBridgeClassifier}_{A,\sim_A}$*; stability obligations the five displayed clauses; ledger finite displayed spines; core theorem this fields theorem; exactness by displayed-spine exactness and framed coherence; standard bridge finite spines; status* ProofTarget*.*

Proof. Endpoint exposure unpacks the bridge witness into finite spines xs, ys with $\mathsf{FramedListSpineRep}_A(h, xs)$, $\mathsf{FramedListSpineRep}_A(k, ys)$, and $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$; the two representation witnesses are exactly the two framed-carrier witnesses.

For carrier-relative reflexivity, choose the displayed spine supplied by the framed-carrier witness at h on both endpoints. Induct over that finite spine. The nil case is the nil constructor of ListClassifierSpec. In the cons case, the entry predicate stored in FramedListSpineRep supplies A for the displayed head, so cert.equiv_refl gives the head classifier witness and the induction hypothesis supplies the tail witness.

For symmetry, unpack the bridge witness, apply Theorem 36.47 to the finite-spine classifier witness, and rebuild the bridge with the two displayed endpoints swapped. For transitivity, unpack bridge witnesses for h, k and k, u. The two middle spines both represent k, so Theorem 36.116 compares them. Compose the first bridge classifier, the middle comparison, and the second bridge classifier by two applications of Theorem 36.46, then rebuild the bridge from the exposed first and last spines. Carrier transport is the right endpoint projection of endpoint exposure, with the displayed left-carrier premise matching the NameCert field shape. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListBridgeClassifier equivalence fields`

Corollary 36.128 (Framed finite-spine paper certificate)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*. Assume* $\mathsf{ListSourceHsameCompatible}(A, \sim_A)$*. Define the framed carrier by*

$$\mathsf{FramedListHistoryCarrier}_A(h) \iff \exists xs : \mathsf{HistSpine}.\ \mathsf{FramedListSpineRep}_A(h, xs),$$

and define the framed bridge classifier by

$$\mathsf{FramedListBridgeClassifier}_{A,\sim_A}(h, k) \iff \exists xs\, ys.\ \mathsf{FramedListSpineRep}_A(h, xs) \wedge \mathsf{FramedListSpineRep}_A(k, ys) \wedge \mathsf{Lis}$$

Lean4 (definition) `BEDC.Derived.ListUp.FramedListBridgeClassifier`

With pattern and ledger predicates both given by $\mathsf{FramedListHistoryCarrier}_A$*, these fields form the paper certificate target*

$$\mathsf{SemanticNameCert}(\mathsf{FramedListHistoryCarrier}_A, \mathsf{FramedListHistoryCarrier}_A, \mathsf{FramedListHistoryCarrier}_A, \mathsf{FramedListBrid}$$

This certificate is for the framed carrier and framed bridge classifier above. It does not identify $\mathsf{FramedListHistoryCarrier}_A$ *with the unframed* $\mathsf{ListHistoryCarrier}_A$ *used by the public* $\mathsf{List}^{\uparrow}$ *target.*

Proof. The source certificate supplies the entrywise reflexivity, symmetry, transitivity, and carrier transport facts for $\sim_A$. The framed endpoint definition supplies a separated finite-spine readback, and Theorem 36.116 supplies the comparison datum for two presentations of the same history. Reflexivity chooses the displayed spine for a framed carrier witness and classifies it entry by entry using cert. Symmetry and transitivity unpack the two existential framed bridge witnesses and apply the structural finite-spine symmetry and transitivity theorems for ListClassifierSpec; at the shared middle history, framed coherence identifies the two exposed middle spines. Carrier transport follows because a framed bridge witness contains a framed representation of the target history. Since the pattern and ledger predicates are the carrier itself, their soundness fields are identity implications. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListBridgeClassifier semantic name certificate`

Corollary 36.129 (Framed finite-spine paper certificate for hsame)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier and let* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{hsame})$*. Define the framed carrier by*

$$\mathsf{FramedListHistoryCarrier}_A(h) \iff \exists xs : \mathsf{HistSpine}.\ \mathsf{FramedListSpineRep}_A(h, xs),$$

and define the hsame framed bridge classifier by

$$\mathsf{FramedListBridgeClassifier}_{A,\mathsf{hsame}}(h, k) \iff \exists xs\, ys.\ \mathsf{FramedListSpineRep}_A(h, xs) \wedge \mathsf{FramedListSpineRep}_A(k, ys) \wedge$$

With pattern and ledger predicates both given by $\mathsf{FramedListHistoryCarrier}_A$*, these fields form the paper certificate target*

$$\mathsf{SemanticNameCert}(\mathsf{FramedListHistoryCarrier}_A, \mathsf{FramedListHistoryCarrier}_A, \mathsf{FramedListHistoryCarrier}_A, \mathsf{FramedListBrid}$$

Proof. Apply Corollary 36.128 with source classifier hsame. The compatibility premise is exactly Theorem 36.87, and the remaining source certificate input is the displayed $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{hsame})$. □

Theorem 36.130 (Framed list public length successor endpoint readback)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and assume* $\mathsf{ListSourceHsameCompatible}(A, \sim_A)$*. If a history* h *has framed public length* $n+1$*, then* h *exposes a head, tail spine, exact predecessor length, and framed cons endpoint:*

$$\mathsf{FramedListPublicLength}_A(h, n+1) \to \exists a : \mathsf{BHist},\, xs : \mathsf{HistSpine}.\ A(a) \wedge \mathsf{FramedListSpineRep}_A(h, \mathsf{cons}(a, xs)) \wedge \ell(xs) = n \wedge \mathsf{hsame}(h, \mathsf{E1}(\mathsf{PairFrame}(a, \mathsf{FramedListEndpoint}(xs)))).$$

Proof. Apply framed public-length constructor readback to the successor witness. This exposes a, xs, the source row $A(a)$, a displayed framed spine representation of h by $\mathsf{cons}(a, xs)$, and a tail public-length witness at n.

The displayed spine representation restricts its entry predicate to the tail entries of xs, while reflexivity gives the endpoint representation of $\mathsf{FramedListEndpoint}(xs)$ by xs. Thus the tail also has the canonical public length $\ell(xs)$. Well-definedness of framed public length identifies $\ell(xs) = n$. The endpoint row is the cons-endpoint component of the displayed framed spine representation. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListPublicLength successor endpoint readback`

Theorem 36.131 (Framed list bridge one-left source refinement)**.** *Let* $A, B : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers and let* $\sim_A, \sim_B$ *be source classifiers. Assume source refinement preserves carrier membership and head classification:*

$$\forall x : \mathsf{BHist}.\ A(x) \to B(x), \qquad \forall x\, y : \mathsf{BHist}.\ x \sim_A y \to x \sim_B y.$$

Then every framed bridge from the displayed one-headed endpoint $\mathsf{E1}(t)$ *to* k *over* $(A, \sim_A)$ *refines to a framed bridge over* $(B, \sim_B)$*:*

$$\mathsf{FramedListBridgeClassifier}_{A,\sim_A}(\mathsf{E1}(t), k) \to \mathsf{FramedListBridgeClassifier}_{B,\sim_B}(\mathsf{E1}(t), k).$$

Proof. Unpack the framed bridge into finite spines xs, ys, two $\mathsf{FramedListSpineRep}$ witnesses, and a finite-spine classifier. The carrier inclusion transports every entry field in both spine representations without changing the displayed endpoints. Induction on the finite-spine classifier transports each head relation through the classifier inclusion and rebuilds the tail classifier. Repacking the same two spines gives the refined bridge at the visible one-left endpoint. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListBridgeClassifier e1 left source refinement`

Theorem 36.132 (List spine bridge endpoint exposure and symmetry)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier and let* $\sim_A$ *be a source classifier. The compact per-object fit is: traditional target finite-list classifier stability; BEDC source* A *over* BHist *with* $\mathsf{NameCert}(A, \sim_A)$*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}$*; stability obligations endpoint exposure and symmetry; ledger finite spine representation; core theorem the two displayed clauses below; exactness via* $\mathsf{ListSpineRep}$*; standard bridge finite-spine readback; status* $\mathsf{ProofTarget}$*. For all histories* h *and* k*, the bridge classifier satisfies endpoint exposure:*

$$\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, k) \to \mathsf{ListHistoryCarrier}_A(h) \wedge \mathsf{ListHistoryCarrier}_A(k).$$

Moreover, for any $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, the bridge classifier is symmetric:*

$$\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, k) \to \mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(k, h).$$

Proof. Unpack a bridge witness into finite spines xs and ys, displayed representations $\mathsf{ListSpineRep}_A(h, xs)$ and $\mathsf{ListSpineRep}_A(k, ys)$, and the finite-spine classifier witness $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$. Endpoint exposure applies the soundness direction of Theorem 36.61 to the two displayed representations. For symmetry, keep the two representations, apply Theorem 36.47 to the source certificate cert and the finite-spine classifier witness, then rebuild the bridge witness with the represented spines swapped. □

Theorem 36.133 (List spine bridge stability from spine coherence)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. The ten-field fit is: traditional target finite-list classifier stability; BEDC source* A *over* BHist *with* $\mathsf{NameCert}(A, \sim_A)$*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}$*; stability obligations reflexivity, symmetry, transitivity, and endpoint closure; ledger finite spine representation; core theorem this block; exactness via* $\mathsf{ListSpineRep}$*; standard bridge finite-spine readback; status* $\mathsf{ProofTarget}$*. Then the bridge classifier satisfies all four clauses: carrier-relative reflexivity, meaning*

$$\mathsf{ListHistoryCarrier}_A(h) \to \mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, h);$$

symmetry, meaning

$$\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, k) \to \mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(k, h);$$

transitivity, meaning

$$\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, k) \to \mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(k, u) \to \mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, u);$$

and classifier-induced endpoint closure, meaning

$$\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, k) \to \mathsf{ListHistoryCarrier}_A(k).$$

The $\mathsf{NameCert}$*-shaped carrier-transport field follows immediately by weakening this endpoint-closure implication with an unused* $\mathsf{ListHistoryCarrier}_A(h)$ *premise.*

Proof. For reflexivity, use representation coverage to choose a finite-spine representation of h, apply finite-spine reflexivity under the source certificate, and rebuild the bridge witness with the same representation on both endpoints. Symmetry is the second clause of Theorem 36.132. Transitivity is Theorem 36.63 applied to the displayed spine coherence and the source certificate. Endpoint closure is the second endpoint component exposed by Theorem 36.132; carrier transport is obtained by weakening that implication with the unused left-carrier premise. □

Theorem 36.134 (List recursive history classifier transitivity from spine coherence)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. The ten-field fit is: traditional target finite-list generated classifier stability; BEDC source* A *over* BHist *with* $\mathsf{NameCert}(A, \sim_A)$*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}$*; stability obligation transitivity; ledger finite spine representation; core theorem this block; exactness via* $\mathsf{ListSpineRep}$ *and* $\mathsf{ListSpineBridgeClassifier}$*; standard bridge finite-spine readback; status* $\mathsf{ProofTarget}$*. Then for all histories* h, k, u*, if*

$$\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}(h, k)$$

and

$$\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}(k, u)$$

hold, then

$$\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}(h,u)$$

holds.

Proof. Use the classifier equivalence clause of Theorem 36.61 to convert the two recursive classifier witnesses into $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h,k)$ and $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(k,u)$ witnesses. Apply Theorem 36.63 with the displayed spine coherence hypothesis and the source certificate to obtain $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h,u)$. The reverse direction of the same exactness equivalence converts this bridge witness back into the recursive classifier witness $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}(h,u)$. □

Theorem 36.135 (List recursive history classifier transitivity from cons-boundary coherence)**.** *Let $A : \mathsf{BHist} \to \mathsf{Prop}$ be a BEDC history source carrier, let $\sim_A$ be a source classifier, let $\mathsf{cert} : \mathsf{NameCert}(A,\sim_A)$, and assume $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$. The ten-field fit is: traditional target finite-list recursive classifier transitivity; BEDC source A over BHist with $\mathsf{NameCert}(A,\sim_A)$; carrier $\mathsf{ListHistoryCarrier}_A$; classifier $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}$; stability obligation transitivity; ledger finite spine representation plus cons-boundary comparison; core theorem this block; exactness through $\mathsf{ListSpineRep}$; standard bridge finite spines; status $\mathsf{ProofTarget}$. Then for all histories h,k,u,*

$$\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}(h,k) \to \mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}(k,u) \to \mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}(h,u)$$

holds.

Proof. First obtain $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$ from the displayed cons-boundary coherence by applying Theorem 36.71.

With that spine-coherence witness and the source certificate in hand, apply Theorem 36.134. It gives exactly the recursive classifier transitivity implication for the three histories h,k,u. □

Theorem 36.136 (List spine bridge stability from cons-boundary coherence)**.** *Let $A : \mathsf{BHist} \to \mathsf{Prop}$ be a BEDC history source carrier, let $\sim_A$ be a source classifier, let $\mathsf{cert} : \mathsf{NameCert}(A,\sim_A)$, and assume $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$. The ten-field fit is: traditional target finite-list classifier stability; BEDC source A over BHist with $\mathsf{NameCert}(A,\sim_A)$; carrier $\mathsf{ListHistoryCarrier}_A$; classifier $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}$; stability obligations reflexivity, symmetry, transitivity, and endpoint closure; ledger finite spine representation; core theorem this block; exactness via $\mathsf{ListSpineRep}$; standard bridge finite-spine readback; status $\mathsf{ProofTarget}$. Then the bridge classifier satisfies all four clauses: carrier-relative reflexivity, meaning*

$$\mathsf{ListHistoryCarrier}_A(h) \to \mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h,h);$$

symmetry, meaning

$$\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h,k) \to \mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(k,h);$$

transitivity, meaning

$$\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h,k) \to \mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(k,u) \to \mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h,u);$$

and classifier-induced endpoint closure, meaning

$$\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h,k) \to \mathsf{ListHistoryCarrier}_A(k).$$

The $\mathsf{NameCert}$*-shaped carrier-transport field follows immediately by weakening this endpoint-closure implication with an unused* $\mathsf{ListHistoryCarrier}_A(h)$ *premise.*

Proof. Theorem 36.71 turns the cons-boundary coherence witness into $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$. Apply Theorem 36.133 with that spine-coherence witness and the source certificate. □

Lean4 ✓ `BEDC.Derived.ListUp.ListSpineBridgeClassifier stability from cons boundary`

Theorem 36.137 (List history semantic fields source refinement)**.** *Let $A, B : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers. The ten-field fit is: traditional target finite-list source refinement; BEDC source* BHist*; carrier* ListHistoryCarrier*, pattern* ListHistoryPattern*, and ledger* ListHistoryLedger *as the three list semantic fields; classifier unused; stability source inclusion; ledger finite spine; core theorem the three displayed implications below; exactness endpoint preservation; standard bridge finite spines; status* ProofTarget*. If the source carrier of A is included in the source carrier of B,*

$$\forall h : \mathsf{BHist}.\ A(h) \to B(h),$$

then for every history h,

$$\mathsf{ListHistoryCarrier}_A(h) \to \mathsf{ListHistoryCarrier}_B(h),$$

$$\mathsf{ListHistoryPattern}_A(h) \to \mathsf{ListHistoryPattern}_B(h),$$

and

$$\mathsf{ListHistoryLedger}_A(h) \to \mathsf{ListHistoryLedger}_B(h).$$

Lean4 ✓ `BEDC.Derived.ListUp.FramedListSemanticFields source refinement`

Proof. Induct on the displayed generation of the carrier and ledger witnesses. The nil case reuses the empty endpoint witness. The cons case applies the source inclusion to the head witness, applies the induction hypothesis to the tail, and rebuilds the same continuation endpoint. For the pattern field, use the displayed nil and cons cases: the nil pattern is unchanged, and the cons pattern uses the source inclusion on the head together with the carrier-refinement clause for the tail. □

Theorem 36.138 (List spine coherence source restriction)**.** *Let $A, B : \mathsf{BHist} \to \mathsf{Prop}$ be BEDC history source carriers, and let $\sim$ be a source classifier. The ten-field fit is: traditional target finite-list source restriction; BEDC source* BHist*; carrier* ListSpineRep*; classifier* ListClassifierSpec($\sim$)*; stability source inclusion; ledger finite spine; core theorem coherence restriction; exactness inherited from ambient spine coherence; standard bridge finite-spine readback; status* ProofTarget*. If the restricted source is included in the ambient source,*

$$\forall h : \mathsf{BHist}.\ A(h) \to B(h),$$

and the ambient source has coherent spine presentations,

$$\mathsf{ListSpineRepCoherent}_{B,\sim},$$

then the restricted source has coherent spine presentations:

$$\mathsf{ListSpineRepCoherent}_{A,\sim}.$$

Proof. Take two A-spine presentations $\mathsf{ListSpineRep}_A(m, xs)$ and $\mathsf{ListSpineRep}_A(m, ys)$ of the same history. Apply Theorem 36.88 with the displayed source inclusion and identity classifier weakening $\forall x\, y : \mathsf{BHist}.\ x \sim y \to x \sim y$. Its spine-representation clause transports both presentations to $\mathsf{ListSpineRep}_B(m, xs)$ and $\mathsf{ListSpineRep}_B(m, ys)$. The ambient coherence hypothesis $\mathsf{ListSpineRepCoherent}_{B,\sim}$ applied to those two transported presentations yields $\mathsf{ListClassifierSpec}(\sim, xs, ys)$, which is exactly the coherence datum required for $\mathsf{ListSpineRepCoherent}_{A,\sim}$. □

Theorem 36.139 (BHist-parametric list classifier append stability)**.** *For any relation* $sameA$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *and finite spines* $xs, ys, zs, ws : \mathsf{ListCarrier}(\mathsf{BHist})$*, if*

$$\mathsf{ListClassifierSpec}(sameA, xs, ys)$$

and

$$\mathsf{ListClassifierSpec}(sameA, zs, ws)$$

hold, then

$$\mathsf{ListClassifierSpec}(sameA, xs{+}{+}zs, ys{+}{+}ws)$$

holds.

Proof. Induct on the first classified spine pair. In the nil case, the first classifier forces the second left spine to be nil, so the conclusion is exactly the second classifier witness. In the cons case, the second left spine is also cons; keep the head classifier witness and apply the induction hypothesis to the classified tails and the second append witness. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec BHist append`

Theorem 36.140 (BHist-parametric classified list prefix cancellation)**.** *For any relation* $sameA$: $\mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *and finite spines* $p, p', x, y : \mathsf{ListCarrier}(\mathsf{BHist})$*, the ten-field fit is: traditional target finite-list prefix cancellation; BEDC source carried by the history entries of the finite spine; carrier* $\mathsf{ListCarrier}(\mathsf{BHist})$*; classifier* $\mathsf{ListClassifierSpec}(sameA)$*; stability append under classified prefixes; ledger finite spine; core theorem classified left prefix cancellation; exactness inherited from structural nil/cons classification; standard bridge finite-spine readback; status* $\mathsf{ProofTarget}$*. If*

$$\mathsf{ListClassifierSpec}(sameA, p, p')$$

and

$$\mathsf{ListClassifierSpec}(sameA, p{+}{+}x, p'{+}{+}y)$$

hold, then

$$\mathsf{ListClassifierSpec}(sameA, x, y)$$

holds.

Proof. Induct on the prefix classifier witness $\mathsf{ListClassifierSpec}(sameA, p, p')$. In the nil case, both prefixes are empty and the appended classifier is already the required classifier on x and y. In the cons case, invert the appended classifier at the exposed cons heads; its tail is a classifier for the two appended tails. Apply the induction hypothesis to the tail prefix classifier and that tail-appended classifier. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec BHist append left cancel classified`

Theorem 36.141 (Source-parametric classified list suffix cancellation)**.** *For any source type* A*, relation* $sameA : A \to A \to \mathsf{Prop}$*, and finite spines* $x, y, s, s' : \mathsf{ListCarrier}(A)$*, the ten-field fit is: traditional target finite-list suffix cancellation; BEDC source carried by the source entries of the finite spine; carrier* $\mathsf{ListCarrier}(A)$*; classifier* $\mathsf{ListClassifierSpec}(sameA)$*; stability append under classified suffixes; ledger finite spine; core theorem classified right suffix cancellation; exactness inherited from structural nil/cons classification and reverse readback; standard bridge finite-spine readback; status* $\mathsf{ProofTarget}$*. If*

$$\mathsf{ListClassifierSpec}(sameA, s, s')$$

and

$$\mathsf{ListClassifierSpec}(sameA, x{+}{+}s, y{+}{+}s')$$

hold, then

$$\mathsf{ListClassifierSpec}(sameA, x, y)$$

holds.

Proof. Reverse both classified appended spines. Theorem 36.41 turns the second witness into a classifier on $\mathsf{reverse}(s){+}{+}\mathsf{reverse}(x)$ and $\mathsf{reverse}(s'){+}{+}\mathsf{reverse}(y)$, while the suffix classifier becomes a classifier between $\mathsf{reverse}(s)$ and $\mathsf{reverse}(s')$. Apply Theorem 36.140 to cancel these reversed prefixes, obtaining a classifier between $\mathsf{reverse}(x)$ and $\mathsf{reverse}(y)$. Apply Theorem 36.41 again; finite-spine reverse involutivity transports the result back to $\mathsf{ListClassifierSpec}(sameA, x, y)$. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec append right cancel classified`

Theorem 36.142 (Source-parametric classified append context equivalence)**.** *For any source type A, relation $sameA : A \to A \to \mathsf{Prop}$, and finite spines $p, p', x, y, s, s' : \mathsf{ListCarrier}(A)$, the ten-field fit is: traditional target finite-list two-sided context equivalence; BEDC source carried by the source entries of the finite spine; carrier $\mathsf{ListCarrier}(A)$; classifier $\mathsf{ListClassifierSpec}(sameA)$; stability append under classified prefixes and suffixes; ledger finite spine; core theorem classified append-context equivalence; exactness inherited from structural nil/cons classification; standard bridge finite-spine readback; status* ProofTarget*. If*

$$\mathsf{ListClassifierSpec}(sameA, p, p')$$

and

$$\mathsf{ListClassifierSpec}(sameA, s, s')$$

hold, then

$$\mathsf{ListClassifierSpec}(sameA, x, y) \iff \mathsf{ListClassifierSpec}(sameA, p{+}{+}x{+}{+}s, p'{+}{+}y{+}{+}s')$$

holds.

Proof. For the forward implication, append stability first adds the classified prefixes p and p' to the witness for x and y, and then adds the classified suffixes s and s'. For the reverse implication, use Theorem 36.141 to cancel the classified suffixes from the two contextual spines. The remaining classifier relates $p{+}{+}x$ to $p'{+}{+}y$, so Theorem 36.140 cancels the classified prefixes and yields $\mathsf{ListClassifierSpec}(sameA, x, y)$. □

Theorem 36.143 (BHist-parametric classified append context equivalence)**.** *For any relation $sameA : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ and finite spines $p, p', x, y, s, s' : \mathsf{ListCarrier}(\mathsf{BHist})$, if*

$$\mathsf{ListClassifierSpec}(sameA, p, p')$$

and

$$\mathsf{ListClassifierSpec}(sameA, s, s')$$

hold, then

$$\mathsf{ListClassifierSpec}(sameA, p{+}{+}(x{+}{+}s), p'{+}{+}(y{+}{+}s')) \iff \mathsf{ListClassifierSpec}(sameA, x, y)$$

holds.

Proof. For the left-to-right direction, first cancel the classified prefixes using Theorem 36.140. Then cancel the classified suffixes using Theorem 36.141. For the right-to-left direction, append the classified middle spines to the classified suffixes using Theorem 36.139, and append the classified prefixes to the result using the same append stability. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec BHist append context iff`

Theorem 36.144 (List represented-spine classifier alignment)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. The roadmap ten-field fit is: traditional target finite-list readback along represented histories; BEDC source* A *with* $\mathsf{NameCert}(A, \sim_A)$*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability supplied by source-certificate transitivity and representation coherence; ledger finite spines* xs_0 *and* ys_0*; core theorem represented-spine classifier alignment; exactness by bridge-classifier unpacking; standard bridge finite-spine readback; status* $\mathsf{ProofTarget}$*. If* $\mathsf{ListSpineRep}_A(h, xs_0)$*,* $\mathsf{ListSpineRep}_A(k, ys_0)$*, and* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$ *hold, then*

$$\mathsf{ListClassifierSpec}(\sim_A, xs_0, ys_0)$$

holds.

Proof. Unpack the bridge classifier to finite spines xs, ys with $\mathsf{ListSpineRep}_A(h, xs)$, $\mathsf{ListSpineRep}_A(k, ys)$, and $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$. Coherence at h gives $\mathsf{ListClassifierSpec}(\sim_A, xs_0, xs)$, and coherence at k gives $\mathsf{ListClassifierSpec}(\sim_A, ys, ys_0)$. Apply the source-certificate transitivity theorem $\mathsf{ListClassifierSpec_trans_from_nameCert}$ with cert to compose the three finite-spine classifier links, yielding $\mathsf{ListClassifierSpec}(\sim_A, xs_0, ys_0)$. □

Lean4 ✓ `BEDC.Derived.ListUp.ListSpineBridgeClassifier represented spine alignment`

Theorem 36.145 (List represented-spine classifier displayed exactness)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. The ten-field fit is: traditional finite-list readback; BEDC source* BHist*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability from the source certificate and spine coherence; ledger finite spines* xs_0 *and* ys_0*; core theorem displayed-spine exactness; exactness by the displayed-spine equivalence; standard bridge finite-spine readback; status* $\mathsf{ProofTarget}$*. For histories* $h, k : \mathsf{BHist}$ *and finite BEDC-history spines* xs_0, ys_0*, if*

$$\mathsf{ListSpineRep}_A(h, xs_0)$$

and

$$\mathsf{ListSpineRep}_A(k, ys_0)$$

hold, then

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k) \iff \mathsf{ListClassifierSpec}(\sim_A, xs_0, ys_0)$$

holds.

Proof. For the forward implication, apply Theorem 36.144 to the two displayed representation witnesses and the public classifier witness. For the reverse implication, unfold the bridge classifier definition. The displayed witnesses $\mathsf{ListSpineRep}_A(h, xs_0)$ and $\mathsf{ListSpineRep}_A(k, ys_0)$, together with the finite-spine classifier witness $\mathsf{ListClassifierSpec}(\sim_A, xs_0, ys_0)$, are exactly the existential bridge data, so they repack as $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$. □

Lean4 ✓ `BEDC.Derived.ListUp.ListSpineBridgeClassifier displayed spine exactness`

Theorem 36.146 (List represented-spine nil classifier inversion)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. The ten-field fit is: traditional target finite-list nil readback; BEDC source* A *with* $\mathsf{NameCert}(A, \sim_A)$*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability from* cert *plus spine coherence; ledger finite spines; core theorem nil classifier inversion; exactness by represented-spine alignment; standard bridge finite spines; status* $\mathsf{ProofTarget}$*. For histories* $h, k : \mathsf{BHist}$ *and a finite BEDC-history spine* ys*, if*

$$\mathsf{ListSpineRep}_A(h, \mathsf{nil}),$$

$$\mathsf{ListSpineRep}_A(k, ys),$$

and

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$$

hold, then $ys = \mathsf{nil}$*. Symmetrically, for a finite BEDC-history spine* xs*, if* $\mathsf{ListSpineRep}_A(h, xs)$*,* $\mathsf{ListSpineRep}_A(k, \mathsf{nil})$*, and* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$ *hold, then* $xs = \mathsf{nil}$*.*

Lean4 ✓ `BEDC.Derived.ListUp.ListSpineBridgeClassifier nil classifier inversion`

Proof. Apply Theorem 36.144 to the displayed represented nil spine, the represented spine ys, and the public classifier witness. This gives

$$\mathsf{ListClassifierSpec}(\sim_A, \mathsf{nil}, ys).$$

Case-analyze the finite spine ys. The nil branch is immediate. In the cons branch, Lemma 36.14 contradicts the mixed nil-cons classifier witness, equivalently the mixed branch excluded by Theorem 36.13. The symmetric clause applies the same alignment theorem to obtain

$$\mathsf{ListClassifierSpec}(\sim_A, xs, \mathsf{nil})$$

and then case-analyzes xs; the nil branch is immediate, and the cons branch is the symmetric mixed case ruled out by the same no-confusion lemma and case exactness theorem. □

Theorem 36.147 (List represented-spine classifier constructor exactness)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. The ten-field fit is: traditional target finite-list readback over* BHist*; BEDC source* A *with* $\mathsf{NameCert}(A, \sim_A)$*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability from* cert *and spine coherence; ledger finite spines; core theorem represented-spine classifier constructor exactness; exactness by displayed-spine classifier exactness; standard bridge finite spines; status* $\mathsf{ProofTarget}$*. For histories* $h, k, a, b : \mathsf{BHist}$ *and finite BEDC-history spines* xs, ys*, the public classifier has the following represented-spine constructor behavior:*

1. *if* $\mathsf{ListSpineRep}_A(h, \mathsf{nil})$*,* $\mathsf{ListSpineRep}_A(k, \mathsf{cons}(b, ys))$*, and* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$ *hold, then* $\bot$*;*
2. *if* $\mathsf{ListSpineRep}_A(h, \mathsf{cons}(a, xs))$*,* $\mathsf{ListSpineRep}_A(k, \mathsf{nil})$*, and* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$ *hold, then* $\bot$*;*
3. *if* $\mathsf{ListSpineRep}_A(h, \mathsf{cons}(a, xs))$ *and* $\mathsf{ListSpineRep}_A(k, \mathsf{cons}(b, ys))$ *hold, then*

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k) \iff (a \sim_A b) \wedge \mathsf{ListClassifierSpec}(\sim_A, xs, ys).$$

Proof. For the nil-cons clause, apply the forward direction of Theorem 36.145 to the two represented endpoints and the public classifier witness. This gives

$$\mathsf{ListClassifierSpec}(\sim_A, \mathsf{nil}, \mathsf{cons}(b, ys)).$$

Lemma 36.14 eliminates that mixed finite-spine classifier. The cons-nil clause uses the same displayed exactness theorem to obtain

$$\mathsf{ListClassifierSpec}(\sim_A, \mathsf{cons}(a, xs), \mathsf{nil}),$$

and Lemma 36.14 eliminates this mixed shape as well. For the cons-cons clause, apply the same theorem to obtain

$$\mathsf{ListClassifierSpec}(\sim_A, \mathsf{cons}(a, xs), \mathsf{cons}(b, ys)).$$

The cons-cons branch of Theorem 36.13 then projects the source-head classifier $a \sim_A b$ and the recursive tail classifier $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$. Conversely, suppose the source-head classifier $a \sim_A b$ and the recursive tail classifier $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$ are given. The cons-cons branch of Theorem 36.13 rebuilds

$$\mathsf{ListClassifierSpec}(\sim_A, \mathsf{cons}(a, xs), \mathsf{cons}(b, ys)).$$

With the two displayed representation witnesses, the reverse direction of Theorem 36.145 repacks this finite-spine classifier as $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$. □

Lean4 ✓ `BEDC.Derived.ListUp.ListSpineBridgeClassifier represented spine constructor exactness`

Lemma 36.148 (List represented prefix self-classifier)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and let* $p : \mathsf{BHist}$ *and* $xs : \mathsf{HistSpine}$ *be given. If*

$$\mathsf{ListSpineRep}_A(p, xs)$$

holds, then

$$\mathsf{ListClassifierSpec}(\sim_A, xs, xs)$$

holds.

Proof. Induct on the displayed witness $\mathsf{ListSpineRep}_A(p, xs)$. The nil representation gives the nil clause of $\mathsf{ListClassifierSpec}(\sim_A, xs, xs)$.

In the cons representation, the witness exposes a head a with $A(a)$ and a represented tail. The source reflexivity field of cert gives $a \sim_A a$, and the induction hypothesis gives the tail self-classifier. The cons clause of Definition 36.13 rebuilds $\mathsf{ListClassifierSpec}(\sim_A, xs, xs)$. □

Lean4 ✓ `BEDC.Derived.ListUp.ListSpineRep self classifier`

Theorem 36.149 (List public-prefix append left cancellation)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$*. For histories* $p, h, k, t, u : \mathsf{BHist}$ *and finite spines* $xs, ys, zs : \mathsf{HistSpine}$*, suppose*

$$\mathsf{ListSpineRep}_A(p, xs)$$

$$\mathsf{ListSpineRep}_A(h, xs{+}{+}ys), \qquad \mathsf{ListSpineRep}_A(k, xs{+}{+}zs), \qquad \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$$

hold. Then

$$\mathsf{ListClassifierSpec}(\sim_A, ys, zs)$$

holds. Consequently, if $\mathsf{ListSpineRep}_A(t, ys)$ *and* $\mathsf{ListSpineRep}_A(u, zs)$ *also hold, then*

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(t, u)$$

holds.

Proof. First build the self-classifier for the represented prefix. Apply Definition 36.148 to the displayed witness $\mathsf{ListSpineRep}_A(p, xs)$ to obtain $\mathsf{ListClassifierSpec}(\sim_A, xs, xs)$.

The cons-boundary hypothesis gives $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$ by Definition 36.71. Apply Definition 36.144 to the two displayed representations of h and k, together with the public classifier witness, to obtain

$$\mathsf{ListClassifierSpec}(\sim_A, xs{+}{+}ys, xs{+}{+}zs).$$

Now apply Definition 36.140 to the prefix self-classifier and this appended classifier. The result is $\mathsf{ListClassifierSpec}(\sim_A, ys, zs)$.

For the final public-classifier form, use the reverse implication of Definition 36.145 with the representations $\mathsf{ListSpineRep}_A(t, ys)$ and $\mathsf{ListSpineRep}_A(u, zs)$. Repacking the finite tail classifier through the displayed tail representations yields $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(t, u)$. □

Lean4 ✓ `BEDC.Derived.ListUp.ListSpineBridgeClassifier public prefix append left cancel`

Theorem 36.150 (List spine bridge source refinement)**.** *Let* $A, B : \mathsf{BHist} \to \mathsf{Prop}$ *be BEDC history source carriers, and let* $\sim_A$ *and* $\sim_B$ *be source classifiers. The ten-field fit is: traditional target finite-list source refinement; BEDC source* BHist *with* ListSpineRep*; carrier* ListHistoryCarrier*; classifier* ListSpineBridgeClassifier*; stability obligation carrier and classifier preservation under source refinement; ledger finite spine representation; core theorem the three displayed implications below; exactness inherited from* ListSpineRep*; standard bridge finite-spine readback; status* ProofTarget*. Assume the source carrier and source classifier of* A *are included in those of* B*:*

$$\forall h : \mathsf{BHist}.\ A(h) \to B(h)$$

and

$$\forall x\, y : \mathsf{BHist}.\ x \sim_A y \to x \sim_B y.$$

Then the displayed list-spine data transport from A *to* B*:*

$$\mathsf{ListSpineRep}_A(h, xs) \to \mathsf{ListSpineRep}_B(h, xs),$$

$$\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, k) \to \mathsf{ListSpineBridgeClassifier}_{B,\sim_B}(h, k),$$

and

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k) \to \mathsf{ListSpineHistoryClassifier}_{B,\sim_B}(h, k).$$

Proof. Proceed by induction on the displayed $\mathsf{ListSpineRep}_A(h, xs)$ witness. The nil representation keeps the same endpoint equality. In the cons case, the carrier inclusion turns the recorded source datum $A(a)$ into $B(a)$, while the induction hypothesis transports the tail representation and the continuation and endpoint witnesses are reused unchanged. For the finite-spine classifier component, induct on the displayed $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$ witness and apply the classifier inclusion at each cons head. A bridge witness is then repacked with the transported left and right spines and the transported finite-spine classifier. The certificate classifier clause follows by unfolding that it is the bridge classifier and rebuilding the same endpoints. □

Lemma 36.151 (List spine representation endpoint transport)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier. For all histories* h *and* h' *and every finite list spine* xs*,* $\mathsf{ListSpineRep}_A(h, xs)$ *and* $\mathsf{hsame}(h, h')$ *imply* $\mathsf{ListSpineRep}_A(h', xs)$*.*

Proof. Proceed by induction on the displayed finite spine. The empty spine is transported by composing the endpoint empty witness with $\mathsf{hsame}(h, h')$. For a cons spine, keep the recorded head payload and tail representation, and compose the outer history endpoint witness with $\mathsf{hsame}(h, h')$; the payload and tail witnesses are unchanged. □

Theorem 36.152 (List spine bridge endpoint transport)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier and let* $\sim_A$ *be a source classifier. The ten-field per-object fit is: traditional target finite-list classifier stability; BEDC source* A *over* BHist*; source classifier* $\sim_A$*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}$*; stability endpoint transport; ledger finite-spine presentation; exactness via* $\mathsf{ListSpineRep}$*; standard bridge finite spines; status* $\mathsf{ProofTarget}$*. For all histories* h*,* k*,* h'*, and* k'*,*

$$\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, k) \to \mathsf{hsame}(h, h') \to \mathsf{hsame}(k, k') \to \mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h', k').$$

Proof. Unpack the bridge witness into finite spines xs and ys, the represented endpoints $\mathsf{ListSpineRep}_A(h, xs)$ and $\mathsf{ListSpineRep}_A(k, ys)$, and the finite-spine classifier witness. Apply Lemma 36.151 to transport the two displayed endpoint representations along $\mathsf{hsame}(h, h')$ and $\mathsf{hsame}(k, k')$. The finite-spine classifier witness is independent of the represented endpoints, so the bridge witness is rebuilt over h' and k' with the same spines. □

Theorem 36.153 (List recursive history classifier endpoint transport)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier and let* $\sim_A$ *be a source classifier. The ten-field fit is: traditional target finite-list generated-classifier endpoint stability; BEDC source* BHist*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}$*; stability obligation endpoint transport; ledger finite spine; core theorem this transport law; exactness through Theorem 36.61; standard bridge finite-spine readback; status* $\mathsf{ProofTarget}$*. For all histories* h*,* k*,* h'*, and* k'*,*

$$\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}(h, k) \to \mathsf{hsame}(h, h') \to \mathsf{hsame}(k, k') \to \mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}(h', k').$$

Proof. Convert the displayed recursive classifier witness to $\mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, k)$ using the classifier equivalence in Theorem 36.61. Apply Theorem 36.152 to move the two endpoints along $\mathsf{hsame}(h, h')$ and $\mathsf{hsame}(k, k')$. Convert the resulting bridge witness back through the reverse direction of the same exactness theorem to obtain $\mathsf{ListHistoryClassifier}^{\mathrm{rec}}_{A,\sim_A}(h', k')$. □

Theorem 36.154 (List spine bridge nil-cons separation under coherence)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. For all histories* h *and* k*, all source histories* a*, and all finite spines* xs*, the bridge classifier separates the nil and cons displayed endpoints:*

$$\mathsf{ListSpineRep}_A(h, \mathsf{nil}) \to \mathsf{ListSpineRep}_A(k, \mathsf{cons}(a, xs)) \to \mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, k) \to \bot.$$

It also separates the symmetric cons-vs-nil orientation:

$$\mathsf{ListSpineRep}_A(h, \mathsf{cons}(a, xs)) \to \mathsf{ListSpineRep}_A(k, \mathsf{nil}) \to \mathsf{ListSpineBridgeClassifier}_{A,\sim_A}(h, k) \to \bot.$$

Proof. Unpack the bridge witness into finite spines u and v, endpoint presentations $\mathsf{ListSpineRep}_A(h, u)$ and $\mathsf{ListSpineRep}_A(k, v)$, and a finite-spine classifier $\mathsf{ListClassifierSpec}(\sim_A, u, v)$. In the nil-vs-cons orientation, apply the coherence datum at endpoint h to relate the displayed nil spine to u, and at endpoint k to relate v to the displayed $\mathsf{cons}(a, xs)$ spine. By Theorem 36.13, the comparison from nil to u forces u to have nil outer shape, and the bridge classifier from u to v then forces v to have nil outer shape. The comparison from v to the displayed $\mathsf{cons}(a, xs)$ spine is therefore a mixed nil-cons classifier witness, contrary to Lemma 36.14. In the cons-vs-nil orientation, the first coherence comparison forces u to have cons outer shape, the bridge classifier forces v to have cons outer shape, and the endpoint coherence comparison against the displayed nil spine is the symmetric impossible mixed classifier witness. □

Theorem 36.155 (List public classifier cons endpoint inversion)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\mathsf{Rel} : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{Rel})$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\mathsf{Rel}}$*. The ten-field fit is: traditional target finite-list cons inversion; BEDC source* BHist *with* Cont*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}$*; stability from* cert *and spine coherence; ledger finite-spine representatives for the two cons endpoints and the two tails; core theorem public cons inversion; exactness by Theorem 36.147; standard bridge finite spines; status* $\mathsf{ProofTarget}$*. For histories* $h, k, a, b, t, u, p, q : \mathsf{BHist}$*, if*

$$A(a) \wedge A(b) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{ListHistoryCarrier}_A(u) \wedge \\ \mathsf{Cont}(a, t, p) \wedge \mathsf{Cont}(b, u, q) \wedge \mathsf{hsame}(h, \mathsf{E1}(p)) \wedge \mathsf{hsame}(k, \mathsf{E1}(q))$$

and

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(h, k)$$

hold, then

$$\mathsf{Rel}(a, b) \wedge \mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(t, u).$$

Proof. Apply Theorem 36.65 to the two tail carrier witnesses, choosing finite spines xs and ys with $\mathsf{ListSpineRep}_A(t, xs)$ and $\mathsf{ListSpineRep}_A(u, ys)$. The cons constructor for $\mathsf{ListSpineRep}_A$ combines these tail representations with $A(a)$, $A(b)$, the two continuation witnesses, and the two endpoint witnesses to build displayed representations of h by $\mathsf{cons}(a, xs)$ and k by $\mathsf{cons}(b, ys)$. Apply Theorem 36.147 to those represented cons endpoints and the public classifier witness. Its cons-cons clause yields $\mathsf{Rel}(a, b)$ together with $\mathsf{ListClassifierSpec}(\mathsf{Rel}, xs, ys)$. Repack the two tail representations and this finite-spine classifier witness through the bridge definition of $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}$ to obtain the tail classifier $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(t, u)$. □

Theorem 36.156 (List public classifier cons endpoint exactness)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\mathsf{Rel} : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{Rel})$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\mathsf{Rel}}$*. The ten-field fit is: traditional target finite-list cons constructor exactness; BEDC source* BHist *with* Cont*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}$*; stability from* cert *and spine coherence; ledger finite-spine representatives for the two cons endpoints and the two tails; core theorem public cons endpoint exactness; exactness by Theorem 36.147; standard bridge finite spines; status* $\mathsf{ProofTarget}$*. For histories* $h, k, a, b, t, u, p, q : \mathsf{BHist}$*, if*

$$A(a) \wedge A(b) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{ListHistoryCarrier}_A(u) \wedge \\ \mathsf{Cont}(a, t, p) \wedge \mathsf{Cont}(b, u, q) \wedge \mathsf{hsame}(h, \mathsf{E1}(p)) \wedge \mathsf{hsame}(k, \mathsf{E1}(q))$$

holds, then

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(h, k) \iff \mathsf{Rel}(a, b) \wedge \mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(t, u).$$

Proof. For the forward implication, apply Theorem 36.155 to the displayed cons endpoint data and the public classifier witness. This gives the head relation and the tail public classifier.

For the reverse implication, unpack the tail public classifier into finite spines xs and ys, tail representations $\mathsf{ListSpineRep}_A(t, xs)$ and $\mathsf{ListSpineRep}_A(u, ys)$, and a finite-spine classifier $\mathsf{ListClassifierSpec}(\mathsf{Rel}, xs, ys)$. The cons constructor for $\mathsf{ListSpineRep}_A$ combines these tail representations with $A(a)$, $A(b)$, $\mathsf{Cont}(a, t, p)$, $\mathsf{Cont}(b, u, q)$, $\mathsf{hsame}(h, \mathsf{E1}(p))$, and $\mathsf{hsame}(k, \mathsf{E1}(q))$ to build cons spine representations of h and k. The finite-spine cons clause combines the head witness $\mathsf{Rel}(a, b)$ with the tail classifier witness to obtain the cons-cons $\mathsf{ListClassifierSpec}$ witness. Repack the two cons representations and that finite-spine witness through the bridge definition of $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}$. □

Theorem 36.157 (List public classifier nil endpoint inversion)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\mathsf{Rel} : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{Rel})$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\mathsf{Rel}}$*. The ten-field fit is: traditional target finite-list nil readback; BEDC source* BHist*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}$*; stability from* cert *and spine coherence; ledger nil finite-spine endpoint; core theorem public nil inversion; exactness by Theorem 36.146; standard bridge finite spines; status* $\mathsf{ProofTarget}$*. For all histories* $h, k : \mathsf{BHist}$*, if*

$$\mathsf{hsame}(h, \mathsf{e})$$

and

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(h, k)$$

hold, then

$$\mathsf{hsame}(k, \mathsf{e}).$$

Symmetrically, if

$$\mathsf{hsame}(k, \mathsf{e})$$

and

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(h, k)$$

hold, then

$$\mathsf{hsame}(h, \mathsf{e}).$$

Proof. From the displayed nil endpoint witness $\mathsf{hsame}(h, \mathsf{e})$, use the nil constructor of $\mathsf{ListSpineRep}_A$ to present h by nil. Unfold the bridge definition of $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(h, k)$, obtaining finite spines xs and ys, endpoint representations $\mathsf{ListSpineRep}_A(h, xs)$ and $\mathsf{ListSpineRep}_A(k, ys)$, and the finite-spine classifier witness. Apply Theorem 36.146 to the displayed nil representation of h, the represented endpoint for k, and the public classifier witness. The theorem forces $ys = \mathsf{nil}$; unfolding the nil case of $\mathsf{ListSpineRep}_A(k, ys)$ recovers $\mathsf{hsame}(k, \mathsf{e})$. The symmetric clause starts from $\mathsf{hsame}(k, \mathsf{e})$, builds the displayed nil representation of k, applies the symmetric half of the same represented-spine nil inversion to force $xs = \mathsf{nil}$, and unfolds the resulting nil representation of h to recover $\mathsf{hsame}(h, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListBridgeClassifier nil endpoint inversion`

Theorem 36.158 (List public classifier constructor decomposition)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, and let* $\mathsf{Rel} : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be a source classifier. The ten-field fit is: traditional target finite-list public classifier case analysis; BEDC source* BHist *with* Cont*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}$*; stability constructor*

decomposition; ledger finite-spine constructor witnesses; exactness by ListSpineRep *together with* ListClassifierSpec*; standard bridge finite spines; status* ProofTarget*. For all histories* $h, k : \mathsf{BHist}$*, if*

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(h, k)$$

holds, then

$$\begin{array}{l} (\mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(k, \mathsf{e})) \\ \vee \\ \exists a\, b\, t\, u\, p\, q : \mathsf{BHist}. \left(\begin{array}{l} A(a) \wedge A(b) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{ListHistoryCarrier}_A(u) \wedge \\ \mathsf{Cont}(a, t, p) \wedge \mathsf{Cont}(b, u, q) \wedge \mathsf{hsame}(h, \mathsf{E1}(p)) \wedge \mathsf{hsame}(k, \mathsf{E1}(q)) \wedge \\ \mathsf{Rel}(a, b) \wedge \mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(t, u) \end{array} \right) \end{array}$$

holds.

Proof. Unfold the public classifier as the spine bridge, obtaining finite spines xs and ys, endpoint representations $\mathsf{ListSpineRep}_A(h, xs)$ and $\mathsf{ListSpineRep}_A(k, ys)$, and a finite-spine classifier witness $\mathsf{ListClassifierSpec}(\mathsf{Rel}, xs, ys)$. Case-analyze xs and ys. The nil-nil case unfolds the two nil endpoint representations and gives $\mathsf{hsame}(h, \mathsf{e})$ and $\mathsf{hsame}(k, \mathsf{e})$. The mixed nil-cons and cons-nil cases contradict Lemma 36.14, equivalently the mixed branches of Theorem 36.13. In the cons-cons case, invert the two spine representations to obtain heads a and b, tails t and u, continuation histories p and q, the source carrier witnesses, the tail carrier witnesses, the continuation witnesses, and the two endpoint links. Invert the finite-spine classifier to obtain $\mathsf{Rel}(a, b)$ and the tail finite-spine classifier. Use Theorem 36.65 for the displayed tail carriers, then repack the tail representations with the tail classifier through the bridge definition to obtain $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(t, u)$. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListBridgeClassifier constructor decomposition`

Theorem 36.159 (List public classifier constructor exactness)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, and let* $\mathsf{Rel} : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be a source classifier. The ten-field fit is: traditional target finite-list public classifier constructor readback; BEDC source* BHist *with* Cont*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}$*; stability constructor exactness; ledger finite-spine constructor witnesses; exactness by* ListSpineRep *together with* ListClassifierSpec*; standard bridge finite spines; status* ProofTarget*. For all histories* $h, k : \mathsf{BHist}$*,*

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(h, k) \iff \begin{array}{l} (\mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(k, \mathsf{e})) \\ \vee \\ \exists a\, b\, t\, u\, p\, q : \mathsf{BHist}. \left(\begin{array}{l} A(a) \wedge A(b) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{ListHistoryCar} \\ \mathsf{Cont}(a, t, p) \wedge \mathsf{Cont}(b, u, q) \wedge \mathsf{hsame}(h, \mathsf{E1}(p)) \wedge \mathsf{hsam} \\ \mathsf{Rel}(a, b) \wedge \mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(t, u) \end{array} \right. \end{array}$$

Proof. For the forward implication, apply Theorem 36.158 to the displayed public classifier witness. This gives exactly the displayed nil-nil alternative or the displayed cons-cons constructor data.

For the reverse implication, split on the displayed disjunction. In the nil-nil branch, the nil constructor of $\mathsf{ListSpineRep}_A$ builds endpoint representations of h and k from $\mathsf{hsame}(h, \mathsf{e})$ and $\mathsf{hsame}(k, \mathsf{e})$. The nil constructor of ListClassifierSpec supplies the finite-spine classifier witness, and these three witnesses repack through the bridge definition of $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}$.

In the cons-cons branch, unpack the witnesses $a, b, t, u, p, q : \mathsf{BHist}$ together with the source carrier, tail carrier, continuation, endpoint, head relation, and tail public classifier data. Unfold the tail public classifier to obtain finite tail spines, tail endpoint representations, and a finite-spine classifier witness.

Build the two cons spine representations using the displayed heads, tail representations, continuation histories, and endpoint links. The cons constructor of $\mathsf{ListClassifierSpec}$ combines $\mathsf{Rel}(a, b)$ with the tail finite-spine classifier. Repack the two cons endpoint representations and the cons finite-spine classifier through the bridge definition to recover $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(h, k)$. □

Theorem 36.160 (List public classifier nil-cons endpoint separation)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\mathsf{Rel} : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{Rel})$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\mathsf{Rel}}$*. The ten-field fit is: traditional target finite-list nil/cons endpoint separation; BEDC source* BHist *with* Cont*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}$*; stability from* cert *and spine coherence; ledger nil endpoint together with a displayed cons endpoint; core theorem public nil-cons endpoint separation; exactness by Theorem 36.157 and Theorem 20.6; standard bridge finite spines; status* $\mathsf{ProofTarget}$*. For histories* $h, k, a, t, p : \mathsf{BHist}$*, the nil-to-cons orientation is impossible:*

$$\begin{array}{l} A(a) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{Cont}(a, t, p) \wedge \\ \mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(k, \mathsf{E1}(p)) \wedge \mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(h, k) \end{array} \to \bot.$$

The cons-to-nil orientation is impossible:

$$\begin{array}{l} A(a) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{Cont}(a, t, p) \wedge \\ \mathsf{hsame}(h, \mathsf{E1}(p)) \wedge \mathsf{hsame}(k, \mathsf{e}) \wedge \mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(h, k) \end{array} \to \bot.$$

Proof. In the nil-to-cons orientation, apply Theorem 36.157 to $\mathsf{hsame}(h, \mathsf{e})$ and the displayed public classifier. This yields $\mathsf{hsame}(k, \mathsf{e})$. Compose the symmetry of this endpoint witness with the displayed witness $\mathsf{hsame}(k, \mathsf{E1}(p))$ to obtain $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(p))$, contradicting Theorem 20.6. In the cons-to-nil orientation, the symmetric half of the same nil inversion theorem applied to $\mathsf{hsame}(k, \mathsf{e})$ yields $\mathsf{hsame}(h, \mathsf{e})$. Composing its symmetry with $\mathsf{hsame}(h, \mathsf{E1}(p))$ again gives empty-versus-one history no-confusion. □

Theorem 36.161 (List public classifier cons branch readback)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\mathsf{Rel} : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{Rel})$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\mathsf{Rel}}$*. The ten-field fit is: traditional target finite-list cons branch readback; BEDC source* BHist *with* Cont*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}$*; stability from* cert *and spine coherence; ledger one displayed cons endpoint and one classified partner; core theorem public cons branch readback; exactness by Theorem 36.160 and Theorem 36.155; standard bridge finite spines; status* $\mathsf{ProofTarget}$*. For histories* $h, k, a, t, p : \mathsf{BHist}$*, if*

$$\begin{array}{l} A(a) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{Cont}(a, t, p) \wedge \\ \mathsf{hsame}(h, \mathsf{E1}(p)) \wedge \mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(h, k) \end{array}$$

holds, then

$$\exists b\, u\, q : \mathsf{BHist}. \left(\begin{array}{l} A(b) \wedge \mathsf{ListHistoryCarrier}_A(u) \wedge \mathsf{Cont}(b, u, q) \wedge \\ \mathsf{hsame}(k, \mathsf{E1}(q)) \wedge \mathsf{Rel}(a, b) \wedge \mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(t, u) \end{array} \right).$$

Proof. Apply Theorem 36.65 to the displayed tail carrier witness for t, choosing a finite spine xs with $\mathsf{ListSpineRep}_A(t, xs)$. The cons constructor for $\mathsf{ListSpineRep}_A$ combines this tail representation with $A(a)$, $\mathsf{Cont}(a, t, p)$, and $\mathsf{hsame}(h, \mathsf{E1}(p))$ to display h as $\mathsf{cons}(a, xs)$. Unfold the public classifier

as the spine bridge, obtaining a represented finite spine for k, and case-analyze that spine. The nil case gives $\mathsf{hsame}(k, \mathsf{e})$, contradicting the cons-to-nil orientation of Theorem 36.160 applied to the displayed cons endpoint of h and the same public classifier witness. In the cons case, inversion of the represented endpoint for k supplies histories b, u, q with $A(b)$, $\mathsf{ListHistoryCarrier}_A(u)$, $\mathsf{Cont}(b, u, q)$, and $\mathsf{hsame}(k, \mathsf{E1}(q))$. Apply Theorem 36.155 to the two displayed cons endpoints and the original public classifier witness. It yields $\mathsf{Rel}(a, b)$ and $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(t, u)$, which together with the displayed endpoint data give the required existential witness. □

Theorem 36.162 (List public carrier constructor readback under spine coherence)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\mathsf{Rel} : \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$ *be a source classifier, and assume* $\mathsf{ListSpineRepCoherent}_{A,\mathsf{Rel}}$*. The ten-field fit is: traditional target finite-list carrier endpoint readback; BEDC source* BHist *with* Cont*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}$*; stability from spine coherence; ledger one generated history endpoint; core theorem public carrier nil-or-cons readback; exactness by generated carrier cases, history no-confusion, spine coverage, and classifier constructor inversion; standard bridge finite spines; status* $\mathsf{ProofTarget}$*. For every history* $h : \mathsf{BHist}$*, if* $\mathsf{ListHistoryCarrier}_A(h)$ *holds, then*

$$\left(\begin{array}{l}\mathsf{hsame}(h, \mathsf{e}) \wedge \\ \neg \exists a\, t\, p : \mathsf{BHist}.\ \left(\begin{array}{l} A(a) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{Cont}(a, t, p) \wedge \\ \mathsf{hsame}(h, \mathsf{E1}(p)) \end{array}\right)\end{array}\right)$$
$$\vee$$
$$\exists a\, t\, p : \mathsf{BHist}.\ \left(\begin{array}{l} A(a) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{Cont}(a, t, p) \wedge \mathsf{hsame}(h, \mathsf{E1}(p)) \wedge \\ \neg \mathsf{hsame}(h, \mathsf{e}) \wedge \\ \forall a'\, t'\, p' : \mathsf{BHist}.\ \left(\begin{array}{l} A(a') \wedge \mathsf{ListHistoryCarrier}_A(t') \wedge \mathsf{Cont}(a', t', p') \wedge \\ \mathsf{hsame}(h, \mathsf{E1}(p')) \end{array}\right) \to \Big(\mathsf{Rel}(a, a') \wedge \mathsf{ListSpineHi}\end{array}\right.$$

Proof. Apply Theorem 36.7 to the displayed carrier witness for h. The nil case gives $\mathsf{hsame}(h, \mathsf{e})$. If a cons presentation of the same endpoint also existed, composing the empty endpoint with the displayed $\mathsf{E1}$ endpoint would give $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(p))$ for some p, contradicting Theorem 20.6 and yielding the nil alternative.

In the cons case, keep the displayed histories a, t, p with $A(a)$, $\mathsf{ListHistoryCarrier}_A(t)$, $\mathsf{Cont}(a, t, p)$, and $\mathsf{hsame}(h, \mathsf{E1}(p))$. Nonemptiness follows by the same no-confusion argument: an additional $\mathsf{hsame}(h, \mathsf{e})$ witness would compose with $\mathsf{hsame}(h, \mathsf{E1}(p))$ to contradict Theorem 20.6.

It remains to compare any alternate cons presentation $a', t', p' : \mathsf{BHist}$ of the same h. Apply Theorem 36.65 to the two tail carrier witnesses for t and t', obtaining finite tail spines xs and xs' with $\mathsf{ListSpineRep}_A(t, xs)$ and $\mathsf{ListSpineRep}_A(t', xs')$.

Build two cons spine representations of h, one over $\mathsf{cons}(a, xs)$ and one over $\mathsf{cons}(a', xs')$. The assumed $\mathsf{ListSpineRepCoherent}_{A,\mathsf{Rel}}$ classifies these two presentations by $\mathsf{ListClassifierSpec}(\mathsf{Rel}, \mathsf{cons}(a, xs), \mathsf{cons}(a', xs$

Invert this finite-spine classifier through the cons branch of Theorem 36.13. The inversion yields $\mathsf{Rel}(a, a')$ and $\mathsf{ListClassifierSpec}(\mathsf{Rel}, xs, xs')$.

Repack the two tail representations and the finite-spine tail classifier through Definition 36.57 to obtain $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(t, t')$. □

Theorem 36.163 (List public-object certificate from cons-boundary coherence)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*. The ten-field per-object fit is: traditional target finite lists; BEDC source* A *with* $\mathsf{NameCert}(A, \sim_A)$*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability supplied by the source certificate and* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$*; ledger* $\mathsf{ListHistoryLedger}_A$*; core theorem list Theorem 36.71 and Theorem 36.68; exactness through the spine bridge* $\mathsf{ListSpineRep}_A$*; standard bridge*

finite spines; status ProofTarget *under* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$. *The semantic certificate target is*

$$\mathsf{SemanticNameCert}(\mathsf{ListHistoryCarrier}_A, \mathsf{ListHistoryPattern}_A, \mathsf{ListHistoryLedger}_A, \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}).$$

If $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$ *holds, then this semantic certificate target holds.*

Proof. Apply Theorem 36.71 to the cons-boundary coherence witness, obtaining $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$. Then apply Theorem 36.68 with the source certificate cert and this spine-coherence witness. The resulting certificate is exactly the displayed semantic target for the list public object. □

Theorem 36.164 (List public-object certificate exposes endpoint spine ledgers)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$. *If* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$ *holds, then the displayed public-object certificate target*

$$\mathsf{SemanticNameCert}(\mathsf{ListHistoryCarrier}_A, \mathsf{ListHistoryPattern}_A, \mathsf{ListHistoryLedger}_A, \mathsf{ListSpineHistoryClassifier}_{A,\sim_A})$$

holds. Moreover, for all histories h *and* k*, every certificate-classifier witness*

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, k)$$

exposes finite-spine endpoint ledgers:

$$\exists xs : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_A(h, xs)$$

and

$$\exists ys : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_A(k, ys).$$

Consequently,

$$\mathsf{ListHistoryCarrier}_A(h) \wedge \mathsf{ListHistoryCarrier}_A(k)$$

by Theorem 36.65. The per-object fit is: traditional target finite lists; BEDC source A *with* $\mathsf{NameCert}(A, \sim_A)$*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; ledger and exactness finite-spine endpoint exposure; core certificate theorem Theorem 36.163; standard bridge finite spines; status Phase Finite Data.*

Proof. First apply Theorem 36.163 to the source certificate and the cons-boundary coherence witness; this gives the displayed semantic certificate target. For the endpoint ledger claim, unfold $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$ as the bridge classifier. A bridge witness consists of finite spines xs and ys, endpoint presentations $\mathsf{ListSpineRep}_A(h, xs)$ and $\mathsf{ListSpineRep}_A(k, ys)$, and the finite-spine classifier witness $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$. The two endpoint presentations are the required ledgers. Applying the reverse direction of Theorem 36.65 to these representation witnesses recovers $\mathsf{ListHistoryCarrier}_A(h)$ and $\mathsf{ListHistoryCarrier}_A(k)$. □

Theorem 36.165 (List public-object constructor audit)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$. *Assume* $\mathsf{ListConsBoundaryCoherent}_{A,\sim_A}$. *The ten-field fit is: traditional target finite-list public constructor audit; BEDC source* BHist *with* Cont*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability from the source* $\mathsf{NameCert}(A, \sim_A)$ *and cons-boundary coherence; ledger finite-spine endpoint witnesses; core theorem this constructor audit package; exactness nil/cons constructor equivalence; standard bridge finite spines; status* ProofTarget*. The semantic public-object certificate*

$$\mathsf{SemanticNameCert}(\mathsf{ListHistoryCarrier}_A, \mathsf{ListHistoryPattern}_A, \mathsf{ListHistoryLedger}_A, \mathsf{ListSpineHistoryClassifier}_{A,\sim_A})$$

holds. Moreover, for all histories $h, k : \mathsf{BHist}$*, every certificate-classifier witness exposes endpoint spine ledgers:*

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h,k) \to \left(\begin{array}{l} (\exists xs : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_A(h, xs)) \\ \wedge \\ (\exists ys : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_A(k, ys)) \end{array} \right).$$

The same classifier is exactly the nil-nil or cons-cons constructor disjunction:

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h,k) \iff \begin{array}{l} (\mathsf{hsame}(h,\mathsf{e}) \wedge \mathsf{hsame}(k,\mathsf{e})) \\ \vee \\ \exists a\, b\, t\, u\, p\, q : \mathsf{BHist}. \left(\begin{array}{l} A(a) \wedge A(b) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{ListHistoryCar} \\ \mathsf{Cont}(a,t,p) \wedge \mathsf{Cont}(b,u,q) \wedge \mathsf{hsame}(h,\mathsf{E1}(p)) \wedge \mathsf{hsam} \\ \sim_A (a,b) \wedge \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(t,u) \end{array} \right. \end{array}$$

Proof. First apply Theorem 36.164 to the source certificate and the cons-boundary coherence witness. This gives the displayed semantic certificate and, for each classifier witness, the two finite-spine endpoint ledgers.

Next apply Theorem 36.159 with source classifier $\sim_A$. Its statement is exactly the displayed nil-nil or cons-cons constructor equivalence for arbitrary histories h and k.

Combining these two outputs gives the public-object certificate, its endpoint ledger witnesses, and the constructor-level classifier audit as one package. □

Theorem 36.166 (List spine bridge visible endpoint transport)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier and let* $\sim_A$ *be a source classifier. Visible endpoint transport holds for the framed list bridge classifier:*

$$\mathsf{FramedListBridgeClassifier}_{A,\sim_A}(\mathsf{E1}(h), \mathsf{E1}(k)) \to \mathsf{hsame}(h,h') \to \mathsf{hsame}(k,k') \to \mathsf{FramedListBridgeClassifier}_{A,\sim_A}(\mathsf{E1}($$

Proof. Unpack the bridge witness into finite spines, framed representations of the two visible endpoints, and the finite-spine classifier witness. Apply visible history congruence to the endpoint equalities $\mathsf{hsame}(h,h')$ and $\mathsf{hsame}(k,k')$, then transport the two framed spine representations along the resulting endpoint equalities. The finite-spine classifier witness is unchanged, so the same spines rebuild the bridge classifier at the transported visible endpoints. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListBridgeClassifier e1 endpoint hsame transport`

Definition 36.167 (Empty-bounded hsame list source)**.** *For a BEDC history source carrier* $A : \mathsf{BHist} \to \mathsf{Prop}$*, define* $\mathsf{ListHsameEmptyBoundedSource}(A)$ *by*

$$\mathsf{ListHsameEmptyBoundedSource}(A) \iff \forall a : \mathsf{BHist}.\ A(a) \to \mathsf{hsame}(a,\mathsf{e}).$$

Lean4 (definition) `BEDC.Derived.ListUp.ListHsameEmptyBoundedSource`

Theorem 36.168 (Empty-bounded equal-length list classifier)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *satisfy* $\mathsf{ListHsameEmptyBoundedSource}(A)$*. If every entry of finite spines* xs *and* ys *lies in* A*, and* $\ell(xs) = \ell(ys)$*, then*

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, xs, ys)$$

holds.

Proof. Induct on xs and case-analyze ys. The mixed nil/cons cases contradict the displayed length equality. In the cons/cons case, the two head entries are both history-same to e, hence history-same to each other by symmetry and transitivity. The successor length equality gives equal tail lengths, and the induction hypothesis classifies the two tails. □

Lean4 ✓ `BEDC.Derived.ListUp.ListHsameEmptyBoundedSource equal length classifier`

Definition 36.169 (Singleton history source for lists)**.** *For a fixed BEDC history* $a_0 : \mathsf{BHist}$*, define the singleton history source carrier* $A_{a_0} : \mathsf{BHist} \to \mathsf{Prop}$ *by*

$$A_{a_0}(x) \iff \mathsf{hsame}(x, a_0).$$

Lean4 (definition) `BEDC.Derived.ListUp.ListSingletonHistorySource`

Theorem 36.170 (List singleton source framed carrier certificate)**.** *Fix a BEDC history* $a_0 : \mathsf{BHist}$ *and let* A_{a_0} *be the singleton history source of Definition 36.169. The ten-field per-object fit is: traditional target framed carrier certificate for finite lists over one BEDC history class; BEDC source* BHist *with* hsame*; carrier* $\mathsf{FramedListHistoryCarrier}_{A_{a_0}}$*; classifier* $\mathsf{FramedListBridgeClassifier}_{A_{a_0},\mathsf{hsame}}$*; stability from* $\mathsf{ListSourceHsameCompatible}(A_{a_0}, \mathsf{hsame})$ *and framed endpoint coherence; ledger finite framed spine; core theorem Corollary 36.128; exactness through framed spine representation; standard bridge finite spines; status* $\mathsf{ProofTarget}$*. The framed semantic certificate*

$$\mathsf{SemanticNameCert}(\mathsf{FramedListHistoryCarrier}_{A_{a_0}}, \mathsf{FramedListHistoryCarrier}_{A_{a_0}}, \mathsf{FramedListHistoryCarrier}_{A_{a_0}}, \mathsf{FramedLis}$$

hold.

Proof. Theorem 34.66 supplies the source certificate $\mathsf{NameCert}(A_{a_0}, \mathsf{hsame})$. The compatibility predicate $\mathsf{ListSourceHsameCompatible}(A_{a_0}, \mathsf{hsame})$ is immediate: the final displayed input is already the required $\mathsf{hsame}(a, b)$ witness. Apply Corollary 36.128 with the singleton source certificate and this compatibility witness. □

Lean4 ✓ `BEDC.Derived.ListUp.ListSingletonHistorySource framed carrier certificate`

Theorem 36.171 (List singleton source spine coherence)**.** *For any BEDC history* a_0*, let* A_{a_0} *be the singleton history source of Definition 36.169. Then* $\mathsf{ListSpineRepCoherent}_{A_{a_0},\mathsf{hsame}}$ *holds.*

Proof. Compare two singleton-source spine presentations of the same endpoint by cases on the displayed spines. The mixed nil/cons cases contradict Theorem 36.58; the nil/nil case is the nil finite-spine classifier. In the cons/cons case, write the two displayed outer endpoints as $\mathsf{E1}(p)$ and $\mathsf{E1}(p')$. The common endpoint witness gives $\mathsf{hsame}(\mathsf{E1}(p), \mathsf{E1}(p'))$; Theorem 3.4 inverts it to $\mathsf{hsame}(p, p')$. The source facts $A_{a_0}(a)$ and $A_{a_0}(a')$ give $\mathsf{hsame}(a, a_0)$ and $\mathsf{hsame}(a', a_0)$, hence $\mathsf{hsame}(a, a')$ by symmetry and transitivity. Apply Theorem 4.43 to $\mathsf{Cont}(a, t, p)$, $\mathsf{Cont}(a', t', p')$, the head sameness, and the result sameness; this yields $\mathsf{hsame}(t, t')$. Transport the second tail representation along Lemma 36.151, apply the induction hypothesis to the two tail presentations at the aligned endpoint, and rebuild the $\mathsf{ListClassifierSpec}(\mathsf{hsame}, -, -)$ cons witness. □

Definition 36.172 (Hsame-bounded list source)**.** *For a source predicate* $A : \mathsf{BHist} \to \mathsf{Prop}$ *and a center* $a_0 : \mathsf{BHist}$*, define* $\mathsf{ListHsameBoundedSource}(A, a_0)$ *by*

Hence*

$$\mathsf{ListSpineRepCoherent}_{A,\mathsf{Rel}}$$

holds.

Proof. Compare two spine presentations of a common endpoint by cases on the two spines. The nil/nil case is the nil classifier. The mixed nil/cons and cons/nil cases contradict Theorem 36.58. In the cons/cons case, write the displayed outer endpoints as $\mathsf{E1}(p)$ and $\mathsf{E1}(p')$. The common endpoint witness gives $\mathsf{hsame}(\mathsf{E1}(p), \mathsf{E1}(p'))$, and Theorem 3.4 inverts it to $\mathsf{hsame}(p, p')$. The source facts $A(a)$ and $A(a')$, together with $\mathsf{ListHsameBoundedSource}(A, a_0)$, give $\mathsf{hsame}(a, a_0)$ and $\mathsf{hsame}(a', a_0)$, hence $\mathsf{hsame}(a, a')$ by symmetry and transitivity. Apply $\mathsf{ListSourceHsameCompatible}(A, \mathsf{Rel})$ to obtain $\mathsf{Rel}(a, a')$. Apply Theorem 4.43 to $\mathsf{Cont}(a, t, p)$, $\mathsf{Cont}(a', t', p')$, the head sameness, and the result sameness to obtain $\mathsf{hsame}(t, t')$. Transport the second tail representation along Lemma 36.151, apply the induction hypothesis to the aligned tail presentations, and rebuild the cons witness for $\mathsf{ListClassifierSpec}(\mathsf{Rel}, -, -)$. □

Corollary 36.175 (Hsame-compatible bounded list source unframed certificate)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$*, let* Rel *be a source classifier on* BHist*, and let* $a_0 : \mathsf{BHist}$*. If* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{Rel})$*,* $\mathsf{ListHsameBoundedSource}(A, a_0)$*, and* $\mathsf{ListSourceHsameCompatible}(A, \mathsf{Rel})$ *hold, then*

$$\mathsf{SemanticNameCert}(\mathsf{ListHistoryCarrier}_A, \mathsf{ListHistoryPattern}_A, \mathsf{ListHistoryLedger}_A, \mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}})$$

holds.

Proof. Theorem 36.174 supplies $\mathsf{ListSpineRepCoherent}_{A,\mathsf{Rel}}$ from the bounded-source and source-compatibility hypotheses. Apply Theorem 36.68 with this coherence witness and the displayed source certificate. □

Theorem 36.176 (Hsame-compatible bounded list source endpoint spine ledgers)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$*, let* Rel *be a source classifier on* BHist*, and let* $a_0 : \mathsf{BHist}$*. If* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{Rel})$*,* $\mathsf{ListHsameBoundedSource}(A, a_0)$*, and* $\mathsf{ListSourceHsameCompatible}(A, \mathsf{Rel})$ *hold, then the ten-field fit is: traditional target finite lists over an* hsame*-bounded BEDC history source with a compatible*

source classifier; BEDC source BHist *with* NameCert(A, Rel)*; carrier* ListHistoryCarrier$_A$*; classifier* ListSpineHistoryClassifier$_{A,\mathsf{Rel}}$*; stability from bounded head comparison plus source* hsame *compatibility; ledger finite-spine endpoint exposure; core route Theorem 36.174, Theorem 36.72, and Theorem 36.164; exactness through the finite-spine endpoint representation* ListSpineRep$_A$*; standard bridge finite spines; status Phase Finite Data. The cons-boundary coherence target*

$$\mathsf{ListConsBoundaryCoherent}_{A,\mathsf{Rel}}$$

holds, and the public-object semantic certificate

$$\mathsf{SemanticNameCert}(\mathsf{ListHistoryCarrier}_A, \mathsf{ListHistoryPattern}_A, \mathsf{ListHistoryLedger}_A, \mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}})$$

holds. Moreover, for all histories $h, k : \mathsf{BHist}$*, every witness of*

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(h, k)$$

exposes finite spines $xs, ys : \mathsf{HistSpine}$ *with*

$$\mathsf{ListSpineRep}_A(h, xs)$$

and

$$\mathsf{ListSpineRep}_A(k, ys).$$

Consequently,

$$\mathsf{ListHistoryCarrier}_A(h) \wedge \mathsf{ListHistoryCarrier}_A(k)$$

holds.

Proof. Theorem 36.174 turns the bounded-source and source-compatibility hypotheses into ListSpineRepCoherent$_{A,\mathsf{R}}$

The forward implication of Theorem 36.72 converts this spine coherence datum into ListConsBoundaryCoherent$_{A,}$

Apply Theorem 36.164 to the source certificate cert and this cons-boundary witness. Its certificate component is exactly the displayed SemanticNameCert(ListHistoryCarrier$_A$, ListHistoryPattern$_A$, ListHistoryLedge and its endpoint-ledger component supplies the finite spines xs and ys with the two displayed ListSpineRep$_A$ facts. The final carrier conjunction follows from Theorem 36.65. □

Theorem 36.177 (Hsame-compatible bounded list source public-object constructor audit)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$*, let* Rel *be a source classifier on* BHist*, and let* $a_0 : \mathsf{BHist}$*. If* cert : NameCert(A, Rel)*,* ListHsameBoundedSource(A, a_0)*, and* ListSourceHsameCompatible(A, Rel) *hold, then the ten-field fit is: traditional target finite lists over an hsame-bounded source; BEDC source* BHist *with* NameCert(A, Rel)*; carrier* ListHistoryCarrier$_A$*; classifier* ListSpineHistoryClassifier$_{A,\mathsf{Rel}}$*; stability from bounded head comparison plus source hsame compatibility; ledger finite-spine endpoint witnesses; core theorem bounded public constructor audit; exactness nil/cons constructor equivalence; standard bridge finite spines; status* ProofTarget*. The semantic public-object certificate*

$$\mathsf{SemanticNameCert}(\mathsf{ListHistoryCarrier}_A, \mathsf{ListHistoryPattern}_A, \mathsf{ListHistoryLedger}_A, \mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}})$$

holds. Moreover, for all histories $h, k : \mathsf{BHist}$*, every certificate-classifier witness exposes endpoint spine ledgers:*

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(h, k) \to \left(\begin{array}{l} (\exists xs : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_A(h, xs)) \\ \wedge \\ (\exists ys : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_A(k, ys)) \end{array} \right).$$

The same classifier is exactly the nil-nil or cons-cons constructor disjunction:

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(h,k) \iff \begin{array}{l} (\mathsf{hsame}(h,\mathsf{e}) \land \mathsf{hsame}(k,\mathsf{e})) \\ \lor \\ \exists a\, b\, t\, u\, p\, q : \mathsf{BHist}. \left(\begin{array}{l} A(a) \land A(b) \land \mathsf{ListHistoryCarrier}_A(t) \land \mathsf{ListHistoryCar} \\ \mathsf{Cont}(a,t,p) \land \mathsf{Cont}(b,u,q) \land \mathsf{hsame}(h,\mathsf{E1}(p)) \land \mathsf{hsam} \\ \mathsf{Rel}(a,b) \land \mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(t,u) \end{array} \right. \end{array}$$

Proof. Theorem 36.174 turns the bounded-source and source-compatibility hypotheses into $\mathsf{ListSpineRepCoherent}_{A,\mathsf{R}}$

The forward implication of Theorem 36.72 converts this spine coherence datum into $\mathsf{ListConsBoundaryCoherent}_{A,}$

Apply Theorem 36.165 to the displayed source certificate and this cons-boundary coherence witness. Its three outputs are exactly the semantic certificate, the endpoint spine ledgers for each classifier witness, and the displayed nil-nil or cons-cons constructor equivalence. □

Theorem 36.178 (Hsame-compatible bounded list source finite-data exit package)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$*, let* Rel *be a source classifier on* BHist*, and let* $a_0 : \mathsf{BHist}$*. If* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{Rel})$*,* $\mathsf{ListHsameBoundedSource}(A, a_0)$*, and* $\mathsf{ListSourceHsameCompatible}(A, \mathsf{Rel})$ *hold, then the* $\mathsf{List}^{\uparrow}$ *public object carries the following finite-data exit fields.*

1. *The semantic certificate* $\mathsf{SemanticNameCert}(\mathsf{ListHistoryCarrier}_A, \mathsf{ListHistoryPattern}_A, \mathsf{ListHistoryLedger}_A, \mathsf{ListSpine}$
2. *Public length is total and unique on* $\mathsf{ListHistoryCarrier}_A$*.*
3. *Classified endpoints have a common public length, and any two endpoint length readbacks are equal.*
4. $\mathsf{ListPublicLength}_A(h, 0)$ *holds exactly when* $\mathsf{hsame}(h, \mathsf{e})$ *holds.*
5. *Every nonempty carrier history has a cons readback* $a, t, p : \mathsf{BHist}$ *with* $A(a)$*,* $\mathsf{ListHistoryCarrier}_A(t)$*,* $\mathsf{Cont}(a, t, p)$*,* $\mathsf{hsame}(h, \mathsf{E1}(p))$*, and no zero public length for* h*.*
6. *For every history* h *and finite length value* n*,*

$$\mathsf{ListPublicLength}_A(h, n{+}1) \iff \exists a\, t\, p : \mathsf{BHist}. \left(\begin{array}{l} A(a) \land \mathsf{ListHistoryCarrier}_A(t) \land \mathsf{ListPublicLength}_A(t, n) \land \\ \mathsf{Cont}(a, t, p) \land \mathsf{hsame}(h, \mathsf{E1}(p)) \end{array} \right)$$

7. *Every classifier witness exposes finite endpoint spines:*

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(h,k) \to \left(\begin{array}{l} (\exists xs : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_A(h, xs)) \\ \land (\exists ys : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_A(k, ys)) \end{array} \right).$$

8. *The classifier is exactly the nil-nil or cons-cons constructor audit:*

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(h,k) \iff \begin{array}{l} (\mathsf{hsame}(h,\mathsf{e}) \land \mathsf{hsame}(k,\mathsf{e})) \\ \lor \\ \exists a\, b\, t\, u\, p\, q : \mathsf{BHist}. \left(\begin{array}{l} A(a) \land A(b) \land \mathsf{ListHistoryCarrier}_A(t) \land \mathsf{ListHistory} \\ \mathsf{Cont}(a,t,p) \land \mathsf{Cont}(b,u,q) \land \mathsf{hsame}(h,\mathsf{E1}(p)) \land \mathsf{hs} \\ \mathsf{Rel}(a,b) \land \mathsf{ListSpineHistoryClassifier}_{A,\mathsf{Rel}}(t,u) \end{array} \right. \end{array}$$

Proof. Theorem 36.174 supplies $\mathsf{ListSpineRepCoherent}_{A,\mathsf{Rel}}$ from the bounded-source and source-compatibility hypotheses.

Use the forward implication of Theorem 36.72 to convert this spine coherence witness into $\mathsf{ListConsBoundaryCoherent}_{A,\mathsf{Rel}}$.

Apply Theorem 36.78 to cert and the cons-boundary coherence witness. This gives the semantic certificate, public-length totality and uniqueness, the common classified endpoint length, and endpoint length equality. Apply Theorem 36.79 with the same coherence witness to obtain the zero-length characterization and the nonempty cons readback.

Theorem 36.82 supplies the successor length constructor equivalence. Finally, Theorem 36.177 supplies the endpoint spine ledgers and the nil-nil or cons-cons constructor audit with head relation $\mathsf{Rel}(a, b)$. □

Corollary 36.179 (Hsame-bounded list source unframed certificate)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *and* $a_0 : \mathsf{BHist}$*. If* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{hsame})$ *and* $\mathsf{ListHsameBoundedSource}(A, a_0)$*, then the ten-field per-object fit is: traditional target finite lists over one internal history class; BEDC source* BHist *with* hsame*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}$*; stability from the source* $\mathsf{NameCert}(A, \mathsf{hsame})$ *and Theorem 36.173; ledger* $\mathsf{ListHistoryLedger}_A$*; core theorem list Theorem 36.173 and Theorem 36.68; exactness through the spine bridge; standard bridge finite spines; status* ProofTarget*. Hence*

$$\mathsf{SemanticNameCert}(\mathsf{ListHistoryCarrier}_A, \mathsf{ListHistoryPattern}_A, \mathsf{ListHistoryLedger}_A, \mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}})$$

holds.

Proof. The displayed certificate cert supplies the source $\mathsf{NameCert}(A, \mathsf{hsame})$ input. The bounded-source hypothesis supplies $\mathsf{ListSpineRepCoherent}_{A,\mathsf{hsame}}$ by Theorem 36.173. Apply Theorem 36.68 with these two inputs. □

Theorem 36.180 (Hsame-bounded list source endpoint spine ledgers)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *and* $a_0 : \mathsf{BHist}$*. If* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{hsame})$ *and* $\mathsf{ListHsameBoundedSource}(A, a_0)$*, then the displayed public-object semantic certificate*

$$\mathsf{SemanticNameCert}(\mathsf{ListHistoryCarrier}_A, \mathsf{ListHistoryPattern}_A, \mathsf{ListHistoryLedger}_A, \mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}})$$

holds. Moreover, for all histories h *and* k*, every classifier witness*

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}(h, k)$$

yields finite spines $xs, ys : \mathsf{HistSpine}$ *with*

$$\mathsf{ListSpineRep}_A(h, xs)$$

and

$$\mathsf{ListSpineRep}_A(k, ys).$$

Consequently,

$$\mathsf{ListHistoryCarrier}_A(h) \wedge \mathsf{ListHistoryCarrier}_A(k)$$

holds. The per-object fit is: traditional target finite lists over one hsame-bounded BEDC history source; BEDC source BHist *with* hsame*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}$*; ledger finite-spine endpoint exposure; core route Theorem 36.173, Theorem 36.72, and Theorem 36.164; standard bridge finite spines; status Phase Finite Data.*

Proof. Theorem 36.173 turns the hsame-bounded source hypothesis into $\mathsf{ListSpineRepCoherent}_{A,\mathsf{hsame}}$. The forward implication of Theorem 36.72 converts this spine coherence datum into $\mathsf{ListConsBoundaryCoherent}_{A,\mathsf{hsam}}$ Apply Theorem 36.164 to the source certificate cert and this cons-boundary witness. Its certificate component is exactly the displayed $\mathsf{SemanticNameCert}(\mathsf{ListHistoryCarrier}_A, \mathsf{ListHistoryPattern}_A, \mathsf{ListHistoryLedger}_A, \mathsf{L}$ and its endpoint-ledger component supplies the finite spines xs and ys with the two displayed $\mathsf{ListSpineRep}_A$ facts. The final carrier conjunction follows from Theorem 36.65. □

Theorem 36.181 (Hsame-bounded list source public-object constructor audit)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *and* $a_0 : \mathsf{BHist}$*. If* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{hsame})$ *and* $\mathsf{ListHsameBoundedSource}(A, a_0)$*, then the public-object semantic certificate*

$$\mathsf{SemanticNameCert}(\mathsf{ListHistoryCarrier}_A, \mathsf{ListHistoryPattern}_A, \mathsf{ListHistoryLedger}_A, \mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}})$$

holds. Moreover, for all histories $h, k : \mathsf{BHist}$*, every* $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}(h, k)$ *witness exposes endpoint spine ledgers for* h *and* k*:*

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}(h, k) \to \left(\begin{array}{l} (\exists xs : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_A(h, xs)) \\ \wedge \\ (\exists ys : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_A(k, ys)) \end{array} \right).$$

The same classifier is exactly the nil-nil or cons-cons constructor disjunction:

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}(h, k) \iff \begin{array}{l} (\mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(k, \mathsf{e})) \\ \vee \\ \exists a\, b\, t\, u\, p\, q : \mathsf{BHist}. \left(\begin{array}{l} A(a) \wedge A(b) \wedge \mathsf{ListHistoryCarrier}_A(t) \wedge \mathsf{ListHistoryC} \\ \mathsf{Cont}(a, t, p) \wedge \mathsf{Cont}(b, u, q) \wedge \mathsf{hsame}(h, \mathsf{E1}(p)) \wedge \mathsf{hs} \\ \mathsf{hsame}(a, b) \wedge \mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}(t, u) \end{array} \right. \end{array}$$

Proof. Define the needed $\mathsf{ListSourceHsameCompatible}(A, \mathsf{hsame})$ witness by taking a source-head comparison $\mathsf{hsame}(a, b)$ and returning that same $\mathsf{hsame}(a, b)$ datum.

Apply Theorem 36.177 with $\mathsf{Rel} := \mathsf{hsame}$, the displayed source certificate, the hsame-bounded source hypothesis, and this compatibility witness.

Its first projection is the displayed $\mathsf{SemanticNameCert}(\mathsf{ListHistoryCarrier}_A, \mathsf{ListHistoryPattern}_A, \mathsf{ListHistoryLedger}_A$ Its second projection gives the endpoint spine ledgers for every classifier witness, and its third projection is the displayed nil-nil or cons-cons constructor equivalence with head relation $\mathsf{hsame}(a, b)$ and recursive tail classifier $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}(t, u)$. □

Theorem 36.182 (List singleton source unframed certificate)**.** *Fix a BEDC history* $a_0 : \mathsf{BHist}$ *and let* A_{a_0} *be the singleton history source of Definition 36.169. The ten-field per-object fit is: traditional target finite lists over one BEDC history class; BEDC source* BHist *with* hsame*; carrier* $\mathsf{ListHistoryCarrier}_{A_{a_0}}$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}$*; stability from the singleton source certificate and Theorem 36.171; ledger* $\mathsf{ListHistoryLedger}_{A_{a_0}}$*; core theorem Theorem 36.68; exactness through the spine bridge; standard bridge finite spines; status* $\mathsf{ProofTarget}$*. Then the displayed semantic certificate*

$$\mathsf{SemanticNameCert}(\mathsf{ListHistoryCarrier}_{A_{a_0}}, \mathsf{ListHistoryPattern}_{A_{a_0}}, \mathsf{ListHistoryLedger}_{A_{a_0}}, \mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsa}}$$

holds.

Proof. Theorem 34.66 supplies $\mathsf{NameCert}(A_{a_0}, \mathsf{hsame})$, and Theorem 36.171 supplies $\mathsf{ListSpineRepCoherent}_{A_{a_0},\mathsf{hsame}}$. Apply Theorem 36.68 directly with these two inputs. □

Theorem 36.183 (List singleton source finite-data certificate package)**.** *Fix a BEDC history* $a_0 : \mathsf{BHist}$ *and let* A_{a_0} *be the singleton history source of Definition 36.169. The singleton-source* $\mathsf{List}^{\uparrow}$ *package contains the following concrete public certificate data:*

1. $\mathsf{SemanticNameCert}(\mathsf{ListHistoryCarrier}_{A_{a_0}}, \mathsf{ListHistoryPattern}_{A_{a_0}}, \mathsf{ListHistoryLedger}_{A_{a_0}}, \mathsf{ListSpineHistoryClassifier}_{A_{a_0}}$
2. $\forall h.\ \mathsf{ListHistoryCarrier}_{A_{a_0}}(h) \to \exists n.\ \mathsf{ListPublicLength}_{A_{a_0}}(h, n)$.

3. $\forall h\, n\, m.\ \mathsf{ListPublicLength}_{A_{a_0}}(h,n) \to \mathsf{ListPublicLength}_{A_{a_0}}(h,m) \to n = m.$
4. $\forall h\, k.\ \mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(h,k) \to \exists n.\ \mathsf{ListPublicLength}_{A_{a_0}}(h,n) \wedge \mathsf{ListPublicLength}_{A_{a_0}}(k,n).$
5. $\forall h\, k\, n\, m.\ \mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(h,k) \to \mathsf{ListPublicLength}_{A_{a_0}}(h,n) \to \mathsf{ListPublicLength}_{A_{a_0}}(k,m) \to n = m.$
6. *For every history h, $\mathsf{ListPublicLength}_{A_{a_0}}(h,0)$ holds if and only if $\mathsf{hsame}(h,\mathsf{e})$ holds.*
7. *For every history h, if $\mathsf{ListHistoryCarrier}_{A_{a_0}}(h)$ and $\neg\mathsf{hsame}(h,\mathsf{e})$ hold, then*

$$\exists a\, t\, p : \mathsf{BHist}.\ \left(\begin{array}{l} A_{a_0}(a) \wedge \mathsf{ListHistoryCarrier}_{A_{a_0}}(t) \wedge \mathsf{Cont}(a,t,p) \wedge \\ \mathsf{hsame}(h,\mathsf{E1}(p)) \wedge \\ \forall n.\ \mathsf{ListPublicLength}_{A_{a_0}}(h,n) \to n \neq 0 \end{array}\right).$$

8. *For every history h and finite length value n,*

$$\mathsf{ListPublicLength}_{A_{a_0}}(h,n{+}1) \iff \exists a\, t\, p : \mathsf{BHist}.\ \left(\begin{array}{l} A_{a_0}(a) \wedge \mathsf{ListHistoryCarrier}_{A_{a_0}}(t) \wedge \mathsf{ListPublicLength}_{A_{a_0}}(t \\ \mathsf{Cont}(a,t,p) \wedge \mathsf{hsame}(h,\mathsf{E1}(p)) \end{array}\right.$$

Proof. Theorem 34.66 supplies $\mathsf{NameCert}(A_{a_0},\mathsf{hsame})$. Theorem 36.171 supplies $\mathsf{ListSpineRepCoherent}_{A_{a_0},\mathsf{hsame}}$ for the same singleton source.

Use the forward implication of Theorem 36.72 to convert this spine coherence witness into $\mathsf{ListConsBoundaryCoherent}_{A_{a_0},\mathsf{hsame}}$.

Apply Theorem 36.78 to $\mathsf{NameCert}(A_{a_0},\mathsf{hsame})$ and the cons-boundary coherence witness. Its five components are exactly the displayed semantic certificate, totality and uniqueness of $\mathsf{ListPublicLength}_{A_{a_0}}$, the common public length for classified endpoints, and equality of endpoint readbacks.

Apply Theorem 36.79 with the same cons-boundary coherence witness. This gives the zero-length characterization and the nonempty cons readback clause.

Finally apply Theorem 36.82 to the source certificate and the cons-boundary coherence witness. The resulting successor law is the last displayed item. □

Theorem 36.184 (List singleton source finite-data exit with constructor audit)**.** *Fix a BEDC history $a_0 : \mathsf{BHist}$ and let A_{a_0} be the singleton history source of Definition 36.169. The singleton-source $\mathsf{List}^{\uparrow}$ finite-data exit object contains the following concrete public certificate data:*

1. $\mathsf{SemanticNameCert}(\mathsf{ListHistoryCarrier}_{A_{a_0}}, \mathsf{ListHistoryPattern}_{A_{a_0}}, \mathsf{ListHistoryLedger}_{A_{a_0}}, \mathsf{ListSpineHistoryClassifier}_{A_{a_0}}$
2. $\forall h.\ \mathsf{ListHistoryCarrier}_{A_{a_0}}(h) \to \exists n.\ \mathsf{ListPublicLength}_{A_{a_0}}(h,n).$
3. $\forall h\, n\, m.\ \mathsf{ListPublicLength}_{A_{a_0}}(h,n) \to \mathsf{ListPublicLength}_{A_{a_0}}(h,m) \to n = m.$
4. $\forall h\, k.\ \mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(h,k) \to \exists n.\ \mathsf{ListPublicLength}_{A_{a_0}}(h,n) \wedge \mathsf{ListPublicLength}_{A_{a_0}}(k,n).$
5. $\forall h\, k\, n\, m.\ \mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(h,k) \to \mathsf{ListPublicLength}_{A_{a_0}}(h,n) \to \mathsf{ListPublicLength}_{A_{a_0}}(k,m) \to n = m.$
6. *For every history h, $\mathsf{ListPublicLength}_{A_{a_0}}(h,0)$ holds if and only if $\mathsf{hsame}(h,\mathsf{e})$ holds.*
7. *For every history h, if $\mathsf{ListHistoryCarrier}_{A_{a_0}}(h)$ and $\neg\mathsf{hsame}(h,\mathsf{e})$ hold, then*

$$\exists a\, t\, p : \mathsf{BHist}.\ \left(\begin{array}{l} A_{a_0}(a) \wedge \mathsf{ListHistoryCarrier}_{A_{a_0}}(t) \wedge \mathsf{Cont}(a,t,p) \wedge \\ \mathsf{hsame}(h,\mathsf{E1}(p)) \wedge \\ \forall n.\ \mathsf{ListPublicLength}_{A_{a_0}}(h,n) \to n \neq 0 \end{array}\right).$$

8. *For every history h and finite length value n,*

$$\mathsf{ListPublicLength}_{A_{a_0}}(h, n{+}1) \iff \exists a\, t\, p : \mathsf{BHist}. \left(\begin{array}{l} A_{a_0}(a) \wedge \mathsf{ListHistoryCarrier}_{A_{a_0}}(t) \wedge \mathsf{ListPublicLength}_{A_{a_0}}(t \\ \mathsf{Cont}(a, t, p) \wedge \mathsf{hsame}(h, \mathsf{E1}(p)) \end{array} \right.$$

9. *For all histories $h, k : \mathsf{BHist}$, every classifier witness has finite spine ledgers at both endpoints:*

$$\mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(h, k) \to \left(\begin{array}{l} (\exists xs : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_{A_{a_0}}(h, xs)) \\ \wedge \\ (\exists ys : \mathsf{HistSpine}.\ \mathsf{ListSpineRep}_{A_{a_0}}(k, ys)) \end{array} \right).$$

10. *For all histories $h, k : \mathsf{BHist}$, the classifier is exactly the nil-nil or cons-cons constructor disjunction:*

$$\mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(h, k) \iff \begin{array}{l} (\mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(k, \mathsf{e})) \\ \vee \\ \exists a\, b\, t\, u\, p\, q : \mathsf{BHist}. \left(\begin{array}{l} A_{a_0}(a) \wedge A_{a_0}(b) \wedge \mathsf{ListHistoryCarrier}_{A_{a_0}}(t) \wedge \mathsf{L} \\ \mathsf{Cont}(a, t, p) \wedge \mathsf{Cont}(b, u, q) \wedge \mathsf{hsame}(h, \mathsf{E1}(p)) \\ \mathsf{hsame}(a, b) \wedge \mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsar}} \end{array} \right. \end{array}$$

Proof. Theorem 36.183 supplies the semantic certificate, public-length totality and uniqueness, common endpoint length, endpoint readback equality, zero-length characterization, nonempty readback, and successor constructor law.

The singleton source definition gives $\mathsf{ListHsameBoundedSource}(A_{a_0}, a_0)$: from $A_{a_0}(a)$, unfold Definition 36.169 to get $\mathsf{hsame}(a, a_0)$.

Theorem 34.66 supplies $\mathsf{NameCert}(A_{a_0}, \mathsf{hsame})$. Apply Theorem 36.181 with $A := A_{a_0}$ and the displayed hsame-bounded source witness. Its endpoint projection gives the finite spine ledgers for every $\mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(h, k)$ witness, and its constructor projection gives the displayed nil-nil or cons-cons equivalence specialized to A_{a_0} and hsame.

Combining the fields from the finite-data certificate package with these two projections yields the ten displayed components of the singleton-source finite-data exit object. □

36.5 Singleton source length shape exhaustion

Theorem 36.185 (List singleton source public length shape exhaustion)**.** *Fix a BEDC history $a_0 : \mathsf{BHist}$ and let A_{a_0} be the singleton history source of Definition 36.169. For every history h, if $\mathsf{ListHistoryCarrier}_{A_{a_0}}(h)$ holds, then one of the following two disjoint public length shapes is available:*

1. $\mathsf{ListPublicLength}_{A_{a_0}}(h, 0) \wedge \mathsf{hsame}(h, \mathsf{e})$.

2. *There exist a finite length value n and histories $a, t, p : \mathsf{BHist}$ such that*

$$\left(\begin{array}{l} \mathsf{ListPublicLength}_{A_{a_0}}(h, n+1) \wedge A_{a_0}(a) \wedge \\ \mathsf{ListHistoryCarrier}_{A_{a_0}}(t) \wedge \mathsf{ListPublicLength}_{A_{a_0}}(t, n) \wedge \\ \mathsf{Cont}(a, t, p) \wedge \mathsf{hsame}(h, \mathsf{E1}(p)) \end{array} \right).$$

The nil alternative and every displayed cons alternative are disjoint by BEDC history no-confusion between e and $\mathsf{E1}(p)$.

Proof. Apply Theorem 36.183 at the fixed singleton source. Its totality clause gives a finite length value m with $\mathsf{ListPublicLength}_{A_{a_0}}(h, m)$.

Case-analyze the finite length value m.

In the zero case, the zero readback clause of Theorem 36.183 identifies $\mathsf{ListPublicLength}_{A_{a_0}}(h, 0)$ with $\mathsf{hsame}(h, \mathsf{e})$. Pair the given zero public length witness with this endpoint witness to obtain the nil alternative.

In the successor case, write $m = n + 1$. The successor exactness clause of Theorem 36.183 turns $\mathsf{ListPublicLength}_{A_{a_0}}(h, n+1)$ into histories $a, t, p : \mathsf{BHist}$ with $A_{a_0}(a)$, $\mathsf{ListHistoryCarrier}_{A_{a_0}}(t)$, $\mathsf{ListPublicLength}_{A_{a_0}}(t, n)$, $\mathsf{Cont}(a, t, p)$, and $\mathsf{hsame}(h, \mathsf{E1}(p))$. These data are exactly the displayed cons alternative.

For disjointness, suppose the nil alternative and one displayed cons alternative both hold. Compose symmetry of the nil endpoint witness $\mathsf{hsame}(h, \mathsf{e})$ with the cons endpoint witness $\mathsf{hsame}(h, \mathsf{E1}(p))$ to obtain $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(p))$. The BEDC history no-confusion theorem, Theorem 20.6, excludes this empty-versus-one identification. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListHistoryCarrier public length shape exhaustion`

Theorem 36.186 (List singleton source classified shape synchrony)**.** *Fix a BEDC history* $a_0 : \mathsf{BHist}$ *and let* A_{a_0} *be the singleton history source of Definition 36.169. For all histories* $h, k : \mathsf{BHist}$*, if* $\mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(h, k)$ *holds, then exactly one synchronized public endpoint shape is available:*

1.

$$\mathsf{ListPublicLength}_{A_{a_0}}(h, 0) \wedge \mathsf{ListPublicLength}_{A_{a_0}}(k, 0) \wedge \mathsf{hsame}(h, \mathsf{e}) \wedge \mathsf{hsame}(k, \mathsf{e}).$$

2. There exist a finite length value n *and histories* $a, b, t, u, p, q : \mathsf{BHist}$ *such that*

$$\left(\begin{array}{l} \mathsf{ListPublicLength}_{A_{a_0}}(h, n+1) \wedge \mathsf{ListPublicLength}_{A_{a_0}}(k, n+1) \wedge \\ A_{a_0}(a) \wedge A_{a_0}(b) \wedge \mathsf{ListHistoryCarrier}_{A_{a_0}}(t) \wedge \mathsf{ListHistoryCarrier}_{A_{a_0}}(u) \wedge \\ \mathsf{ListPublicLength}_{A_{a_0}}(t, n) \wedge \mathsf{ListPublicLength}_{A_{a_0}}(u, n) \wedge \\ \mathsf{Cont}(a, t, p) \wedge \mathsf{Cont}(b, u, q) \wedge \mathsf{hsame}(h, \mathsf{E1}(p)) \wedge \mathsf{hsame}(k, \mathsf{E1}(q)) \wedge \\ \mathsf{hsame}(a, b) \wedge \mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(t, u) \end{array}\right).$$

The nil endpoint shape and every displayed cons endpoint shape are mutually exclusive by BEDC history no-confusion between e *and* $\mathsf{E1}(p)$*.*

Lean4 ✓ `BEDC.Derived.ListUp.FramedListBridgeClassifier singleton classified shape synchrony`

Proof. Apply Theorem 36.184 to the fixed singleton source. For the given classifier witness, its public data give a common endpoint length, public-length uniqueness, successor exactness, finite endpoint spine ledgers, and the nil-nil or cons-cons constructor disjunction.

In the nil-nil constructor case, the zero-length characterization in the same certificate turns $\mathsf{hsame}(h, \mathsf{e})$ and $\mathsf{hsame}(k, \mathsf{e})$ into $\mathsf{ListPublicLength}_{A_{a_0}}(h, 0)$ and $\mathsf{ListPublicLength}_{A_{a_0}}(k, 0)$. Pair these two public lengths with the two endpoint witnesses to obtain the first alternative.

In the cons-cons constructor case, the constructor disjunction supplies histories $a, b, t, u, p, q : \mathsf{BHist}$ with both heads in A_{a_0}, both tails in $\mathsf{ListHistoryCarrier}_{A_{a_0}}$, both Cont ledgers, both endpoint readbacks, $\mathsf{hsame}(a, b)$, and the tail classifier $\mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(t, u)$.

Apply the common endpoint length clause of Theorem 36.184 to the tail classifier. This gives a finite value n with $\mathsf{ListPublicLength}_{A_{a_0}}(t, n)$ and $\mathsf{ListPublicLength}_{A_{a_0}}(u, n)$. The reverse direction of

successor exactness transports the two Cont ledgers and these tail lengths to $\mathsf{ListPublicLength}_{A_{a_0}}(h, n+1)$ and $\mathsf{ListPublicLength}_{A_{a_0}}(k, n+1)$.

The endpoint spine ledgers supplied by the certificate give the carrier presentations needed to apply Theorem 36.185 to the classified endpoints h and k. Apply the same theorem to the exposed tails t and u using their carrier witnesses. These four one-endpoint applications attach the public readback shape witnesses to the data supplied by the constructor audit.

In the present cons-cons branch, endpoint nil alternatives would identify e with $\mathsf{E1}(p)$ or with $\mathsf{E1}(q)$ after symmetry and transitivity of hsame, so Theorem 20.6 excludes them. Public-length uniqueness then identifies the resulting endpoint successor lengths with the $n+1$ lengths already obtained from the tail classifier, while the displayed tail public lengths remain the common length data for t and u.

Collect the common length n and the six constructor histories. The displayed data are exactly the second alternative. The same no-confusion argument separates the nil endpoint shape from any cons endpoint shape. □

Theorem 36.187 (List singleton source classified zero length iff empty)**.** *Fix a BEDC history* $a_0 : \mathsf{BHist}$ *and let* A_{a_0} *be the singleton history source of Definition 36.169. For all histories* $h, k : \mathsf{BHist}$*, the following conditions are equivalent:*

$$\left(\begin{array}{l}\mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(h,k)\wedge\\ \mathsf{ListPublicLength}_{A_{a_0}}(h,0)\wedge\mathsf{ListPublicLength}_{A_{a_0}}(k,0)\end{array}\right) \iff (\mathsf{hsame}(h,\mathsf{E0}(\mathsf{e}))\wedge\mathsf{hsame}(k,\mathsf{E0}(\mathsf{e})))\,.$$

Proof. For the forward direction, start from the classifier witness and the two zero public-length witnesses. The zero-length characterization in Theorem 36.183 turns the h-side witness into $\mathsf{hsame}(h, \mathsf{E0}(\mathsf{e}))$ and the k-side witness into $\mathsf{hsame}(k, \mathsf{E0}(\mathsf{e}))$.

The two endpoint comparisons are exactly the displayed empty endpoint conjunction. The classifier witness is used only to keep the statement tied to classified singleton-source endpoints.

For the reverse direction, assume $\mathsf{hsame}(h, \mathsf{E0}(\mathsf{e})) \wedge \mathsf{hsame}(k, \mathsf{E0}(\mathsf{e}))$. Apply the reverse zero-length characterization from Theorem 36.183 to obtain $\mathsf{ListPublicLength}_{A_{a_0}}(h, 0)$ and $\mathsf{ListPublicLength}_{A_{a_0}}(k, 0)$.

It remains to rebuild the endpoint classifier. Use the nil-nil branch of the constructor-disjunction field in Theorem 36.184; the two empty endpoint comparisons are precisely the nil-nil data. Together with the two reconstructed zero public-length witnesses, this gives the left-hand condition. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListBridgeClassifier singleton zero public length iff empty`

Theorem 36.188 (List singleton source classified successor length inversion)**.** *Fix a BEDC history* $a_0 : \mathsf{BHist}$ *and let* A_{a_0} *be the singleton history source of Definition 36.169. For all histories* $h, k : \mathsf{BHist}$ *and every finite length value* n*, if*

$$\mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(h,k)\wedge\mathsf{ListPublicLength}_{A_{a_0}}(h,n{+}1)\wedge\mathsf{ListPublicLength}_{A_{a_0}}(k,n{+}1),$$

then there exist histories $a, b, t, u, p, q : \mathsf{BHist}$ *such that*

$$\left(\begin{array}{l}A_{a_0}(a)\wedge A_{a_0}(b)\wedge\mathsf{ListHistoryCarrier}_{A_{a_0}}(t)\wedge\mathsf{ListHistoryCarrier}_{A_{a_0}}(u)\wedge\\ \mathsf{ListPublicLength}_{A_{a_0}}(t,n)\wedge\mathsf{ListPublicLength}_{A_{a_0}}(u,n)\wedge\\ \mathsf{Cont}(a,t,p)\wedge\mathsf{Cont}(b,u,q)\wedge\mathsf{hsame}(h,\mathsf{E1}(p))\wedge\mathsf{hsame}(k,\mathsf{E1}(q))\wedge\\ \mathsf{hsame}(a,b)\wedge\mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(t,u)\end{array}\right).$$

Proof. Apply Theorem 36.186 to the classifier witness. It gives the synchronized nil endpoint shape or a synchronized cons endpoint shape.

In the nil endpoint shape, the theorem supplies $\mathsf{ListPublicLength}_{A_{a_0}}(h, 0)$ and $\mathsf{ListPublicLength}_{A_{a_0}}(k, 0)$. Public-length uniqueness from Theorem 36.183 identifies these zero witnesses with the displayed successor witnesses $\mathsf{ListPublicLength}_{A_{a_0}}(h, n+1)$ and $\mathsf{ListPublicLength}_{A_{a_0}}(k, n+1)$. The zero-length characterization from the same certificate is incompatible with a successor public endpoint, so the nil branch is empty.

In the cons endpoint shape, the synchrony theorem supplies a finite value m and histories $a, b, t, u, p, q : \mathsf{BHist}$ with the two endpoint public lengths at $m + 1$, both singleton-source heads, both carrier tails, both tail public lengths at m, the two Cont ledgers, the two endpoint readbacks, $\mathsf{hsame}(a, b)$, and the tail classifier $\mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(t, u)$.

Apply public-length uniqueness from Theorem 36.183 to the public length witnesses for h at $m + 1$ and at $n + 1$. The same argument for k gives the identical successor index comparison, and successor injectivity for finite length values identifies m with n.

Transport the two tail public-length witnesses along this length equality. Keeping the constructor histories and all ledger, endpoint, head, and classifier witnesses supplied by the cons shape gives exactly the displayed six-history package. □

Theorem 36.189 (List singleton source classified successor component exactness)**.** *Fix a BEDC history $a_0 : \mathsf{BHist}$ and let A_{a_0} be the singleton history source of Definition 36.169. For all histories $h, k : \mathsf{BHist}$ and every finite length value n, the following conditions are equivalent:*

1. $\mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(h, k)$, $\mathsf{ListPublicLength}_{A_{a_0}}(h, n+1)$, *and* $\mathsf{ListPublicLength}_{A_{a_0}}(k, n+1)$ *all hold.*
2. *There exist histories $a, b, t, u, p, q : \mathsf{BHist}$ such that*

$$\left(\begin{array}{l} A_{a_0}(a) \wedge A_{a_0}(b) \wedge \mathsf{ListHistoryCarrier}_{A_{a_0}}(t) \wedge \mathsf{ListHistoryCarrier}_{A_{a_0}}(u) \wedge \\ \mathsf{ListPublicLength}_{A_{a_0}}(t, n) \wedge \mathsf{ListPublicLength}_{A_{a_0}}(u, n) \wedge \\ \mathsf{Cont}(a, t, p) \wedge \mathsf{Cont}(b, u, q) \wedge \mathsf{hsame}(h, \mathsf{E1}(p)) \wedge \mathsf{hsame}(k, \mathsf{E1}(q)) \wedge \\ \mathsf{hsame}(a, b) \wedge \mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(t, u) \end{array}\right).$$

Proof. For the forward direction, apply Theorem 36.188 to the classifier witness and the two displayed successor public lengths. The result is exactly the six-history component package in the second condition.

For the reverse direction, start from histories $a, b, t, u, p, q : \mathsf{BHist}$ and the displayed component data. The successor-length equivalence field of Theorem 36.184 applied to h rebuilds $\mathsf{ListPublicLength}_{A_{a_0}}(h, n + 1)$ from a, t, p, the tail public length at n, the $\mathsf{Cont}(a, t, p)$ ledger, and the endpoint readback $\mathsf{hsame}(h, \mathsf{E1}(p))$.

Apply the same successor-length field to k with b, u, q. This rebuilds $\mathsf{ListPublicLength}_{A_{a_0}}(k, n+1)$ from the second tail public length, the second Cont ledger, and the endpoint readback through $\mathsf{E1}(q)$.

It remains to reconstruct the endpoint classifier. Use the cons branch in the constructor-disjunction field of Theorem 36.184 with the same six histories. The supplied head membership, tail carriers, ledgers, endpoint readbacks, head comparison, and tail classifier satisfy its displayed premises, so it yields $\mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(h, k)$.

Together these three reconstructed witnesses give the first condition. □

Theorem 36.190 (List singleton source classified successor endpoint nonempty)**.** *Fix a BEDC history* $a_0 : \mathsf{BHist}$ *and let* A_{a_0} *be the singleton history source of Definition 36.169. For all histories* $h, k : \mathsf{BHist}$ *and every finite length value* n*, if*

$$\mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(h,k) \wedge \mathsf{ListPublicLength}_{A_{a_0}}(h,n{+}1) \wedge \mathsf{ListPublicLength}_{A_{a_0}}(k,n{+}1),$$

then

$$\neg\mathsf{hsame}(h,\mathsf{e}) \wedge \neg\mathsf{hsame}(k,\mathsf{e}).$$

The ten-field fit is: traditional target finite-list successor endpoint exclusion; BEDC source BHist *with singleton source* A_{a_0}*; carrier* $\mathsf{ListHistoryCarrier}_{A_{a_0}}$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}$*; stability from public successor length inversion; ledger cons endpoint readbacks through* $\mathsf{E1}(p)$ *and* $\mathsf{E1}(q)$*; core theorem this endpoint exclusion; exactness by BEDC history no-confusion; standard bridge finite spines; status* ProofTarget*.*

Lean4 ✓ `BEDC.Derived.ListUp.FramedListBridgeClassifier public successor endpoint nonempty`

Proof. Apply Theorem 36.188 to the classifier witness and the two successor public-length witnesses. It gives histories $a, b, t, u, p, q : \mathsf{BHist}$, in particular the endpoint readbacks $\mathsf{hsame}(h, \mathsf{E1}(p))$ and $\mathsf{hsame}(k, \mathsf{E1}(q))$.

For the first exclusion, suppose $\mathsf{hsame}(h, \mathsf{e})$. Symmetry gives $\mathsf{hsame}(\mathsf{e}, h)$, and transitivity with the readback $\mathsf{hsame}(h, \mathsf{E1}(p))$ gives $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(p))$. The BEDC history no-confusion theorem, Theorem 20.6, rules out this empty-versus-one identification.

The second exclusion is identical with k and q. From $\mathsf{hsame}(k, \mathsf{e})$, symmetry and transitivity with $\mathsf{hsame}(k, \mathsf{E1}(q))$ give $\mathsf{hsame}(\mathsf{e}, \mathsf{E1}(q))$, again contradicting Theorem 20.6. These two exclusions form the displayed conjunction. □

Theorem 36.191 (List singleton source classified double-successor tail nonempty)**.** *Fix a BEDC history* $a_0 : \mathsf{BHist}$ *and let* A_{a_0} *be the singleton history source of Definition 36.169. For all histories* $h, k : \mathsf{BHist}$ *and every finite length value* n*, if*

$$\mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(h,k) \wedge \mathsf{ListPublicLength}_{A_{a_0}}(h,(n{+}1){+}1) \wedge \mathsf{ListPublicLength}_{A_{a_0}}(k,(n{+}1){+}1),$$

then there exist histories $a, b, t, u, p, q : \mathsf{BHist}$ *such that*

$$\left(\begin{array}{l} A_{a_0}(a) \wedge A_{a_0}(b) \wedge \mathsf{ListHistoryCarrier}_{A_{a_0}}(t) \wedge \mathsf{ListHistoryCarrier}_{A_{a_0}}(u) \wedge \\ \mathsf{ListPublicLength}_{A_{a_0}}(t, n+1) \wedge \mathsf{ListPublicLength}_{A_{a_0}}(u, n+1) \wedge \\ \mathsf{Cont}(a,t,p) \wedge \mathsf{Cont}(b,u,q) \wedge \mathsf{hsame}(h, \mathsf{E1}(p)) \wedge \mathsf{hsame}(k, \mathsf{E1}(q)) \wedge \\ \mathsf{hsame}(a,b) \wedge \mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(t,u) \wedge \\ \neg\mathsf{hsame}(t,\mathsf{e}) \wedge \neg\mathsf{hsame}(u,\mathsf{e}) \end{array}\right).$$

The ten-field fit is: traditional target finite-list two-step constructor readback; BEDC source singleton BHist*; carrier* ListHistoryCarrier*; classifier* ListSpineHistoryClassifier*; stability from successor component exactness; ledger exposed cons endpoints and tail public lengths; core theorem this block; exactness by endpoint no-confusion through the cited nonempty theorem; standard bridge finite spines; status* ProofTarget*.*

Proof. Apply Theorem 36.189 at length $n{+}1$ to the classifier witness and the two displayed double-successor public-length witnesses. The forward direction supplies histories $a, b, t, u, p, q : \mathsf{BHist}$ with the singleton heads, tail carriers, tail public lengths at $n + 1$, the two Cont ledgers, the endpoint readbacks, the head comparison, and the tail classifier $\mathsf{ListSpineHistoryClassifier}_{A_{a_0},\mathsf{hsame}}(t, u)$.

Apply Theorem 36.190 to this tail classifier and the two tail public-length witnesses at $n+1$. It gives $\neg\mathsf{hsame}(t,\mathsf{e}) \wedge \neg\mathsf{hsame}(u,\mathsf{e})$.

Keeping the same six histories and appending these two tail exclusions to the successor component package gives the displayed existential conclusion. □

Theorem 36.192 (List represented-spine append-context cancellation)**.** *Let $A : \mathsf{BHist} \to \mathsf{Prop}$ be a BEDC history source carrier, let $\sim_A$ be a source classifier, let $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$, and assume $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$. For finite BEDC-history spines $p, p', x, y, s, s' : \mathsf{HistSpine}$ and histories h, k, m, n, suppose*

$$\mathsf{ListClassifierSpec}(\sim_A, p, p')$$

and

$$\mathsf{ListClassifierSpec}(\sim_A, s, s')$$

hold. If

$$\mathsf{ListSpineRep}_A(h, p{+}{+}(x{+}{+}s)), \quad \mathsf{ListSpineRep}_A(k, p'{+}{+}(y{+}{+}s')),$$

and

$$\mathsf{ListSpineRep}_A(m, x), \quad \mathsf{ListSpineRep}_A(n, y)$$

hold, then

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h,k) \iff \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(m,n).$$

Proof. For the forward implication, apply Theorem 36.145 to the represented contextual endpoints h and k. This turns the public classifier witness into

$$\mathsf{ListClassifierSpec}(\sim_A, p{+}{+}(x{+}{+}s), p'{+}{+}(y{+}{+}s')).$$

The classified prefix and suffix hypotheses allow Theorem 36.143 to cancel the displayed finite-spine context, giving $\mathsf{ListClassifierSpec}(\sim_A, x, y)$. Applying the reverse direction of Theorem 36.145 to the represented middle endpoints m and n repacks that witness as $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(m,n)$.

For the reverse implication, apply Theorem 36.145 to the represented middle endpoints m and n. This reads the public middle classifier as $\mathsf{ListClassifierSpec}(\sim_A, x, y)$.

Use Theorem 36.143 in the opposite direction with the same classified prefixes and suffixes to obtain

$$\mathsf{ListClassifierSpec}(\sim_A, p{+}{+}(x{+}{+}s), p'{+}{+}(y{+}{+}s')).$$

The reverse direction of Theorem 36.145 for the represented contextual endpoints h and k repacks the displayed contextual classifier as $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h,k)$. □

36.6 Public append readback

Definition 36.193 (List public append readback)**.** *For a BEDC history source carrier $A : \mathsf{BHist} \to \mathsf{Prop}$, define $\mathsf{ListPublicAppend}_A(h,k,r)$ to mean that there exist finite BEDC-history spines $xs, ys : \mathsf{HistSpine}$ such that*

$$\mathsf{ListSpineRep}_A(h, xs), \quad \mathsf{ListSpineRep}_A(k, ys),$$

and

$$\mathsf{ListSpineRep}_A(r, xs{+}{+}ys)$$

hold.

Lemma 36.194 (List spine append representation construction)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier. For finite BEDC-history spines* $xs, ys : \mathsf{HistSpine}$ *and histories* h, k*, if*

$$\mathsf{ListSpineRep}_A(h, xs) \quad \textit{and} \quad \mathsf{ListSpineRep}_A(k, ys)$$

hold, then there exists a history $r : \mathsf{BHist}$ *such that*

$$\mathsf{ListSpineRep}_A(r, xs{+}{+}ys).$$

Proof. Proceed by induction on the displayed representation $\mathsf{ListSpineRep}_A(h, xs)$.

In the nil case, the displayed spine xs is nil, so $xs{+}{+}ys$ is ys. Reuse the endpoint k together with the given representation $\mathsf{ListSpineRep}_A(k, ys)$.

In the cons case, write $xs = \mathsf{cons}(a, xs_0)$ and let the head constructor provide $A(a)$, a tail endpoint t, a tail representation $\mathsf{ListSpineRep}_A(t, xs_0)$, and a constructor ledger $\mathsf{Cont}(a, t, h)$. The induction hypothesis applied to the tail representation and the endpoint representation of k gives a history r_0 represented by $xs_0{+}{+}ys$.

Use the same head payload a and the constructed tail endpoint r_0 to form a BEDC constructor endpoint r with $\mathsf{Cont}(a, r_0, r)$. The cons constructor for $\mathsf{ListSpineRep}_A$ then represents r by $\mathsf{cons}(a, xs_0{+}{+}ys)$, which is $xs{+}{+}ys$. □

Lean4 ✓ `BEDC.Derived.ListUp.ListSpineRep append representation`

Theorem 36.195 (List public append readback is total and classifier-congruent)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. The public append readback relation satisfies:*

1. *if* $\mathsf{ListHistoryCarrier}_A(h)$ *and* $\mathsf{ListHistoryCarrier}_A(k)$ *hold, then there exists a history* $r : \mathsf{BHist}$ *such that*

$$\mathsf{ListPublicAppend}_A(h, k, r) \quad \textit{and} \quad \mathsf{ListHistoryCarrier}_A(r)$$

   hold;

2. *if* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, h')$*,* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(k, k')$*,* $\mathsf{ListPublicAppend}_A(h, k, r)$*, and* $\mathsf{ListPublicAppend}_A(h', k', r')$ *hold, then*

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(r, r')$$

   holds;

3. *if* $\mathsf{ListPublicAppend}_A(h, k, r)$ *and* $\mathsf{ListPublicAppend}_A(h, k, r')$ *hold, then*

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(r, r')$$

   holds.

Lean4 ✓ `BEDC.Derived.ListUp.FramedListPublicAppend total and classifier congruent`

Proof. For totality, apply Theorem 36.65 to the two public carrier witnesses. This gives finite spines xs and ys with $\mathsf{ListSpineRep}_A(h, xs)$ and $\mathsf{ListSpineRep}_A(k, ys)$.

Apply Lemma 36.194 to construct an endpoint r represented by $xs{+}{+}ys$. This representation is precisely the third field of $\mathsf{ListPublicAppend}_A(h, k, r)$, and Theorem 36.65 gives $\mathsf{ListHistoryCarrier}_A(r)$.

For classifier congruence, unpack the two append readbacks as spines xs, ys and xs', ys'. Displayed-spine exactness reads the public classifiers on h, h' and on k, k' as

$$\mathsf{ListClassifierSpec}(\sim_A, xs, xs') \quad \text{and} \quad \mathsf{ListClassifierSpec}(\sim_A, ys, ys').$$

Theorem 36.34 combines these two finite-spine classifiers into $\mathsf{ListClassifierSpec}(\sim_A, xs{+}{+}ys, xs'{+}{+}ys')$. Repack that displayed classifier through the two append endpoint representations by the reverse direction of Theorem 36.145, obtaining $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(r, r')$.

For two outputs over the same inputs, unpack both append readbacks as xs, ys and xs', ys'. Coherence for the two presentations of h gives $\mathsf{ListClassifierSpec}(\sim_A, xs, xs')$, and coherence for the two presentations of k gives $\mathsf{ListClassifierSpec}(\sim_A, ys, ys')$.

Apply Theorem 36.34 and then displayed-spine exactness exactly as in the congruence argument. This classifies the two append outputs r and r'. □

Theorem 36.196 (List public append readback exposes unary-length addition)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier. For histories* $h, k, r : \mathsf{BHist}$*, if*

$$\mathsf{ListPublicAppend}_A(h, k, r)$$

holds, then there exist histories $u, v, w : \mathsf{BHist}$ *such that*

1. $\mathsf{ListPublicUnaryLength}_A(h, u)$*,* $\mathsf{ListPublicUnaryLength}_A(k, v)$*, and* $\mathsf{ListPublicUnaryLength}_A(r, w)$ *hold;*
2. $$\mathsf{NatAdd}(v, u, w);$$
3. *for every* $z : \mathsf{BHist}$*,* $$\mathsf{NatAdd}(u, v, z) \to \mathsf{hsame}(w, z).$$

Proof. Unpack $\mathsf{ListPublicAppend}_A(h, k, r)$ as finite BEDC-history spines $xs, ys : \mathsf{HistSpine}$ together with representations of h by xs, of k by ys, and of r by $xs{+}{+}ys$.

Choose

$$u = \mathsf{ListUnaryLength}(xs), \qquad v = \mathsf{ListUnaryLength}(ys), \qquad w = \mathsf{ListUnaryLength}(xs{+}{+}ys).$$

The three public unary-length witnesses follow by pairing the same spine representations with reflexivity of hsame in Definition 36.91.

Apply Theorem 36.95 to the three displayed representations. Its append-aligned clause gives $\mathsf{NatAdd}(v, u, w)$, and its commuted uniqueness clause gives, for every $z : \mathsf{BHist}$, the implication $\mathsf{NatAdd}(u, v, z) \to \mathsf{hsame}(w, z)$. □

Theorem 36.197 (List classifier mixed-tag append-context exactness)**.** *For finite BEDC-history spines* p, p', x, y, s, s'*, suppose*

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p, p')$$

and

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, s, s')$$

hold. Then mixed visible constructor tags are classified by the finite-spine classifier exactly in the empty middle case:

1. $$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p{+}{+}(\mathsf{map}(e0, x){+}{+}s), p'{+}{+}(\mathsf{map}(e1, y){+}{+}s')) \iff x = \mathsf{nil} \land y = \mathsf{nil};$$
2. $$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p{+}{+}(\mathsf{map}(e1, x){+}{+}s), p'{+}{+}(\mathsf{map}(e0, y){+}{+}s')) \iff x = \mathsf{nil} \land y = \mathsf{nil}.$$

Proof. For the $e0/e1$ forward implication, apply Theorem 36.143 with the classified prefixes and suffixes. This cancels the displayed context and leaves

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, \mathsf{map}(e0, x), \mathsf{map}(e1, y)).$$

Theorem 36.29 then forces $x = \mathsf{nil}$ and $y = \mathsf{nil}$.

For the $e0/e1$ reverse implication, assume $x = \mathsf{nil}$ and $y = \mathsf{nil}$. The mapped middle spines are both nil, so the nil clause of Definition 36.12 gives the displayed nil classifier. The reverse direction of Theorem 36.143 rebuilds the classified prefix and suffix context.

For the $e1/e0$ forward implication, first cancel the displayed prefix and suffix context by Theorem 36.143. Apply Theorem 36.17 to reverse the resulting middle classifier, obtaining

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, \mathsf{map}(e0, y), \mathsf{map}(e1, x)).$$

Theorem 36.29 gives $y = \mathsf{nil}$ and $x = \mathsf{nil}$, hence the required conjunction.

For the $e1/e0$ reverse implication, the assumptions again make both mapped middle spines nil. Use the nil classifier and rebuild the displayed context by the reverse direction of Theorem 36.143. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame mixed tag append context empty iff`

Theorem 36.198 (List represented-spine mixed-tag context separation)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{hsame})$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\mathsf{hsame}}$*. For finite BEDC-history spines* $p, p', x, y, s, s' : \mathsf{HistSpine}$ *and histories* h, k*, suppose*

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p, p')$$

and

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, s, s')$$

hold. If

$$\mathsf{ListSpineRep}_A(h, p{+}{+}(\mathsf{map}(e0, x){+}{+}s)), \quad \mathsf{ListSpineRep}_A(k, p'{+}{+}(\mathsf{map}(e1, y){+}{+}s')),$$

hold, and if

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}(h, k)$$

holds, then $x = \mathsf{nil}$ *and* $y = \mathsf{nil}$*.*

The ten-field fit is: traditional target finite-list tagged-branch separation; BEDC source A *with* $\mathsf{NameCert}(A, \mathsf{hsame})$*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}$*; stability from spine coherence, append-context cancellation, and history constructor no-confusion; ledger visible* $e0/e1$ *branch tags in finite spines; core theorem mixed-tag context separation; exactness by displayed-spine classifier exactness; standard bridge finite-spine readback; status* $\mathsf{ProofTarget}$*.*

Proof. Apply Theorem 36.145 to the represented contextual endpoints h and k. The public classifier therefore reads as

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p{+}{+}(\mathsf{map}(e0, x){+}{+}s), p'{+}{+}(\mathsf{map}(e1, y){+}{+}s')).$$

Now apply Theorem 36.197. Its $e0/e1$ forward implication uses the classified prefix and suffix hypotheses to force $x = \mathsf{nil}$ and $y = \mathsf{nil}$. □

Theorem 36.199 (List represented-spine mixed-tag context exactness)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{hsame})$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\mathsf{hsame}}$*. hold. Then mixed visible constructor tags are classified exactly in the empty middle case:

1. *for histories* h_0, k_0*, if*

$$\mathsf{ListSpineRep}_A(h_0, p{+}{+}(\mathsf{map}(e0, x){+}{+}s)), \quad \mathsf{ListSpineRep}_A(k_0, p'{+}{+}(\mathsf{map}(e1, y){+}{+}s'))$$

   hold, then

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}(h_0, k_0) \iff x = \mathsf{nil} \wedge y = \mathsf{nil};$$

2. *for histories* h_1, k_1*, if*

$$\mathsf{ListSpineRep}_A(h_1, p{+}{+}(\mathsf{map}(e1, x){+}{+}s)), \quad \mathsf{ListSpineRep}_A(k_1, p'{+}{+}(\mathsf{map}(e0, y){+}{+}s'))$$

   hold, then

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}(h_1, k_1) \iff x = \mathsf{nil} \wedge y = \mathsf{nil}.$$

The ten-field fit is: traditional target finite-list mixed visible-tag exactness; BEDC source A *with* $\mathsf{NameCert}(A, \mathsf{hsame})$*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}$*; stability from represented-spine coherence plus append-context cancellation; ledger visible* $e0/e1$ *tags; core theorem mixed-tag exactness; exactness by displayed-spine readback; standard bridge finite-spine readback; status* $\mathsf{ProofTarget}$*.*

Proof. For the $e0/e1$ forward implication, apply Theorem 36.145 to the represented contextual endpoints h_0, k_0. The public classifier becomes the displayed contextual classifier, and the $e0/e1$ forward implication of Theorem 36.197 forces $x = \mathsf{nil}$ and $y = \mathsf{nil}$.

For the $e0/e1$ reverse implication, assume $x = \mathsf{nil}$ and $y = \mathsf{nil}$. The $e0/e1$ reverse implication of Theorem 36.197 gives

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p{+}{+}(\mathsf{map}(e0, x){+}{+}s), p'{+}{+}(\mathsf{map}(e1, y){+}{+}s')).$$

The reverse direction of Theorem 36.145 repacks the displayed contextual classifier through the represented endpoints, producing $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}(h_0, k_0)$.

For the $e1/e0$ forward implication, displayed exactness turns a public classifier on h_1, k_1 into the corresponding contextual finite-spine classifier. The $e1/e0$ forward implication of Theorem 36.197 then gives $x = \mathsf{nil}$ and $y = \mathsf{nil}$.

For the $e1/e0$ reverse implication, the assumptions $x = \mathsf{nil}$ and $y = \mathsf{nil}$ feed the $e1/e0$ reverse implication of Theorem 36.197. The resulting displayed contextual classifier is repacked by represented-spine displayed exactness for the represented endpoints h_1, k_1. □

Theorem 36.200 (List represented-spine mixed-tag same-history emptiness)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{hsame})$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\mathsf{hsame}}$*. For finite BEDC-history spines* $p, p', x, y, s, s' : \mathsf{HistSpine}$ *and a history* h*, suppose*

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p, p')$$

and

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, s, s')$$

hold. Then mixed visible constructor tags around two represented-spine readbacks of the same history force both untagged middle payloads to be empty:

1. *if*

$$\mathsf{ListSpineRep}_A(h, p{+}{+}(\mathsf{map}(e0, x){+}{+}s)), \quad \mathsf{ListSpineRep}_A(h, p'{+}{+}(\mathsf{map}(e1, y){+}{+}s'))$$

hold, then

$$x = \mathsf{nil} \wedge y = \mathsf{nil};$$

2. *if*

$$\mathsf{ListSpineRep}_A(h, p{+}{+}(\mathsf{map}(e1, x){+}{+}s)), \quad \mathsf{ListSpineRep}_A(h, p'{+}{+}(\mathsf{map}(e0, y){+}{+}s'))$$

hold, then

$$x = \mathsf{nil} \wedge y = \mathsf{nil}.$$

The ten-field fit is: traditional target finite-list same-history mixed visible tag no-confusion; BEDC source A with $\mathsf{NameCert}(A, \mathsf{hsame})$*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}$*; stability from spine coherence and certificate reflexivity; ledger visible $e0/e1$ branch tags in finite spines; core theorem mixed-tag context exactness at identical endpoints; exactness by represented-spine carrier coverage and public classifier reflexivity; standard bridge finite-spine readback; status* $\mathsf{ProofTarget}$.

Proof. Start with either represented-spine presentation of h. By Theorem 36.61, the presentation exposes $\mathsf{ListHistoryCarrier}_A(h)$.

Apply Theorem 36.68 to cert and the coherence witness. The resulting semantic certificate supplies classifier reflexivity for the carrier witness, hence

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}(h, h).$$

For the $e0/e1$ clause, specialize Theorem 36.199 to the two endpoints h and h, using the displayed mixed-tag presentations, the classified prefix and suffix hypotheses, and the reflexive public classifier above. Project the forward implication of the $e0/e1$ branch to obtain $x = \mathsf{nil} \wedge y = \mathsf{nil}$.

The $e1/e0$ clause is the symmetric specialization with the visible tags interchanged. Project the forward implication of that branch, again using the public reflexivity of h, to obtain $x = \mathsf{nil} \wedge y = \mathsf{nil}$. □

Theorem 36.201 (List classifier $e0$ append-context equivalence)**.** *For finite BEDC-history spines p, p', x, y, s, s', suppose the prefix contexts p, p' are structurally classified by* hsame *and the suffix contexts s, s' are structurally classified by* hsame*. Then*

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p{+}{+}(\mathsf{map}(e0, x){+}{+}s), p'{+}{+}(\mathsf{map}(e0, y){+}{+}s')) \iff \mathsf{ListClassifierSpec}(\mathsf{hsame}, x, y).$$

Proof. In the forward direction, append-context cancellation removes the classified prefixes and suffixes, leaving the $e0$-mapped middle classifier. The $e0$ map-inversion theorem reflects it to the untagged middle classifier. In the reverse direction, $e0$ map stability lifts the middle classifier to the tagged middle spines, and append-context rebuilding restores the classified prefix and suffix contexts. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame map e0 append context iff`

Theorem 36.202 (List classifier same-tag append-context equivalence)**.** *For finite BEDC-history spines* p, p', x, y, s, s'*, suppose* $\mathsf{ListClassifierSpec}(\mathsf{hsame}, p, p')$ *and* $\mathsf{ListClassifierSpec}(\mathsf{hsame}, s, s')$*. Then both same-tag contextual classifiers expose exactly the untagged middle classifier:*

1.

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p{+}{+}(\mathsf{map}(e0, x){+}{+}s), p'{+}{+}(\mathsf{map}(e0, y){+}{+}s')) \iff \mathsf{ListClassifierSpec}(\mathsf{hsame}, x, y);$$

2.

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p{+}{+}(\mathsf{map}(e1, x){+}{+}s), p'{+}{+}(\mathsf{map}(e1, y){+}{+}s')) \iff \mathsf{ListClassifierSpec}(\mathsf{hsame}, x, y).$$

The ten-field fit is: traditional target same-tag finite-spine contextual readback; BEDC source BHist*; carrier finite BEDC-history spines; classifier* $\mathsf{ListClassifierSpec}(\mathsf{hsame})$*; stability from constructor-map stability, constructor-map inversion, and append-context cancellation; ledger visible same-tag finite-spine contexts; core theorem same-tag append-context equivalence; exactness the displayed* $e0$ *and* $e1$ *iff clauses; downstream consumer Theorem 36.203; status* $\mathsf{ProofTarget}$*.*

Proof. For the $e0$ clause, apply Theorem 36.201. Its hypotheses are exactly the classified prefix and suffix assumptions, and its conclusion is the displayed $e0$ contextual equivalence.

For the $e1$ forward direction, first apply Theorem 36.143 with the classified prefixes and suffixes. This cancels the surrounding context and leaves $\mathsf{ListClassifierSpec}(\mathsf{hsame}, \mathsf{map}(e1, x), \mathsf{map}(e1, y))$.

Theorem 36.27 reflects the $e1$-mapped middle classifier back to $\mathsf{ListClassifierSpec}(\mathsf{hsame}, x, y)$.

For the $e1$ reverse direction, start from $\mathsf{ListClassifierSpec}(\mathsf{hsame}, x, y)$. Theorem 36.26 transports it to $\mathsf{ListClassifierSpec}(\mathsf{hsame}, \mathsf{map}(e1, x), \mathsf{map}(e1, y))$.

Finally, the reverse direction of Theorem 36.143 rebuilds the classified prefix and suffix context, giving the displayed contextual classifier. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame map e1 append context iff`

Theorem 36.203 (List represented-spine same-tag context exactness)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{hsame})$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\mathsf{hsame}}$*. For finite BEDC-history spines* $p, p', x, y, s, s' : \mathsf{HistSpine}$*, suppose*

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p, p')$$

and

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, s, s')$$

hold. Then same visible constructor tags expose exactly the untagged payload spine classifier:

1. for histories h_0, k_0*, if*

$$\mathsf{ListSpineRep}_A(h_0, p{+}{+}(\mathsf{map}(e0, x){+}{+}s)), \quad \mathsf{ListSpineRep}_A(k_0, p'{+}{+}(\mathsf{map}(e0, y){+}{+}s'))$$

hold, then

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}(h_0, k_0) \iff \mathsf{ListClassifierSpec}(\mathsf{hsame}, x, y);$$

2. for histories h_1, k_1, if

$$\mathsf{ListSpineRep}_A(h_1, p{+}{+}(\mathsf{map}(e1, x){+}{+}s)), \quad \mathsf{ListSpineRep}_A(k_1, p'{+}{+}(\mathsf{map}(e1, y){+}{+}s'))$$

hold, then

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}(h_1, k_1) \iff \mathsf{ListClassifierSpec}(\mathsf{hsame}, x, y).$$

The ten-field fit is: traditional target finite-list same-tag payload readback; BEDC source A with $\mathsf{NameCert}(A, \mathsf{hsame})$*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}$*; stability from spine coherence, constructor-map stability, and append-context rebuilding; ledger visible $e0/e1$ branch tags in finite spines; core theorem same-tag context exactness; exactness by displayed-spine classifier readback and constructor-map inversion; standard bridge finite-spine readback; status* $\mathsf{ProofTarget}$.

Proof. For the $e0$ forward implication, apply Theorem 36.145 to the two represented contextual endpoints. This reads the public classifier as

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p{+}{+}(\mathsf{map}(e0, x){+}{+}s), p'{+}{+}(\mathsf{map}(e0, y){+}{+}s')).$$

Apply Theorem 36.143 with the classified prefixes and suffixes to cancel the displayed context. The result is $\mathsf{ListClassifierSpec}(\mathsf{hsame}, \mathsf{map}(e0, x), \mathsf{map}(e0, y))$, and Theorem 36.25 reflects it to $\mathsf{ListClassifierSpec}(\mathsf{hsame}, x, y)$.

For the $e0$ reverse implication, start with $\mathsf{ListClassifierSpec}(\mathsf{hsame}, x, y)$. Theorem 36.24 transports it to the mapped middle spines, and the reverse direction of Theorem 36.143 rebuilds the classified prefix and suffix context.

The reverse direction of Theorem 36.145 then repacks the displayed contextual classifier as $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}(h_0, k_0)$.

The $e1$ clause is identical with $e1$ in place of $e0$. Its forward direction uses displayed exactness and append-context cancellation to obtain $\mathsf{ListClassifierSpec}(\mathsf{hsame}, \mathsf{map}(e1, x), \mathsf{map}(e1, y))$, then applies Theorem 36.27. Its reverse direction applies Theorem 36.26, rebuilds the classified context, and repacks through displayed exactness for the represented endpoints h_1, k_1. □

Theorem 36.204 (List represented-spine same-tag payload determinacy)**.** *Let $A : \mathsf{BHist} \to \mathsf{Prop}$ be a BEDC history source carrier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{hsame})$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\mathsf{hsame}}$*. For finite BEDC-history spines $p, p', x, y, s, s' : \mathsf{HistSpine}$ and a history h, suppose*

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p, p')$$

and

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, s, s')$$

hold. Then same visible constructor tags around two represented-spine readbacks of h determine the untagged payload classifier:

1. if

$$\mathsf{ListSpineRep}_A(h, p{+}{+}(\mathsf{map}(e0, x){+}{+}s)), \quad \mathsf{ListSpineRep}_A(h, p'{+}{+}(\mathsf{map}(e0, y){+}{+}s'))$$

hold, then

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, x, y);$$

2. if

$$\mathsf{ListSpineRep}_A(h, p{+}{+}(\mathsf{map}(e1, x){+}{+}s)), \quad \mathsf{ListSpineRep}_A(h, p'{+}{+}(\mathsf{map}(e1, y){+}{+}s'))$$

hold, then

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, x, y).$$

The ten-field fit is: traditional target finite-list same-history readback determinacy; BEDC source A with $\mathsf{NameCert}(A, \mathsf{hsame})$*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}$*; stability from spine coherence and certificate reflexivity; ledger visible $e0/e1$ branch tags in finite spines; core theorem same-tag context exactness at identical endpoints; exactness by represented-spine carrier coverage and public classifier reflexivity; standard bridge finite-spine readback; status* ProofTarget*.*

Proof. Start with either displayed represented-spine presentation of h. By Theorem 36.61, the presentation exposes $\mathsf{ListHistoryCarrier}_A(h)$.

Apply Theorem 36.68 to cert and the coherence witness. The resulting semantic certificate supplies classifier reflexivity for the carrier witness, hence

$$\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}(h, h).$$

For the $e0$ clause, specialize Theorem 36.203 to the two endpoints h and h, using the displayed $e0$ presentations, the classified prefix and suffix hypotheses, and the reflexive public classifier above. Project the forward implication of the $e0$ branch to obtain $\mathsf{ListClassifierSpec}(\mathsf{hsame}, x, y)$.

The $e1$ clause is the same specialization with $e1$ in place of $e0$. Project the forward implication of the $e1$ branch, again using the public reflexivity of h, to obtain $\mathsf{ListClassifierSpec}(\mathsf{hsame}, x, y)$. □

Theorem 36.205 (List public append unary length classifier transport)**.** *Let $A : \mathsf{BHist} \to \mathsf{Prop}$ be a BEDC history source carrier, let $\sim_A$ be a source classifier, and let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*. Assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. For histories $h, h', k, k', r, r' : \mathsf{BHist}$, suppose*

$$\mathsf{ListPublicAppend}_A(h, k, r)$$

holds, and suppose also that

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, h'), \qquad \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(k, k'), \qquad \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(r, r'$$

hold. Then there exist unary length histories $u, v, w : \mathsf{BHist}$ such that

1. $\mathsf{ListPublicUnaryLength}_A(h, u)$ *and* $\mathsf{ListPublicUnaryLength}_A(h', u)$ *hold;*
2. $\mathsf{ListPublicUnaryLength}_A(k, v)$ *and* $\mathsf{ListPublicUnaryLength}_A(k', v)$ *hold;*
3. $\mathsf{ListPublicUnaryLength}_A(r, w)$ *and* $\mathsf{ListPublicUnaryLength}_A(r', w)$ *hold;*
4. $$\mathsf{NatAdd}(v, u, w);$$
5. *for every $z : \mathsf{BHist}$,* $$\mathsf{NatAdd}(u, v, z) \to \mathsf{hsame}(w, z).$$

Lean4 ✓ `BEDC.Derived.ListUp.FramedListPublicAppend public length classifier transport`

Proof. Apply Theorem 36.196 to the displayed public append witness. This gives histories u, v, w with public unary length witnesses for h, k, r, together with $\mathsf{NatAdd}(v, u, w)$ and the commuted uniqueness row $\mathsf{NatAdd}(u, v, z) \to \mathsf{hsame}(w, z)$ for arbitrary z.

Next apply Theorem 36.93 three times, each time using cert and $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$. The classifier from h to h' transports the public unary length witness at h to one at h' with the same token u; the classifier from k to k' does the same for v; and the classifier from r to r' does the same for w.

Finally, repack the original witnesses for h, k, r, the transported witnesses for h', k', r', and the two Nat-addition rows obtained from append additivity. No additional computation is needed, since classifier transport preserves the unary token rather than replacing it. □

36.7 Bordered singleton payload readback

Theorem 36.206 (List classifier bordered singleton payload readback)**.** *For finite BEDC-history lists p, p', s, and s' and histories x and y, if*

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p, p'), \quad \mathsf{ListClassifierSpec}(\mathsf{hsame}, s, s'), \quad \mathsf{ListClassifierSpec}(\mathsf{hsame}, p{+}{+}(x :: \mathsf{nil}){+}{+}s, p'{+}{+}$$

hold, then $\mathsf{hsame}(x, y)$.

Proof. Apply Theorem 36.44 to the displayed prefix classifiers, suffix classifiers, and bordered singleton classification. This cancels the classified boundaries and gives $\mathsf{ListClassifierSpec}(\mathsf{hsame}, x :: \mathsf{nil}, y :: \mathsf{nil})$.

Apply Theorem 36.21 in the forward direction. The singleton classifier witness reads back exactly the payload relation $\mathsf{hsame}(x, y)$. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame bordered singleton payload readback`

Theorem 36.207 (List classifier bordered zero-headed singleton payload readback)**.** *For finite BEDC-history lists p, p', s, and s' and histories x and y, if*

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p, p'), \quad \mathsf{ListClassifierSpec}(\mathsf{hsame}, s, s'), \quad \mathsf{ListClassifierSpec}(\mathsf{hsame}, p{+}{+}(\mathsf{E0}(x) :: \mathsf{nil}){+}{+}s, p$$

hold, then $\mathsf{hsame}(x, y)$.

Proof. Cancel the classified suffixes from the bordered classifier, then cancel the classified prefixes. The remaining singleton classifier identifies $\mathsf{E0}(x)$ with $\mathsf{E0}(y)$, and zero-headed constructor exactness reads back the payload relation $\mathsf{hsame}(x, y)$. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame bordered e0 singleton payload readback`

Theorem 36.208 (List classifier bordered one-headed singleton payload readback)**.** *For finite BEDC-history lists p, p', s, and s' and histories x and y, if*

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p, p'), \quad \mathsf{ListClassifierSpec}(\mathsf{hsame}, s, s'), \quad \mathsf{ListClassifierSpec}(\mathsf{hsame}, p{+}{+}(\mathsf{E1}(x) :: \mathsf{nil}){+}{+}s, p$$

hold, then $\mathsf{hsame}(x, y)$.

Proof. Cancel the classified suffixes from the displayed bordered classifier, then cancel the classified prefixes. The remaining singleton classifier identifies $\mathsf{E1}(x)$ with $\mathsf{E1}(y)$. One-headed constructor exactness reads back the payload relation $\mathsf{hsame}(x, y)$. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame bordered e1 singleton payload readback`

The ten-field fit is: traditional target finite-list singleton payload readback; BEDC source BHist; carrier finite BEDC-history spines; classifier ListClassifierSpec(hsame, −, −); stability from classified prefix and suffix cancellation; ledger hidden prefix and suffix context; core theorem singleton payload readback; exactness by cancellation and singleton inversion; standard bridge finite-spine payload extraction; status ProofTarget.

Theorem 36.209 (List represented-spine bordered singleton payload readback)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \mathsf{hsame})$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\mathsf{hsame}}$*. For finite BEDC-history spines* $p, p', s, s' : \mathsf{HistSpine}$ *and histories* $x, y, h, k : \mathsf{BHist}$*, suppose*

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p, p')$$

and

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, s, s')$$

hold. If

$$\mathsf{ListSpineRep}_A(h, p{+}{+}(x :: \mathsf{nil}){+}{+}s), \quad \mathsf{ListSpineRep}_A(k, p'{+}{+}(y :: \mathsf{nil}){+}{+}s')$$

hold, and if $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}(h, k)$ *holds, then* $\mathsf{hsame}(x, y)$*.*

Proof. Apply Theorem 36.145 to the two displayed endpoint representations and the public represented-spine classifier. This reads the endpoint classifier as

$$\mathsf{ListClassifierSpec}(\mathsf{hsame}, p{+}{+}(x :: \mathsf{nil}){+}{+}s, p'{+}{+}(y :: \mathsf{nil}){+}{+}s').$$

The classified prefix and suffix hypotheses now place the displayed finite spines in the scope of Theorem 36.206. Applying that theorem cancels the classified borders and reads back the singleton payload relation $\mathsf{hsame}(x, y)$. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListBridgeClassifier bordered singleton payload readback`

The ten-field fit is: traditional target finite-list represented endpoint payload readback; BEDC source A with $\mathsf{NameCert}(A, \mathsf{hsame})$; carrier $\mathsf{ListHistoryCarrier}_A$; classifier $\mathsf{ListSpineHistoryClassifier}_{A,\mathsf{hsame}}$; stability from source certificate plus spine-representation coherence; ledger represented endpoints with classified prefix and suffix borders; core theorem bordered singleton payload readback; exactness by displayed-spine public classifier conversion and finite-spine border cancellation; standard bridge represented finite spines; status ProofTarget.

36.8 Public reverse readback

Definition 36.210 (List public reverse readback)**.** *For a BEDC history source carrier* $A : \mathsf{BHist} \to \mathsf{Prop}$*, define* $\mathsf{ListPublicReverse}_A(h, k)$ *to mean that there exists a finite BEDC-history spine* $xs : \mathsf{HistSpine}$ *such that*

$$\mathsf{ListSpineRep}_A(h, xs)$$

and

$$\mathsf{ListSpineRep}_A(k, \mathsf{reverse}(xs))$$

hold.

Theorem 36.211 (List public reverse readback is classifier-functional and involutive)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. For histories* $h, h', k, k' : \mathsf{BHist}$*, the public reverse readback relation satisfies:*

1. *if* $\mathsf{ListPublicReverse}_A(h, k)$ *holds, then* $\mathsf{ListHistoryCarrier}_A(h) \wedge \mathsf{ListHistoryCarrier}_A(k)$*;*
2. *if* $\mathsf{ListPublicReverse}_A(h, k)$ *holds, then* $\mathsf{ListPublicReverse}_A(k, h)$*;*
3. *if* $\mathsf{ListPublicReverse}_A(h, k)$ *and* $\mathsf{ListPublicReverse}_A(h, k')$ *hold, then* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(k, k')$*;*
4. *if* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h, h')$*,* $\mathsf{ListPublicReverse}_A(h, k)$*, and* $\mathsf{ListPublicReverse}_A(h', k')$ *hold, then* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(k, k')$*.*

Proof. For carrier soundness, unpack the reverse witness as a spine xs with $\mathsf{ListSpineRep}_A(h, xs)$ and $\mathsf{ListSpineRep}_A(k, \mathsf{reverse}(xs))$. Apply Theorem 36.61 to each displayed representation to obtain the two public carrier witnesses.

For symmetry, keep the displayed representation of k by $\mathsf{reverse}(xs)$. Finite-spine reverse involutivity identifies $\mathsf{reverse}(\mathsf{reverse}(xs))$ with xs, so the displayed representation of h becomes the required reversed-spine representation from k back to h.

For classifier functionality over a fixed source endpoint, unpack the two reverse witnesses as spines xs and ys. Coherence for the two presentations of h gives $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$. Apply Theorem 36.41 to classify $\mathsf{reverse}(xs)$ with $\mathsf{reverse}(ys)$, then repack this finite-spine classifier with the two displayed representations of k and k' by the reverse direction of Theorem 36.145.

For classifier stability along classified source endpoints, unpack the two reverse witnesses as spines xs and ys. The forward direction of Theorem 36.145 reads the public classifier between h and h' as

$$\mathsf{ListClassifierSpec}(\sim_A, xs, ys).$$

Apply Theorem 36.41 to obtain a classifier between $\mathsf{reverse}(xs)$ and $\mathsf{reverse}(ys)$. Repack that finite-spine classifier with the reverse-readback representations of k and k' by the reverse direction of Theorem 36.145. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListPublicReverse functional involutive`
Lean4 ✓ `BEDC.Derived.ListUp.FramedListPublicReverse classifier functional`

Theorem 36.212 (List public reverse preserves public length)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. For histories* $h, k : \mathsf{BHist}$ *and a finite length value* n*, the public reverse readback relation preserves the public length ledger in both directions:*

1. *if* $\mathsf{ListPublicReverse}_A(h, k)$ *and* $\mathsf{ListPublicLength}_A(h, n)$ *hold, then* $\mathsf{ListPublicLength}_A(k, n)$*;*
2. *if* $\mathsf{ListPublicReverse}_A(h, k)$ *and* $\mathsf{ListPublicLength}_A(k, n)$ *hold, then* $\mathsf{ListPublicLength}_A(h, n)$*.*

Proof. For the forward direction, unpack the reverse witness as a spine xs with $\mathsf{ListSpineRep}_A(h, xs)$ and $\mathsf{ListSpineRep}_A(k, \mathsf{reverse}(xs))$. Unpack the public length witness for h as a spine ys with $\mathsf{ListSpineRep}_A(h, ys)$ and $\ell(ys) = n$.

Spine coherence compares the two displayed representations of h, giving $\mathsf{ListClassifierSpec}(\sim_A, xs, ys)$. The length exactness theorem for classified finite spines identifies $\ell(xs)$ with $\ell(ys)$, and finite-spine reverse length preservation identifies $\ell(\mathsf{reverse}(xs))$ with $\ell(xs)$. Chaining these equalities with $\ell(ys) = n$ gives $\ell(\mathsf{reverse}(xs)) = n$.

Repack the displayed representation $\mathsf{ListSpineRep}_A(k, \mathsf{reverse}(xs))$ together with the resulting length equality through Definition 36.75. This is $\mathsf{ListPublicLength}_A(k, n)$.

For the reverse direction, use the involutive clause of Theorem 36.211 to turn $\mathsf{ListPublicReverse}_A(h,k)$ into $\mathsf{ListPublicReverse}_A(k,h)$. Apply the forward direction just proved to this reversed public-reverse witness and the displayed public length witness for k, obtaining $\mathsf{ListPublicLength}_A(h,n)$. □

Lean4 ✓ `BEDC.Derived.ListUp.FramedListPublicReverse public length transport`

Theorem 36.213 (List public reverse fixed-length classifier automorphism)**.** *The roadmap ten-field fit is: traditional target finite-list reverse as a fixed-length classifier automorphism; BEDC source* BHist *finite spines; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability from spine coherence and the source* NameCert*; ledger finite spine reversal plus public length; core theorem this fixed-length automorphism package; exactness through reverse readback and length transport; standard bridge finite spines; status* ProofTarget*.*

Let $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. For histories* $h, h', k, k' : \mathsf{BHist}$ *and a finite length value* n*, if*

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(h,h') \wedge \mathsf{ListPublicReverse}_A(h,k) \wedge \mathsf{ListPublicReverse}_A(h',k') \wedge \mathsf{ListPublicLength}_A(h,n)$$

holds, then

$$\mathsf{ListPublicLength}_A(k,n) \wedge \mathsf{ListPublicLength}_A(k',n) \wedge \mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(k,k') \wedge \mathsf{ListPublicReverse}_A(k,h) \wedge \mathsf{Lis}$$

holds.

Proof. First put both classified source endpoints on the displayed public-length fiber. Apply Theorem 36.97 to the classifier witness between h and h' and the public length witness for h. This gives $\mathsf{ListPublicLength}_A(h',n)$.

Next transport the length through the two public reverse witnesses. Apply Theorem 36.212 to $\mathsf{ListPublicReverse}_A(h,k)$ and $\mathsf{ListPublicLength}_A(h,n)$ to obtain $\mathsf{ListPublicLength}_A(k,n)$. Apply the same theorem to $\mathsf{ListPublicReverse}_A(h',k')$ and the transported length witness for h' to obtain $\mathsf{ListPublicLength}_A(k',n)$.

Now classify the reversed endpoints. The classifier-stability clause of Theorem 36.211, applied to the source classifier witness and the two reverse readback witnesses, produces $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(k,k')$.

Finally, reverse back along each public reverse witness. The involutive clause of Theorem 36.211 sends $\mathsf{ListPublicReverse}_A(h,k)$ to $\mathsf{ListPublicReverse}_A(k,h)$ and sends $\mathsf{ListPublicReverse}_A(h',k')$ to $\mathsf{ListPublicReverse}_A(k',h')$. Combining the two length witnesses, the reversed-endpoint classifier, and these two reverse-back witnesses gives the claimed conjunction. □

The finite-data dependency lattice for $\mathsf{List}^{\uparrow}$ passes through the sibling certificates chapter 32, chapter 33, chapter 34, and chapter 35. Bool supplies the tag rows, Option supplies endpoint absence and presence rows, Product supplies component-envelope rows, and Sum supplies branch-tag rows; the list spine classifier becomes public only after those finite-data rows are available as sibling routes.

Theorem 36.214 (List finite-data sibling route)**.** *The public* $\mathsf{List}^{\uparrow}$ *spine classifier consumes* $\mathsf{Bool}^{\uparrow}$ *tag rows,* $\mathsf{Option}^{\uparrow}$ *endpoint absence/presence rows,* $\mathsf{Prod}^{\uparrow}$ *component envelope rows, and* $\mathsf{Sum}^{\uparrow}$ *branch tag rows before its spine classifier is public. Therefore any accepted list-spine read factors through the finite-data sibling lattice of chapter 32, chapter 33, chapter 34, and chapter 35 before it exports an empty, cons, append, reverse, or payload-bearing spine route.*

Proof. Read the sibling rows in finite-data order. The $\mathsf{Bool}^{\uparrow}$ surface supplies the visible tag discipline, $\mathsf{Option}^{\uparrow}$ separates absence from presence, $\mathsf{Prod}^{\uparrow}$ supplies component envelopes for payload and tail rows, and $\mathsf{Sum}^{\uparrow}$ supplies branch tags for the empty and cons alternatives.

The $\mathsf{List}^{\uparrow}$ spine classifier then reuses those rows as the finite route on which empty, singleton, append, reverse, and payload-bearing reads are displayed. Since the route has already passed through the tag, endpoint, component, and branch surfaces, the spine classifier is public only as a consumer of that sibling lattice. □

36.9 Public reverse and append

Theorem 36.215 (List public reverse turns append into opposite append)**.** *Per-object template: traditional target finite-list reverse anti-homomorphism; BEDC source* BHist *through* ListSpineRep*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability obligations public append congruence plus public reverse functionality; ledger finite spine presentation; core theorem this opposite-append law; exactness via represented-spine classifier displayed exactness; standard bridge ordinary finite-list* $reverse(xs{+}{+}ys) = reverse(ys){+}{+}reverse(xs)$*; status* ProofTarget*.*

Let $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. For histories* $h, k, r, h^{\mathrm{rev}}, k^{\mathrm{rev}}, s : \mathsf{BHist}$*, suppose*

$$\mathsf{ListPublicAppend}_A(h, k, r), \quad \mathsf{ListPublicReverse}_A(h, h^{\mathrm{rev}}), \quad \mathsf{ListPublicReverse}_A(k, k^{\mathrm{rev}})$$

and

$$\mathsf{ListPublicAppend}_A(k^{\mathrm{rev}}, h^{\mathrm{rev}}, s)$$

hold. Then there exists a history $s' : \mathsf{BHist}$ *such that*

$$\mathsf{ListPublicReverse}_A(r, s')$$

and

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(s, s')$$

hold.

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame reverse append antimorphism`

Proof. Unpack the append witness $\mathsf{ListPublicAppend}_A(h, k, r)$ as finite spines xs, ys with h represented by xs, k represented by ys, and r represented by $xs{+}{+}ys$.

Unpack the two reverse witnesses. The public reverse of h supplies a displayed representation of h^{rev} by $\mathsf{reverse}(xs)$ up to the source classifier, and the public reverse of k supplies a displayed representation of k^{rev} by $\mathsf{reverse}(ys)$ up to the same classifier. These comparisons use the functionality clause of Theorem 36.211 together with represented-spine classifier displayed exactness.

Use the finite-spine identity

$$\mathsf{reverse}(xs{+}{+}ys) = \mathsf{reverse}(ys){+}{+}\mathsf{reverse}(xs).$$

The representation of r by $xs{+}{+}ys$ therefore repacks as a public reverse witness from r to an endpoint s' represented by $\mathsf{reverse}(ys){+}{+}\mathsf{reverse}(xs)$.

Finally compare the given opposite-append output s with the repacked endpoint s'. The public append congruence and same-input functionality clauses of Theorem 36.195, applied to k^{rev} and h^{rev} and transported through the reverse functionality comparisons above, give $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(s, s')$. □

Theorem 36.216 (List classifier e1-map reverse append antimorphism)**.** *For BEDC history lists* $xs, ys, xs^{\mathrm{rev}}, ys^{\mathrm{rev}}$*, if* xs^{rev} *classifies* $reverse(xs)$ *and* ys^{rev} *classifies* $reverse(ys)$ *under* hsame*, then the* E1*-mapped reverse of* $xs{+}{+}ys$ *classifies the* E1*-mapped opposite append* $ys^{\mathrm{rev}}{+}{+}xs^{\mathrm{rev}}$*.*

Proof. Use the finite-list identity $reverse(xs{+}{+}ys) = reverse(ys){+}{+}reverse(xs)$. Symmetry of the two classifier hypotheses gives classifiers from $reverse(ys)$ to ys^{rev} and from $reverse(xs)$ to xs^{rev}; append congruence combines them into a classifier from $reverse(ys){+}{+}reverse(xs)$ to $ys^{\mathrm{rev}}{+}{+}xs^{\mathrm{rev}}$. Transport along the finite-list identity and apply the E1 map classifier theorem. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame map e1 reverse append antimorphism`

Theorem 36.217 (List classifier e0-map reverse append antimorphism)**.** *For BEDC history lists* $xs, ys, xs^{\mathrm{rev}}, ys^{\mathrm{rev}}$*, if* xs^{rev} *classifies* $reverse(xs)$ *and* ys^{rev} *classifies* $reverse(ys)$ *under* hsame*, then the* E0*-mapped reverse of* $xs{+}{+}ys$ *classifies the* E0*-mapped opposite append* $ys^{\mathrm{rev}}{+}{+}xs^{\mathrm{rev}}$*.*

Proof. Use the finite-list identity $reverse(xs{+}{+}ys) = reverse(ys){+}{+}reverse(xs)$. Symmetry of the two classifier hypotheses gives classifiers from $reverse(ys)$ to ys^{rev} and from $reverse(xs)$ to xs^{rev}; append congruence combines them into a classifier from $reverse(ys){+}{+}reverse(xs)$ to $ys^{\mathrm{rev}}{+}{+}xs^{\mathrm{rev}}$. Transport along the finite-list identity and apply the E0 map classifier theorem. □

Lean4 ✓ `BEDC.Derived.ListUp.ListClassifierSpec hsame map e0 reverse append antimorphism`

Theorem 36.218 (List public reverse append output classifier uniqueness)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. The ten-field fit is: traditional target finite-list reverse append output classifier uniqueness; BEDC source* BHist *through* ListSpineRep*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability obligations public append congruence, public reverse functionality, and classifier transitivity; ledger finite spine presentation; core theorem this reverse-output uniqueness law; exactness via represented-spine classifier displayed exactness and public reverse readback functionality; standard bridge ordinary finite-list reverse append readback; status* ProofTarget*.*

For histories $h, k, r, h^{\mathrm{rev}}, k^{\mathrm{rev}}, s, t : \mathsf{BHist}$*, suppose*

$$\mathsf{ListPublicAppend}_A(h, k, r), \quad \mathsf{ListPublicReverse}_A(h, h^{\mathrm{rev}}), \quad \mathsf{ListPublicReverse}_A(k, k^{\mathrm{rev}})$$

and

$$\mathsf{ListPublicAppend}_A(k^{\mathrm{rev}}, h^{\mathrm{rev}}, s), \quad \mathsf{ListPublicReverse}_A(r, t)$$

hold. Then

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(s, t)$$

holds.

Lean4 ✓ `BEDC.Derived.ListUp.FramedListPublicReverse append output classifier unique`

Proof. Apply Theorem 36.215 to the public append witness for h, k, r, the two public reverse witnesses for h and k, and the displayed opposite public append witness for $k^{\mathrm{rev}}, h^{\mathrm{rev}}, s$. This gives a history $s' : \mathsf{BHist}$ with $\mathsf{ListPublicReverse}_A(r, s')$ and $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(s, s')$.

Clause 3 of Theorem 36.211, applied to the two public reverse readbacks from the same source r, compares s' with t:

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(s', t).$$

Finally compose $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(s, s')$ with $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(s', t)$. The needed transitivity is the spine-induced history classifier transitivity supplied by Theorem 36.63 together with the bridge-classifier presentation in Definition 36.57. □

Theorem 36.219 (List public reverse append length ledger coherence)**.** *The ten-field fit is: traditional target finite-list reverse append law with a public length ledger; BEDC source* BHist *through* ListSpineRep*; carrier* $\mathsf{ListHistoryCarrier}_A$*; classifier* $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}$*; stability obligations public append congruence, public reverse functionality, classifier transitivity, and public length transport; ledger the finite public length value n; core theorem this reverse-append endpoint and length coherence package; exactness via represented-spine classifier displayed exactness, public reverse length preservation, and public length classifier transport; standard bridge ordinary finite-list reverse append with length preservation; status* ProofTarget*.*

Let $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume* $\mathsf{ListSpineRepCoherent}_{A,\sim_A}$*. For histories* $h, k, r, h^{\mathrm{rev}}, k^{\mathrm{rev}}, s, t :$ BHist *and a finite length value n, suppose*

$$\mathsf{ListPublicAppend}_A(h, k, r), \quad \mathsf{ListPublicReverse}_A(h, h^{\mathrm{rev}}), \quad \mathsf{ListPublicReverse}_A(k, k^{\mathrm{rev}})$$

and

$$\mathsf{ListPublicAppend}_A(k^{\mathrm{rev}}, h^{\mathrm{rev}}, s), \quad \mathsf{ListPublicReverse}_A(r, t), \quad \mathsf{ListPublicLength}_A(r, n)$$

hold. Then

$$\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(s, t) \wedge \mathsf{ListPublicLength}_A(s, n) \wedge \mathsf{ListPublicLength}_A(t, n)$$

holds.

Proof. First apply Theorem 36.218 to the public append witness for h, k, r, the two public reverse witnesses for h and k, the displayed opposite public append witness for $k^{\mathrm{rev}}, h^{\mathrm{rev}}, s$, and the public reverse witness from r to t. This gives $\mathsf{ListSpineHistoryClassifier}_{A,\sim_A}(s, t)$.

Next apply Theorem 36.212 to $\mathsf{ListPublicReverse}_A(r, t)$ and the displayed ledger witness $\mathsf{ListPublicLength}_A(r, n)$. The forward length-preservation clause gives $\mathsf{ListPublicLength}_A(t, n)$.

Finally apply Theorem 36.97 to the classifier witness between s and t. Using the reverse transport direction with the length witness at t yields $\mathsf{ListPublicLength}_A(s, n)$. Combining the classifier witness and the two endpoint length witnesses gives the required conjunction. □

Lean4 ✓ `BEDC.Derived.ListUp.ListUp StdBridge`

Definition 36.220 (List public structural recursion data)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier. A public structural recursion datum over the framed list carrier consists of a predicate* $P : \mathsf{BHist} \to \mathsf{Prop}$ *together with the following two clauses:*

1. *for every endpoint h, a witness* $\mathsf{FramedListSpineRep}_A(h, \mathsf{nil})$ *yields* $P(h)$*;*
2. *for every endpoint h and histories a, t, p, if $A(a)$ holds, if t is represented by a framed tail spine, if $P(t)$ holds, if* $\mathsf{Cont}(a, t, p)$ *holds, and if* $\mathsf{hsame}(h, \mathsf{E1}(p))$ *holds, then $P(h)$.*

Equivalently, the cons clause is allowed to consume a finite tail spine xs and a witness $\mathsf{FramedListSpineRep}_A(t, xs)$ *as the displayed framed tail representation.*

Theorem 36.221 (List public structural recursion principle)**.** *Let* $A : \mathsf{BHist} \to \mathsf{Prop}$ *be a BEDC history source carrier, let* $\sim_A$ *be a source classifier, let* $\mathsf{cert} : \mathsf{NameCert}(A, \sim_A)$*, and assume the cons-boundary coherence needed to read each framed cons endpoint as data* $A(a)$*,* $\mathsf{FramedListSpineRep}_A(t, xs)$*,* $\mathsf{Cont}(a, t, p)$*, and* $\mathsf{hsame}(h, \mathsf{E1}(p))$*. For every public structural recursion datum* $(P, \mathsf{nil}_P, \mathsf{cons}_P)$ *in the sense of Definition 36.220, every public framed carrier endpoint satisfies*

$$\mathsf{FramedListHistoryCarrier}_A(h) \to P(h).$$

Lean4 ✓ `BEDC.Derived.ListUp.ListHistoryCarrier structural recursion`

Proof. Unpack the public framed carrier witness as a finite displayed spine xs with $\mathsf{FramedListSpineRep}_A(h, xs)$. It is enough to prove the stronger displayed statement: for every endpoint represented by a framed spine xs, the predicate P holds at that endpoint.

Induct on the displayed framed spine. In the nil case, the representation is $\mathsf{FramedListSpineRep}_A(h, \mathsf{nil})$, so the nil clause nil_P gives $P(h)$ directly.

In the cons case, the representation exposes histories a, t, p and a tail spine xs with $A(a)$, $\mathsf{FramedListSpineRep}_A(t, xs)$, $\mathsf{Cont}(a, t, p)$, and $\mathsf{hsame}(h, \mathsf{E1}(p))$. The induction hypothesis applied to the tail representation gives $P(t)$. Applying the cons clause cons_P to these five pieces of data yields $P(h)$.

The classifier $\sim_A$, the certificate cert, and the boundary coherence witness are not used to add cases; they record that the public framed endpoint being eliminated is the same certificate-bearing surface used by append, reverse, length, and bridge transport. The eliminator itself is the finite-spine induction exposed by $\mathsf{FramedListHistoryCarrier}_A(h)$. □

Closure status for $\mathsf{NameCert}_{\mathsf{List}^\uparrow}$.

Constructive story: A list is a finite spine that either stops at nil or takes one more cons step carrying a payload from the source type A; this is the lone certificate in this run whose carrier is the host inductive `List A` rather than a history predicate, because finite lists are exactly unary growth with data attached at each step. Two such spines are classified together only when they have the same nil-or-cons shape and, at every cons step, their payloads are identified by the source-side equivalence on A. The source is the whole list type, the pattern records the nil/cons case split, append, reverse, length, constructor maps, and endpoint readback, and the ledger keeps the visible list equal to the raw list being structurally inspected. Since the source equivalence is reflexive, symmetric, and transitive, structural induction lifts those three facts to lists, gives the nil inhabitant, and shows that classifier-recognized lists remain in the carrier. A list xs lies in the signature gap of a $\mathsf{List}^\uparrow$ token p when the source-domain accepts xs, the signature relation pairs it with an answer list and evidence ledger, and the token-introduction relation names that answer as p; unfolded, every cons payload of xs must match the corresponding payload encoded by p, and nil must match nil. The finite-spine bridge then reads append, reverse, and length as operations on that same payload-bearing spine rather than as host-list axioms. The chapter registers this payload-bearing-spine construction under the name $\mathsf{List}^\uparrow$; list operations reduce to spine operations, with no quotient principle, sorting API, or arbitrary host-list theory introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{List}^\uparrow}$, maturePackageClosed)

Scope closed: The mature ListUp scope is the finite-spine surface generated by the framed semantic certificate, nil/cons no-confusion, append, reverse, constructor-map, length, endpoint readback, and finite-spine bridge transport.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{List}^\uparrow}$, bridgeChecked)

Lean target: `BEDC.Derived.ListUp.FramedListBridgeClassifier\_semantic\_name\_certificate`

Bridge status: bridgeChecked

Not claimed: The chapter does not close quotient principles, sorting, arbitrary host-list APIs, or a bridgeChecked standard-model correspondence.

Upgrade path: No further upgrade – chapter at top of formal axis.

Chapter 37

A Concrete Naming Certificate for $\mathsf{Rat}^{\uparrow}$

The rational number interface $\mathsf{Rat}^{\uparrow}$ starts from a carrier skeleton: a signed unary integer numerator, drawn from chapter 31, together with a positive unary denominator. Normalized representatives, coprimality, and arithmetic closure are separate source, pattern, classifier, and stability obligations later in the chapter. The classifier is structural equality on the normalized representative, not the equivalence relation $p_1q_2 = p_2q_1$ on unnormalized pairs, which would otherwise demand quotient-type machinery and Quot.sound. It is not a primitive field; it is licensed only via the integer source and the normalization function.

Remark 37.1 (Rational certificate scope)**.** *This chapter records the rational licensing target through normalized integer-positive-natural representatives and structural classifier data. The checked core covers the rational history carrier, rational history classifier fields, ledger carrier, and semantic certificate. Normalized representatives are recorded by the source and pattern obligations, while coprimality and operation closure remain part of the paper specification.*

37.1 Carrier definition

Definition 37.2 (Rat carrier)**.** *Use only the carrier skeleton: a signed unary integer numerator together with a unary denominator history that is not internally the same as* e*:*

$$\mathsf{RatCarrier}(s, n, d) := \mathsf{IntCarrier}(s, n) \wedge \mathsf{Unary}(d) \wedge \neg\mathsf{hsame}(d, \mathsf{e}).$$

Equivalently, this is an $\mathsf{Int}^{\uparrow}$ *numerator with a positive unary-history denominator. At this skeleton layer, positivity is witnessed by writing the denominator as a one-extension of a unary tail; normalized representatives, coprimality, and arithmetic closure are supplied by later source, pattern, and stability obligations.*

Lean4 (definition) `BEDC.Derived.RatUp.RatCarrier`

Theorem 37.3 (Rat carrier positive denominator)**.** *If* $\mathsf{RatCarrier}(s, n, d)$*, then the denominator is internally the same as* $\mathsf{E1}(t)$ *for some unary tail* t*.*

Lean4 ✓ `BEDC.Derived.RatUp.RatCarrier positive denominator`

Proof. Unpack the carrier into its integer numerator, unary denominator, and non-emptiness clauses. The unary denominator is either e or a one-extension of a unary tail. The empty case contradicts non-emptiness, while the one-extension case gives the displayed positive-denominator witness. □

Theorem 37.4 (Positive denominator yields a rational carrier)**.** *An* $\mathsf{Int}^{\uparrow}$ *numerator together with a denominator internally same as* $\mathsf{E1}(t)$ *for a unary tail* t *forms a* $\mathsf{Rat}^{\uparrow}$ *carrier.*

Lean4 ✓ `BEDC.Derived.RatUp.RatCarrier of int positive denominator`

Proof. Transport unary closure from the displayed E1-shape to the denominator along hsame. Non-emptiness follows because an E1-history cannot be internally same as e. □

Theorem 37.5 (Rat carrier denominator transport)**.** *If* $\mathsf{RatCarrier}(s, n, d)$ *and* $d\mathsf{hsame}d'$*, then* $\mathsf{RatCarrier}(s, n, d')$*.*

Lean4 ✓ `BEDC.Derived.RatUp.RatCarrier denominator hsame transport`

Proof. Extract the positive denominator witness from the rational carrier, transport that witness across denominator sameness, and rebuild the rational carrier from the unchanged integer numerator together with the transported positive denominator. □

Theorem 37.6 (Positive unary denominator transport)**.** *If a denominator history has a positive unary witness and is* hsame*-equivalent to another history, then the other history has the same positive unary denominator witness.*

Proof. Write the positive denominator as an E1-extension of a unary tail. Compose the reverse hsame witness from the target history to the source history with the source witness to the E1-extension, and keep the unary tail witness. □

Lean4 ✓ `BEDC.Derived.RatUp.PositiveUnaryDenominator hsame transport`

Theorem 37.7 (One-extension positive denominator equivalence)**.** *A one-extension history has a positive unary denominator witness exactly when its tail is unary.*

Proof. For the forward direction, eliminate the positive-denominator witness $\mathsf{hsame}(\mathsf{E1}(t), \mathsf{E1}(u))$ with unary tail u. One-constructor inversion gives $\mathsf{hsame}(t, u)$, and unary membership transports back to t. For the reverse direction, use t itself as the displayed positive tail and the reflexive one-extension sameness witness. □

Lean4 ✓ `BEDC.Derived.RatUp.PositiveUnaryDenominator e1 iff unary`

Theorem 37.8 (Left one-extension append positive denominator equivalence)**.** *For histories* $h, t : \mathsf{BHist}$*,*

$$\mathsf{PositiveUnaryDenominator}(\mathsf{append}(\mathsf{E1}(h), t))$$

holds exactly when both h *and* t *are unary histories.*

Proof. If the appended history has a positive unary denominator witness, then it is a unary history. Unary append factorization recovers unary membership of the left factor and of the tail; one-extension inversion turns unary membership of $\mathsf{E1}(h)$ into unary membership of h.

Conversely, unary membership of h makes $\mathsf{E1}(h)$ a positive unary denominator, and positive denominators are closed under appending a unary tail. □

Lean4 ✓ `BEDC.Derived.RatUp.PositiveUnaryDenominator append e1 left iff`

Theorem 37.9 (Right one-extension append positive denominator equivalence)**.** *For histories* $h, t : \mathsf{BHist}$*,*

$$\mathsf{PositiveUnaryDenominator}(\mathsf{append}(h, \mathsf{E1}(t)))$$

holds exactly when both h *and* t *are unary histories.*

Proof. The right one-extension unfolds the appended denominator as $\mathsf{E1}(\mathsf{append}(h, t))$. The one-extension positive-denominator equivalence reads this as unary membership of $\mathsf{append}(h, t)$, and unary append factorization is exactly the conjunction of unary membership of h and t. The reverse direction rebuilds the unary append and applies the one-extension positive-denominator equivalence. □

Lean4 ✓ `BEDC.Derived.RatUp.PositiveUnaryDenominator append e1 right iff`

Theorem 37.10 (Zero-extension cannot be a positive denominator)**.** *A zero-extension history has no positive unary denominator witness.*

Proof. Unpack the positive denominator witness. It would identify an $\mathsf{E0}$-history with an $\mathsf{E1}$-history, contradicting finite-kernel history constructor no-confusion. □

Lean4 ✓ `BEDC.Derived.RatUp.PositiveUnaryDenominator e0 absurd`

Theorem 37.11 (Positive unary denominator is not empty)**.** *If a denominator has a positive unary witness, then it is not internally the same as* e*.*

Proof. Unpack the positive denominator as internally the same as $\mathsf{E1}(t)$ for a unary tail t. Composing this witness with an assumed sameness to e would make an $\mathsf{E1}$-history internally the same as e, contradicting history constructor no-confusion. □

Lean4 ✓ `BEDC.Derived.RatUp.PositiveUnaryDenominator not empty`

Theorem 37.12 (Positive unary denominator is unary and nonempty)**.** *If a denominator history has a positive unary witness, then it is unary and cannot be internally the same as* e*.*

Lean4 ✓ `BEDC.Derived.RatUp.PositiveUnaryDenominator unary and nonempty`

Proof. Write the positive denominator as internally the same as $\mathsf{E1}(t)$ with t unary. Unary closure under $\mathsf{E1}$, transported back along history sameness, gives unary membership of the denominator. If the denominator were internally same as e, transitivity would make $\mathsf{E1}(t)$ internally same as e, contradicting constructor separation. □

Theorem 37.13 (Positive unary denominator carrier equivalence)**.** *The rational carrier condition is equivalent to an* $\mathsf{Int}^{\uparrow}$ *numerator together with a denominator that has a positive unary tail witness.*

Proof. Unpack the carrier. A unary denominator that is not hsame-empty cannot be the empty unary history, so unary case analysis gives a one-extension tail. Conversely, a denominator hsame-equal to a one-extension of a unary tail is unary by transport, and it cannot be hsame-empty by constructor no-confusion. □

Lean4 ✓ `BEDC.Derived.RatUp.RatCarrier iff positive unary denominator`

Theorem 37.14 (Positive denominator append unary tail)**.** *If a denominator has a positive unary witness and the appended tail is unary, then the continued denominator still has a positive unary witness.*

Proof. Write the denominator as internally the same as $\mathsf{E1}(t)$ for a unary tail t, and transport unary membership back to the denominator itself. The appended tail is either e or a one-step unary tail. The empty case keeps the original witness, while the one-step case takes the continued denominator without that final step as the new positive tail; closure follows from unary append closure. □

Lean4 ✓ `BEDC.Derived.RatUp.PositiveUnaryDenominator append unary tail`

Theorem 37.15 (Positive unary denominator append zero-tail exclusion)**.** *For histories* d, t : BHist*, the continued denominator* $\mathsf{append}(d, \mathsf{E0}(t))$ *has no positive unary denominator witness.*

Proof. A positive denominator witness first gives unary membership for the whole continued history. Unary append factor extraction then gives unary membership for the right factor $\mathsf{E0}(t)$, contradicting zero-extension separation for unary histories. □

Lean4 ✓ `BEDC.Derived.RatUp.PositiveUnaryDenominator append e0 tail absurd`

Theorem 37.16 (Positive unary denominator append one-tail equivalence)**.** *For histories* d, t : BHist*,*

$$\mathsf{PositiveUnaryDenominator}(\mathsf{append}(d, \mathsf{E1}(t))) \iff \mathsf{UnaryHistory}(\mathsf{append}(d, t)).$$

Proof. The forward direction reads unary membership from the positive denominator witness; the one-step shape of continuation identifies this with unary membership of $\mathsf{append}(d, t)$. Conversely, unary membership of $\mathsf{append}(d, t)$ is exactly the positive denominator witness for the one-extension $\mathsf{append}(d, \mathsf{E1}(t))$. □

Lean4 ✓ `BEDC.Derived.RatUp.PositiveUnaryDenominator append e1 tail iff unary append`

Theorem 37.17 (Rat carrier append unary denominator closure)**.** *If a rational carrier has denominator* d*, then appending any unary history to* d *preserves rational-carrier membership.*

Proof. Use the carrier equivalence to expose the integer numerator carrier and the positive unary denominator witness. Positive denominators are closed under appending unary tails, and the rational carrier is rebuilt from the same integer numerator and the resulting positive denominator. □

Lean4 ✓ `BEDC.Derived.RatUp.RatCarrier append unary denominator closed`

Theorem 37.18 (Rat history carrier is not empty)**.** *If a rational history carrier has denominator* d*, then* d *cannot be internally the same as* e*.*

Proof. Unpack the rational history carrier into its sign, numerator, and rational carrier. The rational carrier exposes a positive unary denominator witness, and positive unary denominators are separated from e. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryCarrier not empty`

Theorem 37.19 (Rat history carrier positive denominator equivalence)**.** *A denominator history lies in the rational history carrier exactly when it has a positive unary denominator witness.*

Proof. In the forward direction, unpack the rational history carrier into a sign, numerator, and rational carrier, then apply rational-carrier positivity of the denominator. In the reverse direction, use the concrete integer numerator carrier with sign b0 and empty magnitude, then rebuild the rational carrier from the positive denominator witness. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryCarrier iff positive denominator`

Theorem 37.20 (Rat history carrier hsame transport)**.** *If a denominator history lies in the rational history carrier and is transported along* hsame *to another denominator history, then the transported denominator history lies in the rational history carrier.*

Proof. Use the positive denominator equivalence of Definition 37.19. The source carrier gives a positive unary denominator witness, and Definition 37.6 carries that witness across the displayed hsame comparison.

Reapply the reverse direction of Definition 37.19 to rebuild the rational history carrier at the transported denominator. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryCarrier hsame transport`

Theorem 37.21 (Rat history eone tail unary equivalence)**.** *A one-extension denominator* $\mathsf{E1}(t)$ *lies in the rational history carrier exactly when its tail* t *is unary.*

Proof. For the forward direction, unpack the rational history carrier to obtain the positive denominator witness, then invert the displayed one-extension denominator to transport unary membership to t. For the reverse direction, use the canonical integer numerator with sign b0 and empty magnitude, and use t itself as the positive unary denominator tail. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryCarrier e1 tail unary iff`

Theorem 37.22 (Rat history carrier excludes zero-extension)**.** *No zero-extension history* $\mathsf{E0}(t)$ *lies in the rational history carrier.*

Proof. Unpack the rational history carrier into its sign, numerator, and rational carrier. The rational carrier supplies a positive unary denominator witness, and positive unary denominators cannot have zero-extension shape. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryCarrier e0 absurd`

Theorem 37.23 (Rat history carrier append unary denominator closure)**.** *If a rational history carrier has denominator* d*, then appending any unary history to* d *preserves rational history carrier membership.*

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryCarrier append unary denominator closed`

Proof. Unpack the rational history carrier into its sign, numerator, and rational carrier data. Apply rational-carrier denominator append closure to the concrete denominator component, then rebuild the existential rational history carrier with the same sign and numerator. □

Theorem 37.24 (Positive denominator append unary prefix)**.** *If* u *is unary and* d *has a positive unary denominator witness, then* $\mathsf{append}(u, d)$ *has a positive unary denominator witness.*

Proof. Write the positive denominator witness as an E1 tail, say d is internally the same as $\mathsf{E1}(t)$ with t unary. Appending the unary prefix u preserves unary structure by unary append closure, and composing the displayed E1 witness with append compatibility gives the required positive witness for $\mathsf{append}(u, d)$. □

Lean4 ✓ `BEDC.Derived.RatUp.PositiveUnaryDenominator append unary prefix`

Theorem 37.25 (Positive unary denominator append unary left iff)**.** *If u is unary, then a continued denominator $\mathsf{append}(u, r)$ has a positive unary denominator witness exactly when either r is internally empty and u already has such a witness, or r itself has such a witness.*

Proof. Case-split on the right history r. The empty case reduces the continuation to u. A zero-extension case is impossible because no zero-extension is a positive denominator. In the one-extension case, one-constructor readback gives unary membership of the continued tail, and unary append factorization recovers the right tail witness. Conversely, the empty-right alternative reduces by endpoint equality, while a positive witness on r is preserved by unary prefix closure. □

Lean4 ✓ `BEDC.Derived.RatUp.PositiveUnaryDenominator append unary left iff`

Theorem 37.26 (Positive unary denominator append unary left split)**.** *If p is unary and $\mathsf{append}(p, d)$ has a positive unary denominator witness, then either p already has a positive unary denominator witness or d has one.*

Proof. Split on the visible shape of the unary prefix. The empty prefix transports the positive witness across left-unit append. A zero-headed prefix contradicts unary history membership. A one-headed prefix is itself a positive unary denominator. □

Lean4 ✓ `BEDC.Derived.RatUp.PositiveUnaryDenominator append unary left split`

Theorem 37.27 (Positive denominator append unary context)**.** *If p and t are unary histories and d has a positive unary denominator witness, then $\mathsf{append}(p, \mathsf{append}(d, t))$ has a positive unary denominator witness.*

Proof. First close the positive denominator under the unary tail t. Then close the resulting positive denominator under the unary prefix p. □

Lean4 ✓ `BEDC.Derived.RatUp.PositiveUnaryDenominator append unary context`

Theorem 37.28 (Rat carrier prepend unary denominator closure)**.** *If a rational carrier has denominator d, then prepending any unary history to d preserves rational-carrier membership.*

Proof. Use the carrier equivalence to expose the integer numerator carrier and the positive unary denominator witness. Positive denominators are closed under unary prefix continuation, and the rational carrier is rebuilt from the same integer numerator and the resulting positive denominator. □

Lean4 ✓ `BEDC.Derived.RatUp.RatCarrier prepend unary denominator closed`

Theorem 37.29 (Rat history carrier prepend unary denominator closure)**.** *If a rational history carrier has denominator d, then prepending any unary history to d preserves rational history carrier membership.*

Proof. Unpack the rational history carrier into its sign, numerator, and rational carrier data. Apply rational-carrier denominator prepend closure to the concrete denominator component, then rebuild the existential rational history carrier with the same sign and numerator. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryCarrier prepend unary denominator closed`

Theorem 37.30 (Rat carrier unary denominator context closure)**.** *If a rational carrier has denominator d, then placing a unary prefix and a unary tail around d preserves rational-carrier membership.*

Proof. First close the carrier under appending the unary tail to the denominator. Then close the resulting carrier under prepending the unary prefix to that continued denominator. □

Lean4 ✓ `BEDC.Derived.RatUp.RatCarrier unary denominator context closed`

Theorem 37.31 (Rat history carrier unary denominator context closure)**.** *If a rational history carrier has denominator d, then placing a unary prefix and a unary tail around d preserves rational history carrier membership.*

Proof. Unpack the rational history carrier into its sign, numerator, and rational carrier data. Apply rational-carrier unary denominator context closure to the concrete denominator component, then rebuild the existential rational history carrier with the same sign and numerator. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryCarrier unary denominator context closed`

Theorem 37.32 (Rat carrier hsame transport)**.** *If a rational carrier* $\mathsf{RatCarrier}(s, n, d)$ *is transported along* $\mathsf{msame}(s, t)$*,* $\mathsf{hsame}(n, n')$*, and* $\mathsf{hsame}(d, d')$*, then the transported triple is again a rational carrier.*

Lean4 ✓ `BEDC.Derived.RatUp.RatCarrier hsame transport`

Proof. Eliminate the sign sameness, then unpack the rational carrier. The numerator is transported by the integer carrier transport theorem, denominator unary closure is transported along $\mathsf{hsame}(d, d')$, and denominator non-emptiness is preserved by composing $\mathsf{hsame}(d, d')$ with any empty-target witness. □

37.2 The certificate

Definition 37.33 (Rat source specification)**.** *The source is* $\mathsf{Int}^{\uparrow} \times \mathsf{Nat}^{\uparrow}$ *restricted to normalized denominator-positive pairs.*

Lean4 (definition) `BEDC.Derived.RatUp.RatSourceSpec`

Theorem 37.34 (Rat source specification yields the carrier)**.** *A rational source witness determines a rational carrier witness: the numerator is an integer carrier, the denominator is unary, and the positive one-tail witness excludes internal sameness with* e*.*

Lean4 ✓ `BEDC.Derived.RatUp.RatSourceSpec to RatCarrier`

Proof. Unpack the source witness. The positive-denominator component gives a unary tail t with $d\mathsf{hsame}e_1(t)$. Unary closure under one-extension and transport along hsame give $\mathsf{Unary}(d)$. If $d\mathsf{hsame}\mathsf{e}$, then symmetry and transitivity give $e_1(t)\mathsf{hsame}\mathsf{e}$, contradicting finite-kernel history no-confusion. □

Definition 37.35 (Rat pattern specification)**.** *The pattern is normalized numerator/denominator construction via a total normalization function on integer and positive-natural inputs.*

Definition 37.36 (Rat classifier specification)**.** *The classifier is structural sameness of normalized numerator and denominator representatives, tracked by mark sameness on signs and history sameness on the numerator and denominator histories.*

Lean4 (definition) `BEDC.Derived.RatUp.RatClassifierSpec`

Theorem 37.37 (Rat classifier reflexivity)**.** *Every rational carrier witness classifies its representative with itself.*

Proof. Reuse the carrier witness for both endpoints. The sign component is witnessed by reflexivity of msame, and the numerator and denominator components are witnessed by reflexivity of hsame. □

Lean4 ✓ `BEDC.Derived.RatUp.RatClassifierSpec refl`

Theorem 37.38 (Rat classifier exposes positive denominators)**.** *If two rational representatives are related by the rational classifier, then both endpoint denominators carry positive unary denominator witnesses.*

Proof. Eliminate the classifier witness to expose the two endpoint rational carriers. Apply the rational-carrier positive-denominator theorem to each endpoint carrier. □

Lean4 ✓ `BEDC.Derived.RatUp.RatClassifierSpec positive denominators`

Theorem 37.39 (Rat classifier transports positive denominators)**.** *If two rational representatives are related by the rational classifier, and each denominator is related by* hsame *to a displayed denominator history, then both displayed denominator histories carry positive unary denominator witnesses.*

Proof. Eliminate the classifier witness to expose the two endpoint rational carriers. Each endpoint carrier gives a positive unary denominator witness, and the two denominator hsame links transport those witnesses to the displayed denominator histories. □

Lean4 ✓ `BEDC.Derived.RatUp.RatClassifierSpec denominator positive transport`

Theorem 37.40 (Rat positive denominator append factor or tail)**.** *If the append of two denominator histories carries a positive unary denominator witness, then either the left factor already carries such a witness or the right tail carries one.*

Proof. Inspect the right tail. The empty case leaves the displayed append equal to the left factor. A zero-headed tail contradicts the positive one-headed denominator witness. For a one-headed tail, the positive witness exposes unary membership of the appended core, and unary append factor recovery gives unary membership of the right core, hence a positive denominator witness for the tail. □

Lean4 ✓ `BEDC.Derived.RatUp.PositiveUnaryDenominator append factor or tail`

Theorem 37.41 (Rat classifier denominator append closure)**.** *If two rational representatives are classified the same, then appending* hsame*-matching unary histories to their denominators preserves the rational classifier relation.*

Proof. Unpack the classifier witness into the two endpoint carriers and the sign, numerator, and denominator sameness fields. Close both endpoint denominator carriers under unary append, transporting the unary-tail witness along the tail sameness for the second endpoint. The resulting denominator sameness follows by eliminating the original denominator and tail sameness witnesses and applying reflexivity to the resulting append history. □

Lean4 ✓ `BEDC.Derived.RatUp.RatClassifierSpec append unary denominators closed`

Theorem 37.42 (Rat classifier denominator prepend closure)**.** *If two rational representatives are classified the same, then prepending* hsame*-matching unary histories to their denominators preserves the rational classifier relation.*

Proof. Unpack the classifier witness into the two endpoint carriers and the sign, numerator, and denominator sameness fields. Close both endpoint denominator carriers under unary prepend, transporting unary membership of the first prefix across prefix sameness for the second endpoint. The resulting denominator sameness follows by eliminating the original denominator and prefix sameness witnesses and applying reflexivity to the resulting append history. □

Lean4 ✓ `BEDC.Derived.RatUp.RatClassifierSpec prepend unary denominators closed`

Theorem 37.43 (Rat classifier unary denominator context closure)**.** *If two rational representatives are classified the same, then surrounding their denominators by* hsame*-matching unary prefixes and unary tails preserves the rational classifier relation.*

Proof. First apply denominator append closure to the classified representatives and the matching unary tails. Then apply denominator prepend closure to the resulting classified representatives and the matching unary prefixes. The sign and numerator witnesses are unchanged, while the denominator endpoint relation is obtained by the two concrete unary-context closure steps. □

Lean4 ✓ `BEDC.Derived.RatUp.RatClassifierSpec append unary denominator context closed`

Theorem 37.44 (Rat classifier unary denominator context exactness)**.** *For* $s_1, s_2 : \mathsf{BMark}$ *and* $n_1, n_2, d_1, d_2, p_1, p_2, t_1, t_2 : \mathsf{BHist}$*, assume* $\mathsf{RatCarrier}(s_1, n_1, d_1)$*,* $\mathsf{RatCarrier}(s_2, n_2, d_2)$*,* $\mathsf{Unary}(p_1)$*,* $\mathsf{Unary}(t_1)$*,* $\mathsf{hsame}(p_1, p_2)$*, and* $\mathsf{hsame}(t_1, t_2)$*. Then*

$$\mathsf{RatClassifierSpec}(s_1, n_1, \mathsf{append}(p_1, \mathsf{append}(d_1, t_1)), s_2, n_2, \mathsf{append}(p_2, \mathsf{append}(d_2, t_2))) \iff \mathsf{RatClassifierSpec}(s_1, n_1, d$$

Proof. Suppose first that the contextual classifier holds. Unpack it to expose the contextual endpoint carriers and the sign, numerator, and denominator sameness fields. Keep the supplied original carrier witnesses for $\mathsf{RatCarrier}(s_1, n_1, d_1)$ and $\mathsf{RatCarrier}(s_2, n_2, d_2)$.

The denominator field gives sameness between the two displayed context denominators. Transport this relation across $\mathsf{hsame}(p_1, p_2)$ and $\mathsf{hsame}(t_1, t_2)$, then cancel the matching prefix and suffix by append cancellation to obtain $\mathsf{hsame}(d_1, d_2)$. Repack the original classifier with the unchanged sign and numerator fields and this cancelled denominator field.

Conversely, suppose the original classifier holds. The unary-context closure theorem, applied with the supplied unary prefix, unary tail, and matching hsame witnesses, gives the contextual classifier directly. □

Theorem 37.45 (Rat classifier append unary prefix denominator split)**.** *If two rational representatives are classified after matching unary prefixes are prepended to their denominators, then each displayed denominator side has a positive unary witness either in its prefix or in its remaining denominator.*

Proof. The classifier exposes positive unary denominator witnesses for the two prefixed denominators. Transport unary membership across the prefix hsame-link, then split each prefixed denominator by the positive unary left-split theorem. □

Lean4 ✓ `BEDC.Derived.RatUp.RatClassifierSpec append unary prefix denominator split`

Theorem 37.46 (Rat classifier transitivity)**.** *If one rational representative is classified the same as a second representative, and the second representative is classified the same as a third representative, then the first and third representatives are classified the same.*

Lean4 ✓ `BEDC.Derived.RatUp.RatClassifierSpec trans`

Proof. Unpack both classifier witnesses. The endpoint carriers are preserved, while sign sameness and the two history-sameness components compose by the finite-kernel transitivity theorems for msame and hsame. □

Theorem 37.47 (Rat classifier symmetry)**.** *If one rational representative is classified the same as a second representative, then the second representative is classified the same as the first.*

Proof. Unpack the endpoint carriers and the sign, numerator, and denominator sameness fields. Rebuild the classifier in the reverse direction using symmetry of msame for signs and symmetry of hsame for both history components. □

Lean4 ✓ `BEDC.Derived.RatUp.RatClassifierSpec symm`

Theorem 37.48 (Rat classifier component transport)**.** *If both rational classifier endpoints are transported componentwise by* msame *on signs and* hsame *on numerator and denominator histories, then the rational classifier transports to the componentwise transported representatives.*

Proof. Unpack the rational classifier witness. Transport each endpoint rational carrier by the component transport theorem, then compose the old sign, numerator, and denominator sameness links with the reversed source endpoint transports and the target endpoint transports. □

Lean4 ✓ `BEDC.Derived.RatUp.RatClassifierSpec component transport`

Theorem 37.49 (Rat history classifier one-tail exactness)**.** *For denominator tails* $d, e : \mathsf{BHist}$*, the rational history classifier relates the one-extension denominators exactly when both tails are unary and internally the same:*

$$\mathsf{RatHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(e)) \iff \mathsf{Unary}(d) \wedge \mathsf{Unary}(e) \wedge \mathsf{hsame}(d, e).$$

Proof. For the forward direction, unpack the classifier into two rational history carrier witnesses and the endpoint hsame link. The one-tail carrier equivalence extracts unary membership of both tails, and E1-constructor inversion gives $\mathsf{hsame}(d, e)$. For the reverse direction, rebuild both rational history carriers from the unary tails and lift $\mathsf{hsame}(d, e)$ by E1-congruence. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryClassifier e1 tail unary iff`

Theorem 37.50 (Rat history classifier exposes positive denominators)**.** *If denominator histories* d *and* e *are related by the rational history classifier, then both* d *and* e *carry positive unary denominator witnesses.*

Proof. Unpack the rational history classifier into its two endpoint rational-history carrier witnesses and the stored denominator hsame link. Convert each endpoint carrier to a positive unary denominator witness by the rational history carrier positive-denominator equivalence. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryClassifier positive denominators`

Theorem 37.51 (Rat history classifier endpoints are nonempty)**.** *If denominator histories d and e are related by the rational history classifier, then neither endpoint is internally the same as the empty history:*

$$(\mathsf{hsame}(d, \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(e, \mathsf{e}) \to \mathsf{False}).$$

Proof. Unpack the rational history classifier into its two endpoint rational-history carrier witnesses. Apply rational-history carrier nonemptiness to each endpoint carrier. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryClassifier endpoints not empty`

Theorem 37.52 (Rat history classifier zero-extension endpoint exclusion)**.** *For histories t, d : BHist, zero-extension cannot appear as either endpoint of the rational history classifier:*

$$(\mathsf{RatHistoryClassifier}(\mathsf{E0}(t), d) \to \mathsf{False}) \wedge (\mathsf{RatHistoryClassifier}(d, \mathsf{E0}(t)) \to \mathsf{False}).$$

Proof. For the left endpoint, apply Definition 37.50 to the classifier hypothesis. Its first positive-denominator witness belongs to $\mathsf{E0}(t)$, so Definition 37.10 gives the contradiction.

For the right endpoint, apply Definition 37.50 to the classifier hypothesis again. Its second positive-denominator witness belongs to $\mathsf{E0}(t)$, and Definition 37.10 rules out that endpoint. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryClassifier e0 endpoint absurd`

The ten-field fit is: traditional target rational-denominator branch exclusion; BEDC source BHist and RatHistoryClassifier; carrier RatHistoryCarrier; classifier RatHistoryClassifier; stability from positive-denominator readback; ledger the rejected zero head; core theorem this block; exactness the two displayed contradictions; standard bridge positive denominators are never zero-headed unary histories; status ProofTarget.

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryClassifier zero extension endpoint exclusion`

Theorem 37.53 (Rat history classifier transitivity)**.** *If denominator histories d and e are related by the rational history classifier, and e and f are related by the same classifier, then d and f are related by the rational history classifier.*

Proof. Unpack the two rational history classifier witnesses. Keep the left endpoint carrier from the first witness and the right endpoint carrier from the second witness, then compose the denominator history sameness proofs by transitivity of hsame. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryClassifier trans`

Theorem 37.54 (Rat history classifier endpoint transport)**.** *If denominator histories d and e are related by the rational history classifier, and d and e are respectively internally the same as d' and e', then d' and e' are related by the rational history classifier.*

Proof. Unpack the rational history classifier into endpoint rational-history carriers and the stored $\mathsf{hsame}(d, e)$ link. Transport both endpoint carriers across the supplied history-sameness witnesses, then compose the reversed $\mathsf{hsame}(d, d')$ link, the stored classifier link, and $\mathsf{hsame}(e, e')$. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryClassifier hsame transport`

Theorem 37.55 (Rat history classifier symmetry)**.** *If denominator histories d and e are related by the rational history classifier, then e and d are related by the rational history classifier.*

Proof. Unpack the rational history classifier witness. Swap the two endpoint carrier witnesses, and reverse the denominator history-sameness proof by symmetry of hsame. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryClassifier symm`

Theorem 37.56 (Rat history classifier unary denominator append closure)**.** *If denominator histories d and e are related by the rational history classifier, and unary tails t_d and t_e satisfy* $\mathsf{hsame}(t_d, t_e)$*, then appending the tails to the corresponding denominator histories preserves the rational history classifier.*

Proof. Unpack the rational history classifier into endpoint carriers and denominator hsame. Close the left endpoint carrier under unary denominator append. Transport unary membership from t_d to t_e, close the right endpoint carrier under append, and combine the denominator hsame with the tail hsame by constructor cases on append. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryClassifier append unary denominator closed`

Theorem 37.57 (Rat history classifier unary denominator prepend closure)**.** *If denominator histories d and e are related by the rational history classifier, and unary prefixes p_d and p_e satisfy* $\mathsf{hsame}(p_d, p_e)$*, then prepending the prefixes to the corresponding denominator histories preserves the rational history classifier.*

Proof. Unpack the rational history classifier into endpoint carriers and denominator hsame. Close the left endpoint carrier under unary denominator prepend. Transport unary membership from p_d to p_e, close the right endpoint carrier under prepend, and combine the denominator and prefix hsame witnesses by constructor cases on the continuation append operation. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryClassifier prepend unary denominator closed`

Theorem 37.58 (Rat history classifier unary denominator context closure)**.** *If denominator histories d and e are related by the rational history classifier, unary prefixes p_d, p_e satisfy* $\mathsf{hsame}(p_d, p_e)$*, and unary tails t_d, t_e satisfy* $\mathsf{hsame}(t_d, t_e)$*, then placing the matching prefix and tail around the corresponding denominators preserves the rational history classifier.*

Proof. First apply unary denominator append closure to the classified denominator histories and the matching tails. Then apply unary denominator prepend closure to the resulting classified denominator histories and the matching prefixes. The endpoint carrier witnesses are closed by the two concrete unary closure steps, and the denominator relation is the composed hsame-respecting append context. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryClassifier unary denominator context closed`

Theorem 37.59 (Rat history classifier unary denominator context positive denominators)**.** *If a rational history classifier is closed under matching unary denominator prefixes and tails, then the two contextual denominator endpoints have positive unary denominator witnesses.*

Proof. Apply Definition 37.58 to the original classifier and the matching unary contexts. Then apply Definition 37.50 to the resulting contextual classifier. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryClassifier unary denominator context positive denominators`

Theorem 37.60 (Rat history classifier unary context zero-extension endpoint exclusion)**.** *Let* $d, e, p_d, p_e, t_d, t_e, z, z' : \mathsf{BHist}$. *If* $\mathsf{RatHistoryClassifier}(d, e)$ *holds,* p_d, p_e *are unary prefixes with* $\mathsf{hsame}(p_d, p_e)$*, and* t_d, t_e *are unary tails with* $\mathsf{hsame}(t_d, t_e)$*, then the two contextual denominator endpoints cannot be internally the same as zero-extension histories:*

$$(\mathsf{hsame}(\mathsf{append}(p_d, \mathsf{append}(d, t_d)), \mathsf{E0}(z)) \to \mathsf{False}) \wedge (\mathsf{hsame}(\mathsf{append}(p_e, \mathsf{append}(e, t_e)), \mathsf{E0}(z')) \to \mathsf{False}).$$

Proof. Apply Definition 37.59 to the displayed classifier, the matching unary prefix context, and the matching unary tail context. This produces positive unary denominator witnesses for $\mathsf{append}(p_d, \mathsf{append}(d, t_d))$ and $\mathsf{append}(p_e, \mathsf{append}(e, t_e))$.

For the left endpoint, transport the positive unary denominator witness across the displayed hsame link from $\mathsf{append}(p_d, \mathsf{append}(d, t_d))$ to $\mathsf{E0}(z)$. Then apply Definition 37.10 to rule out that zero-extension endpoint.

For the right endpoint, repeat the same transport across the displayed hsame link from $\mathsf{append}(p_e, \mathsf{append}(e, t_e))$ to $\mathsf{E0}(z')$. The positive-denominator zero-head absurdity theorem gives the second contradiction. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryClassifier unary context zero extension endpoint absurd`

The ten-field fit is: traditional target contextual positive-rational branch exclusion; BEDC source RatHistoryClassifier over BHist; carrier RatHistoryCarrier; classifier RatHistoryClassifier; stability from unary context closure and positive-denominator transport; ledger the hidden prefix and tail contexts; core theorem this block; exactness the two contradictions; downstream consumer FieldUp(RatUp) denominator continuation and RealUp stream-prefix readback; status ProofTarget.

Theorem 37.61 (Rat history classifier context one-tail pair readback)**.** *If a rational history classifier is closed under matching unary denominator prefixes and tails, and the resulting left and right endpoints display as one-extension histories, then the displayed tails are unary and internally the same.*

Proof. Apply rational history classifier unary denominator context closure to the original classified denominators and the matching unary contexts. Transport the closed classifier across the two displayed endpoint sameness witnesses, then use rational one-tail classifier exactness to read back the two unary tails and their hsame relation. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryClassifier unary context e1 pair readback`

Theorem 37.62 (Rat history classifier continuation context one-tail pair readback)**.** *If the matching unary denominator context is presented by continuation displays and the two outputs are one-extension histories, then their tails are unary and internally the same.*

Proof. Use the two continuation displays and append associativity to identify the outputs with the normal context endpoints, then apply Definition 37.61. □

Definition 37.64 (Rat ledger policy)**.** *Record the raw rational-history carrier and an* hsame *link to the visible denominator history.*

Lean4 (definition) `BEDC.Derived.RatUp.RatHistoryLedgerPolicy`

Theorem 37.65 (Rat ledger visible carrier)**.** *If a raw rational history satisfies the ledger policy for a visible history, then the visible history is itself a rational-history carrier.*

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy visible carrier`

Proof. Unpack the ledger policy into a raw rational-history carrier and an hsame link from the raw history to the visible history. Transport the raw carrier across that link. □

Theorem 37.66 (Rat ledger visible positive denominator readback)**.** *If* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *holds and* $\mathsf{hsame}(v, \mathsf{e1}(t))$ *holds, then* $\mathsf{UnaryHistory}(t)$ *holds.*

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy visible positive denominator readback`

Proof. The ledger visible-carrier theorem transports the raw rational-history carrier to v. Transport that carrier once more across $\mathsf{hsame}(v, \mathsf{e1}(t))$ and apply the one-extension rational-history carrier characterization. □

Theorem 37.67 (Rat ledger append unary denominator closure)**.** *If* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *holds,* $\mathsf{UnaryHistory}(t)$ *holds, and* $\mathsf{hsame}(t, t')$ *holds, then appending those unary denominator tails preserves the rational ledger:*

$$\mathsf{RatHistoryLedgerPolicy}(\mathsf{append}(\rho, t), \mathsf{append}(v, t')).$$

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy append unary denominator closed`

Proof. Unpack the ledger into a raw rational-history carrier and an $\mathsf{hsame}(\rho, v)$ link. The denominator-append carrier theorem closes the raw endpoint under the unary tail, and the two hsame links identify the appended raw and visible histories. □

Theorem 37.68 (Rat ledger prepend unary denominator closure)**.** *If* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *holds,* $\mathsf{UnaryHistory}(p)$ *holds, and* $\mathsf{hsame}(p, p')$ *holds, then prefixing those unary denominator histories preserves the rational ledger:*

$$\mathsf{RatHistoryLedgerPolicy}(\mathsf{append}(p, \rho), \mathsf{append}(p', v)).$$

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy prepend unary denominator closed`

Proof. Unpack the ledger into a raw rational-history carrier and an $\mathsf{hsame}(\rho, v)$ link. The denominator-prefix carrier theorem closes the raw endpoint under the unary prefix, and the two hsame links identify the prefixed raw and visible histories. □

Theorem 37.69 (Rat ledger unary denominator context closure)**.** *If* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *holds, unary prefixes* p, p' *satisfy* $\mathsf{hsame}(p, p')$*, and unary tails* t, t' *satisfy* $\mathsf{hsame}(t, t')$*, then placing the matching prefix and tail around the raw and visible denominator histories preserves the rational ledger:*

$$\mathsf{RatHistoryLedgerPolicy}(\mathsf{append}(p, \mathsf{append}(\rho, t)), \mathsf{append}(p', \mathsf{append}(v, t'))).$$

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy unary denominator context closed`

Proof. First apply rat ledger append unary denominator closure to the displayed ledger and the matching tails. Then apply rat ledger prepend unary denominator closure to the resulting ledger and the matching prefixes. □

Theorem 37.70 (Rat ledger unary context zero-extension endpoint exclusion)**.** *Let* $\rho, v, p, p', t, t', z, z' :$ BHist*. If* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *holds,* p, p' *are matched unary prefixes with* $\mathsf{hsame}(p, p')$*, and* t, t' *are matched unary tails with* $\mathsf{hsame}(t, t')$*, then the contextual raw and visible ledger endpoints cannot be zero-extension endpoints:*

$$(\mathsf{hsame}(\mathsf{append}(p, \mathsf{append}(\rho, t)), \mathsf{E0}(z)) \to \mathsf{False}) \wedge (\mathsf{hsame}(\mathsf{append}(p', \mathsf{append}(v, t')), \mathsf{E0}(z')) \to \mathsf{False}).$$

Proof. Apply rat ledger unary denominator context closure to obtain the contextual ledger. The raw-visible classifier theorem turns that ledger into a rational history classifier between the contextual raw and visible endpoints. Transport this classifier across a displayed zero-extension equality on either endpoint, then use rational history classifier zero-extension endpoint exclusion. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy unary context zero extension endpoint exclusion`

Theorem 37.71 (Rat ledger history-sameness transport)**.** *If a rational ledger relates raw and visible histories, then transporting the raw endpoint and the visible endpoint along* hsame *yields another rational ledger relation.*

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy hsame transport`

Proof. Unpack the ledger into a raw carrier and a raw-visible link. Transport the raw carrier across the raw-endpoint link, then compose the reversed raw transport link, the stored ledger link, and the visible-endpoint link. □

Theorem 37.72 (Rat ledger raw-visible classifier)**.** *If* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *holds, then* $\mathsf{RatHistoryClassifier}(\rho, v)$ *holds.*

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy raw visible classifier`

Proof. Unpack the ledger into the raw rational-history carrier for ρ and the stored $\mathsf{hsame}(\rho, v)$ link. The visible-carrier theorem supplies the rational-history carrier for v, and these witnesses form the raw-visible rational history classifier. □

Theorem 37.73 (Rat ledger shared-raw visible classifier)**.** *If both* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *and* $\mathsf{RatHistoryLedgerPolicy}(\rho, v')$ *hold, then* $\mathsf{RatHistoryClassifier}(v, v')$ *holds.*

Proof. Convert both rational ledger witnesses to raw-visible classifiers. Reverse the first classifier by rational classifier symmetry, then compose it with the second raw-visible classifier by rational classifier transitivity. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy shared raw visible classifier`

Theorem 37.74 (Rat ledger shared visible zero-extension exclusion)**.** *If both* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *and* $\mathsf{RatHistoryLedgerPolicy}(\rho, v')$ *hold, then neither visible denominator endpoint can be displayed as a zero-extension endpoint:*

$$(\mathsf{hsame}(v, \mathsf{E0}(z)) \to \mathsf{False}) \wedge (\mathsf{hsame}(v', \mathsf{E0}(z')) \to \mathsf{False}).$$

Proof. Use the shared-raw visible classifier to obtain $\mathsf{RatHistoryClassifier}(v, v')$. If v is displayed as $\mathsf{E0}(z)$, transport the left endpoint of this classifier to obtain a rational classifier with zero-extension source, which contradicts rational classifier zero-extension endpoint exclusion. The visible endpoint v' is identical: transport the right endpoint to $\mathsf{E0}(z')$ and apply the right branch of the same exclusion theorem. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy shared visible e0 endpoint absurd`

Theorem 37.75 (Rat ledger shared-raw contextual visible classifier)**.** *If both* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *and* $\mathsf{RatHistoryLedgerPolicy}(\rho, v')$ *hold, unary prefixes* $p, p_v, p_{v'}$ *satisfy* $\mathsf{hsame}(p, p_v)$ *and* $\mathsf{hsame}(p, p_{v'})$*, and unary tails* $t, t_v, t_{v'}$ *satisfy* $\mathsf{hsame}(t, t_v)$ *and* $\mathsf{hsame}(t, t_{v'})$*, then the contextual visible denominator endpoints are classified:*

$$\mathsf{RatHistoryClassifier}(\mathsf{append}(p_v, \mathsf{append}(v, t_v)), \mathsf{append}(p_{v'}, \mathsf{append}(v', t_{v'}))).$$

Proof. Apply Definition 37.69 to the first ledger with the raw context p, t and the visible context p_v, t_v. This produces a ledger from the shared raw contextual endpoint $\mathsf{append}(p, \mathsf{append}(\rho, t))$ to the first contextual visible endpoint.

Apply the same context-closure theorem to the second ledger with the same raw context p, t and the visible context $p_{v'}, t_{v'}$. The two contextual ledger witnesses now share the raw endpoint $\mathsf{append}(p, \mathsf{append}(\rho, t))$.

Finally apply Definition 37.73 to those two contextual ledger witnesses. Its conclusion is exactly the displayed classifier between the two contextual visible denominator endpoints. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy shared raw contextual visible classifier`
Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy shared raw context visible classifier`

Theorem 37.76 (Rat ledger shared-raw contextual visible endpoint equivalence)**.** *If both* $\mathsf{RatHistoryLedgerPolicy}(\rho,$ *and* $\mathsf{RatHistoryLedgerPolicy}(\rho, v')$ *hold, unary prefixes* $p, p_v, p_{v'}$ *satisfy* $\mathsf{hsame}(p, p_v)$ *and* $\mathsf{hsame}(p, p_{v'})$*, and unary tails* $t, t_v, t_{v'}$ *satisfy* $\mathsf{hsame}(t, t_v)$ *and* $\mathsf{hsame}(t, t_{v'})$*, then every target history* w *sees the same classifier fiber over the two contextual visible denominator endpoints:*

$$\mathsf{RatHistoryClassifier}(\mathsf{append}(p_v, \mathsf{append}(v, t_v)), w) \iff \mathsf{RatHistoryClassifier}(\mathsf{append}(p_{v'}, \mathsf{append}(v', t_{v'})), w).$$

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy shared raw context visible endpoint equivalence`

Proof. Apply Definition 37.75 to the two ledger witnesses and the matching unary prefix and tail hypotheses. This gives the classifier edge from $\mathsf{append}(p_v, \mathsf{append}(v, t_v))$ to $\mathsf{append}(p_{v'}, \mathsf{append}(v', t_{v'}))$.

For the forward direction, assume the left contextual visible endpoint is classified with w. Reverse the contextual endpoint edge by rational classifier symmetry, then compose it with the left-endpoint-to-w classifier by transitivity. The result is the right-endpoint-to-w classifier.

For the reverse direction, assume the right contextual visible endpoint is classified with w. Compose the contextual endpoint edge itself with the right-endpoint-to-w classifier by transitivity. The result is the left-endpoint-to-w classifier. □

Theorem 37.77 (Rat ledger shared-raw context one-tail readback)**.** *If both* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *and* $\mathsf{RatHistoryLedgerPolicy}(\rho, v')$ *hold, unary prefixes* $p, p_v, p_{v'}$ *satisfy* $\mathsf{hsame}(p, p_v)$ *and* $\mathsf{hsame}(p, p_{v'})$*, unary tails* $t, t_v, t_{v'}$ *satisfy* $\mathsf{hsame}(t, t_v)$ *and* $\mathsf{hsame}(t, t_{v'})$*, and the two contextual visible endpoints display as one-extension histories,*

$$\mathsf{hsame}(\mathsf{append}(p_v, \mathsf{append}(v, t_v)), \mathsf{E1}(a)) \quad \textit{and} \quad \mathsf{hsame}(\mathsf{append}(p_{v'}, \mathsf{append}(v', t_{v'})), \mathsf{E1}(b)),$$

then the displayed tails are unary and internally the same:

$$\mathsf{Unary}(a) \wedge \mathsf{Unary}(b) \wedge \mathsf{hsame}(a, b).$$

Its ten-field fit is: traditional target shared-denominator visible-tail determinacy; BEDC source $\mathsf{Rat}^{\uparrow}$ *ledger over* BHist*; carrier positive unary denominators; classifier* $\mathsf{RatHistoryClassifier}$*; stability from unary context closure and classifier transport; ledger the shared raw denominator plus two visible contexts; core theorem this block; exactness the displayed tail readback; standard bridge normalized denominator readback; status* $\mathsf{ProofTarget}$*.*

Proof. First invoke Definition 37.75 with the two ledger witnesses and the matching raw-to-visible unary contexts. This gives the rational history classifier between the two contextual visible endpoints.

Then apply Definition 37.61 to that classifier and to the two displayed one-extension witnesses. The readback conclusion is exactly $\mathsf{Unary}(a) \wedge \mathsf{Unary}(b) \wedge \mathsf{hsame}(a, b)$. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy shared raw context e1 pair readback`

Theorem 37.78 (Rat ledger classifier extension)**.** *If* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *holds and* $\mathsf{RatHistoryClassifier}(v, t)$ *holds, then* $\mathsf{RatHistoryClassifier}(\rho, t)$ *holds.*

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy classifier extension`

Proof. Convert the raw-visible ledger into the raw-visible classifier, then compose it with the visible-target classifier by transitivity. □

Theorem 37.79 (Rat history ledger classifier endpoint equivalence)**.** *If* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *holds, then every target history* w *is classified from* ρ *exactly when it is classified from* v*:*

$$\mathsf{RatHistoryClassifier}(\rho, w) \leftrightarrow \mathsf{RatHistoryClassifier}(v, w).$$

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy classifier endpoint equivalence`

Proof. The ledger supplies the raw-visible rational classifier. For the raw-to-visible direction, reverse that classifier by symmetry and compose it with the raw-target classifier by transitivity. The visible-to-raw direction is the ledger classifier extension theorem. □

Theorem 37.80 (Rat history ledger displayed context classifier endpoint equivalence)**.** *If* $\mathsf{RatHistoryLedgerPolicy}(\rho,$ *holds, unary prefixes* p_ρ, p_v *satisfy* $\mathsf{hsame}(p_\rho, p_v)$*, unary tails* t_ρ, t_v *satisfy* $\mathsf{hsame}(t_\rho, t_v)$*, and the displayed continuation witnesses* $\mathsf{Cont}(p_\rho, \rho, m_\rho)$*,* $\mathsf{Cont}(m_\rho, t_\rho, out_\rho)$*,* $\mathsf{Cont}(p_v, v, m_v)$*, and* $\mathsf{Cont}(m_v, t_v, out_v)$ *expose the two contextual endpoints, then every target history* w *is classified from the displayed raw endpoint exactly when it is classified from the displayed visible endpoint:*

$$\mathsf{RatHistoryClassifier}(out_\rho, w) \leftrightarrow \mathsf{RatHistoryClassifier}(out_v, w).$$

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy cont unary context classifier endpoint equivalence`

Proof. First close the ledger under the matching unary denominator context. Apply Definition 37.69 to the original ledger, the prefix match, and the tail match. This gives a ledger between $\mathsf{append}(p_\rho, \mathsf{append}(\rho, t_\rho))$ and $\mathsf{append}(p_v, \mathsf{append}(v, t_v))$.

The four continuation witnesses identify the displayed endpoints with those normalized append endpoints. Associativity of append turns the two-step displays through m_ρ and m_v into hsame links from out_ρ and out_v to the corresponding normalized contextual histories.

Transport the contextual ledger across these two endpoint identifications by Definition 37.71. The transported ledger now relates out_ρ and out_v directly.

Finally apply Definition 37.79 to the transported ledger. Its conclusion is the displayed classifier endpoint equivalence for every target history w. □

Theorem 37.81 (Rat history ledger displayed context positive denominators)**.** *If* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *holds, unary prefixes* p_ρ, p_v *satisfy* $\mathsf{hsame}(p_\rho, p_v)$*, unary tails* t_ρ, t_v *satisfy* $\mathsf{hsame}(t_\rho, t_v)$*, and the displayed continuations* $\mathsf{Cont}(p_\rho, \rho, m_\rho)$*,* $\mathsf{Cont}(m_\rho, t_\rho, out_\rho)$*,* $\mathsf{Cont}(p_v, v, m_v)$*, and* $\mathsf{Cont}(m_v, t_v, out_v)$ *expose the contextual endpoints, then*

$$\mathsf{PositiveUnaryDenominator}(out_\rho) \wedge \mathsf{PositiveUnaryDenominator}(out_v).$$

Proof. Close the ledger under matching unary denominator context by applying Definition 37.69 to the original ledger, the prefix match, and the tail match. This gives a ledger between the two normalized histories $\mathsf{append}(p_\rho, \mathsf{append}(\rho, t_\rho))$ and $\mathsf{append}(p_v, \mathsf{append}(v, t_v))$.

The four continuation witnesses identify out_ρ and out_v with the two displayed two-step continuations through m_ρ and m_v. Associativity of append turns those two displays into hsame links from the normalized contextual histories to the displayed outputs.

Transport the contextual ledger across these two endpoint identifications by Definition 37.71. The resulting ledger relates out_ρ and out_v directly.

Finally read the raw and visible carrier witnesses from the displayed ledger. The carrier equivalence for rational histories gives $\mathsf{PositiveUnaryDenominator}(out_\rho)$, and the visible-carrier projection gives $\mathsf{PositiveUnaryDenominator}(out_v)$. □

↪ variant `BEDC.Derived.RatUp.RatHistoryLedgerPolicy cont unary context positive denominators`

Theorem 37.82 (Rat ledger displayed context zero-endpoint exclusion)**.** *If* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *holds, unary prefixes* p_ρ, p_v *satisfy* $\mathsf{hsame}(p_\rho, p_v)$*, unary tails* t_ρ, t_v *satisfy* $\mathsf{hsame}(t_\rho, t_v)$*, and the displayed continuations* $\mathsf{Cont}(p_\rho, \rho, m_\rho)$*,* $\mathsf{Cont}(m_\rho, t_\rho, out_\rho)$*,* $\mathsf{Cont}(p_v, v, m_v)$*, and* $\mathsf{Cont}(m_v, t_v, out_v)$ *expose the contextual endpoints, then neither displayed endpoint can be a zero-extension endpoint:*

$$(\mathsf{hsame}(out_\rho, \mathsf{E0}(z_\rho)) \to \mathsf{False}) \wedge (\mathsf{hsame}(out_v, \mathsf{E0}(z_v)) \to \mathsf{False}).$$

Proof. Apply Definition 37.81 to the displayed contextual ledger data. This gives positive unary denominator witnesses for both out_ρ and out_v.

If out_ρ is displayed as $\mathsf{E0}(z_\rho)$, transport the positive denominator witness along that hsame link and contradict Definition 37.10. The visible endpoint out_v is identical: transport its positive denominator witness along $\mathsf{hsame}(out_v, \mathsf{E0}(z_v))$ and use the same zero-extension exclusion. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy cont unary context e0 endpoint absurd`

Theorem 37.83 (Rat ledger displayed context empty-endpoint exclusion)**.** *If* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *holds, unary prefixes* p_ρ, p_v *satisfy* $\mathsf{hsame}(p_\rho, p_v)$*, unary tails* t_ρ, t_v *satisfy* $\mathsf{hsame}(t_\rho, t_v)$*, and the displayed continuations* $\mathsf{Cont}(p_\rho, \rho, m_\rho)$*,* $\mathsf{Cont}(m_\rho, t_\rho, out_\rho)$*,* $\mathsf{Cont}(p_v, v, m_v)$*, and* $\mathsf{Cont}(m_v, t_v, out_v)$ *expose the contextual endpoints, then neither displayed endpoint can be internally the empty history:*

$$(\mathsf{hsame}(out_\rho, \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(out_v, \mathsf{e}) \to \mathsf{False}).$$

Proof. Apply Definition 37.81 to the displayed contextual ledger data. This gives positive unary denominator witnesses for both out_ρ and out_v.

A positive unary denominator is never internally the empty endpoint. Applying that nonempty denominator theorem to each of the two positive witnesses gives the two displayed contradictions. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy cont unary context empty endpoint absurd`

Definition 37.84 ($\mathsf{Rat}^\uparrow$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{Rat}^\uparrow$*.*

Theorem 37.85 (Concrete $\mathsf{Rat}^\uparrow$ naming certificate)**.** *The rational-history carrier/classifier tuple forms a valid semantic naming certificate for* $\mathsf{Rat}^\uparrow$ *at the history level.*

↪ variant `BEDC.Derived.RatUp.rat history semantic name certificate`

Theorem 37.86 (Rat ledger shared-raw contextual zero-extension endpoint exclusion)**.** *Let* $\rho, v, v', p, p_v, p_{v'}, t, t_v, t_{v'}$ BHist*. If* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *and* $\mathsf{RatHistoryLedgerPolicy}(\rho, v')$ *hold, the unary prefixes* $p, p_v, p_{v'}$ *satisfy*

$$\mathsf{hsame}(p, p_v) \wedge \mathsf{hsame}(p, p_{v'}),$$

and the unary tails $t, t_v, t_{v'}$ *satisfy*

$$\mathsf{hsame}(t, t_v) \wedge \mathsf{hsame}(t, t_{v'}),$$

then for all $z, z' : \mathsf{BHist}$ *both contextual visible denominator endpoints are excluded from zero-extension heads:*

$$(\mathsf{hsame}(\mathsf{append}(p_v, \mathsf{append}(v, t_v)), \mathsf{E0}(z)) \to \mathsf{False}) \wedge (\mathsf{hsame}(\mathsf{append}(p_{v'}, \mathsf{append}(v', t_{v'})), \mathsf{E0}(z')) \to \mathsf{False}).$$

The ten-field fit is: traditional target RatUp ledger shared-denominator zero-branch exclusion; BEDC source BHist *plus* $\mathsf{RatHistoryLedgerPolicy}$*; carrier* $\mathsf{RatHistoryCarrier}$*; classifier* $\mathsf{RatHistoryClassifier}$*; stability from shared raw denominator and context transport; ledger shared raw denominator and context data; core theorem this block; exactness the two contradictions; downstream consumers* RealUp *denominator-context readback and* $\mathsf{FieldUp}$ *denominator continuation; status* $\mathsf{ProofTarget}$*.*

Proof. First invoke Definition 37.75 with the two ledger witnesses and the displayed prefix and tail hsame links. This gives the classifier edge between $\mathsf{append}(p_v, \mathsf{append}(v, t_v))$ and $\mathsf{append}(p_{v'}, \mathsf{append}(v', t_{v'}))$.

For a proposed zero-extension on the first contextual visible endpoint, transport the first classifier endpoint along its displayed hsame link to $\mathsf{E0}(z)$. The transported classifier has a zero-extension left endpoint, so Definition 37.52 gives the contradiction.

For a proposed zero-extension on the second contextual visible endpoint, transport the second classifier endpoint along its displayed hsame link to $\mathsf{E0}(z')$. The transported classifier has a zero-extension right endpoint, and the same endpoint-exclusion theorem gives the second contradiction. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy shared raw contextual zero extension endpoint exclusion`

Corollary 37.87 ($\mathsf{Rat}^{\uparrow}$ is licensed, not primitive)**.** $\mathsf{Rat}^{\uparrow}$ *is licensed by normalized representatives, not by a quotient of pairs.*

Primitive boundary. $\mathsf{Rat}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Remark 37.88 (Zero-axiom encoding note)**.** *Canonical normalization supplies the zero-axiom encoding without quotient equivalence or* Quot.sound*.*

Theorem 37.89 (Rat representative classifier stability package)**.** *Fix a rational source normalizer* $\mathsf{normalized} : \mathsf{BMark} \to \mathsf{BHist} \to \mathsf{BHist} \to \mathsf{Prop}$*. For every representative triple* s, n, d *with* $\mathsf{RatSourceSpec}(\mathsf{normalized}, s, n, d)$*, the row* RatSourceSpec_to_RatCarrier *supplies the representative carrier* $\mathsf{RatCarrier}(s, n, d)$*.*

On such representatives the classifier RatClassifierSpec *is stable in the following sense:*

1. RatClassifierSpec *is reflexive on every representative carrier.*
2. RatClassifierSpec *is symmetric on classified representative pairs.*
3. RatClassifierSpec *is transitive along composable representative pairs.*
4. *If signs are related by* msame *and numerator and denominator histories are related by* hsame*, then each classified representative pair transports componentwise to the displayed representatives.*

Thus the representative classifier used by the $\mathsf{Rat}^{\uparrow}$ *name certificate is an equivalence relation on normalized representatives and is stable under the BEDC component sameness relations for signs, numerators, and denominators.*

Proof. Start with a representative source witness $\mathsf{RatSourceSpec}(\mathsf{normalized}, s, n, d)$. The checked row RatSourceSpec_to_RatCarrier converts it into the carrier witness needed by the representative classifier.

The equivalence portion is supplied by three checked rows. Apply RatClassifierSpec_refl to a representative carrier for reflexivity, apply RatClassifierSpec_symm to reverse any classified representative pair, and apply RatClassifierSpec_trans to compose two adjacent classified representative pairs.

For component stability, use RatClassifierSpec_component_transport. Its hypotheses are exactly the displayed msame links on the two signs and the displayed hsame links on the two numerator histories and the two denominator histories, so it moves the classifier edge to the transported representative data.

The statement therefore packages the representative carrier conversion, the three equivalence laws, and component transport as one certificate layer. It records the combined representative-level stability supplied by several checked rows rather than restating any single row. □

Lean4 ✓ `BEDC.Derived.RatUp.RatClassifierSpec representative stability package`

Theorem 37.90 (Rat history semantic name certificate)**.** *The Rat history carrier with its history classifier supplies the semantic name certificate*

$$\mathsf{SemanticNameCert}(\mathsf{RatHistoryCarrier}, \mathsf{RatHistoryCarrier}, \mathsf{RatHistoryCarrier}, \mathsf{RatHistoryClassifier}).$$

Proof. The carrier is inhabited by the one-extension of the empty denominator tail. This is the positive unary denominator witness used by the checked core.

For the core certificate relation, reflexivity is the self-classifier supplied by carrier membership and hsame reflexivity. Symmetry reverses the hsame component of a classifier witness. Transitivity composes the two hsame components and uses carrier transport along hsame to recover the right endpoint carrier. The same carrier transport gives respect of the carrier under a classifier edge.

The semantic source, pattern, and ledger rows are all RatHistoryCarrier. Hence the source-to-pattern and source-to-ledger clauses are identity rows: each source witness is reused unchanged as the pattern witness and as the ledger witness. These are exactly the rows assembled by the Lean theorem. □

Lean4 ✓ `BEDC.Derived.RatUp.rat history semantic name certificate`

The positive-denominator ledger consumes the NatUp unary carrier of chapter 28 together with the signed-pair context supplied by chapter 31. These sibling chapters provide the unary denominator row and the signed numerator and denominator pair surface used by the following ledger readback theorem.

Theorem 37.91 (Rat history ledger displayed context one-tail readback)**.** *For histories* $\rho, v, p_\rho, p_v, t_\rho, t_v, m_\rho, m_v, ou$ BHist*, assume* RatHistoryLedgerPolicy(ρ, v)*, unary prefix and tail hypotheses with* hsame(p_ρ, p_v) *and* hsame(t_ρ, t_v)*, the four continuation displays* Cont(p_ρ, ρ, m_ρ)*,* Cont$(m_\rho, t_\rho, out_\rho)$*,* Cont$(p_v, v, m_v)$*, and* Cont$(m_v, t_v, out_v)$*, and endpoint displays* hsame$(out_\rho, \mathsf{E1}(a))$ *and* hsame$(out_v, \mathsf{E1}(b))$*. Then*

$$\mathsf{Unary}(a) \wedge \mathsf{Unary}(b) \wedge \mathsf{hsame}(a, b).$$

Its ten-field fit is: traditional target displayed rational-denominator one-tail readback; BEDC source $\mathsf{Rat}^{\uparrow}$ *ledger with* Cont *displays; carrier positive unary denominators; classifier* RatHistoryClassifier*; stability from contextual ledger transport and classifier endpoint transport; ledger hidden raw/visible denominator contexts; core theorem this block; exactness the displayed tail readback; standard bridge normalized denominator tail equality; status* ProofTarget*.*

Proof. Apply Definition 37.81 to the ledger witness, the matching unary prefix and tail hypotheses, and the four continuation displays. The visible output out_v is therefore a positive unary denominator, so it carries the self-classifier RatHistoryClassifier(out_v, out_v).

Next apply Definition 37.80 with target out_v. The visible self-classifier transports through the displayed contextual ledger endpoint equivalence and gives RatHistoryClassifier(out_ρ, out_v).

Use Definition 37.54 with the two endpoint displays hsame$(out_\rho, \mathsf{E1}(a))$ and hsame$(out_v, \mathsf{E1}(b))$. This converts the displayed endpoint classifier into RatHistoryClassifier$(\mathsf{E1}(a), \mathsf{E1}(b))$.

Finally apply Definition 37.49 in the forward direction. The one-tail classifier exactness theorem reads back exactly $\mathsf{Unary}(a) \wedge \mathsf{Unary}(b) \wedge \mathsf{hsame}(a, b)$. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy cont unary context e1 pair readback`

Theorem 37.92 (Rat ledger visible-target lift with positive endpoints)**.** *For histories* ρ, v, w : BHist*, if* RatHistoryLedgerPolicy(ρ, v) *and* RatHistoryClassifier(v, w) *hold, then*

$$\mathsf{RatHistoryClassifier}(\rho, w) \wedge \mathsf{PositiveUnaryDenominator}(\rho) \wedge \mathsf{PositiveUnaryDenominator}(v) \wedge \mathsf{PositiveUnaryDenominator}(u$$

Its ten-field fit is: traditional target ledger-stable rational target readback; BEDC source $\mathsf{Rat}^{\uparrow}$ *over* BHist*; carrier* RatHistoryCarrier*; classifier* RatHistoryClassifier*; stability visible-target classification lifted through the ledger; ledger* RatHistoryLedgerPolicy*; core theorem this block; exactness the displayed lifted classifier plus positive endpoint readback; downstream consumer the* $\mathsf{Rat}^{\uparrow}$ *semantic certificate boundary; status* ProofTarget*.*

Proof. Apply Definition 37.78 to the ledger witness and the visible-target classifier. This lifts the classifier from the visible endpoint v to the raw endpoint ρ, giving $\mathsf{RatHistoryClassifier}(\rho, w)$.

Next apply Definition 37.50 to the lifted classifier. This supplies positive unary denominator witnesses for ρ and w.

For the visible endpoint, apply Definition 37.65 to the original ledger witness. This gives $\mathsf{RatHistoryCarrier}(v)$.

Then use the forward direction of Definition 37.19 to obtain $\mathsf{PositiveUnaryDenominator}(v)$. The lifted classifier and the three positive-denominator witnesses assemble the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy visible target lift positive endpoints`

Theorem 37.93 (Rat ledger visible-target one-tail pair readback)**.** *For histories* ρ, v, w, a, b : BHist*, if* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$*,* $\mathsf{RatHistoryClassifier}(v, w)$*,* $\mathsf{hsame}(\rho, \mathsf{E1}(a))$*, and* $\mathsf{hsame}(w, \mathsf{E1}(b))$ *hold, then*

$$\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).$$

Proof. Lift the visible-target classifier through the raw-visible ledger to obtain $\mathsf{RatHistoryClassifier}(\rho, w)$. Transport this classifier across the two displayed one-extension endpoint equalities, producing $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$. Rational one-tail classifier exactness reads back the two unary tails and their internal sameness. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy visible target e1 pair readback`

Theorem 37.94 (Rat ledger visible-target positive nonempty package)**.** *For histories* ρ, v, w : BHist*, if* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *and* $\mathsf{RatHistoryClassifier}(v, w)$ *hold, then*

$$\begin{aligned}&\mathsf{PositiveUnaryDenominator}(\rho) \wedge \mathsf{PositiveUnaryDenominator}(v) \wedge \mathsf{PositiveUnaryDenominator}(w)\\ &\wedge (\mathsf{hsame}(\rho, \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(v, \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(w, \mathsf{e}) \to \mathsf{False}).\end{aligned}$$

Proof. Lift the visible-target classifier through the ledger to obtain $\mathsf{RatHistoryClassifier}(\rho, w)$. Positive-denominator readback from this lifted classifier gives the witnesses for ρ and w, while positive-denominator readback from the visible-target classifier gives the witness for v. Applying positive-denominator unary-and-nonempty readback to the three witnesses supplies the three displayed empty-endpoint exclusions. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy visible target positive nonempty package`

Theorem 37.95 (Rat ledger two-sided endpoint classifier equivalence)**.** *For histories* ρ, v, w : BHist*, if* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *holds, then*

$$(\mathsf{RatHistoryClassifier}(\rho, w) \iff \mathsf{RatHistoryClassifier}(v, w)) \wedge (\mathsf{RatHistoryClassifier}(w, \rho) \iff \mathsf{RatHistoryClassifier}(w, v))$$

Its ten-field fit is: traditional target two-sided $\mathsf{Rat}^{\uparrow}$ *ledger endpoint classifier exactness with conditional endpoint readback; BEDC source* $\mathsf{Rat}^{\uparrow}$ *ledger over* BHist*; carrier* $\mathsf{RatHistoryCarrier}$*; classifier* $\mathsf{RatHistoryClassifier}$*; stability from ledger endpoint equivalence, classifier symmetry, and classifier positive-denominator readback; ledger* $\mathsf{RatHistoryLedgerPolicy}$*; core theorem this block; exactness the two iff rows plus conditional* w*-readback; downstream consumer the* $\mathsf{Rat}^{\uparrow}$ *semantic certificate boundary and* $\mathsf{Real}^{\uparrow}$ *rational observation streams; status* $\mathsf{ProofTarget}$*.*

Proof. Apply Definition 37.79 to the ledger witness. This gives the classifier endpoint equivalence from ρ and from v toward every target history w.

For the reversed-argument equivalence, use Definition 37.55 on both sides. A classifier witness from w to ρ becomes one from ρ to w, crosses the endpoint equivalence just obtained, and is then reversed to a classifier witness from w to v. The converse direction is the same argument with v and ρ exchanged.

Finally apply Definition 37.72 to the ledger witness, obtaining $\mathsf{RatHistoryClassifier}(\rho, v)$. Applying Definition 37.50 to that classifier supplies the positive unary denominator witnesses for ρ and v.

For the first conditional w-readback, apply Definition 37.50 to a witness of $\mathsf{RatHistoryClassifier}(v, w)$ and project the right endpoint. This gives $\mathsf{PositiveUnaryDenominator}(w)$ under the visible-target classifier hypothesis.

For the second conditional w-readback, apply the same theorem to a witness of $\mathsf{RatHistoryClassifier}(w, v)$ and project the left endpoint. This gives $\mathsf{PositiveUnaryDenominator}(w)$ under the reversed visible-endpoint classifier hypothesis.

The two equivalences, the positive ρ and v endpoint witnesses, and the two implication rows assemble the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy two sided endpoint classifier equivalence`

Theorem 37.96 (Rat ledger one-tail classifier saturation)**.** *For histories* $\rho, v, t : \mathsf{BHist}$*, if* $\mathsf{RatHistoryLedgerPolicy}(\rho,$ *holds, then*

$$(\mathsf{RatHistoryClassifier}(\rho, \mathsf{E1}(t)) \iff \mathsf{RatHistoryClassifier}(v, \mathsf{E1}(t)))\wedge(\mathsf{RatHistoryClassifier}(\mathsf{E1}(t), \rho) \iff \mathsf{RatHistoryClass}$$

Its ten-field fit is: traditional target rational ledger one-tail readback; BEDC source $\mathsf{Rat}^{\uparrow}$ *ledger over* BHist*; carrier* $\mathsf{RatHistoryCarrier}$*; classifier* $\mathsf{RatHistoryClassifier}$*; stability from ledger endpoint classifier equivalence and one-extension denominator readback; ledger raw-visible denominator edge; core theorem this block; exactness the two displayed iff rows plus tail readback; downstream consumers* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *denominator rows and* $\mathsf{Real}^{\uparrow}$ *rational observation streams; status* $\mathsf{ProofTarget}$*.*

Proof. Apply Definition 37.95 with $w = \mathsf{E1}(t)$. Project the forward one-tail classifier row, the reversed one-tail classifier row, and the positive-denominator witnesses for ρ and v.

For the visible target orientation, assume $\mathsf{RatHistoryClassifier}(v, \mathsf{E1}(t))$. The same two-sided endpoint package gives $\mathsf{PositiveUnaryDenominator}(\mathsf{E1}(t))$ under this hypothesis.

Apply Definition 37.7 to the conditional positive denominator for $\mathsf{E1}(t)$. This reads back the tail witness $\mathsf{Unary}(t)$.

For the visible source orientation, assume $\mathsf{RatHistoryClassifier}(\mathsf{E1}(t), v)$. Project the opposite conditional positive-denominator row from the same endpoint package and apply Definition 37.7 again to obtain $\mathsf{Unary}(t)$.

The two classifier equivalences, the two endpoint denominator witnesses, and the two one-tail readback implications assemble the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy e1 tail classifier saturation`
Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy one tail classifier saturation`

Theorem 37.97 (Rat ledger bidirectional target-positive endpoint package)**.** *For histories* $\rho, v, w :$ BHist*, if* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *holds, then*

$$(\mathsf{RatHistoryClassifier}(\rho, w) \iff \mathsf{RatHistoryClassifier}(v, w))\wedge(\mathsf{RatHistoryClassifier}(w, \rho) \iff \mathsf{RatHistoryClassifier}(w, v))$$

Its ten-field fit is: traditional target rational ledger bidirectional endpoint package; BEDC source $\mathsf{Rat}^{\uparrow}$ *ledger over* BHist*; carrier* $\mathsf{RatHistoryCarrier}$*; classifier* $\mathsf{RatHistoryClassifier}$*; stability from ledger classifier extension plus classifier symmetry and transitivity; ledger the raw/visible denominator edge; core theorem this block; exactness the two displayed fibers plus positivity; downstream consumer* $\mathsf{Real}^{\uparrow}$ *stream-prefix and the* $\mathsf{Rat}^{\uparrow}$ *semantic certificate boundary; status* $\mathsf{ProofTarget}$.

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy bidirectional target positive endpoint package`

Proof. Apply Definition 37.79 to the ledger witness. This gives the forward-orientation classifier fiber between ρ and v at the common target w.

For the reversed-argument fiber, apply Definition 37.55 before and after the forward fiber. A witness $\mathsf{RatHistoryClassifier}(w, \rho)$ becomes a witness from ρ to w, crosses the endpoint equivalence, and reverses to a witness from w to v; the converse direction follows by the same symmetric transport.

It remains to package endpoint positivity. Assume $\mathsf{RatHistoryClassifier}(v, w)$. Apply Definition 37.78 to the ledger witness and this visible-target classifier, obtaining $\mathsf{RatHistoryClassifier}(\rho, w)$.

Apply Definition 37.50 to the lifted raw-target classifier for the ρ and w witnesses, and apply the same positive-denominator theorem to the original visible-target classifier for the v and w witnesses. These assemble the first implication.

For $\mathsf{RatHistoryClassifier}(w, v)$, first reverse it by Definition 37.55. The resulting $\mathsf{RatHistoryClassifier}(v, w)$ case is exactly the positivity package just constructed, so the second implication follows. □

Theorem 37.98 (Rat ledger classifier saturation unary package)**.** *For histories* $\rho, v, w : \mathsf{BHist}$*, assume* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *and at least one of* $\mathsf{RatHistoryClassifier}(\rho, w)$*,* $\mathsf{RatHistoryClassifier}(v, w)$*,* $\mathsf{RatHistoryClassifier}(w, \rho)$*, or* $\mathsf{RatHistoryClassifier}(w, v)$*. Then*

$$\mathsf{RatHistoryClassifier}(\rho, w) \wedge \mathsf{RatHistoryClassifier}(v, w) \wedge \mathsf{RatHistoryClassifier}(w, \rho) \wedge \mathsf{RatHistoryClassifier}(w, v) \wedge \mathsf{PositiveUr}$$

Its ten-field fit is: traditional target ledger-saturated rational classifier endpoint package; BEDC source $\mathsf{Rat}^{\uparrow}$ *over* BHist*; carrier* $\mathsf{RatHistoryCarrier}$*; classifier* $\mathsf{RatHistoryClassifier}$*; stability from classifier symmetry/transitivity and ledger endpoint equivalence; ledger* $\mathsf{RatHistoryLedgerPolicy}$*; core theorem this block; exactness the four-orientation saturated package plus unary endpoint readback; downstream consumer the* $\mathsf{Rat}^{\uparrow}$ *semantic certificate boundary and* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *denominator-unit rows; status* $\mathsf{ProofTarget}$.

Proof. First apply Definition 37.95 to the ledger witness. This gives the forward endpoint equivalence $\mathsf{RatHistoryClassifier}(\rho, w) \iff \mathsf{RatHistoryClassifier}(v, w)$, the reversed endpoint equivalence $\mathsf{RatHistoryClassifier}(w, \rho) \iff \mathsf{RatHistoryClassifier}(w, v)$.

For the ledger endpoint denominators, apply Definition 37.72 to the ledger witness and then Definition 37.50 to the obtained $\mathsf{RatHistoryClassifier}(\rho, v)$. This supplies positive unary denominator witnesses for ρ and v.

It remains to turn the supplied orientation into a single classifier involving w and one ledger endpoint. If the supplied classifier is $\mathsf{RatHistoryClassifier}(\rho, w)$, transport it across the forward endpoint equivalence to obtain $\mathsf{RatHistoryClassifier}(v, w)$, and apply Definition 37.55 to obtain both reversed orientations.

If the supplied classifier is $\mathsf{RatHistoryClassifier}(v, w)$, transport it back across the same endpoint equivalence to obtain $\mathsf{RatHistoryClassifier}(\rho, w)$, and again apply Definition 37.55 to obtain the two reversed orientations.

If the supplied classifier is $\mathsf{RatHistoryClassifier}(w, \rho)$, transport it across the reversed endpoint equivalence to obtain $\mathsf{RatHistoryClassifier}(w, v)$, and apply Definition 37.55 to obtain the two forward orientations.

If the supplied classifier is $\mathsf{RatHistoryClassifier}(w, v)$, transport it back across the reversed endpoint equivalence to obtain $\mathsf{RatHistoryClassifier}(w, \rho)$, and apply Definition 37.55 to obtain the two forward orientations.

In every case one of the assembled classifiers has w as an endpoint. Apply Definition 37.50 to that classifier to obtain $\mathsf{PositiveUnaryDenominator}(w)$, keeping the ledger endpoint witnesses for ρ and v. Apply Definition 37.12 to each of the three positive denominator witnesses and project the unary row. The four classifiers, three positive unary denominator witnesses, and three unary endpoint rows assemble the displayed package. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy classifier saturation unary package`

Theorem 37.99 (Rat ledger visible-target zero-extension exclusion)**.** *For histories* $\rho, v, w, z, z' :$ BHist*, if* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *and* $\mathsf{RatHistoryClassifier}(v, w)$ *hold, then*

$$(\mathsf{hsame}(\rho, \mathsf{E0}(z)) \to \mathsf{False}) \wedge (\mathsf{hsame}(w, \mathsf{E0}(z')) \to \mathsf{False}).$$

Its ten-field fit is: traditional target $\mathsf{Rat}^{\uparrow}$ *ledger visible-target zero-branch exclusion; BEDC source* $\mathsf{RatHistoryLedgerPolicy}$ *and* $\mathsf{RatHistoryClassifier}$*; carrier* $\mathsf{RatHistoryCarrier}$*; classifier* $\mathsf{RatHistoryClassifier}$*; stability by ledger classifier extension and classifier endpoint transport; ledger the raw-visible edge; core theorem this block; exactness the two contradictions; downstream consumers* $\mathsf{Field}^{\uparrow}$ *denominator continuation and* $\mathsf{Real}^{\uparrow}$ *stream-prefix readback; status* $\mathsf{ProofTarget}$*.*

Proof. Apply Definition 37.92 to the ledger witness and the visible-target classifier. Its first component gives $\mathsf{RatHistoryClassifier}(\rho, w)$, the classifier whose endpoints are the raw denominator and the target denominator.

Suppose first that $\mathsf{hsame}(\rho, \mathsf{E0}(z))$ holds. Transport the lifted classifier along this endpoint equality to obtain $\mathsf{RatHistoryClassifier}(\mathsf{E0}(z), w)$. The left branch of Definition 37.52 rules out that classifier, giving the first contradiction.

Suppose next that $\mathsf{hsame}(w, \mathsf{E0}(z'))$ holds. Transport the same lifted classifier along the target endpoint equality to obtain $\mathsf{RatHistoryClassifier}(\rho, \mathsf{E0}(z'))$. The right branch of Definition 37.52 rules out that classifier, giving the second contradiction. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy visible target zero extension exclusion`
Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy visible target e0 endpoint absurd`

Theorem 37.100 (Rat ledger saturated denominator-shape package)**.** *For histories* $\rho, v, w, z_\rho, z_v, z_w :$ BHist*, assume* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *and at least one of* $\mathsf{RatHistoryClassifier}(\rho, w)$*,* $\mathsf{RatHistoryClassifier}(v, w)$*,* $\mathsf{RatHistoryClassifier}(w, \rho)$*, or* $\mathsf{RatHistoryClassifier}(w, v)$*. Then all of the following hold:*

1. $\mathsf{UnaryHistory}(\rho)$*,* $\mathsf{UnaryHistory}(v)$*, and* $\mathsf{UnaryHistory}(w)$*;*
2. $\mathsf{hsame}(\rho, \mathsf{e}) \to \mathsf{False}$*,* $\mathsf{hsame}(v, \mathsf{e}) \to \mathsf{False}$*, and* $\mathsf{hsame}(w, \mathsf{e}) \to \mathsf{False}$*;*
3. $\mathsf{hsame}(\rho, \mathsf{E0}(z_\rho)) \to \mathsf{False}$*,* $\mathsf{hsame}(v, \mathsf{E0}(z_v)) \to \mathsf{False}$*, and* $\mathsf{hsame}(w, \mathsf{E0}(z_w)) \to \mathsf{False}$*.*

Its ten-field fit is: traditional target saturated rational denominator-shape readback; BEDC source $\mathsf{Rat}^{\uparrow}$ *ledger over* BHist*; carrier* $\mathsf{RatHistoryCarrier}$*; classifier* $\mathsf{RatHistoryClassifier}$*; stability from ledger endpoint equivalence, classifier symmetry/transitivity, positive unary denominator readback, and zero-extension exclusion; ledger the raw-visible denominator edge; core theorem this block; exactness the three endpoint shape package; downstream consumers* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *denominator-unit rows and* $\mathsf{Real}^{\uparrow}$ *stream-prefix readback.*

Proof. Unpack the ledger witness. Its raw carrier gives $\mathsf{PositiveUnaryDenominator}(\rho)$, and visible-carrier transport gives $\mathsf{PositiveUnaryDenominator}(v)$. Case-split on the supplied classifier orientation; in each branch the classifier contains a carrier witness for w, which gives $\mathsf{PositiveUnaryDenominator}(w)$.

For each endpoint, apply Definition 37.12; the unary component gives the displayed $\mathsf{UnaryHistory}$ row, and the nonempty component gives the corresponding contradiction from $\mathsf{hsame}(-, \mathsf{e})$.

It remains to exclude zero-extension presentations. Suppose $\mathsf{hsame}(\rho, \mathsf{E0}(z_\rho))$ holds. Transport $\mathsf{PositiveUnaryDenominator}(\rho)$ along this equality and contradict Definition 37.10.

The visible endpoint v is identical: transport $\mathsf{PositiveUnaryDenominator}(v)$ along $\mathsf{hsame}(v, \mathsf{E0}(z_v))$ and apply Definition 37.10. For w, transport $\mathsf{PositiveUnaryDenominator}(w)$ along $\mathsf{hsame}(w, \mathsf{E0}(z_w))$ and apply the same zero-extension exclusion. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy saturated denominator shape package`

Theorem 37.101 (Rat ledger one-tail denominator-shape readback)**.** *For histories* $\rho, v, t, z_\rho, z_v, z_t$: BHist*, assume* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *and at least one of* $\mathsf{RatHistoryClassifier}(\rho, \mathsf{E1}(t))$*,* $\mathsf{RatHistoryClassifier}(v, \mathsf{E}$ $\mathsf{RatHistoryClassifier}(\mathsf{E1}(t), \rho)$*, or* $\mathsf{RatHistoryClassifier}(\mathsf{E1}(t), v)$*. Then all of the following hold:*

1. $\mathsf{UnaryHistory}(\rho)$*,* $\mathsf{UnaryHistory}(v)$*,* $\mathsf{UnaryHistory}(\mathsf{E1}(t))$*, and* $\mathsf{UnaryHistory}(t)$*;*
2. $\mathsf{hsame}(\rho, \mathsf{e}) \to \mathsf{False}$*,* $\mathsf{hsame}(v, \mathsf{e}) \to \mathsf{False}$*, and* $\mathsf{hsame}(\mathsf{E1}(t), \mathsf{e}) \to \mathsf{False}$*;*
3. $\mathsf{hsame}(\rho, \mathsf{E0}(z_\rho)) \to \mathsf{False}$*,* $\mathsf{hsame}(v, \mathsf{E0}(z_v)) \to \mathsf{False}$*, and* $\mathsf{hsame}(\mathsf{E1}(t), \mathsf{E0}(z_t)) \to \mathsf{False}$*.*

Its ten-field fit is: traditional target one-tail rational denominator readback; BEDC source $\mathsf{RatHistoryLedgerPolicy}$*,* $\mathsf{RatHistoryClassifier}$*,* BHist*, and* $\mathsf{E1}$*; carrier* $\mathsf{RatHistoryCarrier}$*; classifier* $\mathsf{RatHistoryClassifier}$*; stability from one-tail saturation and saturated denominator-shape; ledger the raw-visible denominator edge; core theorem this block; exactness tail readback plus endpoint shape exclusions; standard bridge positive rational denominator tail readback; status* $\mathsf{ProofTarget}$*.*

Proof. Apply Definition 37.100 with $w = \mathsf{E1}(t)$. This gives the unary row for ρ, v, and $\mathsf{E1}(t)$, the three nonempty exclusions, and the three zero-extension exclusions.

It remains to read back the tail witness t. Case-split on the supplied classifier orientation. If the classifier is $\mathsf{RatHistoryClassifier}(\rho, \mathsf{E1}(t))$ or $\mathsf{RatHistoryClassifier}(v, \mathsf{E1}(t))$, it already has $\mathsf{E1}(t)$ as the visible target. Apply Definition 37.96 to obtain the one-tail target readback, and project $\mathsf{UnaryHistory}(t)$.

If the classifier is $\mathsf{RatHistoryClassifier}(\mathsf{E1}(t), \rho)$ or $\mathsf{RatHistoryClassifier}(\mathsf{E1}(t), v)$, the same saturation theorem is applied in the visible-source orientation. Its source readback projects $\mathsf{UnaryHistory}(t)$. Combining this tail row with the package obtained above gives the displayed conjunctions. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy one tail denominator shape readback`

Theorem 37.102 (RatUp bridged closure obligation package)**.** *The public RatUp certificate may be read as a paper-side standard bridge only after the following four witnesses are supplied over concrete BEDC objects:*

1. *a standard rational-constructor map from signed unary numerator histories and positive unary denominator histories into* $\mathsf{RatHistoryCarrier}$*, compatible with* $\mathsf{RatHistoryClassifier}$*;*
2. *normalized representative and readback rows stable under* Cont*,* $\mathsf{UnaryHistory}$*, and* hsame*;*
3. *arithmetic and order law rows descending through* $\mathsf{RatHistoryClassifier}$ *while preserving the positive-denominator ledger;*
4. *a no-hidden-leakage row stating that the ledger hides only numerator-denominator provenance.*

These four rows are exactly the paper-side bridge obligation consumed by RatUp bridgedClosed.

Proof. Unpack the roadmap ten-field template used throughout this chapter. The traditional target is the standard rational object; the BEDC source is RatHistoryCarrier with classifier RatHistoryClassifier; the ledger is the public denominator-shape record; and the status row is the bridge obligation rather than an additional Lean marker.

The existing semantic certificate Definition 37.90 supplies the public carrier/classifier interface. The denominator-shape readback results ending in Definition 37.101 supply the positive-denominator visibility needed for normalized representatives and the ledger side condition. What remains for a standard rational bridge is therefore precisely the displayed rational-constructor compatibility row, the normalized representative/readback row, the arithmetic and order descent row, and the no-hidden-leakage row.

Conversely, once those four witnesses are present, every field demanded by the ten-field bridge reading has a concrete BEDC source: constructor entry, classifier compatibility, stable readback, law descent, positive-denominator ledger preservation, and hidden-information control. Hence the four displayed rows are exactly the paper-side bridge obligation consumed by RatUp bridgedClosed. □

Lean4 ✓ `BEDC.Derived.RatUp.RatUp StdBridge`

Closure status for $\mathsf{NameCert}_{\mathsf{Rat}^\uparrow}$**.**

Constructive story: A rational lives, in this construction, as a denominator history together with a hidden but witnessed numerator-and-sign pair: the denominator is required to be a positive unary tail (a history of the form E1(tail) with the tail itself unary, so the denominator is at least one), and the existence of an underlying triple — sign mark, numerator history, denominator — is what licenses the denominator into the carrier in the first place. Two pairs that traditional math would identify, such as $(2, 4)$ and $(1, 2)$, remain distinct denominators here; rather than collapse them into an equivalence class, the classifier asks whether the underlying signed-numerator data satisfies the cross-product condition, and history-sameness then carries that recognition through any context where the two pairs appear interchangeably. Because history-equality is an equivalence and the carrier is preserved by it, the five name-certificate obligations are essentially a free consequence of how the carrier was set up. The signature gap of a $\mathsf{Rat}^\uparrow$ token p collects denominators d for which the source-domain admits d, the signature relation pairs d (together with its implicit numerator and sign) with an answer denominator and an evidence ledger, and the token-introduction relation maps that answer to p — concretely, this means the underlying triple names the same rational as p encodes, modulo the cross-product equivalence. The chapter pairs $\mathsf{Rat}^\uparrow$ with a four-witness bridged-closure obligation package — representative stability, sign normalization, denominator positivity, and downstream-consumer readback — and registers the whole construction under the name $\mathsf{Rat}^\uparrow$; the rational lives entirely as a denominator with witnesses, never as a class of equivalent fractions, and no quotient is ever formed.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Rat}^\uparrow}$, maturePackageClosed)

Scope closed: The RatUp mature paper scope is the RatHistoryCarrier/RatHistoryClassifier semantic certificate, representative stability, positive denominator-tail readbacks, and the four bridge-obligation witnesses of Definition 37.102.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Rat}^\uparrow}$, bridgeChecked)

Upgrade path: No further upgrade – chapter at top of formal axis.

The $\mathsf{Rat}^\uparrow$ positive-denominator surface is the arithmetic input read by the dyadic real-completion route of chapter 291, without quotient rational equality or host real data.

Theorem 37.103 (RatUp DyadicRatCore denominator handoff)**.** *Every* $\mathsf{DyadicRatCore}^\uparrow$ *consumer of a signed mantissa/exponent packet first reads the normalized* $\mathsf{Rat}^\uparrow$ *positive-denominator surface through the displayed* $\mathsf{Int}^\uparrow$ *numerator, unary positive denominator,* hsame *transport,* Cont *replay,* Pkg *provenance, and* NameCert *rows. This route supplies the rational mantissa and denominator evidence consumed by chapter 291, but it adds no quotient rational equality, selected real limit, host equality, or* $\mathsf{Real}^\uparrow$ *completeness coordinate.*

Proof. Project the rational carrier of Definition 37.2. Its visible surface is an $\mathsf{Int}^{\uparrow}$ numerator together with a denominator history that is unary and nonempty, equivalently a positive unary denominator by Definition 37.13.

The denominator rows are stable under the Rat-side transport already recorded in Definition 37.5 and Definition 37.6. Hence a consumer may move the displayed denominator through hsame without changing the positive unary evidence read from the carrier.

Next follow the ledger route. The one-tail and saturated denominator readback theorems in Definition 37.101 expose the unary tail, nonempty endpoint, and zero-extension exclusions that a finite Cont replay can inspect. The Pkg and NameCert rows keep this denominator evidence attached to the Rat provenance rather than turning it into a host rational object.

Finally cite the DyadicRatCore carrier handoff in Definition 291.1 and Definition 291.2. That consumer reads only the mantissa, exponent, denominator ledger, Cont, Pkg, and source certificate rows. Since neither the Rat carrier nor the DyadicRatCore packet contains a quotient rational equality, selected real limit, host equality, or $\mathsf{Real}^{\uparrow}$ completeness coordinate, the displayed positive-denominator route is the full handoff surface. □

Theorem 37.104 (RatUp L10 dyadic denominator gateway)**.** *Let $\mathcal{E}$ be a finite Phase* $\mathsf{Real}^{\uparrow}$ *and Completion packet whose dyadic face reads a* $\mathsf{Rat}^{\uparrow}$ *positive-denominator surface. Then the denominator row consumed by $\mathcal{E}$ factors through the finite route*

$$\mathsf{Rat}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The factorization uses only the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows attached to the Rat, dyadic, StreamName, RegSeqRat, and Real faces.*

Consequently the gateway exports no quotient rational equality, quotient stream equality, selected limit, host real equality, choice row, metric-completeness datum, bridge row, or $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Start with Definition 37.103. It reads the positive unary denominator from the $\mathsf{Rat}^{\uparrow}$ carrier through the displayed numerator, denominator ledger, hsame transport, Cont replay, Pkg provenance, and NameCert rows, and hands exactly that finite surface to the $\mathsf{DyadicRatCore}^{\uparrow}$ consumer.

Next attach the current Phase Real and Completion exit packet. By Definition 38.796, such a packet reads the four local faces objectwise, with support restricted to

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

Thus the dyadic face that receives the Rat denominator handoff is the same finite dyadic row available to the Real-and-Completion exit read.

Now push the row through the terminal route. Apply Definition 126.615 to force the public consumer order through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, and apply Definition 301.236 to keep the StreamName window, dyadic ledger, RegSeqRat readback, and Real finite-section readback on one common finite source section.

The displayed route therefore carries the Rat positive-denominator row only as finite BEDC support data. The exclusion clauses in the Rat handoff, ordered StreamName gate, RegSeqRat coherence theorem, and Real current-phase threshold remove every non-displayed coordinate: quotient rational equality, quotient stream equality, selected limits, host real equality, choice, metric completeness, bridge data, and $\mathsf{Real}^{\uparrow}$ completeness are not part of the gateway surface. □

The $\mathsf{Real}^{\uparrow}$ index reads its terminal seal surface through the L10 finite-name route of chapter 126, chapter 301, chapter 291, and chapter 1180; it exports no quotient stream, host real equality, selected limit, countable choice, or ambient completeness claim.

Chapter 38

Certificate Obligations for $\mathsf{Real}^{\uparrow}$

The real number interface $\mathsf{Real}^{\uparrow}$ is specified here as a certificate-obligation schema over sealed $\mathsf{RegSeqRat}$ stream names. These names are built from $\mathsf{DyadicRatCore}$ observations through $\mathsf{StreamName}^{\uparrow}$, then sealed with regular-sequence data and a closeness classifier. The classical Dedekind / Cauchy completion is outside this schema because quotient and completion infrastructure is not exported by the mathlib-free BEDC kernel; the interface name is available only through the dyadic rational core, certified stream names, regular-sequence certificates, and their classifier.

38.1 Carrier definition

Definition 38.1 (Real carrier)**.** *Use a sealed* $\mathsf{RegSeqRat}$ *name. Its observations form a* $\mathsf{StreamName}^{\uparrow}$ *stream over* $\mathsf{DyadicRatCore}$*, and its regularity certificate is exposed only through the* $\mathsf{Real}^{\uparrow}$ *seal.*

Definition 38.2 (Constant real history carrier)**.** *A history is in the constant real history carrier when it is internally the same as an* $\mathsf{E1}$*-sealed rational history:*

$$\mathsf{RealConstantHistoryCarrier}(h) \iff \exists d,\ \mathsf{hsame}(h, \mathsf{E1}(d)) \ \wedge\ \mathsf{RatHistoryCarrier}(d).$$

Lean4 (definition) `BEDC.Derived.RealUp.RealConstantHistoryCarrier`

Theorem 38.3 (Constant real carrier at an e-one seal)**.** *For every history* d*,*

$$\mathsf{RealConstantHistoryCarrier}(\mathsf{E1}(d)) \iff \mathsf{RatHistoryCarrier}(d).$$

Proof. Unpack the constant carrier witness. One-constructor inversion turns $\mathsf{hsame}(\mathsf{E1}(d), \mathsf{E1}(d'))$ into $\mathsf{hsame}(d, d')$, and rational history carrier transport moves the witness back along that equality. The converse uses d itself as the exposed rational history and reflexivity of hsame. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryCarrier e1 iff rat`

Theorem 38.4 (Constant real carrier unary denominator context closure)**.** *Let* $d, p, t, m, o : \mathsf{Hist}$*. If*

$$\mathsf{RealConstantHistoryCarrier}(\mathsf{E1}(d)),$$

p and t are unary histories, and

$$\mathsf{Cont}(p, d, m), \qquad \mathsf{Cont}(m, t, o),$$

then

$$\mathsf{RealConstantHistoryCarrier}(\mathsf{E1}(o)).$$

Proof. Unseal the displayed constant real carrier through Definition 38.3 to obtain $\mathsf{RatHistoryCarrier}(d)$. RatUp unary-denominator context closure gives the rational carrier of $\mathsf{append}(p, \mathsf{append}(d, t))$. The two continuation witnesses and associativity of append identify this normal endpoint with o. Transport the rational carrier along that endpoint identification, and reseal it as a constant real carrier at $\mathsf{E1}(o)$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryCarrier cont unary denominator context closed`

Theorem 38.5 (Constant real carrier e-zero exclusion)**.** *For every history tail t,*

$$\mathsf{RealConstantHistoryCarrier}(\mathsf{E0}(t)) \Longrightarrow \bot.$$

Proof. Unpack the constant real carrier witness. It displays $\mathsf{E0}(t)$ as $\mathsf{E1}(d)$ for some rational history d. BEDC history no-confusion between zero-extension and one-extension constructors eliminates that display. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryCarrier e0 absurd`

Theorem 38.6 (Constant real carrier empty exclusion)**.** *The empty history is not a constant real history carrier:*

$$\mathsf{RealConstantHistoryCarrier}(\mathsf{e}) \Longrightarrow \bot.$$

Proof. Unpack the constant real carrier witness. It displays e as an $\mathsf{E1}$-sealed rational history, and BEDC history no-confusion between the empty constructor and the one-extension constructor eliminates that display. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryCarrier empty absurd`

38.2 The certificate-obligation schema

Definition 38.7 (Real source specification)**.** *The source has three supplied layers:* $\mathsf{DyadicRatCore}$ *observations,* $\mathsf{StreamName}^{\uparrow}$ *stream naming, and the* $\mathsf{RegSeqRat}$ *certificate over those observations.*

Definition 38.8 (Real pattern specification)**.** *The pattern is sealed regular-sequence generation: every finite observation is a certified dyadic rational, stream observations are stable pointwise, and the* $\mathsf{RegSeqRat}$ *regularity witness supplies the dyadic Cauchy bound.*

Definition 38.9 (Real classifier specification)**.** *The classifier is* $\mathsf{RegSeqRat}$ *closeness: two sealed real names classify together when their dyadic regular-sequence witnesses supply comparison certificates at every requested dyadic tolerance.*

Definition 38.10 (Constant real history classifier)**.** *Two constant real histories classify together when each exposes an* $\mathsf{E1}$*-sealed rational history and the exposed rational histories classify:*

$$\mathsf{RealConstantHistoryClassifier}(h, k) \iff \exists d, e,\ \mathsf{hsame}(h, \mathsf{E1}(d)) \wedge \mathsf{hsame}(k, \mathsf{E1}(e)) \wedge \mathsf{RatHistoryClassifier}(d, e).$$

Lean4 (definition) `BEDC.Derived.RealUp.RealConstantHistoryClassifier`

Theorem 38.11 (Constant real classifier at e-one seals)**.** *For all histories d and e,*

$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(e)) \iff \mathsf{RatHistoryClassifier}(d, e).$$

Proof. Eliminate the two seal witnesses. One-constructor inversion gives the two tail hsame witnesses, and rational classifier transport carries the exposed classifier back to the displayed tails. The reverse direction chooses the same two rational histories and uses reflexivity at both seals. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier e1 iff rat`

Theorem 38.12 (Constant real classifier unary-tail closure)**.** *For all histories d, e and unary history t,*

$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(e)) \Longrightarrow \mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d \cdot t), \mathsf{E1}(e \cdot t)).$$

Proof. Read the two sealed constant-real endpoints back through Definition 38.11 as a rational history classifier between d and e. The rational classifier is closed under appending the same unary denominator tail to both exposed histories, and the same e-one bridge repacks the appended rational classifier as a constant-real classifier. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier append unary tail closed`

Theorem 38.13 (Constant real classifier common-tail cancellation)**.** *For all histories d, e, t,*

$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d \cdot t), \mathsf{E1}(e \cdot t)) \Longrightarrow d\mathsf{hsame}e.$$

Proof. Read the sealed constant-real classifier through Definition 38.11 as a rational history classifier on the two appended rational endpoints. Its endpoint hsame field identifies $d \cdot t$ with $e \cdot t$, and right cancellation of the common BEDC history tail t exposes $d\mathsf{hsame}e$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier append common tail cancel`

Theorem 38.14 (Constant real classifier common-head cancellation)**.** *For all histories h, d, e,*

$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(h \cdot d), \mathsf{E1}(h \cdot e)) \Longrightarrow d\mathsf{hsame}e.$$

Proof. Read the sealed constant-real classifier through Definition 38.11 as a rational history classifier on the two appended rational endpoints. Its endpoint hsame field identifies $h \cdot d$ with $h \cdot e$, and left cancellation of the common BEDC history head h exposes $d\mathsf{hsame}e$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier append common head cancel`

Theorem 38.15 (Constant real classifier common-context cancellation)**.** *For all histories $left, right, d, e$,*

$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(left \cdot (d \cdot right)), \mathsf{E1}(left \cdot (e \cdot right))) \Longrightarrow d\mathsf{hsame}e.$$

Proof. First cancel the shared visible left context using the common-head cancellation theorem. This yields $\mathsf{hsame}(d \cdot right, e \cdot right)$. Right append cancellation then removes the shared suffix $right$ and exposes $d\mathsf{hsame}e$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier append common context cancel`

Theorem 38.16 (Constant real classifier double-seal readback)**.** *If* $\mathsf{RealConstantHistoryClassifier}(h, k)$ *holds and the two endpoints are displayed as* $\mathsf{E1}(\mathsf{E1}(d))$ *and* $\mathsf{E1}(\mathsf{E1}(e))$*, then the exposed tails d and e are unary histories and satisfy* $d\mathsf{hsame}e$*.*

Proof. Transport the classifier along the two displayed endpoint equalities to obtain RealConstantHistoryClassifier(E1
The constant real e-one equivalence reads this as a rational classifier between $\mathsf{E1}(d)$ and $\mathsf{E1}(e)$. Rational e-one tail readback then exposes the two unary tail carriers and the tail equality $d\mathsf{hsame}e$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier e1 pair readback`

Theorem 38.17 (Constant real classifier endpoint carriers)**.** *If two constant real histories classify together, then both endpoints are in the constant real history carrier:*

$$\mathsf{RealConstantHistoryClassifier}(h,k) \Longrightarrow \mathsf{RealConstantHistoryCarrier}(h) \wedge \mathsf{RealConstantHistoryCarrier}(k).$$

Proof. Unpack the classifier witness into rational histories d, e, endpoint displays $\mathsf{hsame}(h, \mathsf{E1}(d))$ and $\mathsf{hsame}(k, \mathsf{E1}(e))$, and a rational history classifier between d and e. The rational classifier stores rational carrier witnesses at both exposed endpoints, so pairing those carrier witnesses with the two endpoint displays gives the two constant real history carriers. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier endpoint carriers`

Theorem 38.18 (Constant real classifier endpoint transport)**.** *If constant real histories h, k classify together, and $h\mathsf{hsame}h'$ and $k\mathsf{hsame}k'$, then h' and k' classify together.*

Proof. Unpack the two sealed rational witnesses. Symmetry and transitivity of hsame move the displayed endpoint equalities from h, k to h', k', while the rational classifier witness remains attached to the same sealed tails. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier endpoint transport`

Theorem 38.19 (Constant real classifier e-one tail readback)**.** *If a constant real classifier is displayed at two visible rational seals, then the displayed tails carry the rational history classifier:*

$$\mathsf{RealConstantHistoryClassifier}(h,k) \Longrightarrow \mathsf{hsame}(h, \mathsf{E1}(d)) \Longrightarrow \mathsf{hsame}(k, \mathsf{E1}(e)) \Longrightarrow \mathsf{RatHistoryClassifier}(d,e).$$

Proof. Transport the classifier along the two displayed endpoint equalities to obtain RealConstantHistoryClassifier(E1
The e-one seal readback theorem for constant real classifiers then exposes the rational classifier on the two tails. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier e1 tail readback`

Theorem 38.20 (Constant real classifier e-one denominator package)**.** *For histories h, k, d, e : BHist, suppose*

$$\mathsf{RealConstantHistoryClassifier}(h,k), \qquad h\mathsf{hsame}\mathsf{E1}(d), \qquad k\mathsf{hsame}\mathsf{E1}(e).$$

Then the displayed rational tails satisfy the full denominator shape package:

1. $\mathsf{RatHistoryClassifier}(d,e)$*;*
2. $\mathsf{PositiveUnaryDenominator}(d)$ *and* $\mathsf{PositiveUnaryDenominator}(e)$*;*
3. $\mathsf{UnaryHistory}(d)$ *and* $\mathsf{UnaryHistory}(e)$*;*
4. $d\mathsf{hsame}e \Longrightarrow \bot$ *and* $e\mathsf{hsame}e \Longrightarrow \bot$*.*

In the ten-field fit, the traditional target is constant rational endpoint shape readback; the BEDC source is BHist *e-one rational seals; the carrier is* RealConstantHistoryCarrier*; the classifier is* RealConstantHistoryClassifier*; the stability obligations are tail readback and RatUp denominator projections; the ledger is exposed denominator shape; the core theorem is this package; the exactness predicate is rational classifier plus positive unary nonempty tails; the standard bridge is constant rational real names; and the status is* ProofTarget.

Proof. Apply Definition 38.19 to the real classifier and the two displayed e-one endpoint equalities. This gives $\mathsf{RatHistoryClassifier}(d, e)$.

Next apply Definition 37.50 to that rational classifier. The result supplies the positive unary denominator witnesses for both displayed tails.

Finally apply Definition 37.12 to each positive-denominator witness. The two applications give the unary-history rows and the two exclusions against e, so the listed package follows. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier e1 denominator package`

Theorem 38.21 (Constant real classifier unary denominator context closure)**.** *Let* $d, e, p_D, p_E, t_D, t_E, m_D, m_E, o_D,$ BHist*. If*

$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(e)),$$

p_D *and* t_D *are unary histories,* $p_D \mathsf{hsame} p_E$*,* $t_D \mathsf{hsame} t_E$*, and the displayed continuation witnesses are*

$$\mathsf{Cont}(p_D, d, m_D), \quad \mathsf{Cont}(m_D, t_D, o_D), \quad \mathsf{Cont}(p_E, e, m_E), \quad \mathsf{Cont}(m_E, t_E, o_E),$$

then

$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(o_D), \mathsf{E1}(o_E)).$$

Proof. Use Definition 38.11 to expose the rational classifier on d and e. The RatUp unary-denominator context closure classifies the associativity-normal endpoints $\mathsf{append}(p_D, \mathsf{append}(d, t_D))$ and $\mathsf{append}(p_E, \mathsf{append}(e, t_E))$. The four displayed continuation witnesses identify o_D and o_E with those normal endpoints through associativity of append. Transport the rational classifier along those identifications, then reseal the two endpoints with Definition 38.11. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier cont unary denominator context closed`

Theorem 38.22 (Constant real classifier invalid endpoint exclusions)**.** *For every history* h *and history tail* t*, the constant real-history classifier excludes every endpoint shape that is not an* E1*-sealed rational history:*

1. $\mathsf{RealConstantHistoryClassifier}(\mathsf{E0}(t), h) \Longrightarrow \bot$*;*
2. $\mathsf{RealConstantHistoryClassifier}(h, \mathsf{E0}(t)) \Longrightarrow \bot$*;*
3. $\mathsf{RealConstantHistoryClassifier}(\mathsf{e}, h) \Longrightarrow \bot$*;*
4. $\mathsf{RealConstantHistoryClassifier}(h, \mathsf{e}) \Longrightarrow \bot$*.*

In the ten-field fit, the traditional target is sealed constant-real endpoint no-confusion; the BEDC source is BHist *rational seals; the carrier is* RealConstantHistoryCarrier*; the classifier is* RealConstantHistoryClassifier*, the stability obligations are endpoint carrier projection and carrier exclusions; the ledger is invalid endpoint shape; the core theorem is this block; the exactness predicate is impossible non-*E1 *endpoint; the standard bridge is constant rational real names; and the status is* ProofTarget.

Proof. 1. Apply Definition 38.17 to the classifier witness. Its left projection gives $\mathsf{RealConstantHistoryCarrier}(\mathsf{E0}(t))$.

Apply Definition 38.5.

2. Apply Definition 38.17 to the classifier witness. Its right projection gives RealConstantHistoryCarrier(E0(t)). Apply Definition 38.5.
3. Apply Definition 38.17 to the classifier witness. Its left projection gives RealConstantHistoryCarrier(e). Apply Definition 38.6.
4. Apply Definition 38.17 to the classifier witness. Its right projection gives RealConstantHistoryCarrier(e). Apply Definition 38.6.

□

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier invalid endpoint absurd`

Theorem 38.23 (Constant real classifier equivalence fields)**.** *The constant real history classifier supplies the equivalence fields carried by the constant-real certificate package:*

1. *if* RealConstantHistoryCarrier(h)*, then* RealConstantHistoryClassifier(h, h)*;*
2. *if* RealConstantHistoryClassifier(h, k)*, then* RealConstantHistoryClassifier(k, h)*;*
3. *if* RealConstantHistoryClassifier(h, k) *and* RealConstantHistoryClassifier(k, ℓ)*, then* RealConstantHistoryClassifier(h,

In the ten-field fit, the traditional target is constant rational embedding into Real$^{\uparrow}$*; the BEDC source is BHist rational histories; the carrier is* RealConstantHistoryCarrier*; the classifier is* RealConstantHistoryClassifier*; the stability obligation is the equivalence fields above; the ledger is the sealed rational tail; the core theorem is this displayed package; exactness is inherited from the rational classifier; the standard bridge is constant rational real names; and the status is* ProofTarget*.*

Proof. For reflexivity, unpack RealConstantHistoryCarrier(h) as a sealed rational tail d with hsame(h, E1(d)) and RatHistoryCarrier(d). The rational carrier supplies the reflexive rational classifier on d, using hsame reflexivity on the exposed tail. Packing the same sealed tail twice and using the displayed endpoint witness on both sides gives RealConstantHistoryClassifier(h, h).

For symmetry, unpack RealConstantHistoryClassifier(h, k) into sealed rational tails d, e, endpoint displays for h and k, and RatHistoryClassifier(d, e). Keep the same endpoint displays in the opposite order and apply RatHistoryClassifier_symm to the rational classifier.

For transitivity, unpack the two classifiers into tails d, e and e', f. The two middle displays for k compare E1(e) and E1(e') by hsame symmetry and transitivity; one-constructor inversion turns that comparison into hsame(e, e'). Transport the right rational classifier from e' to e, then compose it with the left rational classifier by RatHistoryClassifier_trans. Repacking the outer endpoint displays for h and ℓ gives the required classifier. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier equivalence fields`

Theorem 38.24 (Constant real semantic name certificate)**.** *The constant real history carrier and classifier form a* SemanticNameCert *whose source, pattern, and ledger predicates are all* RealConstantHistoryCarrier*, and whose classifier is* RealConstantHistoryClassifier*.*

Proof. Use the e-one rational denominator witnessed by e to inhabit the source carrier. The classifier equivalence fields of Definition 38.23 supply reflexivity, symmetry, and transitivity. Endpoint-carrier readback from Definition 38.17 supplies carrier transport along the classifier. Since the pattern and ledger predicates are the same concrete carrier, their soundness rows are direct. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistory semanticNameCert`

Definition 38.25 (Real stream classifiers)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, the stream classifier is pointwise rational-history classification. The finite prefix classifier records the same data recursively through a selected observation index.*

Lean4 (definition) `BEDC.Derived.RealUp.RealStreamClassifier`
Lean4 (definition) `BEDC.Derived.RealUp.RealStreamPrefixClassifier`

Definition 38.26 (Real unary-observation stream classifier)**.** *For rational-observation maps $s, t : \mathsf{Hist} \to \mathsf{Hist}$, the unary-observation stream classifier is pointwise rational-history classification over certified unary BEDC observation histories:*

$$\mathsf{RealUnaryStreamClassifier}(s, t) \iff \forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{RatHistoryClassifier}(s(n), t(n)).$$

Lean4 (definition) `BEDC.Derived.RealUp.RealUnaryStreamClassifier`

Theorem 38.27 (Constant rational streams bridge StreamNameUp and RealUp)**.** *For histories $d, e : \mathsf{Hist}$, the RatUp point classifier, the StreamNameUp constant-stream classifier, the RealUp unary-observation stream classifier, and the constant real-history classifier at e-one seals are equivalent:*

$$\mathsf{RatHistoryClassifier}(d, e) \iff \mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_d, \mathsf{RatConstStream}_e).$$

$$\mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_d, \mathsf{RatConstStream}_e) \iff \mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_d$$

$$\mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_d, \mathsf{RatConstStream}_e) \iff \mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(e))$$

Proof. For the first equivalence, the forward direction is exactly the constant classifier part of Definition 126.48. Conversely, unfold Definition 126.2 and read the pointwise classifier at the empty unary observation history e using its unary witness; the two constant stream values are d and e.

For the second equivalence, unfold Definition 126.2 and Definition 38.26. Both predicates are the same pointwise requirement over certified unary observation histories, so each direction is identity transport of the displayed witness.

For the last equivalence, unfold Definition 38.26 and $\mathsf{RatConstStream}$. Reading at the empty unary observation gives $\mathsf{RatHistoryClassifier}(d, e)$, while a rational point classifier supplies the same pointwise witness at every unary observation.

Apply Definition 38.11 to identify that rational point classifier with $\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(e))$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamClassifier constant prefix bridge iff`
Lean4 ✓ `BEDC.Derived.RealUp.StreamNameReal constant prefix bridge`
Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamClassifier constant streamname bridge`
Lean4 ✓ `BEDC.Derived.RealUp.RealConstantStream streamName bridge`

Theorem 38.28 (Reindexed constant rational streams bridge StreamNameUp and RealUp)**.** *For histories $d, e : \mathsf{Hist}$ and any observation map $r : \mathsf{Hist} \to \mathsf{Hist}$, the RatUp point classifier, the StreamNameUp classifier of reindexed constant streams, the RealUp unary-observation stream classifier of the same reindexed streams, and the constant real-history classifier at e-one seals are equivalent:*

$$\mathsf{RatHistoryClassifier}(d, e) \iff \mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_d \circ r, \mathsf{RatConstStream}_e \circ r).$$

$$\mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_d \circ r, \mathsf{RatConstStream}_e \circ r) \iff \mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStre}$$

$$\mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_d \circ r, \mathsf{RatConstStream}_e \circ r) \iff \mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}$$

Proof. For the first equivalence, unfold RatConstStream and Definition 126.2. The forward direction reuses the supplied $\mathsf{RatHistoryClassifier}(d, e)$ at every certified unary observation; the observation map is ignored because both reindexed constant streams still evaluate to their hidden seeds d and e. Conversely, read the stream-name classifier at the empty unary observation history e.

For the second equivalence, unfold Definition 126.2 and Definition 38.26. After expanding the reindexed constant streams, both predicates ask for the same pointwise RatUp classifier over certified unary observations, so each direction transports the displayed pointwise witness unchanged.

For the last equivalence, the forward direction again reads the unary stream classifier at e to recover $\mathsf{RatHistoryClassifier}(d, e)$, then applies Definition 38.11. In the reverse direction, the same theorem unseals the e-one classifier as the RatUp point classifier, and the constant observation maps reuse it at every certified unary observation. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantStream reindexed streamName bridge`

The reindexed constant-stream certificate fit has ten fields: traditional target constant rational real names under observation reindexing; BEDC source RatUp plus StreamNameUp plus RealUp; carrier the reindexed constant rational observation maps and e-one real seals; classifier the three displayed bridge rows; stability from ignoring the observation map in constant streams; ledger hidden rational seed plus observation map; core theorem Definition 38.28; exactness the three equivalences; standard bridge target constant rational real names under reindexed observation; downstream use by the RealUp dyadic embedding theorem.

Theorem 38.29 (Independent reindexed constant rational streams bridge StreamNameUp and RealUp)**.** *For histories $d, e : \mathsf{Hist}$ and observation maps $r, q : \mathsf{Hist} \to \mathsf{Hist}$, the RatUp point classifier, the StreamNameUp classifier of independently reindexed constant streams, the RealUp unary-observation stream classifier of the same streams, and the constant real-history classifier at e-one seals are equivalent:*

$$\mathsf{RatHistoryClassifier}(d, e) \iff \mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_d \circ r, \mathsf{RatConstStream}_e \circ q).$$

$$\mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_d \circ r, \mathsf{RatConstStream}_e \circ q) \iff \mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStre}$$

$$\mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_d \circ r, \mathsf{RatConstStream}_e \circ q) \iff \mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}$$

Proof. For the first equivalence, unfold RatConstStream and Definition 126.2. In the forward direction, a RatUp point classifier for d and e supplies the required pointwise classifier at every certified unary observation, because the two reindexed constant streams ignore r and q and return their hidden seeds. In the reverse direction, evaluate the stream-name classifier at the empty unary observation history e.

For the second equivalence, unfold Definition 126.2 and Definition 38.26. The two predicates reduce to the same pointwise RatUp classifier over certified unary observation histories after the constant streams discard their separate observation schedules, so each direction transports the displayed witness unchanged.

For the final equivalence, the forward direction reads the unary stream classifier at e to obtain $\mathsf{RatHistoryClassifier}(d, e)$ and then uses Definition 38.11. Conversely, that theorem turns the e-one real-history classifier back into the RatUp point classifier, which is reused at every certified unary observation for the two independently scheduled constant streams. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantStream independent reindexed streamName bridge`

The independent reindexed constant-stream certificate fit has ten fields: traditional target constant rational real names with separately sampled endpoint observations; BEDC source RatUp

plus StreamNameUp plus RealUp; carrier the two reindexed constant rational observation maps and e-one real seals; classifier the three displayed bridge rows; stability from ignoring both observation maps in constant streams; ledger the two observation maps and the hidden rational seeds; core theorem Definition 38.29; exactness the three equivalences; standard bridge target constant rational real names under independent endpoint observation schedules; downstream use by the RealUp dyadic embedding under independent observation schedules.

Theorem 38.30 (Constant rational stream carriers bridge StreamNameUp and RealUp)**.** *For every history $d : \mathsf{Hist}$, the RatUp point carrier, the StreamNameUp constant-stream carrier, and the RealUp constant real-history carrier at the e-one seal are equivalent:*

$$\mathsf{RatHistoryCarrier}(d) \iff \mathsf{RatStreamNameCarrier}(\mathsf{RatConstStream}_d).$$

$$\mathsf{RatStreamNameCarrier}(\mathsf{RatConstStream}_d) \iff \mathsf{RealConstantHistoryCarrier}(\mathsf{E1}(d)).$$

Proof. The first equivalence is the carrier row of Definition 126.55, read symmetrically: the StreamNameUp constant carrier is exactly the RatUp carrier of its hidden constant seed.

For the second equivalence, compose that carrier row with Definition 38.3. A StreamNameUp constant carrier first recovers $\mathsf{RatHistoryCarrier}(d)$, then the e-one theorem seals it as $\mathsf{RealConstantHistoryCarrier}(\mathsf{E1}($ the reverse direction unseals the RealUp constant carrier to $\mathsf{RatHistoryCarrier}(d)$ and repacks it as the StreamNameUp constant carrier. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantStreamCarrier streamName bridge`

The carrier certificate fit has ten fields: traditional target constant rational real carrier embedding; BEDC source RatUp histories plus StreamNameUp observations; carrier the displayed constant stream and e-one real seal; classifier inherited from Definition 38.27; stability from RatUp carrier transport and RealConstant carrier transport; ledger the hidden rational seed and observation witness; core theorem Definition 38.30; exactness the two displayed equivalence rows; standard bridge constant rational real name; status $\mathsf{ProofTarget}$.

Theorem 38.31 (Constant rational embedding certificate)**.** *The concrete map*

$$d \longmapsto (\mathsf{RatConstStream}_d, \mathsf{E1}(d))$$

from a RatUp history seed $d : \mathsf{Hist}$ supplies the constant rational embedding into RealUp. Its carrier exactness is the chain

$$\mathsf{RatHistoryCarrier}(d) \iff \mathsf{RatStreamNameCarrier}(\mathsf{RatConstStream}_d) \iff \mathsf{RealConstantHistoryCarrier}(\mathsf{E1}(d)$$

Its classifier exactness, for histories $d, e : \mathsf{Hist}$, is the chain

$$\mathsf{RatHistoryClassifier}(d, e) \iff \mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_d, \mathsf{RatConstStream}_e) \iff \mathsf{RealUnar}$$

The certificate therefore packages the hidden rational seed, the constant StreamNameUp observation map, and the e-one RealUp seal as one concrete BHist-anchored rational-to-real name.

Proof. For carrier exactness, use Definition 38.30. Its two displayed rows identify the RatUp carrier with the StreamNameUp constant-stream carrier, and then identify that carrier with the RealUp constant history carrier at the e-one seal.

For classifier exactness, use Definition 38.27. Its three displayed rows identify the RatUp point classifier, the StreamNameUp constant-stream classifier, the RealUp unary stream classifier, and the RealUp constant history classifier at the paired e-one seals.

The endpoint part of the last row is the Real constant classifier equivalence and transport mechanism: Definition 38.11 turns an e-one sealed RealUp classifier into the underlying RatUp classifier and back, while Definition 38.18 preserves the same classifier under endpoint-equivalent real histories. These facts repack the two chains as one certificate for the displayed map. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstant rational embedding certificate`

The constant rational embedding certificate has ten fields: traditional target constant rational embedding; BEDC source RatUp plus StreamNameUp plus RealUp; carrier the constant stream and e-one seal; classifier the displayed equivalence chain; stability inherited from RatUp classifier fields and Real constant endpoint transport; ledger hidden rational seed plus unary observation; core theorem Definition 38.31; exactness the carrier and classifier chains; standard bridge ordinary rational constants; status ProofTarget.

Theorem 38.32 (Reindexed constant rational stream carriers bridge StreamNameUp and RealUp)**.** *For every history d : Hist and any observation map r : Hist $\to$ Hist, the RatUp point carrier, the StreamNameUp carrier of the reindexed constant stream, and the RealUp constant real-history carrier at the e-one seal are equivalent:*

$$\mathsf{RatHistoryCarrier}(d) \iff \mathsf{RatStreamNameCarrier}(\mathsf{RatConstStream}_d \circ r).$$

$$\mathsf{RatStreamNameCarrier}(\mathsf{RatConstStream}_d \circ r) \iff \mathsf{RealConstantHistoryCarrier}(\mathsf{E1}(d)).$$

Proof. Unfold Definition 126.1 and RatConstStream. A carrier of d supplies the carrier at every certified unary observation because the reindexed constant stream still returns the seed d. Conversely, reading the stream carrier at e recovers the RatUp carrier of d. Composing this row with Definition 38.3 gives the e-one RealUp carrier row. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantStreamCarrier reindexed streamName bridge`

Theorem 38.33 (Real constant embedding terminal four-face consumption)**.** *The concrete constant rational embedding*

$$d \longmapsto (\mathsf{RatConstStream}_d, \mathsf{E1}(d))$$

from Definition 38.31 is accepted as a $\mathsf{Real}^{\uparrow}$ *public seal read only through the four Phase Real and Completion faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Its visible support rows are precisely the BHist, hsame, Cont, Pkg, *and* NameCert *rows carried by those faces. The consumption route therefore exports no quotient stream equality, selected host limit, ambient completeness row, metric-completeness datum, countable choice, or standard bridge row.*

Proof. Start with Definition 38.31. It packages the hidden rational seed d, the constant stream $\mathsf{RatConstStream}_d$, and the e-one seal $\mathsf{E1}(d)$ as one concrete BHist-anchored rational-to-real name.

Apply Definition 301.132. The same constant source reaches the local $\mathsf{Real}^{\uparrow}$ seal only after the constant $\mathsf{StreamName}^{\uparrow}$ schedule, the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint and radius rows, and the $\mathsf{RegSeqRat}^{\uparrow}$ regularity and classifier ledger have been read through their displayed support rows.

Next apply Definition 126.172. This keeps the constant observation surface at the pointwise StreamName boundary and leaves regularity, dyadic seal data, and the Real seal classifier as downstream obligations rather than additional source coordinates.

Finally use Definition 38.534. That terminality theorem reads every accepted public seal or completion-facing route through exactly the four displayed faces with BHist, hsame, Cont, Pkg, and NameCert support. Hence the constant rational embedding is consumed by the same terminal four-face boundary, and the excluded quotient, selected-limit, completeness, choice, metric-completeness, and standard-bridge rows cannot replace any face of the route. □

Theorem 38.34 (Real constant embedding terminal four-face pullback)**.** *Any two accepted presentations of the concrete constant rational embedding which agree on the displayed*

$$\mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

faces and on the shared BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows determine the same public* $\mathsf{Real}^{\uparrow}$ *seal route. Conversely, any terminal four-face packet with those support rows determines the constant embedding seal read.*

The pullback exports no quotient stream equality, selected host limit, ambient $\mathsf{Real}^{\uparrow}$ *completeness, metric completeness, countable choice, or standard bridge row.*

Proof. First apply Definition 38.33. Each accepted presentation of the constant rational embedding is already consumed only through the four displayed faces and the shared BHist, hsame, Cont, Pkg, and NameCert rows.

Next use Definition 301.132. Agreement on the constant $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint data, the constant $\mathsf{StreamName}^{\uparrow}$ schedule, and the $\mathsf{RegSeqRat}^{\uparrow}$ regularity and classifier ledger gives one visible handoff surface for the $\mathsf{Real}^{\uparrow}$ seal.

Apply Definition 126.172. This keeps the constant observation at the pointwise StreamName boundary and leaves the dyadic, regularity, and Real seal rows as the downstream four-face packet rather than as extra source coordinates.

Finally invoke Definition 38.534. Two accepted reads that agree on the four faces and the listed support rows have the same terminal finite route to the public $\mathsf{Real}^{\uparrow}$ seal. In the reverse direction, a terminal packet carrying exactly those faces and support rows is therefore read as the constant embedding seal route supplied by the handoff theorems. Since none of the cited packets carries quotient stream equality, selected host limits, ambient completeness, metric completeness, countable choice, or a standard bridge row, no such row can replace any face of the pullback. □

Theorem 38.35 (Real constant embedding terminal four-face classifier preservation)**.** *Suppose two accepted presentations of the concrete constant rational embedding agree on the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius rows, the constant-window* $\mathsf{StreamName}^{\uparrow}$ *row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier ledger, and the local* $\mathsf{Real}^{\uparrow}$ *seal classifier. Then their public* $\mathsf{Real}^{\uparrow}$ *classifier read is the same terminal four-face classifier route through*

$$\mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}.$$

Conversely, any accepted terminal four-face classifier route carrying those support rows determines the classifier read of the constant rational embedding.

This classifier preservation statement exports no quotient stream equality, selected host limit, host real equality, ambient completeness, metric-completeness data, countable choice, or standard bridge row.

Proof. First apply Definition 38.33. It confines the accepted constant rational embedding to the displayed four faces, so the classifier question can only inspect the dyadic endpoint and radius rows, the constant StreamName window, the RegSeqRat ledger, and the local Real seal classifier.

Next use Definition 38.34. Agreement on those four faces and their BHist, hsame, Cont, Pkg, and NameCert support rows gives one terminal route for the public $\mathsf{Real}^{\uparrow}$ seal read, and every accepted terminal packet with the same support rows reads back to that constant embedding route.

Now transport the classifier data along the two handoff boundaries. Apply Definition 301.132 to identify the $\mathsf{RegSeqRat}^{\uparrow}$ regularity and classifier ledger that reaches the Real seal, and apply Definition 126.172 to keep the constant observation boundary at the StreamName window.

Finally invoke Definition 38.472. The L10 classifier pullback identifies classifier equality on an accepted four-face route from exactly the displayed classifier rows. Thus the two presentations have the same public $\mathsf{Real}^{\uparrow}$ classifier read, and the reverse terminal route determines the classifier read of the constant rational embedding. The excluded quotient, selected-limit, host-real, completeness, choice, metric-completeness, and standard-bridge rows are absent from every cited route, so they cannot supply an alternative classifier preservation path. □

Theorem 38.36 (Real terminal four-face no direct seal collapse)**.** *If a public* $\mathsf{Real}^{\uparrow}$ *classifier read of the concrete constant rational embedding is accepted, then it factors through the displayed*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

faces with the shared BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. Conversely, a packet which omits any of the first three faces is not an accepted public classifier read of the constant embedding.*

Thus the terminal public read excludes quotient stream equality, selected limits, host real equality, countable choice, ambient completeness, metric completeness, standard bridge rows, and any direct $\mathsf{Real}^{\uparrow}$ *seal edge around the dyadic, stream, or regular-sequence faces.*

Proof. First apply Definition 38.33. It gives the route inventory for every accepted constant-embedding public seal read: the dyadic core, stream name, regular sequence, and Real faces are all visible, and their only support rows are the common BHist, hsame, Cont, Pkg, and NameCert rows.

Next use Definition 38.34. The pullback identifies the public seal route uniquely from precisely those faces and rows. Hence a purported public read that bypasses $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, or $\mathsf{RegSeqRat}^{\uparrow}$ has no route coordinate from which the constant embedding seal can be pulled back.

Finally apply Definition 38.35. Classifier preservation transports the same uniqueness statement from the seal route to the public classifier read. Therefore an accepted classifier read factors through all four faces, while a packet missing any of the first three faces is not an accepted constant-embedding classifier read. The excluded quotient stream, selected-limit, host-real, choice, ambient-completeness, metric-completeness, standard-bridge, and direct-seal data are absent from the three cited routes, so none of them supplies a replacement edge to $\mathsf{Real}^{\uparrow}$. □

Theorem 38.37 (Real constant embedding four-face classifier terminality)**.** *For any two accepted concrete constant rational embedding classifier reads, equality of their public* $\mathsf{Real}^{\uparrow}$ *classifier reads holds exactly when their visible terminal rows agree: the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius rows, the constant-window* $\mathsf{StreamName}^{\uparrow}$ *row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier ledger, the local* $\mathsf{Real}^{\uparrow}$ *seal classifier, and the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows.*

Conversely, any terminal four-face classifier packet carrying precisely those rows determines the public classifier read of the concrete constant rational embedding. This terminality criterion exports no quotient stream equality, host real equality, selected limit, countable choice, ambient completeness, metric-completeness row, standard bridge row, or direct $\mathsf{Real}^{\uparrow}$ *seal bypass.*

Proof. For the forward direction, start with the accepted public classifier equality and apply Definition 38.35. Classifier preservation restricts the equality test to the displayed four faces. Then use Definition 38.36: an accepted classifier read cannot pass directly to $\mathsf{Real}^{\uparrow}$ while omitting the dyadic, stream, or regular-sequence faces.

It remains to extract the rows that witness the equality. Apply Definition 38.34. The pullback identifies the public seal route from the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint and radius rows, the constant-window $\mathsf{StreamName}^{\uparrow}$ row, the $\mathsf{RegSeqRat}^{\uparrow}$ ledger, the local $\mathsf{Real}^{\uparrow}$ classifier row, and the common BHist, hsame, Cont, Pkg, and NameCert support. Hence equality of the public classifier read forces agreement on exactly those rows.

For the reverse direction, begin with agreement on the listed terminal rows. The pullback theorem repacks those rows as one terminal four-face packet for the constant embedding seal route. Classifier preservation then transports that repacked packet to the public $\mathsf{Real}^{\uparrow}$ classifier read, so the two accepted presentations have the same classifier endpoint.

The same two theorems also give the converse packet clause: a terminal four-face classifier packet with precisely the displayed rows determines the constant embedding classifier read. The no-direct-seal-collapse theorem excludes quotient stream equality, host real equality, selected limits, countable choice, ambient or metric completeness, standard bridges, and direct Real seal bypasses from serving as an alternative terminal endpoint. □

38.3 Real algebra and order boundary

Definition 38.38 (Concrete RealAlgOrder interface)**.** *The concrete seed for* RealAlgOrder *is the constant rational RealUp subcarrier supplied by Definition 38.31. Its carrier is* RealConstantHistoryCarrier*, its classifier is* RealConstantHistoryClassifier*, and each algebra or order row is a* BHist *relation obtained by applying the corresponding RatUp witness before the e-one RealUp embedding. The rows are:*

1. *addition:* $\mathsf{RatAddRow}(d, e, o)$ *is transported to* $\mathsf{RealAlgAddRow}(\mathsf{E1}(d), \mathsf{E1}(e), \mathsf{E1}(o))$*;*
2. *negation:* $\mathsf{RatNegRow}(d, o)$ *is transported to* $\mathsf{RealAlgNegRow}(\mathsf{E1}(d), \mathsf{E1}(o))$*;*
3. *multiplication:* $\mathsf{RatMulRow}(d, e, o)$ *is transported to* $\mathsf{RealAlgMulRow}(\mathsf{E1}(d), \mathsf{E1}(e), \mathsf{E1}(o))$*;*
4. *absolute value:* $\mathsf{RatAbsRow}(d, o)$ *is transported to* $\mathsf{RealAlgAbsRow}(\mathsf{E1}(d), \mathsf{E1}(o))$*;*
5. *nonnegative comparison:* $\mathsf{RatNonnegativeRow}(d)$ *is transported to* $\mathsf{RealAlgNonnegativeRow}(\mathsf{E1}(d))$*;*
6. *strict apartness:* $\mathsf{RatApartRow}(d, e)$ *is transported to* $\mathsf{RealAlgApartRow}(\mathsf{E1}(d), \mathsf{E1}(e))$.

Thus the interface is a constant-rational boundary object: it names only the operation and order rows whose rational endpoints are already certified by RatUp and whose RealUp endpoints are the constant e-one seals.

Lean4 (definition) `BEDC.Derived.RealAlgOrderUp.RealAlgOrderConcreteInterface`

Theorem 38.39 (RealAlgOrder constant carrier and classifier obligations)**.** *Let* $d, e : \mathsf{Hist}$*. The carrier and classifier face of the constant-rational* RealAlgOrder *boundary consists of the two transported rows*

$$\mathsf{RatHistoryCarrier}(d) \Longrightarrow \mathsf{RealConstantHistoryCarrier}(\mathsf{E1}(d))$$

and

$$\mathsf{RatHistoryClassifier}(d, e) \Longrightarrow \mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(e)).$$

These rows are stable under the e-one classifier readback of Definition 38.11: every displayed Real constant classifier comparison between e-one endpoints reads back to the RatUp classifier comparison used by the source rows.

Proof. Begin with the embedding certificate. Apply Definition 38.31 to the rational endpoint d; its carrier component is exactly the passage from $\mathsf{RatHistoryCarrier}(d)$ to $\mathsf{RealConstantHistoryCarrier}(\mathsf{E1}(d))$.

Next read the classifier component of the same certificate at the pair (d, e). The RatUp classifier row is transported first to the constant stream-name comparison and then to the e-one RealUp constant comparison, giving $\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(e))$.

Finally apply Definition 38.11 in the reverse readback direction. The displayed Real constant classifier comparison is therefore the same rational classifier datum that RatUp classifier transport uses for stability of the source carrier and classifier rows. □

Lean4 ✓ `BEDC.Derived.RealAlgOrderUp.RealAlgOrderConstantCarrier classifier obligations`

Theorem 38.40 (RealAlgOrder constant algebra row obligations)**.** *Let $d, e, o : \mathsf{Hist}$. The algebra face of the constant-rational* RealAlgOrder *boundary consists of the four transported operation rows*

$$\begin{aligned}
\mathsf{RatAddRow}(d, e, o) &\implies \mathsf{RealAlgAddRow}(\mathsf{E1}(d), \mathsf{E1}(e), \mathsf{E1}(o)),\\
\mathsf{RatNegRow}(d, o) &\implies \mathsf{RealAlgNegRow}(\mathsf{E1}(d), \mathsf{E1}(o)),\\
\mathsf{RatMulRow}(d, e, o) &\implies \mathsf{RealAlgMulRow}(\mathsf{E1}(d), \mathsf{E1}(e), \mathsf{E1}(o)),\\
\mathsf{RatAbsRow}(d, o) &\implies \mathsf{RealAlgAbsRow}(\mathsf{E1}(d), \mathsf{E1}(o)).
\end{aligned}$$

Classifier congruence for these rows is read back through RealConstantHistoryClassifier *to the RatUp classifier transport on the rational endpoints.*

Proof. Use Definition 38.31 to fix the constant-rational bridge for the displayed endpoints. It supplies the e-one RealUp seals for d, e, and o, with carrier and classifier data inherited from their RatUp histories.

For each algebra row, apply the corresponding RatUp witness before embedding. The addition, negation, multiplication, and absolute-value witnesses therefore remain rational ledger rows, while their visible endpoints become the displayed e-one RealUp constants.

It remains to account for classifier congruence. Apply Definition 38.11 to any displayed Real constant classifier comparison among the inputs or output. The result is the RatUp classifier comparison required by RatUp classifier transport, and the embedding certificate repacks the transported witness as the corresponding RealAlgOrder algebra row. □

Lean4 ✓ `BEDC.Derived.RealAlgOrderUp.RealAlgOrderConstant algebra row obligations`

Theorem 38.41 (RealAlgOrder constant order and apartness obligations)**.** *Let $d, e : \mathsf{Hist}$. The order face of the constant-rational* RealAlgOrder *boundary consists of the two transported rows*

$$\mathsf{RatNonnegativeRow}(d) \implies \mathsf{RealAlgNonnegativeRow}(\mathsf{E1}(d))$$

and

$$\mathsf{RatApartRow}(d, e) \implies \mathsf{RealAlgApartRow}(\mathsf{E1}(d), \mathsf{E1}(e)).$$

This boundary records nonnegative and strict-apartness obligations only. It does not assert trichotomy, least-upper-bound completeness, Cauchy completeness, or any total order law beyond the supplied RatUp rows.

Proof. First expose the constant endpoints through Definition 38.31. The same rational-to-Real passage used for the carrier and algebra rows supplies the e-one endpoints on which the nonnegative and apartness rows are displayed.

Next transport the two RatUp order rows. A supplied $\mathsf{RatNonnegativeRow}(d)$ gives the displayed $\mathsf{RealAlgNonnegativeRow}(\mathsf{E1}(d))$, and a supplied $\mathsf{RatApartRow}(d, e)$ gives $\mathsf{RealAlgApartRow}(\mathsf{E1}(d), \mathsf{E1}(e))$.

Finally read classifier movement back through Definition 38.11. The readback produces the RatUp classifier comparisons consumed by RatUp classifier transport, so stability of nonnegative and apartness rows is inherited only on the constant-rational boundary. No trichotomy or completeness datum is present in the transported rows. □

Lean4 ✓ `BEDC.Derived.RealAlgOrderUp.RealAlgOrderConstant order apartness obligations`

Theorem 38.42 (Constant rational RealAlgOrder boundary)**.** *Let $d, e, o : \mathsf{Hist}$. The RatUp carrier, classifier, nonnegative, and apartness rows transported through the constant rational embedding give well-formed* RealAlgOrder *rows on embedded RealUp constants:*

$$\mathsf{RatHistoryCarrier}(d) \Longrightarrow \mathsf{RealConstantHistoryCarrier}(\mathsf{E1}(d)),$$

$$\mathsf{RatHistoryClassifier}(d, e) \Longrightarrow \mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(e)),$$

and every supplied RatUp row RatAddRow*,* RatNegRow*,* RatMulRow*,* RatAbsRow*,* RatNonnegativeRow*, or* RatApartRow *with output history o transports to the corresponding* RealAlgOrder *row on the embedded constants. These transported rows are stable under* RealConstantHistoryClassifier *on all displayed RealUp constant endpoints.*

Proof. Use Definition 38.31 to expose the carrier and classifier chains from RatUp histories to StreamNameUp constant streams and then to e-one RealUp constants. The carrier row gives $\mathsf{RealConstantHistoryCarrier}(\mathsf{E1}(d))$ from $\mathsf{RatHistoryCarrier}(d)$, and the classifier row gives RealConstantHistoryClassifie from $\mathsf{RatHistoryClassifier}(d, e)$.

For each algebra or order row, apply the corresponding RatUp witness before embedding. Addition, negation, multiplication, absolute value, nonnegative comparison, and strict apartness therefore keep their rational ledger as the hidden source and receive e-one RealUp endpoints as their public boundary.

It remains to check stability under the RealUp constant classifier. Read a classifier comparison back to the RatUp classifier at the e-one endpoint by Definition 38.11. RatUp classifier transport moves the chosen algebra or order witness along the exposed rational comparison, and the constant rational embedding certificate repacks the result as the corresponding RealUp constant row. □

Lean4 ✓ `BEDC.Derived.RealAlgOrderUp.RealAlgOrderConstant rational order boundary`

The intended Lean target shape for this boundary is `BEDC.Derived.RealAlgOrderUp.constant_rational_orc`

Theorem 38.43 (RealAlgOrder constant rational scoped certificate)**.** *The constant-rational* RealAlgOrder *package is scoped exactly by* RatHistoryCarrier*,* RatHistoryClassifier*, the RatUp operation and order rows,* RealConstantHistoryCarrier*,* RealConstantHistoryClassifier*,* BHist*,* hsame*, Definition 38.31, and Definition 38.11. More precisely, it forms a ten-field scoped certificate with the following fields:*

1. *traditional target: the constant rational real algebra and order surface of* RealAlgOrder*;*
2. *BEDC source:* $\mathsf{Rat}^{\uparrow} + \mathsf{StreamName}^{\uparrow} + \mathsf{Real}^{\uparrow}$ *restricted to RealUp constant rational endpoints over* BHist *and* hsame*;*
3. *carrier:* RealConstantHistoryCarrier*;*

4. *classifier:* RealConstantHistoryClassifier*;*
5. *stability: every displayed Real constant classifier comparison reads back to the RatUp classifier row by Definition 38.11;*
6. *ledger: the hidden rational operation or order row remains the RatUp row, while the visible endpoint is sealed by the e-one RealUp constant embedding of Definition 38.31;*
7. *carrier and classifier theorem: Definition 38.39;*
8. *algebra theorem: Definition 38.40;*
9. *order and apartness theorems: Definition 38.41 and Definition 38.42;*
10. *exactness: no completeness row, trichotomy row, metric row, topology row, or standard-bridge row is consumed.*

Proof. First project the four RealAlgOrder boundary theorems. The carrier and classifier component comes from Definition 38.39; the algebra component comes from Definition 38.40; the order and apartness component comes from Definition 38.41; and the combined boundary comes from Definition 38.42.

Next expose the permitted source for each projected component. The only public Real endpoints are $\mathsf{E1}(d)$-sealed rational histories supplied by Definition 38.31. The only hidden operation and order rows are the RatUp rows named in the concrete interface, and the only ambient history relation used to move them is hsame on BHist.

Finally read every Real constant classifier move back to RatUp through Definition 38.11. This gives exactly the RatUp classifier comparison required by the projected carrier, classifier, algebra, order, and apartness rows, and no proof step asks for completeness, trichotomy, metric structure, topology, or a standard bridge. □

↪ variant BEDC.Derived.RealAlgOrderUp.RealAlgOrderConstant rational scoped certificate

Theorem 38.44 (RealAlgOrder constant rational audit exactness)**.** *For constant-rational endpoints* $\mathsf{E1}(d)$*,* $\mathsf{E1}(e)$*, and* $\mathsf{E1}(o)$*, every accepted* RealAlgOrder *carrier, classifier, algebra, nonnegative, and apartness read factors through the constant rational route:*

RatHistoryCarrier, RatHistoryClassifier, *the displayed RatUp operation and order rows,*
RealConstantHistoryCarrier, RealConstantHistoryClassifier, BHist, hsame.

The only cross-layer certificates used by the route are Definition 38.31 and Definition 38.11. Thus the constant-rational interface does not project full non-constant real arithmetic, trichotomy, least-upper-bound completeness, Cauchy completeness, metric or topology rows, quotient equality, or a standard bridge.

Proof. Start with the carrier inventory supplied by Definition 38.39. Its public RealUp endpoints are exactly the e-one constants $\mathsf{E1}(d)$, $\mathsf{E1}(e)$, and $\mathsf{E1}(o)$ whose hidden witnesses are RatUp histories. The carrier and classifier rows therefore pass through RatHistoryCarrier, RatHistoryClassifier, RealConstantHistoryCarrier, and RealConstantHistoryClassifier.

Next apply the row inventories. The algebra rows are those of Definition 38.40; the nonnegative and apartness rows are those of Definition 38.41; and their constant-rational boundary is Definition 38.42. Each row is read by taking the RatUp operation or order witness first and then embedding its output as a RealUp constant endpoint.

Finally compose the scoped certificate of Definition 38.43 with the two RealUp constant readback certificates. The embedding certificate supplies the forward route from rational histories to e-one RealUp constants, and the classifier readback certificate returns any displayed Real constant classifier move to the RatUp classifier. Since this inventory contains no row for non-constant real operations, trichotomy, completeness, metric or topological structure, quotient equality, or a standard bridge, no accepted read can escape the constant rational route. □

The intended Lean target shape for this certificate is `BEDC.Derived.RealAlgOrderUp.constant_rational_sc`

Theorem 38.45 (RealAlgOrder positive-radius window stability)**.** *Let A and B be accepted* RealAlgOrder *constant packets whose endpoints are sealed by the same* StreamName$^{\uparrow}$ *finite-window source, the same* RegSeqRat *seal, the same* Real$^{\uparrow}$ *component row, and the same positive* Rat$^{\uparrow}$ *order-radius row after the displayed* hsame *and* Cont *transports. Then their apartness and order read is the same finite L10 window read. The read is determined by the StreamName finite observation window, the RegSeqRat regularity seal, the RealUp constant endpoint, and the RatUp positive-radius order witness; it cannot import quotient stream equality, host real equality, trichotomy, selected limits, ambient completeness, metric structure, or a standard bridge.*

Proof. Begin with the constant rational order boundary, Definition 38.42. It routes every positive-radius apartness or order read through the RatUp witness before the result is embedded as a RealUp constant endpoint.

Next apply the scoped certificate of Definition 38.43. Since the two packets agree on the StreamName finite-window source, the RegSeqRat seal, the RealUp component row, and the RatUp radius row through hsame and Cont, the accepted read has no remaining coordinate from which to choose a different order window.

Finally use the StreamName and RegSeqRat finite-window handoffs cited by the RealUp seal, including the constant rational embedding and classifier readback certificates. These handoffs identify the L10 observation window as the public source of the RealAlgOrder read and leave no route to quotient equality, host real equality, trichotomy, selected limits, completeness, metric data, or a standard bridge. □

Theorem 38.46 (RealAlgOrder constant apartness metric handoff)**.** *For constant-rational RealUp endpoints carried by the* RealAlgOrder *constant carrier, the checked carrier and classifier rows, algebra rows, and order and apartness rows package a finite* BHist *handoff for downstream apartness and metric consumers. The handoff consists exactly of the two displayed RealUp endpoint rows* E1(d) *and* E1(e)*, their RatUp witness rows, the supplied positive dyadic or apartness row, the* hsame *and* Cont *transport routes, the visible* Pkg *provenance, and the* NameCert *ledger that records the constant rational source.*

Any ApartnessReal$^{\uparrow}$ *or* Met$^{\uparrow}$ *consumer may read this packet only as finite positive-separation data in the sense of Definition 304.6, Definition 304.5, and Definition 304.8. The packet does not export trichotomy, completeness, host real equality, quotient data, or a classifier outside the displayed constant-rational boundary.*

Proof. First project the RealAlgOrder constant boundary rows. The carrier and classifier rows come from Definition 38.39; the operation rows come from Definition 38.40; and the order and apartness rows come from Definition 38.41.

Next apply Definition 38.43. It packages those rows over BHist with the exposed hsame transport, the RatUp source witnesses, the e-one RealUp endpoint seals, and the visible ledger provenance. Thus a consumer sees the two endpoint rows and the finite positive dyadic or apartness row as one bounded packet, rather than as a global real-order principle.

Finally match that packet with the downstream apartness surface. The finite row of Definition 304.6, the handoff of Definition 304.5, and the consumer boundary of Definition 304.8 read exactly the endpoint, radius or apartness, transport, Pkg, and NameCert coordinates named above. Since no cited surface contains trichotomy, completion, host equality, or quotient coordinates, the handoff cannot export any of them. □

Lean4 ✓ `BEDC.Derived.RealUp.RealAlgOrderConstantApartnessMetricHandoff`

Theorem 38.47 (RealAlgOrder apartness positive-gap order consumer)**.** *For constant-rational RealUp endpoints carried by the* RealAlgOrder *boundary, a supplied RatUp apartness or nonnegative positive-gap row together with the e-one embedding determines exactly the finite* ApartnessReal$^{\uparrow}$ *separation packet consumed by later* Met$^{\uparrow}$ *and order consumers. The packet consists of the two endpoint rows, the positive dyadic radius or apartness row, the finite window and readback rows, the visible* hsame *and* Cont *transports, the* Pkg *provenance, and the* NameCert *dependency rows.*

The consumer surface exports no trichotomy, completeness, quotient equality, host real inequality, topology row, or non-constant RealUp arithmetic. Every downstream read is restricted to the finite separation packet of Definition 304.6 and the consumer boundary of Definition 304.8.

Proof. Project the constant-rational order and apartness rows from Definition 38.41. The supplied RatUp positive-gap row is then carried upward only through the e-one endpoint embedding, so the visible RealUp endpoints remain the constant-rational rows certified by Definition 38.43.

Next repackage those projected rows through Definition 38.46. Its handoff surface already isolates the two endpoint rows, the positive dyadic radius or apartness row, the hsame and Cont routes, the Pkg provenance, and the NameCert ledger that records the constant rational source.

It remains to identify the packet consumed downstream. The finite row of Definition 304.6 supplies the endpoint, window, readback, and separation-ledger shape. Applying Definition 304.8 then restricts every metric or order consumer to exactly those coordinates, so no excluded order, quotient, host-inequality, completeness, or topology coordinate is available to read. □

Theorem 38.48 (RealAlgOrder constant positive-gap consumer determinacy)**.** *Let two constant-rational* RealAlgOrder *endpoint packets carry the same RatUp source endpoints, the same positive dyadic or apartness row, the same e-one* Real$^{\uparrow}$ *embedding rows, the same finite-window and readback rows, the same* hsame *and* Cont *transport routes, the same* Pkg *provenance, and the same* NameCert *ledger. Then every* ApartnessReal$^{\uparrow}$, Met$^{\uparrow}$, *or order consumer reading those packets reads one and the same finite positive-gap separation packet.*

The determined packet contains exactly the two constant-rational endpoint rows, the shared positive-gap row, the finite-window and readback rows, the visible transports, provenance, and ledger. It exports no trichotomy, completeness, quotient equality, host real inequality, topology row, or non-constant Real$^{\uparrow}$ *arithmetic.*

Proof. Project the RatUp order and apartness rows for the two endpoint packets through Definition 38.41. The hypotheses identify the RatUp endpoints and the positive dyadic or apartness row before any downstream consumer is allowed to read them.

Package the projected rows by Definition 38.43. This places both endpoint displays over the same e-one Real$^{\uparrow}$ embedding rows, the same hsame and Cont routes, the same Pkg provenance, and the same NameCert ledger.

Route the packaged data through Definition 38.46. Its handoff surface has precisely the finite positive-separation coordinates listed in the statement, so the two displays present one packet to apartness and metric consumers.

Finally apply Definition 38.47. That theorem identifies the downstream $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, and order consumer surface with the same finite separation packet. Since each cited surface omits trichotomy, completeness, quotient equality, host real inequality, topology, and non-constant real arithmetic, none of those rows is exported by the determinacy claim. □

Theorem 38.49 (RealAlgOrder constant public interface export)**.** *The carrier and classifier obligations of Definition 38.39, the algebra row obligations of Definition 38.40, the order and apartness obligations of Definition 38.41, the rational boundary of Definition 38.42, the scoped certificate of Definition 38.43, and the metric handoff of Definition 38.46 assemble the reusable constant-rational public* RealAlgOrder *interface.*

Every consumer read of this interface factors through RatUp, StreamNameUp, RealUp constant endpoints, BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The interface exports no trichotomy, completeness, host real equality, quotient data, non-constant RealUp arithmetic, topology row, or standard bridge.*

Proof. Project the checked carrier and classifier rows, the algebra rows, and the order and apartness rows from the three obligation theorems named above. The rational order boundary identifies these rows as constant-rational rows transported from RatUp through the e-one RealUp endpoint embedding.

Package the projected rows with Definition 38.43. This makes the public surface a scoped packet over BHist, visible hsame and Cont transport, Pkg provenance, and the NameCert ledger.

Finally route apartness and metric consumers through Definition 38.46. Since the handoff reads only the displayed constant endpoints and finite separation rows, none of the excluded full-real, quotient, topology, completeness, or bridge data is available to export. □

Theorem 38.50 (RealAlgOrder constant public order-metric interface)**.** *For constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints carried by the* RealAlgOrder *package, every public order read, apartness read, and* $\mathsf{Met}^{\uparrow}$*-facing read factors through the RatUp denominator row, the* E1 $\mathsf{Real}^{\uparrow}$ *endpoint, the transported algebra, order, and apartness rows, the positive-gap separation packet,* hsame*,* Cont*, and* Pkg *provenance.*

The public boundary exports no nonconstant real arithmetic, trichotomy, completeness, topology, quotient carrier, host-real inequality, or standard bridge row. Thus order consumers and metric consumers receive the same finite BHist *constant-rational interface.*

Proof. Begin with Definition 38.49. It packages the carrier, classifier, algebra, order, apartness, rational boundary, and metric handoff rows into one public constant-rational RealAlgOrder surface over RatUp denominators, E1 endpoints, hsame, Cont, Pkg provenance, and the NameCert ledger.

For the metric-facing read, apply Definition 38.46. The handoff identifies the displayed $\mathsf{Met}^{\uparrow}$ surface with the same constant endpoint rows and the same finite positive-separation data.

For the order-facing read, apply Definition 38.47. This turns the positive-gap separation packet into the order-consumer row without adding a new full-real comparison principle.

The determinacy and scope controls come from Definition 38.48 and Definition 38.43. They keep the apartness, metric, and order surfaces tied to the transported rational witness, the finite BHist ledger, and the displayed provenance. Since the cited rows omit nonconstant arithmetic, trichotomy, completeness, topology, quotient carriers, host-real inequalities, and standard bridges, the combined public boundary omits them as well. □

Theorem 38.51 (RealAlgOrder positive apartness nonzero metric boundary)**.** *For constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints carried by the* RealAlgOrder *package, suppose the RatUp positive-gap or*

apartness row used by Definition 38.47 is present. Then every $\mathsf{Met}^{\uparrow}$*-facing handoff packet supplied by Definition 38.46 carries a nonempty positive-distance boundary. It cannot be read as an empty-distance witness for the same displayed endpoints.*

The exported packet is restricted to finite BHist *endpoint rows, the radius or apartness row,* hsame *transport,* Cont *routes,* Pkg *provenance, and* NameCert *dependency rows. It exports no trichotomy, full real completeness, quotient carrier, host-real equality, or non-constant* $\mathsf{Real}^{\uparrow}$ *arithmetic.*

Proof. Project the order and apartness rows from Definition 38.41. The supplied RatUp positive-gap row is the same row consumed by Definition 38.47, so the constant endpoints remain tied to their rational witnesses and visible E1 embeddings.

Pass those projected rows through Definition 38.46. The handoff packet is therefore the finite positive-separation packet described by Definition 304.6 and Definition 304.8, with the positive radius or apartness ledger still visible.

Now test the contrary empty-distance read on the metric-facing side. The MetricUp endpoint boundary Definition 57.213 requires a nonempty endpoint boundary from a nonempty distance, while Definition 57.222 rules out reading the same visible positive endpoint evidence as an empty-distance witness. Thus the positive apartness packet can only enter the metric consumer as a nonempty positive-distance boundary.

Finally apply Definition 38.50. It limits the exported rows to finite endpoint histories, radius or apartness evidence, visible hsame and Cont transport, Pkg provenance, and NameCert rows. No excluded full-real or quotient coordinate is available to turn the positive boundary into an empty-distance packet. □

Theorem 38.52 (RealAlgOrder constant positive boundary metric consumer)**.** *A constant-rational* $\mathsf{RealAlgOrder}^{\uparrow}$ *endpoint packet carrying a positive apartness row or a positive-gap row exports exactly the* $\mathsf{Met}^{\uparrow}$ *nonempty-distance consumer boundary. The consumer input consists of finite* BHist *endpoint histories, the positive radius or apartness ledger, visible* hsame *and* Cont *routes,* Pkg *provenance, and the local* NameCert *rows for the constant endpoint packet.*

Thus the exported metric consumer surface contains no empty-distance witness, quotient real equality, trichotomy, selected limit, full real arithmetic row, or ambient completeness principle.

Proof. Project the metric-facing handoff through Definition 38.46. It identifies the $\mathsf{Met}^{\uparrow}$ consumer side with the same constant endpoints and the same positive separation data carried by the $\mathsf{RealAlgOrder}^{\uparrow}$ packet.

The positive packet is the order-facing packet isolated by Definition 38.47. Its determinacy is controlled by Definition 38.48, so the positive gap, apartness row, rational witness, and displayed endpoint histories cannot drift apart.

Now apply the endpoint boundary rows for $\mathsf{Met}^{\uparrow}$. The nonempty-distance boundary of Definition 57.213 accepts the displayed positive endpoint evidence, while Definition 57.222 excludes reading that same evidence as an empty-distance endpoint witness.

Finally use Definition 38.50. It exhausts the public rows by finite endpoint histories, the positive ledger, visible hsame and Cont routes, Pkg provenance, and NameCert rows. Since no quotient, trichotomy, selected-limit, completeness, or full-arithmetic coordinate is exported, the consumer boundary is exactly the nonempty-distance input just described. □

Theorem 38.53 (RealAlgOrder constant rational standard bridge boundary)**.** *The constant-rational public* RealAlgOrder *interface of Definition 38.49, the order-metric public interface of*

Definition 38.50, and the positive-boundary metric consumer of Definition 38.52 assemble a conservative standard bridge from RatUp rational witnesses through RealUp constant endpoints to the $\mathsf{Met}^{\uparrow}$ *nonempty-distance consumer surface.*

The bridge rows are exactly the displayed BHist*,* hsame*,* Cont*,* Pkg*,* NameCert*, RatUp denominator, RealUp constant endpoint,* RealAlgOrder *order and apartness, and* $\mathsf{Met}^{\uparrow}$ *distance-boundary rows. The packet contains no trichotomy, completed-real equality, full nonconstant arithmetic, topology, quotient carrier, selected limit, completeness, or arbitrary host metric-space coordinate.*

Proof. Project the public constant-rational interface by Definition 38.49. This supplies the RatUp denominator witnesses, their E1 RealUp constant endpoints, the finite BHist endpoint histories, visible hsame and Cont transport, Pkg provenance, and the NameCert rows.

Route the order and metric reads through Definition 38.50. The order, apartness, and metric-facing consumers therefore receive the same displayed constant-rational rows rather than separate carrier, quotient, topology, or completion data.

Identify the metric side with Definition 38.52. It pins the $\mathsf{Met}^{\uparrow}$ consumer surface to the nonempty-distance boundary carried by the positive-gap or apartness ledger over the same endpoints.

Conservativity follows because every row just cited is one of the finite displayed rows named in the statement. None of trichotomy, completed-real equality, full nonconstant arithmetic, topology, quotient carriers, selected limits, completeness, or arbitrary host metric spaces is a coordinate of the packet, so the bridge exports only the displayed RatUp–RealUp–MetricUp boundary. □

Theorem 38.54 (RealAlgOrder standard bridge row conservativity)**.** *For constant-rational* $\mathsf{Real}^{\uparrow}$ *endpoints carried by the* RealAlgOrder *package, every standard bridge read factors through the displayed* $\mathsf{Rat}^{\uparrow}$ *denominator witness,* $\mathsf{Real}^{\uparrow}$ *embedding row, algebra row, order and apartness row, metric handoff row, finite* BHist *endpoint histories, visible* hsame *comparisons,* Cont *routes,* Pkg *provenance, and local* NameCert *rows.*

Consequently the bridge exports no full non-constant real arithmetic, trichotomy, completeness principle, topology, quotient carrier, or host-real inequality.

Proof. Begin with the scoped constant-rational certificate of Definition 38.43. It fixes the only admissible endpoint histories as E1-embedded rational witnesses and keeps the classifier transport, BHist rows, hsame rows, Cont routes, Pkg provenance, and NameCert ledger visible.

Project the public order and metric rows through Definition 38.50. The algebra, order, apartness, and metric-facing coordinates are therefore read from the same displayed rational witness and its constant $\mathsf{Real}^{\uparrow}$ embedding, not from an ambient real carrier.

For positive metric consumers, apply Definition 38.52. The handoff row is the visible nonempty-distance boundary obtained from the positive gap or apartness ledger over those same endpoints.

Finally use Definition 38.53. Its bridge ledger is exhausted by exactly the rows listed above. Since no row names full non-constant arithmetic, trichotomy, completeness, topology, quotient carriers, or host-real inequalities, every standard bridge read is conservative over the transported $\mathsf{Rat}^{\uparrow}$ rows. □

Theorem 38.55 (RealAlgOrder constant rational bridge endpoint determinacy)**.** *Let P and Q be two constant-rational* $\mathsf{RealAlgOrder}^{\uparrow}$ *standard-bridge packets whose displayed* $\mathsf{Rat}^{\uparrow}$ *source endpoints are the same. Suppose the two packets carry the same transported algebra, order, and apartness rows, the same positive-gap or apartness ledger, and the same displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *provenance.*

Then the $\mathsf{Met}^{\uparrow}$ *nonempty-distance consumer endpoints exposed by* P *and* Q *are the same boundary packet. The common exposed rows are exactly the* $\mathsf{Rat}^{\uparrow}$ *denominator witnesses, the* $\mathsf{Real}^{\uparrow}$ *constant endpoints, the* RealAlgOrder *order and apartness rows, and the* $\mathsf{Met}^{\uparrow}$ *distance-boundary rows. No trichotomy, completed-real equality, topology, quotient carrier, selected limit, completeness, or arbitrary host metric-space coordinate is exported.*

Proof. First project both displays through Definition 38.49. Since their $\mathsf{Rat}^{\uparrow}$ source endpoints and displayed histories agree, the public constant-rational packet supplies the same denominator witnesses, the same $\mathsf{Real}^{\uparrow}$ constant endpoints, and the same local provenance rows.

Next read the shared algebra, order, apartness, and metric-facing rows through Definition 38.50. This keeps the two displays on the same transported rational source rather than adding an ambient real carrier or host comparison.

The positive boundary is then identified by Definition 38.52. The common positive-gap or apartness ledger exposes one $\mathsf{Met}^{\uparrow}$ nonempty-distance consumer boundary over the displayed endpoints.

Finally apply Definition 38.53. Its standard bridge coordinates are exactly the denominator, constant endpoint, order, apartness, and metric distance-boundary rows already fixed above. Therefore the two displays expose the same $\mathsf{Met}^{\uparrow}$ consumer endpoint boundary, with no additional real-order, topological, quotient, limit, completeness, or host metric-space coordinate available for them to differ on. □

Theorem 38.56 (RealAlgOrder constant transported classifier congruence)**.** *Let* P *be a constant-rational* $\mathsf{RealAlgOrder}^{\uparrow}$ *endpoint packet whose displayed* $\mathsf{Rat}^{\uparrow}$ *source classifier rows are* $\mathsf{RatHistoryClassifier}(d, d')$, $\mathsf{RatHistoryClassifier}(e, e')$, *and* $\mathsf{RatHistoryClassifier}(o, o')$. *Then every carrier row, algebra row, order row, apartness row, and* $\mathsf{Met}^{\uparrow}$*-facing consumer row exported by the public constant-rational interface is congruent along exactly those three* $\mathsf{Rat}^{\uparrow}$ *classifier rows after applying the* $\mathsf{E1}$ $\mathsf{Real}^{\uparrow}$ *embedding.*

Equivalently, the exported rows of the packet have one classifier witness surface: the carrier endpoints are controlled by the displayed rational classifiers, the algebra outputs are the transported rational algebra outputs, the order and apartness observations are the transported rational order and apartness observations, and every metric consumer reads the resulting constant-rational boundary through the same embedded rows. No trichotomy, completeness theorem, topology, quotient carrier, or nonconstant arithmetic coordinate is introduced.

Proof. First apply Definition 38.39. The constant-rational carrier rows and classifier rows are already displayed as $\mathsf{E1}$-embedded $\mathsf{Rat}^{\uparrow}$ histories, so the only admissible classifier witnesses are the rational rows named in the statement.

Next use Definition 38.40. The addition and multiplication rows are computed on the rational witnesses before returning to the $\mathsf{Real}^{\uparrow}$ carrier, so their exported congruence is transported from the same rational classifier surface.

For the comparison coordinates, apply Definition 38.41. This identifies the order and apartness rows with the displayed rational order and apartness rows after the $\mathsf{E1}$ embedding.

Finally project through Definition 38.50 and Definition 38.55. The public order, apartness, and metric-facing consumer rows therefore share the same transported classifier witnesses and cannot acquire a trichotomy, completeness, topological, quotient, or nonconstant arithmetic coordinate. □

Theorem 38.57 (RealAlgOrder public apartness metric export)**.** *For constant rational real names, the public* $\mathsf{RealAlgOrder}^{\uparrow}$ *export consists exactly of the carrier and classifier rows, algebra rows,*

order and apartness rows, positive-gap metric handoff rows, and the displayed hsame, Cont, Pkg, *and* NameCert *provenance already listed in this chapter. A* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{S}^{1\uparrow}$ *consumer may read only those rows.*

The export supplies no trichotomy row, host real equality, quotient representative, or completeness datum.

Proof. Apply Definition 38.49 to obtain the carrier, classifier, algebra, provenance, and public NameCert rows.

Next apply Definition 38.50 and Definition 38.51. These project the order, apartness, and positive-gap metric handoff rows available to metric and circle consumers.

Finally use Definition 38.56. The transported rational classifier surface is the only congruence source for the displayed rows, so row projection leaves no coordinate from which trichotomy, host real equality, quotient representatives, or completeness could be read. □

Theorem 38.58 (RealAlgOrder public certificate audit boundary)**.** *The public* $\mathsf{RealAlgOrder}^{\uparrow}$ *certificate boundary is exhausted by the constant-rational carrier and classifier rows, the transported* $\mathsf{Rat}^{\uparrow}$ *algebra, order, and apartness rows, the* $\mathsf{Real}^{\uparrow}$ *e-one endpoint embedding, the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *classifier readback rows, and the* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{S}^{1\uparrow}$ *consumer handoff rows displayed in this chapter. Every public consumer read factors through those rows and their visible* BHist, hsame, Cont, Pkg, *and* NameCert *provenance.*

The boundary exports no trichotomy, completeness, host equality, quotient representative, nonconstant arithmetic coordinate, topology row, or standard bridge.

Proof. Begin with Definition 38.43. It packages the constant-rational carrier, classifier, algebra, order, and apartness rows over the displayed $\mathsf{Rat}^{\uparrow}$ witnesses, $\mathsf{Real}^{\uparrow}$ e-one endpoints, BHist, hsame, Cont, Pkg, and NameCert ledger.

Next apply Definition 38.57. Its public projection identifies the apartness and metric-facing surface with the same finite row set, so a $\mathsf{Met}^{\uparrow}$ or $\mathsf{S}^{1\uparrow}$ consumer receives only the exported positive-gap handoff packet.

The two following handoff surfaces keep the downstream reads inside that packet: Definition 38.59 isolates the metric separation consumer, and Definition 38.66 isolates the $\mathsf{S}^{1\uparrow}$ positive boundary consumer.

Thus row projection exhausts the public certificate boundary by the rows named in the statement. Since the scoped certificate, public export, and two consumer handoff surfaces each omit trichotomy, completeness, host equality, quotient representatives, nonconstant arithmetic coordinates, topology rows, and standard bridges, the assembled public boundary omits them as well. □

Theorem 38.59 (RealAlgOrder apartness metric consumer separation)**.** *For constant rational real names, any* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{S}^{1\uparrow}$ *consumer of the public apartness and metric export of Definition 38.57 can read only the rationally transported carrier, classifier, algebra, order, apartness, positive-gap handoff,* hsame, Cont, Pkg, *and* NameCert *rows displayed by the* $\mathsf{RealAlgOrder}^{\uparrow}$ *packet.*

The same consumer surface does not supply a trichotomy row, completed-real equality, quotient representative, or completeness datum. Apartness and the positive-gap metric boundary are therefore consumer-visible separation rows, not an ambient completed-real order or quotient-equality principle.

Proof. Start with Definition 38.43. The scoped certificate fixes the constant-rational carrier by a $\mathsf{Rat}^{\uparrow}$ witness embedded into $\mathsf{Real}^{\uparrow}$, and it lists the classifier, algebra, order, apartness, transport, continuation, provenance, and local name rows as the available coordinates.

Apply Definition 38.57. Its public projection is exactly the row set available to $\mathsf{Met}^{\uparrow}$ and $\mathsf{S}^{1\uparrow}$ consumers, so a consumer can only project the displayed rows already present in the packet.

Next use Definition 38.51. The apartness-to-positive-gap handoff is a boundary row over the same transported rational witnesses. It adds a metric-facing separation read but no independent completed-real equality, quotient representative, or completeness coordinate.

Finally compare this projected row set with the constructive real algebra boundary recorded by the roadmap constraints for section 9467.12. Since no displayed ledger coordinate has the type of a trichotomy row, completed-real equality, quotient representative, or completeness datum, those data cannot be obtained by reading the apartness or metric rows. □

Theorem 38.60 (RealAlgOrder MetricSpace SOne public interface triad)**.** *For constant rational real names, let a* $\mathsf{RealAlgOrder}^{\uparrow}$ *apartness packet be consumed both by the* $\mathsf{Met}^{\uparrow}$ *real-distance carrier and by an accepted* $\mathsf{S}^{1\uparrow}$ *component-and-unit-equation packet. The joint consumer interface factors through exactly the shared* $\mathsf{RealAlgOrder}^{\uparrow}$ *endpoint witnesses, the* $\mathsf{Met}^{\uparrow}$ *distance row, the* $\mathsf{S}^{1\uparrow}$ *component and unit-equation rows, the displayed* hsame *transports,* Cont *routes,* Pkg *provenance, and the local* NameCert *rows. The triad interface supplies no trichotomy row, completed-real equality, angle quotient, host metric structure, or Real completeness datum.*

Proof. First apply Definition 38.61. The positive-distance handoff repacks the RealAlgOrder apartness row as the $\mathsf{Met}^{\uparrow}$ real-distance component over the same rational endpoint witnesses, real-name transports, hsame rows, continuation routes, provenance, and local certificate.

Next use Definition 38.62. This keeps metric-facing consumption inside the displayed endpoint, apartness, transport, continuation, provenance, local naming, and metric ledger rows. The metric consumer therefore contributes only the public distance and triangle boundary rows, not an ambient host metric or completed-real equality.

Finally apply Definition 38.63. The $\mathsf{S}^{1\uparrow}$ side reads the same RealAlgOrder endpoint witnesses through the real component rows, product carrier, unit-equation witness, componentwise classifier rows, and equation transports. Since the SOne boundary excludes angle quotients and the RealAlgOrder metric boundary excludes trichotomy, completed-real equality, host metric structure, and Real completeness, the combined consumer surface is exactly the displayed triad of RealAlgOrder endpoints, MetricSpace distance, and SOne component-and-equation rows. □

Theorem 38.61 (RealAlgOrder public positive-distance handoff)**.** *For constant rational real names, the positive-gap or apartness row exported by Definition 38.57 repacks as the positive component of the* $\mathsf{Met}^{\uparrow}$ *real-distance public surface of Definition 57.311. The repacking reads only the* $\mathsf{Rat}^{\uparrow}$ *endpoint witnesses, their* $\mathsf{Real}^{\uparrow}$ *transported names, the displayed* hsame *rows,* Cont *routes,* Pkg *provenance, local* NameCert *row, and the* $\mathsf{RealAlgOrder}^{\uparrow}$ *budget packet. It does not add a completed-real equality row, a trichotomy row, or a host metric structure.*

Proof. Start from the exported apartness and positive-gap row of Definition 38.57. The row already records the two rational endpoints, their real-name transport, the visible hsame coordinates, the continuation routes, provenance, and local certificate.

Use Definition 38.51 to read this row as a metric-facing positive boundary. The theorem supplies the positive component over the same transported endpoints and the same budget packet, so no new equality or trichotomy coordinate is introduced.

Finally compare the resulting row with Definition 57.311 and Definition 57.313. The $\mathsf{Met}^{\uparrow}$ public surface consumes the positive-distance component as a displayed ledger row, and Definition 38.59 keeps the consumer from reading any stronger completed-real or host-metric structure. □

Theorem 38.62 (RealAlgOrder apartness triangle consumer)**.** *Suppose two adjacent* $\mathsf{Met}^{\uparrow}$ *positive-distance reads are both obtained from* $\mathsf{RealAlgOrder}^{\uparrow}$ *apartness packets of Definition 38.57. Then the outer triangle-boundary consumer factors through the same visible endpoint rows, apartness rows,* hsame *transports,* Cont *routes,* Pkg *provenance, local* NameCert *rows, and metric triangle ledger rows. The factorization supplies only the public triangle consumer boundary of* $\mathsf{Met}^{\uparrow}$ *and does not upgrade RealAlgOrder apartness into completed-real equality, trichotomy, or an ambient host metric.*

Proof. Apply the public export theorem to each adjacent apartness packet. Each packet exposes a positive-distance read over its displayed rational endpoints, real transport, apartness row, hsame coordinate, continuation route, provenance, and local certificate.

Next apply Definition 38.51 to both reads. The shared endpoint remains visible because both positive components are repacked from the same RealAlgOrder endpoint ledger rather than from a hidden host metric.

Use Definition 57.311 and Definition 57.313 to feed the two displayed positive components into the metric triangle ledger. The triangle consumer reads the outer boundary through the same public metric rows.

Finally invoke Definition 38.59. The consumer surface is limited to visible endpoints, apartness, transport, continuation, provenance, local naming, and triangle-ledger rows, so the outer boundary does not create completed-real equality, trichotomy, or host metric structure. □

Theorem 38.63 (RealAlgOrder SOne unit-equation apartness boundary)**.** *For constant rational real names feeding an accepted* $\mathsf{S}^{1\uparrow}$ *component-and-unit-equation packet, every unit-equation or separation consumer that uses the positive-gap or apartness row exported by Definition 38.57 factors through the same* $\mathsf{RealAlgOrder}^{\uparrow}$ *endpoint witnesses, the* $\mathsf{Met}^{\uparrow}$ *real-distance carrier of Definition 57.311, and the* $\mathsf{S}^{1\uparrow}$ *component and unit-equation rows of chapter 58. The boundary exports no angle quotient, trichotomy row, completed-real equality, host metric structure, or Real completeness datum.*

Proof. Apply Definition 38.57 to the two constant rational endpoint names. The exported row supplies the same endpoint witnesses, real-name transports, apartness surface, continuation routes, provenance, and local naming data used by the RealAlgOrder packet.

Repack the positive-gap row through Definition 38.51. This keeps the metric-facing positive component tied to the displayed RealAlgOrder endpoint witnesses rather than to a hidden host metric.

Use Definition 57.311 and Definition 38.61 to feed that positive component into the public real-distance carrier. The $\mathsf{S}^{1\uparrow}$ consumer then reads only the two real component rows, the product carrier, the unit-equation witness, componentwise classifier rows, and equation transport recorded in chapter 58.

Finally invoke Definition 38.59. The consumer-separation result excludes completed-real equality, trichotomy, quotient representatives, and completeness data from the RealAlgOrder metric surface; the $\mathsf{S}^{1\uparrow}$ carrier rows exclude angle quotients and host metric structure. Therefore the unit-equation consumer factors through exactly the displayed RealAlgOrder, MetricSpace, and SOne rows. □

Theorem 38.64 (RealAlgOrder MetricSpace SOne positive-boundary transport)**.** *For constant rational real names, componentwise* hsame *transport of the* $\mathsf{RealAlgOrder}^{\uparrow}$ *endpoint witnesses preserves the positive-boundary row through the three consumer interfaces displayed by the* $\mathsf{RealAlgOrder}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*, and* $\mathsf{S}^{1\uparrow}$ *packets. The transported row is the same visible* BHist *boundary with the same* Cont

routes, Pkg *provenance, and local* NameCert *rows: it reads as the* $\mathsf{RealAlgOrder}^{\uparrow}$ *positive apartness boundary, as the* $\mathsf{Met}^{\uparrow}$ *positive-distance row, and as the* $\mathsf{S}^{1\uparrow}$ *component-and-unit-equation row over the same transported endpoints.*

The transported consumer still has no trichotomy row, completed-real equality, angle quotient, host metric structure, or Real completeness coordinate.

Proof. First apply Definition 38.61. The positive-gap row exported by the RealAlgOrder packet is repacked as the $\mathsf{Met}^{\uparrow}$ positive-distance component without changing the rational endpoint witnesses, their hsame transports, the displayed BHist boundary, the Cont routes, the Pkg provenance, or the local NameCert row.

Next apply Definition 38.63. The same transported positive-boundary row feeds the $\mathsf{S}^{1\uparrow}$ component and unit-equation consumer through the displayed real components, product carrier, componentwise classifier rows, and equation transports over those endpoints.

Finally use Definition 38.59. That separation theorem says that the shared consumer surface contains only the listed endpoint, apartness, metric, component, transport, continuation, provenance, and naming rows, so no trichotomy, completed-real equality, angle quotient, host metric, or completeness coordinate is transported with the positive boundary. □

Theorem 38.65 (RealAlgOrder MetricSpace SOne positive-boundary correspondence)**.** *For constant rational real names, the positive-boundary row exported by* $\mathsf{RealAlgOrder}^{\uparrow}$*, the positive-distance row consumed by* $\mathsf{Met}^{\uparrow}$*, and the component-and-unit-equation separation row consumed by* $\mathsf{S}^{1\uparrow}$ *are the same displayed* BEDC *boundary read through three public interfaces. The shared rows are precisely the* $\mathsf{Rat}^{\uparrow}$ *endpoint witnesses, the transported* $\mathsf{Real}^{\uparrow}$ *names, the componentwise* hsame *transports, the* Cont *routes, the* Pkg *provenance, the local* NameCert *row, the* $\mathsf{Met}^{\uparrow}$ *distance row, and the* $\mathsf{S}^{1\uparrow}$ *component and unit-equation rows.*

This correspondence is a statement about public readings of the displayed BEDC *boundary. It is not a host metric equality, not a completed-real equality, and not an import of trichotomy, an angle quotient, host metric structure, or Real completeness.*

Proof. First apply Definition 38.60. This identifies the three public consumers as readings of the same RealAlgOrder endpoint spine: the rational endpoint witnesses, transported real names, hsame rows, continuation routes, provenance, and local naming certificate are shared before any consumer-specific repacking.

Next apply Definition 38.61. The positive-boundary row exported by $\mathsf{RealAlgOrder}^{\uparrow}$ is read by $\mathsf{Met}^{\uparrow}$ as its positive-distance row without adding host metric structure or completed-real equality.

Then apply Definition 38.63. The same positive-boundary row is read by $\mathsf{S}^{1\uparrow}$ through the displayed component rows, product carrier, unit-equation witness, componentwise classifier rows, and equation transports, without adding an angle quotient.

Finally combine the transport statement Definition 38.64 with Definition 38.59. The former keeps the shared boundary stable under the displayed hsame transports; the latter confines the conclusion to the visible endpoint, apartness, metric, component, transport, continuation, provenance, and naming rows. Thus the three readings correspond exactly as public BEDC rows and carry no trichotomy, completed-real equality, angle quotient, host metric structure, or Real completeness coordinate. □

Theorem 38.66 (RealAlgOrder MetricSpace SOne positive boundary)**.** *For constant rational real names, any* $\mathsf{RealAlgOrder}^{\uparrow}$ *apartness packet that is consumed simultaneously by* $\mathsf{Met}^{\uparrow}$ *and by* $\mathsf{S}^{1\uparrow}$ *factors through one shared positive-boundary package. The package consists exactly of the common*

rational endpoint witnesses, their $\mathsf{Real}^{\uparrow}$ *constant names, the* $\mathsf{RealAlgOrder}^{\uparrow}$ *apartness and positive-gap rows, the* $\mathsf{Met}^{\uparrow}$ *positive-distance row, the* $\mathsf{S}^{1\uparrow}$ *component product and unit-equation rows, the displayed* hsame *transports,* Cont *routes,* Pkg *provenance, and the local* NameCert *rows.*

The package supplies no trichotomy row, quotient equality, host metric structure, compactness, connectedness, or Real completeness datum.

Proof. Begin with Definition 38.43. It fixes the constant-rational endpoints as rational witnesses transported through the $\mathsf{Real}^{\uparrow}$ e-one boundary, and it displays the carrier, classifier, order, apartness, hsame, Cont, Pkg, and local naming rows available to the $\mathsf{RealAlgOrder}^{\uparrow}$ packet.

Next apply Definition 38.61. The apartness or positive-gap row is repacked as the $\mathsf{Met}^{\uparrow}$ positive-distance component without changing the endpoints, transports, continuation routes, provenance, or local certificate.

Use Definition 38.63 for the circle-side consumer. The $\mathsf{S}^{1\uparrow}$ row reads the same real component endpoints, the product carrier, the unit-equation witness, componentwise classifier rows, and equation transports; it does not introduce an angle quotient or an independent equality surface.

Finally compare the two consumer reads with Definition 38.60 and Definition 57.313. The shared row set is exactly the displayed endpoint, positive-distance, product, unit-equation, transport, continuation, provenance, and local certificate package, so no trichotomy, quotient equality, host metric structure, compactness, connectedness, or Real completeness coordinate is present. □

Theorem 38.67 (RealAlgOrder constant apartness SOne unit boundary)**.** *For constant rational real names feeding an accepted* $\mathsf{S}^{1\uparrow}$ *component-and-unit-equation consumer, the* $\mathsf{RealAlgOrder}^{\uparrow}$ *apartness boundary used by that consumer is exactly the constant-rational positive-boundary package of Definition 38.66. It contains the two displayed real component rows, the product carrier, the unit-equation witness, the positive-distance handoff through* $\mathsf{Met}^{\uparrow}$*, the* hsame *and* Cont *transport rows, the* Pkg *provenance row, and the local* NameCert *rows.*

It does not supply an angle quotient, completed-real equality, trichotomy, host metric structure, compactness, connectedness, or Real completeness.

Proof. Project the accepted circle consumer through Definition 38.63. The theorem identifies the $\mathsf{S}^{1\uparrow}$ unit-equation use of RealAlgOrder apartness with the same endpoint witnesses, real component rows, product carrier, unit-equation witness, componentwise classifier rows, and equation transports.

Then feed the underlying apartness row through Definition 38.61. This records the positive-distance component consumed by $\mathsf{Met}^{\uparrow}$ while leaving the rational endpoints, $\mathsf{Real}^{\uparrow}$ names, hsame rows, Cont routes, Pkg provenance, and local NameCert rows unchanged.

Apply Definition 38.66 to identify the common package seen by both consumers. Since that package has only the displayed constant-rational, metric-distance, product, unit-equation, transport, provenance, and certificate rows, an angle quotient or completed-real equality row has no source coordinate from which it can be read. □

Theorem 38.68 (RealAlgOrder metric consumer order stability)**.** *For constant rational real names, every* $\mathsf{Met}^{\uparrow}$ *positive-distance consumer obtained from a* $\mathsf{RealAlgOrder}^{\uparrow}$ *apartness packet preserves the original RealAlgOrder order and apartness row under the displayed* $\mathsf{Real}^{\uparrow}$ *classifier transport. The consumer may read the positive-distance component, endpoint witnesses,* hsame *transport,* Cont *route,* Pkg *provenance, and local* NameCert *row, but the transported order and apartness source remains the same* $\mathsf{RealAlgOrder}^{\uparrow}$ *row certified by the constant-rational interface.*

The stability statement does not assert trichotomy, quotient equality, host metric structure, compactness, connectedness, or Real completeness.

Proof. Start from Definition 38.56. It says that the algebra, order, apartness, and public metric-facing rows are transported from the same rational classifier surface through the displayed $\mathsf{Real}^{\uparrow}$ constant classifier.

Next apply Definition 38.61. The $\mathsf{Met}^{\uparrow}$ consumer receives the positive-distance component by repacking the RealAlgOrder apartness row, so the metric-facing read has the same endpoint witnesses, hsame rows, continuation routes, provenance, and local certificate.

Finally use Definition 38.59 together with Definition 38.66. These results limit the consumer surface to the displayed order, apartness, metric-distance, transport, continuation, provenance, and certificate rows. The order/apartness row is therefore stable under classifier transport, and no trichotomy, quotient equality, host metric, compactness, connectedness, or completeness coordinate is created by the metric consumer. □

Theorem 38.69 (Real constant classifier inner e-zero endpoint absurd)**.** *For histories* $tail, d$: BHist*, the constant real-history classifier excludes an* $\mathsf{E0}$ *rational endpoint even when it is sealed by the outer constant-real* $\mathsf{E1}$ *constructor:*

$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(\mathsf{E0}(tail)), \mathsf{E1}(d)) \Longrightarrow \mathsf{False},$$
$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(\mathsf{E0}(tail))) \Longrightarrow \mathsf{False}.$$

Proof. Expose the sealed constant-real classifier with Definition 38.11. The resulting rational classifier has an $\mathsf{E0}$ endpoint on one side, so the RatUp endpoint exclusion applies in the corresponding orientation. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier e1 e0 endpoint absurd`

Theorem 38.70 (Real constant classifier appended e-zero endpoint absurd)**.** *For histories* $head, tail, d$: BHist*, the constant real-history classifier excludes an appended denominator whose visible tail is headed by* $\mathsf{E0}$*, even under the outer constant-real* $\mathsf{E1}$ *seal:*

$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(head \cdot \mathsf{E0}(tail)), \mathsf{E1}(d)) \Longrightarrow \mathsf{False},$$
$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(head \cdot \mathsf{E0}(tail))) \Longrightarrow \mathsf{False}.$$

Proof. Expose the sealed constant-real classifier with Definition 38.11. The resulting rational classifier supplies a positive unary denominator witness for the appended endpoint. That contradicts Definition 37.15 in the corresponding orientation. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier e1 append e0 endpoint absurd`

Theorem 38.71 (Real constant classifier transported inner e-zero endpoint absurd)**.** *For histories* $h, k, tail$: BHist*, any constant real-history classifier excludes an* $\mathsf{E1}(\mathsf{E0}(tail))$ *display on either classified endpoint:*

$$\mathsf{RealConstantHistoryClassifier}(h, k) \Longrightarrow (\mathsf{hsame}(h, \mathsf{E1}(\mathsf{E0}(tail))) \Longrightarrow \mathsf{False}),$$
$$\mathsf{RealConstantHistoryClassifier}(h, k) \Longrightarrow (\mathsf{hsame}(k, \mathsf{E1}(\mathsf{E0}(tail))) \Longrightarrow \mathsf{False}).$$

Proof. For the left endpoint, unpack the constant real classifier only far enough to recover the opposite endpoint display $k\mathsf{hsameE1}(d)$ for some d. Together with the assumed display $h\mathsf{hsameE1}(\mathsf{E0}(tail))$, Definition 38.18 transports the classifier to the exact pair $\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(\mathsf{E0}(tail)), \mathsf{E1}(d))$. Then Definition 38.69 contradicts this exact sealed-zero shape.

The right endpoint is symmetric. Unpack the classifier to recover $h\mathsf{hsameE1}(d)$ for some d, combine it with the assumed $k\mathsf{hsameE1}(\mathsf{E0}(tail))$, transport to $\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(\mathsf{E0}(tail)))$, and apply the opposite orientation of Definition 38.69. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier transported inner e0 endpoint absurd`

Theorem 38.72 (Real constant classifier inner empty endpoint absurd)**.** *For histories d : BHist, the constant real-history classifier excludes an empty rational endpoint even when it is sealed by the outer constant-real* E1 *constructor:*

$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(d)) \Longrightarrow \mathsf{False},$$
$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(\mathsf{e})) \Longrightarrow \mathsf{False}.$$

Proof. Expose the sealed constant-real classifier with Definition 38.11. In the first orientation this gives a rational classifier $\mathsf{RatHistoryClassifier}(\mathsf{e}, d)$; in the second orientation it gives $\mathsf{RatHistoryClassifier}(d, \mathsf{e})$.

Apply Definition 37.51 to the exposed rational classifier in the corresponding orientation. The relevant endpoint nonemptiness clause contradicts $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$ by reflexivity. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier e1 empty endpoint absurd`

Theorem 38.73 (Real constant classifier transported inner empty endpoint absurd)**.** *For histories h, k : BHist, any constant real-history classifier excludes an* $\mathsf{E1}(\mathsf{e})$ *display on either classified endpoint:*

$$\mathsf{RealConstantHistoryClassifier}(h, k) \Longrightarrow (\mathsf{hsame}(h, \mathsf{E1}(\mathsf{e})) \Longrightarrow \mathsf{False}),$$
$$\mathsf{RealConstantHistoryClassifier}(h, k) \Longrightarrow (\mathsf{hsame}(k, \mathsf{E1}(\mathsf{e})) \Longrightarrow \mathsf{False}).$$

Proof. For the left endpoint, unpack the constant real classifier only far enough to recover the opposite endpoint display $k\mathsf{hsameE1}(d)$ for some d. Combine that display with the assumed $h\mathsf{hsameE1}(\mathsf{e})$ and apply Definition 38.18. This gives the exact transported classifier $\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(d))$.

The left orientation of Definition 38.72 contradicts that transported classifier.

For the right endpoint, unpack the classifier to recover $h\mathsf{hsameE1}(d)$ for some d. Combine it with the assumed $k\mathsf{hsameE1}(\mathsf{e})$, transport to $\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(\mathsf{e}))$, and apply the right orientation of Definition 38.72. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier transported inner empty endpoint absurd`

Theorem 38.74 (Real constant classifier appended e-zero tail absurd)**.** *For histories $d, e, tail$: BHist, the constant real-history classifier excludes a sealed rational denominator whose visible denominator ends in an appended zero-headed tail:*

$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d \cdot \mathsf{E0}(tail)), \mathsf{E1}(e)) \Longrightarrow \mathsf{False},$$
$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(e), \mathsf{E1}(d \cdot \mathsf{E0}(tail))) \Longrightarrow \mathsf{False}.$$

Proof. For the left orientation, expose the constant RealUp classifier with Definition 38.11. The resulting RatUp classifier relates $d \cdot \mathsf{E0}(tail)$ to e, so Definition 37.50 gives the left positive-denominator row. This contradicts Definition 37.15.

For the right orientation, expose the same constant RealUp classifier with Definition 38.11. The resulting RatUp classifier relates e to $d \cdot \mathsf{E0}(tail)$, so Definition 37.50 gives the right positive-denominator row. This again contradicts Definition 37.15. □

The ten-field fit is: traditional target constant RealUp denominator endpoint exclusion; BEDC source RealUp constant classifiers plus RatUp denominator shape; carrier BHist; classifier RealConstantHistoryClassi stability by e-one exposure and positive-denominator transport; ledger visible append head and zero-headed tail; core theorem Definition 38.74; exactness impossibility of appended zero-headed denominators; standard bridge finite rational denominator sanity; status ProofTarget.

Theorem 38.75 (Real constant classifier malformed inner denominator exclusions)**.** *For histories* $d, p, z : \mathsf{BHist}$*, the constant real-history classifier excludes every exposed rational denominator that is internally empty or ends with an appended e-zero tail:*

$$\begin{aligned}
&\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(d)) \Longrightarrow \mathsf{False},\\
&\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(\mathsf{e})) \Longrightarrow \mathsf{False},\\
&\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(p \cdot \mathsf{E0}(z)), \mathsf{E1}(d)) \Longrightarrow \mathsf{False},\\
&\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(p \cdot \mathsf{E0}(z))) \Longrightarrow \mathsf{False}.
\end{aligned}$$

In the ten-field fit, the traditional target is constant-real malformed denominator exclusion; the BEDC source is BHist *e-one rational seals and RatUp positive-denominator shape; the carrier is* RealConstantHistoryCarrier*; the classifier is* RealConstantHistoryClassifier*; the stability obligations are e-one exposure,* hsame *reflexivity, and RatUp denominator projection; the ledger is empty and appended e-zero denominator shapes; the core theorem is this four-way exclusion; the exactness predicate is impossibility of nonpositive exposed denominator tails; the standard bridge is constant rational real names; and the status is* ProofTarget*.*

Proof. For each clause, first expose the sealed constant-real classifier with Definition 38.11. The displayed assumption becomes a RatUp classifier on the two inner histories.

For the two inner-empty clauses, apply Definition 37.51 to the exposed RatUp classifier. In the left orientation the first nonemptiness row contradicts $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$ by reflexivity; in the right orientation the second nonemptiness row gives the same contradiction.

For the left appended e-zero-tail clause, apply Definition 37.50 to the exposed RatUp classifier. The left projection gives a positive unary denominator witness for $p \cdot \mathsf{E0}(z)$, contradicting Definition 37.15.

For the right appended e-zero-tail clause, the same positive-denominator projection gives the witness on the right endpoint $p \cdot \mathsf{E0}(z)$. This is again impossible by Definition 37.15. □

Theorem 38.76 (Real constant classifier transported malformed inner denominator exclusions)**.** *For histories* $h, k, p_h, z_h, p_k, z_k : \mathsf{BHist}$*, a constant real-history classifier excludes transported empty sealed endpoints and transported appended e-zero sealed denominators on either endpoint:*

$$\begin{aligned}
&\mathsf{RealConstantHistoryClassifier}(h, k) \Longrightarrow (\mathsf{hsame}(h, \mathsf{E1}(\mathsf{e})) \Longrightarrow \mathsf{False}),\\
&\mathsf{RealConstantHistoryClassifier}(h, k) \Longrightarrow (\mathsf{hsame}(k, \mathsf{E1}(\mathsf{e})) \Longrightarrow \mathsf{False}),\\
&\mathsf{RealConstantHistoryClassifier}(h, k) \Longrightarrow (\mathsf{hsame}(h, \mathsf{E1}(p_h \cdot \mathsf{E0}(z_h))) \Longrightarrow \mathsf{False}),\\
&\mathsf{RealConstantHistoryClassifier}(h, k) \Longrightarrow (\mathsf{hsame}(k, \mathsf{E1}(p_k \cdot \mathsf{E0}(z_k))) \Longrightarrow \mathsf{False}).
\end{aligned}$$

Proof. The two empty endpoint clauses are exactly the transported inner-empty endpoint exclusions from Definition 38.73.

For the left appended e-zero clause, unpack the constant classifier just far enough to recover an opposite endpoint display $k\mathsf{hsameE1}(d)$ for some history d. Together with the assumed display $h\mathsf{hsameE1}(p_h \cdot \mathsf{E0}(z_h))$, Definition 38.18 transports the classifier to $\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(p_h \cdot \mathsf{E0}(z_h)), \mathsf{E1}(d))$. The left clause of Definition 38.74 contradicts this transported classifier.

For the right appended e-zero clause, unpack symmetrically to recover $h\mathsf{hsameE1}(d)$ for some history d. Transport the assumed display $k\mathsf{hsameE1}(p_k \cdot \mathsf{E0}(z_k))$ across Definition 38.18, obtaining $\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(p_k \cdot \mathsf{E0}(z_k)))$. The right clause of Definition 38.74 gives the contradiction. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier transported malformed inner denominator absurd`

The ten-field fit is: traditional target transported RealUp denominator sanity; BEDC source RealUp constant classifiers plus RatUp positive-denominator shape; carrier BHist; classifier RealConstantHistoryClas stability row endpoint transport; ledger transported empty endpoints and appended e-zero denominator displays; core theorem Definition 38.76; exactness impossibility of empty or zero-headed sealed denominators; downstream bridge RealUp constant-name denominator sanity; status ProofTarget.

Theorem 38.77 (Real constant classifier transported complete malformed inner denominator exclusions)**.** *For histories $h, k, t_h, t_k, p_h, z_h, p_k, z_k$: BHist, a constant real-history classifier excludes every transported malformed sealed denominator boundary: inner empty, inner e-zero, and appended e-zero denominators on either endpoint:*

$$\begin{aligned}
&\mathsf{RealConstantHistoryClassifier}(h,k) \Longrightarrow (\mathsf{hsame}(h, \mathsf{E1}(\mathsf{e})) \Longrightarrow \mathsf{False}),\\
&\mathsf{RealConstantHistoryClassifier}(h,k) \Longrightarrow (\mathsf{hsame}(k, \mathsf{E1}(\mathsf{e})) \Longrightarrow \mathsf{False}),\\
&\mathsf{RealConstantHistoryClassifier}(h,k) \Longrightarrow (\mathsf{hsame}(h, \mathsf{E1}(\mathsf{E0}(t_h))) \Longrightarrow \mathsf{False}),\\
&\mathsf{RealConstantHistoryClassifier}(h,k) \Longrightarrow (\mathsf{hsame}(k, \mathsf{E1}(\mathsf{E0}(t_k))) \Longrightarrow \mathsf{False}),\\
&\mathsf{RealConstantHistoryClassifier}(h,k) \Longrightarrow (\mathsf{hsame}(h, \mathsf{E1}(p_h \cdot \mathsf{E0}(z_h))) \Longrightarrow \mathsf{False}),\\
&\mathsf{RealConstantHistoryClassifier}(h,k) \Longrightarrow (\mathsf{hsame}(k, \mathsf{E1}(p_k \cdot \mathsf{E0}(z_k))) \Longrightarrow \mathsf{False}).
\end{aligned}$$

Proof. Project the first two displayed rows from Definition 38.76. These give the left and right transported inner-empty exclusions.

Project the two e-zero rows from Definition 38.71, using t_h for the left endpoint and t_k for the right endpoint.

Finally project the last two displayed rows from Definition 38.76. Together the empty rows, the e-zero rows, and the appended e-zero rows have exactly the six displayed orientations. □

The ten-field fit is: traditional target RealUp constant malformed sealed-denominator exclusion; BEDC source RealUp constant classifier plus RatUp denominator shape; carrier BHist; classifier RealConstantHistoryClassifier; stability endpoint transport; ledger empty, e-zero, and appended e-zero inner shapes; core theorem Definition 38.77; exactness full transported malformed sealed-denominator impossibility; standard bridge constant rational real names; status ProofTarget.

Theorem 38.78 (Real constant classifier full malformed endpoint exclusion package)**.** *For histories $h, k, tail_h, tail_k, inner_h, inner_k, p_h, p_k, z_h, z_k$: BHist, a constant real-history classifier excludes every malformed outer display and every sealed malformed inner display on either endpoint:*

$$\begin{aligned}
&\mathsf{RealConstantHistoryClassifier}(h,k) \Longrightarrow\\
&\quad (\mathsf{hsame}(h,\mathsf{e}) \Longrightarrow \mathsf{False}) \wedge (\mathsf{hsame}(k,\mathsf{e}) \Longrightarrow \mathsf{False}) \wedge\\
&\quad (\mathsf{hsame}(h, \mathsf{E0}(tail_h)) \Longrightarrow \mathsf{False}) \wedge (\mathsf{hsame}(k, \mathsf{E0}(tail_k)) \Longrightarrow \mathsf{False}) \wedge\\
&\quad (\mathsf{hsame}(h, \mathsf{E1}(\mathsf{e})) \Longrightarrow \mathsf{False}) \wedge (\mathsf{hsame}(k, \mathsf{E1}(\mathsf{e})) \Longrightarrow \mathsf{False}) \wedge\\
&\quad (\mathsf{hsame}(h, \mathsf{E1}(\mathsf{E0}(inner_h))) \Longrightarrow \mathsf{False}) \wedge (\mathsf{hsame}(k, \mathsf{E1}(\mathsf{E0}(inner_k))) \Longrightarrow \mathsf{False}) \wedge\\
&\quad (\mathsf{hsame}(h, \mathsf{E1}(p_h \cdot \mathsf{E0}(z_h))) \Longrightarrow \mathsf{False}) \wedge (\mathsf{hsame}(k, \mathsf{E1}(p_k \cdot \mathsf{E0}(z_k))) \Longrightarrow \mathsf{False}).
\end{aligned}$$

Proof. We prove the ten clauses by grouping the visible endpoint shapes.

1. For the outer empty displays, transport the classifier along $\mathsf{hsame}(h,\mathsf{e})$ or $\mathsf{hsame}(k,\mathsf{e})$ and the reflexive display on the other endpoint. This gives an exact classifier with an e endpoint, so the corresponding empty endpoint clause of Definition 38.22 gives the contradiction.

2. For the outer E0 displays, use the same endpoint transport with $\mathsf{hsame}(h, \mathsf{E0}(tail_h))$ or $\mathsf{hsame}(k, \mathsf{E0}(tail_k))$. The transported classifier has an exact E0 endpoint, and the e-zero endpoint clause of Definition 38.22 excludes it.

3. For the sealed $\mathsf{E1}(\mathsf{E0}(-))$ displays, apply Definition 38.71 directly to the original classifier. Its two projections are exactly the two required exclusions for $inner_h$ and $inner_k$.
4. For the sealed empty displays, unpack the classifier enough to recover an opposite sealed endpoint $k\mathsf{hsameE1}(d)$ or $h\mathsf{hsameE1}(d)$. Endpoint transport then gives an exact classifier $\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(\mathsf{e}), \mathsf{E1}(d))$ or $\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(\mathsf{e}))$. The two orientations of Definition 38.72 exclude these exact sealed-empty classifiers.
5. For the appended e-zero sealed displays, unpack the same opposite sealed endpoint and transport to $\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(p_h{\cdot}\mathsf{E0}(z_h)), \mathsf{E1}(d))$ or $\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d), \mathsf{E1}(p_k{\cdot}\mathsf{E0}(z_k)))$. The two orientations of Definition 38.74 contradict those transported classifiers.

□

The ten-field fit is: traditional target full malformed constant-real endpoint coverage package; BEDC source constant RealUp classifier endpoint transport and sealed rational endpoint exclusions; carrier BHist; classifier RealConstantHistoryClassifier; stability row outer endpoint transport plus sealed endpoint readback; ledger outer empty, outer e-zero, sealed empty, sealed e-zero, and sealed appended e-zero displays on both sides; core theorem Definition 38.78; exactness no malformed outer or sealed inner constant-real endpoint display on either endpoint; downstream bridge RealUp carrier, NameCert, and dyadic embedding endpoint sanity; status ProofTarget.

Definition 38.79 (Malformed sealed real denominator display)**.** *For a history $h : \mathsf{BHist}$, the predicate* $\mathsf{MalformedRealSealedDenom}(h)$ *records exactly the three sealed denominator displays excluded by the transported RealUp denominator sanity ledger: empty, inner e-zero, and appended e-zero denominators.*

$$\mathsf{MalformedRealSealedDenom}(h) := \mathsf{hsame}(h, \mathsf{E1}(\mathsf{e})) \vee \exists t : \mathsf{BHist},\ \mathsf{hsame}(h, \mathsf{E1}(\mathsf{E0}(t))) \vee \exists p, z : \mathsf{BHist},\ \mathsf{hsame}(h, \mathsf{E1}(p{\cdot}\mathsf{E0}$$

Lean4 (definition) `BEDC.Derived.RealUp.MalformedRealSealedDenom`

Theorem 38.80 (Real constant classifier no malformed sealed denominator displays)**.** *For histories $h, k : \mathsf{BHist}$, a constant real-history classifier excludes malformed sealed denominator displays at both transported endpoints:*

$$\mathsf{RealConstantHistoryClassifier}(h, k) \Longrightarrow (\mathsf{MalformedRealSealedDenom}(h) \Longrightarrow \mathsf{False}) \wedge (\mathsf{MalformedRealSealedDenom}(k)$$

Proof. Unfold MalformedRealSealedDenom on the left endpoint. In the empty-display case, apply the first clause of Definition 38.77.

In the inner e-zero-display case on the left endpoint, use the displayed witness t and apply the third clause of the same theorem.

In the appended e-zero-display case on the left endpoint, use the displayed witnesses p, z and apply the fifth clause of the same theorem.

Unfold MalformedRealSealedDenom on the right endpoint. In the empty-display case, apply the second clause of Definition 38.77.

In the inner e-zero-display case on the right endpoint, use the displayed witness t and apply the fourth clause of the same theorem.

In the appended e-zero-display case on the right endpoint, use the displayed witnesses p, z and apply the sixth clause of the same theorem. □

The ten-field fit is: traditional target reusable transported RealUp denominator sanity predicate; BEDC source the six transported malformed sealed-endpoint exclusions; carrier BHist; classifier RealConstantHistoryClassifier; stability row endpoint transport already concentrated in Definition 38.77; ledger exactly transported empty endpoints, inner e-zero endpoints, and appended e-zero denominator displays; core theorem Definition 38.80; exactness one predicate forbids empty, inner e-zero, and appended e-zero sealed denominator displays on either endpoint; downstream bridge RealUp NameCert and dyadic-embedding denominator sanity; status ProofTarget.

Theorem 38.81 (Real constant classifier no transported malformed sealed denominator displays)**.** *For histories h, k, h', k' : BHist, classifier exclusion of malformed sealed real denominators survives endpoint* hsame *transport:*

$$\mathsf{RealConstantHistoryClassifier}(h,k) \Longrightarrow \mathsf{hsame}(h,h') \Longrightarrow \mathsf{hsame}(k,k') \Longrightarrow (\mathsf{MalformedRealSealedDenom}(h') \Longrightarrow \mathsf{Fals}$$

Proof. Unfold MalformedRealSealedDenom at the transported left endpoint. For each displayed malformed shape of h', compose the endpoint row $\mathsf{hsame}(h,h')$ with that display by hsame transitivity.

In the empty case this gives $\mathsf{hsame}(h, \mathsf{E1}(\mathsf{e}))$. In the inner e-zero case, for the displayed witness t, it gives $\mathsf{hsame}(h, \mathsf{E1}(\mathsf{E0}(t)))$. In the appended e-zero case, for displayed witnesses p, z, it gives $\mathsf{hsame}(h, \mathsf{E1}(p \cdot \mathsf{E0}(z)))$.

These three alternatives are exactly the three clauses of $\mathsf{MalformedRealSealedDenom}(h)$. Apply the left projection of Definition 38.80 to the original classifier and the transported malformed display.

Unfold MalformedRealSealedDenom at the transported right endpoint. For each displayed malformed shape of k', compose the endpoint row $\mathsf{hsame}(k,k')$ with that display by hsame transitivity.

In the empty case this gives $\mathsf{hsame}(k, \mathsf{E1}(\mathsf{e}))$. In the inner e-zero case, for the displayed witness t, it gives $\mathsf{hsame}(k, \mathsf{E1}(\mathsf{E0}(t)))$. In the appended e-zero case, for displayed witnesses p, z, it gives $\mathsf{hsame}(k, \mathsf{E1}(p \cdot \mathsf{E0}(z)))$.

These three alternatives are exactly the three clauses of $\mathsf{MalformedRealSealedDenom}(k)$. Apply the right projection of Definition 38.80 to the original classifier and the transported malformed display. □

The ten-field fit is: traditional target transported constant-real denominator sanity; BEDC source BHist, hsame, the RealUp constant classifier, and the malformed sealed denominator predicate; carrier BHist; classifier RealConstantHistoryClassifier; stability row endpoint hsame transport; ledger transported empty, inner e-zero, and appended e-zero sealed denominators; core theorem Definition 38.81; exactness exclusion of malformed transported endpoints; standard bridge constant rational real names; status ProofTarget.

Definition 38.82 (Real constant malformed endpoint display)**.** *For a history h : BHist, the predicate* $\mathsf{MalformedRealEndpoint}(h)$ *records exactly the reusable endpoint displays excluded by the RealUp constant classifier: an outer empty endpoint, an outer e-zero endpoint, or a sealed malformed denominator display.*

$$\mathsf{MalformedRealEndpoint}(h) := \mathsf{hsame}(h, \mathsf{e}) \vee \exists t : \mathsf{BHist},\ \mathsf{hsame}(h, \mathsf{E0}(t)) \vee \mathsf{MalformedRealSealedDenom}(h).$$

Lean4 (definition) `BEDC.Derived.RealUp.MalformedRealEndpoint`

Theorem 38.83 (Real constant classifier no transported malformed endpoint displays)**.** *For histories h, k, h', k' : BHist, constant real-history classifier exclusion of malformed endpoint displays survives endpoint* hsame *transport:*

$$\mathsf{RealConstantHistoryClassifier}(h,k) \Longrightarrow \mathsf{hsame}(h,h') \Longrightarrow \mathsf{hsame}(k,k') \Longrightarrow (\mathsf{MalformedRealEndpoint}(h') \Longrightarrow \mathsf{False}) \wedge ($$

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier no transported malformed endpoint displays`

Proof. Unfold MalformedRealEndpoint at the transported left endpoint. In the outer empty case, compose $\mathsf{hsame}(h, h')$ with $\mathsf{hsame}(h', \mathsf{e})$ by hsame transitivity. Transport the classifier along this left endpoint display and a reflexive right endpoint display, then apply the left-empty clause of Definition 38.22.

In the outer e-zero case, use the displayed witness t and compose $\mathsf{hsame}(h, h')$ with $\mathsf{hsame}(h', \mathsf{E0}(t))$. Transport the classifier to an exact classifier with left endpoint $\mathsf{E0}(t)$, then apply the left e-zero clause of Definition 38.22.

In the sealed denominator case, apply the left projection of Definition 38.81 to the original classifier, the two endpoint transport rows, and the displayed $\mathsf{MalformedRealSealedDenom}(h')$ witness.

Unfold MalformedRealEndpoint at the transported right endpoint. In the outer empty case, compose $\mathsf{hsame}(k, k')$ with $\mathsf{hsame}(k', \mathsf{e})$ by hsame transitivity. Transport the classifier along a reflexive left endpoint display and this right endpoint display, then apply the right-empty clause of Definition 38.22.

In the outer e-zero case, use the displayed witness t and compose $\mathsf{hsame}(k, k')$ with $\mathsf{hsame}(k', \mathsf{E0}(t))$. Transport the classifier to an exact classifier with right endpoint $\mathsf{E0}(t)$, then apply the right e-zero clause of Definition 38.22.

In the sealed denominator case, apply the right projection of Definition 38.81 to the original classifier, the two endpoint transport rows, and the displayed $\mathsf{MalformedRealSealedDenom}(k')$ witness. □

The ten-field fit is: traditional target RealUp constant endpoint hygiene; BEDC source BHist, hsame, and the RealUp constant classifier; carrier BHist; classifier RealConstantHistoryClassifier; stability row endpoint hsame transport; ledger outer empty, outer e-zero, and malformed sealed denominator displays on transported endpoints; core theorem Definition 38.83; exactness no transported malformed RealUp constant endpoint display on either endpoint; downstream bridge RealUp NameCert endpoint sanity; status ProofTarget.

Theorem 38.84 (Real constant classifier appended e-one tail unary readback)**.** *For histories $d, e, tail_D, tail_E$, a constant RealUp classifier whose two rational denominators are displayed as appended e-one tails reads back both unary factors and the rational endpoint classifier:*

$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d{\cdot}\mathsf{E1}(tail_D)), \mathsf{E1}(e{\cdot}\mathsf{E1}(tail_E))) \Longrightarrow \mathsf{UnaryHistory}(d) \wedge \mathsf{UnaryHistory}(tail_D) \wedge \mathsf{UnaryHis}$$

Proof. Use the e-one RealUp/RatUp classifier equivalence to expose the underlying RatUp history classifier. Its positive-denominator fields apply to both displayed denominators. The appended e-one denominator decomposition reads each positive denominator as unary evidence for its head and tail, and the remaining classifier field is the displayed endpoint hsame relation. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier append e1 tail unary readback`

Theorem 38.85 (Real constant classifier common-head e-one tail readback)**.** *For histories $left, d, e, tail_D, tail_E$, a common visible head in two displayed constant RealUp e-one tail denominators can be read back to the five unary factors and the central denominator comparison:*

$$\begin{aligned}&\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(left \cdot (d \cdot \mathsf{E1}(tail_D))), \mathsf{E1}(left \cdot (e \cdot \mathsf{E1}(tail_E))))\\ &\quad \Longrightarrow \mathsf{hsame}(tail_D, tail_E) \Longrightarrow\\ &\quad \mathsf{UnaryHistory}(left) \wedge \mathsf{UnaryHistory}(d) \wedge \mathsf{UnaryHistory}(e) \wedge \mathsf{UnaryHistory}(tail_D) \wedge \mathsf{UnaryHistory}(tail_E) \wedge \mathsf{hsame}(\end{aligned}$$

Proof. Use associativity of BEDC append to expose the endpoints as appended e-one tails with heads $left \cdot d$ and $left \cdot e$. The appended e-one tail readback theorem gives unary evidence for both composite heads, the two tails, and the displayed endpoint comparison. Split the composite unary heads into their factors. The assumed tail comparison identifies the two e-one tail suffixes, so BEDC append right cancellation removes the shared suffix; append left cancellation then removes the common head and yields $\mathsf{hsame}(d, e)$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier append common head e1 tail readback`

Theorem 38.86 (Real constant classifier appended e-one matched-tail head readback)**.** *For histories* $d, e, tail_D, tail_E$*, if*

$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(d \cdot \mathsf{E1}(tail_D)), \mathsf{E1}(e \cdot \mathsf{E1}(tail_E))) \wedge \mathsf{hsame}(tail_D, tail_E),$$

then

$$\mathsf{UnaryHistory}(d) \wedge \mathsf{UnaryHistory}(tail_D) \wedge \mathsf{UnaryHistory}(e) \wedge \mathsf{UnaryHistory}(tail_E) \wedge \mathsf{hsame}(d, e).$$

Proof. Apply Definition 38.84 to the displayed classifier. This gives the four unary rows for d, $tail_D$, e, and $tail_E$, together with endpoint equality $\mathsf{hsame}(d \cdot \mathsf{E1}(tail_D), e \cdot \mathsf{E1}(tail_E))$.

The assumed tail agreement $\mathsf{hsame}(tail_D, tail_E)$ transports through the e-one constructor and right append congruence. Hence the right endpoint may be read with the same displayed tail as the left endpoint: $\mathsf{hsame}(e \cdot \mathsf{E1}(tail_E), e \cdot \mathsf{E1}(tail_D))$.

Endpoint transport therefore presents a constant-real classifier of $\mathsf{E1}(d \cdot \mathsf{E1}(tail_D))$ against $\mathsf{E1}(e \cdot \mathsf{E1}(tail_D))$. Apply Definition 38.13 with common tail $\mathsf{E1}(tail_D)$ to obtain $\mathsf{hsame}(d, e)$, and combine this with the four unary rows already read back. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier append e1 matched tail head readback`

The ten-field fit is: traditional target finite denominator-tail agreement readback for RealUp constants; BEDC source RealUp constant classifiers plus RatUp positive-denominator readback; carrier BEDC histories; classifier RealConstantHistoryClassifier; stability by endpoint transport, e-one congruence, append congruence, and common-tail cancellation; ledger displayed denominator heads and displayed e-one tails; core theorem Definition 38.86; exactness the displayed five-row conjunction; standard bridge finite RegSeqRat denominator-tail readback; status ProofTarget.

Theorem 38.87 (Real constant classifier appended e-one tail denominator package)**.** *For histories* $d, e, tail_D, tail_E, z_D, z_E : \mathsf{BHist}$*, write* $D = d \cdot \mathsf{E1}(tail_D)$ *and* $E = e \cdot \mathsf{E1}(tail_E)$*. If*

$$\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(D), \mathsf{E1}(E)),$$

then the appended rational denominators satisfy the following package:

1. $\mathsf{RatHistoryClassifier}(D, E)$*;*
2. $\mathsf{PositiveUnaryDenominator}(D)$ *and* $\mathsf{PositiveUnaryDenominator}(E)$*;*
3. $\mathsf{UnaryHistory}(d)$*,* $\mathsf{UnaryHistory}(tail_D)$*,* $\mathsf{UnaryHistory}(e)$*, and* $\mathsf{UnaryHistory}(tail_E)$*;*
4. $D\mathsf{hsame}e \Longrightarrow \bot$ *and* $E\mathsf{hsame}e \Longrightarrow \bot$*;*
5. $D\mathsf{hsameE0}(z_D) \Longrightarrow \bot$ *and* $E\mathsf{hsameE0}(z_E) \Longrightarrow \bot$*;*
6. $D\mathsf{hsame}E$*.*

Proof. Apply Definition 38.11 to the displayed constant RealUp classifier. This exposes the underlying $\mathsf{RatHistoryClassifier}(D, E)$ and keeps its classifier field available for the final $D\mathsf{hsame}E$ row.

Next apply Definition 37.50 to the rational classifier. The result supplies positive unary denominator witnesses for both appended tails. Applying Definition 37.9 to each witness decomposes the two appended e-one denominators into the four unary factor rows.

Finally apply Definition 37.12 to the two positive-denominator witnesses to obtain the two exclusions against e. If either appended denominator were history-same to a zero-extension, transport the corresponding positive-denominator witness along that sameness and contradict Definition 37.10. The hsame row is the rational classifier endpoint field, equivalently the checked unary readback theorem above. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstantHistoryClassifier append e1 tail denominator package`

Definition 38.88 (Real constant appended-tail denominator package)**.** *For histories* $d, e, tail_D, tail_E, z_D, z_E : \mathsf{Hist}$*, set*

$$D = d \cdot \mathsf{E1}(tail_D) \qquad \text{and} \qquad E = e \cdot \mathsf{E1}(tail_E).$$

The predicate $\mathsf{RealConstantAppendedTailDenominatorPackage}(d, e, tail_D, tail_E, z_D, z_E)$ *is the conjunction of the following six rows:*

1. $\mathsf{RatHistoryClassifier}(D, E)$*;*
2. $\mathsf{PositiveUnaryDenominator}(D)$ *and* $\mathsf{PositiveUnaryDenominator}(E)$*;*
3. $\mathsf{UnaryHistory}(d)$*,* $\mathsf{UnaryHistory}(tail_D)$*,* $\mathsf{UnaryHistory}(e)$*, and* $\mathsf{UnaryHistory}(tail_E)$*;*
4. $D\mathsf{hsame}\mathsf{e} \Longrightarrow \bot$ *and* $E\mathsf{hsame}\mathsf{e} \Longrightarrow \bot$*;*
5. $D\mathsf{hsame}\mathsf{E0}(z_D) \Longrightarrow \bot$ *and* $E\mathsf{hsame}\mathsf{E0}(z_E) \Longrightarrow \bot$*;*
6. $D\mathsf{hsame}E$*.*

Definition 38.89 (Real constant appended-tail full denominator-tail package)**.** *For histories* $d, e, tail_D, tail_E, u_D, u_E, z_D, z_E : \mathsf{Hist}$*, set*

$$D = d \cdot \mathsf{E1}(tail_D) \qquad \text{and} \qquad E = e \cdot \mathsf{E1}(tail_E).$$

The predicate $\mathsf{RealConstantAppendedTailFullDenominatorTailPackage}(d, e, tail_D, tail_E, u_D, u_E, z_D, z_E)$ *is the denominator package Definition 38.88 together with*

1. $\mathsf{hsame}(D, u_D \cdot \mathsf{E0}(z_D)) \Longrightarrow \bot$*;*
2. $\mathsf{hsame}(E, u_E \cdot \mathsf{E0}(z_E)) \Longrightarrow \bot$*;*
3. $\mathsf{hsame}(d, e)$*.*

Theorem 38.90 (Real constant appended e-one tail rational-stream bridge readback)**.** *For histories* $d, e, tail_D, tail_E, z_D, z_E : \mathsf{Hist}$ *and observation maps* $r, q : \mathsf{Hist} \to \mathsf{Hist}$*, set*

$$D = d \cdot \mathsf{E1}(tail_D) \qquad \text{and} \qquad E = e \cdot \mathsf{E1}(tail_E).$$

Write the four bridge classifier rows as

$$A = \mathsf{RatHistoryClassifier}(D, E), \qquad B = \mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q),$$

$$U = \mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q), \qquad C = \mathsf{RealConstantHistoryClassifier}(\mathsf{E1}$$

Let

$$R = \mathsf{UnaryHistory}(d) \wedge \mathsf{UnaryHistory}(tail_D) \wedge \mathsf{UnaryHistory}(e) \wedge \mathsf{UnaryHistory}(tail_E) \wedge \mathsf{hsame}(D, E).$$

Let $P(D, E, z_D, z_E)$ *abbreviate* $\mathsf{RealConstantAppendedTailDenominatorPackage}(d, e, tail_D, tail_E, z_D, z_E)$ *from Definition 38.88. Then the bridge rows are linked by*

$$(A \Longleftrightarrow B) \wedge (B \Longleftrightarrow U) \wedge (U \Longleftrightarrow C),$$

and every row reads back the same appended-tail unary readback row:

$$(A \Longrightarrow R) \wedge (B \Longrightarrow R) \wedge (U \Longrightarrow R) \wedge (C \Longrightarrow R),$$

and the same appended-tail denominator package:

$$(A \Longrightarrow P(D, E, z_D, z_E)) \wedge (B \Longrightarrow P(D, E, z_D, z_E)) \wedge (U \Longrightarrow P(D, E, z_D, z_E)) \wedge (C \Longrightarrow P(D, E, z_D, z_E)).$$

Proof. Instantiate Definition 38.29 with the histories D and E and the observation maps r and q. The three resulting equivalences are exactly the displayed links $A \Longleftrightarrow B$, $B \Longleftrightarrow U$, and $U \Longleftrightarrow C$.

The direct readback from C is Definition 38.87, applied to the decompositions $D = d \cdot \mathsf{E1}(tail_D)$ and $E = e \cdot \mathsf{E1}(tail_E)$ with the displayed zero witnesses z_D and z_E. This gives every row of $P(D, E, z_D, z_E)$ at once, with projections taken from Definition 38.88.

The direct readback from A starts with the rational classifier $\mathsf{RatHistoryClassifier}(D, E)$. Apply Definition 37.50 to obtain both positive unary denominator rows. Apply Definition 37.9 to the two positive-denominator witnesses to read back the four unary factors.

Next apply Definition 37.12 to obtain both exclusions against e. If either appended denominator were history-same to $\mathsf{E0}(z_D)$ or $\mathsf{E0}(z_E)$, transport the corresponding positive-denominator witness across that equality and contradict Definition 37.10. The final $D\mathsf{hsame}E$ row is the endpoint sameness field of the rational classifier.

For B, transport along $A \Longleftrightarrow B$ back to A and use the direct rational readback. For U, either transport through $B \Longleftrightarrow U$ and then $A \Longleftrightarrow B$, or transport through $U \Longleftrightarrow C$ and use the direct constant-history readback. The unary row R is the unary-factor and endpoint-sameness part of the same package. Thus every bridge classifier row recovers R and the full package $P(D, E, z_D, z_E)$. □

Theorem 38.91 (Real constant appended-tail bridge denominator package)**.** *For histories* $d, e, tail_D, tail_E, z_D, z_E$ Hist *and observation maps* $r, q : \mathsf{Hist} \to \mathsf{Hist}$*, set*

$$D = d \cdot \mathsf{E1}(tail_D) \qquad \textit{and} \qquad E = e \cdot \mathsf{E1}(tail_E).$$

Write the bridge classifier rows as

$$A = \mathsf{RatHistoryClassifier}(D, E), \qquad B = \mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q),$$

$$U = \mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q), \qquad C = \mathsf{RealConstantHistoryClassifier}(\mathsf{E1}$$

Let $P(D, E, z_D, z_E)$ *abbreviate* $\mathsf{RealConstantAppendedTailDenominatorPackage}(d, e, tail_D, tail_E, z_D, z_E)$ *from Definition 38.88. Then every bridge row entails this package:*

$$(A \Longrightarrow P(D, E, z_D, z_E)) \wedge (B \Longrightarrow P(D, E, z_D, z_E)) \wedge (U \Longrightarrow P(D, E, z_D, z_E)) \wedge (C \Longrightarrow P(D, E, z_D, z_E)).$$

Proof. The C row gives the package directly. Apply Definition 38.87 to the displayed decompositions $D = d \cdot \mathsf{E1}(tail_D)$ and $E = e \cdot \mathsf{E1}(tail_E)$, with the endpoint zero witnesses z_D and z_E. The rows are the named projections of Definition 38.88.

The bridge equivalences are those of Definition 38.90. From U, use the final bridge equivalence to obtain C, then apply the preceding package readback.

From B, use the second bridge equivalence and then the final bridge equivalence. This reaches the constant real-history row, so the same package readback supplies $P(D, E, z_D, z_E)$.

From A, use all three bridge equivalences in order. The resulting C row again yields the complete appended-tail denominator package. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstant appended tail bridge denominator package`

Theorem 38.92 (Real constant appended-tail bridge denominator package exactness)**.** *For histories $d, e, tail_D, tail_E, z_D, z_E : \mathsf{Hist}$ and observation maps $r, q : \mathsf{Hist} \to \mathsf{Hist}$, set*

$$D = d \cdot \mathsf{E1}(tail_D) \qquad \text{and} \qquad E = e \cdot \mathsf{E1}(tail_E).$$

Write the bridge classifier rows as

$$A = \mathsf{RatHistoryClassifier}(D, E), \qquad B = \mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q),$$

$$U = \mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q), \qquad C = \mathsf{RealConstantHistoryClassifier}(\mathsf{E1}$$

Let $P(D, E, z_D, z_E)$ abbreviate $\mathsf{RealConstantAppendedTailDenominatorPackage}(d, e, tail_D, tail_E, z_D, z_E)$ *from Definition 38.88. Then the denominator package is exact for the bridge rows:*

$$P(D, E, z_D, z_E) \iff A \wedge B \wedge U \wedge C.$$

Proof. Assume $P(D, E, z_D, z_E)$. Its first row is the rational history classifier A. Apply Definition 38.90 to the displayed histories and observation maps. The three bridge equivalences carry A to B, then to U, and then to C, so the four bridge rows hold together.

Conversely assume $A \wedge B \wedge U \wedge C$. Project the final row C and apply Definition 38.87 to the decompositions $D = d \cdot \mathsf{E1}(tail_D)$ and $E = e \cdot \mathsf{E1}(tail_E)$, with the zero witnesses z_D and z_E. This recovers every row of $P(D, E, z_D, z_E)$ as named in Definition 38.88. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstant appended tail bridge denominator package exactness`

Theorem 38.93 (Real constant appended-tail bridge single-row denominator package exactness)**.** *For histories $d, e, tail_D, tail_E, z_D, z_E : \mathsf{Hist}$ and observation maps $r, q : \mathsf{Hist} \to \mathsf{Hist}$, use the same definitions of D, E, the bridge rows A, B, U, C, and the appended-tail denominator package $P(D, E, z_D, z_E)$ as in Definition 38.92. If $D = d \cdot \mathsf{E1}(tail_D)$ and $E = e \cdot \mathsf{E1}(tail_E)$, then each concrete bridge row is exact for the denominator package:*

$$(A \iff P(D, E, z_D, z_E)) \wedge (B \iff P(D, E, z_D, z_E)) \wedge (U \iff P(D, E, z_D, z_E)) \wedge (C \iff P(D, E, z_D, z_E)).$$

Proof. The row-to-package directions are the four projections of Definition 38.91 under the displayed appended-tail decompositions.

For the package-to-row directions, assume $P(D, E, z_D, z_E)$. Apply Definition 38.92 under the same decompositions. The resulting conjunction $A \wedge B \wedge U \wedge C$ supplies the corresponding row by projection.

Combining the four row-to-package projections with these four projections from the exactness conjunction gives the stated rowwise equivalences for A, B, U, C. □

The single-row denominator bridge fit has ten fields: traditional target faithful constant rational embedding into RealUp; BEDC source RatUp plus StreamNameUp plus RealUp; carrier the appended-tail rational histories D, E and the independently reindexed constant streams; classifier rows A, B, U, C; stability from constant streams ignoring r and q; ledger the e-one denominator tails $tail_D, tail_E$ with heads d, e and zero witnesses z_D, z_E; core theorem Definition 38.90 together with Definition 38.91; exactness predicate $P(D, E, z_D, z_E)$ supplied by Definition 38.92; downstream bridge the dyadic RealUp embedding; status ProofTarget.

Theorem 38.94 (Real constant appended-tail bridge appended e-zero exclusion without tail agreement)**.** *For histories $d, e, tail_D, tail_E, u_D, u_E, z_D, z_E : \mathsf{Hist}$ and observation maps $r, q : \mathsf{Hist} \to \mathsf{Hist}$, set*

$$D = d \cdot \mathsf{E1}(tail_D) \qquad \text{and} \qquad E = e \cdot \mathsf{E1}(tail_E).$$

Write the bridge classifier rows as

$$A = \mathsf{RatHistoryClassifier}(D, E), \qquad B = \mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q),$$

$$U = \mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q), \qquad C = \mathsf{RealConstantHistoryClassifier}(\mathsf{E1}$$

Let $R(D, E, u_D, u_E, z_D, z_E)$ denote the paired exclusions

$$(\mathsf{hsame}(D, u_D \cdot \mathsf{E0}(z_D)) \Longrightarrow \bot) \wedge (\mathsf{hsame}(E, u_E \cdot \mathsf{E0}(z_E)) \Longrightarrow \bot).$$

Then every bridge row entails $R(D, E, u_D, u_E, z_D, z_E)$:

$$(A \Longrightarrow R(D, E, u_D, u_E, z_D, z_E)) \wedge (B \Longrightarrow R(D, E, u_D, u_E, z_D, z_E)) \wedge (U \Longrightarrow R(D, E, u_D, u_E, z_D, z_E)) \wedge (C \Longrightarrow R(D,$$

Proof. Apply Definition 38.91. For each of the four bridge rows A, B, U, C, this supplies the package $P(D, E, z_D, z_E)$.

Project the two positive-denominator rows of P. If $\mathsf{hsame}(D, u_D \cdot \mathsf{E0}(z_D))$, transport the $\mathsf{PositiveUnaryDenominator}(D)$ witness across the displayed appended e-zero-tail sameness and contradict Definition 37.15.

The same argument applied to E transports the $\mathsf{PositiveUnaryDenominator}(E)$ witness across $\mathsf{hsame}(E, u_E \cdot \mathsf{E0}(z_E))$ and gives the second contradiction. These two contradictions are exactly $R(D, E, u_D, u_E, z_D, z_E)$ for each bridge row. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstant appended tail bridge appended e0 tail absurd`

Theorem 38.95 (Real constant appended-tail bridge full denominator-tail package)**.** *For histories $d, e, tail_D, tail_E, u_D, u_E, z_D, z_E : \mathsf{Hist}$ and observation maps $r, q : \mathsf{Hist} \to \mathsf{Hist}$, set*

$$D = d \cdot \mathsf{E1}(tail_D) \qquad \text{and} \qquad E = e \cdot \mathsf{E1}(tail_E).$$

Write the bridge classifier rows as

$$A = \mathsf{RatHistoryClassifier}(D, E), \qquad B = \mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q),$$

$$U = \mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q), \qquad C = \mathsf{RealConstantHistoryClassifier}(\mathsf{E1}$$

Let $P(D, E, z_D, z_E)$ abbreviate $\mathsf{RealConstantAppendedTailDenominatorPackage}(d, e, tail_D, tail_E, z_D, z_E)$ *from Definition 38.88. Let $Q(D, E, u_D, u_E, z_D, z_E)$ abbreviate* $\mathsf{RealConstantAppendedTailFullDenominatorTailPackag}$ *from Definition 38.89. If $\mathsf{hsame}(tail_D, tail_E)$, then every bridge row entails this full denominator-tail package:*

$$(A \Longrightarrow Q(D, E, u_D, u_E, z_D, z_E)) \wedge (B \Longrightarrow Q(D, E, u_D, u_E, z_D, z_E)) \wedge (U \Longrightarrow Q(D, E, u_D, u_E, z_D, z_E)) \wedge (C \Longrightarrow Q(D$$

Proof. Assume $\mathsf{hsame}(tail_D, tail_E)$. Apply Definition 38.91. For each of the four bridge rows A, B, U, C, this supplies the package $P(D, E, z_D, z_E)$.

Independently, Definition 38.94 gives the two appended e-zero-tail exclusions for D and E under each bridge row.

It remains to determine the matched heads. The final row of P gives $D\mathsf{hsame}E$. The tail hypothesis transports through the $\mathsf{E1}$ constructor, and append congruence rewrites $e \cdot \mathsf{E1}(tail_E)$ as $e \cdot \mathsf{E1}(tail_D)$. Thus the endpoint comparison has a common right suffix $\mathsf{E1}(tail_D)$, so BEDC append right cancellation yields $\mathsf{hsame}(d, e)$.

These three consequences together with the already recovered package P are exactly the named projections of $Q(D, E, u_D, u_E, z_D, z_E)$ from Definition 38.89 for each bridge row. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstant appended tail bridge full denominator tail package`

Theorem 38.96 (Real constant appended-tail bridge full denominator-tail package exactness)**.** *For histories $d, e, tail_D, tail_E, u_D, u_E, z_D, z_E : \mathsf{Hist}$ and observation maps $r, q : \mathsf{Hist} \to \mathsf{Hist}$, use the same definitions of D, E, the bridge rows A, B, U, C, and the full package $Q(D, E, u_D, u_E, z_D, z_E)$ as in Definition 38.95. If $\mathsf{hsame}(tail_D, tail_E)$, then the full denominator-tail package is exact for the bridge rows:*

$$Q(D, E, u_D, u_E, z_D, z_E) \iff A \wedge B \wedge U \wedge C.$$

Proof. Assume $Q(D, E, u_D, u_E, z_D, z_E)$. Project its $P(D, E, z_D, z_E)$ component and apply Definition 38.92. This gives the four bridge rows $A \wedge B \wedge U \wedge C$.

Conversely assume $\mathsf{hsame}(tail_D, tail_E)$ and $A \wedge B \wedge U \wedge C$. Apply Definition 38.95 under the tail agreement. The first projected implication has type $A \Longrightarrow Q(D, E, u_D, u_E, z_D, z_E)$, and the projected row A supplies its premise. Hence the full package $Q(D, E, u_D, u_E, z_D, z_E)$ holds. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstant appended tail bridge full denominator tail package exactness`

Theorem 38.97 (Real constant appended-tail bridge common-head full denominator-tail package)**.** *For histories $left, d, e, tail_D, tail_E, u_D, u_E, z_D, z_E : \mathsf{Hist}$ and observation maps $r, q : \mathsf{Hist} \to \mathsf{Hist}$, set*

$$D = left \cdot (d \cdot \mathsf{E1}(tail_D)) \qquad \text{and} \qquad E = left \cdot (e \cdot \mathsf{E1}(tail_E)).$$

Write the bridge classifier rows as

$$A = \mathsf{RatHistoryClassifier}(D, E), \qquad B = \mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q),$$

$$U = \mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q), \qquad C = \mathsf{RealConstantHistoryClassifier}(\mathsf{E1}$$

Let $P(D, E, z_D, z_E)$ be the appended-tail denominator package of Definition 38.91 applied to the heads $left \cdot d$ and $left \cdot e$. Let $Q(D, E, u_D, u_E, z_D, z_E)$ denote $P(D, E, z_D, z_E)$ together with

1. $\mathsf{hsame}(D, u_D \cdot \mathsf{E0}(z_D)) \Longrightarrow \bot$ *and* $\mathsf{hsame}(E, u_E \cdot \mathsf{E0}(z_E)) \Longrightarrow \bot$;
2. $\mathsf{UnaryHistory}(left)$, $\mathsf{UnaryHistory}(d)$, $\mathsf{UnaryHistory}(e)$, $\mathsf{UnaryHistory}(tail_D)$, *and* $\mathsf{UnaryHistory}(tail_E)$;
3. $\mathsf{hsame}(D, E)$;
4. $\mathsf{hsame}(d, e)$.

If $\mathsf{hsame}(tail_D, tail_E)$, then every bridge row entails this common-head full denominator-tail package:

$$(A \Longrightarrow Q(D, E, u_D, u_E, z_D, z_E)) \wedge (B \Longrightarrow Q(D, E, u_D, u_E, z_D, z_E)) \wedge (U \Longrightarrow Q(D, E, u_D, u_E, z_D, z_E)) \wedge (C \Longrightarrow Q(D$$

Proof. Assume $\mathsf{hsame}(tail_D, tail_E)$. Apply Definition 38.95 with the denominator heads $left \cdot d$ and $left \cdot e$. For each of the four bridge rows A, B, U, C, this supplies the denominator package $P(D, E, z_D, z_E)$, the two appended e-zero-tail exclusions, and the composite head comparison $\mathsf{hsame}(left \cdot d, left \cdot e)$.

The same package supplies unary evidence for the composite heads $left \cdot d$ and $left \cdot e$, and for the two tails. Split the unary append factors in the two composite heads. This gives unary rows for $left$, d, and e, together with the already recovered unary rows for $tail_D$ and $tail_E$.

It remains to expose the central head equality. The displayed comparison $D\mathsf{hsame}E$ has the two endpoints $left \cdot (d \cdot \mathsf{E1}(tail_D))$ and $left \cdot (e \cdot \mathsf{E1}(tail_E))$. The tail hypothesis identifies the two e-one suffixes, and the existing common-tail cancellation gives $\mathsf{hsame}(left \cdot d, left \cdot e)$.

Finally apply append-left cancellation to the common head $left$. This removes the shared visible context and yields $\mathsf{hsame}(d, e)$. Combining these rows gives $Q(D, E, u_D, u_E, z_D, z_E)$ for each bridge classifier row. □

The common-head full denominator-tail fit has ten fields: traditional target constant rational denominator canonicalization under a shared stream context; BEDC source RatUp plus StreamNameUp plus RealUp; carrier the common-head appended-tail rational histories D, E and their reindexed constant streams; classifier rows A, B, U, C; stability from constant-stream reindexing, e-one-tail transport, and append cancellation; ledger the visible head $left$, central heads d, e, tails $tail_D, tail_E$, and zero witnesses z_D, z_E; core theorem list Definition 38.95 and Definition 38.85; exactness predicate $Q(D, E, u_D, u_E, z_D, z_E)$; standard bridge the constant RatUp-to-RealUp stream bridge; status ProofTarget.

Theorem 38.98 (Real constant appended-tail bridge common-head full denominator-tail package exactness)**.** *For histories $left, d, e, tail_D, tail_E, u_D, u_E, z_D, z_E$: Hist and observation maps r, q : Hist $\to$ Hist, use the same definitions of D, E, the bridge rows A, B, U, C, and the common-head package $Q(D, E, u_D, u_E, z_D, z_E)$ as in Definition 38.97. If $\mathsf{hsame}(tail_D, tail_E)$, then the common-head full denominator-tail package is exact for the four bridge rows:*

$$Q(D, E, u_D, u_E, z_D, z_E) \Longleftrightarrow A \wedge B \wedge U \wedge C.$$

Proof. Assume $Q(D, E, u_D, u_E, z_D, z_E)$. Project its appended-tail denominator package $P(D, E, z_D, z_E)$, where the denominator heads are $left \cdot d$ and $left \cdot e$. Apply Definition 38.92 to obtain $A \wedge B \wedge U \wedge C$.

Conversely assume $\mathsf{hsame}(tail_D, tail_E)$ and $A \wedge B \wedge U \wedge C$. Project the row A from the conjunction. Apply Definition 38.97 under the tail agreement; its first projection has type $A \Longrightarrow Q(D, E, u_D, u_E, z_D, z_E)$. The projected row A supplies the premise, so $Q(D, E, u_D, u_E, z_D, z_E)$ holds. □

Theorem 38.99 (Real constant appended-tail bridge single-row full denominator-tail exactness)**.** *For histories $d, e, tail_D, tail_E, u_D, u_E, z_D, z_E$: Hist and observation maps r, q : Hist $\to$ Hist, use the same definitions of D, E, the bridge rows A, B, U, C, and the full package $Q(D, E, u_D, u_E, z_D, z_E)$ as in Definition 38.95. If $\mathsf{hsame}(tail_D, tail_E)$, then each concrete bridge row is exact for the full denominator-tail package:*

$$(A \Longleftrightarrow Q(D, E, u_D, u_E, z_D, z_E)) \wedge (B \Longleftrightarrow Q(D, E, u_D, u_E, z_D, z_E)) \wedge (U \Longleftrightarrow Q(D, E, u_D, u_E, z_D, z_E)) \wedge (C \Longleftrightarrow Q($$

Proof. Assume $\mathsf{hsame}(tail_D, tail_E)$. The row-to-package directions are the four projections of Definition 38.95 under this tail agreement.

For the package-to-row directions, assume $Q(D, E, u_D, u_E, z_D, z_E)$. Apply Definition 38.96 under the same tail agreement. The resulting conjunction $A \wedge B \wedge U \wedge C$ supplies the corresponding row by projection.

Combining the four row-to-package projections with these four projections from the exactness conjunction gives the stated rowwise equivalences for A, B, U, C. □

Theorem 38.100 (Real constant appended-tail bridge head-tail agreement equivalence)**.** *For histories $d, e, tail_D, tail_E, z_D, z_E : \mathsf{Hist}$ and observation maps $r, q : \mathsf{Hist} \to \mathsf{Hist}$, set*

$$D = d \cdot \mathsf{E1}(tail_D) \qquad \text{and} \qquad E = e \cdot \mathsf{E1}(tail_E).$$

Write the bridge classifier rows as

$$A = \mathsf{RatHistoryClassifier}(D, E), \qquad B = \mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q),$$

$$U = \mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q), \qquad C = \mathsf{RealConstantHistoryClassifier}(\mathsf{E1}$$

Then each bridge row identifies denominator-head agreement with displayed e-one-tail agreement:

$$(A \Longrightarrow (\mathsf{hsame}(d, e) \Longleftrightarrow \mathsf{hsame}(tail_D, tail_E))) \wedge (B \Longrightarrow (\mathsf{hsame}(d, e) \Longleftrightarrow \mathsf{hsame}(tail_D, tail_E))) \wedge (U \Longrightarrow (\mathsf{hsame}(d, e$$

Proof. Fix one of the bridge rows A, B, U, C. Apply Definition 38.91 to the same displayed data and the chosen row. This recovers the denominator package $P(D, E, z_D, z_E)$, whose final component is $D\mathsf{hsame}E$.

For the direction from displayed tail agreement to head agreement, assume $\mathsf{hsame}(tail_D, tail_E)$. Transport this equality through the $\mathsf{E1}$ constructor and the right append context $e \cdot (-)$, so the endpoint comparison $D\mathsf{hsame}E$ is read against the common suffix $\mathsf{E1}(tail_D)$. BEDC right append cancellation then yields $\mathsf{hsame}(d, e)$.

For the direction from head agreement to displayed tail agreement, assume $\mathsf{hsame}(d, e)$. Transport this equality through the left append context $(-) \cdot \mathsf{E1}(tail_E)$, so the same endpoint comparison is read with common left head d. BEDC left append cancellation gives $\mathsf{hsame}(\mathsf{E1}(tail_D), \mathsf{E1}(tail_E))$, and e-one constructor inversion gives $\mathsf{hsame}(tail_D, tail_E)$.

The argument uses only the selected row to recover $D\mathsf{hsame}E$, so repeating it for A, B, U, and C gives the four displayed implications. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstant appended tail bridge head tail agreement iff`

Theorem 38.101 (Real constant appended-tail bridge malformed sealed denominator exclusion)**.** *For histories $d, e, tail_D, tail_E, z_D, z_E : \mathsf{Hist}$ and observation maps $r, q : \mathsf{Hist} \to \mathsf{Hist}$, set*

$$D = d \cdot \mathsf{E1}(tail_D) \qquad \text{and} \qquad E = e \cdot \mathsf{E1}(tail_E).$$

Write the bridge classifier rows as

$$A = \mathsf{RatHistoryClassifier}(D, E), \qquad B = \mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q),$$

$$U = \mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q), \qquad C = \mathsf{RealConstantHistoryClassifier}(\mathsf{E1}$$

Let $M(D, E)$ denote the paired malformed sealed denominator exclusion

$$(\mathsf{MalformedRealSealedDenom}(\mathsf{E1}(D)) \Longrightarrow \mathsf{False}) \wedge (\mathsf{MalformedRealSealedDenom}(\mathsf{E1}(E)) \Longrightarrow \mathsf{False}).$$

Then every bridge row entails the same exclusion predicate:

$$(A \Longrightarrow M(D, E)) \wedge (B \Longrightarrow M(D, E)) \wedge (U \Longrightarrow M(D, E)) \wedge (C \Longrightarrow M(D, E)).$$

Proof. Apply Definition 38.91 to the displayed data. For any chosen bridge row among A, B, U, C, this recovers the package $P(D, E, z_D, z_E)$, including the positive-denominator rows and the nonempty rows for D and E.

Unfold Definition 38.79 at $\mathsf{E1}(D)$. The endpoint D has three branches.

1. In the sealed-empty branch, e-one constructor inversion turns $\mathsf{hsame}(\mathsf{E1}(D), \mathsf{E1}(\mathsf{e}))$ into $D\mathsf{hsame}\mathsf{e}$, contradicting the nonempty row for D from the package.
2. In the sealed inner e-zero branch, use the displayed witness t. E-one constructor inversion turns $\mathsf{hsame}(\mathsf{E1}(D), \mathsf{E1}(\mathsf{E0}(t)))$ into $D\mathsf{hsame}\mathsf{E0}(t)$. Transport the positive-denominator witness for D across this sameness by Definition 37.6; the transported witness contradicts Definition 37.10.
3. In the sealed appended e-zero branch, use the displayed witnesses p, z. E-one constructor inversion turns $\mathsf{hsame}(\mathsf{E1}(D), \mathsf{E1}(p \cdot \mathsf{E0}(z)))$ into $D\mathsf{hsame}p \cdot \mathsf{E0}(z)$. Transport the positive-denominator witness for D across this sameness by Definition 37.6; the transported witness contradicts Definition 37.15.

Unfold Definition 38.79 at $\mathsf{E1}(E)$. The endpoint E has the same three branches.

1. In the sealed-empty branch, e-one constructor inversion turns $\mathsf{hsame}(\mathsf{E1}(E), \mathsf{E1}(\mathsf{e}))$ into $E\mathsf{hsame}\mathsf{e}$, contradicting the nonempty row for E from the package.
2. In the sealed inner e-zero branch, use the displayed witness t. E-one constructor inversion turns $\mathsf{hsame}(\mathsf{E1}(E), \mathsf{E1}(\mathsf{E0}(t)))$ into $E\mathsf{hsame}\mathsf{E0}(t)$. Transport the positive-denominator witness for E across this sameness by Definition 37.6; the transported witness contradicts Definition 37.10.
3. In the sealed appended e-zero branch, use the displayed witnesses p, z. E-one constructor inversion turns $\mathsf{hsame}(\mathsf{E1}(E), \mathsf{E1}(p \cdot \mathsf{E0}(z)))$ into $E\mathsf{hsame}p \cdot \mathsf{E0}(z)$. Transport the positive-denominator witness for E across this sameness by Definition 37.6; the transported witness contradicts Definition 37.15.

These two endpoint exclusions are exactly $M(D, E)$ for each of the four bridge-row implications. □

Lean4 ✓ `BEDC.Derived.RealUp.RealConstant appended tail bridge malformed sealed denominator exclusion`

Theorem 38.102 (Real constant appended-tail bridge full denominator sanity exactness)**.** *For histories $d, e, tail_D, tail_E, u_D, u_E, z_D, z_E : \mathsf{Hist}$ and observation maps $r, q : \mathsf{Hist} \to \mathsf{Hist}$, use the same definitions of D, E, the bridge rows A, B, U, C, the full denominator-tail package $Q(D, E, u_D, u_E, z_D, z_E)$, and the malformed sealed denominator exclusion $M(D, E)$ as in Definition 38.96 and Definition 38.101. Let $S(D, E, u_D, u_E, z_D, z_E)$ denote the combined denominator-sanity package*

$$S(D, E, u_D, u_E, z_D, z_E) := Q(D, E, u_D, u_E, z_D, z_E) \wedge M(D, E).$$

If $\mathsf{hsame}(tail_D, tail_E)$, then the combined package is exact for the bridge rows:

$$S(D, E, u_D, u_E, z_D, z_E) \iff A \wedge B \wedge U \wedge C.$$

Proof. Assume $\mathsf{hsame}(tail_D, tail_E)$.

For the forward direction, assume $S(D, E, u_D, u_E, z_D, z_E)$. Project its $Q(D, E, u_D, u_E, z_D, z_E)$ component and apply Definition 38.96 under the tail agreement. This gives $A \wedge B \wedge U \wedge C$.

For the reverse direction, assume $A \wedge B \wedge U \wedge C$. Apply Definition 38.96 under the same tail agreement to recover $Q(D, E, u_D, u_E, z_D, z_E)$.

It remains to build $M(D, E)$. Apply Definition 38.101 to the displayed data. The first projected implication has type $A \implies M(D, E)$, and the A row supplied by the row conjunction gives $M(D, E)$.

Conjoining the recovered $Q(D, E, u_D, u_E, z_D, z_E)$ with $M(D, E)$ is exactly $S(D, E, u_D, u_E, z_D, z_E)$. □

The malformed sealed bridge denominator certificate fit has ten fields: traditional target constant rational bridge denominator sanity; BEDC source RatUp plus StreamNameUp plus RealUp over BHist; carrier the appended-tail rational histories D, E; classifiers the four concrete rows A, B, U, C; stability from denominator package readback, e-one inversion, and positive-denominator transport; ledger malformed sealed empty, inner e-zero, and appended e-zero displays; core theorem Definition 38.101; exactness the common exclusion predicate for all bridge rows; standard bridge RegSeqRat constant embedding denominator sanity; status $\mathsf{ProofTarget}$.

The bridge-readback certificate fit has ten fields: traditional target faithful constant rational embedding into RealUp; BEDC source RatUp plus StreamNameUp plus RealUp; carrier the appended-tail rational histories D, E and the independently reindexed constant streams; classifier rows A, B, U, C; stability from constant streams ignoring r and q; ledger the appended e-one denominator tails $tail_D, tail_E$ together with heads d, e and the appended e-zero-tail exclusions; core theorem Definition 38.90 together with Definition 38.91, Definition 38.92, and Definition 38.95, with exactness supplied by Definition 38.96; under tail agreement the equivalence $Q(D, E, u_D, u_E, z_D, z_E) \iff A \wedge B \wedge U \wedge C$ recovers R, the denominator package $P(D, E, z_D, z_E)$, the appended e-zero-tail exclusions, and the matched denominator heads from any bridge classifier row; standard bridge RegSeqRat denominator-tail canonicalization; status $\mathsf{ProofTarget}$.

Theorem 38.103 (Real constant-tail carrier and classifier obligations)**.** *For histories $d, e, tail_D, tail_E, z_D, z_E$: Hist and observation maps $r, q : \mathsf{Hist} \to \mathsf{Hist}$, set*

$$D = d \cdot \mathsf{E1}(tail_D) \qquad \text{and} \qquad E = e \cdot \mathsf{E1}(tail_E).$$

The appended-tail histories D and E provide the RealUp constant-tail carrier obligation, and the four bridge rows

$$A = \mathsf{RatHistoryClassifier}(D, E), \qquad B = \mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q),$$

$$U = \mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q), \qquad C = \mathsf{RealConstantHistoryClassifier}(\mathsf{E1}$$

provide the classifier obligation through RatUp, StreamNameUp, unary RealUp, and constant-history RealUp.

Proof. The carrier is the concrete BEDC history carrier already used by the constant-tail readback package: D and E are obtained by BEDC append from the visible denominator heads d, e and their displayed e-one tails.

For the classifier obligation, apply Definition 38.90. Its four named rows are exactly A, B, U, and C under the displayed definitions of D and E.

The denominator package readback is sharpened by Definition 38.92. Thus the same concrete carriers support all four classifier faces without changing the history endpoints or the observation maps. □

Theorem 38.104 (Real constant-tail stability and ledger obligations)**.** *For histories $d, e, tail_D, tail_E, u_D, u_E, z_D, z_E$ Hist and observation maps $r, q : \mathsf{Hist} \to \mathsf{Hist}$, set*

$$D = d \cdot \mathsf{E1}(tail_D) \qquad \text{and} \qquad E = e \cdot \mathsf{E1}(tail_E).$$

Write the bridge rows as

$A = \mathsf{RatHistoryClassifier}(D, E), \qquad B = \mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q),$

$U = \mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q), \qquad C = \mathsf{RealConstantHistoryClassifier}(\mathsf{E1}$

The appended-tail denominator package, the head-tail agreement equivalence, and the malformed sealed-denominator exclusion provide the RealUp constant-tail stability and ledger obligations: the ledger records the visible heads d, e, the displayed e-one tails $tail_D, tail_E$, the zero witnesses z_D, z_E, and the appended e-zero witnesses u_D, u_E, while stability is transport along A, B, U, and C.

Proof. Apply Definition 38.92 to identify the denominator package with the simultaneous bridge rows $A \wedge B \wedge U \wedge C$. This supplies the package ledger: rational classifier, positive denominators, unary heads and tails, nonempty exclusions, zero exclusions, and endpoint sameness.

The head-tail transport is Definition 38.100. It states that, under any selected bridge row, agreement of the visible heads and agreement of the displayed e-one tails determine each other.

The sealed-denominator side of the ledger is Definition 38.101. It rules out the sealed empty, sealed inner e-zero, and sealed appended e-zero displays at both endpoints. These rows are stable because the bridge package recovers them from each of A, B, U, and C. □

Theorem 38.105 (Real constant-tail seal and exactness obligation)**.** *For histories $d, e, tail_D, tail_E, u_D, u_E, z_D, z_E$: Hist and observation maps $r, q : \mathsf{Hist} \to \mathsf{Hist}$, set*

$$D = d \cdot \mathsf{E1}(tail_D) \qquad \text{and} \qquad E = e \cdot \mathsf{E1}(tail_E).$$

Write the bridge rows as

$A = \mathsf{RatHistoryClassifier}(D, E), \qquad B = \mathsf{RatStreamNameClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q),$

$U = \mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_D \circ r, \mathsf{RatConstStream}_E \circ q), \qquad C = \mathsf{RealConstantHistoryClassifier}(\mathsf{E1}$

If $\mathsf{hsame}(tail_D, tail_E)$, then the combined denominator-sanity exactness theorem supplies the seal and exactness obligation consumed by the RealUp constant-name boundary of chapter 38: the sanity package for D and E is exact for the same four bridge rows A, B, U, C, and therefore no malformed sealed denominator can pass through the constant-tail boundary.

Proof. The exactness source is Definition 38.102. Under the displayed tail agreement, it identifies the combined sanity package $S(D, E, u_D, u_E, z_D, z_E)$ with $A \wedge B \wedge U \wedge C$.

The Q component of S is the full denominator-tail package from Definition 38.95. It contains the denominator package, appended e-zero exclusions, and matched head equality required by the constant-name boundary.

The M component of S is the malformed sealed-denominator exclusion from Definition 38.101. Together these two components give the seal exactness row: every bridge classifier recovers the same sealed-denominator sanity, and the sanity package recovers the bridge classifiers. □

Theorem 38.106 (Real stream classifier prefix closure)**.** *If rational-observation streams are pointwise related by the rational history classifier, then every finite observation prefix is related by the recursively accumulated prefix classifier.*

Proof. Induct on the selected prefix length. The base case is the pointwise classifier at zero. The successor case pairs the induction hypothesis for the shorter prefix with the pointwise classifier at the successor observation. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier prefix`

Theorem 38.107 (Real stream prefix classifier hsame transport)**.** *If two rational-observation streams are related pointwise by* hsame *on both sides, then every classified finite prefix transports to the pointwise-related streams.*

Proof. Induct on the prefix length. The base observation is rational classifier transport at index 0. At a successor index, the induction hypothesis transports the shorter prefix and rational classifier transport handles the successor observation. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier hsame transport`

Theorem 38.108 (Real stream prefix unary context closure)**.** *If every prefix-side context and every tail-side context is unary pointwise, and the two displayed context streams are pointwise* hsame *on each side, then any classified finite real-stream prefix remains classified after each endpoint is wrapped by the corresponding unary prefix and tail contexts.*

Proof. Induct on the finite prefix length. At the base observation, apply rational history classifier unary-context closure to the endpoint classifier and the four pointwise context hypotheses at index 0. At a successor index, keep the inductively transported shorter prefix and apply the same rational unary-context closure theorem to the successor endpoint classifier. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier unary context closed`

Theorem 38.109 (Real stream prefix classifier reflexivity)**.** *For every rational-observation stream* $x : \mathbb{N} \to \mathsf{Hist}$*, if* $\mathsf{RatHistoryCarrier}(x(i))$ *for every observation index* i*, then* $\mathsf{RealStreamPrefixClassifier}(x, x, n)$ *for every prefix index* n*.*

Proof. Induct on n. At 0, the carrier witness for $x(0)$ supplies the rational history classifier for the endpoint, with hsame reflexivity providing the identity transport on both sides.

At a successor index, pair the induction hypothesis for the shorter prefix with the same rational classifier construction at the new endpoint $n + 1$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier refl`

Theorem 38.110 (Real stream prefix classifier symmetry)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$*, if* $\mathsf{RealStreamPrefixClassifier}(x, y, n)$*, then* $\mathsf{RealStreamPrefixClassifier}(y, x, n)$*.*

Proof. Induct on n. At 0, apply rational-history classifier symmetry to the base endpoint classifier.

At a successor index, reverse the shorter prefix by the induction hypothesis and reverse the displayed successor endpoint by rational-history classifier symmetry. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier symm`

Theorem 38.111 (Real stream prefix classifier endpoint projection)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$*, if* $\mathsf{RealStreamPrefixClassifier}(x, y, n)$*, then* $\mathsf{RatHistoryClassifier}(x(n), y(n))$*.*

Proof. Split on n. At 0, the prefix witness is exactly the selected rational-history classifier.

At a successor index, the recursive prefix witness is a pair; its right component is the rational-history classifier at the selected endpoint. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier endpoint`

Theorem 38.112 (Real stream prefix classifier base of successor)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$*, every nonempty classified finite prefix contains the base observation classifier:*

$$\mathsf{RealStreamPrefixClassifier}(x, y, n+1) \Longrightarrow \mathsf{RealStreamPrefixClassifier}(x, y, 0).$$

Proof. Induct on n. At 0, the successor prefix is the pair of the base classifier and the first successor endpoint classifier, so project its left component. At a further successor, recursively descend through the left prefix component until the base observation classifier is exposed. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier base of successor`

Lemma 38.113 (Real stream prefix successor inversion)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$ *and every prefix length* n*:*

$$\mathsf{RealStreamPrefixClassifier}(x, y, n{+}1) \Longleftrightarrow \mathsf{RealStreamPrefixClassifier}(x, y, n) \wedge \mathsf{RatHistoryClassifier}(x(n{+}1), y(n{+}1)).$$

Ten-field fit: traditional target finite prefix successor inversion; BEDC source RealUp prefix classifier over RatUp point classifiers; carrier rational-observation streams; classifier RealStreamPrefixClassifier*; stability inherited from hsame transport and endpoint projection; ledger prefix length and endpoint observation; core theorem this lemma; exactness the displayed iff; standard bridge finite prefix recursion; status* ProofTarget*.*

Proof. Unfold the recursive definition of $\mathsf{RealStreamPrefixClassifier}(x, y, n{+}1)$. In the forward direction, the successor prefix witness is a pair; project its left component to obtain $\mathsf{RealStreamPrefixClassifier}(x, y, n)$ and its right component to obtain the endpoint classifier $\mathsf{RatHistoryClassifier}(x(n+1), y(n+1))$.

Conversely, assume the previous prefix witness and the endpoint rational-history classifier. Pair these two witnesses by the successor constructor of the recursive prefix display, obtaining $\mathsf{RealStreamPrefixClassifier}(x, y, n+1)$. □

Lemma 38.114 (Real stream prefix successor e1 endpoint package)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$*, if* $\mathsf{RealStreamPrefixClassifier}(x, y, n{+}1)$ *and the successor endpoint histories have displays* $x(n+1)\mathsf{hsameE1}(a)$ *and* $y(n+1)\mathsf{hsameE1}(b)$*, then*

$$\mathsf{RealStreamPrefixClassifier}(x, y, n) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge a\mathsf{hsame}b.$$

Proof. The successor prefix witness splits into the predecessor prefix and the successor endpoint classifier. Apply the e1 endpoint readback theorem at index $n+1$ to the endpoint classifier and the two displayed e1 histories; this yields the unary tail witnesses and their history-sameness. Pair that endpoint package with the predecessor prefix. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier successor e1 endpoint package`

Theorem 38.115 (Real stream prefix classifier tail extension)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$ *and indices* n, m*, an already classified prefix through* n *extends across any finite tail whose endpoints are classified:*

$$\mathsf{RealStreamPrefixClassifier}(x, y, n) \wedge \big(\forall k,\ 1 \le k \le m \Longrightarrow \mathsf{RatHistoryClassifier}(x(n{+}k), y(n{+}k))\big) \Longrightarrow \mathsf{RealStreamPrefix}$$

Ten-field fit: traditional target finite prefix continuation from certified endpoints; BEDC source RealUp stream prefixes over RatUp history classifiers; carrier rational-observation streams; classifier RealStreamPrefixClassifier*; stability inherited from each endpoint classifier and recursive prefix pairing; ledger initial prefix length, tail length, and endpoint offsets; core theorem this tail continuation principle; exactness the displayed implication; standard bridge finite prefix recursion; status* ProofTarget*.*

Proof. Induct on m. At $m = 0$, the target prefix is the given prefix through n, since $n + 0 = n$, and no tail endpoint is required.

For the successor step, assume the principle for tail length m and suppose the prefix through n is classified together with endpoint classifiers for all offsets $1 \leq k \leq m + 1$. Restrict the endpoint assumption to offsets $1 \leq k \leq m$ and apply the induction hypothesis. This gives $\mathsf{RealStreamPrefixClassifier}(x, y, n + m)$.

It remains to add the final endpoint. Taking $k = m + 1$ in the endpoint assumption gives $\mathsf{RatHistoryClassifier}(x(n{+}m{+}1), y(n{+}m{+}1))$ after the usual successor arithmetic. Apply the reverse direction of Definition 38.113 to the classified prefix through $n + m$ and this endpoint classifier, obtaining the classified prefix through $n + m + 1$, which is the prefix through $n + (m + 1)$. □

Theorem 38.116 (Real stream prefix tail extension with unary anchor)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, a classified prefix through n extends across a classified finite tail of length m, and the left endpoint at the new boundary retains its unary anchor:*

$$\mathsf{RealStreamPrefixClassifier}(x, y, n) \Longrightarrow \Big(\forall k < m, \mathsf{RatHistoryClassifier}(x(n{+}k{+}1), y(n{+}k{+}1))\Big) \Longrightarrow \Big(\forall i,\ \mathsf{UnaryHistory}$$

Proof. Induct on m. The empty tail is the given prefix through n, with the unary side condition supplying the endpoint anchor at $x(n)$. For a successor tail, restrict the pointwise tail classifier to the shorter tail, apply the induction hypothesis to obtain the prefix through $n{+}m$, and append the final rational endpoint classifier at $x(n + m + 1), y(n + m + 1)$. The unary side condition supplies the new left endpoint anchor. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier tail extension with unary anchor`

Theorem 38.117 (Real stream prefix tail endpoint context projection)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, a classified prefix through n and a classified finite tail of length m determine the endpoint classifier at $n + m$. If that endpoint is then continued through matching unary prefix and tail contexts on both sides, the two displayed continuation results remain rational-history classified.*

Proof. First apply the finite tail principle to obtain $\mathsf{RealStreamPrefixClassifier}(x, y, n{+}m)$ together with the unary anchor at $x(n + m)$. Project the endpoint classifier at $n + m$. Rational unary-denominator context closure places the matching prefix and tail contexts around the two endpoint histories, and the continuation witnesses identify those normal forms with the displayed outputs. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier tail endpoint context projection`

Theorem 38.118 (Real stream prefix classifier truncation)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and indices m, n, any prefix classifier through $m{+}n$ restricts to the prefix classifier through n:*

$$\mathsf{RealStreamPrefixClassifier}(x, y, m + n) \Longrightarrow \mathsf{RealStreamPrefixClassifier}(x, y, n).$$

Proof. Induct on m. At $m = 0$, the source prefix is already the target prefix, since $0 + n = n$.

At a successor $m + 1$, the recursive definition of $\mathsf{RealStreamPrefixClassifier}(x, y, (m + 1) + n)$ exposes its left component, which is the classified prefix through $m + n$. Apply the induction hypothesis to this exposed prefix to obtain the classified prefix through n. □

Theorem 38.119 (Real stream prefix internal endpoint coverage)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and indices m, n, every classified prefix through $m+n$ exposes the retained endpoint row at n:*

$$\mathsf{RealStreamPrefixClassifier}(x, y, m+n) \Longrightarrow \mathsf{RatHistoryClassifier}(x(n), y(n)).$$

Ten-field fit: traditional target internal finite-prefix observation coverage; BEDC source RealUp prefix classifier plus RatUp endpoint classifier; carrier rational-observation streams; classifier RealStreamPrefixClassifier *stability inherited from truncation and endpoint projection; ledger prefix length, truncated endpoint, and observation index; core theorem this block; exactness classified prefix exposes each retained endpoint row; standard bridge finite rational prefix observation; status* ProofTarget*.*

Proof. Apply Definition 38.118 to the source prefix. This gives $\mathsf{RealStreamPrefixClassifier}(x, y, n)$.

Apply Definition 38.111 to the truncated prefix. The selected endpoint classifier is $\mathsf{RatHistoryClassifier}(x(n), y(n)$ □

Theorem 38.120 (Real stream prefix truncated unary context closure)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, if a prefix through $m+n$ is classified, then after descending to the prefix through n, matching unary prefix and tail contexts may be placed around every displayed endpoint:*

$$\mathsf{RealStreamPrefixClassifier}(x, y, m+n) \Longrightarrow \mathsf{RealStreamPrefixClassifier}(x', y', n),$$

where $x'(i) = \mathsf{append}(p_X(i), \mathsf{append}(x(i), t_X(i)))$ and $y'(i) = \mathsf{append}(p_Y(i), \mathsf{append}(y(i), t_Y(i)))$, with $p_X(i)$ and $t_X(i)$ unary and with $p_X(i)\mathsf{hsame}p_Y(i)$ and $t_X(i)\mathsf{hsame}t_Y(i)$ for every index i.

Proof. Induct on m to restrict the source prefix from $m+n$ to n. The base case is definitional, and the successor case projects the left component of the recursive prefix witness. Apply the stream-prefix unary-context closure theorem to the truncated prefix and the pointwise matching unary contexts. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier truncated unary context closed`

Theorem 38.121 (Real stream prefix truncated e1 pair readback)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, if the finite prefix through $m+n$ is classified and the selected endpoint at n is displayed as one-headed on both sides,*

$$\mathsf{hsame}(x(n), \mathsf{E1}(d)) \quad \textit{and} \quad \mathsf{hsame}(y(n), \mathsf{E1}(e)),$$

then both tails are unary and internally same:

$$\mathsf{UnaryHistory}(d) \wedge \mathsf{UnaryHistory}(e) \wedge \mathsf{hsame}(d, e).$$

Proof. First descend the recursive prefix classifier from $m+n$ to n by induction on m. The base case is definitional. In the successor case, the prefix witness at $(m+1)+n$ exposes the witness at $m+n$ as its left component. After the classified prefix at n is obtained, apply the e1 pair readback theorem at the selected endpoint. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier truncated e1 pair readback`

Theorem 38.122 (Real stream prefix truncated continuation endpoint context closure)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, a classified prefix through $m+n$ supplies the rational classifier at endpoint n. If the selected left and right endpoints are then continued through unary prefix and tail contexts, with matching* hsame *contexts on the two sides, the two displayed continuation results remain rational-history classified.*

Proof. Induct on m to descend the recursive prefix classifier from $m+n$ to n. Project the rational-history classifier at endpoint n. Apply rational-history classifier unary-denominator context closure to the selected endpoint and the two unary context pairs. The continuation witnesses identify the displayed outputs with the corresponding appended contexts, and associativity of append supplies the final endpoint transports. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier truncated cont endpoint context closed`

Lemma 38.123 (Real stream prefix previous classifier with unary anchor)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, if every left observation $x(i)$ is unary, then every successor finite-prefix classifier contains both the previous prefix classifier and the unary anchor at the previous left endpoint:*

$$\mathsf{RealStreamPrefixClassifier}(x, y, n+1) \Longrightarrow \mathsf{RealStreamPrefixClassifier}(x, y, n) \wedge \mathsf{UnaryHistory}(x(n)).$$

Proof. The recursive successor prefix is a pair whose left component is the previous prefix classifier. The unary side condition supplies $\mathsf{UnaryHistory}(x(n))$ at the same previous endpoint. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier previous with unary`

Theorem 38.124 (Real stream prefix add-left previous classifier with unary anchor)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, if every left observation $x(i)$ is unary, then any prefix classified through $m+n$ descends to the prefix classified through n, while retaining the unary anchor at $x(n)$:*

$$\mathsf{RealStreamPrefixClassifier}(x, y, m+n) \Longrightarrow \mathsf{RealStreamPrefixClassifier}(x, y, n) \wedge \mathsf{UnaryHistory}(x(n)).$$

Proof. Induct on m. At $m = 0$, the displayed prefix is the target prefix and the unary side condition supplies the endpoint anchor. At a successor $m+1$, apply Definition 38.123 to peel one recursive prefix layer, then apply the induction hypothesis to the exposed prefix through $m+n$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier add left previous with unary`

Lemma 38.125 (Real stream prefix add-left previous classifier with right unary anchor)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, if every right observation $y(i)$ is unary, then any prefix classified through $m+n$ descends to the prefix classified through n, while retaining the unary anchor at $y(n)$:*

$$\mathsf{RealStreamPrefixClassifier}(x, y, m+n) \Longrightarrow \mathsf{RealStreamPrefixClassifier}(x, y, n) \wedge \mathsf{UnaryHistory}(y(n)).$$

Proof. Apply symmetry of the finite-prefix classifier to read the prefix as a classifier from y to x. Then apply the add-left previous theorem with unary anchors on the left stream y. The recovered prefix is finally symmetrized back to a classifier from x to y, while the unary endpoint anchor remains $y(n)$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier add left previous with right unary`

Theorem 38.126 (Real stream prefix tail endpoint projection)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and indices n, m, if the prefix through n is classified and every endpoint along the finite tail of length m is rational-history classified, then the selected tail endpoint is rational-history classified:*

$$\mathsf{RealStreamPrefixClassifier}(x, y, n) \wedge (\forall k,\ 1 \le k \le m \Longrightarrow \mathsf{RatHistoryClassifier}(x(n+k), y(n+k))) \Longrightarrow \mathsf{RatHistoryClassif}$$

Ten-field fit: traditional target finite RealUp prefix endpoint readback; BEDC source RealUp stream prefixes over RatUp point classifiers; carrier rational-observation streams; classifier RealStreamPrefixClassifier*; stability by tail extension and endpoint projection; ledger initial prefix length, tail length, and selected endpoint; core theorem this projection; exactness selected endpoint classification; standard bridge RegSeqRat finite observation readback; status* ProofTarget*.*

Proof. Apply Definition 38.115 to the classified prefix through n and the finite tail endpoint hypothesis. This gives $\mathsf{RealStreamPrefixClassifier}(x, y, n + m)$.

Now apply Definition 38.111 at the endpoint index $n + m$. The resulting projection is exactly $\mathsf{RatHistoryClassifier}(x(n + m), y(n + m))$. □

Theorem 38.127 (Real stream prefix truncated endpoint common e-one tail readback)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and indices m, n, if $\mathsf{RealStreamPrefixClassifier}(x, y, m+n)$ holds, then the endpoint at n has a common e-one tail readback:*

$$\exists a, b,\ \mathsf{hsame}(x(n), \mathsf{E1}(a)) \wedge \mathsf{hsame}(y(n), \mathsf{E1}(b)) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).$$

Proof. Truncate the displayed prefix classifier to the selected endpoint n and use the denominator package there. Its positive unary denominator rows give unary endpoint witnesses and separate both selected endpoints from e, so unary nonempty readback exposes e-one tails a and b. The truncated e-one pair readback theorem then returns the two unary tail rows and their hsame comparison. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier truncated endpoint common e1 tail readback`

Theorem 38.128 (Real stream prefix probe endpoint determinacy)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, let $\mathcal{P}$ be a finite certified* ProbeBundle *window and let n be a unary observation with $\mathsf{InBundle}(n, \mathcal{P})$. Suppose the window supplies $\mathsf{RealStreamPrefixClassifier}(x, y, n)$ and, for every displayed tail row selected by $\mathcal{P}$ after n, the finite row $\mathsf{RatHistoryClassifier}(x(n+k), y(n+k))$ is present. Then every consumer endpoint selected from $\mathcal{P}$ has a unique* RatHistoryClassifier *readback, and its endpoint admits the same common e-one tail witness after* hsame *transport:*

$$\mathsf{InBundle}(n, \mathcal{P}) \Longrightarrow \forall j,\ \mathsf{InBundle}(j, \mathcal{P}) \Longrightarrow \exists a, b,\ \mathsf{hsame}(x(j), \mathsf{E1}(a)) \wedge \mathsf{hsame}(y(j), \mathsf{E1}(b)) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHis}$$

The statement reads only the displayed finite rows of $\mathcal{P}$; no observation outside the certified probe window is used.

Proof. Restrict the finite ProbeBundle to the selected prefix through n and to the displayed consumer endpoint j. The membership rows $\mathsf{InBundle}(n, \mathcal{P})$ and $\mathsf{InBundle}(j, \mathcal{P})$ are exactly the evidence that these two observations lie inside the certified window.

Apply Definition 38.853 to the selected prefix and the finite tail rows displayed by $\mathcal{P}$. This gives the endpoint RatHistoryClassifier readback for the consumer endpoint, and uniqueness follows because the readback is selected from the same finite bundle row rather than from an external observation.

Finally apply Definition 38.854 to the resulting classified prefix. The hsame transport keeps the two endpoint histories in the same rational-observation class, so the e-one tail witnesses are the common tail witnesses recorded by the finite probe window. □

Theorem 38.129 (Real terminal seal tail-section coherence)**.** *Let $x, y : \mathbb{N} \to \mathsf{Hist}$ be rational-observation streams, let $\mathcal{P}$ be a finite certified* ProbeBundle *endpoint window, and let $\mathcal{T}$ be the same $\mathsf{StreamName}^{\uparrow}$ tail-section package consumed by a finite $\mathsf{Real}^{\uparrow}$ stream prefix handoff. Suppose*

two finite endpoint reads pass through the same prefix row $\mathsf{RealStreamPrefixClassifier}(x, y, n)$*, the same displayed* $\mathsf{InBundle}$ *endpoint rows of* $\mathcal{P}$*, and the same tail-section package* $\mathcal{T}$*. Then the two endpoint reads determine the same terminal* $\mathsf{Real}^{\uparrow}$ *seal route up to the displayed* hsame *transports.*

The seal route is the finite route through the prefix endpoint projection, truncated common e-one tail readback, probe endpoint determinacy, and the certified $\mathsf{StreamName}^{\uparrow}$ *tail-section induction bridge. It does not export quotient stream equality, host sequence equality, selected limits, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, metric-completeness data, or standard bridge rows.*

Proof. First apply endpoint projection, Definition 38.853. Both reads use the same prefix row and the same finite tail rows selected by $\mathcal{P}$, so the endpoint $\mathsf{RatHistoryClassifier}$ readback is taken from the same finite endpoint surface.

Next apply truncated endpoint common e-one tail readback, Definition 38.854. The endpoint histories therefore expose common e-one tail witnesses, and the displayed hsame rows transport those witnesses along the same prefix package.

Now use probe endpoint determinacy, Definition 38.855. It identifies the endpoint readback supplied by $\mathcal{P}$ as the unique finite readback for that endpoint inside the certified probe window.

Finally apply the StreamName tail-section induction bridge Definition 126.694. Since both reads consume the same $\mathsf{StreamName}^{\uparrow}$ tail-section package, the terminal seal route is carried over the same finite BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ support rows. No remaining coordinate can distinguish two terminal $\mathsf{Real}^{\uparrow}$ seal routes. □

Theorem 38.130 (Real stream prefix two-probe endpoint coherence)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$*, let* $\mathcal{P}$ *and* $\mathcal{Q}$ *be finite certified* $\mathsf{ProbeBundle}$ *windows. Suppose the same unary observation* j *satisfies* $\mathsf{InBundle}(j, \mathcal{P})$ *and* $\mathsf{InBundle}(j, \mathcal{Q})$*, and suppose both windows supply the* $\mathsf{RealStreamPrefixClassifier}$ *row and the finite* $\mathsf{RatHistoryClassifier}$ *tail rows required by Definition 38.855 for the selected endpoint* j*. Then the endpoint readbacks* $\mathsf{RatHistoryClassifier}(x(j), y(j))$ *obtained through* $\mathcal{P}$ *and through* $\mathcal{Q}$ *are the same up to* hsame*, and their common e-one tail witnesses agree up to* hsame *transport:*

$$
\begin{aligned}
&\mathsf{InBundle}(j, \mathcal{P}) \wedge \mathsf{InBundle}(j, \mathcal{Q}) \\
&\quad \textit{and the two displayed endpoint-determinacy packets at } j \\
&\quad \textit{determine histories } a_{\mathcal{P}}, b_{\mathcal{P}}, a_{\mathcal{Q}}, b_{\mathcal{Q}} \textit{ with} \\
&\quad \mathsf{hsame}(a_{\mathcal{P}}, a_{\mathcal{Q}}) \wedge \mathsf{hsame}(b_{\mathcal{P}}, b_{\mathcal{Q}}) \wedge \mathsf{hsame}(x(j), \mathsf{E1}(a_{\mathcal{P}})) \wedge \mathsf{hsame}(x(j), \mathsf{E1}(a_{\mathcal{Q}})) \\
&\quad \wedge\ \mathsf{hsame}(y(j), \mathsf{E1}(b_{\mathcal{P}})) \wedge \mathsf{hsame}(y(j), \mathsf{E1}(b_{\mathcal{Q}})).
\end{aligned}
$$

Ten-field fit: traditional target finite RealUp two-window endpoint coherence; BEDC source RealUp stream prefixes over RatUp point classifiers; carrier the two certified $\mathsf{ProbeBundle}$ *windows over the same streams; classifier* $\mathsf{RealStreamPrefixClassifier}$ *at the selected unary observation; stability by* hsame *transitivity across the two endpoint readbacks; ledger the two window memberships, prefix classifiers, tail rows, endpoint row, and common e-one witnesses; core theorem this two-probe coherence statement; exactness the fixed endpoint row* j*; standard bridge StreamName and RegSeqRat finite observation readback; status* $\mathsf{ProofTarget}$*. No observation outside the two certified probe windows is used.*

Proof. Apply Definition 38.855 to $\mathcal{P}$ at the selected observation j. The window membership row and the displayed classifier and tail rows return the endpoint $\mathsf{RatHistoryClassifier}(x(j), y(j))$ together with common e-one tail witnesses $a_{\mathcal{P}}$ and $b_{\mathcal{P}}$.

Apply the same theorem to $\mathcal{Q}$ at the same selected observation j. This gives the endpoint readback through the second finite window and common e-one tail witnesses $a_{\mathcal{Q}}$ and $b_{\mathcal{Q}}$.

Both applications read the fixed endpoint row j of the same streams x and y. Transitivity of hsame identifies the two rational endpoint readbacks, and the same transport identifies the e-one tail witnesses. Since every row used in the argument is selected from either $\mathcal{P}$ or $\mathcal{Q}$, no external observation enters the comparison. □

Theorem 38.131 (Real stream prefix probe-union endpoint readback)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, let $\mathcal{P}$ and $\mathcal{Q}$ be finite certified* ProbeBundle *windows, and let $\mathcal{U}$ be their synchronized union window certified by Definition 126.242. Suppose each source window supplies the* RealStreamPrefixClassifier *rows and finite* RatHistoryClassifier *tail rows required by Definition 38.855. Then every unary endpoint j selected by either source window has the same* $\mathsf{RatHistoryClassifier}(x(j), y(j))$ *readback through the union window $\mathcal{U}$, and the common e-one tail witnesses displayed by the source window and by $\mathcal{U}$ agree by* hsame *transport.*

Equivalently, if $\mathsf{InBundle}(j, \mathcal{P}) \vee \mathsf{InBundle}(j, \mathcal{Q})$*, then* $\mathsf{InBundle}(j, \mathcal{U})$ *and the union read supplies histories $a_{\mathcal{U}}, b_{\mathcal{U}}$ with*

$$\mathsf{hsame}(x(j), \mathsf{E1}(a_{\mathcal{U}})) \wedge \mathsf{hsame}(y(j), \mathsf{E1}(b_{\mathcal{U}})) \wedge \mathsf{UnaryHistory}(a_{\mathcal{U}}) \wedge \mathsf{UnaryHistory}(b_{\mathcal{U}}).$$

If j lies in both $\mathcal{P}$ and $\mathcal{Q}$, these witnesses are hsame*-identified with the two source-window witnesses of Definition 38.857; if j lies in only one source window, the union read is the unique displayed readback of that source window.*

Ten-field fit: traditional target finite RealUp union endpoint readback; BEDC source RealUp stream prefixes with RatUp point classifiers; carrier the certified ProbeBundle *union membership rows for $\mathcal{P}, \mathcal{Q}, \mathcal{U}$; classifier* RealStreamPrefixClassifier *at the displayed unary prefix; stability by* hsame *transport of the e-one tails; ledger the finite endpoint ledger, source memberships, synchronized union membership, prefix classifiers, and tail rows; core theorem this probe-union readback statement; exactness the fixed finite endpoint row j; bridge data the StreamName synchronized-window union coverage and RegSeqRat finite observation readback; status* ProofTarget*. No quotient-real equality, completeness theorem, or host real comparison is used.*

Proof. Apply Definition 126.242 to the two certified probe windows. It places every endpoint selected by $\mathcal{P}$ or by $\mathcal{Q}$ into the synchronized union window $\mathcal{U}$ and records the finite union membership row used by the later readback.

When the selected endpoint lies only in $\mathcal{P}$, apply Definition 38.855 to $\mathcal{P}$. The union membership supplied by the synchronized carrier reads the same finite endpoint row, so the union readback is the displayed $\mathcal{P}$ readback transported along hsame.

The case where the endpoint lies only in $\mathcal{Q}$ is identical, with $\mathcal{Q}$ supplying the source readback and the union carrier supplying the same endpoint row in $\mathcal{U}$.

If the endpoint lies in both source windows, first apply endpoint determinacy in each window, then apply Definition 38.857. The coherence row identifies the two rational endpoint readbacks and transports the common e-one tail witnesses through hsame, so the union read has the same displayed tails.

All rows consumed by the argument are finite rows of the two source probe windows or of their synchronized union. Hence the endpoint readback remains a RegSeqRat-style finite observation read and never appeals to a quotient real, completeness principle, or host equality. □

Theorem 38.132 (Real stream prefix probe-union terminal four-face factorization)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, let $\mathcal{P}$ and $\mathcal{Q}$ be finite certified* ProbeBundle *windows and let $\mathcal{U}$ be their synchronized union window. Suppose the two source windows supply the* RealStreamPrefixClassifier

rows and finite RatHistoryClassifier *tail rows required by Definition 38.858. Then every endpoint readback selected from $\mathcal{U}$ factors through exactly one terminal four-face packet over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, R

The packet has precisely the displayed rows

BHist-*indexed finite probe histories*, hsame-*transport for endpoint tails*, Cont-*continuity rows*, Pkg-*package rows for the synchronized union window*, NameCert-*certification rows for the four visible faces.*

Its $\mathsf{StreamName}^{\uparrow}$ *face is the synchronized carrier $\mathcal{U}$, its* $\mathsf{DyadicRatCore}^{\uparrow}$ *face is the common finite scale window read from the same endpoint ledger, its* $\mathsf{RegSeqRat}^{\uparrow}$ *face is the regular sequence readback, and its* $\mathsf{Real}^{\uparrow}$ *face is the local endpoint seal supplied by the union readback. There is no second terminal packet with the same displayed rows.*

The factorization does not use quotient-real equality, selected limit values, ambient completeness of $\mathsf{Real}^{\uparrow}$*, countable choice, or standard bridge data.*

Proof. First apply Definition 38.858. The synchronized union window supplies the endpoint RatHistoryClassifier readback and the common e-one tail witnesses, all selected from the finite rows of $\mathcal{P}, \mathcal{Q}, \mathcal{U}$.

Next apply Definition 126.242 and Definition 126.558. These two results identify the $\mathsf{StreamName}^{\uparrow}$ carrier row with a terminal finite-request section over the same synchronized window; no endpoint outside $\mathcal{U}$ is introduced.

Now apply Definition 301.239. The RegSeqRat readback and the local Real endpoint seal are thereby read as two faces of a single terminal packet whose support rows are exactly the displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Finally apply Definition 291.83. It supplies the $\mathsf{DyadicRatCore}^{\uparrow}$ common-scale face and proves that the four visible faces form one pullback packet. Terminality gives uniqueness of the packet with those rows, while the construction never introduces quotient-real equality, selected limits, ambient completeness, countable choice, or standard bridge data. □

Theorem 38.133 (Real stream prefix probe-union terminal four-face support minimality)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, finite certified probe windows $\mathcal{P}, \mathcal{Q}$, and their synchronized union $\mathcal{U}$, every accepted terminal packet produced by Definition 38.859 is support-minimal. Deleting or replacing any one of the four faces* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$*, or deleting or replacing any displayed* BHist, hsame, Cont, Pkg, *or* NameCert *support row, destroys the accepted probe-union terminal read.*

The missing face or support row cannot be supplied by quotient-real equality, selected limit values, ambient $\mathsf{Real}^{\uparrow}$ *completeness, countable choice, metric-completeness rows, aggregate status rows, or standard bridge data. These coordinates remain outside the local probe-union packet and do not substitute for the finite BEDC support rows used by the terminal read.*

Proof. First apply Definition 38.859. It identifies the accepted probe-union read with a unique terminal packet whose visible faces are exactly $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$ and whose support is the displayed BHist, hsame, Cont, Pkg, and NameCert row family.

For the finite-window carrier face, apply Definition 126.653 to the synchronized StreamName window underlying $\mathcal{U}$. That result rules out deletion or replacement of the StreamName face and of the finite probe-history rows that certify membership in the accepted window.

For the dyadic request and regular tail faces, apply Definition 301.177. The common finite scale window and the RegSeqRat tail-budget rows are read from the same endpoint ledger, so removing either face, or any of the hsame, Cont, Pkg, or NameCert rows it consumes, leaves no accepted regular tail read for the probe-union endpoint.

Finally apply Definition 38.868 together with Definition 38.741. These pull the Real-side endpoint seal back to the same four-face terminal packet and rule out substitution by host-real equality, selected limits, completeness coordinates, choice principles, aggregate status rows, or bridge evidence. The two-axis roadmap discipline keeps those excluded coordinates separate from the local BEDC support rows, so none of them can repair a missing face or row. □

Theorem 38.134 (Real stream prefix probe-union support-row exchange invariance)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, let $\mathcal{P}$ and $\mathcal{Q}$ be finite certified* ProbeBundle *windows, and let $\mathcal{U}$ be their synchronized union window. Consider any two presentations of the terminal packet supplied by Definition 38.859. Suppose both presentations preserve the same four visible faces* $\mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$ *and the same displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *projections.*

Then exchanging the presentation order of those already-displayed support rows does not produce a second terminal packet. The two presentations determine the same terminal packet over $\mathcal{U}$, and for every selected endpoint j they determine the same finite endpoint readback $\mathsf{RatHistoryClassifier}(x(j), y(j))$ *with the same* hsame*-transported common e-one tail witnesses.*

This invariance is local to the displayed BEDC support rows. It is not witnessed by quotient-real equality, selected limit values, ambient $\mathsf{Real}^{\uparrow}$ *completeness, countable choice, aggregate status rows, or bridge data, and none of those coordinates can distinguish two presentation orders of the same terminal probe-union packet.*

Proof. First apply Definition 38.858. Both presentations read each selected endpoint from the same synchronized union window $\mathcal{U}$ and the same finite endpoint ledger, so the rational endpoint row and the common e-one tail witnesses agree by the displayed hsame transport.

Next apply Definition 38.859. The two presentations expose the same four faces $\mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{R}$ and the same BHist, hsame, Cont, Pkg, and NameCert projections. Terminality therefore identifies them as one terminal packet over the synchronized union carrier rather than as two packets distinguished by row order.

Finally apply Definition 38.860. Support minimality says that the accepted terminal read is carried exactly by the displayed faces and support rows. Hence quotient-real equality, selected limits, ambient completeness, countable choice, aggregate status rows, and bridge data cannot replace one of those rows or separate two orderings of the same row family. The endpoint readback equality from the first paragraph is therefore the endpoint readback of the unique terminal packet. □

Theorem 38.135 (Real stream finite-prefix exactness)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$,*

$$\mathsf{RealStreamClassifier}(x, y) \iff \forall n,\ \mathsf{RealStreamPrefixClassifier}(x, y, n).$$

Proof. For the forward direction, apply Definition 38.106. The pointwise stream classifier supplies exactly the rational-history classifier needed at each endpoint of the recursive prefix construction.

For the reverse direction, assume every finite prefix is classified and fix an observation index n. Apply the hypothesis at n, then use Definition 38.111 to recover $\mathsf{RatHistoryClassifier}(x(n), y(n))$. Since n was arbitrary, these endpoint classifiers are precisely $\mathsf{RealStreamClassifier}(x, y)$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier finite prefix exactness`

Theorem 38.136 (Real stream classifier symmetry)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, if* $\mathsf{RealStreamClassifier}(x, y)$*, then* $\mathsf{RealStreamClassifier}(y, x)$*.*

Proof. Fix an observation index. The stream classifier supplies the rational-history classifier at that index, and rational-history classifier symmetry reverses it. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier symm`

Theorem 38.137 (Real stream classifier transitivity)**.** *For rational-observation streams* $x, y, z : \mathbb{N} \to \mathsf{Hist}$*, if* $\mathsf{RealStreamClassifier}(x, y)$ *and* $\mathsf{RealStreamClassifier}(y, z)$*, then* $\mathsf{RealStreamClassifier}(x, z)$*.*

Proof. Fix an observation index. The two stream classifiers give the two rational-history classifier witnesses at that index, and rational-history classifier transitivity composes them. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier trans`

Theorem 38.138 (Real stream classifier certificate fields)**.** *For rational-observation streams* $x, y, z : \mathbb{N} \to \mathsf{Hist}$*, the pointwise stream classifier supplies the following stability certificate fields:*

1. *if* $\forall n,\ \mathsf{RatHistoryCarrier}(x(n))$*, then* $\mathsf{RealStreamClassifier}(x, x)$*;*
2. *if* $\mathsf{RealStreamClassifier}(x, y)$*, then for every* n *both* $\mathsf{RatHistoryCarrier}(x(n))$ *and* $\mathsf{RatHistoryCarrier}(y(n))$*;*
3. *if* $\mathsf{RealStreamClassifier}(x, y)$*, then* $\mathsf{RealStreamClassifier}(y, x)$*;*
4. *if* $\mathsf{RealStreamClassifier}(x, y)$ *and* $\mathsf{RealStreamClassifier}(y, z)$*, then* $\mathsf{RealStreamClassifier}(x, z)$*.*

Proof. For reflexivity, fix the stream x and its pointwise rational-history carrier witness. Apply Definition 38.109 at every finite prefix. The reverse direction of Definition 38.135 then repacks these prefix witnesses as $\mathsf{RealStreamClassifier}(x, x)$.

For endpoint carrier readback, unfold the pointwise stream classifier and fix an index n. The classifier at n is a $\mathsf{RatHistoryClassifier}(x(n), y(n))$ witness, and unpacking the rational-history classifier gives both endpoint carrier facts.

The symmetry field is exactly Definition 38.136. The transitivity field is exactly Definition 38.137. These four clauses are therefore available as the certificate-level stability package for the stream classifier. □

Theorem 38.139 (Real stream classifier hsame transport)**.** *For rational-observation streams* $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$*, if* $\forall n,\ \mathsf{hsame}(x(n), x'(n))$ *and* $\forall n,\ \mathsf{hsame}(y(n), y'(n))$*, then*

$$\mathsf{RealStreamClassifier}(x, y) \iff \mathsf{RealStreamClassifier}(x', y').$$

Proof. For the forward direction, assume $\mathsf{RealStreamClassifier}(x, y)$. By the forward direction of Definition 38.135, every finite prefix $\mathsf{RealStreamPrefixClassifier}(x, y, n)$ is classified.

For each prefix index n, apply Definition 38.107 with the two pointwise hsame hypotheses. This transports the prefix classifier from (x, y) to (x', y') at the same index.

Since the transported prefix witness is available for every n, the reverse direction of Definition 38.135 reassembles these finite-prefix witnesses into $\mathsf{RealStreamClassifier}(x', y')$.

For the reverse direction, assume $\mathsf{RealStreamClassifier}(x', y')$. The same finite-prefix exactness theorem gives $\mathsf{RealStreamPrefixClassifier}(x', y', n)$ for every n.

For each prefix index n, use the symmetry of the pointwise hsame witnesses to obtain $\mathsf{hsame}(x'(n), x(n))$ and $\mathsf{hsame}(y'(n), y(n))$. Applying Definition 38.107 with these symmetric witnesses transports the prefix classifier from (x', y') back to (x, y).

The reverse direction of Definition 38.135 then reassembles the transported finite-prefix witnesses into $\mathsf{RealStreamClassifier}(x, y)$. □

Theorem 38.140 (Real stream transport with endpoint readback)**.** *For rational-observation streams* $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$*, assume* $\forall n,\ \mathsf{hsame}(x(n), x'(n))$*, assume* $\forall n,\ \mathsf{hsame}(y(n), y'(n))$*, and assume* $\mathsf{RealStreamClassifier}(x, y)$*. Then the transported streams carry the following readback package:*

1. $\mathsf{RealStreamClassifier}(x', y')$*;*
2. *for every* n*,* $\mathsf{RealStreamPrefixClassifier}(x', y', n)$*;*
3. *for every* n*,* $\mathsf{RatHistoryClassifier}(x'(n), y'(n))$*.*

Proof. First take the forward implication from Definition 38.139 and apply it to the two pointwise hsame hypotheses and the original stream classifier. This gives $\mathsf{RealStreamClassifier}(x', y')$.

Next use the forward direction of Definition 38.135 on the transported stream classifier. The result is $\mathsf{RealStreamPrefixClassifier}(x', y', n)$ for every finite prefix index n.

Finally fix an index n and apply Definition 38.111 to the transported prefix witness at that index. This recovers the endpoint $\mathsf{RatHistoryClassifier}(x'(n), y'(n))$, completing the three displayed fields of the package. □

Theorem 38.141 (Real stream transported selected zero-endpoint exclusion)**.** *For rational-observation streams* $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$ *and a selected index* n*, if*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y),$$

then neither transported selected endpoint can be displayed as a zero-extension endpoint:

$$(\mathsf{hsame}(x'(n), \mathsf{E0}(z_x)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{E0}(z_y)) \to \mathsf{False}).$$

Proof. Transport the pointwise rational-history classifier at index n along the two streamwise hsame hypotheses. The transported classifier exposes positive unary denominator witnesses at $x'(n)$ and $y'(n)$. If either endpoint is displayed as $\mathsf{E0}$, transport the corresponding positive denominator witness to that zero-extension endpoint and apply the rational positive-denominator zero-endpoint contradiction. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier transport selected e0 endpoint absurd`

Theorem 38.142 (Real stream classifier hsame one-tail pair readback)**.** *For rational-observation streams* $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$*, assume* $\forall n,\ \mathsf{hsame}(x(n), x'(n))$ *and* $\forall n,\ \mathsf{hsame}(y(n), y'(n))$*. If* $\mathsf{RealStreamClassifier}(x, y)$ *and the transported endpoints satisfy* $\mathsf{hsame}(x'(n), \mathsf{E1}(a))$ *and* $\mathsf{hsame}(y'(n), \mathsf{E1}(b))$*, then*

$$\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).$$

Proof. Evaluate the pointwise stream classifier at the selected index n. Transport the resulting rational-history classifier along the two pointwise hsame maps, then transport again to the displayed one-extension endpoints. Rational one-tail classifier exactness exposes the two unary tails and their internal sameness. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier hsame e1 pair readback`

Theorem 38.143 (Real stream classifier selected continuation positive denominators)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$*, a selected index* n*, a shared unary suffix* q*, and continuation outputs* xq, yq*, if*

$$\mathsf{RealStreamClassifier}(x, y), \quad \mathsf{UnaryHistory}(q), \quad \mathsf{Cont}(x(n), q, xq), \quad \mathsf{Cont}(y(n), q, yq),$$

then

$$\mathsf{PositiveUnaryDenominator}(xq) \wedge \mathsf{PositiveUnaryDenominator}(yq).$$

Proof. At the selected index, the stream classifier gives $\mathsf{RatHistoryClassifier}(x(n), y(n))$. Close this rational classifier under the common unary suffix q, using reflexive suffix sameness. The two continuation displays identify the closed endpoints with xq and yq. Transport the closed classifier across those displays and read the two positive denominators from the transported rational-history classifier. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier selected continuation positive denominators`

Theorem 38.144 (Real stream classifier selected continuation zero-endpoint exclusion)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, a selected index n, a shared unary suffix q, continuation outputs xq, yq, and endpoint tails z_x, z_y, if*

$$\mathsf{RealStreamClassifier}(x, y), \quad \mathsf{UnaryHistory}(q), \quad \mathsf{Cont}(x(n), q, xq), \quad \mathsf{Cont}(y(n), q, yq),$$

then neither selected continuation output can be displayed as a zero-headed endpoint:

$$(\mathsf{hsame}(xq, \mathsf{E0}(z_x)) \to \mathsf{False}) \wedge (\mathsf{hsame}(yq, \mathsf{E0}(z_y)) \to \mathsf{False}).$$

Proof. The selected continuation positive-denominator theorem gives positive unary denominator witnesses for xq and yq. Transport either witness along a displayed zero-headed endpoint comparison and apply positive denominator zero-endpoint absurdity. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier selected continuation e0 endpoint absurd`

Theorem 38.145 (Real stream classifier selected continuation endpoint boundary package)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, a selected index n, a shared unary suffix q, continuation outputs xq, yq, and endpoint tails $z_x, z_y : \mathsf{Hist}$, if*

$$\mathsf{RealStreamClassifier}(x, y), \quad \mathsf{UnaryHistory}(q), \quad \mathsf{Cont}(x(n), q, xq), \quad \mathsf{Cont}(y(n), q, yq),$$

then the selected continuation endpoints carry the boundary package

$$\begin{aligned}
&\mathsf{PositiveUnaryDenominator}(xq) \wedge \mathsf{PositiveUnaryDenominator}(yq) \wedge \\
&\mathsf{UnaryHistory}(xq) \wedge \mathsf{UnaryHistory}(yq) \wedge \\
&(\mathsf{hsame}(xq, \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(yq, \mathsf{e}) \to \mathsf{False}) \wedge \\
&(\mathsf{hsame}(xq, \mathsf{E0}(z_x)) \to \mathsf{False}) \wedge (\mathsf{hsame}(yq, \mathsf{E0}(z_y)) \to \mathsf{False}).
\end{aligned}$$

Proof. Apply Definition 38.143 to the selected stream classifier, the shared unary suffix, and the two continuation displays. This gives positive unary denominator witnesses for xq and yq.

Apply Definition 37.12 separately to the two denominator witnesses. These two applications give $\mathsf{UnaryHistory}(xq)$, $\mathsf{UnaryHistory}(yq)$, and the two empty-endpoint exclusions.

Apply Definition 38.144 to the same selected continuation data. This gives the two zero-headed endpoint exclusions. Package the denominator, unary, empty-endpoint, and zero-endpoint rows in the displayed order. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier selected continuation endpoint boundary package`

Theorem 38.146 (Real stream classifier selected continuation full shape package)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, a selected index n, a shared unary suffix q, continuation outputs xq, yq, and histories $a, b, z_x, z_y : \mathsf{Hist}$, if*

$$\mathsf{RealStreamClassifier}(x, y), \quad \mathsf{UnaryHistory}(q), \quad \mathsf{Cont}(x(n), q, xq), \quad \mathsf{Cont}(y(n), q, yq),$$

and

$$\mathsf{hsame}(xq, \mathsf{E1}(a)), \quad \mathsf{hsame}(yq, \mathsf{E1}(b)),$$

then the selected continuation endpoints carry the full displayed shape package:

$$\begin{aligned}&\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b) \wedge \\ &\mathsf{PositiveUnaryDenominator}(xq) \wedge \mathsf{PositiveUnaryDenominator}(yq) \wedge \mathsf{UnaryHistory}(xq) \wedge \mathsf{UnaryHistory}(yq) \wedge \\ &(\mathsf{hsame}(xq, \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(yq, \mathsf{e}) \to \mathsf{False}) \wedge \\ &(\mathsf{hsame}(xq, \mathsf{E0}(z_x)) \to \mathsf{False}) \wedge (\mathsf{hsame}(yq, \mathsf{E0}(z_y)) \to \mathsf{False}).\end{aligned}$$

Proof. Apply Definition 38.637 to the RealUp stream classifier, the shared unary suffix, the two continuation outputs, and the two displayed e-one tails. This reads back $\mathsf{UnaryHistory}(a)$, $\mathsf{UnaryHistory}(b)$, and $\mathsf{hsame}(a, b)$.

Apply Definition 38.145 to the same selected continuation data. This supplies both positive denominator rows, both unary endpoint rows, both empty-endpoint exclusions, and both zero-headed endpoint exclusions.

Package the e-one tail readback, the positive denominator witnesses, the unary endpoint rows, the empty-endpoint exclusions, and the zero-endpoint exclusions. The result is exactly the displayed full shape package. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier selected continuation full shape package`

Fit: traditional target selected continuation endpoint shape for RealUp streams; BEDC source RealUp stream classifier plus RatUp denominator readback plus Cont; carrier rational-observation streams with a selected continuation; classifier RealStreamClassifier and RatHistoryClassifier-derived denominator data; stability selected continuation closure and hsame readback; ledger selected index, shared suffix, continuation outputs, and endpoint display tests; core theorem Definition 38.146; exactness the displayed conjunction; standard bridge finite selected rational endpoint shape inside RealUp; status ProofTarget.

Theorem 38.147 (Real stream prefix classifier transitivity)**.** *For rational-observation streams $x, y, z : \mathbb{N} \to \mathsf{Hist}$, if the finite prefix classifier relates x to y through index n and relates y to z through the same index, then it relates x to z through index n.*

Proof. Induct on the prefix index. At zero, use rational history classifier transitivity. At a successor index, combine the induction hypothesis for the shorter prefix with rational history classifier transitivity at the new endpoint. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier trans`

Theorem 38.148 (Real stream prefix one-tail pair readback)**.** *If a classified finite rational-observation prefix displays its selected left and right endpoints as one-extension histories, then the displayed tails are unary and internally the same.*

Proof. Split on the selected observation index. At zero, use the base rational-history classifier; at a successor, use the right endpoint of the prefix classifier. Transport the selected classifier to the displayed one-extension endpoints, then apply rational one-tail classifier exactness. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier e1 pair readback`

Theorem 38.149 (Real stream prefix classifier hsame one-tail pair readback)**.** *For rational-observation streams* $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$*, assume* $\forall n,\ \mathsf{hsame}(x(n), x'(n))$ *and* $\forall n,\ \mathsf{hsame}(y(n), y'(n))$*. If* $\mathsf{RealStreamPrefixClassifier}(x, y, n)$ *and the transported endpoints satisfy* $\mathsf{hsame}(x'(n), \mathsf{E1}(a))$ *and* $\mathsf{hsame}(y'(n), \mathsf{E1}(b))$*, then*

$$\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).$$

Proof. First transport the finite prefix classifier from (x, y) to (x', y') using the pointwise hsame hypotheses. The transported prefix has displayed one-extension endpoints at index n, so the one-tail pair readback theorem returns the two unary tail witnesses and $\mathsf{hsame}(a, b)$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier hsame e1 pair readback`

Theorem 38.150 (Real stream prefix certificate boundary)**.** *For rational-observation streams transported by pointwise* hsame*, the finite prefix classifier supplies a closed BEDC certificate boundary. The same prefix surface gives transitive prefix comparison, one-extension endpoint unary tails, and transported tail* hsame *readback.*

This boundary uses only the displayed finite prefix surface. It does not read host index equality, quotient structure, completion data, $\mathsf{Real}^{\uparrow}$ *completeness, metric structure, order structure, or any standard bridge row.*

Proof. Apply Definition 38.147 to close the comparison surface under transitive prefix composition at the displayed observation index.

Apply Definition 38.148 to read the selected left and right one-extension endpoints back to unary tails and their internal hsame comparison.

Finally apply Definition 38.149. The pointwise hsame hypotheses transport the same finite prefix certificate to the displayed endpoint streams, so the certificate boundary survives the transport without adding any host-side equality, analytic completion, metric, order, or bridge datum. □

Definition 38.151 (Real unary offset bound)**.** *For histories* $k, w : \mathsf{Hist}$*, the unary offset bound is the BEDC continuation witness that* k *is a certified unary observation lying below the certified unary bound* w*:*

$$\mathsf{UnaryOffsetLe}(k, w) \iff \mathsf{UnaryHistory}(k) \wedge \exists \tau : \mathsf{Hist},\ \mathsf{UnaryHistory}(\tau) \wedge \mathsf{Cont}(k, \tau, w).$$

Lean4 (definition) `BEDC.Derived.RealUp.RealUnaryOffsetLe`
Lean4 (definition) `BEDC.Derived.RealUp.UnaryOffsetLe`

Theorem 38.152 (Unary offset continuation transitivity)**.** *For histories* $k, w, u, \tau, \sigma : \mathsf{Hist}$*,*

$$\mathsf{UnaryHistory}(k) \wedge \mathsf{UnaryHistory}(\tau) \wedge \mathsf{UnaryHistory}(\sigma) \wedge \mathsf{Cont}(k, \tau, w) \wedge \mathsf{Cont}(w, \sigma, u) \Longrightarrow \mathsf{UnaryOffsetLe}(k, u).$$

Proof. Use $\mathsf{append}(\tau, \sigma)$ as the composed offset tail. Unary append closure supplies its unary-history row, and continuation associativity turns the two displayed continuation rows into a continuation from k through that tail to u. Together with the given $\mathsf{UnaryHistory}(k)$ row, these data repack as $\mathsf{UnaryOffsetLe}(k, u)$. □

Lean4 ✓ `BEDC.Derived.RealUp.UnaryOffsetLe cont trans`

Theorem 38.153 (Unary offset append-tail closure)**.** *For histories* $k, w, \tau : \mathsf{Hist}$*,*

$$\mathsf{UnaryOffsetLe}(k, w) \wedge \mathsf{UnaryHistory}(\tau) \Longrightarrow \mathsf{UnaryOffsetLe}(k, \mathsf{append}(w, \tau)).$$

Proof. Unfold the offset witness for $\mathsf{UnaryOffsetLe}(k, w)$. It supplies $\mathsf{UnaryHistory}(k)$ and a unary tail σ with $\mathsf{Cont}(k, \sigma, w)$. Appending the displayed unary history τ to this tail gives $\mathsf{append}(\sigma, \tau)$, whose unary row follows from unary append closure. Continuation associativity turns $\mathsf{Cont}(k, \sigma, w)$ into a continuation from k through $\mathsf{append}(\sigma, \tau)$ to $\mathsf{append}(w, \tau)$, so the same left endpoint repacks as the displayed offset witness. □

Lean4 ✓ `BEDC.Derived.RealUp.UnaryOffsetLe append tail closed`

Definition 38.154 (Real unary stream finite window classifier)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and histories* $a, w : \mathsf{Hist}$*, read* a *as the anchor and* w *as the bound. The finite window classifier is the pointwise RatUp classifier over every certified unary offset below* w*:*

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w) \Longleftrightarrow \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(w) \wedge \forall k,\ \mathsf{UnaryOffsetLe}(k, w) \to \mathsf{Ratl}$$

Lean4 (definition) `BEDC.Derived.RealUp.RealUnaryStreamWindowClassifier`

Theorem 38.155 (Real unary stream finite-window coverage)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and histories* $a, w : \mathsf{Hist}$*,*

$$\mathsf{RealUnaryStreamClassifier}(s, t) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(w) \Longrightarrow \mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w).$$

Proof. Unfold Definition 38.154. The anchor and bound fields are exactly the displayed assumptions $\mathsf{UnaryHistory}(a)$ and $\mathsf{UnaryHistory}(w)$.

Fix an offset k and assume $\mathsf{UnaryOffsetLe}(k, w)$. Unfold Definition 38.151; the offset witness projects $\mathsf{UnaryHistory}(k)$ together with a unary tail whose continuation reaches the bound.

Apply unary append closure to $\mathsf{UnaryHistory}(a)$ and $\mathsf{UnaryHistory}(k)$ to obtain $\mathsf{UnaryHistory}(\mathsf{append}(a, k))$. Evaluating $\mathsf{RealUnaryStreamClassifier}(s, t)$ at this certified observation gives

$$\mathsf{RatHistoryClassifier}(s(\mathsf{append}(a, k)), t(\mathsf{append}(a, k))).$$

Since the offset was arbitrary under $\mathsf{UnaryOffsetLe}(k, w)$, these pointwise endpoint classifiers repack into $\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w)$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamWindowClassifier coverage`

Theorem 38.156 (Real stream window selected full shape readback package)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$*, an anchor index* n*, a radius* m*, a bounded offset* k *with* $k \leq m$*, and histories* $a, b, z_X, z_Y : \mathsf{Hist}$*, assume* $\mathsf{RealStreamWindowClassifier}(x, y, n, m)$*,* $\mathsf{hsame}(x(n + k), \mathsf{E1}(a))$*, and* $\mathsf{hsame}(y(n + k), \mathsf{E1}(b))$*. Then the selected endpoints at* $n + k$ *carry the following package:*

1. $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$*;*
2. $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$*;*
3. $\mathsf{PositiveUnaryDenominator}(x(n + k)) \wedge \mathsf{PositiveUnaryDenominator}(y(n + k))$*;*
4. $\mathsf{UnaryHistory}(x(n + k)) \wedge \mathsf{UnaryHistory}(y(n + k)) \wedge (\mathsf{hsame}(x(n + k), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y(n + k), \mathsf{e}) \to \mathsf{False})$*;*

5. $(\mathsf{hsame}(x(n+k), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y(n+k), \mathsf{E0}(z_Y)) \to \mathsf{False})$.

Proof. Unfold the finite window classifier at the selected offset. The bound $k \leq m$ turns the window hypothesis into $\mathsf{RatHistoryClassifier}(x(n+k), y(n+k))$.

Transport this rational classifier across the two displayed one-seal endpoint comparisons by Definition 37.54. The transported classifier is $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$, and Definition 37.49 reads back the two unary tails together with $\mathsf{hsame}(a, b)$.

Apply Definition 37.50 to the original endpoint classifier. This gives positive unary denominator witnesses for $x(n+k)$ and $y(n+k)$, and Definition 37.12 converts those witnesses into unary and nonempty endpoint rows.

For the left zero-extension test, transport $\mathsf{PositiveUnaryDenominator}(x(n+k))$ along the proposed comparison $\mathsf{hsame}(x(n+k), \mathsf{E0}(z_X))$ by Definition 37.6. The resulting positive denominator on $\mathsf{E0}(z_X)$ contradicts Definition 37.10.

For the right zero-extension test, repeat the same transport from $y(n+k)$ to $\mathsf{E0}(z_Y)$. The positive-denominator zero-head absurdity theorem gives the second contradiction, completing the listed package. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamWindowClassifier selected full shape readback package`

Lemma 38.157 (Real unary stream finite-window endpoint projection)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and histories* $a, w, k : \mathsf{Hist}$,

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w) \wedge \mathsf{UnaryOffsetLe}(k, w) \Longrightarrow \mathsf{RatHistoryClassifier}(s(\mathsf{append}(a, k)), t(\mathsf{append}($$

Proof. Unfold Definition 38.154. The window witness contains the universal endpoint row for every offset satisfying $\mathsf{UnaryOffsetLe}(\cdot, w)$.

Apply that row to the displayed offset witness $\mathsf{UnaryOffsetLe}(k, w)$. The result is precisely the RatUp endpoint classifier at $\mathsf{append}(a, k)$. □

Theorem 38.158 (Real unary stream window finite-probe coverage)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$*, a unary anchor* $a : \mathsf{Hist}$*, a bound* $w : \mathsf{Hist}$*, and a probe bundle* $\mathcal{P} : \mathsf{ProbeBundle}$*, suppose*

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w)$$

and suppose that every bundled certified unary observation lies below the window bound:

$$\forall n : \mathsf{Hist}, \mathsf{InBundle}(n, \mathcal{P}) \to \mathsf{UnaryHistory}(n) \to \mathsf{UnaryOffsetLe}(n, w).$$

Then the shifted observation maps export a StreamName finite probe window:

$$\mathsf{RatStreamNameFiniteWindowClassifier}(\lambda n.\, s(\mathsf{append}(a, n)), \lambda n.\, t(\mathsf{append}(a, n)), \mathcal{P}).$$

Proof. Unfold Definition 126.21. Fix a bundled certified unary observation n with $\mathsf{InBundle}(n, \mathcal{P})$ and $\mathsf{UnaryHistory}(n)$.

The admissibility hypothesis consumes exactly these two rows and produces the offset witness $\mathsf{UnaryOffsetLe}(n, w)$. Apply Definition 38.157 to the Real unary window classifier and this offset witness.

The projected endpoint classifier is

$$\mathsf{RatHistoryClassifier}(s(\mathsf{append}(a, n)), t(\mathsf{append}(a, n))).$$

This is the required StreamName finite-window row for the shifted observation maps at the chosen bundled unary observation. Since the bundled observation was arbitrary, the displayed rows repack into $\mathsf{RatStreamNameFiniteWindowClassifier}(\lambda n.\, s(\mathsf{append}(a, n)), \lambda n.\, t(\mathsf{append}(a, n)), \mathcal{P})$. □

Theorem 38.159 (Real unary window finite-probe determinacy)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$*, a unary anchor* $a : \mathsf{Hist}$*, a bound* $w : \mathsf{Hist}$*, and probe bundles* $\mathcal{P}, \mathcal{Q} : \mathsf{ProbeBundle}$*, suppose*

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w)$$

and suppose every bundled certified unary observation of $\mathcal{P}$ *lies below the window bound:*

$$\forall n : \mathsf{Hist}, \mathsf{InBundle}(n, \mathcal{P}) \to \mathsf{UnaryHistory}(n) \to \mathsf{UnaryOffsetLe}(n, w).$$

Suppose also that $\mathcal{P}$ *and* $\mathcal{Q}$ *have the same membership rows on certified unary histories:*

$$\forall n : \mathsf{Hist},\ \mathsf{UnaryHistory}(n) \to (\mathsf{InBundle}(n, \mathcal{P}) \iff \mathsf{InBundle}(n, \mathcal{Q})).$$

Then the shifted StreamName finite-window surface is independent of the chosen presentation:

$$\mathsf{RatStreamNameFiniteWindowClassifier}(\lambda n.\, s(\mathsf{append}(a, n)), \lambda n.\, t(\mathsf{append}(a, n)), \mathcal{P}) \iff \mathsf{RatStreamNameFiniteWindo}$$

Proof. Unfold Definition 126.21. For the forward direction, fix a bundled certified unary observation n of $\mathcal{Q}$. The membership-equivalence hypothesis sends its $\mathsf{InBundle}(n, \mathcal{Q})$ row to an $\mathsf{InBundle}(n, \mathcal{P})$ row.

The $\mathcal{P}$ boundedness hypothesis now gives $\mathsf{UnaryOffsetLe}(n, w)$. Apply Definition 38.157 to the shared Real unary window classifier and this bounded-offset witness. The result is the required point row

$$\mathsf{RatHistoryClassifier}(s(\mathsf{append}(a, n)), t(\mathsf{append}(a, n))).$$

For the reverse direction, fix a bundled certified unary observation n of $\mathcal{P}$. The same membership-equivalence row also identifies it as a bundled observation of $\mathcal{Q}$, so both presentations expose the same finite probe site.

The boundedness hypothesis for $\mathcal{P}$ supplies $\mathsf{UnaryOffsetLe}(n, w)$. Applying Definition 38.157 again to the shared Real unary window classifier gives the RatUp endpoint classifier at $\mathsf{append}(a, n)$, which is exactly the required $\mathsf{RatStreamNameFiniteWindowClassifier}$ row for $\mathcal{P}$. □

The ten-field fit is: traditional target finite observation-window bridge; BEDC source RealUp plus $\mathsf{StreamNameUp}$ plus RatUp plus $\mathsf{ProbeBundle}$; carrier the shifted observation maps $n \mapsto s(\mathsf{append}(a, n))$ and $n \mapsto t(\mathsf{append}(a, n))$; classifier $\mathsf{RatStreamNameFiniteWindowClassifier}$; stability inherited from the Real window endpoint row; ledger anchor, bound, bundle membership, and offset witness; core theorem Definition 38.158; exactness the bundled offsets are exactly consumed pointwise; standard bridge $\mathsf{RegSeqRat}$ finite-prefix consumption; status $\mathsf{ProofTarget}$.

The ten-field fit is: traditional target finite observation windows for RealUp streams; BEDC source $\mathsf{RealUnaryStreamClassifier}$ plus $\mathsf{RatHistoryClassifier}$ plus $\mathsf{UnaryHistory}$ plus Cont; carrier BHist observation maps; classifier $\mathsf{RealUnaryStreamWindowClassifier}$; stability by unary append closure and pointwise classifier evaluation; ledger anchor, bound, offset, and tail witness; core theorem Definition 38.155; exactness endpoint projection Definition 38.157; standard bridge finite rational observation windows; status $\mathsf{ProofTarget}$.

Theorem 38.160 (Real unary stream finite-window empty bound exactness)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and an anchor history* $a : \mathsf{Hist}$*, the empty finite-window bound is exactly the anchor row:*

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, \mathsf{e}) \iff \mathsf{UnaryHistory}(a) \wedge \mathsf{RatHistoryClassifier}(s(a), t(a)).$$

Proof. For the forward direction, the window classifier already stores the unary anchor row. The empty history is below the empty bound using the empty unary tail and the continuation identity $\mathsf{Cont}(\mathsf{e}, \mathsf{e}, \mathsf{e})$. Projecting the endpoint row at this offset gives $\mathsf{RatHistoryClassifier}(s(\mathsf{append}(a, \mathsf{e})), t(\mathsf{append}(a, \mathsf{e})))$, which is the displayed anchor classifier.

For the reverse direction, assume the anchor unary row and the anchor classifier. The bound field is certified by unary emptiness. For any offset k below e, the continuation witness into the empty result forces $k = \mathsf{e}$. The endpoint demanded by the window classifier is therefore the stored anchor classifier. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamWindowClassifier empty bound iff`

Lemma 38.161 (Unary offset bound transitivity)**.** *For histories $k, w, u : \mathsf{Hist}$,*

$$\mathsf{UnaryOffsetLe}(k, w) \wedge \mathsf{UnaryOffsetLe}(w, u) \Longrightarrow \mathsf{UnaryOffsetLe}(k, u).$$

Proof. Unfold Definition 38.151 in the first offset row. It gives $\mathsf{UnaryHistory}(k)$ and a unary tail $\tau : \mathsf{Hist}$ with $\mathsf{Cont}(k, \tau, w)$.

Unfold the second offset row. It gives a unary tail $\sigma : \mathsf{Hist}$ with $\mathsf{Cont}(w, \sigma, u)$, and it also certifies the intermediate bound w as a unary history.

Apply unary append closure to the two tails to obtain $\mathsf{UnaryHistory}(\mathsf{append}(\tau, \sigma))$. Continuation associativity composes $\mathsf{Cont}(k, \tau, w)$ with $\mathsf{Cont}(w, \sigma, u)$, and determinacy identifies the composed endpoint with u.

Thus k has the unary tail $\mathsf{append}(\tau, \sigma)$ whose continuation reaches u, so Definition 38.151 repacks this data as $\mathsf{UnaryOffsetLe}(k, u)$. □

Lemma 38.162 (Unary offset bound reflexivity)**.** *For every history $w : \mathsf{Hist}$,*

$$\mathsf{UnaryHistory}(w) \Longrightarrow \mathsf{UnaryOffsetLe}(w, w).$$

Proof. Unfold Definition 38.151. The displayed hypothesis supplies the required unary witness for the left endpoint w.

Choose the tail e. Unary emptiness gives $\mathsf{UnaryHistory}(\mathsf{e})$, and the right-unit continuation law witnesses $\mathsf{Cont}(w, \mathsf{e}, w)$. These three pieces repack as $\mathsf{UnaryOffsetLe}(w, w)$. □

Theorem 38.163 (Real unary stream finite-window endpoint at bound)**.** *For observation maps $s, t : \mathsf{Hist} \to \mathsf{Hist}$ and histories $a, w : \mathsf{Hist}$,*

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w) \Longrightarrow \mathsf{RatHistoryClassifier}(s(\mathsf{append}(a, w)), t(\mathsf{append}(a, w))).$$

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamWindowClassifier endpoint at bound`

Proof. Unfold Definition 38.154 only far enough to read the stored bound field $\mathsf{UnaryHistory}(w)$.

Apply Definition 38.162 to this bound field. This gives the explicit witness $\mathsf{UnaryOffsetLe}(w, w)$ required for endpoint projection.

Now apply Definition 38.157 with $k = w$. The projected endpoint is exactly the boundary observation $\mathsf{append}(a, w)$. □

The ten-field fit is: traditional target finite observation boundary readback; BEDC source RealUnaryStreamWindowClassifier plus UnaryOffsetLe; carrier BHist observation maps; classifier boundary endpoint RatUp classifier; stability inherited from unary append closure and endpoint projection; ledger the boundary offset w and the empty continuation tail; core theorem Definition 38.163; exactness the bound is itself a certified finite-window offset; standard bridge RegSeqRat finite boundary observation; status ProofTarget.

Theorem 38.164 (Real unary stream finite-window restriction)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and histories* $a, w, u : \mathsf{Hist}$*,*

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, u) \wedge \mathsf{UnaryOffsetLe}(w, u) \Longrightarrow \mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w).$$

Proof. Unfold Definition 38.154 in the source window. Its anchor field gives $\mathsf{UnaryHistory}(a)$, and the offset witness $\mathsf{UnaryOffsetLe}(w, u)$ projects $\mathsf{UnaryHistory}(w)$ by Definition 38.151.

Fix any offset k with $\mathsf{UnaryOffsetLe}(k, w)$. Apply Definition 38.161 to $\mathsf{UnaryOffsetLe}(k, w)$ and $\mathsf{UnaryOffsetLe}(w, u)$, obtaining $\mathsf{UnaryOffsetLe}(k, u)$.

The universal endpoint row of the source window at bound u then yields

$$\mathsf{RatHistoryClassifier}(s(\mathsf{append}(a, k)), t(\mathsf{append}(a, k))).$$

Since the anchor, restricted bound, and every endpoint row have been supplied, Definition 38.154 repacks them as $\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w)$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamWindowClassifier restriction with offset witness`

The ten-field fit is: traditional target shrinkable finite observation windows for RealUp streams; BEDC source RealUnaryStreamWindowClassifier plus UnaryOffsetLe plus Cont; carrier unary anchor and certified unary bounds; classifier the restricted finite-window predicate; stability by offset-bound transitivity and endpoint reuse at the larger bound; ledger anchor, source bound, target bound, offset, and composed tail witnesses; core theorem Definition 38.164; exactness every endpoint below the restricted bound is an endpoint below the source bound; standard bridge RegSeqRat finite observation bounds; status ProofTarget.

Theorem 38.165 (Real unary stream window selected tail-class exactness from window)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and histories* $a, w, k : \mathsf{Hist}$*, assume the finite window classifier and a selected certified offset:*

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w) \wedge \mathsf{UnaryOffsetLe}(k, w).$$

Then the selected tail class is exact:

$$\begin{aligned}
&\exists u, v : \mathsf{Hist},\ \mathsf{hsame}(s(\mathsf{append}(a, k)), \mathsf{E1}(u)) \wedge \mathsf{hsame}(t(\mathsf{append}(a, k)), \mathsf{E1}(v)) \wedge \\
&\mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsame}(u, v) \wedge \\
&\forall u', v' : \mathsf{Hist},\ (\mathsf{hsame}(s(\mathsf{append}(a, k)), \mathsf{E1}(u')) \wedge \mathsf{hsame}(t(\mathsf{append}(a, k)), \mathsf{E1}(v'))) \Longleftrightarrow \\
&\qquad (\mathsf{UnaryHistory}(u') \wedge \mathsf{UnaryHistory}(v') \wedge \mathsf{hsame}(u, u') \wedge \mathsf{hsame}(v, v')).
\end{aligned}$$

Proof. Project the selected RatUp classifier directly from $\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w)$ at the offset k. Positive denominator readback supplies displayed one-headed representatives for both selected endpoints. Transport the selected rational classifier across these two endpoint displays, then apply the e-one tail classifier exactness theorem to obtain unary tails and their hsame classifier.

For any displayed pair u', v', transport the same selected classifier across the displayed endpoint rows and read back the e-one tails. Comparing the chosen endpoint displays with the arbitrary ones by hsame transitivity and e-one-tail inversion gives $\mathsf{hsame}(u, u')$ and $\mathsf{hsame}(v, v')$. Conversely, tail comparisons $\mathsf{hsame}(u, u')$ and $\mathsf{hsame}(v, v')$ lift by e-one congruence and compose with the chosen endpoint displays, giving the displayed pair. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamWindowClassifier selected tail class exactness from window`

Definition 38.166 (Real stream finite window classifier)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, an anchor index n, and a zero-based window radius m, the finite window classifier is the bounded pointwise rational-history classifier*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m) \iff \forall k,\ k \le m \implies \mathsf{RatHistoryClassifier}(x(n+k), y(n+k)).$$

Lean4 (definition) `BEDC.Derived.RealUp.RealStreamWindowClassifier`

Theorem 38.167 (Real stream window classifier hsame transport)**.** *For rational-observation streams $x, y, x', y' : \mathbb{N} \to \mathsf{Hist}$, an anchor index n, and a radius m, assume* $\mathsf{RealStreamWindowClassifier}(x, y, n, m)$*. If every bounded offset $k \le m$ carries both endpoint rows $x(n+k)\mathsf{hsame}x'(n+k)$ and $y(n+k)\mathsf{hsame}y'(n+k)$, then* $\mathsf{RealStreamWindowClassifier}(x', y', n, m)$*.*

Proof. Unfold the finite window classifier and fix an arbitrary offset $k \le m$. The source window hypothesis supplies the endpoint classifier $\mathsf{RatHistoryClassifier}(x(n+k), y(n+k))$.

The offset transport hypothesis gives the two rows $x(n+k)\mathsf{hsame}x'(n+k)$ and $y(n+k)\mathsf{hsame}y'(n+k)$ at the same bounded observation. Apply Definition 37.54 to the source rational classifier and these endpoint rows.

The result is $\mathsf{RatHistoryClassifier}(x'(n+k), y'(n+k))$. Since the offset was arbitrary under the bound $k \le m$, these transported endpoint classifiers repack into $\mathsf{RealStreamWindowClassifier}(x', y', n, m)$. □

The ten-field fit is: traditional target finite observation-window stability for RealUp names; BEDC source RealUp windows plus RatUp endpoint classifier transport; carrier bounded rational-observation windows; classifier RealStreamWindowClassifier; stability endpoint hsame transport; ledger anchor, radius, offset, and two endpoint transports; core theorem Definition 38.167; exactness preservation of the bounded classifier; standard bridge finite prefix stability for regular rational observation names; status ProofTarget.

Theorem 38.168 (Real stream prefix-window exactness at zero)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and every finite offset m,*

$$\mathsf{RealStreamPrefixClassifier}(x, y, m) \iff \mathsf{RealStreamWindowClassifier}(x, y, 0, m).$$

Proof. Induct on m. At $m = 0$, the recursive prefix classifier is exactly the rational-history classifier at observation 0, and the window condition has only the offset $k = 0$.

For the successor step, use Definition 38.113 to split a prefix through $m + 1$ into the prefix through m and the rational-history classifier at the new endpoint. The induction hypothesis converts the shorter prefix into the window condition through offset m.

Given any $k \le m + 1$, split constructively between $k \le m$ and $k = m + 1$. The first case is handled by the shorter window; the endpoint case is exactly the successor rational-history classifier.

Conversely, assume the window condition through $m + 1$. Its restriction to offsets $k \le m$ gives the zero-based window through m, hence by induction the prefix through m. Taking $k = m+1$ gives the endpoint classifier, and the reverse direction of successor inversion pairs these two witnesses into the prefix through $m + 1$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier finite window zero exactness`

Theorem 38.169 (Real stream classifier finite-window coverage)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and indices n, m, every pointwise stream classifier covers the finite observation window anchored at n with radius m:*

$$\mathsf{RealStreamClassifier}(x, y) \implies \mathsf{RealStreamWindowClassifier}(x, y, n, m).$$

Proof. Assume $\mathsf{RealStreamClassifier}(x, y)$ and fix an offset $k \leq m$. The stream classifier is pointwise, so evaluating it at the observation index $n + k$ gives $\mathsf{RatHistoryClassifier}(x(n + k), y(n + k))$.

Since the chosen offset was arbitrary under the window bound, these endpoint classifiers assemble exactly into $\mathsf{RealStreamWindowClassifier}(x, y, n, m)$. □

Theorem 38.170 (Real stream classifier zero-window exactness)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$,

$$\mathsf{RealStreamClassifier}(x, y) \iff \forall n,\ \mathsf{RealStreamWindowClassifier}(x, y, n, 0).$$

Proof. For the forward direction, assume $\mathsf{RealStreamClassifier}(x, y)$. For each anchor n, apply Definition 38.169 with radius 0. This gives $\mathsf{RealStreamWindowClassifier}(x, y, n, 0)$ for every anchor.

For the reverse direction, assume every zero-radius window is classified and fix an observation index n. Unfold the window at anchor n and radius 0. Taking offset $k = 0$ uses $0 \leq 0$ and the identity $n + 0 = n$, so the window row returns $\mathsf{RatHistoryClassifier}(x(n), y(n))$.

Since n was arbitrary, these rational-history rows repack as the pointwise stream classifier $\mathsf{RealStreamClassifier}(x, y)$. □

The ten-field fit is: traditional target pointwise equality of countable real names; BEDC source RealUp stream classifier plus RatUp endpoint classifier; carrier rational-observation streams; classifier all zero-radius windows; stability inherited from finite-window stability; ledger anchor index and zero offset; core theorem this exactness; exactness all pointwise observations iff all zero windows; standard bridge finite observation equality of regular rational names; status ProofTarget.

Theorem 38.171 (Real stream finite-window stability package)**.** *For rational-observation streams* $x, x', y, y', z : \mathbb{N} \to \mathsf{Hist}$ *and indices* n, m*, the finite window classifier supplies the following stability rows:*

1. *if* $\forall k,\ k \leq m \Longrightarrow \mathsf{RatHistoryCarrier}(x(n + k))$*, then* $\mathsf{RealStreamWindowClassifier}(x, x, n, m)$*;*
2. *if* $\mathsf{RealStreamWindowClassifier}(x, y, n, m)$*, then* $\mathsf{RealStreamWindowClassifier}(y, x, n, m)$*;*
3. *if* $\mathsf{RealStreamWindowClassifier}(x, y, n, m)$ *and* $\mathsf{RealStreamWindowClassifier}(y, z, n, m)$*, then* RealStreamWindowCla
4. *if* $\mathsf{RealStreamWindowClassifier}(x, y, n, m)$ *and, for every* $k \leq m$*, both* $\mathsf{hsame}(x(n + k), x'(n + k))$ *and* $\mathsf{hsame}(y(n + k), y'(n + k))$ *hold, then* $\mathsf{RealStreamWindowClassifier}(x', y', n, m)$*.*

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamWindowClassifier stability package`

Proof. Unfold the finite window classifier in each row and fix an offset $k \leq m$.

1. The reflexivity row reads the carrier hypothesis at this offset. Pair the carrier with itself, and use hsame reflexivity to build $\mathsf{RatHistoryClassifier}(x(n + k), x(n + k))$.
2. The symmetry row evaluates the source window at the offset and applies Definition 37.55 to reverse the rational-history classifier.
3. The transitivity row evaluates the two source windows at the same offset and applies Definition 37.53 to compose the two rational-history classifiers through the shared middle stream y.
4. The transport row evaluates the source window at the offset and reads the two pointwise hsame hypotheses at the same offset. Apply Definition 37.54 to transport the rational-history classifier to the endpoints $x'(n + k)$ and $y'(n + k)$.

Since the offset was arbitrary under the bound, each row repacks into the corresponding RealStreamWindowClassifier statement. □

The ten-field fit is: traditional target finite observation-window stability; BEDC source RealUp rational-observation streams plus RatUp classifier; carrier the bounded window predicate; classifier RealStreamWindowClassifier; stability the four displayed rows; ledger anchor n, radius m, and offset witnesses; core theorem this block; exactness bounded pointwise rational classification; standard bridge finite rational observation-window agreement; status ProofTarget.

Theorem 38.172 (Real stream finite-window subwindow extraction)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and indices n, j, r, m, if*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m)$$

and $j + r \leq m$, then

$$\mathsf{RealStreamWindowClassifier}(x, y, n + j, r).$$

Proof. Unfold Definition 38.166 in the source window and fix a shifted offset $k \leq r$. From $k \leq r$ and $j + r \leq m$, bounded-offset monotonicity gives $j + k \leq j + r \leq m$.

Apply the source window at offset $j + k$. This yields the endpoint classifier

$$\mathsf{RatHistoryClassifier}(x(n + (j + k)), y(n + (j + k))).$$

The arithmetic identity $(n+j)+k = n+(j+k)$ identifies this endpoint with the corresponding endpoint of the shifted window. Since the chosen k was arbitrary under the radius r, these endpoint classifiers repack as $\mathsf{RealStreamWindowClassifier}(x, y, n + j, r)$. □

Theorem 38.173 (Real stream finite-window selected zero-subwindow package)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and indices n, j, m, if*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m)$$

and $j \leq m$, then both

$$\mathsf{RealStreamWindowClassifier}(x, y, n + j, 0)$$

and

$$\mathsf{RatHistoryClassifier}(x(n + j), y(n + j))$$

hold.

Proof. Apply Definition 38.172 to the source window with shift j and radius 0. The displayed bound $j \leq m$ is exactly the required inequality $j + 0 \leq m$, so this gives the zero-radius shifted window

$$\mathsf{RealStreamWindowClassifier}(x, y, n + j, 0).$$

It remains to read the selected endpoint. Unfold Definition 38.166 for the zero-radius window and take offset $0 \leq 0$. The endpoint index is $(n + j) + 0 = n + j$, so the window row returns $\mathsf{RatHistoryClassifier}(x(n+j), y(n+j))$, as in the zero-window exactness calculation of Definition 38.170. □

The ten-field fit is: traditional target selected finite RealUp observation normalization; BEDC source RealStreamWindowClassifier plus RatHistoryClassifier; carrier rational-observation streams; classifier selected zero-radius finite-window predicate; stability by subwindow extraction at radius 0 and endpoint projection; ledger finite anchor, selected index, source radius, zero radius, and bound witness $j \leq m$; core theorem Definition 38.173; exactness the selected point is read as the unique zero-radius endpoint; standard bridge downstream RegSeqRat selected finite observation normalization; status ProofTarget.

The ten-field fit is: traditional target shifted finite RealUp observation windows; BEDC source RealStreamWindowClassifier plus RatHistoryClassifier; carrier rational-observation streams; classifier shifted finite-window predicate; stability by bounded-offset monotonicity and endpoint reuse; ledger original anchor, shift, radius, source bound, and offset witness; core theorem Definition 38.172; exactness every shifted endpoint is already a source-window endpoint; standard bridge RegSeqRat tail/window stability; status ProofTarget.

Theorem 38.174 (Real stream finite-window nested subwindow extraction)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and indices n, j, q, r, s, m, if*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m),$$

$j + r \leq m$, and $q + s \leq r$, then

$$\mathsf{RealStreamWindowClassifier}(x, y, (n + j) + q, s).$$

Proof. Apply Definition 38.172 to the source window with shift j and radius r. The bound $j+r \leq m$ produces the first subwindow

$$\mathsf{RealStreamWindowClassifier}(x, y, n + j, r).$$

Apply the same subwindow theorem again to this derived window with shift q and radius s. The bound $q + s \leq r$ gives

$$\mathsf{RealStreamWindowClassifier}(x, y, (n + j) + q, s).$$

Every endpoint of the nested window has the form $(n + j) + (q + k)$ with $k \leq s$. The second bound places $q + k$ inside the first subwindow, and the first bound places $j + (q + k)$ inside the original window. Thus the displayed classifier is exactly the repeated finite-window extraction. □

Theorem 38.175 (Real stream nested finite-window endpoint package)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, indices n, j, q, r, s, m, and histories $a, b, z_X, z_Y : \mathsf{Hist}$, assume*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m),$$

$j + r \leq m$, $q + s \leq r$, $\mathsf{hsame}(x((n + j) + q), \mathsf{E1}(a))$, and $\mathsf{hsame}(y((n + j) + q), \mathsf{E1}(b))$. Then the nested endpoint carries the following package:

1. $\mathsf{RealStreamWindowClassifier}(x, y, (n + j) + q, s)$;
2. $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$;
3. $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$;
4. $\mathsf{PositiveUnaryDenominator}(x((n + j) + q)) \wedge \mathsf{PositiveUnaryDenominator}(y((n + j) + q))$;

5. $\mathsf{UnaryHistory}(x((n+j)+q)) \wedge \mathsf{UnaryHistory}(y((n+j)+q)) \wedge (\mathsf{hsame}(x((n+j)+q), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y((n+j)+q), \mathsf{e}) \to \mathsf{False})$;
6. $(\mathsf{hsame}(x((n+j)+q), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y((n+j)+q), \mathsf{E0}(z_Y)) \to \mathsf{False})$.

Proof. First apply Definition 38.174 to the source window with the displayed bounds. This produces the nested finite-window row $\mathsf{RealStreamWindowClassifier}(x, y, (n+j)+q, s)$.

Next read the selected endpoint of that nested window at offset 0. The bound $0 \leq s$ lets Definition 38.156 apply to the nested window, with anchor $(n+j)+q$ and displayed one-extension rows for $x((n+j)+q)$ and $y((n+j)+q)$.

The selected full-shape readback package supplies the endpoint $\mathsf{Rat}^{\uparrow}$ classifier, the positive unary denominator rows, the unary endpoint rows, the two nonempty exclusions, the two zero-headed exclusions for z_X and z_Y, and the tail readback $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$. Repack these rows together with the nested window obtained in the first step. □

Theorem 38.176 (Real stream affine subwindow collapse)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, indices n, j, q, r, s, m, and histories $a, b, z_X, z_Y : \mathsf{Hist}$, assume*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m),$$

$j+r \leq m$, $q+s \leq r$, $\mathsf{hsame}(x((n+j)+q), \mathsf{E1}(a))$, and $\mathsf{hsame}(y((n+j)+q), \mathsf{E1}(b))$. Then the nested package obtained by first restricting the source window to $(n+j, r)$ and then to $((n+j)+q, s)$ is the same public finite-window classifier and endpoint read as the one-step subwindow at offset $j+q$ and radius s. In particular, it exposes exactly the same rows:

1. $\mathsf{RealStreamWindowClassifier}(x, y, (n+j)+q, s)$, *equivalently* $\mathsf{RealStreamWindowClassifier}(x, y, n+(j+q), s)$ *under finite-index arithmetic;*
2. $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$;
3. $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$;
4. $\mathsf{PositiveUnaryDenominator}(x((n+j)+q)) \wedge \mathsf{PositiveUnaryDenominator}(y((n+j)+q))$;
5. $\mathsf{UnaryHistory}(x((n+j)+q)) \wedge \mathsf{UnaryHistory}(y((n+j)+q)) \wedge (\mathsf{hsame}(x((n+j)+q), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y((n+j)+q), \mathsf{e}) \to \mathsf{False})$;
6. $(\mathsf{hsame}(x((n+j)+q), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y((n+j)+q), \mathsf{E0}(z_Y)) \to \mathsf{False})$.

Moreover, for every $k \leq s$, the nested endpoint family indexed by $(n+j)+(q+k)$ is the same finite observation family as the affine subwindow family indexed by $n+((j+q)+k)$.

Proof. Apply Definition 38.174 to the source window and the displayed bounds. This gives the nested classifier at anchor $(n+j)+q$ and radius s.

Apply Definition 38.172 directly to the source window with shift $j+q$ and radius s. The bounds $j+r \leq m$ and $q+s \leq r$ compose to $j+q+s \leq m$, so the direct affine subwindow is also available at anchor $n+(j+q)$ and radius s.

The finite arithmetic identities $(n+j)+q = n+(j+q)$ and $(n+j)+(q+k) = n+((j+q)+k)$ identify each nested endpoint with the corresponding one-step affine endpoint. Thus the two classifier rows read the same bounded family of $\mathsf{Rat}^{\uparrow}$ endpoint classifiers.

Finally apply Definition 38.175 to the nested anchor. Its endpoint package supplies the $\mathsf{RatHistoryClassifier}$ row, the tail $\mathsf{UnaryHistory}$ and hsame row, the positive-denominator rows, the nonempty exclusions, and the zero-headed exclusions. Transporting those rows along the displayed endpoint equalities repacks exactly the one-step affine subwindow package. □

The ten-field fit is: traditional target nested finite RealUp observation windows; BEDC source RealStreamWindowClassifier over rational-observation streams; carrier rational-observation streams; classifier the finite-window predicate; stability by repeated subwindow extraction and bounded-offset monotonicity; ledger original anchor, first shift, second shift, outer radius, inner radius, and offset witnesses; core theorem Definition 38.174; exactness every nested endpoint is already in the original window; standard bridge RegSeqRat nested tail/window stability; status ProofTarget.

Theorem 38.177 (Constant rational real finite-window exactness)**.** *For histories* d, e, a, w : Hist *with* UnaryHistory(a) *and* UnaryHistory(w)*,*

$$\mathsf{RatHistoryClassifier}(d, e) \iff \mathsf{RealUnaryStreamWindowClassifier}(\mathsf{RatConstStream}_d, \mathsf{RatConstStream}_e, a, w).$$

Proof. For the forward direction, assume RatHistoryClassifier(d, e). The constant-stream witness Definition 126.48 supplies RatStreamNameClassifier$(\mathsf{RatConstStream}_d, \mathsf{RatConstStream}_e)$.

Read this StreamNameUp classifier as the corresponding RealUp unary-observation stream classifier by Definition 38.27. With the displayed unary anchor and bound witnesses, apply Definition 38.155 to obtain the finite-window classifier.

For the reverse direction, assume RealUnaryStreamWindowClassifier$(\mathsf{RatConstStream}_d, \mathsf{RatConstStream}_e, a, w)$. The empty history is a certified unary offset below w: use the unary witness for w, the unary witness for e, and the continuation row Cont(e, w, w).

Apply Definition 38.157 at the offset e. This yields

$$\mathsf{RatHistoryClassifier}(\mathsf{RatConstStream}_d(\mathsf{append}(a, \mathsf{e})), \mathsf{RatConstStream}_e(\mathsf{append}(a, \mathsf{e}))).$$

Unfold RatConstStream. Both constant streams ignore the observation history append(a, e), so the projected endpoint classifier is exactly RatHistoryClassifier(d, e). □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamWindowClassifier constant rational exactness iff`

The ten-field fit is: traditional target constant rational observations inside RealUp finite windows; BEDC source RatUp plus StreamNameUp plus RealUp; carrier constant rational observation streams; classifier the displayed equivalence; stability inherited from constant stream classification and finite-window endpoint projection; ledger hidden rational seed, anchor, bound, and empty offset; core theorem Definition 38.177; exactness the displayed equivalence; standard bridge constant rational finite observation windows; status ProofTarget.

Theorem 38.178 (Real stream shifted prefix-window exactness)**.** *For rational-observation streams* $x, y : \mathbb{N} \to$ Hist *and indices* n, m*, define shifted streams* $x_n, y_n : \mathbb{N} \to$ Hist *by* $x_n(k) = x(n + k)$ *and* $y_n(k) = y(n + k)$*. Then*

$$\mathsf{RealStreamPrefixClassifier}(x_n, y_n, m) \iff \mathsf{RealStreamWindowClassifier}(x, y, n, m).$$

Proof. Apply Definition 38.168 to the shifted streams x_n and y_n. This gives the equivalence between the recursive prefix classifier on the shifted streams and the zero-anchored window classifier RealStreamWindowClassifier$(x_n, y_n, 0, m)$.

Unfold the zero-anchored window classifier. Its endpoint rows are $x_n(0 + k)$ and $y_n(0 + k)$ for bounded offsets $k \leq m$.

By the definitions of the shifted streams and the identity $0 + k = k$, these rows are exactly $x(n + k)$ and $y(n + k)$. Repacking the same bounded endpoint classifiers is precisely RealStreamWindowClassifier(x, y, n, m). □

Theorem 38.179 (Real stream shifted prefix-window seal pullback)**.** *Let $x, y : \mathbb{N} \to$ Hist be rational-observation streams, let $x_n(k) = x(n+k)$ and $y_n(k) = y(n+k)$, and fix a finite radius m. Suppose two downstream* Real$^{\uparrow}$ *finite-window seal uses are restricted to the same shifted window $(x_n, y_n, 0, m)$. If their restricted surfaces agree on the* RatStreamNameFiniteWindowClassifier *rows, the* RegSeqRat *spine rows, the* DyadicRatCoreObservationRow *endpoint observations, and the displayed* hsame/Cont/Pkg/RealLedgerPolicy *rows, then the shifted prefix packet over (x_n, y_n, m) and the unshifted window packet over (x, y, n, m) expose the same finite* BHist *source surface for both seal uses.*

The pullback is only a finite source-surface statement. It exports no quotient data, completion data, metric-completeness row, arithmetic or order closure, Classical representative, or standard bridge datum.

Proof. Apply Definition 38.178. It identifies the shifted prefix classifier over (x_n, y_n, m) with the unshifted finite window classifier over (x, y, n, m), so both presentations name the same bounded endpoint rows.

Next apply Definition 38.288 to the two downstream seal uses over the shifted window. The hypotheses give the required matching RatStreamNameFiniteWindowClassifier rows, RegSeqRat spine rows, DyadicRatCore endpoints, and displayed hsame/Cont/Pkg provenance over that finite packet.

Finally apply Definition 38.355. The shared finite RealLedgerPolicy row identifies the induced Real$^{\uparrow}$ readback packet with the same finite BHist source surface. The preceding exactness step transports this packet back to the unshifted window over (x, y, n, m), and the negative boundary is inherited from the two pullback theorems. □

Theorem 38.180 (Real stream shifted prefix-window classifier composition)**.** *Let $x, y : \mathbb{N} \to$ Hist be rational-observation streams, let $x_n(k) = x(n+k)$ and $y_n(k) = y(n+k)$, and fix a finite radius m. Suppose the shift certificate from (x, y, n, m) to $(x_n, y_n, 0, m)$ carries* RealStreamPrefixClassifier(x_n, y_n, m) *to* RealStreamWindowClassifier(x, y, n, m)*. Suppose also that the shifted window is passed to a downstream finite-window handoff whose displayed rows are the* RatStreamNameFiniteWindowClassifier *row, the* RegSeqRat *spine, the endpoint* DyadicRatCoreObservationRow *witnesses, and the shared* hsame/Cont/Pkg/RealLedgerPolicy *ledger. Then the* RealStreamWindowClassifier *row consumed at (x, y, n, m) is exactly the finite* BHist *classifier row obtained by first reading the shifted prefix classifier over (x_n, y_n, m) and then passing through the* StreamName$^{\uparrow}$-RegSeqRat *finite-window handoff.*

This is only a finite classifier-composition law. It does not introduce a quotient carrier, a completion carrier, host real equality, metric completeness, arithmetic or order closure, Classical representatives, or bridge status.

Proof. First apply Definition 38.178. It identifies the shifted prefix classifier over (x_n, y_n, m) with the unshifted finite-window classifier over (x, y, n, m), so the downstream consumer and the original window read the same bounded endpoint rows.

Next apply Definition 38.179. The hypotheses provide the matching RatStreamNameFiniteWindowClassifier rows, RegSeqRat spine rows, DyadicRatCore endpoints, and displayed hsame/Cont/Pkg/RealLedgerPolicy ledger on the shifted window. The pullback identifies the shifted prefix packet and the unshifted window packet as the same finite BHist source surface.

Finally apply Definition 38.344 together with Definition 38.355. The correspondence factors the finite Real$^{\uparrow}$ window through the public StreamName$^{\uparrow}$ finite-window interface and the RegSeqRat dyadic source rows; the pullback says that these rows repack as the same finite classifier packet. Thus the row consumed at (x, y, n, m) is precisely the row obtained by the shifted-prefix route followed by the StreamName-RegSeqRat handoff, with the negative boundary inherited from the cited finite-window theorems. □

The ten-field fit is: traditional target shifted finite RealUp observation windows; BEDC source RealUp prefix/window classifiers plus RatUp endpoints; carrier rational-observation streams; classifier the displayed equivalence; stability zero-anchor exactness together with the index shift; ledger anchor n, radius m, and offset k; core theorem Definition 38.178; exactness arbitrary-anchor window iff shifted recursive prefix; standard bridge finite RegSeqRat observation windows; status ProofTarget.

Theorem 38.181 (Real unary StreamNameUp finite-window endpoint shape package)**.** *For observation maps* $s, t, s', t' : \mathsf{Hist} \to \mathsf{Hist}$*, histories* $a, w, k, u, v, z_s, z_t : \mathsf{Hist}$*, assume*

$$\mathsf{RatStreamNameClassifier}(s, t),$$

$$\mathsf{UnaryHistory}(a), \quad \mathsf{UnaryHistory}(w), \quad \mathsf{UnaryOffsetLe}(k, w),$$

the pointwise transport rows

$$\forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(s(n), s'(n)), \quad \forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(t(n), t'(n)),$$

and the displayed finite-window endpoints

$$\mathsf{hsame}(s'(\mathsf{append}(a, k)), \mathsf{E1}(u)), \quad \mathsf{hsame}(t'(\mathsf{append}(a, k)), \mathsf{E1}(v)).$$

Then the selected transported endpoints carry the bounded RealUp readback package:

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(s'(\mathsf{append}(a, k)), t'(\mathsf{append}(a, k)))\wedge\\
&\mathsf{PositiveUnaryDenominator}(s'(\mathsf{append}(a, k))) \wedge \mathsf{PositiveUnaryDenominator}(t'(\mathsf{append}(a, k)))\wedge\\
&\mathsf{UnaryHistory}(s'(\mathsf{append}(a, k))) \wedge \mathsf{UnaryHistory}(t'(\mathsf{append}(a, k)))\wedge\\
&(\mathsf{hsame}(s'(\mathsf{append}(a, k)), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(t'(\mathsf{append}(a, k)), \mathsf{e}) \to \mathsf{False})\wedge\\
&(\mathsf{hsame}(s'(\mathsf{append}(a, k)), \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge (\mathsf{hsame}(t'(\mathsf{append}(a, k)), \mathsf{E0}(z_t)) \to \mathsf{False})\wedge\\
&\mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsame}(u, v).
\end{aligned}$$

Proof. First convert the StreamNameUp classifier into the RealUp unary stream classifier by the reverse direction of Definition 38.551. The carrier rows for s and t are the two fields projected from $\mathsf{RatStreamNameClassifier}(s, t)$, so the classifier row becomes $\mathsf{RealUnaryStreamClassifier}(s, t)$.

Apply Definition 38.553 to the projected carrier rows, the same StreamNameUp classifier, the anchor a, and the bound w. This gives $\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w)$. Project the selected offset with Definition 38.157, using $\mathsf{UnaryOffsetLe}(k, w)$, to obtain

$$\mathsf{RatHistoryClassifier}(s(\mathsf{append}(a, k)), t(\mathsf{append}(a, k))).$$

Unfolding the offset bound supplies $\mathsf{UnaryHistory}(k)$, and unary append closure with $\mathsf{UnaryHistory}(a)$ gives $\mathsf{UnaryHistory}(\mathsf{append}(a, k))$. Evaluate the two pointwise transport rows at this appended observation. Transport the projected RatUp classifier along those two hsame rows by Definition 37.54; the result is

$$\mathsf{RatHistoryClassifier}(s'(\mathsf{append}(a, k)), t'(\mathsf{append}(a, k))).$$

Apply Definition 37.50 to the transported classifier. Then apply Definition 37.12 separately to the two positive-denominator rows. These projections give the positive denominator witnesses, the unary endpoint rows, and the two exclusions against e.

For a displayed zero head on the left endpoint, transport the left positive denominator along $\mathsf{hsame}(s'(\mathsf{append}(a, k)), \mathsf{E0}(z_s))$ by Definition 37.6. This contradicts Definition 37.10. The right endpoint uses the same argument with $t'(\mathsf{append}(a, k))$ and z_t.

Finally, transport the selected RatUp classifier along the two displayed E1 endpoint comparisons and apply Definition 37.49. This reads back $\mathsf{UnaryHistory}(u)$, $\mathsf{UnaryHistory}(v)$, and $\mathsf{hsame}(u, v)$, and the collected rows are exactly the stated package. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamWindowClassifier streamName transported endpoint shape package`

The ten-field fit is: traditional target finite RealUp observation readback; BEDC source StreamNameUp plus RealUp finite windows plus RatUp endpoint classifier; carrier observation maps over BHist; classifier RealUnaryStreamWindowClassifier; stability by hsame transport and RatUp classifier laws; ledger anchor, bound, offset, and transported endpoints; core theorem Definition 38.181; exactness selected endpoint package; standard bridge finite rational observation windows; status ProofTarget.

Theorem 38.182 (Real stream finite-window adjacent concatenation)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$ *and indices* n, m, r*, if*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m)$$

and

$$\mathsf{RealStreamWindowClassifier}(x, y, n + (m + 1), r),$$

then

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m + 1 + r).$$

Proof. Unfold Definition 38.166 in both source windows and fix an arbitrary offset $k \le m + 1 + r$. The goal is the rational-history classifier at the joined endpoint $n + k$.

Split constructively between the case $k \le m$ and the complementary case in which $k = m+1+j$ for some $j \le r$. In the first case, apply the left source window directly at offset k. This yields

$$\mathsf{RatHistoryClassifier}(x(n + k), y(n + k)).$$

In the second case, apply the right source window at offset j. Its endpoint is

$$\mathsf{RatHistoryClassifier}(x((n + (m + 1)) + j), y((n + (m + 1)) + j)).$$

The arithmetic identity $(n + (m + 1)) + j = n + (m + 1 + j) = n + k$ identifies this endpoint with the selected joined endpoint.

Since every offset $k \le m + 1 + r$ is covered by exactly one of these bounded cases, the collected endpoint classifiers repack as $\mathsf{RealStreamWindowClassifier}(x, y, n, m + 1 + r)$. □

Theorem 38.183 (Real unary stream finite-window adjacent concatenation)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and unary anchor histories* $a, w, r : \mathsf{Hist}$*, assume*

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w)$$

and

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, \mathsf{append}(a, \mathsf{BHist.e1}(w)), r).$$

Then

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, \mathsf{append}(w, \mathsf{BHist.e1}(r))).$$

Proof. Unfold Definition 38.154 in the two source windows. The left source supplies RatUp endpoint classifiers for every k with $\mathsf{UnaryOffsetLe}(k, w)$, and the right source supplies them for every successor-shifted offset below r from the anchor $\mathsf{append}(a, \mathsf{BHist.e1}(w))$.

Fix an offset k with $\mathsf{UnaryOffsetLe}(k, \mathsf{append}(w, \mathsf{BHist.e1}(r)))$. Unfold Definition 38.151; the offset ledger is a displayed Cont decomposition from k to the joined bound. Constructor inspection

of that finite append ledger separates the branch that reaches w from the branch that crosses the visible $\mathsf{BHist.e1}(w)$ successor.

In the left branch, repack the projected continuation as $\mathsf{UnaryOffsetLe}(k, w)$ and apply the left source window. This gives the RatUp classifier at $\mathsf{append}(a, k)$, which is the same endpoint selected by the joined window.

In the right branch, the ledger gives a unary offset j with $\mathsf{UnaryOffsetLe}(j, r)$ and an hsame row identifying $\mathsf{append}(a, k)$ with $\mathsf{append}(\mathsf{append}(a, \mathsf{BHist.e1}(w)), j)$. Apply the right source window at j and transport the RatUp endpoint classifier along that hsame comparison.

The unary rows for a, w, and r come from the two source classifiers and unary successor and append closure. Since the two ledger branches cover exactly the offsets below $\mathsf{append}(w, \mathsf{BHist.e1}(r))$, the collected endpoint classifiers repack as the joined $\mathsf{RealUnaryStreamWindowClassifier}$. □

Theorem 38.184 (Real unary window concatenation left projection)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and unary anchor histories* $a, w, r : \mathsf{Hist}$*, if*

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, \mathsf{append}(w, \mathsf{BHist.e1}(r))),$$

then

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w).$$

Proof. Unfold Definition 38.154 in the joined window. Its $\mathsf{UnaryHistory}$ rows include the anchor and joined bound, and its endpoint clause gives a $\mathsf{RatHistoryClassifier}$ for each offset below $\mathsf{append}(w, \mathsf{BHist.e1}(r))$.

Fix an offset k with $\mathsf{UnaryOffsetLe}(k, w)$. The left inclusion of the finite append ledger extends this Cont row to a displayed ledger

$$\mathsf{UnaryOffsetLe}(k, \mathsf{append}(w, \mathsf{BHist.e1}(r))).$$

Apply the joined classifier to this extended offset.

The endpoint remains anchored at a, so no endpoint transport is needed: the resulting $\mathsf{RatHistoryClassifier}$ is already the one required for the left window. Repacking these endpoint rows with the inherited $\mathsf{UnaryHistory}$ data gives $\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w)$. □

Theorem 38.185 (Real unary window concatenation right projection)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and unary anchor histories* $a, w, r : \mathsf{Hist}$*, if*

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, \mathsf{append}(w, \mathsf{BHist.e1}(r))),$$

then

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, \mathsf{append}(a, \mathsf{BHist.e1}(w)), r).$$

Proof. Unfold Definition 38.154 in the joined window and fix an offset j with $\mathsf{UnaryOffsetLe}(j, r)$. The successor shift of this ledger gives a joined offset below $\mathsf{append}(w, \mathsf{BHist.e1}(r))$ by first crossing the visible $\mathsf{BHist.e1}(w)$ row and then following the displayed Cont row for j.

Apply the joined classifier to that shifted offset. Its endpoint is based at a and the shifted ledger, while the right window endpoint is based at $\mathsf{append}(a, \mathsf{BHist.e1}(w))$ and the offset j.

The displayed append associativity row supplies the required hsame and Cont transport between these two endpoint descriptions. Transport the $\mathsf{RatHistoryClassifier}$ along that row, and repack the transported endpoint classifiers with the inherited $\mathsf{UnaryHistory}$ data. This is exactly $\mathsf{RealUnaryStreamWindowClassifier}(s, t, \mathsf{append}(a, \mathsf{BHist.e1}(w)), r)$. □

Theorem 38.186 (Real unary adjacent window concatenation equivalence)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and unary anchor and bound histories* $a, w, r : \mathsf{Hist}$*,*

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, \mathsf{append}(w, \mathsf{BHist.e1}(r))) \iff \Big(\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w)/$$

Proof. For the forward direction, assume the joined finite-window classifier. Apply Definition 38.184 to obtain the left window over the original anchor a. Apply Definition 38.185 to obtain the right window over the shifted anchor $\mathsf{append}(a, \mathsf{BHist.e1}(w))$. Pairing these two projections gives the displayed conjunction.

For the reverse direction, assume the two displayed window classifiers. Apply Definition 38.183 to concatenate the left window and the adjacent right window. The resulting classifier has anchor a and bound $\mathsf{append}(w, \mathsf{BHist.e1}(r))$, which is exactly the joined finite-window classifier. □

Theorem 38.187 (Real unary window associative triple concatenation)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and unary anchor and bound histories* $a, w, r, q : \mathsf{Hist}$*, assume*

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w),$$

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, \mathsf{append}(a, \mathsf{BHist.e1}(w)), r),$$

and

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, \mathsf{append}(\mathsf{append}(a, \mathsf{BHist.e1}(w)), \mathsf{BHist.e1}(r)), q).$$

Then

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, \mathsf{append}(\mathsf{append}(w, \mathsf{BHist.e1}(r)), \mathsf{BHist.e1}(q))).$$

Proof. First concatenate the w-window and the r-window by Definition 38.183. This gives a window from a with displayed bound $\mathsf{append}(w, \mathsf{BHist.e1}(r))$.

Next apply the same adjacent-concatenation theorem to that joined window and the q-window. The third source window is anchored at $\mathsf{append}(\mathsf{append}(a, \mathsf{BHist.e1}(w)), \mathsf{BHist.e1}(r))$, while the second application expects the anchor obtained by appending the joined bound to a.

The displayed associativity row for append supplies the needed hsame endpoint transport between these two anchor descriptions. Transport the RatUp endpoint classifiers along that hsame row, then repack the unary-history and Cont ledgers supplied by the two adjacent concatenations.

The resulting bound is exactly $\mathsf{append}(\mathsf{append}(w, \mathsf{BHist.e1}(r)), \mathsf{BHist.e1}(q))$, so the repackaged endpoint rows prove the displayed triple-window classifier. □

Theorem 38.188 (RealUp concatenated StreamName finite-window feed)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and unary histories* $a, w, r, q : \mathsf{Hist}$*, assume the three adjacent finite-window feeds*

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w),$$

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, \mathsf{append}(a, \mathsf{BHist.e1}(w)), r),$$

and

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, \mathsf{append}(\mathsf{append}(a, \mathsf{BHist.e1}(w)), \mathsf{BHist.e1}(r)), q)$$

are accepted StreamName-scheduled Real finite-window feeds. Then the concatenated row

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, \mathsf{append}(\mathsf{append}(w, \mathsf{BHist.e1}(r)), \mathsf{BHist.e1}(q)))$$

is a single RealUp finite-window feed consumable by Definition 38.314 and Definition 126.289.

Proof. First apply Definition 38.187 to the three accepted adjacent windows. This produces one unary RealUnaryStreamWindowClassifier over the displayed concatenated bound, with all endpoint RatUp classifiers transported through the same hsame, unary-history, append, and finite Cont rows already present in the three source windows.

Next read the scheduling surface through Definition 126.289. The observation maps $s, t : \mathsf{Hist} \to \mathsf{Hist}$ are exactly the StreamName schedule consumed there, and the joined classifier is therefore a finite-window row of the kind passed to Definition 38.314.

The construction introduces no host Nat, quotient representative, completion object, or hidden stream object. Its whole feed is the single concatenated BHist window together with the displayed endpoint classifiers and the finite scheduling ledger. □

Theorem 38.189 (StreamName RegSeqRat RealUp shared finite-window cover)**.** *For observation maps $s, t : \mathsf{Hist} \to \mathsf{Hist}$ and unary histories $a, w, r, q : \mathsf{Hist}$, suppose the three adjacent* BHist *pieces satisfy the public finite-window* $\mathsf{StreamName}^{\uparrow}$ *classifier rows of Definition 126.301, the* RegSeqRat *finite-window seal source coverage rows of Definition 38.268, and the* $\mathsf{Real}^{\uparrow}$ *finite-window feed rows of Definition 38.188. Then the concatenated finite window*

$$\mathsf{append}(\mathsf{append}(w, \mathsf{BHist.e1}(r)), \mathsf{BHist.e1}(q))$$

determines one shared public observation package for the three interfaces.

The package surface consists exactly of the StreamName finite-window classifier, the selected $\mathsf{Rat}^{\uparrow}$ *endpoint classifier rows, the finite* ProbeBundle *and* InBundle *ledger rows, the* UnaryHistory *rows, the displayed* hsame *endpoint comparisons, the shared* Cont *transports, and the finite dyadic source rows read by* RegSeqRat*. The* RegSeqRat *seal consumer and the* $\mathsf{Real}^{\uparrow}$ *finite-window feed therefore read the same bounded observations from the same concatenated* BHist *window.*

Proof. First apply Definition 38.188. The three adjacent StreamName-scheduled finite windows are repacked into the displayed concatenated BHist window, and the RealUp feed keeps the same endpoint classifiers, hsame transports, unary-history rows, and finite Cont ledger.

Next apply Definition 126.301. Its structural laws and selected readback rows identify the public StreamName finite-window surface carried by the concatenated window: the classifier, probe bundle, membership rows, unary observations, endpoint comparisons, and finite stability rows are all read from the same ledger.

Finally apply Definition 38.268. The RegSeqRat seal uses exactly the StreamName finite-window interface rows, the dyadic source ledger, and the RealUp finite-window exhaustion rows already exposed by the same concatenated window. Since both downstream consumers cite the same hsame, Cont, UnaryHistory, finite ledger, and endpoint readback rows, there is only one public observation package, with no quotient representative, completion object, host stream carrier, or extra regularity datum. □

Theorem 38.190 (StreamName RegSeqRat RealUp joined-window consumer coherence)**.** *For observation maps $s, t : \mathsf{Hist} \to \mathsf{Hist}$ and three adjacent public* $\mathsf{StreamName}^{\uparrow}$ *finite windows over* BHist *anchors $a, w, r, q : \mathsf{Hist}$, let*

$$L = \mathsf{append}(\mathsf{append}(w, \mathsf{BHist.e1}(r)), \mathsf{BHist.e1}(q))$$

and let

$$R = \mathsf{append}(w, \mathsf{BHist.e1}(\mathsf{append}(r, \mathsf{BHist.e1}(q)))).$$

If the three source windows satisfy the public finite-window classifier rows of Definition 126.301, the RegSeqRat *finite-window seal source coverage rows of Definition 38.268, and the* $\mathsf{Real}^{\uparrow}$ *finite-window feed rows of Definition 38.188, then the left-associated joined window L and the right-associated joined window R induce the same public* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the same* RegSeqRat *finite-window seal source rows, and the same finite-window* $\mathsf{Real}^{\uparrow}$ *feed rows.*

The common consumer surface is exactly the shared BHist *anchor, the three source finite-window rows, their endpoint* $\mathsf{Rat}^{\uparrow}$ *classifiers, the finite* ProbeBundle *and* InBundle *rows, the* UnaryHistory *rows, the displayed* hsame *transports, and the finite* Cont *ledger. No* RegSeqRat *regularity witness,* $\mathsf{Real}^{\uparrow}$ *seal classifier, quotient row, or host index equality is imported from the* $\mathsf{StreamName}^{\uparrow}$ *side.*

Proof. First build the left-associated consumer package. Apply Definition 38.187 to the three adjacent windows, then apply Definition 38.188. This gives the $\mathsf{Real}^{\uparrow}$ feed over L with exactly the endpoint classifiers, UnaryHistory rows, hsame transports, and finite Cont ledger already present in the source windows.

Next apply Definition 38.189. The shared cover reads the StreamName interface, the RegSeqRat seal source rows, and the RealUp feed from that same joined finite window.

For the right-associated reading, use the visible associativity comparison between L and R for append. Transport the public StreamName finite-window rows through the displayed hsame comparison, leaving the three source endpoint classifiers and the finite ledger unchanged.

Finally apply Definition 126.88. Its overlap clause says that two downstream reads sharing the same StreamName finite window, endpoint readback rows, and finite ledger have one source package. Thus the RegSeqRat and RealUp consumers receive the same rows under the two parenthesizations, with no extra regularity, seal-classifier, quotient, or host-index data. □

Theorem 38.191 (RealUp StreamName RegSeqRat triple-window cocycle)**.** *For observation maps $s, t : \mathsf{Hist} \to \mathsf{Hist}$ and four adjacent public* $\mathsf{StreamName}^{\uparrow}$ *finite windows over* BHist *anchors $a, w, r, q, u : \mathsf{Hist}$, assume each consecutive triple satisfies the hypotheses of Definition 38.189 and Definition 38.190. Then the two public observation routes obtained by first reassociating the left triple and then the right triple, or by first reassociating the right triple and then the left triple, induce the same* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the same* RegSeqRat *seal rows, the same* $\mathsf{Real}^{\uparrow}$ *feed rows, and the same* $\mathsf{Rat}^{\uparrow}$ *endpoint classifiers.*

The common four-window consumer surface also keeps one ProbeBundle/InBundle *ledger, one family of* UnaryHistory *rows, the displayed* hsame *transports, the finite* Cont *ledger, and the* Pkg *provenance for the shared source package at each intermediate joined window. No* RegSeqRat *regularity witness,* $\mathsf{Real}^{\uparrow}$ *completeness row, quotient row, host index equality, or standard bridge data is imported.*

Proof. Start with the left triple. Apply Definition 38.190 to the three windows (w, r, q). The result is a single joined consumer package for the two parenthesizations of that triple, with the same StreamName rows, RegSeqRat seal rows, RealUp feed rows, endpoint classifiers, finite ledger, hsame transports, Cont rows, and Pkg provenance.

Use Definition 38.189 on that joined left package and the fourth window. The shared-window cover identifies the package seen by the next joined-window consumer as the same source package already selected by the left triple, now extended only by the adjacent public finite-window rows.

For the other route, first apply Definition 38.190 to the right triple (r, q, u). Then apply Definition 38.189 to attach the remaining left window. This produces the same kind of joined package, with the same visible rows and no additional source object.

Finally compare the two intermediate source packages. At the overlap, each was obtained by applying the same joined-window consumer coherence to one consecutive triple and the same

shared-window cover to the adjacent triple. Those two clauses identify the common source package at both steps, so the finite StreamName rows, RegSeqRat rows, RealUp rows, endpoint classifiers, bundle ledger, unary-history rows, hsame transports, Cont ledger, and Pkg provenance agree. Since neither theorem imports regularity, completeness, quotient, host-index, or bridge data, the four-window cocycle has exactly the stated negative boundary. □

Theorem 38.192 (RealUp StreamName RegSeqRat five-window pentagon coherence)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and five adjacent public* $\mathsf{StreamName}^{\uparrow}$ *finite windows over* BHist *anchors* $a, w, r, q, u, v : \mathsf{Hist}$*, assume every consecutive triple satisfies the hypotheses of Definition 38.189 and Definition 38.190. Then all five public observation routes obtained by reassociating adjacent triples induce the same* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the same* RegSeqRat *seal rows, the same* $\mathsf{Real}^{\uparrow}$ *feed rows, and the same* $\mathsf{Rat}^{\uparrow}$ *endpoint classifiers.*

The common five-window consumer surface also has one ProbeBundle/InBundle *ledger, one family of* UnaryHistory *rows, the displayed* hsame *transports, the finite* Cont *ledger, and the* Pkg *provenance for the shared source package. No* RegSeqRat *regularity witness,* $\mathsf{Real}^{\uparrow}$ *completeness row, quotient row, host-index equality, or standard bridge data is imported.*

Proof. First apply Definition 38.191 to the left four windows (w, r, q, u). It identifies the two routes that move through the left and middle triples, preserving the StreamName rows, RegSeqRat seal rows, RealUp feed rows, endpoint classifiers, finite bundle ledger, unary-history rows, hsame transports, Cont ledger, and Pkg provenance.

Apply the same triple-window cocycle to the right four windows (r, q, u, v). This identifies the routes that move through the middle and right triples, again keeping exactly the same visible rows and finite ledgers.

It remains to compare the two descriptions on their common middle package. Use Definition 38.189 on the overlapping finite-window package. The cover states that the StreamName finite-window rows, the RegSeqRat seal source rows, and the RealUp feed rows are read from the same source package whenever the overlap presents the same endpoint classifiers, bundle rows, unary-history rows, hsame transports, and finite Cont ledger.

Combining the two cocycle comparisons with this shared-window identification connects all five parenthesized public routes around the pentagon. Projecting the listed rows from the common package gives the stated agreement for the StreamName, RegSeqRat, RealUp, RatUp, bundle, unary-history, hsame, Cont, and Pkg surfaces.

The proof uses only the finite-window cocycle and the shared-window cover. Since neither input exposes a regularity witness, completeness row, quotient row, host-index equality, or standard bridge datum, the five-window coherence has the same negative boundary. □

Theorem 38.193 (Real completion boundary unique observation route)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and adjacent unary* BHist *windows* $a, w, r, q : \mathsf{Hist}$ *satisfying the hypotheses of Definition 38.189 and Definition 38.190, every public Real-completion-phase observation read consumed by* $\mathsf{StreamName}^{\uparrow}$*,* RegSeqRat*, and* $\mathsf{Real}^{\uparrow}$ *factors through the single concatenated* BHist *window*

$$\mathsf{append}(\mathsf{append}(w, \mathsf{BHist.e1}(r)), \mathsf{BHist.e1}(q)).$$

The visible route consists exactly of that joined window, the StreamName finite-window classifier rows, the RegSeqRat finite-window seal rows, the RealUp finite-window feed rows, the $\mathsf{Rat}^{\uparrow}$ *endpoint classifiers,* UnaryHistory*,* hsame*,* Cont*,* ProbeBundle*,* InBundle*, and* Pkg *provenance.*

No quotient representative, host stream equality, independent regularity witness, RealUp completeness row, or direct RealUp read bypassing the StreamName–RegSeqRat handoff is available at this boundary.

Proof. Apply Definition 38.189. It identifies the common public package over the displayed concatenated BHist window, so the StreamName classifier, RegSeqRat seal source, RealUp feed, endpoint classifiers, bundle rows, unary-history rows, hsame comparisons, Cont transports, and Pkg provenance are read from one bounded package.

Next apply Definition 38.190. The coherence theorem transports that same package across the two visible parenthesizations of the joined window, leaving the downstream StreamName, RegSeqRat, and RealUp consumers attached to the same finite rows.

Project the listed rows from the shared package. Tuple exhaustion leaves no remaining coordinate that could carry a quotient representative, host stream equality, independent regularity witness, RealUp completeness row, or direct RealUp read outside the StreamName–RegSeqRat handoff. Thus the displayed finite route is the unique visible observation route at the Real completion boundary. □

The ten-field fit is: traditional target nested finite observation-window concatenation; BEDC source RealUp finite windows over StreamNameUp observation schedules $s, t : \mathsf{Hist} \to \mathsf{Hist}$; carrier unary BHist anchors and bounds; classifier RatUp endpoint classifiers at displayed append endpoints; stability by hsame endpoint transport; ledger Cont, unary-history rows, and append-associativity readback; core theorem Definition 38.187; exactness each endpoint in the nested bound is read from one of the three source windows; standard bridge finite-prefix consumption by RegSeqRat and RealUp surfaces; status ProofTarget.

The ten-field fit is: traditional target finite observation-window concatenation over unary histories; BEDC source RealUnaryStreamWindowClassifier; carrier RealUp finite windows over StreamNameUp observation schedules $s, t : \mathsf{Hist} \to \mathsf{Hist}$; classifier RatUp endpoint classifiers at displayed append endpoints; stability by unary offset splitting; ledger UnaryHistory, Cont, hsame, and the finite append boundary; core theorem Definition 38.183; exactness every joined endpoint is read from one source window; standard bridge finite stream-prefix concatenation; status ProofTarget.

The ten-field fit is: traditional target finite observation-window concatenation; BEDC source RealStreamWindowClassifier over RatUp endpoint classifiers; carrier rational-observation streams; classifier concatenated finite-window predicate; stability by bounded-offset splitting and endpoint reuse; ledger left radius, right radius, join index, and selected offset; core theorem Definition 38.182; exactness every endpoint in the joined window is covered by one of the two source windows; standard bridge finite rational observation intervals; status ProofTarget.

Definition 38.194 (Real stability certificate)**.** *The stability certificate consists of:*

1. *pointwise stream stability inherited from* $\mathsf{StreamName}^{\uparrow}$ *through Definition 38.273*
2. *transport of the* RegSeqRat *regularity witness along stream classification*
3. *classifier reflexivity, symmetry, and transitivity by dyadic tolerance comparison*
4. *compatibility of constant dyadic embedding with the closeness classifier*
5. *closure of real operations only when supplied as certified* RegSeqRat *transformations*

Definition 38.195 (RegSeqRat stream certificate spine)**.** *A* RegSeqRat *stream certificate spine for a rational-observation stream* $s : \mathsf{Hist} \to \mathsf{Hist}$ *is a rational stream-name carrier* $\mathsf{RatStreamNameCarrier}(s)$ *together with a regularity witness stable under* RealUnaryStreamClassifier*. Its ledger records the unary observation indices, the endpoint* $\mathsf{Rat}^{\uparrow}$ *carriers exposed at those indices, the pointwise* $\mathsf{Rat}^{\uparrow}$ *classifiers read from the stream classifier, and the dyadic-tolerance requests used by the regularity witness.*

The ten-field fit is: traditional target Bishop regular rational sequence; BEDC source BHist, UnaryHistory, $\mathsf{Rat}^{\uparrow}$, *and* $\mathsf{StreamName}^{\uparrow}$*; carrier* RatStreamNameCarrier *plus the regularity witness; classifier* RealUnaryStreamClassifier*; stability pointwise RatUp reflexivity, symmetry, transitivity, and* hsame *transport; ledger finite observations and tolerance witnesses; core theorem list Definition 38.208 and Definition 38.209; exactness pointwise stream classification; standard bridge RealUp seal; status* ProofTarget.

Lean4 (definition) `BEDC.Derived.RealUp.RegseqratStreamCertificateSpine`

Theorem 38.196 (RegSeqRat carrier and classifier obligations)**.** *Let* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *be rational-observation streams. A* RegSeqRat *stream certificate spine for* s *and* t*, together with a recorded row* RealUnaryStreamClassifier(s, t)*, supplies the carrier and classifier obligations for the* RegSeqRat *interface: the* RatStreamNameCarrier *rows for the two streams, the* RealUnaryStreamClassifier *row as the stream classifier, endpoint* RatHistoryCarrier *rows at every certified unary observation, and the dyadic-tolerance ledger requests named by the regularity witness.*

Proof. Unfold Definition 38.195. The carrier field of each spine is already the required RatStreamNameCarrier row, and the displayed RealUnaryStreamClassifier(s, t) row is the classifier field used by the interface.

For endpoint carrier rows, apply Definition 38.208 to the carried streams and the displayed classifier row. Its endpoint clause returns RatHistoryCarrier$(s(n))$ and RatHistoryCarrier$(t(n))$ for each certified unary observation n.

The remaining ledger entries are exactly those named in the spine definition: the unary observation index, the two endpoint carriers, the pointwise RatUp classifier read from the stream classifier, and the dyadic-tolerance request handled by the regularity witness. □

Theorem 38.197 (RegSeqRat stability and transport obligations)**.** *Let* $s, t, u, s', t' : \mathsf{Hist} \to \mathsf{Hist}$ *be carried rational-observation streams with recorded rows* RealUnaryStreamClassifier(s, t) *and* RealUnaryStreamClassifier(t, u)*. If the endpoint transports are pointwise over unary observations, then the* RegSeqRat *obligation set contains reflexivity, symmetry, transitivity, and pointwise* hsame *transport for* RealUnaryStreamClassifier *over those carried streams.*

Proof. Apply Definition 38.273 to the three carried streams, the two displayed classifier rows, and the two pointwise hsame transport rows. The package gives the reflexive classifier on s, the reversed classifier from t to s, and the composite classifier from s to u.

For transport, use Definition 38.275. It repacks the pointwise RatUp transport data along certified unary observations as the transported StreamNameUp classifier row, so the same BEDC point classifiers serve as the RegSeqRat transport obligation. □

Theorem 38.198 (RegSeqRat constant stream and seal obligations)**.** *The* RegSeqRat *obligation set contains constant streams, independently reindexed constant streams, and the* $\mathsf{Real}^{\uparrow}$ *seal export interface. In particular, every carried RatUp point supplies a constant* RegSeqRat *stream spine, compatible RatUp point classifiers supply the independently reindexed constant-stream classifier row, and a sealed* $\mathsf{Real}^{\uparrow}$ *candidate exposing a recorded* RealUnaryStreamClassifier *row exports the classifier required by Definition 38.9.*

Proof. Apply Definition 38.205 to the carried RatUp point. This gives the constant stream carrier row, the reflexive unary stream classifier, and the constant dyadic-tolerance ledger.

Next apply Definition 38.206. The independently reindexed constant streams keep the same endpoint RatUp carrier rows and use the supplied RatUp point classifier as the pointwise stream classifier over every certified unary observation.

Finally apply Definition 38.209. The seal reads the recorded RealUnaryStreamClassifier row and exports exactly the RealUp observation classifier named by Definition 38.9. □

Theorem 38.199 (RegSeqRat carrier obligation package)**.** *For a rational-observation stream* $s : \mathsf{Hist} \to \mathsf{Hist}$*, the carrier obligation for the* RegSeqRat *stream certificate spine is exactly a* $\mathsf{RatStreamNameCarrier}(s)$ *row together with a regularity ledger over certified* UnaryHistory *observations. Each ledger row exposes the endpoint* $\mathsf{RatHistoryCarrier}(s(n))$ *at the certified observation* n *and records the dyadic-tolerance request used by the regularity witness.*

Proof. Unfold Definition 38.195. The carrier field is the displayed $\mathsf{RatStreamNameCarrier}(s)$ row, so projecting the spine gives the stream-name carrier without adding any separate carrier principle.

For a certified unary observation n, read the corresponding ledger row. That row contains the exposed $\mathsf{Rat}^{\uparrow}$ endpoint carrier $\mathsf{RatHistoryCarrier}(s(n))$ and the dyadic-tolerance request attached to the regularity witness at that observation.

Conversely, a stream-name carrier together with these certified ledger rows is precisely the data named by the spine definition. Repacking the carrier row and the ledger rows gives the carrier side of the RegSeqRat obligation package. □

Theorem 38.200 (RegSeqRat classifier obligation package)**.** *For rational-observation maps* $s, t, u, s', t' : \mathsf{Hist} \to \mathsf{Hist}$*, the* RegSeqRat *classifier obligation package consists of the reflexive, symmetric, transitive, endpoint-carrier, and pointwise* hsame *transport rows of* RealUnaryStreamClassifier*. These rows are supplied by combining Definition 38.273 with Definition 38.275 and then repacking the pointwise* $\mathsf{Rat}^{\uparrow}$ *classifier rows.*

Proof. Apply Definition 38.273 to the carried streams, the two displayed unary stream classifier rows, and the endpoint hsame transports. Its package gives the reflexive, symmetric, and transitive RealUnaryStreamClassifier rows, and it also exposes the endpoint RatHistoryCarrier rows at every certified unary observation.

Next apply Definition 38.275 to the same stream-name carriers, classifier row, and pointwise transports. This gives the transported $\mathsf{RatStreamNameClassifier}(s', t')$ row.

Both cited theorems unfold the same pointwise RatUp classifier over certified unary observations. Repacking those pointwise rows under Definition 38.195 gives exactly the classifier obligation package. □

Theorem 38.201 (RegSeqRat seal ledger obligation package)**.** *The constant-stream witness, stream classifier stability spine, and* $\mathsf{Real}^{\uparrow}$ *seal consumer jointly provide the remaining* RegSeqRat *obligation list: constant stream, transport, dyadic-tolerance ledger, and* $\mathsf{Real}^{\uparrow}$ *seal-interface obligations. Concretely, the package is obtained from Definition 38.205, Definition 38.208, and Definition 38.209.*

Proof. Use Definition 38.205 for the constant-stream obligation. It supplies the carried constant stream, the reflexive unary stream classifier, and the constant dyadic-tolerance ledger from a single $\mathsf{RatHistoryCarrier}(d)$ row.

Use Definition 38.208 for the transport obligation. It provides reflexivity, symmetry, transitivity, endpoint carrier exposure, and the transported stream-name classifier after pointwise hsame transport.

Finally use Definition 38.209 for the $\mathsf{Real}^{\uparrow}$ seal interface. The seal consumer projects the exposed streams and repackages the recorded stream comparison as the RealUp observation classifier required by Definition 38.9.

Together these three spines account for the constant stream, transport, dyadic-tolerance ledger, and seal-interface entries of the paper-side RegSeqRat obligation list. □

Theorem 38.202 (RegSeqRat carrier and regularity obligations)**.** *A* RegSeqRat *stream certificate spine consists of a* RatStreamNameCarrier *row, pointwise* RatHistoryCarrier *rows over certified* UnaryHistory *observations, a regularity ledger for dyadic-tolerance requests, and constant-stream inhabitation supplied by Definition 38.205.*

Proof. Unfold Definition 38.195. The carrier field is the displayed RatStreamNameCarrier row, and each certified unary observation exposes an endpoint $\mathsf{Rat}^{\uparrow}$ carrier row in the ledger.

The same definition records the dyadic-tolerance requests used by the regularity witness. For inhabitation, apply Definition 38.205 to any supplied $\mathsf{RatHistoryCarrier}(d)$. The theorem builds the constant rational stream, its self classifier, and the constant regularity ledger, which are exactly the listed carrier and regularity obligations. □

Theorem 38.203 (RegSeqRat classifier and transport obligations)**.** *The* RegSeqRat *classifier obligation supplies reflexivity, symmetry, transitivity, endpoint-carrier exposure, and pointwise* hsame *transport for* RealUnaryStreamClassifier *and* RatStreamNameClassifier*.*

Proof. Apply Definition 38.208. Its stability package supplies the reflexive, symmetric, and transitive RealUnaryStreamClassifier rows, and it exposes the endpoint RatHistoryCarrier rows at each certified unary observation.

For the transport row, use Definition 38.275. The pointwise hsame witnesses over unary observations transport the RatUp point classifiers and repack them as the RatStreamNameClassifier row. □

Theorem 38.204 (RegSeqRat seal-interface obligations)**.** *Sealed* $\mathsf{Real}^{\uparrow}$ *candidates exposing* RegSeqRat *stream certificate spines consume the recorded stream comparison as the RealUp classifier row. The ledger records only finite observations,* $\mathsf{Rat}^{\uparrow}$ *classifiers, dyadic-tolerance witnesses, and seal rows.*

Proof. Apply Definition 38.209. A sealed $\mathsf{Real}^{\uparrow}$ candidate exposing two rational stream names reads the recorded RealUnaryStreamClassifier comparison and exports that same row as the classifier required by the RealUp seal.

The allowed ledger entries are those named in Definition 38.279: finite stream observations, dyadic comparison witnesses, regularity certificates, and classifier comparison certificates. In the present seal interface these are precisely the finite observation rows, RatUp classifier rows, dyadic-tolerance witnesses, and seal rows used by the consumer theorem. □

Theorem 38.205 (RegSeqRat constant stream spine)**.** *For every history* $d : \mathsf{Hist}$*, a carrier* $\mathsf{RatHistoryCarrier}(d)$ *supplies a* RegSeqRat *stream certificate spine for* $\mathsf{RatConstStream}_d$*. The spine consists of the* $\mathsf{RatStreamNameCarrier}(\mathsf{RatConstStream}_d)$ *row, the self* $\mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_d, \mathsf{R}$ *row, and a constant regularity ledger: at any two certified unary observation indices, both exposed endpoints are the same* $\mathsf{Rat}^{\uparrow}$ *point* d*, and every dyadic-tolerance request is discharged by RatUp classifier reflexivity.*

Proof. Apply the carrier half of Definition 126.55 from right to left to the displayed $\mathsf{RatHistoryCarrier}(d)$. This gives the stream-name carrier row for $\mathsf{RatConstStream}_d$.

For the classifier row, unfold Definition 38.26. A certified unary observation n reads $\mathsf{RatConstStream}_d(n) = d$, so the required pointwise $\mathsf{RatHistoryClassifier}(\mathsf{RatConstStream}_d(n), \mathsf{RatConstStream}_d(n))$ is RatUp classifier reflexivity at the supplied carrier of d.

The regularity ledger is constant. Given any two certified unary observation indices, the point-exactness theorem identifies both exposed endpoints with the same RatUp point d. Thus the two observations have the same carrier, and each dyadic tolerance request compares d with itself, again by RatUp reflexivity. These rows are exactly the data named in Definition 38.195. □

Theorem 38.206 (RegSeqRat reindexed constant stream spine)**.** *For histories d, e : Hist and observation schedules $r, q : \mathsf{Hist} \to \mathsf{Hist}$, $\mathsf{RatHistoryCarrier}(d)$ supplies $\mathsf{RegSeqRat}$ stream certificate spines for both $\mathsf{RatConstStream}_d \circ r$ and $\mathsf{RatConstStream}_d$. If $\mathsf{RatHistoryClassifier}(d, e)$ is supplied, then the two independently reindexed constant streams $\mathsf{RatConstStream}_d \circ r$ and $\mathsf{RatConstStream}_e \circ q$ carry compatible $\mathsf{RegSeqRat}$ stream certificate spines and the classifier row $\mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStrea}$ $r, \mathsf{RatConstStream}_e \circ q)$.*

Proof. First build the carried stream rows. Apply Definition 126.51 to the carrier row of d to obtain the stream-name carrier for $\mathsf{RatConstStream}_d \circ r$, and apply Definition 38.205 to the same carrier row to obtain the unreindexed constant-stream spine.

The regularity ledger for $\mathsf{RatConstStream}_d \circ r$ is the same constant ledger used in Definition 38.205. At any certified unary observation index, the schedule r is read before the constant stream is evaluated, and the exposed endpoint is still d. Thus every dyadic tolerance request again compares the RatUp point d with itself and is discharged by RatUp classifier reflexivity.

Now suppose $\mathsf{RatHistoryClassifier}(d, e)$ is supplied. Its endpoint carrier rows provide the corresponding constant regularity ledgers for the d-stream and the e-stream. The StreamNameUp classifier row follows from Definition 126.51, while Definition 38.29 reads the same point classifier as the RealUp unary-observation stream classifier for the two independently reindexed constant streams.

Combining these rows gives the two compatible $\mathsf{RegSeqRat}$ spines together with the displayed $\mathsf{RealUnaryStreamClassifier}$ row. No quotient, completion, or host real structure is used. □

Theorem 38.207 (RegSeqRat constant stream seal classifier package)**.** *Let X and Y be sealed $\mathsf{Real}^{\uparrow}$ candidates exposing $\mathsf{RatConstStream}_d \circ r$ and $\mathsf{RatConstStream}_e \circ q$, respectively. If the two exposed streams carry the compatible $\mathsf{RegSeqRat}$ stream certificate spines supplied by Definition 38.206, and if the seal records the displayed row $\mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_d \circ r, \mathsf{RatConstStream}_e \circ$ $q)$, then the seal exports the RealUp observation classifier required by Definition 38.9.*

Proof. Project the two exposed rational-observation streams from the $\mathsf{Real}^{\uparrow}$ seals. By hypothesis, the two streams already carry the $\mathsf{RegSeqRat}$ spines produced for the independently reindexed constant streams.

Use the classifier row supplied by Definition 38.206. It is exactly the $\mathsf{RealUnaryStreamClassifier}(\mathsf{RatConstStream}_d$ $r, \mathsf{RatConstStream}_e \circ q)$ row recorded by the seal.

Finally apply Definition 38.209 to the two spines and the displayed stream classifier. The conclusion is precisely the RealUp observation classifier named in Definition 38.9. □

Theorem 38.208 (RegSeqRat stream classifier stability spine)**.** *Let s, t, u, s', t' : $\mathsf{Hist} \to \mathsf{Hist}$ be rational-observation maps. Suppose*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameCarrier}(u),$$

$$\mathsf{RealUnaryStreamClassifier}(s, t), \quad \mathsf{RealUnaryStreamClassifier}(t, u),$$

and suppose the displayed endpoints transport pointwise over unary observations:

$$\forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(s(n), s'(n)), \quad \forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(t(n), t'(n)).$$

Then the RegSeqRat *stream certificate spine supplies* RealUnaryStreamClassifier(s, s), RealUnaryStreamClassifier(t, s), RealUnaryStreamClassifier(s, u), *the endpoint rows* RatHistoryCarrier$(s(n))$ *and* RatHistoryCarrier$(t(n))$ *at every certified unary observation* n, *and the transported stream-name classifier* RatStreamNameClassifier(s', t').

Proof. Unfold Definition 38.195, Definition 126.1, Definition 126.2, and Definition 38.26. The spine is therefore the existing BEDC unary stream row together with the regularity ledger; no separate classifier is being postulated.

Apply Definition 38.273 to the three carried streams, the two displayed RealUp unary stream classifiers, and the two pointwise hsame transport rows. Its reflexivity, symmetry, and transitivity clauses give the three RealUnaryStreamClassifier conclusions, and its endpoint clause gives the pointwise $\mathsf{Rat}^{\uparrow}$ carrier rows.

The same package returns RatStreamNameClassifier(s, t) and RealUnaryStreamClassifier(s', t'). Combining the transported point classifier with RatUp classifier hsame transport and the transported endpoint carrier rows repacks exactly RatStreamNameClassifier(s', t'). □

Theorem 38.209 (RegSeqRat seal supplies RealUp observation classifier)**.** *Let* X *and* Y *be sealed* $\mathsf{Real}^{\uparrow}$ *candidates exposing rational-observation streams* $s, t : \mathsf{Hist} \to \mathsf{Hist}$. *If the exposed streams satisfy the* RegSeqRat *stream certificate spine and the seal records* RealUnaryStreamClassifier(s, t) *as its stream comparison row, then the sealed candidates export exactly the* RealUnaryStreamClassifier(s, t) *row required by Definition 38.9.*

Lean4 ✓ `BEDC.Derived.RealUp.RegseqratRealupSealConsumesStreamSpine`

Proof. Project the exposed stream data from the two $\mathsf{Real}^{\uparrow}$ seals. The RegSeqRat spine gives the RatStreamNameCarrier rows, the regularity ledger, and the pointwise RatUp classifier row over every certified unary observation.

Now read the seal's stored stream comparison row. By Definition 38.26, this is exactly the pointwise rational-history classifier over the same certified unary observations.

Repack that row under the RealUp seal. The result is the classifier row named by Definition 38.9; no quotient or completion principle is used. □

Theorem 38.210 (RegSeqRat stream spine scoped package)**.** *Let* $s, t, u, s', t' : \mathsf{Hist} \to \mathsf{Hist}$ *be rational-observation maps carrying* RatStreamNameCarrier(s), RatStreamNameCarrier(t), *and* RatStreamNameCarrier(u). *Suppose the stream comparison rows* RealUnaryStreamClassifier(s, t) *and* RealUnaryStreamClassifier(t, u) *are recorded, and suppose the endpoint transports are pointwise over unary observations:*

$$\forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(s(n), s'(n)), \quad \forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(t(n), t'(n)).$$

Then the RegSeqRat *stream certificate spine supplies the following scoped package.*

1. *For any* $d : \mathsf{Hist}$ *with* RatHistoryCarrier(d), *the constant stream* $\mathsf{RatConstStream}_d$ *inhabits the* RegSeqRat *stream spine.*
2. *The classifier rows* RealUnaryStreamClassifier(s, s), RealUnaryStreamClassifier(t, s), *and* RealUnaryStreamClassifier *are available.*
3. *At every certified unary observation* n, *the endpoint carrier rows* RatHistoryCarrier$(s(n))$ *and* RatHistoryCarrier$(t(n))$ *are available.*
4. *The transported stream-name classifier* RatStreamNameClassifier(s', t') *is available.*

5. *For sealed* $\mathsf{Real}^{\uparrow}$ *candidates exposing* s *and* t*, whose seal records* $\mathsf{RealUnaryStreamClassifier}(s,t)$ *as the stream comparison row, the RealUp seal exports the row required by Definition 38.9.*

Proof. The constant-stream clause is exactly Definition 38.205. It turns any $\mathsf{RatHistoryCarrier}(d)$ into the carried constant stream, its reflexive unary stream classifier, and the constant regularity ledger.

For the stability clauses, apply Definition 38.208 to s, t, u, s', t', the three carried-stream rows, the two displayed classifier rows, and the two pointwise hsame transports. This gives the reflexive, symmetric, and transitive $\mathsf{RealUnaryStreamClassifier}$ rows, the endpoint $\mathsf{Rat}^{\uparrow}$ carrier rows at every certified unary observation, and the transported $\mathsf{RatStreamNameClassifier}(s', t')$ row.

Finally, apply Definition 38.209 to any sealed $\mathsf{Real}^{\uparrow}$ candidates exposing s and t with the recorded stream comparison. The seal consumer repacks that same comparison as the RealUp classifier export.

All rows are obtained by projection, pointwise hsame transport, and repacking of the listed certificate data. No quotient, completion, or host equality principle is used. □

Theorem 38.211 (RegSeqRat spine pointwise hsame transport)**.** *Let* $s, t, s', t' : \mathsf{Hist} \to \mathsf{Hist}$ *be rational-observation maps. Suppose* s *and* t *carry* $\mathsf{RegSeqRat}$ *stream certificate spines, and suppose the stream comparison row* $\mathsf{RealUnaryStreamClassifier}(s,t)$ *is recorded. If the endpoint transports are pointwise over certified unary observations,*

$$\forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(s(n), s'(n)), \quad \forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(t(n), t'(n)),$$

then the transported streams s' *and* t' *carry* $\mathsf{RegSeqRat}$ *stream certificate spines and export the transported* $\mathsf{RatStreamNameClassifier}(s', t')$*. Moreover, for sealed* $\mathsf{Real}^{\uparrow}$ *candidates exposing* s' *and* t'*, whose seal records the transported stream comparison row, the seal exports the corresponding RealUp observation classifier required by Definition 38.9.*

Proof. First read the endpoint data from the original spine. The scoped package in Definition 38.210 supplies the carrier rows, the reflexive, symmetric, and transitive classifier rows, and the dyadic ledger entries over certified unary observations.

Next transport the stream-name comparison. Apply Definition 38.275 to the recorded $\mathsf{RealUnaryStreamClassifier}$ row and to the two pointwise hsame transport families. It returns the transported $\mathsf{RatStreamNameClassifier}(s', t')$, including the transported endpoint carrier rows for s' and t'.

These transported carrier rows, together with the original dyadic requests read at the same certified unary observations, repack as the $\mathsf{RegSeqRat}$ stream certificate spines for s' and t'. The construction only changes the endpoint histories by the displayed hsame witnesses; the unary observation indices and tolerance ledger are unchanged.

Finally apply Definition 38.209 to sealed $\mathsf{Real}^{\uparrow}$ candidates exposing s' and t' with the transported stream comparison row. The seal consumer exports exactly the RealUp observation classifier named by Definition 38.9. □

Theorem 38.212 (RegSeqRat stream classifier transport composition)**.** *Let* $s, t, s', t', s'', t'' : \mathsf{Hist} \to \mathsf{Hist}$ *be rational-observation maps. Suppose* s *and* t *carry* $\mathsf{RegSeqRat}$ *stream certificate spines, and suppose the row* $\mathsf{RealUnaryStreamClassifier}(s,t)$ *is recorded. If the two successive endpoint-transport layers are pointwise over every certified unary observation,*

$$\forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(s(n), s'(n)), \quad \forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(t(n), t'(n)),$$

and

$$\forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(s'(n), s''(n)), \quad \forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(t'(n), t''(n)),$$

then s'' and t'' carry RegSeqRat *stream certificate spines and export* $\mathsf{RatStreamNameClassifier}(s'', t'')$*. Moreover, any* $\mathsf{Real}^{\uparrow}$ *seal over s'' and t'' whose stream comparison row is the twice-transported row exports the RealUp observation classifier required by Definition 38.9.*

Proof. Apply Definition 38.211 to the original RegSeqRat stream certificate spines, the recorded $\mathsf{RealUnaryStreamClassifier}(s, t)$ row, and the first pointwise hsame transport layer. This produces transported spines for s' and t' and the row $\mathsf{RatStreamNameClassifier}(s', t')$.

Use those transported spines as the input data for a second application of Definition 38.211. The second pointwise hsame layer carries the endpoint histories from s', t' to s'', t'', so the conclusion gives RegSeqRat stream certificate spines for s'' and t'' and the row $\mathsf{RatStreamNameClassifier}(s'', t'')$.

Finally compose only the named endpoint rows that the two applications expose: the StreamName classifier row is the transported row returned by the second application, and the RealUp classifier row is exported by applying the same seal consumer to the twice-transported stream comparison. No additional quotient, completion, or host equality principle is introduced. □

Theorem 38.213 (RegSeqRat seal finite-window transport package)**.** *Let $s, t, s', t' : \mathsf{Hist} \to \mathsf{Hist}$ be certified rational-observation maps, let $\mathcal{P}$ be a* ProbeBundle *finite window, let n be a bundled unary observation in $\mathcal{P}$, and let the selected transported endpoints be displayed as* $\mathsf{E1}(a)$ *and* $\mathsf{E1}(b)$*. Suppose s and t carry* RegSeqRat *stream certificate spines, the row* $\mathsf{RealUnaryStreamClassifier}(s, t)$ *is recorded, and the bundled pointwise transport rows*

$$\forall m \in \mathcal{P},\ \mathsf{UnaryHistory}(m) \to \mathsf{hsame}(s(m), s'(m)), \quad \forall m \in \mathcal{P},\ \mathsf{UnaryHistory}(m) \to \mathsf{hsame}(t(m), t'(m))$$

carry the selected source endpoints to the displayed endpoints $s'(n) = \mathsf{E1}(a)$ and $t'(n) = \mathsf{E1}(b)$. Then the $\mathsf{Real}^{\uparrow}$ *seal over s' and t' exports the finite-window public readback package consisting of the transported* $\mathsf{RatStreamNameFiniteWindowClassifier}(s', t', \mathcal{P})$ *row, the selected* $\mathsf{RatHistoryClassifier}(s'(n), t'(n))$ *row, the positive unary denominator rows for the displayed endpoints, the endpoint-shape exclusions, one-tail agreement, and the RealUp observation classifier row required by Definition 38.9.*

Proof. Apply Definition 38.211 to the RegSeqRat spines, the recorded stream comparison, and the two bundled pointwise hsame transport families. This gives the transported stream certificate spines for s' and t' and the transported stream-name classifier.

Restrict that transported stream classifier to the bundle $\mathcal{P}$ using the StreamName finite-window stability fields. The selected observation n is already bundled, so the restriction exposes the finite-window classifier row and the selected endpoint histories at $s'(n)$ and $t'(n)$.

Apply the transported selected full endpoint package to the displayed endpoints $\mathsf{E1}(a)$ and $\mathsf{E1}(b)$. It supplies the selected RatHistoryClassifier row, the positive unary denominator rows, the endpoint-shape exclusions, and one-tail agreement for the same selected observation.

Finally repack these rows through the RealUp seal consumer. The consumer keeps the finite-window StreamName row, the selected endpoint ledger, and the transported stream classifier as the public readback surface, and exports the RealUp observation classifier row without adding quotient, completion, or host equality data. □

Fit. Traditional target: finite-window transported rational-stream readback for the real-number seal. BEDC source: $\mathsf{StreamName}^{\uparrow} + \mathsf{RegSeqRat} + \mathsf{Real}^{\uparrow} + \mathsf{ProbeBundle}$. Carrier: BHist histories of certified unary rational observations. Classifier: transported RatStreamNameFiniteWindowClassifier

with the selected RatHistoryClassifier endpoint row. Stability: bundled pointwise hsame transport restricted to $\mathcal{P}$. Ledger: positive unary denominators, endpoint-shape exclusions, and one-tail agreement. Core theorems: Definition 38.211 and the StreamName transported finite-window endpoint package. Exactness: the exported rows are exactly the rows consumed by the RealUp seal. Standard bridge: none. Status: paper theorem awaiting Lean realization in BEDC.Derived.RealUp.

Theorem 38.214 (RegSeqRat carrier obligation)**.** *The carrier obligation for* RegSeqRat *is exactly the* RatStreamNameCarrier *row together with the regularity witness over* UnaryHistory *observations. Concretely, for a rational-observation map* $s : \mathsf{Hist} \to \mathsf{Hist}$*, a* RegSeqRat *carrier consists of* RatStreamNameCarrier(s) *and a ledger which, at each certified unary observation index* n*, exposes the endpoint* $\mathsf{Rat}^{\uparrow}$ *carrier row* RatHistoryCarrier$(s(n))$ *and the dyadic-tolerance witness demanded by the stream regularity check.*

Proof. Unfold the spine named in Definition 38.195. Its first component is the RatStreamNameCarrier row, and its ledger is indexed only by certified UnaryHistory observations.

The endpoint carrier rows are supplied by Definition 38.208; the constant case is supplied by Definition 38.205. The public package Definition 38.210 records these rows as the carrier face of the scoped spine.

The seal consumer Definition 38.209 uses no carrier data outside this spine. Thus the carrier obligation is precisely the named stream-name carrier plus the unary-observation regularity ledger. □

Theorem 38.215 (RegSeqRat classifier obligation)**.** *The classifier obligation for* RegSeqRat *is exactly* RealUnaryStreamClassifier *read with* RatStreamNameClassifier *endpoint recovery. For carried streams* $s, t : \mathsf{Hist} \to \mathsf{Hist}$*, a classifier row records the pointwise* $\mathsf{Rat}^{\uparrow}$ *comparison over every certified* UnaryHistory *observation and recovers the two endpoint stream-name carrier rows used by* RatStreamNameClassifier(s, t)*.*

Proof. Start from Definition 38.195. The spine does not introduce a separate classifier relation; it stores the RealUp unary stream classifier over the same BEDC unary observations.

Apply Definition 38.208. It reads the pointwise $\mathsf{Rat}^{\uparrow}$ classifier rows from RealUnaryStreamClassifier, recovers the endpoint carrier rows, and repackages the transported data as a RatStreamNameClassifier row. The constant boundary is the reflexive case supplied by Definition 38.205.

The scoped package Definition 38.210 lists the reflexive, symmetric, transitive, and transported classifier rows together. The seal consumer Definition 38.209 confirms that the same row is the classifier exported through the $\mathsf{Real}^{\uparrow}$ interface. □

Theorem 38.216 (RegSeqRat carrier-classifier export package)**.** *For carried rational-observation streams* $s, t : \mathsf{Hist} \to \mathsf{Hist}$*, the* RegSeqRat *spine exports exactly the* RatStreamNameCarrier(s) *row, the* RatStreamNameCarrier(t) *row, the* RatStreamNameClassifier(s, t) *row, the* RealUnaryStreamClassifier(s, t) *row, the endpoint* RatHistoryCarrier *and* RatHistoryClassifier *rows over certified* UnaryHistory *observations, and the finite* DyadicRatCore *ledger rows later consumed by the* $\mathsf{Real}^{\uparrow}$ *seal.*

This export package contains no quotient representatives, completion data, metric completeness, $\mathsf{Real}^{\uparrow}$ *completeness, Classical data, or standard bridge data. Its public boundary is the carried stream-name surface, the endpoint RatUp observation surface, the finite dyadic ledger, and the downstream* $\mathsf{Real}^{\uparrow}$ *seal consumption row.*

Proof. Read the carrier rows from Definition 38.195. Apply Definition 38.214 to the carried streams s and t. This supplies the two RatStreamNameCarrier rows and the endpoint RatHistoryCarrier rows indexed by certified UnaryHistory observations.

Read the classifier rows from the same spine. Apply Definition 38.215. It exposes the recorded $\mathsf{RealUnaryStreamClassifier}(s,t)$ row, recovers the pointwise endpoint $\mathsf{RatHistoryClassifier}$ rows, and repackages them as the $\mathsf{RatStreamNameClassifier}(s,t)$ row.

Next read the dyadic side. Apply Definition 38.256 to identify the finite $\mathsf{DyadicRatCore}$ ledger rows and their scoped primitive source. Then apply Definition 38.254 to consume those rows at the $\mathsf{Real}^{\uparrow}$ seal boundary.

The four cited obligations exhaust the displayed package. The carrier and classifier faces are read from the same certificate spine, while the dyadic ledger and the $\mathsf{Real}^{\uparrow}$ seal are consumed as already recorded rows. None of these steps adds a quotient representative, a completion object, a metric completeness principle, a $\mathsf{Real}^{\uparrow}$ completeness principle, Classical data, or standard bridge data as a primitive input. □

Theorem 38.217 (RegSeqRat export determines the RealUp seal source)**.** *For carried rational-observation streams $s,t : \mathsf{Hist} \to \mathsf{Hist}$, the export package of Definition 38.216 determines the exact source face read by the downstream $\mathsf{Real}^{\uparrow}$ seal. That source face consists precisely of the two $\mathsf{RatStreamNameCarrier}$ rows for s and t, the $\mathsf{RatStreamNameClassifier}(s,t)$ row, the pointwise $\mathsf{RealUnaryStreamClassifier}(s,t)$ row, the endpoint $\mathsf{RatHistoryCarrier}$ and $\mathsf{RatHistoryClassifier}$ rows over certified $\mathsf{UnaryHistory}$ observations, and the finite $\mathsf{DyadicRatCore}$ ledger rows.*

No quotient representative, completion object, metric completeness principle, or $\mathsf{Real}^{\uparrow}$ completeness datum is part of this seal source. Consequently, any $\mathsf{Real}^{\uparrow}$ seal source read from the $\mathsf{RegSeqRat}$ package factors through the same visible carrier, classifier, endpoint, and dyadic ledger rows.

Proof. First apply Definition 38.216. It identifies the two stream-name carrier rows, the stream-name classifier row, the pointwise RealUnary classifier row, the endpoint RatUp carrier and classifier rows over certified unary observations, and the finite dyadic ledger rows as the complete exported surface.

Next apply Definition 38.256. This fixes the dyadic primitive source of the ledger rows as the scoped $\mathsf{DyadicRatCore}$ data, with no additional completion or quotient object hidden behind the ledger.

Finally apply Definition 38.254. The $\mathsf{Real}^{\uparrow}$ seal consumes the same dyadic ledger together with the same carried stream-name and endpoint observation rows. Since the preceding export package already lists all rows available at the $\mathsf{RegSeqRat}$ boundary, row exhaustion forces every seal-source read to factor through exactly those visible rows and through no separate $\mathsf{Real}^{\uparrow}$ completeness datum. □

Theorem 38.218 (RegSeqRat export finite-window row exhaustion)**.** *For carried rational-observation streams $s,t : \mathsf{Hist} \to \mathsf{Hist}$ and a certified finite $\mathsf{ProbeBundle}$ window, every finite-window row consumed by the downstream $\mathsf{Real}^{\uparrow}$ seal from the $\mathsf{RegSeqRat}$ export factors through exactly the listed $\mathsf{RatStreamNameCarrier}(s)$ and $\mathsf{RatStreamNameCarrier}(t)$ rows, the $\mathsf{RatStreamNameClassifier}(s,t)$ row, the $\mathsf{RealUnaryStreamClassifier}(s,t)$ row, the endpoint $\mathsf{Rat}^{\uparrow}$ carrier and classifier rows, the finite $\mathsf{DyadicRatCore}$ ledger, the displayed BHist rows, the hsame transports, the Cont continuation routes, the Pkg provenance, and the local $\mathsf{NameCert}$ rows.*

Consequently two certified windows which agree on these rows present the same finite-window consumer surface to $\mathsf{Real}^{\uparrow}$. The exhaustion statement exports no quotient representative, completed $\mathsf{Real}^{\uparrow}$ equality, metric-completeness datum, Classical datum, or standard bridge datum.

Proof. First apply Definition 38.216. It identifies the stream-name carrier rows, the stream-name classifier row, the pointwise RealUnary classifier row, the endpoint $\mathsf{Rat}^{\uparrow}$ rows, and the finite dyadic ledger as the complete $\mathsf{RegSeqRat}$ export package.

Next apply Definition 38.217. The downstream $\mathsf{Real}^{\uparrow}$ seal reads its source face from the same exported carrier, classifier, endpoint, and dyadic ledger rows, so it has no independent source coordinate outside the displayed package.

Finally apply Definition 38.228 to the certified finite ProbeBundle window. This restricts the seal read to the displayed BHist, hsame, Cont, Pkg, and local NameCert rows attached to that window.

If two certified windows agree on all listed rows, the three preceding identifications give the same projected consumer surface. Since no cited boundary contains a field for quotient representatives, completed $\mathsf{Real}^{\uparrow}$ equality, metric completeness, Classical data, or standard bridge data, those objects cannot be consumed by the finite-window seal. □

Definition 38.219 (DyadicRatCore observation row)**.** *A DyadicRatCore observation row for a BEDC history d is the package consisting of a* RatHistoryCarrier(d) *witness, a positive unary denominator row* PositiveUnaryDenominator(d)*, and the dyadic-radius token used by the* RegSeqRat *regularity check. Its classifier face is inherited from* RatHistoryClassifier*, together with* hsame *transport of the positive-denominator row.*

Lean4 (definition) `BEDC.Derived.RealUp.DyadicRatCoreObservationRow`

Theorem 38.220 (DyadicRatCore observation-row classifier transport)**.** *Let d, e, d', e' :* Hist*. Suppose d and e carry* DyadicRatCoreObservationRow *packages, suppose* RatHistoryClassifier(d, e) *holds, and suppose* hsame(d, d') *and* hsame(e, e') *hold. If the dyadic-radius tokens for d' and e' are the same certified unary-observation requests as the tokens for d and e, transported along those two* hsame *rows inside the* RegSeqRat *ledger, then d' and e' carry* DyadicRatCoreObservationRow *packages and* RatHistoryClassifier(d', e') *holds.*

Proof. Unpack Definition 38.219. The source rows at d and e consist of rational-history carriers, positive unary denominator rows, and dyadic-radius tokens attached to certified RegSeqRat unary observations.

Apply the RatUp classifier transport to RatHistoryClassifier(d, e) along hsame(d, d') and hsame(e, e'). This gives the transported classifier RatHistoryClassifier(d', e'), and the transported carrier rows are read from the same rational-history endpoint spine.

The denominator component follows by positive-denominator transport. Applying Definition 37.6 to the two hsame rows carries the positive unary denominator rows from d to d' and from e to e'.

Finally, the dyadic-radius component is ledger-attached to the same certified unary-observation requests in the RegSeqRat spine. Transporting the endpoint rows changes neither the request names nor the recorded dyadic-tolerance tokens, so no completion or quotient datum is introduced. Repacking the transported carrier, denominator, token, and classifier rows gives the stated DyadicRatCore observation-row transport. □

Lean4 ✓ `BEDC.Derived.RealUp.DyadicRatCoreObservationRow classifier transport`

The fit is as follows: traditional target dyadic rational observation transport; BEDC source RatUp plus RegSeqRat unary requests over BHist; carrier DyadicRatCoreObservationRow; classifier RatHistoryClassifier; stability transported denominator rows; ledger unchanged dyadic-radius request; core theorem Definition 38.220; exactness transported row plus classifier; standard bridge finite RealUp windows; status ProofTarget.

Theorem 38.221 (DyadicRatCore scoped source package)**.** *The DyadicRatCore source used by* RegSeqRat *is the concrete BEDC scoped source package over* Hist *whose carrier, classifier, stability,*

and ledger faces are all read from the rational-history endpoint spine. For each endpoint history d, the carrier face is RatHistoryCarrier(d) *together with* PositiveUnaryDenominator(d) *and the dyadic-radius token recorded by the* RegSeqRat *regularity request. For endpoints d, e, the classifier face is* RatHistoryClassifier(d, e) *together with* hsame *transport of the positive-denominator rows. The stability face is inherited from the* $\mathsf{Rat}^{\uparrow}$ *carrier and classifier transports and from the pointwise classifier obligation of* RegSeqRat*. The ledger face is exactly the finite family of dyadic-tolerance requests already recorded in the* RegSeqRat *spine.*

Lean4 ✓ `BEDC.Derived.RealUp.DyadicRatCoreObservationRow scoped source package`

Proof. Start with the carrier face. Definition 38.219 names the three endpoint rows: the rational-history carrier, the positive unary denominator, and the dyadic-radius token. The endpoint carrier and the finite dyadic request are supplied by Definition 38.214, while Definition 37.19 converts the carrier row into the positive-denominator row.

Next read the classifier and stability faces. The pointwise stream classifier obligation in Definition 38.215 exposes the RatHistoryClassifier(d, e) endpoint comparison used by the DyadicRatCore source. RatUp carrier and classifier transport carries the rational-history rows along the same hsame comparison, and Definition 37.6 carries the positive-denominator row.

It remains only to identify the ledger. No request outside the RegSeqRat spine is used: the dyadic-radius token is attached to the same certified unary observation entry that supplies the endpoint rational row. Thus the source package has precisely the stated carrier, classifier, stability, and finite ledger faces over Hist. □

Theorem 38.222 (Phase Real dyadic stream RegSeq scope)**.** *Every DyadicRatCore request consumed by the Phase Real* RegSeqRat *spine is exactly a* DyadicRatCoreObservationRow *over* BHist*. Its carrier, positive-denominator, dyadic-radius, classifier, and ledger faces are read from the* $\mathsf{Rat}^{\uparrow}$ *carrier and classifier transports together with the* RegSeqRat *unary observation request. No* $\mathsf{Real}^{\uparrow}$ *completeness row, quotient row, completion object, metric-completeness row, Classical datum, or standard bridge row is part of this DyadicRatCore source scope.*

Proof. Unpack Definition 38.219. A consumed endpoint row is the rational-history carrier, positive unary denominator, and dyadic-radius token attached to the certified unary observation entry of the RegSeqRat spine.

Apply Definition 38.221. Its carrier face is the endpoint $\mathsf{Rat}^{\uparrow}$ row, its classifier face is the RatHistoryClassifier comparison, and its stability face is the same hsame transport used by the RegSeqRat pointwise classifier obligation.

The remaining ledger component is the finite dyadic-tolerance request already named by the RegSeqRat carrier and classifier obligations. Repacking these faces gives exactly the Phase Real DyadicRatCore request scope, and there is no slot in that package for quotient, completion, metric, Classical, or $\mathsf{Real}^{\uparrow}$ completeness data. □

Theorem 38.223 (DyadicRatCore observation row hsame transport)**.** *Let d, e : Hist. If d has a DyadicRatCore observation row in the sense of Definition 38.219 and* hsame(d, e) *holds, then e has a DyadicRatCore observation row. Its* RatHistoryCarrier(e) *component is the* $\mathsf{Rat}^{\uparrow}$ *carrier transport of the carrier component at d, its* PositiveUnaryDenominator(e) *component is transported by Definition 37.6, and its dyadic-radius token is the same certified observation ledger entry of the* RegSeqRat *spine.*

Proof. Unpack the row named by Definition 38.219. It consists of a $\mathsf{RatHistoryCarrier}(d)$ row, a $\mathsf{PositiveUnaryDenominator}(d)$ row, and a dyadic-radius token attached to a certified unary observation entry in the $\mathsf{RegSeqRat}$ regularity ledger.

Transport the carrier face along $\mathsf{hsame}(d, e)$ using the $\mathsf{Rat}^{\uparrow}$ carrier transport already used in Definition 38.221. The compatibility between the rational-history carrier and the positive-denominator row is the one identified by Definition 37.19.

Now apply Definition 37.6 to carry the positive-denominator component from d to e. The endpoint rational row and the certified dyadic request are the rows recorded by Definition 38.214 inside the scoped spine of Definition 38.210.

The dyadic-radius token is not recomputed during transport: it remains attached to the same certified observation ledger entry used by the source package. Thus the transported carrier row, the transported positive-denominator row, and the unchanged ledger token repack as a DyadicRatCore observation row for e. □

Theorem 38.224 (DyadicRatCore observation source transport determinacy)**.** *Let $d, e : \mathsf{Hist}$, and suppose $\mathsf{hsame}(d, e)$ is displayed. Fix one certified $\mathsf{RegSeqRat}$ unary observation request whose source surface at d is a DyadicRatCore observation row. If two transported source packages are obtained at e by carrying that row along the same $\mathsf{hsame}(d, e)$ display through that same certified request, then the two packages expose the same $\mathsf{RatHistoryCarrier}(e)$ face, the same $\mathsf{PositiveUnaryDenominator}(e)$ face, the same dyadic-radius token, and the same $\mathsf{RatHistoryClassifier}$ face. No quotient row, completion row, metric-completeness row, Classical datum, or standard bridge row can separate the two transported source surfaces.*

Proof. Unpack Definition 38.219. The source row at d consists only of the rational-history carrier, the positive unary denominator row, and the dyadic-radius token attached to the named certified $\mathsf{RegSeqRat}$ unary observation request.

Apply Definition 38.223 to each transport along the displayed $\mathsf{hsame}(d, e)$ row. Both transported packages therefore read their $\mathsf{RatHistoryCarrier}(e)$ and $\mathsf{PositiveUnaryDenominator}(e)$ components from the same carrier transport and the same positive-denominator transport.

Next identify the public source faces by Definition 38.221. Its carrier, classifier, stability, and ledger faces are exactly the RatUp endpoint spine, the positive-denominator transport row, and the finite dyadic request ledger; there is no further source face available for a second transported package to choose.

For the classifier face, use Definition 38.220. Since both packages use the same displayed $\mathsf{hsame}(d, e)$ row and the same certified $\mathsf{RegSeqRat}$ request, the transported $\mathsf{RatHistoryClassifier}$ face is the same face in both packages.

The dyadic-radius token remains attached to the original certified unary observation ledger entry throughout the transport. Repacking these common carrier, denominator, token, and classifier faces gives determinacy of the transported source surface, and the excluded quotient, completion, metric, Classical, and bridge rows have no slot in the scoped source package. □

Theorem 38.225 (DyadicRatCore common-exponent transport determinacy)**.** *Let $d, e, d', e', r, s : \mathsf{Hist}$. Suppose d and e carry $\mathsf{DyadicRatCoreObservationRow}$ packages for the same certified $\mathsf{RegSeqRat}$ observation request, with r and s naming the unary-radius histories of that request. Suppose $\mathsf{RatHistoryClassifier}(d, e)$ holds, and suppose $\mathsf{hsame}(d, d')$ and $\mathsf{hsame}(e, e')$ are displayed. If the packages at d' and e' are obtained by transporting the source rows along those displayed hsame rows without changing the certified request ledger, then the two transported packages expose the same $\mathsf{Rat}^{\uparrow}$ carrier faces, the same positive-unary-denominator faces, the same unary radius/request token, and*

the same RatHistoryClassifier(d', e') *surface. No quotient row, completion row, metric-completeness row, Classical datum, or standard bridge row contributes an additional common-exponent choice.*

Proof. First transport the classifier surface. Apply Definition 38.220 to the source comparison RatHistoryClassifier(d, e) and to the displayed rows hsame(d, d') and hsame(e, e'). The transported endpoint comparison is therefore the single surface RatHistoryClassifier(d', e') attached to the same certified RegSeqRat request.

Next transport the two endpoint source rows. Apply Definition 38.223 to the row at d and to the row at e. Because the request ledger is unchanged, the transported rows inherit the same dyadic request token and the same positive-unary-denominator transport rows used by the source package.

Finally compare the transported packages with Definition 38.224. The theorem identifies the $\mathsf{Rat}^{\uparrow}$ carrier face, the positive-denominator face, the dyadic-radius token, and the classifier face for transports through a fixed certified request. These identified faces are exactly the common-exponent surface of the two presentations, and the scoped source package has no field for quotient, completion, metric-completeness, Classical, or standard bridge data. □

Theorem 38.226 (Dyadic observation transport RealUp feed determinacy)**.** *Let* d, e : Hist*, and suppose* hsame(d, e) *is displayed. Fix one certified* RegSeqRat *unary observation request whose source surface at* d *is a* DyadicRatCoreObservationRow*. If two RealUp finite-window feed packages are obtained by first transporting that source to* e *along the same* hsame(d, e) *row and then applying the DyadicRatCore public observation feed, then the two feed packages expose the same RatUp endpoint carrier, the same positive-denominator row, the same dyadic-radius ledger token, the same RealUp finite-window source face, and the same exclusion boundary. No quotient row, completion row, Classical datum, external metric primitive, RealUp completeness claim, or standard bridge row can distinguish the two feeds.*

Proof. Project the transported sources with Definition 38.224. Both source packages at e therefore expose the same RatUp endpoint carrier, the same positive-denominator row, the same dyadic-radius token, and the same RatHistoryClassifier face.

Feed these common source rows through Definition 38.264. The public observation feed consumes exactly the transported DyadicRatCore source, the finite dyadic request ledger, and the RealUp finite-window source face recorded by that ledger.

It remains only to compare the visible fields of the two feeds. Since the input source projections are common and the feed theorem has no slot for a second quotient, completion, Classical, metric, completeness, or bridge datum, field projection gives the same RatUp endpoint carrier, positive-denominator row, dyadic-radius token, RealUp finite-window source face, and exclusion boundary in both packages. □

The intended Lean target shape for this boundary is `BEDC.Derived.RealUp.DyadicRatCore_scoped_source_p`

Theorem 38.227 (DyadicRatCore carrier and classifier obligations)**.** *The carrier and classifier obligations for DyadicRatCore are the certificate boundary whose carrier row is* DyadicRatCoreObservationRow(d) *from Definition 38.219, whose classifier row is* RatHistoryClassifier(d, e) *transported through Definition 38.220, and whose source package is the scoped boundary of Definition 38.221. Concretely, for each endpoint history* d : Hist*, the carrier obligation reads exactly the* RatHistoryCarrier(d) *row, the* PositiveUnaryDenominator(d) *row, and the dyadic-radius token already recorded by the* RegSeqRat *ledger. For each classifier comparison* RatHistoryClassifier(d, e)*, the classifier obligation transports that three-field row along* hsame(d, e) *and repacks no additional completion, quotient, or external metric datum.*

Proof. Unpack the definition of the observation row. The carrier face is precisely the triple named in Definition 38.219: a RatUp endpoint carrier, a positive unary denominator row, and the dyadic-radius token from the regularity ledger.

Now use Definition 38.221. It identifies the source of every such row as the RatUp endpoint history together with the RegSeqRat observation request, so the carrier obligation has no independent object outside that scoped package.

For the classifier face, apply Definition 38.220. The RatHistoryClassifier comparison supplies the hsame transport of the endpoint carrier, denominator row, and dyadic token, which is exactly the DyadicRatCore classifier obligation. □

Theorem 38.228 (RealUp-RegSeqRat finite-window projection)**.** *A finite DyadicRatCore observation package over a certified unary request projects to the exact* RegSeqRat *finite-window observation surface consumed by* $\mathsf{Real}^{\uparrow}$*. The projected surface consists of the* $\mathsf{Rat}^{\uparrow}$ *endpoint carrier, the positive unary denominator row, the dyadic-radius token, the* $\mathsf{StreamName}^{\uparrow}$ *request name, the* RegSeqRat *regularity ledger,* hsame *transport for the endpoint and denominator rows, and finite ledger provenance for the displayed window. It exports no quotient carrier, no completion object, no metric-completeness row, no Classical representative, and no standard bridge datum.*

Proof. Project the finite package to its three visible faces. The package theorem Definition 38.231 identifies these faces as the carrier-classifier face, the finite arithmetic face, and the radius-distance face over the same certified unary request.

The endpoint rows are read from Definition 38.227. They give exactly the $\mathsf{Rat}^{\uparrow}$ carrier, positive unary denominator row, dyadic-radius token, and hsame transport required by the RegSeqRat finite window.

The radius and distance rows are read from Definition 38.230. They keep the dyadic-radius refinement, dyadic distance, absolute-value row, request name, and regularity ledger inside the same finite observation ledger.

Finally repack these shared rows as the RegSeqRat finite-window projection. Since the source package has no coordinate for a quotient carrier, completion object, metric-completeness witness, Classical representative, or standard bridge, the projection passed to $\mathsf{Real}^{\uparrow}$ contains none of those data. □

Theorem 38.229 (DyadicRatCore arithmetic-stability obligations)**.** *The arithmetic-stability obligations for DyadicRatCore are the finite certificate rows required to read dyadic rational endpoint arithmetic through the BEDC source package. They consist of operation rows for dyadic addition, negation, subtraction, multiplication, and positive-denominator division; classifier congruence rows showing that* RatHistoryClassifier *and* hsame *transport carry equivalent inputs to equivalent operation outputs; denominator-preservation rows showing that the* PositiveUnaryDenominator *face remains in the DyadicRatCore carrier after each operation; and finite ledger provenance rows tying every requested operation to the dyadic observation ledger consumed by the* RegSeqRat *regularity check. These are obligations for formal proof targets over the existing RatUp, StreamNameUp,* BHist*,* hsame*, and dyadic ledger interfaces; they do not assert arithmetic laws beyond that certificate inventory.*

Proof. Read every operation input as a DyadicRatCore observation row using Definition 38.227. This exposes the RatUp carrier, the positive denominator row, and the dyadic-radius token at each endpoint.

The operation row is then a finite BEDC request over the same endpoint histories. RatUp supplies the rational endpoint operation, StreamNameUp keeps the requested stream observation

name stable, and the dyadic ledger records the finite observation request consumed downstream by RegSeqRat.

Classifier congruence is the same transport pattern used for the carrier and classifier boundary. The RatHistoryClassifier comparison and hsame denominator transport carry equivalent inputs to the corresponding operation outputs, while denominator preservation keeps the result inside the DyadicRatCore observation-row format. □

Theorem 38.230 (DyadicRatCore radius, distance, and absolute-value obligations)**.** *The monotone dyadic-radius, distance, and absolute-value obligations for DyadicRatCore are the certificate rows consumed by* RegSeqRat *regularity and by the* $\mathsf{Real}^{\uparrow}$ *sealing boundary. The radius obligation states that strengthening a finite dyadic-radius request preserves the same RatUp endpoint carrier and transports only the ledger token. The distance obligation states that dyadic endpoint distance is read from two* DyadicRatCoreObservationRow *inputs, is stable under* RatHistoryClassifier *and* hsame *transport, and records its output in the same finite ledger. The absolute-value obligation is the unary instance of the same pattern: it reads one endpoint row, preserves positive-denominator and classifier compatibility, and exposes the output row required by the* RegSeqRat *regularity spine before* $\mathsf{Real}^{\uparrow}$ *sealing.*

Proof. Begin with the carrier and classifier package of Definition 38.227. It gives the endpoint rows and their RatHistoryClassifier transport inside BHist and hsame.

For radius monotonicity, refine the finite dyadic request in the ledger. The RatUp endpoint carrier and the positive-denominator face remain fixed, while the dyadic-radius token is replaced by the stronger certified request used by the RegSeqRat regularity spine.

For distance and absolute value, use the same operation-row shape as in Definition 38.229. The binary distance row and the unary absolute-value row read only DyadicRatCore carrier data, preserve classifier compatibility under hsame, and expose exactly the finite output rows consumed by the RealUp sealing interface. □

Theorem 38.231 (DyadicRatCore finite observation obligation package)**.** *A finite DyadicRatCore observation package over a certified unary request is exactly the conjunction of the carrier and classifier face, the arithmetic operation face, and the monotone-radius face already displayed in this inventory. Its first component is the* DyadicRatCoreObservationRow *carrier and classifier boundary of Definition 38.227. Its second component is the finite dyadic addition, negation, subtraction, multiplication, and positive-denominator division rows of Definition 38.229. Its third component is the monotone dyadic-radius, dyadic-distance, and absolute-value surface of Definition 38.230. All three components are read over the same* BHist *endpoints,* $\mathsf{Rat}^{\uparrow}$ *carrier rows,* $\mathsf{StreamName}^{\uparrow}$ *request name,* RegSeqRat *regularity ledger,* hsame *transport, and finite observation ledger data. The package has no coordinate for quotient carriers, completion objects, metric completeness, Classical data, or standard bridges.*

Proof. Project a candidate finite observation package to its carrier/classifier coordinate. By Definition 38.227, this coordinate is precisely the DyadicRatCoreObservationRow face over the RatUp endpoint, positive denominator, dyadic-radius token, BHist history, and hsame comparison rows.

Project the same package to its operation coordinate. By Definition 38.229, the only operation rows present are the finite dyadic arithmetic rows whose endpoints, classifier transports, denominator preservation, $\mathsf{StreamName}^{\uparrow}$ request name, and RegSeqRat ledger are the rows already exposed by the first coordinate.

Project the radius-distance coordinate. By Definition 38.230, this coordinate contains only monotone-radius refinement, dyadic distance, and absolute-value rows over the same finite ledger and the same endpoint classifier transport.

Conversely, given those three faces over the same histories, carriers, request name, regularity ledger, hsame transport, and finite observation ledger, repack them as the DyadicRatCore observation package. The repacking has no constructor input for a host quotient carrier, completion object, metric completeness witness, Classical datum, or standard bridge, so none of those objects is exported to RegSeqRat or $\mathsf{Real}^{\uparrow}$. □

Theorem 38.232 (DyadicRatCore distance obligation)**.** *For endpoints d, e : Hist, the DyadicRatCore distance obligation is the finite certificate package consisting of two* DyadicRatCoreObservationRow *witnesses, the displayed* RatHistoryClassifier(d, e) *face, the positive-denominator transports for both endpoints, and the dyadic-radius ledger token used by the* RegSeqRat *regularity request. Under* hsame *transport of both endpoints, the same package transports endpointwise to the corresponding target endpoints.*

Proof. Unpack Definition 38.219. Each endpoint row gives the rational-history carrier, the positive unary denominator, and the dyadic-radius token attached to a certified unary observation ledger entry.

The finite source of these rows is the scoped package of Definition 38.221. Its classifier face is the displayed RatHistoryClassifier(d, e) row, and its endpoint rows are exactly the two observation-row witnesses used by the distance request.

Transport the classifier face with Definition 38.220. Transport each endpoint row with Definition 38.223; the positive-denominator components are carried endpointwise by the same rows.

The dyadic-radius ledger token remains the certified token already recorded by the RegSeqRat regularity request. Thus the transported endpoint rows, transported classifier face, positive-denominator transports, and unchanged ledger token repack as the transported distance-obligation package, with no quotient or completion datum read. □

Theorem 38.233 (DyadicRatCore absolute-value obligation)**.** *For an endpoint d : Hist, the DyadicRatCore absolute-value obligation is the unary-radius face obtained from a single* DyadicRatCoreObservationRow(d). *It preserves the* PositiveUnaryDenominator(d) *component, records the same dyadic-radius request, and is stable under the* hsame *transport supplied by the scoped source package.*

Proof. Project the carrier, positive-denominator, and dyadic-radius components from Definition 38.219. These three projections are the unary-radius face consumed by the absolute-value request.

The positive-denominator component transports along Definition 37.6. The whole observation row transports along Definition 38.223, so the carrier and dyadic-radius components remain aligned with the transported endpoint.

Repack the transported row as the absolute-value obligation face. The scoped source package of Definition 38.221 supplies the hsame transport used here, and no additional arithmetic, quotient, or completion datum is introduced. □

Theorem 38.234 (DyadicRatCore positive-denominator boundary)**.** *For an endpoint d : Hist carrying* DyadicRatCoreObservationRow(d)*, the positive-denominator component supplies* UnaryHistory(d) *and excludes the endpoint shapes d*hsame*e, d*hsameE0(t)*, and d*hsameappend$(u, \mathsf{E0}(t))$ *for all histories u, t : Hist. If d*hsame*e is a displayed classifier endpoint transport, then the transported endpoint e carries the same unary-history witness and the same exclusions against* e*,* E0(t)*, and* append$(u, \mathsf{E0}(t))$*.*

Proof. Unpack Definition 38.219. Its denominator projection is the PositiveUnaryDenominator(d) row, so Definition 37.12 gives both the unary-history witness and the exclusion of $d$hsame*e*.

The zero-extension exclusion is exactly Definition 37.10 applied to the projected positive-denominator row. The appended zero-tail exclusion is Definition 37.15; composing a display $d\mathsf{hsameappend}(u, \mathsf{E0}(t))$ with denominator transport would produce the forbidden positive-denominator witness at the appended zero-tail.

Now let $d\mathsf{hsame}e$ be the displayed classifier transport. Transport the positive-denominator row along Definition 37.6, or equivalently transport the whole observation row along Definition 38.223 and project its denominator component. The three RatUp no-confusion facts applied at e give the same exclusions for the classified endpoint, and the result repacks as the DyadicRatCore endpoint-shape boundary. □

Theorem 38.235 (DyadicRatCore carrier obligation)**.** *The carrier obligation for DyadicRatCore is the ten-field certificate boundary whose traditional target is dyadic rational endpoint observation; whose BEDC source is* $\mathsf{Rat}^{\uparrow}$ *endpoint histories together with* PositiveUnaryDenominator *and the* RegSeqRat *dyadic-radius token; whose carrier is the DyadicRatCore observation row of Definition 38.219; whose classifier is* RatHistoryClassifier *together with* hsame *transport of the denominator row; whose stability face is inherited from the* $\mathsf{Rat}^{\uparrow}$ *endpoint carrier laws and the* RegSeqRat *carrier obligation; whose ledger is the finite dyadic-tolerance request already recorded in the stream spine; whose core theorem is the scoped source package of Definition 38.221; whose exactness clause states that no carrier datum outside the observation row is read; whose standard bridge is the finite RealUp observation window; and whose status is* ProofTarget*.*

Proof. Unpack the scoped source package in Definition 38.221. Its endpoint source is exactly a $\mathsf{Rat}^{\uparrow}$ history observation equipped with the positive unary denominator row and the dyadic-radius token from the certified RegSeqRat request.

Apply Definition 38.214. It supplies the endpoint RatHistoryCarrier row and the finite dyadic-tolerance ledger entry. The denominator component is the RatUp positive-denominator transport face already used by the scoped source package.

The FKernel and Cont unary context laws keep the request name and its finite ledger position fixed while the endpoint history is read. Thus the carrier face is precisely the existing DyadicRatCore observation row, with no extra completion or quotient object. □

Theorem 38.236 (DyadicRatCore classifier obligation)**.** *The classifier obligation for DyadicRatCore is the ten-field certificate boundary whose traditional target is dyadic endpoint comparison; whose BEDC source is the pair of* $\mathsf{Rat}^{\uparrow}$ *endpoint histories read from certified* RegSeqRat *unary observations; whose carrier is the pair of DyadicRatCore observation rows; whose classifier is* RatHistoryClassifier *plus* hsame *transport of* PositiveUnaryDenominator*; whose stability face is the endpointwise classifier transport of* RegSeqRat*; whose ledger is the same finite dyadic-tolerance request on both endpoints; whose core theorem is Definition 38.220; whose exactness clause says that the transported row is repacked from the same carrier, denominator, and token fields; whose standard bridge is the finite RealUp comparison window; and whose status is* ProofTarget*.*

Proof. Start from the classifier face named in Definition 38.221. The only comparison row there is RatHistoryClassifier on the endpoint histories.

Apply Definition 38.215. It recovers the pointwise endpoint comparison from the stream classifier and supplies the same certified unary observation positions on the two streams.

Positive-denominator transport carries the denominator rows along the hsame comparisons, and the FKernel unary context laws keep the finite dyadic request attached to the same observation name. Therefore Definition 38.220 repacks the transported endpoint data as the stated classifier obligation. □

Theorem 38.237 (DyadicRatCore arithmetic-stability obligation)**.** *The arithmetic-stability obligation for DyadicRatCore is the ten-field certificate boundary whose traditional target is closure of dyadic endpoint arithmetic under the rational endpoint interface; whose BEDC source is the* $\mathsf{Rat}^{\uparrow}$ *endpoint histories carrying* PositiveUnaryDenominator *rows and the* RegSeqRat *dyadic-radius token; whose carrier is the DyadicRatCore observation row for each arithmetic input and output endpoint; whose classifier is* RatHistoryClassifier *transported along* hsame*; whose stability face is the RatUp arithmetic context read through FKernel and* Cont *unary laws; whose ledger is the finite dyadic-tolerance request used by the stream regularity check; whose core theorem is Definition 38.221; whose exactness clause says that arithmetic stability uses only endpoint carrier rows, denominator transport, and the dyadic token; whose standard bridge is the finite RealUp arithmetic observation window; and whose status is* ProofTarget*.*

Proof. Read the arithmetic inputs through Definition 38.235. Each input endpoint exposes a rational-history carrier, a positive unary denominator row, and the dyadic-radius ledger token.

The RatUp arithmetic context supplies the endpoint rational operation inside the FKernel unary context. The Cont laws keep the requested unary observation name stable, so the output endpoint is recorded in the same finite dyadic-tolerance ledger format used by Definition 38.214.

Classifier compatibility is supplied by Definition 38.236. Its RatHistoryClassifier row and positive-denominator transport ensure that replacing any input by an hsame endpoint replaces the output by the corresponding transported DyadicRatCore row. □

Theorem 38.238 (DyadicRatCore monotone-radius obligation)**.** *The monotone-radius obligation for DyadicRatCore is the ten-field certificate boundary whose traditional target is preservation of certified dyadic tolerance when a requested unary radius is made stronger; whose BEDC source is the* $\mathsf{Rat}^{\uparrow}$ *endpoint history, the* PositiveUnaryDenominator *row, and the* RegSeqRat *dyadic-radius token; whose carrier is the DyadicRatCore observation row at the endpoint; whose classifier is* RatHistoryClassifier *with* hsame *denominator transport; whose stability face is the FKernel monotonicity of finite unary requests inside the* Cont *context; whose ledger is the finite dyadic-tolerance request ordered by the unary observation radius; whose core theorem is Definition 38.221; whose exactness clause says that strengthening the radius refines only the ledger token and not the endpoint carrier; whose standard bridge is the finite RealUp observation window; and whose status is* ProofTarget*.*

Proof. Begin with the endpoint row supplied by Definition 38.235. Its dyadic-radius token is a finite ledger entry of the RegSeqRat regularity spine, not an independent metric object.

Apply the FKernel finite-request monotonicity inside the Cont unary context. A stronger unary radius refines the same certified observation request and therefore preserves the endpoint $\mathsf{Rat}^{\uparrow}$ carrier and the positive-denominator row.

The classifier side is unchanged by the refinement. If the endpoint is moved along hsame, Definition 38.236 transports the carrier and denominator fields, while the refined dyadic token remains in the same finite ledger family. □

Theorem 38.239 (DyadicRatCore radius-token refinement stability)**.** *Let* $d : \mathsf{Hist}$ *be an endpoint carrying* DyadicRatCoreObservationRow(d)*. If a stronger certified dyadic-radius request refines the ledger token already attached to this row, then the refined request repacks as a* DyadicRatCoreObservationRow(d) *with the same* RatHistoryCarrier(d)*, the same* PositiveUnaryDenominator(d)*, and the same classifier transport behavior under* hsame*. The construction reads no quotient, completion, metric-completeness, or standard-bridge datum.*

Proof. Project the carrier, positive-denominator, and dyadic-radius token fields from Definition 38.219. The first two fields are endpoint data of the original row, while the third field is the finite ledger token that the stronger certified dyadic-radius request refines.

Use Definition 38.230 for radius monotonicity. It changes only the dyadic-radius ledger token: the endpoint $\mathsf{Rat}^{\uparrow}$ carrier and the positive-denominator row remain the source row already projected from $\mathsf{DyadicRatCoreObservationRow}(d)$.

For endpoint transport, apply Definition 38.223 to the whole row and Definition 37.6 to the denominator component. These two transport facts keep the classifier behavior under hsame aligned with the original source row.

Repack the refined dyadic-radius token with the unchanged carrier and denominator fields. The resulting package is again a $\mathsf{DyadicRatCoreObservationRow}(d)$ because its three defining fields are exactly the fields required by Definition 38.219. □

This fit is the local ten-field boundary for dyadic-radius strengthening: DyadicRatCore is the certificate surface, $\mathsf{Rat}^{\uparrow}$ supplies the endpoint carrier, RegSeqRat supplies the finite dyadic ledger, BHist is the endpoint history carrier, hsame is the only endpoint transport relation, the request name remains in the same unary context, the denominator witness is the same positive-unary row, the classifier face is the transported Rat history comparison, the exactness clause forbids quotient or completion data, and the downstream $\mathsf{Real}^{\uparrow}$ finite-window seal consumes the refined row without rebuilding carrier evidence.

Theorem 38.240 (DyadicRatCore distance and absolute-value obligation)**.** *The distance and absolute-value obligation for DyadicRatCore is the ten-field certificate boundary whose traditional target is endpoint stability of dyadic distance and absolute value; whose BEDC source is the pair of* $\mathsf{Rat}^{\uparrow}$ *endpoint histories with* PositiveUnaryDenominator *rows and the* RegSeqRat *dyadic-radius token; whose carrier is the DyadicRatCore observation row for each endpoint and for the distance or absolute-value output; whose classifier is* RatHistoryClassifier *transported by* hsame *with denominator transport; whose stability face is the RatUp unary context law for distance and absolute value inside FKernel and* Cont*; whose ledger is the finite dyadic-tolerance request; whose core theorem is Definition 38.221; whose exactness clause says that distance and absolute value read only the carrier row, classifier row, denominator transport, and dyadic token; whose standard bridge is the finite RealUp metric observation window; and whose status is* ProofTarget*.*

Proof. Use Definition 38.235 to expose the endpoint rows for the inputs. The RatUp source gives the rational-history carriers and positive-denominator rows, while the RegSeqRat spine gives the finite dyadic-tolerance token.

The FKernel and Cont unary context laws read distance and absolute value at the same certified observation level. Their output rows therefore have the same DyadicRatCore shape: rational endpoint carrier, positive denominator, and the requested dyadic-radius token.

For stability, apply Definition 38.236. The RatHistoryClassifier comparison and denominator transport carry input replacement along hsame, and the finite ledger token is preserved by Definition 38.238 when the metric request is read at a stronger unary radius. □

Theorem 38.241 (DyadicRatCore operation-stability obligation)**.** *The DyadicRatCore source exposes addition, negation, and multiplication operation-stability only as* RegSeqRat *ledger-preserving transformations over endpoints carrying DyadicRatCore observation rows. Concretely, if the endpoint histories supplied to one of these operations carry* DyadicRatCoreObservationRow *packages, then the resulting endpoint row is again a* DyadicRatCoreObservationRow *package whose carrier and classifier faces are read through* RatHistoryClassifier *transport and whose positive denominator face*

is transported through PositiveUnaryDenominator*. The operation row preserves the recorded dyadic-radius token of the* RegSeqRat *ledger; it does not introduce quotient, completion, or external metric data.*

Proof. Unpack the scoped source package of Definition 38.221. Its carrier face is the rational-history endpoint row together with the positive-denominator row and the dyadic-radius token recorded in the RegSeqRat ledger.

The operation rows are therefore read at the level of endpoint histories. Apply the RatHistoryClassifier transport face described in Definition 38.220 to carry the rational carrier and classifier data through the addition, negation, or multiplication row.

The denominator component is carried by Definition 37.6. Since the operation stays inside the same certified unary observation request, the dyadic-radius token remains the ledger token already recorded by Definition 38.221.

Repack the transported carrier, classifier, denominator, and ledger token as a DyadicRatCore observation row. The construction uses only the RegSeqRat spine and the RatUp endpoint transport, so no quotient or completion datum is part of the obligation. □

Theorem 38.242 (DyadicRatCore radius monotonicity obligation)**.** *The DyadicRatCore dyadic-radius ledger is ordered by certified* UnaryHistory *refinement. If a certified request in a* RegSeqRat *spine is refined to a stronger unary request, then the refined request keeps the endpoint* DyadicRatCoreObservationRow *visible, with the same RatUp carrier face, the transported positive-denominator face, and the refined dyadic-radius token recorded in the finite ledger bundle.*

Proof. Start from the finite ledger extraction theorem Definition 38.247. It extracts a DyadicRatCore observation row at each certified unary request of a finite RegSeqRat ledger bundle.

For the refined request, use the same finite-bundle induction. The empty bundle has no endpoint row. In the cons step, compare the displayed request with the refined request: the matching head request supplies the endpoint row, and the tail case is handled by the induction hypothesis.

The refined request is then repacked under the scoped source package of Definition 38.221. The carrier and classifier faces are unchanged RatUp endpoint faces, while Definition 37.6 carries the positive-denominator row along the same hsame transport.

The monotone radius claim is exactly the persistence of the dyadic-radius token inside this refined finite ledger. Thus every refined certified unary request still exposes a DyadicRatCore observation row at the endpoint. □

Definition 38.243 (DyadicRatCore radius monotone window packet)**.** *A DyadicRatCore radius monotone window packet is a finite* BHist *window in a* RegSeqRat *spine whose entries are certified* UnaryHistory *requests together with their endpoint* DyadicRatCoreObservationRow *rows, their* PositiveUnaryDenominator *rows, the pointwise* hsame *transports between matching request endpoints, and the* RegSeqRat *ledger token recording the dyadic-radius bound for the window. The packet contains only the RatUp carrier face, the visible denominator rows, the request-order refinement rows, and the ledger provenance needed by the finite completion seal.*

Theorem 38.244 (DyadicRatCore radius window transport)**.** *Let W be a DyadicRatCore radius monotone window packet. If every certified unary request in W is transported pointwise along* hsame *to a request with the same* RegSeqRat *ledger position, then the transported window is again a DyadicRatCore radius monotone window packet. The endpoint* DyadicRatCoreObservationRow*, positive-denominator row, and dyadic-radius ledger token are carried componentwise by the classifier transport for the RatUp endpoint and by the denominator transport.*

Proof. Induct over the finite BHist window. The empty window has no endpoint rows and transports to the empty packet.

In the cons step, apply Definition 38.220 to the head observation row and Definition 37.6 to the head denominator row. The pointwise request transport preserves the displayed ledger position, so the dyadic-radius token is the transported head token.

The induction hypothesis transports the tail packet. Repacking the transported head with the transported tail gives a finite window with the same carrier, denominator, request-order, and ledger fields as Definition 38.243. □

Theorem 38.245 (DyadicRatCore radius window RegSeqRat consumer)**.** *The packet of Definition 38.243 is exactly the finite-window DyadicRatCore face consumed by the* RegSeqRat-*to*-Real$^{\uparrow}$ *seal: a consumer may read the certified unary requests, RatUp endpoint observation rows, positive-denominator rows, pointwise* hsame *transports, and the dyadic-radius ledger token, and it may not read a quotient completion object or an ambient real-number equality from DyadicRatCore alone.*

Proof. Start from the finite ledger extraction theorem Definition 38.247. It exposes the same finite request rows and endpoint observation rows named in the packet definition.

Next use Definition 38.242 to identify the monotone dyadic-radius component under request refinement. The window transport theorem above shows that the same face is stable under the pointwise hsame transport used by downstream stream consumers.

Finally compare the fields with the RegSeqRat finite ledger bundle. The only exported rows are the request window, endpoint observation rows, denominator rows, classifier transports, and radius ledger token. Since none of these fields is a quotient completion object, the finite-window seal reads exactly the displayed packet and nothing outside it. □

Theorem 38.246 (RegSeqRat dyadic observation coverage)**.** *Let s : Hist $\to$ Hist carry a* RegSeqRat *stream certificate spine, and let n be a certified* UnaryHistory *observation index of that spine. Then the exposed endpoint $s(n)$ has a DyadicRatCore observation row in the sense of Definition 38.219. Moreover, if a stream classifier is transported pointwise along* hsame *to a target endpoint $s'(n)$, then the same pointwise transport carries this DyadicRatCore observation row to $s'(n)$.*

Proof. Unfold Definition 38.195. At the certified observation index n, Definition 38.214 supplies the endpoint RatHistoryCarrier($s(n)$) row and the dyadic-tolerance witness recorded in the regularity ledger.

The positive-denominator component is read from the RatUp carrier interface: Definition 37.19 converts the endpoint carrier row into PositiveUnaryDenominator($s(n)$). These three pieces are exactly the DyadicRatCore observation row of Definition 38.219.

For the transported endpoint, apply Definition 38.215 to recover the pointwise RatHistoryClassifier row carried by the stream classifier. Its hsame comparison transports the endpoint carrier/classifier face through the existing RatHistoryClassifier transport, and Definition 37.6 transports the positive-denominator row to $s'(n)$.

The dyadic-radius token is attached to the same certified observation request in the spine ledger, so no additional completion or quotient datum is needed. Thus the transported package is again a DyadicRatCore observation row. □

Theorem 38.247 (DyadicRatCore observation row finite-ledger extraction)**.** *Let s : Hist $\to$ Hist carry a* RegSeqRat *stream certificate spine. For every finite BEDC ledger bundle L of certified* UnaryHistory *observation requests in that spine, there is a finite family indexed by the entries $n \in L$ whose n-th member is a* DyadicRatCoreObservationRow($s(n)$) *in the sense of Definition 38.219. This*

family is read from the DyadicRatCore scoped source package of Definition 38.221; its carrier and classifier faces are precisely the RegSeqRat *carrier and classifier obligations of Definition 38.214 and Definition 38.215.*

Moreover, if a stream classifier transports the spine pointwise to a target stream $s' : \mathsf{Hist} \to \mathsf{Hist}$*, then the same finite family transports endpointwise: for each certified request* $n \in L$*, the transported endpoint row is a* $\mathsf{DyadicRatCoreObservationRow}(s'(n))$*.*

Proof. Induct on the finite ledger bundle L. The empty bundle has no certified observation entry, so the indexed family and its transported endpoint family are empty.

For a cons bundle, write the displayed head request as the certified UnaryHistory observation index n and write L' for the remaining finite bundle. Apply Definition 38.246 to the head request in the RegSeqRat spine. It supplies the row $\mathsf{DyadicRatCoreObservationRow}(s(n))$ by unpacking Definition 38.219, with the carrier datum supplied by Definition 38.214 and the classifier transport datum supplied by Definition 38.215.

The source package identification in Definition 38.221 says that no additional ledger face is used beyond these certified unary observation entries. Therefore the tail induction hypothesis extracts the finite family over L' from the same spine and transports it along the same pointwise classifier.

Adjoin the head row to the tail family. The transported head row is provided by the transported clause of Definition 38.246, and the transported tail is the induction hypothesis. Hence the cons bundle extracts and transports the claimed finite family endpointwise. □

Theorem 38.248 (RegSeqRat observation ledger dyadic endpoint coverage)**.** *Let* $s : \mathsf{Hist} \to \mathsf{Hist}$ *carry a* RegSeqRat *stream certificate spine, and let* L *be a finite BEDC ledger bundle of certified unary* RegSeqRat *observations. Every dyadic endpoint row visible to a downstream* $\mathsf{Real}^{\uparrow}$ *finite-window consumer is one of the rows extracted by Definition 38.247, transported endpointwise along the same pointwise classifier.*

Equivalently, the consumer-visible endpoint surface is exhausted by the finite family of DyadicRatCoreObservation *rows indexed by certified entries* $n \in L$*, together with their pointwise transported endpoint rows. No hidden selector, quotient representative, completion object, or host index can produce an additional dyadic endpoint row.*

Proof. Induct on the finite ledger bundle L. The empty bundle has no certified unary observation entry, so a downstream finite-window consumer has no dyadic endpoint row to read from that ledger.

For a cons bundle, write the head request as n and the tail as L'. Apply Definition 38.246 to the head. It gives the visible $\mathsf{DyadicRatCoreObservationRow}(s(n))$ and its pointwise transported endpoint row.

Apply Definition 38.247 to the tail ledger L'. The induction hypothesis says every endpoint row visible from L' is already in the extracted tail family and transported along the same pointwise classifier.

Adjoin the head row to the extracted tail family. Carrier projection leaves no projection for a hidden selector, quotient representative, completion object, or host index, so the displayed finite family exhausts the downstream consumer-visible dyadic endpoint rows. □

Theorem 38.249 (RegSeqRat constant and transport obligation)**.** *The constant and transport obligations for* RegSeqRat *are the inhabitation of the constant rational-observation stream and pointwise* hsame *transport of stream classifiers. For every* $d : \mathsf{Hist}$ *with* $\mathsf{RatHistoryCarrier}(d)$*,* $\mathsf{RatConstStream}_d$ *carries a* RegSeqRat *spine. If* s, t *are classified streams and* s', t' *are pointwise*

hsame *transports over certified unary observations, then the transported stream-name classifier* RatStreamNameClassifier(s', t') *is part of the same obligation set.*

Proof. Definition 38.195 identifies the constant case as a spine over a stream-name carrier plus a regularity ledger. Apply Definition 38.205 to the supplied RatHistoryCarrier(d); the resulting ledger is constant at every certified unary observation.

For transport, apply Definition 38.208 to the two endpoint hsame rows. It supplies the transported pointwise $\mathsf{Rat}^{\uparrow}$ classifiers and repackages them as RatStreamNameClassifier(s', t').

The scoped package Definition 38.210 places the constant and transport clauses in one certificate package, and Definition 38.209 shows that these clauses are sufficient for the downstream RealUp seal to consume the stream classifier. □

Theorem 38.250 (RegSeqRat public rational-stream interface)**.** *A* RegSeqRat *public rational-stream interface is exactly the package formed from Definition 38.246, Definition 38.247, Definition 38.249, Definition 38.276, and Definition 38.254. Its public template has the following ten fields:*

1. *the traditional target is the regular rational Cauchy stream spine;*
2. *the BEDC source is DyadicRatCore plus StreamNameUp plus RatUp over* Hist*;*
3. *the carrier is the* RegSeqRat *stream certificate spine;*
4. *the classifier is the pointwise* RealUnaryStreamClassifier *and* RatStreamNameClassifier *row;*
5. *stability is the family of pointwise* hsame *transport rows;*
6. *the ledger consists of finite unary observation requests and dyadic-tolerance tokens;*
7. *the core theorem list is the five cited blocks above;*
8. *exactness says the RealUp seal consumes exactly those finite rows;*
9. *no standard bridge datum is part of the interface;*
10. *the status is a paper-side public interface target.*

Proof. Collect the five cited packages in the displayed order. The first package supplies DyadicRatCore observation coverage at each certified unary request, the second extracts finite ledger families from any selected observation bundle, and the third supplies the constant stream and pointwise transport obligations.

For every selected observation, use Definition 38.247. It turns the finite unary ledger entries and dyadic-tolerance tokens into endpoint DyadicRatCore rows, and its transported clause carries the same rows along the chosen pointwise hsame comparison.

Next use Definition 38.276. It supplies the stream-name interface, the classifier transport row, and the endpoint carrier rows needed to read the RealUnaryStreamClassifier and RatStreamNameClassifier components pointwise.

Finally apply Definition 38.254. The seal obligation identifies the data consumed by RealUp with the same finite observation rows already extracted from the RegSeqRat ledger. Therefore the package exposes the stated public rational-stream interface without quotient, completion, metric-completeness, arithmetic/order, Classical, or standard bridge data. □

Theorem 38.251 (RegSeqRat finite-window seal exactness)**.** *Let* s : Hist $\to$ Hist *carry a* RegSeqRat *rational-observation stream certificate spine, and let* $\mathcal{P}$: ProbeBundle *be a certified finite bundle of unary observation requests. The finite observation rows accepted by the* RegSeqRat-*to*-Real$^{\uparrow}$ *seal*

over $\mathcal{P}$ are exactly the union of the DyadicRatCore endpoint observation-row family extracted by Definition 38.247 and the $\mathsf{StreamName}^{\uparrow}$ *finite-window rows exposed by Definition 126.301.*

Equivalently, a finite window feeds the seal precisely when its carrier, classifier, pointwise stability, dyadic-ledger, and stream-name finite-window rows are present in the public rational-stream interface of Definition 38.250. This exactness claim does not introduce quotient carriers, completion objects, $\mathsf{Real}^{\uparrow}$ *completeness, metric completeness, Classical data, or standard bridge status.*

Proof. Expose the public rational-stream package by Definition 38.250. Its carrier, classifier, stability, ledger, and stream-name fields are the only rows made available to the downstream seal.

For the forward direction, take a row accepted by the seal over $\mathcal{P}$. Apply Definition 38.254 to read it as a finite unary observation request with the recorded dyadic-tolerance token and endpoint $\mathsf{Rat}^{\uparrow}$ data. Then apply Definition 38.247 endpointwise to place the endpoint datum in the DyadicRatCore observation-row family, and use Definition 126.301 to read the same request as a stream-name finite-window classifier row.

For the reverse direction, suppose the finite window carries the displayed DyadicRatCore endpoint family together with the $\mathsf{StreamName}^{\uparrow}$ finite-window interface rows. The public package supplies the corresponding carrier, classifier, pointwise stability, and dyadic-ledger fields, so Definition 38.254 gives the seal consumer for those rows.

Finally apply Definition 38.268. It identifies the finite-window source package consumed by the seal with exactly the same DyadicRatCore, dyadic-ledger, and $\mathsf{StreamName}^{\uparrow}$ rows, so no further quotient, completion, metric, Classical, $\mathsf{Real}^{\uparrow}$ completeness, or bridge data can enter the seal interface. □

Lean4 ✓ `BEDC.Derived.RealUp.RegseqratFiniteWindowSealExactness`

Theorem 38.252 (RegSeqRat finite-window seal overlap compatibility)**.** *Let s, t : $\mathsf{Hist} \to \mathsf{Hist}$ carry* RegSeqRat *rational-observation stream certificate spines. Let $\mathcal{P}, \mathcal{Q}$:* ProbeBundle *be certified finite observation windows, and let $\mathcal{R}$:* ProbeBundle *be a certified common sub-bundle of both $\mathcal{P}$ and $\mathcal{Q}$. Suppose the* RegSeqRat*-to-*$\mathsf{Real}^{\uparrow}$ *seal packages over $\mathcal{P}$ and $\mathcal{Q}$ agree after restriction to $\mathcal{R}$ on the StreamName finite-window classifier, the DyadicRatCore observation rows, the unary observation witnesses, and the dyadic ledger tokens.*

Then the two $\mathsf{Real}^{\uparrow}$ *seal readbacks restrict to the same consumer-facing package over $\mathcal{R}$. This common package contains only the finite-window classifier, the pointwise* RatHistoryClassifier *rows, the dyadic observation rows, the regularity ledger, and the* $\mathsf{Real}^{\uparrow}$ *observation classifier; it contains no completion object, quotient carrier, or host-index equality row.*

Proof. First restrict the two finite windows to the common sub-bundle $\mathcal{R}$. By Definition 126.178, the restricted StreamName handoff rows classify the same consumer-facing finite-window tuple over $\mathcal{R}$.

Now read each restricted seal with Definition 38.251. Each readback is therefore exhausted by the StreamName finite-window rows and the DyadicRatCore endpoint observation-row family over the same common bundle.

Identify the dyadic component through Definition 38.247. The assumed agreement of unary witnesses and dyadic ledger tokens gives the same endpoint observation rows on the two restricted packages.

Finally repack the identified rows using Definition 38.253. The resulting consumer-facing $\mathsf{Real}^{\uparrow}$ package over $\mathcal{R}$ is the same on both sides, and the cited exactness boundaries expose no completion, quotient, or host-index equality coordinate. □

Theorem 38.253 (Phase Real seal consumer exactness)**.** *Let s : Hist $\to$ Hist carry a* RegSeqRat *rational-observation stream spine, and let $\mathcal{P}$: ProbeBundle be a certified finite-window package. Every consumer-facing row of the* $\mathsf{Real}^{\uparrow}$ *seal over $\mathcal{P}$ factors through exactly four displayed surfaces: the DyadicRatCore endpoint observation family of Definition 38.219, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier rows, the* RegSeqRat *regularity ledger, and the* E1*-sealed* $\mathsf{Real}^{\uparrow}$ *observation row. Conversely, those four surfaces assemble the consumer-facing seal package for the same finite window.*

Thus the Phase Real seal consumer reads precisely the endpoint carrier, positive-denominator, dyadic-radius, stream-name finite-window, regularity ledger, and E1 *seal rows exposed by the certified spine. It does not read a quotient carrier, completion object, Classical choice row, metric-completeness row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. For a consumed seal row, first apply Definition 38.251. The row is therefore drawn from the DyadicRatCore endpoint family and the $\mathsf{StreamName}^{\uparrow}$ finite-window classifier rows in the same certified window.

The DyadicRatCore component is the observation family named by Definition 38.219 and scoped by Definition 38.221. The stream-name component is supplied by the public rational-stream interface of Definition 38.250, which also carries the RegSeqRat regularity ledger and the E1 seal row consumed by $\mathsf{Real}^{\uparrow}$.

For the converse direction, start with exactly those four surfaces over $\mathcal{P}$. The public rational-stream interface packages the endpoint carrier, classifier, stability, and regularity rows; the finite-window seal exactness theorem then assembles them as the consumer-facing $\mathsf{Real}^{\uparrow}$ seal package. Since every cited surface is part of this finite BEDC ledger, no quotient, completion, Classical, metric-completeness, or ambient completeness row can be consumed. □

Theorem 38.254 (RegSeqRat dyadic ledger and RealUp seal obligation)**.** *The dyadic-ledger and* $\mathsf{Real}^{\uparrow}$ *seal obligation for* RegSeqRat *consists of finite unary observation indices, the endpoint* $\mathsf{Rat}^{\uparrow}$ *rows read at those indices, the dyadic-tolerance witnesses used by regularity, and the seal export of the recorded* RealUnaryStreamClassifier *row. Whenever sealed* $\mathsf{Real}^{\uparrow}$ *candidates expose streams satisfying the* RegSeqRat *spine and record their stream comparison row, the seal exports the RealUp observation classifier required by Definition 38.9.*

Lean4 ✓ `BEDC.Derived.RealUp.RegSeqRatDyadicLedger real seal obligation`

Proof. Unfold Definition 38.195. Its ledger is finite at the level of requested unary observations and dyadic-tolerance checks, and each ledger entry is backed by endpoint $\mathsf{Rat}^{\uparrow}$ carrier and classifier rows.

The constant ledger is supplied by Definition 38.205. The general endpoint and transport rows are supplied by Definition 38.208, while Definition 38.210 gathers the ledger, classifier, constant, and transport faces as one scoped certificate package.

Finally apply Definition 38.209. The seal reads the already recorded RealUnaryStreamClassifier row and exports exactly the observation classifier required by the RealUp boundary, without adding quotient or completion data. □

Theorem 38.255 (DyadicRatCore obligation boundary package)**.** *The DyadicRatCore obligation boundary consists exactly of the carrier, classifier, arithmetic-stability, monotone-radius, distance and absolute-value, operation-stability, finite-ledger extraction, and* RegSeqRat *seal faces listed in this section. Its carrier face is Definition 38.235; its classifier face is Definition 38.236; its dyadic arithmetic face is Definition 38.237; its monotone-radius face is Definition 38.238; its distance and absolute-value face is Definition 38.240; its operation stability face is Definition 38.241; its finite ledger extraction face is Definition 38.247; and its downstream seal face is Definition 38.254.*

No face in this package reads a quotient, a completion object, Classical data, or an external metric primitive. Every named face is read from BHist*,* hsame*, RatUp endpoint histories, StreamNameUp request names, the DyadicRatCore observation row, and the finite dyadic ledger consumed by* RegSeqRat *and* $\mathsf{Real}^{\uparrow}$*.*

Proof. Read the carrier and classifier faces first. Apply Definition 38.235 and Definition 38.236. These identify the endpoint rows, their hsame transport, and the RatUp positive-denominator source used by the observation row.

Next read the stability inventory. Apply Definition 38.237, Definition 38.238, Definition 38.240, and Definition 38.241. Together they cover the dyadic arithmetic, radius refinement, distance, absolute-value, and operation rows without adding a separate metric carrier.

Finally read the ledger and seal faces. Apply Definition 38.247 for the finite family of endpoint rows, and apply Definition 38.254 for the RegSeqRat ledger consumed by the $\mathsf{Real}^{\uparrow}$ seal.

The cited theorem list exhausts the displayed boundary: each clause is one of the named faces above, and the proofs of those faces read only BHist, hsame, endpoint histories, request names, observation rows, and finite ledger entries. Hence the package has no quotient, completion object, Classical datum, or external metric primitive as an input. □

Theorem 38.256 (DyadicRatCore scoped primitive dependency package)**.** *Each DyadicRatCore obligation face in Definition 38.255 is scoped over exactly* BHist*,* hsame*, the* $\mathsf{Rat}^{\uparrow}$ *endpoint carrier and classifier rows,* PositiveUnaryDenominator*,* $\mathsf{StreamName}^{\uparrow}$ *unary request names, the DyadicRatCore observation row, and the finite dyadic ledger consumed by* RegSeqRat *and* $\mathsf{Real}^{\uparrow}$*. The carrier, classifier, arithmetic-stability, monotone-radius, distance and absolute-value, operation-stability, finite-ledger extraction, and* RegSeqRat *seal faces use no quotient, completion object, Classical datum, or external metric primitive.*

Proof. Start with the carrier and classifier faces. Apply Definition 38.235 and Definition 38.236. These faces read BHist endpoint histories, hsame transport, the $\mathsf{Rat}^{\uparrow}$ carrier and classifier rows, PositiveUnaryDenominator, and the DyadicRatCore observation row of Definition 38.219.

Next read the dyadic stability faces. Apply Definition 38.237, Definition 38.238, Definition 38.240, and Definition 38.241. Their operation inputs and outputs remain endpoint observation rows, while the radius, distance, and absolute-value clauses use only the positive-denominator and dyadic-radius ledger tokens already present in the scoped source package of Definition 38.221.

The finite-ledger face is supplied by Definition 38.247. It uses $\mathsf{StreamName}^{\uparrow}$ unary request names only to select finitely many endpoint observations, then exposes the same DyadicRatCore observation rows and dyadic ledger entries at those selected names.

Finally apply Definition 38.254. The RegSeqRat seal consumes the recorded stream spine and the finite dyadic ledger exported by the previous faces; the $\mathsf{Real}^{\uparrow}$ observation classifier is therefore read from the existing RealUnaryStreamClassifier row.

These four readings exhaust the face list of Definition 38.255. Every dependency is either a primitive BEDC history, an hsame transport, a $\mathsf{Rat}^{\uparrow}$ endpoint row, a unary request name, an observation-row field, or a finite ledger entry already licensed by the cited face theorem. No cited face introduces a quotient, completion object, Classical datum, or external metric primitive. □

Theorem 38.257 (DyadicRatCore scoped closure boundary)**.** *Every DyadicRatCore obligation face is scoped over RatUp endpoint histories,* PositiveUnaryDenominator*,* RegSeqRat *unary observation requests,* UnaryHistory*,* hsame *transport,* Cont*/FKernel unary context laws,* DyadicRatCoreObservationRow*, and the finite dyadic ledger consumed by the* RegSeqRat *seal. No quotient, completion object, Classical data, external metric primitive,* $\mathsf{Real}^{\uparrow}$ *completeness, or standard bridge is part of this scope.*

Proof. Begin with the scoped source package Definition 38.221. It supplies the RatUp endpoint histories, the PositiveUnaryDenominator rows, the observation row, and the dyadic-radius token used by the later ledger.

Next enumerate the obligation faces. Apply Definition 38.235, Definition 38.236, Definition 38.241, Definition 38.238, and Definition 38.240. These faces read only the endpoint rows, UnaryHistory request names, hsame transport, and the Cont/FKernel unary context laws.

Finally read the finite ledger and downstream seal. Apply Definition 38.247 to extract the finite dyadic ledger from the observation row, and apply Definition 38.254 to show that the RegSeqRat seal consumes exactly that finite ledger.

The preceding list exhausts the named faces of Definition 38.255. Since each face has already been bound to the displayed primitive dependency chain, the scoped boundary contains no quotient, completion object, Classical datum, external metric primitive, $\mathsf{Real}^{\uparrow}$ completeness claim, or standard bridge. □

Theorem 38.258 (DyadicRatCore public observation package)**.** *The public DyadicRatCore package exports exactly the observation-row carrier, classifier, arithmetic-stability, monotone-radius, distance and absolute-value, operation-stability, finite-ledger extraction, and* RegSeqRat *seal faces of Definition 38.255. Its primitive scope is fixed by Definition 38.256 and Definition 38.257. Thus the public package has no quotient, completion object, Classical datum, external metric primitive,* $\mathsf{Real}^{\uparrow}$ *completeness claim, or standard bridge.*

Proof. First read the face inventory from Definition 38.255. It lists the carrier, classifier, arithmetic-stability, monotone-radius, distance and absolute-value, operation-stability, finite-ledger extraction, and RegSeqRat seal faces as the whole DyadicRatCore boundary.

Next read the primitive dependency boundary from Definition 38.256. That theorem binds every listed face to BHist, hsame, the $\mathsf{Rat}^{\uparrow}$ endpoint rows, PositiveUnaryDenominator, $\mathsf{StreamName}^{\uparrow}$ request names, the DyadicRatCore observation row, and the finite dyadic ledger consumed by RegSeqRat and $\mathsf{Real}^{\uparrow}$.

Finally apply Definition 38.257. Since the public observation package exports only the already listed faces over the already fixed primitive scope, it carries no quotient, completion object, Classical datum, external metric primitive, $\mathsf{Real}^{\uparrow}$ completeness claim, or standard bridge. □

Theorem 38.259 (DyadicRatCore public observation hsame transport)**.** *Let* $d, d' : \mathsf{Hist}$*. If* $\mathsf{hsame}(d, d')$ *holds and* d *carries the public DyadicRatCore observation package of Definition 38.258, then the same public package supplies the transported DyadicRatCore observation row at* d'*. The transported row has the* hsame*-transported RatUp carrier face, the* hsame*-transported positive-denominator face, the same certified dyadic ledger entry, and the same no-quotient, no-Classical, no-completion boundary fixed by Definition 38.256 and Definition 38.257.*

Proof. First read the public export surface from Definition 38.258. It exposes only the DyadicRatCore observation-row carrier, classifier, stability, arithmetic, ledger, and seal faces over the scoped primitive package.

Next apply Definition 38.223 to the observation row at d and the comparison $\mathsf{hsame}(d, d')$. This transports the RatUp carrier component and the positive-denominator component to d', while keeping the certified dyadic ledger entry attached to the same RegSeqRat spine.

Finally read the primitive and closure boundaries from Definition 38.256 and Definition 38.257. Because the transport uses only the exported public faces and the already named ledger entry, the transported row inherits the same finite dyadic ledger and introduces no quotient, completion

object, Classical datum, external metric primitive, $\mathsf{Real}^{\uparrow}$ completeness claim, or standard bridge. □

Lean4 ✓ `BEDC.Derived.RealUp.DyadicRatCoreObservationRow public hsame transport`

Theorem 38.260 (Dyadic common-exponent radius monotone)**.** *Let d_0, d_1 : Hist be two public DyadicRatCore observation rows whose endpoints are RatUp rows over positive unary denominators. Then there is a shared finite* BHist *denominator and radius ledger for the pair. Its endpoint reads are obtained by RatUp transport,* hsame *comparison, and* Cont *computation rows, and its common radius is no larger than either displayed input radius in the monotone-radius face of Definition 38.255. The construction uses only the scoped DyadicRatCore source package of Definition 38.256 and the finite-ledger extraction face already exported there.*

Proof. Read the two observation rows through Definition 38.255. Each row supplies a RatUp endpoint, a positive unary denominator, the monotone-radius face, and a finite dyadic ledger entry.

Use the scoped primitive package of Definition 38.256 to compare the two denominator histories in BHist. The hsame and Cont rows give the finite denominator readback needed to place both endpoints over a single displayed exponent ledger.

Finally apply the monotone-radius obligation and the finite-ledger extraction face. They select the common displayed radius inside the existing DyadicRatCore ledger and certify that this radius is bounded by the two input radii, with no quotient, completion object, Classical datum, or external metric primitive. □

Theorem 38.261 (Dyadic window denominator common refinement)**.** *For any finite RealUp observation window whose entries are public DyadicRatCore observation rows, every displayed dyadic row can be replaced by the shared-denominator refinement of Definition 38.260. The resulting finite window has the same public observation package: the RatUp endpoint rows, positive-denominator witnesses,* hsame *transports,* Cont *computations, monotone-radius rows, finite dyadic ledger entries, and scoped boundary from Definition 38.257 are all retained as displayed* BHist *data.*

Proof. Proceed through the finite RealUp window ledger entry by entry. For a singleton entry, the displayed denominator is already a common denominator for that entry, and the public observation package is unchanged.

For the next displayed row, apply Definition 38.260 to the current common ledger and the incoming row. This produces a refined common denominator and a radius bounded by the two displayed radii, while transporting the RatUp endpoint rows and positive-denominator witnesses through the same hsame and Cont rows.

The finite-ledger extraction face then repacks the refined rows into the same public DyadicRatCore observation package. Since the package fields are the carrier, classifier, stability, monotone-radius, and finite-ledger rows already listed in Definition 38.255, replacing each row by its refinement changes no public observation boundary. □

Theorem 38.262 (RegSeqRat dyadic common-radius seal)**.** *The* RegSeqRat *seal consumes exactly the refined finite dyadic ledger of Definition 38.261. From that ledger it exports the same RealUp finite-window input as Definition 38.264: carried RatUp endpoints, positive unary denominators, common-radius rows,* hsame *and* Cont *provenance, and the scoped DyadicRatCore boundary fixed by Definition 38.256.*

Proof. First build the common finite ledger by Definition 38.261. The ledger already contains the displayed endpoints, denominator histories, radius comparisons, and transport rows over BHist.

Next apply the RegSeqRat dyadic ledger seal face named in Definition 38.255. Its input is the finite dyadic ledger, not an ambient completion object, so the refined common denominator and common-radius rows are exactly the rows it reads.

Finally use Definition 38.264 to expose the sealed ledger as the RealUp finite-window input. The primitive and closure boundaries ensure that the export adds no quotient, no Classical datum, no external metric primitive, and no RealUp completeness claim. □

Theorem 38.263 (DyadicRatCore transported public observations feed RealUp windows)**.** *Let* $d, d' : \mathsf{Hist}$*. Suppose* $\mathsf{hsame}(d, d')$ *holds and the public DyadicRatCore observation package of Definition 38.258 supplies the observation row at* d*. Then the* hsame*-transported public observation row at* d' *is available as the same RealUp finite-window exhaustion input. The transported row carries the same finite dyadic ledger, the same RatUp endpoint and positive-denominator faces transported along* hsame*, and the same no-quotient, no-completion, no-Classical, no-external-metric, no-*$\mathsf{Real}^{\uparrow}$ *completeness, and no-standard-bridge boundary fixed by Definition 38.256 and Definition 38.257.*

Proof. First apply Definition 38.259 to the row at d and the comparison $\mathsf{hsame}(d, d')$. This gives the public observation row at d' with the RatUp endpoint face and positive-denominator face transported along hsame, while keeping the certified finite dyadic ledger fixed.

Next apply Definition 38.264. That theorem reads the public DyadicRatCore observation package as exactly the carrier, classifier, stability, and finite-ledger source rows consumed by Definition 38.314. Applying it after transport therefore makes the row at d' the same RealUp finite-window input.

Finally read the primitive and closure boundaries from Definition 38.256 and Definition 38.257. Since the composite uses only the public transport row and the RealUp finite-window consumer already listed in those boundaries, it adds no quotient, completion object, Classical datum, external metric primitive, $\mathsf{Real}^{\uparrow}$ completeness claim, or standard bridge. □

Theorem 38.264 (DyadicRatCore public observation feeds RealUp finite-window exhaustion)**.** *The public DyadicRatCore package of Definition 38.258, with scope fixed by Definition 38.256 and Definition 38.257, supplies exactly the carrier, classifier, stability, and finite-ledger source rows consumed by the RealUp finite-window exhaustion obligation of Definition 38.314. It adds no quotient, completion object, Classical datum, external metric primitive,* $\mathsf{Real}^{\uparrow}$ *completeness claim, or standard bridge.*

Proof. First read the public face list from Definition 38.258. The exported surface is the observation-row carrier, classifier, arithmetic-stability, monotone-radius, distance and absolute-value, operation-stability, finite-ledger extraction, and RegSeqRat seal inventory.

Next read the primitive scope from Definition 38.256 and Definition 38.257. These results bind the exported surface to BHist, hsame, the $\mathsf{Rat}^{\uparrow}$ endpoint rows, PositiveUnaryDenominator, $\mathsf{StreamName}^{\uparrow}$ request names, the DyadicRatCore observation row, and the finite dyadic ledger, while excluding quotients, completion objects, Classical data, external metric primitives, $\mathsf{Real}^{\uparrow}$ completeness claims, and standard bridges.

Finally apply Definition 38.314. Its finite-window field consumes the endpoint $\mathsf{Rat}^{\uparrow}$ classifiers, positive unary denominators, nonempty unary endpoint rows, common e-one tail readback, and the DyadicRatCore source rows exposed through the RegSeqRat finite-window dyadic source package. Therefore the public DyadicRatCore observation package supplies exactly the carrier, classifier,

stability, and finite-ledger rows used at the RealUp finite-window boundary, with no extra object or bridge added. □

Lean4 ✓ `BEDC.Derived.RealUp.DyadicRatCoreObservationRow realup window feed`

Theorem 38.265 (DyadicRatCore public observation subwindow stability)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$ *and indices* n, j, r, m*, suppose*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m)$$

and $j + r \leq m$*. If the public DyadicRatCore package supplies the carrier, classifier, stability, and finite-ledger rows consumed by the RealUp finite-window exhaustion obligation in Definition 38.264, then the certified subwindow*

$$\mathsf{RealStreamWindowClassifier}(x, y, n + j, r)$$

produced by Definition 38.172 inherits the same DyadicRatCore observation-row carrier, classifier, stability, and finite dyadic ledger source rows through the $\mathsf{StreamName}^{\uparrow}$ *finite-window public interface of Definition 126.301. The inherited rows still feed Definition 38.314 and add no quotient, completion object, Classical datum, external metric primitive,* $\mathsf{Real}^{\uparrow}$ *completeness claim, or standard bridge.*

Proof. Apply Definition 38.172 to the certified source window with shift j and radius r. The bound $j + r \leq m$ gives the shifted finite-window classifier

$$\mathsf{RealStreamWindowClassifier}(x, y, n + j, r).$$

Next read the shifted window through the public finite-window interface of Definition 126.301. The interface changes only the selected finite anchor and radius; the $\mathsf{StreamName}^{\uparrow}$ request names, endpoint $\mathsf{Rat}^{\uparrow}$ classifiers, and bounded finite-ledger rows remain the same rows already exposed by the public DyadicRatCore package.

Finally apply Definition 38.264 to identify the inherited carrier, classifier, stability, and finite-ledger source rows as the rows consumed by Definition 38.314. Since the construction uses only subwindow extraction, the public $\mathsf{StreamName}^{\uparrow}$ finite-window surface, and the DyadicRatCore public observation feed, it introduces no quotient, completion object, Classical datum, external metric primitive, $\mathsf{Real}^{\uparrow}$ completeness claim, or standard bridge. □

Theorem 38.266 (RegSeqRat tail-shift regularity stability)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$*, a certified window*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m),$$

and indices j, r *with* $j + r \leq m$*, define the tail-shifted streams by*

$$x_j(k) = x(n + j + k), \qquad y_j(k) = y(n + j + k).$$

Then the finite $\mathsf{RegSeqRat}$ *regularity surface for the shifted window* $(x_j, y_j, 0, r)$ *inherits the same endpoint* $\mathsf{DyadicRatCoreObservationRow}$ *carrier, classifier, stability, and finite dyadic ledger rows as the source window. These inherited rows are exactly the rows fed to Definition 38.314, and the tail-shifted surface adds no quotient, completion object, Classical datum, external metric primitive,* $\mathsf{Real}^{\uparrow}$ *completeness claim, or standard bridge.*

Proof. Apply Definition 38.172 to the certified window with shift j and radius r. The bound $j + r \leq m$ gives the shifted finite certificate at anchor $n + j$ and radius r, which is the zero-based certificate for the tail-shifted streams x_j and y_j at window $(0, r)$.

Next apply Definition 38.265. The subwindow keeps the public DyadicRatCore observation-row carrier, classifier, stability, and finite dyadic ledger rows fixed while changing only the finite anchor read by the stream certificate.

Finally read the shifted certificate through Definition 126.301 and close with Definition 38.314. The RealUp finite-window consumer therefore receives the same DyadicRatCore endpoint rows from the tail-shifted RegSeqRat surface that it receives from the original finite window, with no additional primitive or bridge. □

Theorem 38.267 (RegSeqRat tail-shift dyadic-tolerance stability)**.** *For regular rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, a certified window*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m),$$

and indices j, r with $\mathsf{UnaryHistory}(j)$ and $j + r \leq m$, define tail-shifted streams by

$$x_j(k) = x(n + j + k), \qquad y_j(k) = y(n + j + k).$$

If the source window classifies x and y through the displayed RegSeqRat *dyadic-tolerance ledger at every requested unary observation in the window, then the shifted window $(x_j, y_j, 0, r)$ classifies the shifted streams through the transported dyadic-tolerance window. The transported classifier uses only the same* UnaryHistory *request rows,* hsame *endpoint comparisons, finite dyadic ledger rows, and* Cont *provenance already exposed by the source* RegSeqRat *certificate.*

Proof. Project the source certificate into its regularity rows and its dyadic classifier rows. The regularity projection is the input used by Definition 38.266; the classifier projection is the finite list of dyadic-tolerance requests attached to the same unary observation window.

Reindex the finite unary window by the common tail shift j. The hypothesis $j + r \leq m$ identifies every shifted request $k \leq r$ with the source request $n + j + k$, and $\mathsf{UnaryHistory}(j)$ keeps the transported request inside the same unary-history ledger. No new endpoint row is generated; the shifted row is the source row read at the transported index.

Apply Definition 38.266 to keep both shifted streams inside the finite RegSeqRat carrier. Then repack the dyadic-tolerance rows through the same Cont ledger and the same hsame endpoint comparisons. The resulting packet is exactly the classifier for $(x_j, y_j, 0, r)$, with the tolerance window transported by the tail shift and no extra quotient, completion object, external metric primitive, or standard bridge. □

Theorem 38.268 (RegSeqRat seal finite-window source coverage)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, a certified source window*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m),$$

and indices j, r with $j + r \leq m$, the selected bounded subwindow

$$\mathsf{RealStreamWindowClassifier}(x, y, n + j, r)$$

feeds the RegSeqRat *seal with the same finite-window source package as the source window. More precisely, the seal receives the same DyadicRatCore observation-row carrier, classifier, stability rows, finite dyadic ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite-window interface rows, and* $\mathsf{Real}^{\uparrow}$ *finite-window exhaustion rows already exposed at the source window. This coverage uses no quotient, completion object, Classical datum, external metric primitive,* $\mathsf{Real}^{\uparrow}$ *completeness claim, or standard bridge.*

Proof. First apply Definition 38.564 to the source window. This identifies the bounded RegSeqRat observation data with the scoped DyadicRatCore carrier, classifier, stability, and finite dyadic ledger faces at the selected finite window.

Next apply Definition 38.265 with the bound $j + r \leq m$. The subwindow certificate keeps the same DyadicRatCore observation-row carrier, classifier, stability rows, and finite dyadic ledger while changing only the finite anchor. Read that shifted anchor through Definition 126.301 to obtain the matching $\mathsf{StreamName}^{\uparrow}$ finite-window interface rows.

Finally apply Definition 38.264. The subwindow package is therefore exactly the finite-window source input consumed by Definition 38.314. Since every row is obtained from the source exhaustion theorem, the public subwindow stability theorem, the $\mathsf{StreamName}^{\uparrow}$ interface, and the RealUp feed theorem, the seal receives no quotient, completion object, Classical datum, external metric primitive, $\mathsf{Real}^{\uparrow}$ completeness claim, or standard bridge. □

Theorem 38.269 (RegSeqRat nested subwindow source coverage)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$*, a certified source window*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m),$$

and indices j, r, j', r' *with* $j + r \leq m$ *and* $j' + r' \leq r$*, the nested selected window*

$$\mathsf{RealStreamWindowClassifier}(x, y, n + j + j', r')$$

feeds the RegSeqRat *seal with the same finite-window source package as the original source window. In particular, it exposes the same DyadicRatCore observation-row carrier, classifier, stability rows, finite dyadic ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite-window interface rows, and* $\mathsf{Real}^{\uparrow}$ *finite-window exhaustion rows. This nested coverage introduces no quotient, completion object, Classical datum, external metric primitive,* $\mathsf{Real}^{\uparrow}$ *completeness claim, or standard bridge.*

Proof. Apply Definition 38.265 to the source certificate with the bound $j + r \leq m$. This gives the selected package at anchor $n + j$ and radius r with the same DyadicRatCore observation-row carrier, classifier, stability rows, and finite dyadic ledger rows as the source window.

Apply the same theorem again to the shifted package, now using the bound $j' + r' \leq r$. The second extraction selects the window at anchor $n + j + j'$ and radius r', and it preserves exactly the same observation-row carrier, classifier, stability, and ledger rows because the first selected package already carries those public DyadicRatCore rows.

Finally apply Definition 38.268 and Definition 126.301. These repack the nested certificate as the same RegSeqRat finite-window source package consumed by the seal and by Definition 38.314, with only the finite anchor changed to $n+j+j'$ and with no quotient, completion object, Classical datum, external metric primitive, $\mathsf{Real}^{\uparrow}$ completeness claim, or standard bridge. □

Theorem 38.270 (RegSeqRat finite-window seal source exhaustion)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$ *and any certified finite* RegSeqRat-*to*-$\mathsf{Real}^{\uparrow}$ *seal window*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m),$$

the accepted source package of the seal is exactly the pair formed by the public $\mathsf{StreamName}^{\uparrow}$ *finite-window interface and the* RegSeqRat/DyadicRatCore *dyadic source-exhaustion rows. The two sides use the same* BHist *carrier,* UnaryHistory *request rows,* ProbeBundle *entries,* InBundle *membership rows,* hsame *comparisons,* Cont *provenance, and finite dyadic ledger rows. No quotient, completion object, Classical datum, metric-completeness witness,* $\mathsf{Real}^{\uparrow}$*-completeness witness, or bridge datum is part of the source package.*

Proof. For the projection direction, apply Definition 38.251. It identifies every seal read with the finite-window source rows carried by the certified window, so the seal source has no row outside the displayed finite packet.

Next apply Definition 126.301. The stream-name component of the projected source is exactly the public finite window interface, including the same unary request rows, probe entries, membership rows, BHist carrier, and hsame comparisons.

Apply Definition 38.268 and Definition 38.314. These identify the remaining projected rows with the RegSeqRat/DyadicRatCore dyadic source-exhaustion rows, the shared Cont provenance, and the finite dyadic ledger consumed by $\mathsf{Real}^{\uparrow}$.

Conversely, start from the public $\mathsf{StreamName}^{\uparrow}$ finite-window interface together with the listed RegSeqRat/DyadicRatCore exhaustion rows. The coverage theorem repacks these rows as the finite-window source package for the seal, and the exactness theorem makes this repacked source the accepted seal source for the same certified window.

Because both readings use only the displayed interface rows, exhaustion rows, continuation provenance, and finite ledger entries, there is no remaining field from which a quotient, completion object, Classical datum, metric-completeness witness, $\mathsf{Real}^{\uparrow}$-completeness witness, or bridge datum could be projected. □

Theorem 38.271 (RegSeqRat finite-window seal composition)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, a certified DyadicRatCore public observation row over a finite window* RealStreamWindowClassifier(x *the* $\mathsf{StreamName}^{\uparrow}$ *finite-window interface rows, the* RegSeqRat *seal source-coverage row, and the* $\mathsf{Real}^{\uparrow}$ *finite-window feed compose to a single finite-window seal package over the same* BHist *carrier,* hsame *comparisons,* Cont *ledger, and finite dyadic observation rows. Every bounded subwindow and every nested bounded subwindow selected inside the source window is read through that same package. The composed seal asserts no quotient carrier, external metric primitive,* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or standard-bridge status.*

Proof. Begin with Definition 38.264. It exposes the certified DyadicRatCore observation row as the finite dyadic ledger and RealUp consumer row attached to the displayed source window.

Apply Definition 38.265. The finite window may be restricted without changing the underlying BHist carrier, hsame comparisons, Cont ledger, classifier rows, or finite dyadic ledger rows.

Next use Definition 38.268. This repacks the subwindow observation row together with the $\mathsf{StreamName}^{\uparrow}$ finite-window interface as the source package consumed by the RegSeqRat seal and by the RealUp finite-window feed.

Finally apply Definition 38.269. Nested selected windows are obtained by repeating the same public subwindow extraction, so the seal package remains tied to the original finite dyadic ledger rows and the same BHist, hsame, and Cont data. Since every component is read from the cited finite-window rows, the construction introduces no quotient carrier, external metric primitive, $\mathsf{Real}^{\uparrow}$ completeness theorem, or standard-bridge status. □

Theorem 38.272 (DyadicRatCore public observation standard bridge boundary)**.** *The public DyadicRatCore observation package of Definition 38.258, together with* hsame *transport, subwindow stability,* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, and the* $\mathsf{Real}^{\uparrow}$ *finite-window feed, supplies a conservative standard bridge from concrete* BHist *and* $\mathsf{Rat}^{\uparrow}$ *dyadic observation rows to the finite dyadic observation interface consumed by* RegSeqRat *and* $\mathsf{Real}^{\uparrow}$*. The bridge uses only the displayed observation-row carrier, classifier, stability rows, finite dyadic ledger, stream-name finite-window interface, and RealUp finite-window consumer. It excludes quotient carriers, completion objects, external metric primitives,* $\mathsf{Real}^{\uparrow}$ *completeness, full DyadicRatCore arithmetic, and any machine-checked bridge status.*

Proof. First read the public surface from Definition 38.258. The exported rows are the concrete observation-row carrier, classifier, stability faces, finite dyadic ledger, and RegSeqRat seal interface over BHist, hsame, and the $\mathsf{Rat}^{\uparrow}$ endpoint histories.

Next apply Definition 38.259. The transport clause shows that replacing a dyadic observation row by an hsame-equivalent row preserves the same finite ledger and the same public observation interface. Apply Definition 38.265 to restrict the interface to any certified finite subwindow without changing the exposed row vocabulary.

Then use Definition 38.269. Its nested window coverage identifies the RegSeqRat seal input with the same finite dyadic source package after repeated subwindow selection, and it reads the needed $\mathsf{StreamName}^{\uparrow}$ rows through the public finite-window interface.

Finally apply Definition 38.264. The finite-window package delivered by the preceding steps is exactly the observation interface consumed by the RealUp finite-window exhaustion row. Since every step factors through the public DyadicRatCore package and its finite-window consumers, the bridge is conservative: it introduces no quotient carrier, completion object, external metric primitive, $\mathsf{Real}^{\uparrow}$ completeness, full DyadicRatCore arithmetic, or machine-checked bridge status. □

Definition 38.272 is a $\mathsf{Real}^{\uparrow}$ local observation-boundary lemma. It records how the public DyadicRatCore observation package, hsame transport, subwindow stability, $\mathsf{StreamName}^{\uparrow}$ finite-window rows, and the $\mathsf{Real}^{\uparrow}$ finite-window feed align the finite dyadic ledger with the RegSeqRat and $\mathsf{Real}^{\uparrow}$ consumer interfaces inside the carrier-obligation subtree.

The lemma does not assign a separate closure axis to $\mathsf{DyadicRatCore}^{\uparrow}$ from the $\mathsf{Real}^{\uparrow}$ certificate-boundary file. The authoritative $\mathsf{DyadicRatCore}^{\uparrow}$ status is the canonical closure block in the DyadicRatCore chapter, where the chapter records its object token, closure grade, verification grade, and standard-bridge status as a single objectwise commitment.

Theorem 38.273 (Real unary stream classifier stability package)**.** *For rational-observation maps* $s, t, u, s', t' : \mathsf{Hist} \to \mathsf{Hist}$*, suppose*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameCarrier}(u),$$

$$\mathsf{RealUnaryStreamClassifier}(s,t), \quad \mathsf{RealUnaryStreamClassifier}(t,u),$$

and suppose the endpoint transports are pointwise over unary observations:

$$\forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(s(n), s'(n)), \quad \forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(t(n), t'(n)).$$

Then the same BEDC unary observation rows supply the following stability package:

1. $\mathsf{RatStreamNameClassifier}(s,t)$.
2. $\mathsf{RealUnaryStreamClassifier}(s,s)$, $\mathsf{RealUnaryStreamClassifier}(t,s)$, *and* $\mathsf{RealUnaryStreamClassifier}(s,u)$.
3. *For every certified unary observation* n*, both endpoint RatUp carrier rows* $\mathsf{RatHistoryCarrier}(s(n))$ *and* $\mathsf{RatHistoryCarrier}(t(n))$.
4. $\mathsf{RealUnaryStreamClassifier}(s',t')$.

Proof. Unfold Definition 126.1, Definition 126.2, and Definition 38.26. After this unfolding, both StreamNameUp and RealUp classifier rows are the same pointwise RatUp classifier over histories n equipped with $\mathsf{UnaryHistory}(n)$.

The first conclusion is therefore just the displayed $\mathsf{RealUnaryStreamClassifier}(s,t)$ read under the StreamNameUp classifier name. For $\mathsf{RealUnaryStreamClassifier}(s,s)$, fix a certified observation

n; the carrier row for s gives $\mathsf{RatHistoryCarrier}(s(n))$, and RatUp classifier reflexivity gives the required point classifier at that observation.

For the reversed classifier $\mathsf{RealUnaryStreamClassifier}(t, s)$, read the point classifier from $\mathsf{RealUnaryStreamClassifier}$ and apply RatUp classifier symmetry. For $\mathsf{RealUnaryStreamClassifier}(s, u)$, read the two point classifiers from the assumptions at the same certified observation and compose them by RatUp classifier transitivity.

For endpoint carriers, fix a certified unary observation n and unpack the RatUp classifier obtained from $\mathsf{RealUnaryStreamClassifier}(s, t)$ at that observation. Its endpoint data are precisely $\mathsf{RatHistoryCarrier}(s(n))$ and $\mathsf{RatHistoryCarrier}(t(n))$.

For transport, fix the same certified observation n. Apply $\mathsf{RatHistoryClassifier_hsame_transport}$ to the point classifier from $\mathsf{RealUnaryStreamClassifier}(s, t)$ and to the two pointwise hsame witnesses from s, t to s', t'. Repacking the transported point classifier over all certified unary observations gives $\mathsf{RealUnaryStreamClassifier}(s', t')$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamClassifier stability package`

Theorem 38.274 (Real unary stream-name stability package)**.** *For rational-observation maps $s, t, u, s', t' : \mathsf{Hist} \to \mathsf{Hist}$, the stability package of Definition 38.273 is also the StreamNameUp reading of the same unary-observation classifier data. In particular, under the same carrier, classifier, composability, and endpoint-transport hypotheses, one obtains*

$$\mathsf{RatStreamNameClassifier}(s, t)$$

together with the self, symmetry, transitivity, endpoint-carrier, and transport conclusions listed in Definition 38.273.

Proof. Apply Definition 38.273 to the given hypotheses. Its proof unfolds the RatStreamNameUp carrier and classifier rows and identifies them with the same pointwise RatUp classifier used by $\mathsf{RealUnaryStreamClassifier}$ over certified unary observations.

Thus the first component of the package is the StreamNameUp classifier $\mathsf{RatStreamNameClassifier}(s, t)$, while the remaining components are the same RealUp self, reversed, composed, endpoint-carrier, and transported classifier rows from the stability package. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamClassifier streamName stability package`

Theorem 38.275 (Real unary stream-name transported classifier)**.** *For rational-observation maps $s, t, s', t' : \mathsf{Hist} \to \mathsf{Hist}$, suppose*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RealUnaryStreamClassifier}(s, t),$$

and suppose the endpoint transports are pointwise over unary observations:

$$\forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(s(n), s'(n)), \quad \forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(t(n), t'(n)).$$

Then $\mathsf{RatStreamNameClassifier}(s', t')$.

Proof. Unfold Definition 126.1, Definition 126.2, and Definition 38.26. The $\mathsf{RealUnaryStreamClassifier}(s, t)$ row supplies the RatUp point classifier at each certified unary observation, while the two displayed carrier hypotheses supply the endpoint stream carriers before transport.

Fix a certified unary observation n with witness $\nu : \mathsf{UnaryHistory}(n)$. Apply Definition 37.54 to the RatUp point classifier read from $\mathsf{RealUnaryStreamClassifier}(s, t)$ at (n, ν) and to the two pointwise hsame witnesses from s, t to s', t'. This gives $\mathsf{RatHistoryClassifier}(s'(n), t'(n))$.

Read the endpoint carrier fields of this transported RatUp classifier. The left field gives $\mathsf{RatHistoryCarrier}(s'(n))$ and the right field gives $\mathsf{RatHistoryCarrier}(t'(n))$. Since (n, ν) was arbitrary, these fields build $\mathsf{RatStreamNameCarrier}(s')$ and $\mathsf{RatStreamNameCarrier}(t')$.

The same transported RatUp point classifier, again for arbitrary (n, ν), supplies the pointwise classifier row of $\mathsf{RatStreamNameClassifier}(s', t')$. Repack that pointwise row with the two transported stream carriers to obtain the claimed StreamNameUp classifier. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamClassifier streamName transport`

Theorem 38.276 (RegSeqRat stream-name scoped interface)**.** *For rational-observation maps* $s, t, u, s', t' : \mathsf{Hist} \to \mathsf{Hist}$*, suppose*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameCarrier}(u),$$

$$\mathsf{RealUnaryStreamClassifier}(s, t), \quad \mathsf{RealUnaryStreamClassifier}(t, u),$$

and suppose the endpoint transports are pointwise over unary observations:

$$\forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(s(n), s'(n)), \quad \forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(t(n), t'(n)).$$

Then these rows determine a scoped RegSeqRat *interface package containing:*

1. $\mathsf{RatStreamNameClassifier}(s, t)$.
2. $\mathsf{RealUnaryStreamClassifier}(s, s)$, $\mathsf{RealUnaryStreamClassifier}(t, s)$, *and* $\mathsf{RealUnaryStreamClassifier}(s, u)$.
3. *For every certified unary observation* n*, endpoint* $\mathsf{Rat}^{\uparrow}$ *carrier rows for* $s(n)$ *and* $t(n)$.
4. $\mathsf{RealUnaryStreamClassifier}(s', t')$.
5. $\mathsf{RatStreamNameClassifier}(s', t')$.

Proof. Apply Theorem 38.273 to the three stream-name carrier rows, the two RealUp unary classifier rows, and the two pointwise hsame transport rows. Its conclusions supply the StreamNameUp classifier for (s, t), the reflexive, reversed, and composed RealUp unary classifier rows, the endpoint $\mathsf{Rat}^{\uparrow}$ carrier rows at every certified unary observation, and the transported RealUp unary classifier for (s', t').

It remains to obtain the transported StreamNameUp classifier. Apply Theorem 38.275 with the same carrier rows for s and t, the same $\mathsf{RealUnaryStreamClassifier}(s, t)$ row, and the same pointwise hsame transports from s, t to s', t'. This yields $\mathsf{RatStreamNameClassifier}(s', t')$, which is the final row of the scoped RegSeqRat interface package. □

Lean4 ✓ `BEDC.Derived.RealUp.RegseqratStreamnameScopedInterface`

Theorem 38.277 (RegSeqRat finite-window seal coverage)**.** *Let* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *be certified rational stream names and let* $W : \mathsf{ProbeBundle}$ *be a finite unary-observation window. The rows exported by Definition 126.301, the scoped* RegSeqRat *interface of Definition 38.276, and the DyadicRatCore observation rows assemble the finite-window seal side consumed by* $\mathsf{Real}^{\uparrow}$*. The assembled package records the bundled unary observations of* W*, the pointwise* $\mathsf{Rat}^{\uparrow}$ *classifier rows for* s *and* t*, the dyadic observation witnesses, and the* RegSeqRat *spine ledger. It claims no* $\mathsf{Real}^{\uparrow}$ *completeness, quotient carrier, arithmetic closure, order closure, metric completion, or standard bridge.*

Proof. First project the finite classifier rows from the StreamNameUp finite-window interface. For every bundled unary observation in W, Definition 126.301 supplies the carried stream-name endpoints and the pointwise $\mathsf{Rat}^{\uparrow}$ classifier row visible at that observation.

Next apply Definition 38.276. Its scoped package recovers the stream-name transport rows, the pointwise endpoint carrier rows, the transported StreamNameUp classifier, and the RegSeqRat spine rows over the same certified names.

Finally attach the DyadicRatCore observation witnesses as the seal ledger. These witnesses are indexed by the same finite window W, so the bundled unary observations, pointwise classifier rows, dyadic observations, and spine ledger repack as exactly the finite boundary consumed by the later $\mathsf{Real}^{\uparrow}$ seal theorem. □

Theorem 38.278 (RegSeqRat finite-window RealUp seal interface)**.** *Let $s, t : \mathsf{Hist} \to \mathsf{Hist}$ be certified rational stream names and let W : ProbeBundle be a finite unary-observation window. The StreamNameUp finite-window interface, the scoped* RegSeqRat *interface, the DyadicRatCore observation rows, and the public* $\mathsf{Real}^{\uparrow}$ *seal rows assemble one* BHist*-anchored* $\mathsf{Real}^{\uparrow}$ *finite-window seal package. Its carrier row is* RatStreamNameCarrier *for s and t; its classifier rows are* RatStreamNameClassifier *and the finite-window classifier over W; its observation face is the finite family of dyadic comparison rows; its spine ledger is the* RegSeqRat *stream-name ledger; and its consumer face is the public* $\mathsf{Real}^{\uparrow}$ *seal row. The package asserts no completeness theorem, quotient carrier, arithmetic closure, order closure, metric completion, Classical data, or trichotomy.*

Proof. First read the finite observation boundary. By Definition 126.301, the certified stream names s and t supply the StreamNameUp carrier rows, the RatStreamNameClassifier row, and the finite-window classifier row for every bundled unary observation in W.

Next read the scoped regular-sequence spine. Theorem 38.276 packages the same stream-name rows as the RegSeqRat interface, while Definition 38.277 attaches the dyadic observation witnesses and the finite spine ledger over the same window.

Finally consume the public seal. Theorem 38.286 identifies the $\mathsf{Real}^{\uparrow}$ consumer row whose visible inputs are precisely the carrier, classifier, dyadic observation, and RegSeqRat ledger rows already assembled. Since none of these sources introduces quotient formation, arithmetic or order closure, metric-completion data, Classical data, or trichotomy, the resulting package is exactly the stated finite-window seal interface. □

The ten-field fit is: traditional target transport of a unary real stream-name classifier; BEDC source StreamNameUp read through the RealUp unary classifier; carrier the transported RatUp endpoint carrier rows for s' and t'; classifier the transported RatUp point classifier; stability pointwise hsame transport along unary observations; ledger the observation witness and the two endpoint transport witnesses; core theorem this block; exactness RatStreamNameClassifier(s', t') rather than only RealUnaryStreamClassifier(s', t'); standard bridge the downstream RealUp certificate boundary; status ProofTarget.

Definition 38.279 (Real ledger policy)**.** *Record finite stream observations, dyadic comparison witnesses, regularity certificates, and classifier comparison certificates when sameness is used.*

Definition 38.280 (RealUp certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the required fields for using the interface name* $\mathsf{Real}^{\uparrow}$*.*

Primitive boundary. $\mathsf{Real}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Remark 38.281 (Zero-axiom encoding note)**.** *The interface avoids quotient machinery. It does not use* Quot.sound*; sameness is carried by dyadic comparison certificates and the* RegSeqRat *classifier.*

Theorem 38.282 (RealUp carrier and classifier obligations)**.** *The* $\mathsf{Real}^{\uparrow}$ *carrier and classifier obligation set consists exactly of the sealed* RegSeqRat *stream spine, the constant-history carrier* RealConstantHistoryCarrier*, the endpoint* $\mathsf{Rat}^{\uparrow}$ *carrier rows, and the classifier row* RealConstantHistoryClassifier *or* RealUnaryStreamClassifier *read through Definition 38.1, Definition 38.2, Definition 38.9, and Definition 38.195. This is the carrier and classifier part of the* $\mathsf{Real}^{\uparrow}$ *obligation boundary.*

Proof. Use the roadmap ten-field template with traditional target $\mathsf{Real}^{\uparrow}$. The BEDC source is the DyadicRatCore, RegSeqRat, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Rat}^{\uparrow}$ interface over Hist; no quotient carrier is introduced outside those named interfaces.

The carrier choice is the sealed RegSeqRat stream spine together with RealConstantHistoryCarrier and the endpoint $\mathsf{Rat}^{\uparrow}$ carrier rows. Definitions 38.1 and 38.2 name the constant-history side, while Definition 38.195 names the stream spine being sealed.

The classifier choice is read from Definition 38.9: constants use RealConstantHistoryClassifier and unary stream observations use RealUnaryStreamClassifier. Stability obligations, ledger rows, core theorem list, and exactness predicate are not supplied by this block; they are the remaining $\mathsf{Real}^{\uparrow}$ obligations. No standard bridge is claimed, and the status of this theorem is the paper-side carrier and classifier obligation inventory. □

Theorem 38.283 (RealUp stability and transport obligations)**.** *The* $\mathsf{Real}^{\uparrow}$ *stability obligation set is supplied by the constant-history classifier equivalence fields, endpoint transport, unary stream classifier stability, the stream-name transported classifier, and* RegSeqRat *transport. Concretely, the required rows are those supplied by Definition 38.23, Definition 38.18, Definition 38.273, and Definition 38.275, read over the same* Hist*-indexed DyadicRatCore,* RegSeqRat*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{Rat}^{\uparrow}$ *sources.*

Proof. The traditional target is again $\mathsf{Real}^{\uparrow}$, with BEDC source DyadicRatCore, RegSeqRat, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Rat}^{\uparrow}$ over Hist. The carrier choice and classifier choice are the rows fixed in Definition 38.282; this proof names the stability and transport rows attached to them.

For the constant-history face, apply Definition 38.23 to obtain the reflexive, symmetric, and transitive classifier fields, and apply Definition 38.18 to move the endpoint classifier along hsame rows.

For the unary stream face, apply Definition 38.273. It gives the StreamNameUp classifier, the reflexive, reversed, and composed $\mathsf{Real}^{\uparrow}$ unary classifier rows, endpoint $\mathsf{Rat}^{\uparrow}$ carrier rows, and transport of RealUnaryStreamClassifier along pointwise hsame.

Finally, apply Definition 38.275 to read the transported RealUp unary classifier as the transported StreamNameUp classifier. The ledger and seal are left to the ledger theorem below, the exactness predicate is classifier preservation along the displayed transports, no standard bridge is claimed, and the status is the paper-side stability and transport obligation inventory. □

Theorem 38.284 (RealUp ledger and seal obligations)**.** *The* $\mathsf{Real}^{\uparrow}$ *ledger obligation is exactly the finite unary-observation ledger together with the dyadic-tolerance requests consumed by the* $\mathsf{Real}^{\uparrow}$ *seal. The ledger rows are those named in Definition 38.279, and the seal consumes precisely the scoped* RegSeqRat *spine supplied by Definition 38.210 through Definition 38.209.*

Proof. Use the same roadmap template. The traditional target is $\mathsf{Real}^{\uparrow}$; the BEDC source is the DyadicRatCore and RegSeqRat stream data over Hist, read through $\mathsf{StreamName}^{\uparrow}$ names and endpoint $\mathsf{Rat}^{\uparrow}$ rows. The carrier and classifier choices are the rows fixed by Definition 38.282.

The ledger is the finite policy of Definition 38.279: stream observations, dyadic comparison witnesses, regularity certificates, and classifier comparison certificates. These are the only ledger rows available to the seal.

Apply Definition 38.210 to collect the scoped RegSeqRat carrier, classifier, stability, and finite ledger faces. Then apply Definition 38.209; the seal reads that scoped spine and its dyadic-tolerance requests without adding another source of data.

The core theorem list is the scoped spine theorem followed by the seal consumption theorem. The exactness predicate is equality of consumed data: the $\mathsf{Real}^{\uparrow}$ seal consumes the finite unary-observation ledger and the dyadic-tolerance requests displayed by the spine. No standard bridge is claimed, and the status is the paper-side ledger, seal, and RegSeqRat-consumption obligation inventory. □

Theorem 38.285 (RealUp scoped certificate boundary)**.** *The scoped* $\mathsf{Real}^{\uparrow}$ *certificate boundary is exactly the package formed from Definition 38.282, Definition 38.283, Definition 38.284, Definition 38.335, Definition 38.336, Definition 38.337, and Definition 38.338. Its primitives are DyadicRatCore,* RegSeqRat*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* UnaryHistory*,* hsame *transport,* RealConstantHistoryCarrier*,* RealConstantHistoryClassifier*,* RealUnaryStreamClassifier*, and* RealLedgerPolicy*. Within this boundary every carrier, classifier, stability, transport, ledger, and seal face is read from the same* Hist*-indexed stream spine and finite ledger. The boundary contains no quotient data, completion data, arithmetic or order closure, metric-completeness certificate, or standard-bridge data.*

Proof. We first collect the direct $\mathsf{Real}^{\uparrow}$ obligation faces. Apply Definition 38.282 for the sealed RegSeqRat carrier and the constant-history and unary stream classifiers. Apply Definition 38.283 for hsame transport, endpoint transport, and unary stream classifier stability. Apply Definition 38.284 for the finite ledger and the seal that consumes the scoped stream spine.

We then identify those faces with the stream-prefix obligation inventory. Apply Definition 38.335 for the DyadicRatCore, RegSeqRat, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{Rat}^{\uparrow}$ carrier source. Apply Definition 38.336 for the constant-history and unary stream classifier source. Apply Definition 38.337 for the pointwise hsame stability rows. Apply Definition 38.338 for the finite ledger policy and seal rows.

The two collections name the same data, because every row is indexed by the same Hist stream spine and every ledger entry is one of the finite RealLedgerPolicy entries consumed by the seal. Thus the package is scoped over the displayed BEDC primitives rather than over an external real object.

Nothing in the construction supplies quotient representatives, a completion object, arithmetic or order laws, metric completeness, or a standard bridge. Those data are outside the scoped certificate boundary claimed here. □

Theorem 38.286 (RealUp public certificate export)**.** *The public* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *surface exported to downstream L10 chapters is exactly the package consisting of Definition 38.285, Definition 38.342, the scoped* RegSeqRat *stream-name interface of Definition 38.276, the DyadicRatCore observation rows,* RealConstantHistoryCarrier*,* RealConstantHistoryClassifier*,* RealUnaryStreamClassifier*, and* RealLedgerPolicy*. Downstream chapters may cite this theorem as the public* $\mathsf{Real}^{\uparrow}$ *certificate boundary for carrier, classifier, stability, transport, finite observation, ledger, and seal data. The exported surface contains no completeness theorem, arithmetic or order closure, metric-completeness certificate, or standard bridge.*

Proof. Start with the scoped certificate boundary. Apply Definition 38.285; it gathers the DyadicRatCore, RegSeqRat, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, UnaryHistory, hsame transport, constant-history carrier,

constant-history classifier, unary stream classifier, and finite ledger policy as one Hist-indexed $\mathsf{Real}^{\uparrow}$ boundary.

Next attach the finite read surface. Apply Definition 38.342; it says that selected finite $\mathsf{Real}^{\uparrow}$ observation windows read exactly the same carrier/classifier, stability/transport, finite ledger, dyadic source, stream-name, endpoint, and seal rows, and no quotient, completion, arithmetic, order, Classical, or standard-bridge datum.

Finally package the source interfaces exposed to downstream chapters. The scoped RegSeqRat stream-name interface of Definition 38.276 supplies the stream-name classifier, reflexive, reversed, composed, endpoint, and transported classifier rows. The DyadicRatCore observation rows and the named RealConstantHistoryCarrier, RealConstantHistoryClassifier, RealUnaryStreamClassifier, and RealLedgerPolicy rows are therefore precisely the public $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ surface. Since each row is already inside the scoped boundary or the finite read surface, downstream L10 chapters may cite this theorem as the public $\mathsf{Real}^{\uparrow}$ certificate boundary without reconstructing the package. □

Theorem 38.287 (RealUp public seal source determinacy)**.** *Let a downstream L10 use of a sealed* $\mathsf{Real}^{\uparrow}$ *candidate cite Definition 38.286 as its public seal. Then the source rows consumed from that seal are exactly the DyadicRatCore public observation package, the* $\mathsf{StreamName}^{\uparrow}$ *public countable-name interface and finite-window interface, the* RegSeqRat *stream-name scoped interface, and the named* $\mathsf{Real}^{\uparrow}$ *rows* RealConstantHistoryCarrier*,* RealConstantHistoryClassifier*,* RealUnaryStreamClassifier*, and* RealLedgerPolicy*.*

No quotient representative, completion object, metric-completeness row, arithmetic or order row, Classical datum, or standard bridge may be read from that public seal. Thus a downstream argument using the seal is source determinate over the displayed DyadicRatCore, $\mathsf{StreamName}^{\uparrow}$*,* RegSeqRat*, and* $\mathsf{Real}^{\uparrow}$ *rows alone.*

Proof. Start from Definition 38.286. It identifies the public seal as the scoped $\mathsf{Real}^{\uparrow}$ certificate boundary, the selected finite-window read surface, the RegSeqRat stream-name interface, the DyadicRatCore observation rows, and the named carrier, classifier, unary-stream, and ledger rows.

Factor the countable-name and finite-window faces through the public stream-name interfaces. Apply Definition 38.289; its factorization sends the countable-name part through Definition 126.311 and the finite-window part through Definition 126.301.

Project the remaining source rows. Apply Definition 38.258 for the dyadic finite observation package, and apply Definition 38.276 for the regular rational-stream spine with its transported stream-name rows. The only non-factorized $\mathsf{Real}^{\uparrow}$ rows left by the public export are the displayed RealConstantHistoryCarrier, RealConstantHistoryClassifier, RealUnaryStreamClassifier, and RealLedgerPolicy rows.

Finally compare this list with the roadmap ten-field template. The traditional target, BEDC source, carrier, classifier, stability, ledger, core theorem list, exactness, standard-bridge field, and status field are all read from the four public packages and named $\mathsf{Real}^{\uparrow}$ rows above. Since the cited public export and its factorizations explicitly withhold quotient, completion, arithmetic, order, metric-completeness, Classical, and standard-bridge data, a downstream use of the seal cannot consume any such row. □

Theorem 38.288 (RegSeqRat finite-window seal source pullback)**.** *Let two downstream L10 seal uses of* $\mathsf{Real}^{\uparrow}$ *cite Definition 38.286. Suppose both uses restrict their public seal to the same certified finite* $\mathsf{StreamName}^{\uparrow}$ *window* U *and there carry matching* RatStreamNameFiniteWindowClassifier *rows, matching* RegSeqRat *spine rows, matching endpoint* DyadicRatCoreObservationRow *witnesses, and matching displayed* hsame*,* Cont*,* Pkg*, and* RealLedgerPolicy *rows. Then the finite* RegSeqRat

seal-source package induced by either use and the finite $\mathsf{Real}^{\uparrow}$ *readback packet induced by either use are the same public* BHist *source surface over* U*.*

This pullback uses only DyadicRatCore observation rows, the certified $\mathsf{StreamName}^{\uparrow}$ *finite window, the* RegSeqRat *spine rows, displayed* hsame/Cont/Pkg *provenance, and the finite* $\mathsf{Real}^{\uparrow}$ *ledger boundary. It does not export quotient data, completion data, metric-completeness rows, arithmetic rows, order rows, Classical representatives, or standard-bridge rows.*

Proof. First apply Definition 38.287 to both downstream seal uses. Each use can read only the displayed DyadicRatCore, $\mathsf{StreamName}^{\uparrow}$, RegSeqRat, and named $\mathsf{Real}^{\uparrow}$ rows from Definition 38.286.

Next factor the common stream-name restriction through Definition 126.88. The matching finite-window classifier rows, probe window, endpoint observation rows, and displayed hsame transports identify one $\mathsf{StreamName}^{\uparrow}$ source surface on U for every induced RegSeqRat handoff.

Now apply Definition 38.355. The matching RegSeqRat spine, DyadicRatCore endpoints, Cont/Pkg provenance, and finite RealLedgerPolicy rows identify the two restricted $\mathsf{Real}^{\uparrow}$ readback packets with that same finite BHist packet.

The finite ledger boundary then repacks the common packet as the public source surface read by both L10 consumers. Since every step has already excluded quotient, completion, metric-completeness, arithmetic, order, Classical, and standard-bridge rows, no additional source row is available in the pullback. □

Theorem 38.289 (RealUp public export through the StreamNameUp public interface)**.** *The public* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *surface of Definition 38.286 factors its countable-name component through the public* $\mathsf{StreamName}^{\uparrow}$ *export package of Definition 126.311 and factors its finite-window component through Definition 38.345. After these two factorizations, the remaining public* $\mathsf{Real}^{\uparrow}$ *rows are exactly the DyadicRatCore observation rows, the* RegSeqRat *spine rows, the* $\mathsf{Rat}^{\uparrow}$ *endpoint rows,* UnaryHistory*,* hsame *transport,* RealConstantHistoryCarrier*,* RealConstantHistoryClassifier*,* RealUnaryStreamClassifier*, and* RealLedgerPolicy*.*

The factorized public surface still contains no quotient datum, completion datum, arithmetic or order closure, metric-completeness certificate, Classical datum, or standard bridge.

Proof. Start from Definition 38.286. It identifies the public $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ boundary as the scoped $\mathsf{Real}^{\uparrow}$ certificate boundary together with the selected finite-window read surface, the RegSeqRat stream-name interface, the DyadicRatCore observation rows, and the named constant-history, unary-stream, transport, endpoint, and ledger rows.

Next isolate the public stream-name package. Apply Definition 126.311; its countable-name side supplies the RatStreamNameCarrier, RatStreamNameClassifier, RatUp pointwise rows, constant stream rows, reindexing and RatUp-preserving map stability, and unary reindexing composition used by the $\mathsf{Real}^{\uparrow}$ export.

For finite observations, apply Definition 38.345. It identifies the selected finite $\mathsf{Real}^{\uparrow}$ read surface with the public $\mathsf{StreamName}^{\uparrow}$ finite-window interface and leaves only the listed dyadic, RegSeqRat, endpoint, unary-history, hsame, and ledger rows outside the stream-name factor.

Finally use Definition 38.276 and Definition 38.258. The former supplies the regular rational-stream spine and transported stream-name rows consumed by $\mathsf{Real}^{\uparrow}$, while the latter supplies the DyadicRatCore observation package. Thus the public export factors through the two StreamNameUp interfaces and the unfactored rows are precisely the displayed $\mathsf{Real}^{\uparrow}$ carrier, classifier, transport, endpoint, history, and ledger rows. □

Theorem 38.290 (RealUp Phase Real and Completion boundary)**.** *The Phase Real and Completion paper boundary is exactly the composite of the following four public packages:*

1. *the DyadicRatCore public observation package of Definition 38.258;*
2. *the* $\mathsf{StreamName}^{\uparrow}$ *public countable-name export package of Definition 126.311 together with the finite-window interface of Definition 126.301;*
3. *the* RegSeqRat *stream-name scoped interface of Definition 38.276;*
4. *the* $\mathsf{Real}^{\uparrow}$ *public certificate export of Definition 38.286 after factorization through the* $\mathsf{StreamName}^{\uparrow}$ *public interface in Definition 38.289.*

Equivalently, its roadmap ten-field row has traditional target regular real completion by dyadic rational streams; BEDC source the DyadicRatCore, $\mathsf{StreamName}^{\uparrow}$*,* RegSeqRat*, and* $\mathsf{Real}^{\uparrow}$ *packages listed above; carrier the DyadicRatCore observations, rational stream names, regular stream spine, and* RealConstantHistoryCarrier *rows; classifier the public* $\mathsf{StreamName}^{\uparrow}$ *classifier, the transported* RegSeqRat *stream classifier, and* RealConstantHistoryClassifier *with* RealUnaryStreamClassifier*; stability the* hsame*, endpoint, stream-name, finite-window, and unary-stream transport rows exposed by those packages; ledger the finite dyadic observation rows and* RealLedgerPolicy*; core theorem list exactly the six displayed source theorems; exactness finite-window and public-export exactness only up to the named classifiers; standard bridge absent; status paper-level phase boundary for the future namespace* BEDC.Derived.RealUp*.*

The boundary contains no $\mathsf{Real}^{\uparrow}$ *completeness theorem, no full* $\mathsf{Real}^{\uparrow}$ *arithmetic or order closure, no metric-completeness certificate, no quotient construction, no Classical datum, and no standard bridge.*

Lean4 ✓ `BEDC.Derived.RealUp.RealUp concrete to schema`

Proof. First collect the four public package faces. Apply Definition 38.258 for the finite dyadic observation source. Apply Definition 126.311 and Definition 126.301 for the public countable-name and finite-window surfaces. Apply Definition 38.276 for the regular rational-stream spine.

Next attach the $\mathsf{Real}^{\uparrow}$ export. Apply Definition 38.286 to read the scoped $\mathsf{Real}^{\uparrow}$ certificate boundary as a public downstream package. Apply Definition 38.289 to factor its countable-name and finite-window components through the public $\mathsf{StreamName}^{\uparrow}$ interfaces, leaving precisely the dyadic, regular-stream, endpoint, unary-history, hsame, carrier, classifier, and ledger rows named in the statement.

Finally repack the collected rows using the roadmap ten-field template. The traditional target, BEDC source, carrier, classifier, stability, ledger, core theorem list, exactness, standard-bridge field, and status field are all read from the cited public packages. Since each cited package explicitly withholds quotient, completion, arithmetic, order, metric-completeness, Classical, and standard-bridge data, the composite phase boundary withholds exactly those data as well. □

Theorem 38.291 (RealUp completion phase interface exhaustion)**.** *Every public consumer row for the Phase Real and Completion package of Definition 38.290 factors through exactly one of the four displayed BEDC surfaces: DyadicRatCore public observation rows,* $\mathsf{StreamName}^{\uparrow}$ *pointwise finite-window rows,* RegSeqRat *regular-spine and dyadic-tolerance rows, or the* $\mathsf{Real}^{\uparrow}$ *seal and readback rows. The exhaustion is exclusive at the consumer boundary: dyadic observations are read only through Definition 38.258, stream-name windows only through the public* $\mathsf{StreamName}^{\uparrow}$ *rows of Definition 126.311 and Definition 126.301, regular-spine and dyadic-tolerance data only through Definition 38.276, and seal/readback data only through the* $\mathsf{Real}^{\uparrow}$ *export and seal interfaces of Definition 38.286, Definition 38.289, Definition 38.287, and Definition 38.278.*

No public consumer row in this phase may read completion data, quotient representatives, host stream equality, or a direct $\mathsf{Real}^{\uparrow}$ *read that bypasses the* $\mathsf{StreamName}^{\uparrow}$–RegSeqRat *handoff.*

Proof. Begin with the composite boundary of Definition 38.290. Its four cases are the only rows placed in the phase package, so a public consumer row must be dyadic, stream-name finite-window, regular-spine with dyadic tolerance, or $\mathsf{Real}^{\uparrow}$ seal/readback data.

In the dyadic case, apply Definition 38.258. It accounts for the public observation rows and exposes no completion, quotient, host equality, or direct $\mathsf{Real}^{\uparrow}$ read.

In the stream-name case, apply Definition 126.311 together with Definition 126.301. These theorems bind pointwise finite windows through the public $\mathsf{StreamName}^{\uparrow}$ surface and do not introduce regular-spine or seal rows.

In the regular-spine case, apply Definition 38.276 and then Definition 38.278 for the dyadic tolerance rows that hand the finite window to the $\mathsf{Real}^{\uparrow}$ seal. This is the only path from a stream-name read to a $\mathsf{Real}^{\uparrow}$ readback row.

In the seal/readback case, apply Definition 38.286, Definition 38.289, and Definition 38.287. The export factors through the public stream-name interface, and seal-source determinacy prevents any second source from serving the same public read. The excluded completion, quotient, host-equality, and direct-read data are absent from each cited surface, hence absent from the exhausted consumer boundary. □

Theorem 38.292 (RealUp completion phase selected-window determinacy)**.** *Let two public consumer rows of the Phase Real and Completion package select the same certified unary finite window from the same accepted boundary packet. Then both selected reads factor through the same displayed route: the DyadicRatCore public observation package, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window interface, the* $\mathsf{RegSeqRat}$ *stream-name scoped interface, and the* $\mathsf{Real}^{\uparrow}$ *seal/readback rows.*

The two selected reads are compared only by the displayed hsame *and classifier rows along this route. No quotient representative, host stream equality, completion object, or direct* $\mathsf{Real}^{\uparrow}$ *bypass is available as a second comparison path.*

Proof. Apply Definition 38.291 to the two public consumer rows. Since both rows select a unary finite window, the exhaustion places them in the stream-name branch before any seal/readback row can be read.

Use Definition 126.301 to identify the selected certified window as a public $\mathsf{StreamName}^{\uparrow}$ finite-window read. Then apply Definition 38.276 and Definition 38.278 to repack that same window as the regular-spine input consumed by the $\mathsf{Real}^{\uparrow}$ seal.

Finally apply Definition 38.287. It rules out a second seal source for the same public read, so the two consumers can be compared only through the displayed hsame and classifier rows. The excluded quotient, host-equality, completion, and direct-bypass data are absent by the exhaustion theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$**.**

Constructive story: The real-number boundary is built by joining four already displayed surfaces: DyadicRatCore public observations, $\mathsf{StreamName}^{\uparrow}$ countable names and finite windows, the RegSeqRat regular stream spine, and the scoped $\mathsf{Real}^{\uparrow}$ seal/readback rows. The carrier accepts only this composite package of dyadic observations, rational stream names, regularity spine, constant-history rows, endpoint transports, and finite-window ledgers; a completion object, quotient carrier, host equality, arithmetic package, order package, or metric-completeness row is not part of the accepted boundary. Two accepted real packets are classified by the public stream-name classifier, the transported regular-stream classifier, and the real constant/history classifier over the same unary observation and ledger rows, rather than by identifying external Cauchy classes. The source specification is the four-package phase boundary, the pattern specification records dyadic observation transport, public StreamName export, finite-window exactness, regular-spine seal consumption, public real export, endpoint determinacy, and consumer-boundary exhaustion, and the ledger keeps each dyadic, stream, regularity, seal, endpoint, and provenance row visible. The five name-certificate obligations are read through these component certificates: a displayed constant rational embedding inhabits the boundary, the component classifiers provide reflexivity, symmetry, and transitivity, and hsame, endpoint, stream-name, and finite-window transports keep the composite package

inside the same boundary. A packet h lies in the signature gap of a $\mathsf{Real}^{\uparrow}$ token p when the source-domain accepts one of the four public package faces, the signature relation pairs it with an answer real-boundary packet and evidence ledger, and the token-introduction relation names that answer as p; unfolded, the dyadic observations, rational stream-name rows, regularity spine, and seal/readback entries match the rows encoded by p. The checked bridge marker attaches only to the constant rational embedding and boundary package recorded here; the chapter registers this phase-real construction under $\mathsf{Real}^{\uparrow}$ without closing completeness, full arithmetic, full order, metric completeness, quotient construction, Classical data, or any external bridge stronger than the checked BEDC schema bridge.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 38.290 is the mature paper boundary over DyadicRatCore, $\mathsf{StreamName}^{\uparrow}$, RegSeqRat, and $\mathsf{Real}^{\uparrow}$, binding the dyadic observations, rational stream names, regular stream spine, public $\mathsf{Real}^{\uparrow}$ certificate export, endpoint and finite-window transports, and finite-window ledger.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.RealUp.RealUp\_StdBridge`

Bridge status: bridgeChecked

Not claimed: This block does not close $\mathsf{Real}^{\uparrow}$ completeness, full arithmetic or order, metric completeness, quotient construction, Classical data, or any external bridge stronger than the checked BEDC schema bridge.

Upgrade path: No further upgrade – chapter at top of formal axis.

Theorem 38.293 (Real stream prefix finite-tail transported endpoint denominator package)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, indices n, m, and transported endpoint histories $u, v : \mathsf{Hist}$, assume*

$$\mathsf{RealStreamPrefixClassifier}(x, y, n),$$
$$\forall k < m,\ \mathsf{RatHistoryClassifier}(x(n+k+1), y(n+k+1)),$$
$$\forall i,\ \mathsf{UnaryHistory}(x(i)),$$

and

$$\mathsf{hsame}(x(n+m), u), \quad \mathsf{hsame}(y(n+m), v).$$

Then the transported finite-tail boundary carries the endpoint denominator package:

$$\mathsf{RatHistoryClassifier}(u, v) \wedge \mathsf{PositiveUnaryDenominator}(u) \wedge \mathsf{PositiveUnaryDenominator}(v) \wedge \mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge (\mathsf{hsame}(u, \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(v, \mathsf{e}) \to \mathsf{False}).$$

Ten-field fit: traditional target finite-tail transported RealUp boundary package; BEDC source RealUp stream prefixes with RatUp finite tail classifiers; carrier rational-observation streams and transported endpoint histories; classifier RealStreamPrefixClassifier *followed by* RatHistoryClassifier*; stability by tail extension with unary anchor, endpoint projection, and endpoint* hsame *transport; ledger base prefix length, tail length, selected boundary, and two endpoint transport rows; core theorem this finite-tail boundary package; exactness classifier, positive denominator, unary, and nonempty rows for u and v; standard bridge RegSeqRat finite boundary observations; status* ProofTarget*.*

Proof. First extend the classified prefix through the displayed finite tail. Apply Definition 38.116 to the prefix through n, the tail classifier row, and the pointwise unary anchor on x. This supplies $\mathsf{RealStreamPrefixClassifier}(x, y, n+m)$, together with the left unary boundary row kept in the construction.

Next apply Definition 38.111 at the boundary index $n+m$. The selected endpoint classifier is $\mathsf{RatHistoryClassifier}(x(n+m), y(n+m))$.

Transport this RatUp classifier along the two displayed hsame rows by Definition 37.54. The transported classifier is $\mathsf{RatHistoryClassifier}(u, v)$.

Finally apply Definition 37.50 to the transported classifier, and then apply Definition 37.12 separately to the two positive-denominator witnesses. These readback rows provide the two positive denominator witnesses, the two unary endpoint witnesses, and the two nonempty exclusions, so the displayed package repacks directly. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier finite tail transported endpoint denominator package`

Theorem 38.294 (Real stream prefix finite-tail transported full endpoint package)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, indices n, m, transported endpoint histories $u, v : \mathsf{Hist}$, and histories $a, b, z_U, z_V : \mathsf{Hist}$, assume*

$$\mathsf{RealStreamPrefixClassifier}(x, y, n),$$

$$\forall k < m,\ \mathsf{RatHistoryClassifier}(x(n+k+1), y(n+k+1)),$$

$$\forall i,\ \mathsf{UnaryHistory}(x(i)),$$

and

$$\mathsf{hsame}(x(n+m), u), \quad \mathsf{hsame}(y(n+m), v), \quad \mathsf{hsame}(u, \mathsf{E1}(a)), \quad \mathsf{hsame}(v, \mathsf{E1}(b)).$$

Then the transported finite-tail boundary carries the full endpoint package:

$$\begin{aligned}&\mathsf{RatHistoryClassifier}(u, v) \wedge \mathsf{PositiveUnaryDenominator}(u) \wedge \mathsf{PositiveUnaryDenominator}(v) \wedge \\ &\mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge (\mathsf{hsame}(u, \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(v, \mathsf{e}) \to \mathsf{False}) \wedge \\ &(\mathsf{hsame}(u, \mathsf{E0}(z_U)) \to \mathsf{False}) \wedge (\mathsf{hsame}(v, \mathsf{E0}(z_V)) \to \mathsf{False}) \wedge \\ &\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).\end{aligned}$$

Ten-field fit: traditional target finite transported rational observation boundary; BEDC source RealUp prefix classifier plus RatUp endpoint classifier and BHist *transports; carrier transported endpoint histories; classifier* RatHistoryClassifier*; stability endpoint* hsame *transport; ledger base prefix, finite tail, transported endpoints, and endpoint display tests; core theorem this block; exactness the displayed full package; standard bridge RegSeqRat finite boundary readback; status* ProofTarget*.*

Proof. First apply Definition 38.293 to the prefix classifier, finite-tail RatUp classifier row, pointwise unary anchor, and two transported endpoint rows. This gives the transported $\mathsf{RatHistoryClassifier}(u, v)$, both positive denominator witnesses, both unary endpoint rows, and both nonempty exclusions.

Next derive the zero-headed exclusions. If u is displayed as $\mathsf{E0}(z_U)$, transport the positive denominator witness for u across that display and apply RatUp positive-denominator zero-headed absurdity. The right endpoint uses the same argument with v and z_V.

Finally transport the transported classifier across the two displayed E1 comparisons. RatUp e-one tail classifier exactness then reads back the two unary tails and their internal sameness, namely $\mathsf{UnaryHistory}(a)$, $\mathsf{UnaryHistory}(b)$, and $\mathsf{hsame}(a, b)$. Together with the denominator package and the two zero-headed exclusions, these rows repack as the displayed full endpoint package. □

Theorem 38.295 (RealUp StreamName tail denominator selector handoff)**.** *Let W_0 and W_1 be selected finite* $\mathsf{Real}^{\uparrow}$ *observation-window packages over the same StreamName endpoints $s, t :$* BHist $\to$ BHist*, the same finite* ProbeBundle *window $\mathcal{P}$, and the same accepted* RegSeqRat *spine row. Suppose they are connected by a StreamName RegSeqRat RealUp tail-selector transport packet. Let $x, y : \mathbb{N} \to \mathsf{Hist}$ be the transported Real stream-prefix endpoint streams read from the selected finite window, let n, m be the displayed base and finite-tail lengths, and let $u, v : \mathsf{Hist}$ be transported endpoints satisfying*

$$\mathsf{RealStreamPrefixClassifier}(x, y, n),$$

$$\forall k < m,\ \mathsf{RatHistoryClassifier}(x(n+k+1), y(n+k+1)),$$

$$\forall i,\ \mathsf{UnaryHistory}(x(i)),$$

and

$$\mathsf{hsame}(x(n+m), u), \qquad \mathsf{hsame}(y(n+m), v).$$

Then the $\mathsf{Real}^{\uparrow}$ *consumer boundary exposes exactly the shared StreamName public denominator selector selected by Definition 126.207, together with the transported finite-tail endpoint denominator package*

$$\mathsf{RatHistoryClassifier}(u,v) \wedge \mathsf{PositiveUnaryDenominator}(u) \wedge \mathsf{PositiveUnaryDenominator}(v) \wedge \mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge (\mathsf{hsame}(u,\mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(v,\mathsf{e}) \to \mathsf{False}).$$

Equivalently, the handoff is a single finite boundary over the shared StreamName selector, the accepted RegSeqRat *finite row, the transported Real stream-prefix endpoints,* BHist, hsame, Cont, *and* Pkg. *It adds no quotient row, completion object, Classical representative, metric-completeness certificate, arithmetic or order row, standard bridge row, or external selector.*

Proof. First apply Definition 126.207 to the transport packet between W_0 and W_1. This identifies the selected finite public denominator selector carried by the StreamName side with the selector read by the finite $\mathsf{Real}^{\uparrow}$ ledger at W_1.

Next apply Definition 38.293 to the transported Real prefix classifier, the finite RatUp tail row, the pointwise unary anchor, and the two endpoint hsame rows. This supplies $\mathsf{RatHistoryClassifier}(u,v)$, the two positive unary denominator rows, the two unary endpoint rows, and the two nonempty endpoint exclusions.

Finally use Definition 38.294 as the readback boundary showing that the same finite-tail hypotheses admit no additional quotient, completion, representative, metric, arithmetic, order, or standard-bridge data. The consumer therefore sees only the shared StreamName denominator selector and the transported endpoint denominator package displayed above. □

Theorem 38.296 (RealUp StreamName tail selector transport determinacy)**.** *Let* H_0 *and* H_1 *be two* $\mathsf{Real}^{\uparrow}$ *StreamName tail-denominator selector handoffs over the same StreamName endpoints* $s, t : \mathsf{BHist} \to \mathsf{BHist}$*, the same finite* ProbeBundle *window* $\mathcal{P}$*, and the same accepted* RegSeqRat *spine row. Suppose both handoffs read their public denominator selector through Definition 126.207. Suppose the first handoff exposes transported Real stream-prefix endpoints* u_0, v_0 *and the second exposes transported Real stream-prefix endpoints* u_1, v_1 *from the same finite row.*

Then the two exposed endpoint denominator packages are classified by the same RatHistoryClassifier *row and expose the same positive-unary denominator rows, unary endpoint rows, and nonempty-endpoint exclusions. In particular the consumer cannot distinguish* H_0 *from* H_1 *by changing the endpoint package: both handoffs reduce to the shared StreamName selector, the same* RegSeqRat *finite spine, and the same transported package over* BHist, hsame, Cont, *and* Pkg. *No quotient, completion, arithmetic or order row, standard bridge row, or external selector row can separate the two handoffs at this boundary.*

Proof. Apply Definition 38.295 to H_0. The result identifies the public consumer boundary of the first handoff with the StreamName denominator selector selected by Definition 126.207 and with the transported finite-tail endpoint denominator package supplied by Definition 38.293.

Apply the same handoff theorem to H_1. The hypotheses have not changed: the StreamName endpoints, the finite ProbeBundle window, and the accepted RegSeqRat spine row are the same, and the public selector is read through the same StreamName theorem. Thus the second endpoint package is read from the same finite-tail denominator package rows as the first.

The endpoint-package theorem records exactly the RatHistoryClassifier row, the positive-unary denominator witnesses, the unary endpoint rows, and the two nonempty-endpoint exclusions. Since

both handoffs consume that same row data, replacing H_0 by H_1 leaves each of those rows fixed at the consumer boundary.

Finally the handoff theorem states the negative boundary: no quotient, completion object, arithmetic or order certificate, standard bridge, or external selector is added. Hence no such row can distinguish the two handoffs, and the exposed endpoint denominator package is determined by the shared StreamName selector and the shared $\mathsf{RegSeqRat}$ finite row. □

Theorem 38.297 (Real stream finite-window adjacent partition)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$ *and indices* n, m, r*,*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m{+}1{+}r) \iff \mathsf{RealStreamWindowClassifier}(x, y, n, m) \wedge \mathsf{RealStreamWindowClassif}$$

Proof. For the forward direction, assume the joined window $\mathsf{RealStreamWindowClassifier}(x, y, n, m{+}1{+}r)$. Apply Definition 38.172 with shift 0 and radius m; the bound $0{+}m \leq m{+}1{+}r$ is immediate, so the left piece is $\mathsf{RealStreamWindowClassifier}(x, y, n, m)$.

Apply Definition 38.172 again with shift $m{+}1$ and radius r. The bound $(m{+}1){+}r \leq m{+}1{+}r$ identifies exactly the right adjacent piece $\mathsf{RealStreamWindowClassifier}(x, y, n + (m + 1), r)$. These two extracted windows form the conjunction.

For the reverse direction, assume the two adjacent pieces. Apply Definition 38.182 to the left piece and the right piece at anchor $n + (m + 1)$. The concatenation theorem repacks the bounded endpoint witnesses into $\mathsf{RealStreamWindowClassifier}(x, y, n, m + 1 + r)$. □

Theorem 38.298 (Real stream finite-window adjacent boundary readback package)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$*, indices* n, m, r*, and histories* $a, b, z_X, z_Y : \mathsf{Hist}$*, assume* $\mathsf{RealStreamWindowClassifier}(x, y, n, m{+}1{+}r)$*,* $\mathsf{hsame}(x(n{+}m), \mathsf{E1}(a))$*, and* $\mathsf{hsame}(y(n{+}m), \mathsf{E1}(b))$*. Then the selected adjacent boundary endpoint at* $n + m$ *carries the following package:*

1. $\mathsf{RealStreamWindowClassifier}(x, y, n, m)$*;*
2. $\mathsf{RealStreamWindowClassifier}(x, y, n + (m + 1), r)$*;*
3. $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$*;*
4. $\mathsf{PositiveUnaryDenominator}(x(n + m)) \wedge \mathsf{PositiveUnaryDenominator}(y(n + m))$*;*
5. $\mathsf{UnaryHistory}(x(n + m)) \wedge \mathsf{UnaryHistory}(y(n + m))$*;*
6. $(\mathsf{hsame}(x(n + m), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y(n + m), \mathsf{e}) \to \mathsf{False})$*;*
7. $(\mathsf{hsame}(x(n + m), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y(n + m), \mathsf{E0}(z_Y)) \to \mathsf{False})$*;*
8. $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$*.*

Proof. Apply the forward direction of Definition 38.297 to the wide window $\mathsf{RealStreamWindowClassifier}(x, y, n, m{+}1{+}r)$. This produces the left window over (n, m) and the right adjacent window over $(n{+}(m{+}1), r)$.

The selected boundary is the offset m inside the wide window. Since $m \leq m + 1 + r$, Definition 38.156 applies to the wide window with $k = m$ and to the displayed one-extension comparisons at $x(n + m)$ and $y(n + m)$.

That selected readback package supplies the RatUp classifier row at $\mathsf{E1}(a)$ and $\mathsf{E1}(b)$, the positive-denominator rows, the unary endpoint rows, the empty and zero-headed exclusions, and the tail agreement $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$. Repack these rows with the two adjacent windows obtained from the partition. □

The ten-field fit is: traditional target adjacent finite RegSeqRat boundary reads; BEDC source RealUp finite windows over RatUp endpoint classifiers and StreamNameUp observation schedules; carrier rational-observation streams and selected unary tails; classifier RealStreamWindowClassifier with the selected RatUp endpoint package; stability by adjacent-window partition and selected full-shape readback; ledger left finite window, right adjacent window, boundary index, displayed one-extension rows, finite ledger rows, UnaryHistory, and hsame; core theorems Definition 38.297 and Definition 38.156; exactness the displayed adjacent boundary package; standard bridge finite RealUp window consumption; status no completion, quotient, or host-index equality data.

Theorem 38.299 (Real unary stream finite-window adjacent partition)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and unary anchor histories* $a, w, r : \mathsf{Hist}$*,*

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, \mathsf{append}(w, \mathsf{BHist.e1}(r)))$$
$$\iff \mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w) \wedge \mathsf{RealUnaryStreamWindowClassifier}(s, t, \mathsf{append}(a, \mathsf{BHist.e1}(w)), r)$$

Proof. For the forward direction, unfold Definition 38.154 in the joined unary window. The displayed append ledger below $\mathsf{append}(w, \mathsf{BHist.e1}(r))$ separates offsets that remain below w from offsets that pass the visible successor $\mathsf{BHist.e1}(w)$.

The first ledger projection supplies every offset required for $\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w)$. The second projection supplies an offset below r from the shifted anchor $\mathsf{append}(a, \mathsf{BHist.e1}(w))$, and the carried hsame row identifies that shifted endpoint with the corresponding endpoint of the joined window. The RatUp endpoint classifier transports along this row.

For the reverse direction, assume the left and right unary windows. Apply Definition 38.183. It repacks the two windows, their UnaryHistory rows, and the finite Cont append ledger into the joined classifier over $\mathsf{append}(w, \mathsf{BHist.e1}(r))$. □

Theorem 38.300 (Real unary adjacent-window terminal source boundary)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and unary anchor and bound histories* $a, w, r : \mathsf{Hist}$*, suppose the joined finite window*

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, \mathsf{append}(w, \mathsf{BHist.e1}(r)))$$

is consumed through a finite RegSeqRat *handoff and then by a terminal finite-window* $\mathsf{Real}^{\uparrow}$ *seal consumer. Then the terminal source-boundary projection is exactly the union of the two adjacent source windows supplied by Definition 38.299. Its rows are:*

1. *the left row* $\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w)$*;*
2. *the right row* $\mathsf{RealUnaryStreamWindowClassifier}(s, t, \mathsf{append}(a, \mathsf{BHist.e1}(w)), r)$*;*
3. *the selected* RatHistoryClassifier *endpoint rows for the boundary and terminal subwindow endpoints;*
4. *the bundled* UnaryHistory *and* InBundle *rows;*
5. *the visible* Cont*,* hsame*,* Pkg*, and* RealLedgerPolicy *provenance rows; and*
6. *the accepted* RegSeqRat *finite-window spine.*

No quotient row, completion object, host index equality, metric-completeness row, arithmetic or order operation, or standard bridge row is introduced by this terminal projection.

Proof. First apply Definition 38.299 to the joined classifier. This separates the source into the left unary window at anchor a and the right unary window at the shifted anchor $\mathsf{append}(a, \mathsf{BHist.e1}(w))$.

Next feed the two finite windows through the StreamName common-refinement source surface. Use Definition 38.400 and Definition 38.399 to identify the common finite source package read by the StreamName rows, the accepted RegSeqRat handoff, and the finite $\mathsf{Real}^{\uparrow}$ consumer.

Finally apply Definition 38.380 and Definition 38.377. The first theorem removes the route choice through the common-refinement packet; the second identifies the terminal seal projection with exactly the classifier, endpoint, bundle, transport, provenance, ledger, and accepted-spine rows just listed. Its exclusion clause gives the absence of quotient, completion, host-index, metric, arithmetic, order, and bridge data. □

Theorem 38.301 (Real stream window RegSeqRat partition handoff)**.** *Let a joined finite* RealStreamWindowClassif *window be partitioned into adjacent left and right windows. Then any accepted* RegSeqRat *handoff and finite* $\mathsf{Real}^{\uparrow}$ *seal read from the joined window factors through the two adjacent partition rows together with the boundary endpoint package.*

The handoff surface consists of the left and right RealStreamWindowClassifier *rows, the selected* RatHistoryClassifier *boundary endpoint row, the displayed* UnaryHistory *and denominator rows, the finite* hsame *and* Cont *transport rows, the* Pkg *provenance, and the accepted* RegSeqRat *spine. It introduces no quotient row, completion object, host index equality, metric-completeness row, arithmetic or order operation, or standard bridge row.*

Proof. First apply Definition 38.297. The joined finite classifier separates into the left window and the right adjacent window, so the source of the accepted RegSeqRat handoff is already displayed as two finite partition rows.

Next use Definition 38.298. The boundary endpoint package supplies the selected RatHistory classifier row, positive-denominator rows, unary rows, endpoint exclusions, and the boundary hsame comparison needed by the handoff.

Finally apply Definition 38.300. The terminal finite-window $\mathsf{Real}^{\uparrow}$ seal reads only the two adjacent source windows, the boundary endpoint package, the visible transport and provenance rows, and the accepted RegSeqRat spine. The same boundary theorem excludes quotient, completion, host-index, metric-completeness, arithmetic, order, and bridge coordinates. □

The ten-field fit is: traditional target finite adjacent observation windows over unary histories; BEDC source RealUp windows over StreamNameUp schedules $s, t : \mathsf{Hist} \to \mathsf{Hist}$; carrier unary anchor and bound histories; classifier RatUp endpoint classifiers at append-selected endpoints; stability by unary offset partition and adjacent concatenation; ledger UnaryHistory, Cont, hsame, left-window rows, right-window rows, and the visible successor split; core theorem Definition 38.299; exactness the joined unary window is equivalent to its left and right adjacent windows; standard bridge RegSeqRat finite-prefix consumption; status ProofTarget.

The ten-field fit is: traditional target finite adjacent observation intervals; BEDC source RealUp finite windows over RatUp endpoint classifiers; carrier rational-observation streams; classifier RealStreamWindowClassifier; stability by subwindow extraction and concatenation; ledger left radius, right radius, join point, and bounded-offset witnesses; core theorem Definition 38.297; exactness the displayed equivalence between the joined window and its adjacent pieces; standard bridge finite RegSeqRat observation intervals; status ProofTarget.

Theorem 38.302 (Real stream finite-window overlap partition)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$ *and indices* n, m, r*,*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m{+}r) \iff \mathsf{RealStreamWindowClassifier}(x, y, n, m) \wedge \mathsf{RealStreamWindowClassifier}($$

Proof. For the forward direction, assume the wide window $\mathsf{RealStreamWindowClassifier}(x, y, n, m+r)$. Apply Definition 38.172 with shift 0 and radius m; the bound $0 + m \leq m + r$ extracts the left window $\mathsf{RealStreamWindowClassifier}(x, y, n, m)$.

Apply Definition 38.172 again with shift m and radius r. The bound $m+r \leq m+r$ extracts the right overlapping window $\mathsf{RealStreamWindowClassifier}(x, y, n+m, r)$. These two extracted windows form the displayed conjunction.

For the reverse direction, assume the two overlapping windows. Unfold Definition 38.166 and fix a selected offset $k \leq m + r$. It remains to produce the RatUp endpoint classifier at $n + k$.

If $k \leq m$, the left window applies directly at offset k and gives

$$\mathsf{RatHistoryClassifier}(x(n + k), y(n + k)).$$

In the remaining bounded-offset case, write $k = m + j$ with $j \leq r$. The right window applies at offset j and gives

$$\mathsf{RatHistoryClassifier}(x((n + m) + j), y((n + m) + j)).$$

The arithmetic identity $(n+m)+j = n+(m+j) = n+k$ identifies this endpoint with the selected endpoint of the wide window.

The two offset cases cover every $k \leq m+r$, with the boundary endpoint $k = m$ shared by both windows. Hence the collected endpoint classifiers repack as $\mathsf{RealStreamWindowClassifier}(x, y, n, m+r)$. □

Theorem 38.303 (Real stream window concatenation exactness)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, an anchor n, a wide bound w, and a certified finite concatenation spine P over (n, w) whose segment windows are (n_i, r_i), the wide classifier*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, w)$$

is equivalent to any certified finite concatenation of the segment classifiers named by P:

$$\mathsf{RealStreamWindowClassifier}(x, y, n, w) \iff \mathsf{ConcatSpine}_P\big(\mathsf{RealStreamWindowClassifier}(x, y, n_i, r_i)\big).$$

The equivalence preserves exactly the scoped $\mathsf{Real}^{\uparrow}$ *read surface: endpoint* $\mathsf{Rat}^{\uparrow}$ *classifiers,* DyadicRatCore *observation rows,* RegSeqRat *spine rows,* $\mathsf{StreamName}^{\uparrow}$ *request names,* UnaryHistory *witnesses,* hsame *transports, and finite ledger rows. It does not use a completion object, metric-completeness data, arithmetic or order closure, quotient data, Classical data, or a bridge row.*

Proof. First convert the concatenation spine to the partition fold. The certified spine rows record exactly the same finite list of anchors, radii, unary append displays, and Cont transitions as the partition spine in Definition 38.308. Repacking these rows changes only the bracketing of the finite segment list, not the displayed observations.

Apply Definition 38.308. It identifies the wide classifier at (n, w) with the finite conjunction of the segment windows named by the spine. The certified concatenation spine is a finite bracketing of the same conjunction, so associating the displayed rows along the spine gives the stated equivalence.

We now identify the public boundary carried by the equivalence. Apply Definition 38.309; both the wide window and the segment presentation expose exactly the endpoint $\mathsf{Rat}^{\uparrow}$ rows, dyadic observation rows, RegSeqRat rows, $\mathsf{StreamName}^{\uparrow}$ names, unary witnesses, hsame transports, and finite ledger rows listed in the statement.

Finally apply Definition 38.310. Its transport rows show that changing from the partition fold to the concatenation spine preserves the same reflexivity, symmetry, transitivity, and pointwise hsame

stability package. Since the three cited surfaces already exclude completion, metric-completeness, arithmetic and order closure, quotient, Classical, and bridge data, the concatenation equivalence introduces none of those rows. □

The ten-field fit is: traditional target overlapping finite rational observation intervals; BEDC source RealStreamWindowClassifier over RatUp endpoint classifiers; carrier rational-observation streams; classifier finite-window predicate; stability by subwindow extraction and bounded-offset splitting; ledger anchor, overlap radius, right radius, shared boundary, and selected offset; core theorem Definition 38.302; exactness the displayed equivalence; standard bridge overlapping finite RegSeqRat observation intervals; status ProofTarget.

Theorem 38.304 (Real stream finite-window overlap boundary readback package)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$*, indices* n, m, r*, and histories* $a, b, z_X, z_Y : \mathsf{Hist}$*, assume* $\mathsf{RealStreamWindowClassifier}(x, y, n, m + r)$*,* $\mathsf{hsame}(x(n + m), \mathsf{E1}(a))$*, and* $\mathsf{hsame}(y(n + m), \mathsf{E1}(b))$*. Then the shared boundary endpoint at* $n + m$ *carries the following package:*

1. $\mathsf{RealStreamWindowClassifier}(x, y, n, m)$*;*
2. $\mathsf{RealStreamWindowClassifier}(x, y, n + m, r)$*;*
3. $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$*;*
4. $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$*;*
5. $\mathsf{PositiveUnaryDenominator}(x(n + m)) \wedge \mathsf{PositiveUnaryDenominator}(y(n + m))$*;*
6. $\mathsf{UnaryHistory}(x(n+m)) \wedge \mathsf{UnaryHistory}(y(n+m)) \wedge (\mathsf{hsame}(x(n+m), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y(n+m), \mathsf{e}) \to \mathsf{False})$*;*
7. $(\mathsf{hsame}(x(n + m), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y(n + m), \mathsf{E0}(z_Y)) \to \mathsf{False})$*.*

Proof. Apply the forward direction of Definition 38.302 to the wide window $\mathsf{RealStreamWindowClassifier}(x, y, n, m+r)$. This produces the left window over (n, m) and the right overlapping window over $(n + m, r)$.

The shared boundary is the selected offset m inside the wide window. Since $m \leq m + r$, Definition 38.156 applies to the wide window with $k = m$ and to the displayed one-extension comparisons at $x(n + m)$ and $y(n + m)$.

That selected readback package gives $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$, the two unary tail witnesses with $\mathsf{hsame}(a, b)$, the positive denominator rows, the unary and nonempty endpoint rows, and the two zero-head exclusions. Repack these rows with the two windows obtained from the overlap partition. □

The ten-field fit is: traditional target shared boundaries of finite RegSeqRat observation intervals; BEDC source RealUp finite windows, RatUp endpoint classifier, and StreamNameUp observation schedule; carrier rational-observation streams; classifier RealStreamWindowClassifier with the selected boundary RatUp package; stability by overlap partition and selected endpoint readback; ledger anchor, left radius, right radius, shared endpoint, and displayed one-extension witnesses; core theorems Definition 38.302 and Definition 38.156; exactness the displayed boundary package; standard bridge RealUp finite-window exhaustion boundary for RegSeqRat finite observations; status ProofTarget.

Theorem 38.305 (Real stream finite-window two-boundary readback package)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$*, indices* n, m, r, s*, and histories* $a_0, b_0, a_1, b_1, z_{X,0}, z_{Y,0}, z_{X,1}, z_{Y,1} : \mathsf{Hist}$*, assume*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m + 1 + r + 1 + s),$$

with displayed one-extension endpoints

$$\mathsf{hsame}(x(n+m), \mathsf{E1}(a_0)) \wedge \mathsf{hsame}(y(n+m), \mathsf{E1}(b_0))$$

and

$$\mathsf{hsame}(x(n+(m+1)+r), \mathsf{E1}(a_1)) \wedge \mathsf{hsame}(y(n+(m+1)+r), \mathsf{E1}(b_1)).$$

Then the two cut points $n+m$ and $n+(m+1)+r$ carry the following finite readback package:

1. *the three segment windows*

   $\mathsf{RealStreamWindowClassifier}(x, y, n, m)$, $\mathsf{RealStreamWindowClassifier}(x, y, n{+}(m{+}1), r)$, $\mathsf{RealStreamWinc}$

2. $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a_0), \mathsf{E1}(b_0))$ *and* $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a_1), \mathsf{E1}(b_1))$*;*

3. $\mathsf{PositiveUnaryDenominator}(x(n{+}m))$*,* $\mathsf{PositiveUnaryDenominator}(y(n{+}m))$*,* $\mathsf{PositiveUnaryDenominator}(x(n{+}(m+1)+r))$*, and* $\mathsf{PositiveUnaryDenominator}(y(n+(m+1)+r))$*;*

4. $\mathsf{UnaryHistory}(x(n{+}m))$*,* $\mathsf{UnaryHistory}(y(n{+}m))$*,* $\mathsf{UnaryHistory}(x(n{+}(m{+}1){+}r))$*, and* $\mathsf{UnaryHistory}(y(n{+}(m+1)+r))$*;*

5. *the empty endpoint exclusions*

   $(\mathsf{hsame}(x(n{+}m), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y(n{+}m), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(x(n{+}(m{+}1){+}r), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y(n{+}($

6. *the zero-head endpoint exclusions*

   $(\mathsf{hsame}(x(n{+}m), \mathsf{E0}(z_{X,0})) \to \mathsf{False}) \wedge (\mathsf{hsame}(y(n{+}m), \mathsf{E0}(z_{Y,0})) \to \mathsf{False}) \wedge (\mathsf{hsame}(x(n{+}(m{+}1){+}r), \mathsf{E0}(z_{X,1})) \to$

7. *the unary tail rows*

   $\mathsf{UnaryHistory}(a_0) \wedge \mathsf{UnaryHistory}(b_0) \wedge \mathsf{hsame}(a_0, b_0) \wedge \mathsf{UnaryHistory}(a_1) \wedge \mathsf{UnaryHistory}(b_1) \wedge \mathsf{hsame}(a_1, b_1).$

Proof. First apply Definition 38.306 to the wide window. The forward direction extracts the left, middle, and right segment windows at (n, m), $(n+(m+1), r)$, and $(n+(m+1)+(r+1), s)$.

The first cut point is the selected offset m of the wide window. Since $m \leq m+1+r+1+s$, Definition 38.156 applies to the wide classifier and to the displayed endpoints at $n+m$.

The second cut point is the selected offset $m+1+r$ of the same wide window. The bound $m+1+r \leq m+1+r+1+s$ lets the same selected full-shape readback theorem apply to the displayed endpoints at $n+(m+1)+r$.

Finally repack the three segment windows with the two selected endpoint packages. The selected readback theorem supplies, at each cut point, the RatHistoryClassifier row, positive denominator rows, unary endpoint rows, empty and zero-head exclusions, and unary tail agreement for the displayed one-extension pair. □

The ten-field fit is: traditional target two cut points of a three-piece finite RegSeqRat observation window; BEDC source RealUp finite windows, RatUp endpoint classifiers, and displayed one-extension endpoints; carrier rational-observation streams; classifier RealStreamWindowClassifier with two selected RatUp readbacks; stability by three-piece partition and selected endpoint readback; ledger anchor, three segment radii, two cut points, and two displayed endpoint pairs; core theorems Definition 38.306 and Definition 38.156; exactness the displayed two-boundary package; standard bridge finite three-piece RegSeqRat observation readback for RealUp; status ProofTarget.

Theorem 38.306 (Real stream finite-window three-piece partition)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and indices n, m, r, s,*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, m{+}1{+}r{+}1{+}s) \iff \mathsf{RealStreamWindowClassifier}(x, y, n, m) \wedge \mathsf{RealStreamWindow}$$

Proof. For the forward direction, assume the wide window $\mathsf{RealStreamWindowClassifier}(x, y, n, m + 1 + r + 1 + s)$. Apply Definition 38.297 with right radius $r + 1 + s$ to split it into the left window at (n, m) and the remaining right block at $(n + (m + 1), r + 1 + s)$.

Apply Definition 38.297 again to that remaining block, now with left radius r and right radius s. This gives the middle window at $(n+(m+1), r)$ and the right window at $(n+(m+1)+(r+1), s)$, and the three extracted windows form the displayed conjunction.

For the reverse direction, assume the three displayed windows. Apply the reverse direction of Definition 38.297 to the middle and right windows, producing the combined right block $\mathsf{RealStreamWindowClassifier}(x, y, n + (m + 1), r + 1 + s)$.

Apply the reverse direction of Definition 38.297 once more to the left window and this combined right block. The result is the wide window $\mathsf{RealStreamWindowClassifier}(x, y, n, m{+}1{+}r{+}1{+}s)$. □

The ten-field fit is: traditional target finite RegSeqRat observation chains; BEDC source RealUp windows over RatUp endpoint classifiers and StreamNameUp observation schedules; carrier rational-observation streams; classifier RealStreamWindowClassifier; stability by adjacent partition and concatenation; ledger two cut points and three bounded-offset blocks; core theorem Definition 38.306; exactness equivalence between the wide window and the three chained windows; standard bridge finite observation interval refinement for RealUp; status ProofTarget.

Definition 38.307 (Real stream finite-window partition spine)**.** *For a rational-observation anchor n and a total finite bound w, a nonempty* BEDC *finite partition spine is a finite* BHist*-coded chain P of unary radius histories $a_0, \ldots, a_{q-1} : \mathsf{Hist}$ together with endpoint continuation rows. Its numeric radii r_i are the unary lengths displayed by the a_i, its segment anchors are*

$$n_0 = n, \qquad n_{i+1} = n_i + (r_i + 1),$$

and its accumulated displayed bound is

$$w = r_0 + 1 + r_1 + 1 + \cdots + 1 + r_{q-1}.$$

The singleton spine has accumulated bound r_0 and one segment at the original anchor. The successor spine appends one unary radius a_i by a native unary append *display and a* Cont *row from the previous endpoint anchor to the next endpoint anchor. Thus every segment named by P is a concrete RealUp finite window* $\mathsf{RealStreamWindowClassifier}(x, y, n_i, r_i)$*, and the final accumulated anchor is obtained only by repeated unary* append *and* Cont *composition.*

Theorem 38.308 (Real stream finite-window partition fold)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, an anchor n, a total bound w, and a certified finite partition spine P over (n, w) with segments (n_i, r_i), the total window classifier is equivalent to the conjunction of the segment classifiers named by P:*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, w) \iff \bigwedge_{(n_i, r_i) \in P} \mathsf{RealStreamWindowClassifier}(x, y, n_i, r_i).$$

For the singleton spine, the right side is the single segment classifier.

Proof. Proceed by induction on the certified partition spine P.

In the singleton case, the spine definition identifies the total bound with the single segment radius. The right side is the same $\mathsf{RealStreamWindowClassifier}(x, y, n, r_0)$ row, so the displayed equivalence is reflexive.

For the successor step, write the predecessor spine as P_0 with accumulated bound u and final anchor $n + u + 1$ in the displayed unary continuation ledger. The new certified unary radius is r, so the successor spine displays the total bound as $u + 1 + r$ and names the new final segment $\mathsf{RealStreamWindowClassifier}(x, y, n + (u + 1), r)$.

For the forward direction of the successor step, apply Definition 38.297 to the total window $\mathsf{RealStreamWindowClassifier}(x, y, n, u{+}1{+}r)$. This gives the predecessor wide window $\mathsf{RealStreamWindowClassifier}(x$ and the new final segment. Apply the induction hypothesis to the predecessor wide window to obtain every segment classifier named by P_0, then conjoin that list with the new final segment.

For the reverse direction, assume the conjunction over the successor spine. Project the predecessor segment conjunction and the new final segment. The induction hypothesis repacks the predecessor segment conjunction into $\mathsf{RealStreamWindowClassifier}(x, y, n, u)$. Apply the reverse direction of Definition 38.297 to this predecessor window and the new final segment, producing $\mathsf{RealStreamWindowClassifier}(x, y, n, u + 1 + r)$.

The three-segment case is the displayed consistency check: taking a spine with three radii m, r, s reduces the induction twice and gives exactly Definition 38.306. Its two displayed cut points are the first two successor anchors in the finite spine ledger. □

The ten-field fit is: traditional target finite RegSeqRat observation partition coverage; BEDC source RealStreamWindowClassifier plus RatHistoryClassifier endpoint rows and Cont with unary anchors; carrier rational-observation streams; classifier RealStreamWindowClassifier over a certified finite partition spine; stability by adjacent partition, induction on the BHist spine, and unary anchor continuation; ledger total bound, segment radii, accumulated anchors, continuation rows, and endpoint classifiers; core theorem Definition 38.308; exactness the displayed fold equivalence; standard bridge RealUp and RegSeqRat finite observation coverage; status ProofTarget.

Theorem 38.309 (RealUp finite-window partition read surface)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, an anchor n, a total bound w, and a certified finite partition spine P over (n, w) with segments (n_i, r_i), the total window $\mathsf{RealStreamWindowClassifier}(x, y, n, w)$ and the conjunction of segment windows*

$$\bigwedge_{(n_i, r_i) \in P} \mathsf{RealStreamWindowClassifier}(x, y, n_i, r_i)$$

expose the same scoped $\mathsf{Real}^{\uparrow}$ certificate boundary rows. These rows are exactly the endpoint $\mathsf{Rat}^{\uparrow}$ classifiers, positive unary denominator rows, nonempty unary endpoint rows, common e-one tail readback wherever the endpoints are displayed as one-headed, finite RealLedgerPolicy *rows, DyadicRatCore observation rows,* RegSeqRat *spine rows,* $\mathsf{StreamName}^{\uparrow}$ *request names,* UnaryHistory *witnesses, and* hsame *transport rows named by the certified window spine. Neither presentation reads quotient data, a completion object, a metric-completeness certificate, arithmetic or order closure, Classical data, or a standard bridge.*

Proof. First transport between the two window presentations. Apply Definition 38.308; the total classifier at (n, w) is equivalent to the finite conjunction of the segment classifiers named by P.

Now read the total presentation through the scoped boundary. Apply Definition 38.342 to the total window. It identifies the endpoint $\mathsf{Rat}^{\uparrow}$ rows, denominator rows, common e-one tail readback, finite ledger rows, dyadic source rows, stream-name rows, unary history witnesses, and hsame transport rows available at the total window.

For each segment (n_i, r_i) supplied by the partition spine, apply Definition 38.342 again to the segment window $\mathsf{RealStreamWindowClassifier}(x, y, n_i, r_i)$. The partition-spine ledger records that the segment anchors and radii are obtained from the same unary radius histories, append displays, and Cont rows used to display the total bound, so the segment reads name only the finite endpoint and dyadic source rows already named by the total presentation.

It remains to identify the primitive boundary. Apply Definition 38.314 for the endpoint package and dyadic finite-window source exhaustion. Apply Definition 38.392 for the carrier, classifier, stability, ledger, and seal rows of the primitive stream-prefix boundary. These two packages contain exactly the rows listed in the statement and exclude quotient, completion, metric-completeness, arithmetic, order, Classical, and standard-bridge data, so the partitioned and total presentations have the same scoped $\mathsf{Real}^{\uparrow}$ read surface. □

Theorem 38.310 (RealUp finite-window partition stability package)**.** *For rational-observation streams $x, x', y, y', z : \mathbb{N} \to \mathsf{Hist}$, an anchor n, a total bound w, and a certified finite partition spine P over (n, w) with segments (n_i, r_i), the four stability rows of* $\mathsf{RealStreamWindowClassifier}$ *commute with the correspondence between the total window at (n, w) and the segment windows named by P.*

Concretely, both the total presentation $\mathsf{RealStreamWindowClassifier}(-, -, n, w)$ *and the segment presentation*

$$\bigwedge_{(n_i, r_i) \in P} \mathsf{RealStreamWindowClassifier}(-, -, n_i, r_i)$$

expose the same scoped stability package:

1. *reflexivity from endpoint carrier rows for each displayed observation;*
2. *symmetry of the window classifier;*
3. *transitivity through the middle stream y;*
4. *pointwise* hsame *transport from (x, y) to (x', y') over the displayed observations.*

The exposed certificate boundary in either presentation is exactly the scoped read surface of Definition 38.309: endpoint $\mathsf{Rat}^{\uparrow}$ *rows,* $\mathsf{DyadicRatCore}$ *observation rows,* $\mathsf{RegSeqRat}$ *spine rows,* $\mathsf{StreamName}^{\uparrow}$ *request names,* $\mathsf{UnaryHistory}$ *witnesses,* hsame *transport rows, and the finite ledger rows named by the certified partition spine.*

Proof. First identify the two window presentations. Apply Definition 38.308 to the certified spine P. It gives the equivalence between the total classifier at (n, w) and the finite conjunction of segment classifiers at the anchors and radii listed by P.

Next apply Definition 38.171 to the total window. Its four rows give reflexivity from the carrier observations, symmetry, transitivity through y, and pointwise hsame transport from (x, y) to (x', y') on every offset $k \leq w$.

For the segment presentation, apply the same stability package to each segment window $\mathsf{RealStreamWindowClassifier}(-, -, n_i, r_i)$. The spine ledger records that every displayed segment offset is one of the observations in the total window, and the finite fold records the reverse containment by collecting the segment windows back into the total classifier.

Finally apply Definition 38.309. It identifies the public rows exposed by the total presentation and by the partitioned presentation as the same endpoint $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}$, $\mathsf{RegSeqRat}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{UnaryHistory}$, hsame, and ledger rows. Therefore transporting any of the four stability rows across the fold does not expose additional data and does not lose any scoped row from the listed $\mathsf{Real}^{\uparrow}$ boundary. □

Theorem 38.311 (RealUp finite-window partition associative read surface)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ over the same* RealStreamWindowClassifier*, let P and Q be certified finite partition spines over the same total window (n, w). Suppose P and Q have the same ordered leaves (n_i, r_i) and differ only by associative rebracketing of the partition spine. Then the two certified presentations expose the same consumer read surface for the window.*

Concretely, the endpoint $\mathsf{Rat}^{\uparrow}$ *classifier rows,* DyadicRatCore *observation rows,* RegSeqRat *spine rows,* $\mathsf{StreamName}^{\uparrow}$ *request names,* UnaryHistory *witnesses,* hsame *transport rows,* Cont *routes, and finite ledger rows determined from P are exactly the rows determined from Q. No completion object, quotient, metric-completeness certificate, Classical choice row, arithmetic or order primitive, or bridge row is exported by either bracketing.*

Proof. Apply Definition 38.308 to the certified spine P. It identifies the total classifier RealStreamWindowClassifier(x with the finite conjunction of the segment classifiers listed by the common ordered leaves.

Apply the same fold theorem to Q. Since the leaves are the same and only the associative spine bracketing changes, both folds land in the same finite conjunction of segment windows.

Now compare the consumer rows through Definition 38.309. The theorem reads each folded presentation as the same endpoint $\mathsf{Rat}^{\uparrow}$, DyadicRatCore, RegSeqRat, $\mathsf{StreamName}^{\uparrow}$, UnaryHistory, hsame, Cont, and finite ledger boundary attached to the displayed leaves.

Finally use Definition 38.310. The stability rows transport across the two fold presentations without exposing any row outside the displayed $\mathsf{Real}^{\uparrow}$ boundary. Thus associative rebracketing of the certified finite partition spine preserves exactly the same consumer read surface. □

Theorem 38.312 (Real stream finite-window partition refinement transitivity)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, a total anchor n, a total bound w, and certified finite partition spines P, Q over (n, w), suppose every segment of Q is displayed in the ledger as a consecutive union of segments of P. If every P-segment (n_i, r_i) carries* RealStreamWindowClassifier(x, y, n_i, r_i)*, then every Q-segment (m_j, s_j) carries* RealStreamWindowClassifier(x, y, m_j, s_j)*.*

Equivalently, the finite ledger exposed by the fine partition P refines the coarser partition ledger Q without changing any endpoint $\mathsf{Rat}^{\uparrow}$ *classifier, dyadic source row, stream-name row, unary witness,* hsame *transport row, or continuation ledger entry at the visible boundary.*

The ten-field fit is: name RealStreamWindow *refinement transitivity; BEDC source* $\mathsf{BHist} + \mathsf{Rat}^{\uparrow} + \mathsf{StreamName}^{\uparrow} +$ RealStreamWindowClassifier*; carrier the certified finite partition spine; classifier* RealStreamWindowClassifier*; pattern consecutive-union refinement of window spines; stability the four classifier rows exposed by Definition 38.310; ledger the refinement witness from fine rows to coarse rows; exactness the unchanged* $\mathsf{Rat}^{\uparrow}$ *endpoint classifier surface; core theorem Definition 38.312; downstream consumer* $\mathsf{Real}^{\uparrow}$ *finite-window certificate closure.*

Proof. Induct on the coarser spine Q. The empty spine has no segment to certify, and the ledger refinement witness contributes no visible row.

For a nonempty coarser spine, read the head segment (m_j, s_j) as the consecutive subspine of P selected by the refinement ledger. Apply Definition 38.308 to that subspine. The given classifiers on the fine P-segments fold into RealStreamWindowClassifier(x, y, m_j, s_j).

Now repack the visible rows for this coarse segment. Apply Definition 38.309 to identify the endpoint $\mathsf{Rat}^{\uparrow}$ rows, dyadic source rows, stream-name rows, unary witnesses, hsame transport rows, and finite ledger entries exposed by the fine subspine and by the coarse segment as the same scoped read surface.

The stability fields are transported across this repacking by Definition 38.310. Removing the consumed fine subspine leaves the tail of P refining the tail of Q, so the induction hypothesis

certifies every remaining coarse segment. Combining the head certificate with the tail certificates gives the claimed refinement transitivity. □

Theorem 38.313 (Real stream finite-window common refinement exactness)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, a total anchor n, a total bound w, and certified finite partition spines P, Q over (n, w), suppose every segment of P and every segment of Q carries* $\mathsf{RealStreamWindowClassifier}(x, y, -, -)$*. Then there is a certified finite partition spine R over (n, w) such that:*

1. *every segment of R carries* $\mathsf{RealStreamWindowClassifier}(x, y, -, -)$*;*
2. *folding the R-segments over each P-block recovers the P presentation, and folding the R-segments over each Q-block recovers the Q presentation;*
3. *the public endpoint rows read from the P, Q, and R presentations are exactly the same* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}$*,* $\mathsf{RegSeqRat}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{UnaryHistory}$*,* hsame*, and finite* Cont *ledger rows.*

Thus two independent certified finite-window presentations of the same RealUp window admit a common refinement whose fold and visible read surface are exact for both presentations.

Proof. Build R by simultaneous induction on the two certified finite spines. The base case is the singleton overlap of the two total-window spines, where the given classifier row is already the required segment row.

In the induction step, compare the first remaining P-segment and Q-segment by their unary endpoint ledgers. If one endpoint is earlier, split the longer current segment at that displayed endpoint; if the endpoints agree, take their common terminal segment. The construction uses only the unary radius histories, accumulated anchors, and Cont rows already present in the two certified spines, so the resulting list is again a certified finite partition spine over (n, w).

For each refined block, apply Definition 38.308. It folds the R-segments contained in a displayed P-block back to the corresponding P-segment classifier, and the same argument folds the R-segments contained in a displayed Q-block back to the corresponding Q-segment classifier.

Next apply Definition 38.312 from R to P and from R to Q. These two refinement readings show that replacing either original presentation by the common refinement does not add or remove any classifier row at the visible boundary.

Finally apply Definition 38.309 to the three presentations and Definition 38.310 to transport the stability rows across the two fold comparisons. The read surfaces are therefore the same endpoint $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}$, $\mathsf{RegSeqRat}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{UnaryHistory}$, hsame, and finite Cont ledger rows, which is the asserted exactness. □

Theorem 38.314 (RealUp finite-window exhaustion obligation)**.** *At the RealUp obligation boundary, the finite-window observation field is supplied by the conjunction of* RealStreamClassifier_finite_prefix_endpoint RealStreamPrefixClassifier_truncated_endpoint_denominator_package, RealStreamPrefixClassifier_truncated_endpo *and the* RegSeqRat *finite-window dyadic source exhaustion package. Consequently every selected finite* $\mathsf{Real}^{\uparrow}$ *observation window exposes endpoint* $\mathsf{Rat}^{\uparrow}$ *classifiers, positive unary denominators, nonempty unary endpoint rows, common e-one tail readback, and exactly the* DyadicRatCore *source rows consumed by the* $\mathsf{Real}^{\uparrow}$ *seal, with no data outside the carriers, classifiers, stability rows, and ledger rows listed in Definition 38.285.*

Lean4 ✓ `BEDC.Derived.RealUp.RealupFiniteWindowExhaustionObligation`

Proof. First collect the endpoint denominator face. Apply Definition 38.541 to the selected finite prefix. It supplies the endpoint $\mathsf{Rat}^{\uparrow}$ classifier, the positive unary denominator witnesses, the unary endpoint rows, and the nonempty endpoint exclusions needed at the selected observation.

Next pass to truncated prefixes. Apply the truncated endpoint denominator package recorded by Definition 38.293. This transports the same endpoint denominator data through the finite tail presentation used by the stream-prefix carrier and classifier rows.

Now read the selected one-headed tails. Apply Definition 38.854; the truncated endpoint package gives the hypotheses needed to expose common e-one tails at the two selected endpoint histories.

Finally identify the consumed source rows. Apply Definition 38.564. It states that the selected bounded RegSeqRat observation reads exactly the two DyadicRatCoreObservationRow endpoint sources and the scoped carrier, classifier, stability, and finite ledger faces named by the dyadic source package. These are precisely the rows allowed by Definition 38.285; hence the finite-window observation field consumes no data outside that boundary. □

Theorem 38.315 (RealUp StreamName RegSeqRat dyadic handoff exhaustion)**.** *Every* $\mathsf{Real}^{\uparrow}$ *finite-window observation whose StreamName face is a* RegSeqRat *handoff factors through exactly the displayed finite source surface: the* RatStreamNameFiniteWindowClassifier *row, the selected* ProbeBundle*,* InBundle*, and* UnaryHistory *rows, the endpoint* $\mathsf{Rat}^{\uparrow}$ *denominator rows, the accepted* RegSeqRat *spine, the DyadicRatCore source rows, the shown* hsame/Cont/Pkg *ledger, and the* RealLedgerPolicy *row.*

This factorization is finite-row only. It exports no completion object, quotient representative, Classical *representative, metric-completeness certificate, arithmetic or order operation, or standard-bridge row.*

Proof. First apply Definition 38.314. It reduces the selected $\mathsf{Real}^{\uparrow}$ observation to endpoint denominator rows, positive unary denominator witnesses, common e-one tail readback, and the DyadicRatCore source rows supplied by the accepted RegSeqRat finite-window dyadic package.

Next apply Definition 126.268. The StreamName face of the same observation contributes only the finite-window classifier row, the shared ProbeBundle, the selected InBundle/UnaryHistory rows, the pointwise RatHistoryClassifier rows, and the displayed hsame/Cont/Pkg provenance that feeds the accepted spine.

Finally use Definition 126.217. The tail-window packet admits no consumer row beyond the displayed classifier, bundle, unary-history, pointwise rational-history, RegSeqRat, DyadicRatCore, and RealLedgerPolicy rows. Therefore the $\mathsf{Real}^{\uparrow}$ finite-window observation factors through exactly the stated handoff surface, and completion, quotient, Classical representative, metric-completeness, arithmetic or order, and standard-bridge rows remain outside the finite ledger. □

Theorem 38.316 (RealUp refinement envelope reindexed consumer invariance)**.** *Let E be a* $\mathsf{Real}^{\uparrow}$ *finite-window refinement envelope over a fixed* $\mathsf{StreamName}^{\uparrow}$ *source, and let P be a* $\mathsf{StreamName}^{\uparrow}$–RegSeqRat *reindexed window package whose selected rational classifier rows feed a certified window W carried by E. The downstream* RegSeqRat *handoff determined by P and the finite-window* $\mathsf{Real}^{\uparrow}$ *seal read determined by W factor through the same envelope-facing rows:* RatStreamNameFiniteWindowClassifier *rows, the* ProbeBundle*,* InBundle*, and* UnaryHistory *rows, the endpoint denominator rows, the* DyadicRatCore *source rows, the shared* hsame *ledger, and the* RealLedgerPolicy *boundary. Consequently the reindexed handoff and the carried seal expose one public read surface, with no exported host index, quotient witness, completion object, or unrecorded stream row.*

Proof. Begin with the reindexed package P. By Definition 126.155, its selected rational rows are exhausted by the reindexed $\mathsf{StreamName}^{\uparrow}$ finite-window classifier rows, the probe and unary-history rows, the endpoint denominator rows, and the dyadic source rows visible in the window.

Next apply Definition 38.324. The RegSeqRat consumer handoff reads those rows through the same shared hsame ledger and the same RealLedgerPolicy boundary used by the carried $\mathsf{Real}^{\uparrow}$ window.

Finally use Definition 38.332 for the carried window W inside E. That theorem forces both the RegSeqRat handoff and the finite-window $\mathsf{Real}^{\uparrow}$ seal through exactly the rows stored in the refinement envelope.

The listed envelope rows therefore form the common public surface. Since the envelope boundary contains no slot for a host index, quotient witness, completion object, or unrecorded stream datum, none of those objects can be exported by either consumer. □

Theorem 38.317 (RealUp StreamName window determinacy boundary)**.** *Let two finite-window observations be admitted by the* $\mathsf{Real}^{\uparrow}$ *seal through the same selected unary observation and the same* RatStreamNameFiniteWindowClassifier *endpoint package. Then the two observations expose the same endpoint* $\mathsf{Rat}^{\uparrow}$ *classifier rows, the same positive denominator witnesses, the same common e-one tail readbacks, and the same* DyadicRatCore *source rows, up to the displayed* hsame *ledger rows permitted by Definition 38.285. No host* Nat *index, host function, quotient, or unrecorded stream object is available to separate the two exposed windows.*

Proof. Begin with the two accepted finite-window observations. Apply Definition 38.320 to each one. The only exposed rows are the selected unary observation, the pointwise RatStreamNameFiniteWindowClassifier row, the endpoint denominator rows, and the dyadic source rows named by the finite-window obligation.

Now use the common StreamName package. The structural laws of Definition 126.25 and the selected full-endpoint package of Definition 126.27 identify the two selected observations and their endpoint classifier rows by the displayed hsame ledger rows. Thus the endpoint $\mathsf{Rat}^{\uparrow}$ classifiers and positive denominator witnesses are the same readable rows of the package.

Finally repack through Definition 38.314. The common endpoint package supplies the hypotheses for the common e-one tail readbacks, and the dyadic source exhaustion supplies the same DyadicRatCore source rows. Since Definition 38.285 permits only these carrier, classifier, stability, and finite ledger rows, the two windows have the same exposed RealUp seal ledger. □

Theorem 38.318 (RealUp finite-window coverage and determinacy package)**.** *Every finite* $\mathsf{Real}^{\uparrow}$ *observation admitted through the* $\mathsf{StreamName}^{\uparrow}$ *finite-window seal factors through one package of public rows: the* RatStreamNameFiniteWindowClassifier *row, the selected* ProbeBundle *and* InBundle *rows, the* UnaryHistory *observation, the endpoint* $\mathsf{Rat}^{\uparrow}$ *denominator rows, the* DyadicRatCore *source rows, the displayed* hsame *ledger, and the finite* RealLedgerPolicy *boundary. Moreover, if two admitted reads use the same selected unary observation and the same endpoint package, then their exposed dyadic source rows agree up to that displayed* hsame *ledger; and any certified unary reindexing of the selected observation preserves exactly the same package.*

Proof. First apply Definition 38.314. It reduces an admitted finite $\mathsf{Real}^{\uparrow}$ window to the endpoint denominator rows, the common e-one tail readback, and the DyadicRatCore source rows visible through the finite seal.

Next apply Definition 38.320. This identifies the StreamName face of the same window: the RatStreamNameFiniteWindowClassifier row, selected probe and bundle rows, unary-history observation, endpoint $\mathsf{Rat}^{\uparrow}$ denominator rows, dyadic source rows, and finite RealLedgerPolicy all sit on the same displayed hsame ledger.

For two reads with the same selected unary observation and endpoint package, use Definition 38.317. The shared StreamName package fixes the endpoint classifiers, denominator witnesses, common e-one tail readbacks, and dyadic source rows up to the displayed hsame ledger.

Finally apply Definition 38.321. Certified unary reindexing transports the selected observation and classifier row while repacking the same endpoint, source, ledger, and finite policy rows. Since no quotient, completion object, host index, or choice datum is exported by these four boundaries, the package is exactly the finite-window coverage and determinacy surface stated above. □

Theorem 38.319 (RealUp open-phase audit boundary)**.** *Every paper-side Phase Real and Completion audit read that reaches* $\mathsf{Real}^{\uparrow}$ *through finite windows factors through exactly the* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier, the* RegSeqRat *dyadic source exhaustion, the* DyadicRatCore *source rows, the endpoint* $\mathsf{Rat}^{\uparrow}$ *denominator rows, the displayed* hsame, Cont, *and* Pkg *ledger, and the local* NameCert *rows. Conversely this package is sufficient for the L10 exit boundary for those reads. It exports no quotient, selected limit, completion theorem, countable-choice row, metric-completeness datum, arithmetic or order extension, or standard bridge.*

Proof. Apply Definition 38.314 to reduce any accepted $\mathsf{Real}^{\uparrow}$ finite-window read to endpoint denominator rows, common tail readback, and dyadic source rows.

Next apply Definition 38.315 and Definition 38.318. These identify the same read through the StreamName finite-window classifier, RegSeqRat dyadic source exhaustion, DyadicRatCore source rows, endpoint $\mathsf{Rat}^{\uparrow}$ rows, displayed ledger, package provenance, and local naming rows.

The cited StreamName, RegSeqRat, and dyadic source rows already supply the forward package read by the roadmap boundary. The non-export clauses follow from the same finite-window exhaustion: none of quotient formation, selected limit choice, completion closure, countable choice, metric completeness, arithmetic or order extension, or a standard bridge is a displayed row of the package. □

Theorem 38.320 (RealUp StreamName finite-window ledger boundary)**.** *Every finite-window observation admitted by the* $\mathsf{Real}^{\uparrow}$ *seal factors through the* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier, the* $\mathsf{Rat}^{\uparrow}$ *endpoint denominator package, and the* RegSeqRat *dyadic source exhaustion rows. Its ledger is exactly the selected unary observation, the pointwise* RatStreamNameFiniteWindowClassifier *row, the endpoint denominator rows, and the dyadic source rows named by Definition 38.314. No host* Nat *index, host function, quotient, or unrecorded infinite stream object is exposed at this boundary.*

Lean4 ✓ `BEDC.Derived.RealUp.RealupStreamnameFiniteWindowLedgerBoundary`

Proof. Start with an observation accepted by the $\mathsf{Real}^{\uparrow}$ seal. Apply Definition 38.314; it reduces the accepted finite window to the denominator package, truncated endpoint readback, and RegSeqRat dyadic source rows allowed by the scoped seal.

The finite-window stream-name component is supplied by Definition 126.22, Definition 126.25, and Definition 126.27. Together these rows identify the selected unary observation, the bundled pointwise classifier, and the endpoint denominator package read by the window.

Finally use Definition 38.285. That boundary permits only the listed carrier, classifier, stability, and finite ledger rows. The StreamName rows and the dyadic source rows therefore repack into the exact ledger stated above, while host Nat data, host functions, quotients, and unrecorded infinite objects have no exported row to inspect. □

Theorem 38.321 (RealUp finite-window reindexed classifier transport)**.** *Let W be a selected finite* $\mathsf{Real}^{\uparrow}$ *observation window admitted through the* $\mathsf{StreamName}^{\uparrow}$ *finite-window seal ledger. Suppose W' is obtained from W by a certified* $\mathsf{StreamName}^{\uparrow}$ *unary reindexer, and suppose the transported* RatStreamNameFiniteWindowClassifier *row and the selected endpoint denominator package are present at W'. Then the transported window exposes the same* $\mathsf{Real}^{\uparrow}$ *finite seal ledger boundary as W: endpoint* $\mathsf{Rat}^{\uparrow}$ *classifier rows, positive denominator witnesses, common e-one tail readback,*

DyadicRatCore *source rows, unary-history rows,* hsame *transport, and the finite* RealLedgerPolicy*. The transported surface exposes no quotient, completion, host* Nat *index, host function,* Classical *datum, metric-completeness certificate, or standard bridge.*

Proof. Start with the certified unary reindexer. Apply Definition 126.19 to transport the selected $\mathsf{StreamName}^{\uparrow}$ observation rows and their hsame stability ledger from W to W'.

Next apply Definition 126.24. The transported finite-window classifier at W' covers exactly the reindexed unary observation rows and the selected endpoint package, so no host Nat index or host function is exported by the StreamName face.

Now identify the RealUp ledger carried by the source window. By Definition 38.320, the original surface of W contains only the selected unary observation, the RatStreamNameFiniteWindowClassifier row, endpoint $\mathsf{Rat}^{\uparrow}$ classifier rows, positive denominator witnesses, common e-one tail readback, DyadicRatCore source rows, and the finite RealLedgerPolicy rows allowed by the seal.

Finally repack the transported rows through Definition 38.314. The scoped boundary permits only carrier, classifier, stability, source, and finite ledger rows, so the reindexed read surface is the same RealUp finite seal ledger boundary and has no quotient, completion, Classical datum, metric-completeness certificate, or standard bridge to inspect. □

Theorem 38.322 (RealUp finite-window feed reindexing stability)**.** *Let W be a selected finite* $\mathsf{Real}^{\uparrow}$ *observation window admitted through the* $\mathsf{StreamName}^{\uparrow}$ *finite-window seal, and let W' be obtained from W by a certified unary* $\mathsf{StreamName}^{\uparrow}$ *reindexer. Suppose the reindexer preserves the transported* RatStreamNameFiniteWindowClassifier *row at W'. Then the public feed read at W' is the same feed read at W: the selected* UnaryHistory *observation, the* ProbeBundle *and* InBundle *rows of the window, the endpoint* $\mathsf{Rat}^{\uparrow}$ *denominator package, the* RegSeqRat *handoff rows, the* DyadicRatCore *source rows, the displayed* hsame *ledger, and the finite* RealLedgerPolicy *boundary.*

The feed comparison exports no quotient row, completion object, host Nat *index, host function, metric-completeness certificate, or standard bridge claim.*

Proof. First transport the finite StreamName face. Apply Definition 126.19 to move the selected unary observation and its hsame ledger along the certified unary reindexer. Then apply Definition 126.24 to identify the transported finite-window classifier with exactly the reindexed observation rows and endpoint denominator package.

Next pass from classifier transport to the RealUp feed boundary. By Definition 38.321, the reindexed classifier row exposes the same finite seal ledger boundary as the source window, including the endpoint $\mathsf{Rat}^{\uparrow}$ denominator rows, DyadicRatCore source rows, displayed hsame transport, and finite RealLedgerPolicy rows.

The RegSeqRat source face is the same public feed. Apply Definition 38.324 to identify the selected StreamName rational rows with the RegSeqRat dyadic handoff rows read by the finite window.

Finally use Definition 38.314. Its boundary lists all carrier, classifier, source, and finite ledger rows admitted by the selected window, including the ProbeBundle and InBundle entries. Since no admitted row is a quotient, completion, host index, host function, metric-completeness certificate, or standard bridge, the transported feed has exactly the same public surface and no additional exported datum. □

Theorem 38.323 (RealUp StreamName reindexing composition boundary)**.** *Let W be a selected finite* $\mathsf{Real}^{\uparrow}$ *observation window admitted through the* $\mathsf{StreamName}^{\uparrow}$ *finite-window seal ledger. Suppose two certified* $\mathsf{StreamName}^{\uparrow}$ *unary reindexers are applied successively to W, and suppose the same selected endpoint package is also read through the single certified composite reindexer. Then*

the successive read and the composite read expose the same finite seal ledger: selected unary observation rows, the RatStreamNameFiniteWindowClassifier *row, endpoint* $\mathsf{Rat}^{\uparrow}$ *denominator rows, positive denominator witnesses, common e-one tail readback,* DyadicRatCore *source rows,* hsame *transport, and the finite* RealLedgerPolicy*.*

In particular, the composite surface has no additional quotient, completion, host Nat *index, host function, unrecorded stream object,* Classical *datum, metric-completeness certificate, or standard bridge beyond the rows already exposed by the two successive unary transports.*

Proof. Start with the two certified unary reindexers. Apply Definition 126.19 to each reindexing step, and use the $\mathsf{StreamName}^{\uparrow}$ reindexing composition law to identify the successive selected unary observation rows with the rows selected by the single composite reindexer.

Next apply Definition 38.321 to the first transported window and again to the second transported window. The finite classifier, endpoint denominator package, common e-one tail readback, and DyadicRatCore source rows are carried componentwise through the same hsame transport ledger.

Finally compare both transported reads with Definition 38.320. That boundary lists the whole finite $\mathsf{Real}^{\uparrow}$ seal ledger, so the successive read and the composite read have the same public rows and no further host-level reindexing datum to inspect. □

Theorem 38.324 (RealUp StreamName-RegSeqRat reindexed ledger handoff)**.** *Let* $\mathcal{W}$ *be a* $\mathsf{StreamName}^{\uparrow}$–RegSeqRat *reindexed window package whose selected rational classifier rows feed a finite* $\mathsf{Real}^{\uparrow}$ *observation window* W*. Then the package exposes exactly the* $\mathsf{Real}^{\uparrow}$ *finite seal ledger boundary for* W*: the selected unary observation row, the* RatStreamNameFiniteWindowClassifier *row, the endpoint denominator rows, and the* RegSeqRat *dyadic source rows selected by the finite window. It exposes no host* Nat *index, host function, quotient, completion object, or unrecorded infinite stream.*

Proof. Start with the displayed reindexed window package. Apply Definition 126.155 to decompose its visible rows into the selected unary observation, the transported RatStreamNameFiniteWindowClassifier row, the endpoint denominator rows, and the RegSeqRat source rows supplied by the package.

Next use Definition 126.79. It is the common handoff from the StreamName finite-window face to the RegSeqRat dyadic source face, so the selected rational classifier rows are the same rows read by the finite $\mathsf{Real}^{\uparrow}$ observation.

Now apply Definition 38.320. The RealUp seal boundary admits exactly the selected unary observation, the finite StreamName classifier row, the endpoint denominator rows, and the dyadic source rows as public ledger entries.

Finally use Definition 126.156. It excludes the host index, host map, quotient, completion object, and unrecorded stream data from the reindexed package, so the package and the $\mathsf{Real}^{\uparrow}$ finite seal expose the same finite boundary. □

Theorem 38.325 (RealUp finite-window exhaustion subwindow closure)**.** *Whenever a* $\mathsf{Real}^{\uparrow}$ *finite-window exhaustion package is exposed for a* $\mathsf{StreamName}^{\uparrow}$ *finite window, every certified subwindow obtained by the* $\mathsf{StreamName}^{\uparrow}$ *finite-window subwindow restriction exposes the same* $\mathsf{Rat}^{\uparrow}$ *endpoint classifier, the same ledger boundary, and the same* $\mathsf{Real}^{\uparrow}$ *read surface restricted to that subwindow. The restricted package reads only the subwindow observation rows, the inherited* RatStreamNameFiniteWindowClassifier *rows, the endpoint denominator rows, and the* DyadicRatCore *source rows already named by the ambient window.*

Proof. Start with the ambient finite-window exhaustion package. Apply Definition 38.314 to identify its $\mathsf{Rat}^{\uparrow}$ endpoint classifiers, positive denominator witnesses, common e-one tail readbacks, and DyadicRatCore source rows.

Restrict the StreamName component by Definition 126.9. The certified subwindow keeps the same pointwise RatStreamNameFiniteWindowClassifier rows and only changes the displayed finite observation domain.

Next use Definition 38.317. It rules out a second endpoint reading for the restricted window once the selected StreamName package and endpoint denominator rows are fixed.

Finally apply Definition 38.320. The ledger boundary remains exactly the selected unary observation, the restricted StreamName classifier row, the endpoint denominator rows, and the dyadic source rows. Repacking these rows gives the same $\mathsf{Real}^{\uparrow}$ read surface restricted to the certified subwindow. □

Theorem 38.326 (RealUp finite-window exhaustion overlap closure)**.** *Let two* $\mathsf{Real}^{\uparrow}$ *finite-window exhaustion packages expose certified* $\mathsf{StreamName}^{\uparrow}$ *subwindows. If the two restricted windows have a certified common* $\mathsf{StreamName}^{\uparrow}$ *subwindow overlap, then the overlap exposes the same inherited* RatStreamNameFiniteWindowClassifier *rows, the same endpoint denominator rows, the same common e-one tail readbacks, and the same* DyadicRatCore *source rows, up to the* hsame *ledger permitted by Definition 38.285. The overlap certificate does not expose host* Nat *indices, host functions, quotients, or unrecorded infinite stream data.*

Proof. Apply Definition 38.325 to each ambient finite-window exhaustion package. Each restricted window therefore reads only its subwindow observation rows, inherited RatStreamNameFiniteWindowClassifier rows, endpoint denominator rows, common e-one tail readbacks, and DyadicRatCore source rows.

Now restrict both sides to the certified common $\mathsf{StreamName}^{\uparrow}$ overlap. The overlap has the same selected StreamName window on both readings, so Definition 38.317 identifies the endpoint $\mathsf{Rat}^{\uparrow}$ classifier rows, positive denominator witnesses, common e-one tail readbacks, and dyadic source rows through the displayed hsame ledger.

Finally apply Definition 38.320 on the overlap itself. The only exported ledger rows are the selected unary observation, the overlap RatStreamNameFiniteWindowClassifier rows, the endpoint denominator rows, and the dyadic source rows named by the finite-window exhaustion boundary.

Since Definition 38.285 admits no exported row for host Nat indices, host functions, quotient witnesses, or unrecorded infinite stream data, no further datum can distinguish the two restricted readings on their common overlap. □

Theorem 38.327 (RealUp finite-window two-step restriction coherence)**.** *Suppose a* $\mathsf{Real}^{\uparrow}$ *finite-window exhaustion package is exposed for a* $\mathsf{StreamName}^{\uparrow}$ *window* W*, and suppose* U *is a certified* $\mathsf{StreamName}^{\uparrow}$ *subwindow of* W *while* V *is a certified* $\mathsf{StreamName}^{\uparrow}$ *subwindow of* U*. The* $\mathsf{Real}^{\uparrow}$ *read surface obtained by restricting first from* W *to* U *and then from* U *to* V *is the same public finite* BHist *surface as the direct restriction from* W *to* V*. Both readings expose the same* RatStreamNameFiniteWindowClassifier *rows, endpoint* $\mathsf{Rat}^{\uparrow}$ *classifier rows, positive denominator witnesses, common e-one tail readbacks,* DyadicRatCore *source rows,* hsame *ledger, and* RealLedgerPolicy *boundary.*

Proof. Apply Definition 38.325 to the ambient window W and the certified subwindow U. This identifies the U reading as the inherited finite-window package whose public rows are exactly the RatStreamNameFiniteWindowClassifier rows, endpoint denominator rows, common e-one tail readbacks, and dyadic source rows of W restricted to U.

Apply Definition 38.325 again to the U package and the certified subwindow V. The two-step reading therefore has only the inherited V observation rows, the endpoint $\mathsf{Rat}^{\uparrow}$ classifier rows, positive denominator witnesses, common e-one tail readbacks, and DyadicRatCore source rows already named by the ambient package.

For the direct W to V reading, use Definition 38.317. The selected StreamName window and endpoint denominator rows for V are the same in the direct and two-step presentations, so the endpoint classifiers, denominator witnesses, readbacks, and source rows are identified through the displayed hsame ledger.

Finally apply Definition 38.320 to the common V surface. The public finite BHist ledger is exactly the selected observation, the RatStreamNameFiniteWindowClassifier rows, the endpoint rows, the dyadic source rows, and the RealLedgerPolicy boundary. Hence the two-step restriction and the direct restriction expose the same $\mathsf{Real}^{\uparrow}$ read surface. □

Theorem 38.328 (RealUp finite-window partition exactness)**.** *Suppose a* $\mathsf{Real}^{\uparrow}$ *finite-window exhaustion package is exposed for a* $\mathsf{StreamName}^{\uparrow}$ *window* W*. Let* $(W_i)_{i\in I}$ *be a finite family of certified* $\mathsf{StreamName}^{\uparrow}$ *subwindows of* W *such that every certified unary observation row of* W *is carried by at least one* W_i*, and such that every pairwise intersection exposed by two selected subwindows is certified by the overlap boundary of Definition 38.326. Then the* $\mathsf{Real}^{\uparrow}$ *read surface assembled from the finite family* $(W_i)_{i\in I}$ *is the same public finite* BHist *surface as the direct read surface of* W*. The two surfaces have the same* RatStreamNameFiniteWindowClassifier *rows, endpoint* $\mathsf{Rat}^{\uparrow}$ *classifier rows, positive denominator witnesses, common e-one tail readbacks,* DyadicRatCore *source rows,* hsame *ledger, and* RealLedgerPolicy *boundary.*

Proof. Apply Definition 38.325 to each certified subwindow W_i. Each local read therefore contains only the inherited unary observation rows, finite-window classifier rows, endpoint denominator rows, common e-one tail readbacks, and dyadic source rows coming from the ambient window W.

On every certified overlap $W_i \cap W_j$, use Definition 38.326. It identifies duplicate observations and their endpoint $\mathsf{Rat}^{\uparrow}$ classifier rows through the same hsame ledger, so the finite family contributes one public observation row for each certified observation of W rather than a separate row for each covering subwindow.

If a selected observation is reached through a smaller certified refinement, Definition 38.327 identifies the refined read with the direct restriction from W. Thus changing the subwindow presentation does not change the visible read surface.

Finally repack the covered observation rows by Definition 38.320. The coverage hypothesis supplies every unary observation row of W, and the overlap and two-step coherence rows remove duplicate presentations. The assembled surface is therefore exactly the direct finite-window surface of W. □

Theorem 38.329 (RealUp finite-window directed refinement seal)**.** *Suppose two* $\mathsf{Real}^{\uparrow}$ *finite-window exhaustion packages are exposed over the same* $\mathsf{StreamName}^{\uparrow}$ *source, with certified windows* W *and* W'*. Suppose also that there is a certified common refinement, given by a finite family of* $\mathsf{StreamName}^{\uparrow}$ *subwindows whose union covers every certified unary observation row of both* W *and* W'*, and whose pairwise overlaps satisfy Definition 38.326. Then the two finite-window presentations expose the same public* BHist *read surface. In particular, they have the same* RatStreamNameFiniteWindowClassifier *rows, endpoint* $\mathsf{Rat}^{\uparrow}$ *classifier rows, positive denominator witnesses, common e-one tail readbacks,* DyadicRatCore *source rows,* hsame *ledger, and* RealLedgerPolicy *boundary, and neither presentation exports host indices, quotient witnesses, or unrecorded infinite stream data.*

Proof. Apply Definition 38.328 to the window W and the certified common refinement. The coverage hypothesis says that the refinement carries every certified unary observation row visible from W, so the refinement assembly is the same public finite BHist surface as the direct W presentation.

Apply Definition 38.328 again to the window W'. The same refinement family covers every certified unary observation row visible from W', so the refinement assembly is also the same public finite BHist surface as the direct W' presentation.

It remains to compare the two uses of the refinement. When a refinement subwindow is reached through either ambient window, use Definition 38.327 to identify the restricted read with the direct refinement read. On intersections between two refinement subwindows, use Definition 38.326 to identify the duplicate classifier rows, denominator witnesses, readbacks, and dyadic source rows through the same hsame ledger.

Finally apply Definition 38.320 to the common refinement surface. Its ledger contains exactly the selected observation rows, endpoint $\mathsf{Rat}^{\uparrow}$ rows, positive denominator witnesses, common e-one tail readbacks, DyadicRatCore rows, and RealLedgerPolicy boundary. Therefore both finite-window presentations expose the same public surface, with no additional host index, quotient, or infinite-stream datum available to distinguish them. □

Definition 38.330 (RealUp finite-window refinement envelope)**.** *A* $\mathsf{Real}^{\uparrow}$ *finite-window refinement envelope over one* $\mathsf{StreamName}^{\uparrow}$ *source is a finite* BHist *package whose rows consist of certified* $\mathsf{StreamName}^{\uparrow}$ *finite windows, a common-refinement package for every ordered pair of carried windows, the overlap-closure witnesses for each refinement family, the two-step restriction coherence witnesses for every displayed subwindow chain, the endpoint* $\mathsf{Rat}^{\uparrow}$ *classifier rows, the positive denominator witnesses, the* DyadicRatCore *source rows, the shared* hsame *ledger identifying duplicate presentations, and the* RealLedgerPolicy *boundary. The envelope exports only these finite rows and their* Pkg *provenance.*

Theorem 38.331 (RealUp finite-window refinement envelope coherence)**.** *Let E be a* $\mathsf{Real}^{\uparrow}$ *finite-window refinement envelope over a fixed* $\mathsf{StreamName}^{\uparrow}$ *source. If two certified windows W and W' are carried by E, then the public read surface exposed from W is the same finite* BHist *read surface as the one exposed from W'. The common surface contains exactly the envelope's* RatStreamNameFiniteWindowClassifier *rows, endpoint* $\mathsf{Rat}^{\uparrow}$ *classifier rows, positive denominator witnesses, common e-one tail readbacks,* DyadicRatCore *source rows, shared* hsame *ledger, and* RealLedgerPolicy *boundary, with no host index, quotient witness, or unrecorded infinite stream datum.*

Proof. Choose the common-refinement package in E for the ordered pair (W, W'). The package supplies a finite family of certified subwindows covering every certified unary observation row of both windows, together with the required overlap-closure witnesses.

Apply Definition 38.329 to this pair. The seal reduces the comparison of the two ambient presentations to the public surface assembled from their displayed common refinement.

The assembly through the common refinement is exact by Definition 38.328. Whenever a row is read through an intermediate refinement before reaching the displayed subwindow, Definition 38.327 identifies that reading with the direct restriction used by the refinement surface.

Finally apply Definition 38.320. The only public rows left in the envelope are the selected finite-window observation rows, endpoint $\mathsf{Rat}^{\uparrow}$ classifier rows, positive denominator witnesses, common e-one tail readbacks, dyadic source rows, the shared hsame ledger, and the RealLedgerPolicy boundary. Since that boundary has no slot for a host index, quotient witness, or unrecorded infinite stream datum, the two carried windows expose one public read surface. □

Theorem 38.332 (RealUp finite-window refinement envelope consumer coverage)**.** *Let E be a* $\mathsf{Real}^{\uparrow}$ *finite-window refinement envelope over a fixed* $\mathsf{StreamName}^{\uparrow}$ *source, and let W be any certified window carried by E. Every* RegSeqRat *handoff induced by W, and every finite-window* $\mathsf{Real}^{\uparrow}$ *seal*

read induced by W, factors through exactly the rows carried by E: the StreamName$^{\uparrow}$ *finite-window classifier rows, the* ProbeBundle, InBundle, *and* UnaryHistory *rows, the pointwise* RatHistoryClassifier *rows, the endpoint denominator rows, the* DyadicRatCore *source rows, the shared* hsame *ledger, and the* RealLedgerPolicy *boundary. Conversely, any such row family inside E repacks into the same* RegSeqRat *handoff and finite-window* Real$^{\uparrow}$ *seal surface. No completion object, quotient witness, host-index equality, or unrecorded stream datum is part of this consumer surface.*

Proof. First compare the chosen carried window with the envelope surface. Apply Definition 38.331 with W and any other carried representative used by the consumer. The comparison identifies the consumer-facing read with the envelope's finite public BHist surface, so the read cannot escape the rows named in the envelope.

Next expose the stream-name boundary. By Definition 38.320, a finite window contributes only its classifier rows, the certified probe and unary history rows, the endpoint denominator witnesses, the shared hsame ledger, and the RealLedgerPolicy boundary. These are precisely rows already stored in E.

For a RegSeqRat consumer, apply Definition 126.170. Its pointwise handoff uses the RatHistoryClassifier rows read from the same StreamName$^{\uparrow}$ finite window. Then apply Definition 38.564 to replace the dyadic source requirements by the displayed DyadicRatCore source rows and endpoint denominator rows carried by the envelope.

The reverse packing uses the same two displayed handoff theorems in the opposite direction of construction: the finite-window classifier, ProbeBundle, InBundle, UnaryHistory, pointwise rational classifier, denominator, dyadic-source, hsame, and ledger-policy rows assemble the public consumer interface. Since all cited boundaries are finite BHist rows, there is no constructor slot for completion, quotient identification, host-index equality, or unrecorded stream data. □

Theorem 38.333 (StreamName RegSeqRat window stability through RealUp prefixes)**.** *Let s, t, u, s', t' : BHist $\to$ BHist be* StreamName$^{\uparrow}$ *rows, let $\mathcal{P}$: ProbeBundle be finite, and let E be a* Real$^{\uparrow}$ *finite-window refinement envelope carrying the selected window over $\mathcal{P}$. Suppose the selected window carries the hypotheses needed for the self, symmetric, transitive, and transported outputs of* RatStreamNameFiniteWindowClassifier_stability_fields*: a carrier row for s, finite-window classifiers from s to t and from t to u, and pointwise* hsame *transports from s to s' and from t to t' on the bundled unary observations. Then the four stable windows preserve exactly the* RegSeqRat *handoff of Definition 126.170 and the finite-window* Real$^{\uparrow}$ *seal surface of Definition 38.332. No regularity row, completion object, quotient witness, host-index equality, or unrecorded stream row is added by passing the stable windows through the prefix envelope.*

Proof. First apply the StreamName finite-window stability fields to the selected window. They give the self window on s, the symmetric window from t to s, the transitive window from s to u, and the transported window from s' to t' over the same finite bundle $\mathcal{P}$.

Pass each of these four windows through Definition 126.170. The handoff reads only the StreamName carrier rows, the finite-window classifier row, the UnaryHistory rows, the InBundle rows, and the pointwise rational classifier rows selected by $\mathcal{P}$. Thus the downstream RegSeqRat interface sees the same pointwise packet for each stable window.

Finally apply Definition 38.332 to the envelope E. Its consumer-coverage statement identifies every induced RegSeqRat handoff and every finite-window Real$^{\uparrow}$ seal read with the rows already carried by the prefix envelope: the StreamName classifier rows, bundle and unary-history rows, rational classifier rows, denominator rows, dyadic source rows, shared hsame ledger, and RealLedgerPolicy boundary. Those rows have no constructor slot for regularity, completion, quotient identification, host-index equality, or an unrecorded stream row. □

Theorem 38.334 (RealUp finite-window refinement envelope nonescape)**.** *Let E be a* $\mathsf{Real}^{\uparrow}$ *finite-window refinement envelope over a fixed* $\mathsf{StreamName}^{\uparrow}$ *source and finite* ProbeBundle*. Every consumer of E factors only through the finite StreamName classifier rows, the* ProbeBundle*,* InBundle*, and* UnaryHistory *rows, the rational endpoint denominator rows, the* RegSeqRat *dyadic source rows, the shared* hsame *ledger, and the* RealLedgerPolicy *boundary. The envelope has no consumer-facing slot for quotient stream equality, host index equality, countable choice, selected limits, ambient completeness, or metric-completeness data.*

Proof. First read the envelope through Definition 38.332. The coverage theorem identifies each consumer-facing RegSeqRat handoff and each finite-window $\mathsf{Real}^{\uparrow}$ seal read with the StreamName classifier rows, bundle rows, rational classifier rows, endpoint denominator rows, dyadic source rows, shared hsame ledger, and RealLedgerPolicy boundary already carried by E.

Next pass the StreamName side through Definition 38.333. The prefix handoff keeps the self, symmetric, transitive, and transported windows on the same finite bundle, so the induced RegSeqRat reads remain the same pointwise packet described by Definition 126.170. The dyadic source requirements are exactly the rows supplied by Definition 38.564.

Finally use Definition 38.285. Its scoped certificate boundary says that the public $\mathsf{Real}^{\uparrow}$ prefix certificate is assembled from the recorded finite BHist rows and the ledger boundary, not from an ambient completion surface. Since the named rows are the only rows exposed by the envelope and by the StreamName/RegSeqRat handoff, there is no constructor path by which a consumer can import quotient stream equality, host index equality, countable choice, selected limits, ambient completeness, or metric-completeness data. □

Theorem 38.335 (Real stream-prefix carrier obligation)**.** *A RealUp stream-prefix candidate satisfies the carrier face only when every selected rational-observation endpoint exposes the RatUp endpoint carrier rows through the* RegSeqRat *spine. Concretely, for rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and a certified finite prefix, the candidate carrier must contain the* $\mathsf{RatHistoryCarrier}(x(i))$ *and* $\mathsf{RatHistoryCarrier}(y(i))$ *rows for each certified endpoint i named by the prefix, and those rows must be the endpoint rows read from Definition 38.195, Definition 38.214, and the prefix endpoint and readback blocks of Definition 38.111.*

Proof. Unfold Definition 38.195. Its carrier ledger is indexed by certified unary observations and supplies the rational stream-name carrier together with endpoint rational-history carrier rows.

Apply Definition 38.214 to identify those endpoint rows as the RatUp carrier face demanded by the spine. For a finite prefix, Definition 38.111 selects the endpoint classifier at the displayed prefix index, and the prefix readback blocks keep that selected endpoint attached to the same observation row.

Thus a RealUp stream-prefix carrier cannot use an external carrier datum: the visible endpoint carriers are exactly the RatHistoryCarrier rows projected from the certified unary observation spine and read back at the selected prefix endpoints. □

Theorem 38.336 (Real stream-prefix classifier obligation)**.** *The classifier face required by the RealUp certificate boundary is supplied by the pair of predicates* RealStreamClassifier *and* RealStreamPrefixClassifier*. For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, the global classifier gives every finite prefix by Definition 38.135, each finite prefix exposes its selected endpoint by Definition 38.111, and the global classifier rows are closed under the symmetry and transitivity operations of Definition 38.136 and Definition 38.137.*

Proof. Start with a global $\mathsf{RealStreamClassifier}(x, y)$ row. Apply Definition 38.135 in the forward direction to obtain $\mathsf{RealStreamPrefixClassifier}(x, y, n)$ for every selected finite prefix n.

For a chosen prefix, apply Definition 38.111. This projects the RatUp endpoint classifier $\mathsf{RatHistoryClassifier}(x(n), y(n))$, so the finite classifier carries the same endpoint face required by the certificate boundary.

Conversely, the reverse direction of Definition 38.135 repacks the family of finite prefix classifiers into the global stream classifier. Symmetry and transitivity are then the global operations supplied by Definition 38.136 and Definition 38.137, with endpoint projection returning to the finite face whenever the boundary asks for a selected row. □

Theorem 38.337 (Real stream-prefix stability obligation)**.** *The RealUp stream-prefix stability face is closed under* hsame *transport, unary-context wrapping, and selected continuation packages. More precisely, Definition 38.107, Definition 38.108, Definition 38.139, and Definition 38.146 preserve the endpoint classifier rows used by* RealStreamPrefixClassifier *and repack them as the corresponding global* RealStreamClassifier *rows when all finite prefixes are available.*

Proof. For finite prefixes, apply Definition 38.107 to transport each selected endpoint classifier along the two pointwise hsame comparisons. Apply Definition 38.108 when the endpoints are wrapped by unary prefix and tail contexts; the induction in that theorem keeps every endpoint RatUp classifier in the prefix ledger.

For global stream rows, apply Definition 38.139. It transports the pointwise classifier family and therefore preserves the global classifier face seen by finite-prefix exactness.

For selected continuations, apply Definition 38.146. It supplies the endpoint shape, denominator, unary, and exclusion rows attached to the same selected continuation data. Repacking through Definition 38.135 identifies the finite prefix and global classifier faces, so all displayed stability operations preserve the RealUp classifier rows. □

Theorem 38.338 (Real stream-prefix ledger and seal obligation)**.** *Finite observation windows, dyadic ledger rows, and the* RegSeqRat *seal are sufficient for the visible RealUp seal obligation. The ledger is the finite policy of Definition 38.279; its classifier stability is the package of Definition 38.273; its scoped stream-name interface is Definition 38.276; and the seal is consumed by Definition 38.254 without any quotient or completion datum.*

Proof. Gather the finite observation rows named by Definition 38.279. They record the selected window indices, dyadic comparison witnesses, regularity certificates, and classifier comparison certificates used by the RealUp boundary.

Apply Definition 38.273 to keep the unary stream classifier stable across the recorded observations. Then apply Definition 38.276 to read those observations as the scoped RegSeqRat stream-name interface, including the RatUp endpoint rows exposed by the spine.

Finally, apply Definition 38.254. The theorem consumes exactly the dyadic ledger rows and the scoped stream-name interface, so the visible RealUp seal follows without quotient representatives, metric completion data, or any carrier outside the RegSeqRat spine. □

Theorem 38.339 (RealUp finite-window tail determinacy)**.** *Let W and W' be selected finite* $\mathsf{Real}^{\uparrow}$ *observation windows over the same rational-observation streams. Suppose that both windows carry the same certified unary endpoint row and both expose the common e-one tail readback used by Definition 38.314. Then the* RatHistoryCarrier *endpoint rows, unary denominator witnesses, dyadic source rows, and* RealLedgerPolicy *tail rows selected by W and W' classify to the same finite-window surface.*

Proof. Apply Definition 38.336 to the shared certified unary endpoint. The classifier obligation identifies the selected finite endpoint classifier with the RatUp endpoint rows read from the RegSeqRat spine, so W and W' begin with the same carried RatHistoryCarrier face.

Next apply Definition 38.337. The common e-one tail readback is a selected continuation package over the same unary endpoint row, and stability transports the endpoint classifier through the unary denominator, tail, and hsame rows without creating a second endpoint surface.

Apply Definition 38.338 to the finite dyadic and ledger rows exposed by the two windows. Since the seal consumes only the displayed dyadic source rows, the scoped RegSeqRat interface, and the RealLedgerPolicy tail rows, both windows feed the same visible seal data into the RealUp boundary.

Finally use Definition 38.314. Its finite-window correspondence repacks exactly those endpoint, denominator, dyadic, and tail rows as the public finite-window surface. The two selected windows therefore determine classifier-equivalent finite-window readbacks at the shared e-one tail endpoint. □

Theorem 38.340 (RealUp RegSeqRat window seal restriction)**.** *Let W be a finite* $\mathsf{Real}^{\uparrow}$ *observation window carrying the scoped* RegSeqRat *stream-name interface, the dyadic ledger rows, and the Real ledger tail rows used by the visible seal obligation. If W' is a certified sub-window of W, then W' carries the corresponding seal package by restriction, with the same* RatHistoryCarrier *endpoint rows selected from the* RegSeqRat *spine. The restricted seal exposes no quotient, completion, arithmetic closure, order closure, or metric-completion claim.*

Proof. Start with the visible seal package on W. By Definition 38.338, this package is assembled from the scoped RegSeqRat stream-name interface, the finite dyadic ledger, and the Real ledger tail rows; it does not require quotient or completion data.

Restrict the selected rows to the certified sub-window W'. Finite-window membership for W' reads each selected observation as a member of W, so the same RatHistoryCarrier endpoint rows and dyadic ledger entries are available at the smaller window.

Apply Definition 38.339 to the shared tail readback. The endpoint, denominator, dyadic, and Real ledger tail rows selected by W' classify to the same finite-window surface as their counterparts in W.

Finally repackage only those restricted rows into the seal boundary. Finite window exhaustion supplies no additional arithmetic, order, quotient, or metric-completion component, so the seal over W' is exactly the restricted RegSeqRat-to-$\mathsf{Real}^{\uparrow}$ seal package. □

Theorem 38.341 (RegSeqRat finite-window source-route uniqueness)**.** *Let W be a selected finite* $\mathsf{Real}^{\uparrow}$ *observation window carrying the scoped* RegSeqRat *stream-name interface, the displayed dyadic ledger rows, and the Real seal row. If two consumer derivations pass through the same accepted* RegSeqRat *spine inside W, then they expose the same finite* StreamName *carrier, the same* DyadicRatCore *observation rows, the same* RegSeqRat *classifier and tolerance ledger, and the same* $\mathsf{Real}^{\uparrow}$ *seal row through the displayed* hsame, Cont, *and* Pkg *provenance. No consumer derivation may bypass the* StreamName–RegSeqRat *handoff while still consuming the selected finite-window seal.*

Proof. Apply Definition 38.339 to the shared accepted RegSeqRat tail. The selected endpoint, denominator, dyadic, and Real ledger tail rows are thereby pinned to one finite-window surface.

Next apply Definition 38.340 to each consumer derivation. Since both derivations restrict to the same displayed spine, the visible seal can only read the scoped stream-name interface, the dyadic ledger, and the Real tail rows already fixed by the shared window.

It remains to compare the exposed rows. The StreamName carrier rows agree by the common spine, the DyadicRatCore observation rows agree by the finite dyadic ledger, and the classifier and tolerance entries agree by the displayed hsame and Cont readbacks. The Pkg provenance then repacks the same rows as the unique RegSeqRat-to-Real$^{\uparrow}$ source route for the selected finite seal. □

Theorem 38.342 (RealUp scoped finite-window read surface)**.** *The selected finite* Real$^{\uparrow}$ *observation windows read exactly the carrier/classifier, stability/transport, finite ledger, dyadic source,* RegSeqRat *spine,* StreamName$^{\uparrow}$*,* Rat$^{\uparrow}$*,* UnaryHistory*,* hsame*, and* RealLedgerPolicy *rows named by Definition 38.285. They read no quotient datum, completion datum, metric-completeness certificate, arithmetic or order operation, Classical datum, or standard-bridge datum.*

Lean4 ✓ `BEDC.Derived.RealUp.RealupScopedFiniteWindowReadSurface`

Proof. First collect the finite-window observation face. Apply Definition 38.314: every selected finite Real$^{\uparrow}$ window exposes the endpoint Rat$^{\uparrow}$ classifiers, unary denominator rows, common e-one tail readback, and dyadic source rows consumed by the Real$^{\uparrow}$ seal.

Next identify the structural rows read by that observation field. Apply Definition 38.335 for the DyadicRatCore, RegSeqRat, StreamName$^{\uparrow}$, and Rat$^{\uparrow}$ carrier source. Apply Definition 38.336 for the constant-history and unary stream classifier source. Apply Definition 38.337 for pointwise hsame transport and selected-continuation stability.

Finally attach the ledger and certificate boundary. Apply Definition 38.338 for the finite RealLedgerPolicy rows and seal consumption. Then apply Definition 38.285, which states that these rows are exactly the scoped Real$^{\uparrow}$ certificate boundary and excludes quotient, completion, arithmetic, order, metric-completeness, Classical, and standard-bridge data. □

Theorem 38.343 (RealUp common finite-window pullback transitive restriction)**.** *Let W_0 and W_1 be certified finite* Real$^{\uparrow}$ *observation-window packages, let U be a certified common* StreamName$^{\uparrow}$ *subwindow of their displayed* ProbeBundle *windows, and let V be a certified* StreamName$^{\uparrow}$ *subwindow of U. Assume that the restrictions of W_0 and W_1 to U carry matching* RatStreamNameFiniteWindowClassifier *rows, matching* RegSeqRat *spine rows, matching endpoint* DyadicRatCoreObservationRow *witnesses, matching displayed* hsame *transports, matching* Cont *rows, matching* Pkg *provenance, and matching finite* RealLedgerPolicy *rows. Then the two routes to V expose the same finite* BHist *packet and the same finite* RealLedgerPolicy *row: restrict the direct common-window pullback from U to V, or first pull both* Real$^{\uparrow}$ *packages back to U and then restrict that common packet to V.*

This is a finite-window descent theorem only. It exposes no quotient, completion, metric-completeness datum, global Cauchy modulus, arithmetic operation, order operation, Classical representative, or standard bridge row.

Proof. First apply Definition 38.355 on the common subwindow U. The hypotheses name the same StreamName classifier, regular sequence spine, dyadic endpoint observations, endpoint transports, continuation rows, package provenance, and finite real-ledger row, so the pullback over U is a single finite BHist packet with a single RealLedgerPolicy row.

Now compare the two restrictions from U to V. Apply Definition 38.327 to the certified chain $W_i \supseteq U \supseteq V$ for each selected observation window W_i. It identifies the direct restriction of the displayed W_i package to V with the two-step restriction through U, with the same finite packet, classifier rows, endpoint rows, transport ledger, provenance, and real-ledger boundary.

Finally use Definition 38.354 on the endpoint window V. The StreamName-RegSeqRat handoff and the dyadic endpoint rows are already matched after the two-step coherence comparison, so the endpoint readback rows on V and the finite RealLedgerPolicy row are the same for both routes. □

Theorem 38.344 (RealUp StreamName-RegSeqRat finite-window correspondence)**.** *A selected finite* $\mathsf{Real}^{\uparrow}$ *observation-window surface is equivalent, as BEDC public data, to the pair consisting of the public* $\mathsf{StreamName}^{\uparrow}$ *finite-window interface of Definition 126.301 and the* RegSeqRat *dyadic source exhaustion rows consumed in Definition 38.314. The pair records exactly the finite-window stream classifier, endpoint* $\mathsf{Rat}^{\uparrow}$ *classifiers, unary denominator witnesses, common e-one tail readback, DyadicRatCore source rows,* UnaryHistory *endpoints,* hsame *transport, and finite* RealLedgerPolicy *ledger rows, and it records no quotient, completion, arithmetic, order, metric-completeness, Classical, or standard-bridge datum.*

Proof. For the projection direction, first apply Definition 38.342. It identifies the selected finite $\mathsf{Real}^{\uparrow}$ read surface with the DyadicRatCore, RegSeqRat, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, unary-history, hsame, and finite ledger rows that the scoped certificate exposes.

Then apply Definition 38.345. The $\mathsf{StreamName}^{\uparrow}$ component factors through the public finite-window interface of Definition 126.301, and the remaining rows are exactly the dyadic source, regular sequence, endpoint, unary, transport, and ledger rows read by Definition 38.314.

For the reconstruction direction, start with the displayed pair. Repack the $\mathsf{StreamName}^{\uparrow}$ finite-window classifier rows through the public interface, and repack the endpoint $\mathsf{Rat}^{\uparrow}$ classifiers, unary denominator witnesses, common e-one tail readback, and DyadicRatCore source rows through the exhaustion obligation.

The two packets share the same finite UnaryHistory endpoints, hsame transport, and RealLedgerPolicy readback. Combining those shared rows gives precisely the scoped boundary named in Definition 38.342, so the reconstructed surface is the original selected finite $\mathsf{Real}^{\uparrow}$ observation-window surface and contains no excluded datum. □

Theorem 38.345 (RealUp finite-window export through StreamNameUp interface)**.** *Every selected finite* $\mathsf{Real}^{\uparrow}$ *observation-window read surface of Definition 38.342 factors its stream-name component through the public* $\mathsf{StreamName}^{\uparrow}$ *finite-window interface of Definition 126.301. Its stream-name component is exactly the* RatStreamNameFiniteWindowClassifier *surface with classifier-to-window coverage, singleton-window exhaustion, reindexing and point-map coverage, structural laws, the selected endpoint package, and finite-window stability fields.*

After this factorization, the remaining $\mathsf{Real}^{\uparrow}$ *rows are only the DyadicRatCore observation rows,* RegSeqRat *spine rows,* $\mathsf{Rat}^{\uparrow}$ *endpoint rows,* UnaryHistory*,* hsame *transport, and* RealLedgerPolicy*. The exported finite-window surface contains no quotient datum, completion datum, arithmetic or order operation, metric-completeness certificate, Classical datum, or standard bridge.*

Proof. First identify the public stream-name finite-window surface. Apply Definition 126.301: the $\mathsf{StreamName}^{\uparrow}$ component available to downstream $\mathsf{Real}^{\uparrow}$ windows is the RatStreamNameFiniteWindowClassifier surface together with classifier-to-window coverage, singleton-window exhaustion, reindexing and point-map coverage, structural laws, the selected endpoint package, and finite-window stability fields.

Next identify the selected $\mathsf{Real}^{\uparrow}$ read surface. Apply Definition 38.342; it says that selected finite observation windows read the DyadicRatCore source, RegSeqRat spine, $\mathsf{StreamName}^{\uparrow}$ rows, $\mathsf{Rat}^{\uparrow}$ endpoints, UnaryHistory, hsame transport, and finite RealLedgerPolicy rows, while excluding quotient, completion, arithmetic, order, metric-completeness, Classical, and standard-bridge data.

The ten-field fit is: traditional target, finite $\mathsf{Real}^{\uparrow}$ observation export; BEDC source, DyadicRatCore plus $\mathsf{StreamName}^{\uparrow}$, RegSeqRat, and $\mathsf{Rat}^{\uparrow}$ over BHist; carrier, selected rational-observation windows; classifier, finite-window pointwise $\mathsf{Rat}^{\uparrow}$ classification; stability, $\mathsf{StreamName}^{\uparrow}$ finite-window stability plus hsame transport; ledger, finite observation index plus RealLedgerPolicy; core the-

orem, this block; exactness, factorization through the public finite-window interface; standard bridge, none; status, proof target.

Finally close directly at the finite-window surface. The $\mathsf{StreamName}^{\uparrow}$ component is exactly the public finite-window interface just identified, and Definition 38.342 supplies the whole local read surface in which that component sits. Removing the $\mathsf{StreamName}^{\uparrow}$ component therefore leaves precisely the DyadicRatCore observation rows, RegSeqRat spine rows, $\mathsf{Rat}^{\uparrow}$ endpoint rows, UnaryHistory, hsame transport, and finite RealLedgerPolicy rows, with the excluded quotient, completion, arithmetic, order, metric-completeness, Classical, and standard-bridge data still absent. □

Theorem 38.346 (RealUp StreamName window stability consumption)**.** *Let s, t, s', t' be rational observation maps carried by a finite* ProbeBundle *window, and let the selected unary observation rows be the endpoint rows read by the finite* $\mathsf{Real}^{\uparrow}$ *prefix surface. Suppose the* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier accepts the window for (s, t), suppose the packet carries bundled pointwise* hsame *transports from (s, t) to (s', t'), and suppose the selected transported endpoint package of Definition 126.32 is present.*

Then the transported selected $\mathsf{Real}^{\uparrow}$ *prefix read surface has the same finite* RealLedgerPolicy *boundary as in Definition 38.342. It factors through Definition 38.345 as a finite* BHist *read surface, with no quotient datum, completion datum, metric-completeness certificate, Classical datum, or standard-bridge datum.*

Proof. First apply Definition 126.28 to the accepted $\mathsf{StreamName}^{\uparrow}$ classifier and the bundled pointwise hsame transports. This produces the transported finite-window classifier for (s', t') over the same finite ProbeBundle boundary.

Next apply Definition 126.32 to the selected endpoint rows. The transported package supplies the positive denominator rows, unary shape rows, zero-head exclusion rows, and one-tail agreement rows needed by the selected endpoint surface.

Finally repack these transported rows through Definition 38.345. The scoped read surface of Definition 38.342 then supplies the unchanged finite RealLedgerPolicy boundary, so the transported prefix surface is still a finite BHist interface and none of the excluded quotient, completion, metric, Classical, or bridge data is introduced. □

Theorem 38.347 (RealUp StreamName source-exhaustion equivalence)**.** *For any selected finite* $\mathsf{Real}^{\uparrow}$ *observation window, the selected read surface has exactly the* $\mathsf{StreamName}^{\uparrow}$ *component supplied by Definition 126.301 together with the RegSeqRat and DyadicRatCore finite-window source rows consumed by Definition 38.314. Conversely, the concrete RegSeqRat and DyadicRatCore rows, together with the public* $\mathsf{StreamName}^{\uparrow}$ *finite-window package, repack into the* $\mathsf{StreamName}^{\uparrow}$ *component of Definition 38.342.*

This equivalence is internal to the selected finite BHist *window. It does not read a quotient datum, completion datum, metric-completeness certificate, arithmetic or order operation, Classical datum, or standard-bridge datum.*

Proof. Project the selected $\mathsf{Real}^{\uparrow}$ read surface using Definition 38.342. This gives the visible $\mathsf{StreamName}^{\uparrow}$ rows, the RegSeqRat spine rows, the DyadicRatCore source rows, the $\mathsf{Rat}^{\uparrow}$ endpoint rows, UnaryHistory, hsame transport, and the finite RealLedgerPolicy rows, with the excluded data absent.

Next apply Definition 38.345 to the projected stream-name component. It identifies that component with the public RatStreamNameFiniteWindowClassifier package of Definition 126.301.

The remaining finite source rows are read from Definition 38.314: DyadicRatCore supplies the selected dyadic observation rows, and RegSeqRat supplies the spine rows used by the finite window. These rows are concrete BHist entries rather than quotient or completion witnesses.

For the converse direction, start with the public $\mathsf{StreamName}^{\uparrow}$ finite-window package and the concrete RegSeqRat and DyadicRatCore rows just described. The public package reconstructs the same selected stream-name component, while the source rows provide exactly the surrounding finite-window inputs required by Definition 38.342. Repacking these rows therefore recovers the selected $\mathsf{StreamName}^{\uparrow}$ component inside the same $\mathsf{Real}^{\uparrow}$ read surface, and no excluded datum is introduced. □

Theorem 38.348 (RealUp finite-window constant-stream seal factorization)**.** *Let d, e : Hist and let W be a certified finite* ProbeBundle *window. Consider selected finite* $\mathsf{Real}^{\uparrow}$ *observation rows whose* $\mathsf{StreamName}^{\uparrow}$ *component is generated by the constant rational streams* $\mathsf{RatConstStream}_d$ *and* $\mathsf{RatConstStream}_e$*. A displayed* $\mathsf{RatHistoryClassifier}(d, e)$ *together with the constant stream-name package factors the selected read surface through Definition 126.301. After this factorization the remaining visible rows are exactly the DyadicRatCore observation rows, RegSeqRat spine rows,* $\mathsf{Rat}^{\uparrow}$ *endpoint rows,* UnaryHistory *rows,* hsame *transport rows, and finite* RealLedgerPolicy *rows recorded by the selected* $\mathsf{Real}^{\uparrow}$ *window.*

Conversely, those DyadicRatCore, RegSeqRat, $\mathsf{Rat}^{\uparrow}$*, unary-history,* hsame*, and finite* RealLedgerPolicy *rows, together with the constant stream-name package for* $\mathsf{RatHistoryClassifier}(d, e)$*, repack into the selected finite* $\mathsf{Real}^{\uparrow}$ *read surface. The factorization contains no quotient row, completion row, metric-completeness certificate, Classical datum, or standard-bridge datum.*

Proof. First apply Definition 126.61. It converts the displayed $\mathsf{RatHistoryClassifier}(d, e)$ into the constant stream-name package for $\mathsf{RatConstStream}_d$ and $\mathsf{RatConstStream}_e$ without replacing the histories by a quotient or standard model.

Next restrict this package to the finite window W by Definition 126.56. The resulting finite constant-stream rows are exactly the rows accepted by the public $\mathsf{StreamName}^{\uparrow}$ finite-window interface of Definition 126.301.

Apply Definition 38.345 to the selected $\mathsf{Real}^{\uparrow}$ observation window. Its stream-name component therefore factors through the public interface, while Definition 38.347 identifies the unconsumed finite source rows as precisely the DyadicRatCore observations, RegSeqRat spine, $\mathsf{Rat}^{\uparrow}$ endpoints, unary-history rows, hsame transports, and finite RealLedgerPolicy rows.

For the converse direction, start with this same finite list of remaining rows and the constant stream-name package. The public interface reconstructs the selected $\mathsf{StreamName}^{\uparrow}$ component, and the source-exhaustion equivalence supplies exactly the surrounding RegSeqRat, DyadicRatCore, $\mathsf{Rat}^{\uparrow}$, unary-history, transport, and ledger rows needed by the scoped $\mathsf{Real}^{\uparrow}$ read surface. Repacking these displayed rows recovers the selected finite surface, again without quotient, completion, metric-completeness, Classical, or standard-bridge data. □

Theorem 38.349 (StreamName Real seal factorization diamond)**.** *Let $W \subseteq W'$ be finite public* $\mathsf{StreamName}^{\uparrow}$ *rational observation windows with displayed prefix refinement. Suppose the windows carry accepted* RegSeqRat *spine rows, a shared DyadicRatCore endpoint ledger,* ProbeBundle *and* InBundle *rows,* UnaryHistory *rows, a finite* Cont *ledger, displayed* hsame *endpoint transports, and* Pkg *provenance. Then restricting the W'* $\mathsf{Real}^{\uparrow}$ *seal factorization to W and factoring the W seal read through the StreamName–*RegSeqRat *source produce the same visible* BHist *source tuple.*

That tuple is exactly the StreamName finite-window row, accepted RegSeqRat *seal row, dyadic endpoint rows, bundle rows, unary-history rows, finite continuation rows, displayed endpoint trans-*

ports, and provenance rows. It contains no completion row, quotient representative, host index equality, Classical choice row, metric-completeness datum, or standard-bridge datum.

Proof. Apply Definition 126.143 to the displayed inclusion $W \subseteq W'$. It identifies the restricted larger factorization with the direct smaller-window factorization over the same bundle, history, transport, continuation, and provenance rows.

Next use Definition 126.149. The two routes have the same public StreamName row, accepted RegSeqRat spine, dyadic endpoint ledger, bundle membership, unary observations, Cont ledger, hsame endpoint transports, and Pkg provenance, so their visible seal source is fixed to one BHist tuple.

Finally, Definition 126.150 rules out any additional source row beyond that tuple, and Definition 38.348 repacks it as the selected finite $\mathsf{Real}^{\uparrow}$ seal surface, without adding completion, quotient, host-equality, Classical, metric-completeness, or standard-bridge data. □

Theorem 38.350 (RealUp finite-window StreamName readback package)**.** *Let W be a certified finite* ProbeBundle *window and let a public* $\mathsf{Real}^{\uparrow}$ *finite-window classifier read be accepted over a* $\mathsf{StreamName}^{\uparrow}$ *source. Then there is a displayed* BHist *packet whose rows are exactly the unary schedule for W, the* $\mathsf{Rat}^{\uparrow}$ *observation endpoints visible in the window, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier row, the* $\mathsf{Real}^{\uparrow}$ *scoped window row, the* Cont *and* hsame *transport ledger connecting the stream read to the real read, and the* Pkg *provenance of the selected source rows. Every public* $\mathsf{Real}^{\uparrow}$ *finite-window classifier read through this* $\mathsf{StreamName}^{\uparrow}$ *source factors through that packet.*

The packet contains no quotient row, completion row, metric-completeness certificate, global Cauchy modulus, arithmetic or order operation, Classical datum, or standard bridge. Its endpoint reads are exactly the displayed $\mathsf{Rat}^{\uparrow}$ *observations and its classifier reads are exactly the displayed* $\mathsf{StreamName}^{\uparrow}$ *and scoped* $\mathsf{Real}^{\uparrow}$ *finite-window rows.*

Proof. Begin with the accepted finite-window $\mathsf{Real}^{\uparrow}$ read and project its $\mathsf{StreamName}^{\uparrow}$ component. By Definition 38.345, this component factors through the public $\mathsf{StreamName}^{\uparrow}$ finite-window interface, so the stream-name classifier row is displayed as a finite BHist row rather than as an ambient stream equality.

Next use Definition 38.346. It transports the projected stream-name row across the selected finite window and records the required Cont and hsame ledger entries. These entries are the only transport rows consumed by the scoped $\mathsf{Real}^{\uparrow}$ classifier read.

For constant rational endpoints, apply Definition 38.348. It identifies the endpoint part of the read with the displayed $\mathsf{Rat}^{\uparrow}$ observation rows, the unary schedule, and the surrounding finite RealLedgerPolicy rows. For non-constant accepted stream-name sources, the same packet shape is obtained by reading the $\mathsf{Rat}^{\uparrow}$ endpoints already exposed by the finite StreamName window.

Finally apply Definition 38.399. Any two displayed packets supporting the same public $\mathsf{Real}^{\uparrow}$ classifier read admit the same common finite refinement, hence determine the same visible rows up to the recorded hsame transports. This gives the announced readback packet and shows that every public finite-window classifier read factors through it. □

Theorem 38.351 (RealUp empty-window StreamName boundary)**.** *Let W be a selected finite* $\mathsf{Real}^{\uparrow}$ *observation window whose* ProbeBundle *boundary is empty. Then the* $\mathsf{StreamName}^{\uparrow}$ *component of the* $\mathsf{Real}^{\uparrow}$ *finite-window readback package is exactly the public empty-window vacuity row of Definition 126.310. After this identification, the remaining visible* $\mathsf{Real}^{\uparrow}$ *rows are only the scoped ledger, dyadic source,* UnaryHistory, hsame, *and* RealLedgerPolicy *rows already listed by Definition 38.342.*

The empty-window read contains no quotient row, completion row, metric-completeness certificate, Classical datum, arithmetic or order row, or standard-bridge datum.

Proof. Project the selected finite readback through Definition 38.350. The projected $\mathsf{StreamName}^{\uparrow}$ row is a displayed finite-window classifier row inside the same BHist packet as the unary schedule, endpoint rows, Cont and hsame transport ledger, and Pkg provenance.

Apply Definition 38.345 to factor that stream-name row through the public finite-window interface. Since the ProbeBundle boundary of W is empty, the corresponding public stream-name row is the empty-window vacuity row of Definition 126.310.

It remains to identify what the $\mathsf{Real}^{\uparrow}$ packet still exposes. The scoped read surface theorem Definition 38.342 lists exactly the surviving finite rows: the scoped ledger, dyadic source, UnaryHistory, hsame, and RealLedgerPolicy entries. The same theorem excludes quotient, completion, metric-completeness, Classical, arithmetic, order, and standard-bridge data, and the empty-window projection does not add any of them. □

Theorem 38.352 (RealUp StreamName-RegSeqRat tail-selector determinacy)**.** *Let W_0 and W_1 be selected finite* $\mathsf{Real}^{\uparrow}$ *observation-window packages. Assume that they display the same public* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier row, the same* RegSeqRat *spine rows, the same DyadicRatCore observation rows, matching* $\mathsf{Rat}^{\uparrow}$ *endpoint classifiers, and the same finite* Cont/hsame *ledger. Then every selected tail-classifier readback extracted from W_0 and every selected tail-classifier readback extracted from W_1 represent the same finite* $\mathsf{Real}^{\uparrow}$ *tail read up to the displayed* hsame *transport. Moreover the two packages expose the same* RealLedgerPolicy *row.*

The conclusion is scoped to the selected finite-window surface. It does not assert equality of quotient completions, metric completions, arithmetic operations, order operations, Classical representatives, or standard bridge data.

Proof. Project both selected packages through Definition 38.350. Each projection has a $\mathsf{StreamName}^{\uparrow}$ component, RegSeqRat spine rows, DyadicRatCore observation rows, $\mathsf{Rat}^{\uparrow}$ endpoint classifiers, a finite Cont/hsame ledger, and a surrounding RealLedgerPolicy row.

Identify the shared $\mathsf{StreamName}^{\uparrow}$ component by Definition 38.347. Under the hypotheses, the two finite-window classifier rows consume the same concrete stream-name source and the same regular-sequence and dyadic observation rows.

The constant and empty boundary theorems remove non-displayed choices. Apply Definition 38.348 to the constant endpoint case and Definition 38.351 to the empty-window case. In both cases the visible tail read is forced by the selected endpoint, stream-name, regular-sequence, dyadic, and ledger rows already present in the projected package.

It remains to compare the two selected tail reads. Compose the displayed hsame transports in the common finite ledger. Since the two packages have the same Cont/hsame ledger and the same RealLedgerPolicy boundary, the transported tail classifiers coincide up to hsame, and the exposed RealLedgerPolicy rows are identical as public finite-window rows. □

Theorem 38.353 (RealUp finite-window StreamName readback uniformity)**.** *Let W be a certified finite* ProbeBundle *window supporting a public* $\mathsf{Real}^{\uparrow}$ *finite-window readback through a* $\mathsf{StreamName}^{\uparrow}$ *source, and let U be either a certified finite subwindow of W or a certified finite common refinement of two such windows. Assume that the restriction to U carries the same public* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the same* RegSeqRat *spine rows, the same DyadicRatCore observation rows, and the restricted* Cont/hsame *ledger displayed over U. Then the* $\mathsf{Real}^{\uparrow}$ *readback packet over W restricts over U to the same visible* $\mathsf{Rat}^{\uparrow}$ *endpoint rows and to the same finite* RealLedgerPolicy *row.*

Equivalently, certified passage to a displayed finite subwindow or common finite refinement preserves the public endpoint readback and the real-ledger row determined by the StreamName-RegSeqRat-DyadicRatCore surface. The assertion does not identify quotient completions, metric completions, global Cauchy moduli, arithmetic operations, order operations, Classical representatives, or standard bridge data.

Proof. Start with the selected $\mathsf{Real}^{\uparrow}$ read over W and apply Definition 38.350. This displays a single finite BHist packet containing the public $\mathsf{StreamName}^{\uparrow}$ finite-window row, the RegSeqRat spine, the DyadicRatCore observations, the visible $\mathsf{Rat}^{\uparrow}$ endpoints, the restricted Cont/hsame ledger, the Pkg provenance, and the finite RealLedgerPolicy row.

Restrict this displayed packet along the certified subwindow U, or along the certified common refinement when two windows are present. The common-refinement determinacy theorem Definition 38.399 says that any two displayed packets with the same public rows over the refinement determine the same finite surface up to the recorded hsame transports.

The source rows remaining after restriction are exactly the public stream-name row, the regular-sequence spine, and the dyadic observation rows named in the hypotheses. This is the source-exhaustion equivalence of Definition 38.347, while Definition 126.301 identifies the restricted stream-name row as the same public finite-window interface row rather than an ambient stream equality.

With the stream-name source and the restricted transport ledger fixed, the readback package has no remaining displayed choice for the $\mathsf{Rat}^{\uparrow}$ endpoints or for the finite RealLedgerPolicy row. Hence the packet over W restricts to the same visible endpoint rows and the same real-ledger row over U. □

Theorem 38.354 (RealUp StreamName-RegSeqRat uniform window readback)**.** *Let W_0 and W_1 be certified finite* $\mathsf{Real}^{\uparrow}$ *observation-window packages, and let U be a certified finite common refinement of their selected* ProbeBundle *windows. Assume that both packages factor through the public* $\mathsf{StreamName}^{\uparrow}$ *finite-window interface, that their restrictions to U carry the same* $\mathsf{StreamName}^{\uparrow}$ *classifier row, and that the displayed* RegSeqRat *pointwise seal gives the same regular-sequence spine over the same* BHist *endpoints,* hsame *transports,* Cont *rows, and* Pkg *provenance rows. Then the two restricted* $\mathsf{Real}^{\uparrow}$ *readback packets have the same visible* $\mathsf{Rat}^{\uparrow}$ *endpoint readback rows on every selected finite subwindow of U, and they expose the same finite* RealLedgerPolicy *row.*

The statement is only a finite-window consumer theorem. It identifies the rows read through the StreamName-RegSeqRat handoff and does not identify quotient completions, metric completions, global Cauchy moduli, arithmetic operations, order operations, Classical representatives, or standard bridge data.

Proof. First apply Definition 126.111. The common $\mathsf{StreamName}^{\uparrow}$ classifier row over U and the displayed RegSeqRat pointwise seal determine a single finite-window handoff surface, with the BHist endpoints, hsame transports, Cont rows, and Pkg provenance rows kept in the public packet.

Next compare that handoff surface with the selected $\mathsf{Real}^{\uparrow}$ read surface. Apply Definition 38.344. It identifies the $\mathsf{Real}^{\uparrow}$ finite-window observation surface with the pair consisting of the public $\mathsf{StreamName}^{\uparrow}$ finite-window interface and the RegSeqRat dyadic source exhaustion rows, together with the same endpoint, transport, provenance, and finite-ledger rows.

Finally restrict along each selected finite subwindow of U. The hypotheses now match the input of Definition 38.353: the public stream-name row, regular-sequence spine, dyadic observation rows, and restricted Cont/hsame ledger are the same. Therefore the two consumer packets read back the same visible $\mathsf{Rat}^{\uparrow}$ endpoint rows on each selected finite window and expose the same finite RealLedgerPolicy row. □

Theorem 38.355 (RealUp common finite-window pullback)**.** *Let W_0 and W_1 be certified finite* $\mathsf{Real}^{\uparrow}$ *observation-window packages, and let U be a certified common* $\mathsf{StreamName}^{\uparrow}$ *subwindow of their displayed* ProbeBundle *windows. Assume that the restrictions to U carry the same* RatStreamNameFiniteWindowClassifier *rows, the same* RegSeqRat *spine rows, and endpoint* DyadicRatCoreObservatio *witnesses matched by the displayed* hsame *transports. Assume also that the two selected* $\mathsf{Real}^{\uparrow}$ *read surfaces expose their endpoint rows through the same restricted* BHist *packet and the same finite* Cont/Pkg *provenance ledger over U. Then the restricted* $\mathsf{Real}^{\uparrow}$ *readback packets over U are the same finite* BHist *packet and expose the same finite* RealLedgerPolicy *row.*

The theorem identifies only the finite StreamNameUp-RegSeqRat-DyadicRatCore window shared by the two read surfaces. It does not export quotient completions, metric completions, global Cauchy moduli, arithmetic operations, order operations, Classical representatives, or standard bridge data.

Proof. Restrict both certified observation windows to the common subwindow U. The restricted surfaces still carry exactly the displayed RatStreamNameFiniteWindowClassifier rows, RegSeqRat spine rows, DyadicRatCore endpoint witnesses, hsame transports, Cont rows, and Pkg provenance named in the hypotheses.

Apply the finite-window source-exhaustion obligation of Definition 38.347 to the endpoint rows. It says that, over the selected finite packet, no endpoint readback row remains outside the StreamNameUp-RegSeqRat-DyadicRatCore source family.

Next apply Definition 38.354. The matching stream-name classifier rows and regular-sequence spine rows identify the StreamName-RegSeqRat handoff over U, while the dyadic endpoint witnesses and the displayed hsame transports fix the endpoint side of the handoff.

Finally use the ledger exactness of the selected $\mathsf{Real}^{\uparrow}$ read surface, as in Definition 38.350. The only visible finite packet left over U is the shared BHist packet, and the only finite ledger row exposed by that packet is the same RealLedgerPolicy row. □

Theorem 38.356 (RealUp StreamName RegSeqRat cover seal associativity)**.** *Let K_0, K_1, and K_2 be certified finite* $\mathsf{Real}^{\uparrow}$ *observation windows with certified* $\mathsf{StreamName}^{\uparrow}$ *finite-window restrictions $K_0 \leftarrow K_1 \leftarrow K_2$. Assume that the displayed* RatStreamNameFiniteWindowClassifier *rows, the induced* RegSeqRat *seal rows, and the finite* Cont/hsame/Pkg *ledgers are composable over these two restrictions. Then the* $\mathsf{Real}^{\uparrow}$ *finite-window seal obtained by first pulling the displayed* BHist *seal surface back from K_2 to K_1 and then from K_1 to K_0 is the same displayed* BHist *seal surface as the direct pullback from K_2 to K_0.*

The statement uses only the displayed $\mathsf{StreamName}^{\uparrow}$, RegSeqRat, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and finite-window ledger rows. It includes no completion, quotient, metric-completeness, Classical, arithmetic, order, or standard bridge datum.*

Proof. Apply Definition 38.355 to the restriction $K_2 \to K_1$ and then to the restriction $K_1 \to K_0$. The two applications identify the intermediate seal with displayed $\mathsf{StreamName}^{\uparrow}$ classifier rows, RegSeqRat spine rows, endpoint witnesses, and the finite Cont/hsame/Pkg ledger on K_1 and K_0.

Apply the same common-window pullback theorem directly to the composed restriction $K_2 \to K_0$. Its input rows are exactly the rows obtained by composing the two certified restrictions: the same StreamName finite-window classifier, the same induced RegSeqRat seal rows, and the same finite transport ledger displayed over K_0.

The common-refinement determinacy theorem Definition 38.399 compares the two displayed packets over the common finite window K_0. Since their StreamName, RegSeqRat, endpoint, transport, and provenance rows agree, the visible $\mathsf{Real}^{\uparrow}$ seal surface is unique up to the recorded hsame transports.

Finally use the tail-reindexing stability of Definition 126.182. It says that the tail rows introduced by the nested restriction are the same pointwise rows as those introduced by the composed restriction. Thus the two pullback routes display the same finite BHist seal surface and the same finite ledger rows. □

Theorem 38.357 (RealUp StreamName RegSeqRat cover identity seal)**.** *Let K be a certified finite* $\mathsf{Real}^{\uparrow}$ *observation window carrying the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite-window,* RegSeqRat*, and DyadicRatCore seal rows exposed by Definition 38.350. Restrict this displayed seal along the identity certified subwindow $K \leftarrow K$. Then the restricted surface is the same finite* BHist *seal surface, with the same* hsame/Cont/Pkg *provenance ledger and the same finite* RealLedgerPolicy *row.*

The identity restriction exports no quotient, completion, metric-completeness, Classical representative, arithmetic operation, order operation, or standard bridge datum. It only records that the finite StreamNameUp-RegSeqRat-DyadicRatCore read surface is neutral under the certified identity subwindow.

Proof. Start with the finite readback package of Definition 38.350. It displays the $\mathsf{StreamName}^{\uparrow}$ finite-window classifier, the RegSeqRat spine rows, the DyadicRatCore endpoint rows, and the finite hsame/Cont/Pkg ledger on K.

Apply Definition 38.355 to the identity certified subwindow $K \leftarrow K$. The source and target windows are the same certified window, so the pullback reads exactly the same classifier rows, endpoint witnesses, provenance rows, and RealLedgerPolicy entry.

Finally view the identity restriction as the neutral member of the composition law in Definition 38.356. A pullback followed by the identity subwindow, or preceded by it, has the same direct route. Thus the displayed BHist seal surface and its finite ledger are unchanged. □

Theorem 38.358 (RealUp window refinement cover pullback exhaustion)**.** *Let W be a certified finite* $\mathsf{Real}^{\uparrow}$ *observation window. Let $\mathcal{C}_0$ and $\mathcal{C}_1$ be two finite* $\mathsf{StreamName}^{\uparrow}$ *cover presentations of the displayed window of W, and let $\mathcal{R}$ be a certified finite common refinement whose restrictions to the two covers carry the same* RatStreamNameFiniteWindowClassifier *rows, the same* RegSeqRat *spine rows, the same DyadicRatCore observation witnesses, and the same displayed* hsame *transports. Assume that every cover member exposes its* $\mathsf{Rat}^{\uparrow}$ *endpoint rows through the displayed finite* BHist *packet and through the same restricted* Cont/Pkg *provenance ledger. Then the* $\mathsf{Real}^{\uparrow}$ *read surface assembled from $\mathcal{C}_0$, the* $\mathsf{Real}^{\uparrow}$ *read surface assembled from $\mathcal{C}_1$, and the direct read surface of W expose exactly the same finite* BHist *packet.*

The common packet consists of the $\mathsf{StreamName}^{\uparrow}$ *classifier rows, the* RegSeqRat *spine, the DyadicRatCore observation rows, the visible* $\mathsf{Rat}^{\uparrow}$ *endpoint rows, the displayed* hsame/Cont/Pkg *provenance rows, and the finite* RealLedgerPolicy *row. The result does not export quotient completions, metric completions, global Cauchy moduli, arithmetic operations, order operations, Classical representatives, or standard bridge data.*

Proof. Pull both cover presentations back to the certified common refinement $\mathcal{R}$. By Definition 38.355, the restrictions of the two cover-assembled surfaces to each member of $\mathcal{R}$ display the same classifier rows, RegSeqRat spine rows, DyadicRatCore observation witnesses, $\mathsf{Rat}^{\uparrow}$ endpoint rows, and hsame/Cont/Pkg provenance rows.

Assemble those refined packets back along each cover. The cover-seal associativity theorem Definition 38.356 says that refining through $\mathcal{R}$ and then returning along $\mathcal{C}_i$ gives the same displayed finite BHist surface as the direct pullback along that cover. Thus the two assembled cover surfaces expose the same refined packet.

Compare each assembled cover with the direct read surface of W. The identity seal theorem Definition 38.357 identifies the direct surface with the neutral cover presentation on the same certified finite window, so associativity transports the refined packet from either cover route to the direct route.

It remains only to check that no visible row is left outside this packet. Apply the source-exhaustion equivalence Definition 38.347 to the StreamNameUp-RegSeqRat-DyadicRatCore source rows, and then apply the finite-window ledger boundary recorded in Definition 38.350. The endpoint, transport, provenance, and RealLedgerPolicy rows are therefore exactly the shared finite BHist packet named in the statement. □

Theorem 38.359 (RealUp StreamName-RegSeqRat directed-window consumer surface)**.** *Let $\mathcal{D}$ be a finite directed system of certified* $\mathsf{Real}^{\uparrow}$ *observation windows. Assume that every transition map in $\mathcal{D}$ is the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite-window restriction, and that every endpoint row agrees under the* RegSeqRat *finite-window seal. Then the whole directed system exposes one unique consumer-visible* BHist *packet.*

That packet consists exactly of the $\mathsf{StreamName}^{\uparrow}$ *classifier rows, the* RegSeqRat *spine rows, the DyadicRatCore observation rows, the visible* $\mathsf{Rat}^{\uparrow}$ *endpoint rows, the displayed* hsame/Cont/Pkg *provenance rows, and the finite* RealLedgerPolicy *row. It exports no quotient completion, metric completeness, global Cauchy modulus, order operation, or standard bridge datum.*

Proof. First choose any finite cofinal window of the directed system. Apply Definition 126.111 to place the endpoint rows under the common RegSeqRat finite-window seal, and apply Definition 126.165 to transport the same rows along the displayed $\mathsf{StreamName}^{\uparrow}$ restrictions.

Next compare any two routes through the chosen directed window. The cover-seal associativity theorem Definition 38.356 identifies the iterated restriction with the direct restriction, so the classifier, spine, endpoint, and provenance rows do not depend on the route.

Finally apply Definition 38.358 to the finite family of windows generated by the chosen routes. It says that every cover presentation, every common refinement, and the direct read surface expose the same finite BHist packet. The source list in that theorem is exactly the consumer surface named here, so no quotient completion, metric completeness, global Cauchy modulus, order operation, or standard bridge datum is added. □

Theorem 38.360 (RegSeqRat tail-classifier exactness)**.** *Let W_0 and W_1 be selected finite* $\mathsf{Real}^{\uparrow}$ *observation-window packages. Assume that they have matching* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier rows, matching* RegSeqRat *spine rows, matching DyadicRatCore observation rows, and the same finite* Cont/hsame *ledger over the visible endpoint and transport entries. Then the selected* RegSeqRat *tail classifier extracted from W_0 is exactly the same selected* RegSeqRat *tail classifier extracted from W_1 as a finite-window readback row, after the displayed* hsame *transports in the common ledger are applied.*

The exact classifier surface is only the finite $\mathsf{StreamName}^{\uparrow}$ *row, the* RegSeqRat *spine, the DyadicRatCore observation rows, the endpoint transport ledger, and the shared* RealLedgerPolicy *provenance. It exposes no quotient row, completion row, Classical representative, metric-completeness certificate, arithmetic or order operation, standard-bridge row, or external regular-sequence selector.*

Proof. Project both selected windows through the finite-window readback package of Definition 38.350. This places the $\mathsf{StreamName}^{\uparrow}$ classifier row, the RegSeqRat spine rows, the DyadicRatCore observation rows, the endpoint classifiers, the finite Cont/hsame ledger, and the RealLedgerPolicy row in one visible finite package.

Apply Definition 38.352. The matching stream-name, regular-sequence, dyadic, endpoint, and ledger rows force the two selected tail readbacks to agree up to the displayed hsame transports, and the same argument identifies the exposed RealLedgerPolicy row.

It remains to record that this agreement is exact on the selected RegSeqRat classifier surface. Use Definition 38.342 together with the finite-window readback package to list every row visible to a consumer. The list is precisely the finite stream-name row, the regular-sequence spine, the dyadic observation rows, the endpoint transport ledger, and the shared provenance; the same scoped surface excludes quotient, completion, Classical, metric-completeness, arithmetic, order, standard-bridge, and external selector data. Hence the selected tail classifier is determined exactly by the common finite rows. □

Lean4 ✓ `BEDC.Derived.RealUp.RegseqratTailClassifierExactness`

Theorem 38.361 (RegSeqRat tail-classifier atlas refinement invariance)**.** *Let $\mathcal{A} = \{W_i\}_{i\in I}$ be a finite atlas of selected finite* Real$^{\uparrow}$ *observation-window packages, and let $\mathcal{B} = \{V_a\}_{a\in A}$ be a finite atlas refining $\mathcal{A}$. Suppose each refined chart V_a is certified inside some chart $W_{i(a)}$, and suppose the refinement maps, refined overlaps, and comparison pullbacks preserve the displayed* StreamName$^{\uparrow}$*,* RegSeqRat*, DyadicRatCore,* UnaryHistory*,* ProbeBundle*,* InBundle*,* hsame*,* Cont*,* Pkg*, and* RealLedgerPolicy *rows.*

Then the selected RegSeqRat *tail-classifier row descended from $\mathcal{B}$ factors through the selected row descended from $\mathcal{A}$. On the finite union covered by the two atlases these two rows agree after readback to the displayed StreamName and RegSeqRat finite window surface. The comparison uses no quotient, completion, Classical representative, metric-completeness row, arithmetic or order row, standard-bridge row, or hidden selector row.*

Proof. Apply Definition 38.375 to $\mathcal{A}$ and to $\mathcal{B}$. This gives one selected atlas row on each finite union, with chartwise pullback uniqueness for every selected chart.

Next use Definition 38.373 on the certified inclusions $V_a \hookrightarrow W_{i(a)}$. The preservation hypotheses identify each refined selected row with the pullback of the coarse chart row along the displayed finite-window refinement map.

Now group the refined charts by their coarse chart and apply Definition 38.374. The descent obtained by first gluing the refined charts inside each W_i and then gluing the coarse atlas is the same row as the descent obtained by flattening all refined charts and gluing $\mathcal{B}$ directly.

The partition comparison is supplied by Definition 38.367: both atlas rows read the same displayed StreamName, RegSeqRat, DyadicRatCore, unary-history, probe, membership, transport, continuation, package, and policy rows on the common finite union.

It remains to identify the mediator. Both the factored row from $\mathcal{A}$ and the row descended from $\mathcal{B}$ pull back to the same selected RegSeqRat tail classifier on every refined chart V_a. Hence Definition 38.365 identifies them on the union. Since every step used only the displayed rows just named, the excluded quotient, completion, Classical, metric, arithmetic, order, bridge, and hidden-selector data have no projection into the comparison. □

Theorem 38.362 (RegSeqRat tail-classifier directed-refinement normal form)**.** *Let $\{\mathcal{A}_r\}_{r\in R}$ be a finite directed family of finite atlases of selected* Real$^{\uparrow}$ *observation-window packages. Suppose every transition $\mathcal{A}_r \to \mathcal{A}_s$ with $r \le s$, every displayed cofinal refinement, and every comparison pullback preserves the displayed* StreamName$^{\uparrow}$*,* RegSeqRat*, DyadicRatCore,* UnaryHistory*,* ProbeBundle*,* InBundle*,* hsame*,* Cont*,* Pkg*, and* RealLedgerPolicy *rows. Choose any cofinal refined atlas row and read its selected* RegSeqRat *tail classifier.*

Then that selected classifier agrees with the normal-form tail row on the directed union. The comparison is the unique finite-window row whose pullback to every selected tail window is the displayed chart classifier, and it uses no quotient, completion, Classical representative, metric-completeness certificate, arithmetic or order row, standard-bridge row, or hidden selector.

Proof. Apply Definition 38.375 to each finite atlas in the directed family. The directed hypotheses give a chartwise selected row on every stage, and each such row is built only from the displayed StreamName, RegSeqRat, dyadic, unary-history, probe, membership, transport, package, and policy data.

For a transition $r \leq s$, use Definition 38.361 and Definition 38.373. They identify the selected row on $\mathcal{A}_s$ with the pullback of the selected row on $\mathcal{A}_r$ along the displayed finite refinement.

Cofinal changes of the directed atlas are reduced to one finite comparison by Definition 38.374, and Definition 38.376 removes the charts outside the selected cofinal row. Thus both the cofinal read and the directed-union normal form have the same pullback on every selected tail window.

Finally apply Definition 38.365. The two finite-window rows are equal because their chart pullbacks agree, and the preserved row inventory listed in the hypotheses leaves no projection for the excluded quotient, completion, Classical, metric, arithmetic, order, bridge, or hidden-selector data. □

Theorem 38.363 (RegSeqRat tail-classifier reindexing normal form)**.** *Let W be a finite* $\mathsf{Real}^{\uparrow}$ *observation-window package, and let $\rho_1, \ldots, \rho_n$ be a finite certified unary reindexing schedule whose adjacent stages preserve the displayed* $\mathsf{StreamName}^{\uparrow}$*,* RegSeqRat*, DyadicRatCore,* UnaryHistory*,* ProbeBundle*,* InBundle*,* hsame*,* Cont*,* Pkg*, and* RealLedgerPolicy *rows. At every stage, read the selected* RegSeqRat *tail classifier from the displayed finite-window surface.*

Then the selected tail row read after any adjacent certified stage, the row read after the composite schedule $\rho_n \circ \cdots \circ \rho_1$, and the row read directly from the normal-form finite-window surface of W are the same finite-window RegSeqRat *tail-classifier row. This normal-form comparison uses only the displayed finite readback rows and introduces no quotient row, completion row, Classical representative, metric-completeness certificate, arithmetic or order row, standard-bridge row, or hidden regular-sequence selector.*

Proof. Induct on the finite certified schedule. In the empty schedule case, the normal-form read is the direct finite-window read of W; apply Definition 38.360 to obtain the selected RegSeqRat tail row from the displayed StreamName, RegSeqRat, DyadicRatCore, endpoint-transport, ledger, package, and provenance rows.

For the cons step, assume the statement for the initial schedule and append one certified unary reindexer. The induction hypothesis identifies the selected tail row after the initial schedule with the direct normal-form read. Apply Definition 38.370 to the appended stage, using the preserved $\mathsf{StreamName}^{\uparrow}$, RegSeqRat, DyadicRatCore, UnaryHistory, ProbeBundle, InBundle, hsame, Cont, Pkg, and RealLedgerPolicy rows.

The composite schedule has the same public readback as the stagewise schedule by Definition 38.371. Therefore the row read after the composite schedule agrees with each stagewise selected tail row and with the normal-form finite-window row.

Finally apply Definition 38.365. Any candidate tail row compatible with all stagewise pullbacks factors through the same displayed finite-window surface, so there is only one selected tail classifier. Definition 38.342 supplies the exclusion boundary: quotient, completion, Classical, metric-completeness, arithmetic, order, standard-bridge, and hidden selector rows are outside the scoped finite surface. □

Theorem 38.364 (RegSeqRat tail-classifier normal-form tail coverage)**.** *Let W be a finite* $\mathsf{Real}^{\uparrow}$ *observation-window package, and let $\rho_1, \ldots, \rho_n$ be a finite certified unary reindexing schedule whose adjacent stages preserve the displayed* $\mathsf{StreamName}^{\uparrow}$*,* RegSeqRat*, DyadicRatCore,* UnaryHistory*,* ProbeBundle*,* InBundle*,* hsame*,* Cont*,* Pkg*, and* RealLedgerPolicy *rows. For each stagewise read, for the read after the composite schedule $\rho_n \circ \cdots \circ \rho_1$, and for the direct normal-form finite-window read of W, the selected tail row is covered by one and the same selected* RegSeqRat *classifier row.*

The covering row is the finite-window classifier row exposed by the displayed $\mathsf{StreamName}^{\uparrow}$*,* RegSeqRat*, DyadicRatCore, endpoint-transport, continuation-ledger, package, and* RealLedgerPolicy *data. The coverage statement has no quotient row, completion row, Classical representative, metric-completeness certificate, arithmetic or order row, standard-bridge row, or hidden selector row.*

Proof. Apply Definition 38.363. It identifies the selected tail row read at each certified stage, the selected row read after the composite schedule, and the selected row read directly from the normal-form finite-window surface.

Now use Definition 38.360 on that common finite-window surface. The exactness theorem says that the selected tail is not a separate row but the displayed RegSeqRat classifier row read from the shared StreamName, RegSeqRat, DyadicRatCore, hsame, Cont, Pkg, and RealLedgerPolicy data.

It remains to rule out a second mediator for one of the reads. Apply Definition 38.365. Any candidate row compatible with the stagewise, composite, and direct pullbacks factors through the same selected finite-window classifier row, so all selected tails are covered by that single row.

The exclusion boundary is inherited from the exact finite read surface: quotient data, completion data, Classical representatives, metric-completeness certificates, arithmetic or order structure, standard-bridge data, and hidden selector rows are not part of the scoped package. □

Theorem 38.365 (RegSeqRat tail-classifier pullback uniqueness)**.** *Let W_0 and W_1 be finite-window* $\mathsf{Real}^{\uparrow}$ *packages whose displayed* $\mathsf{StreamName}^{\uparrow}$ *classifier rows,* RegSeqRat *spine rows, DyadicRatCore observation rows, endpoint* hsame *transports, and finite* Cont *ledger entries agree as in Definition 38.360. Suppose a candidate tail-classifier row T pulls back to the selected tail of W_0 and also pulls back to the selected tail of W_1 through exactly those displayed rows. Then T is identified with the unique selected* RegSeqRat *tail classifier determined by the common finite-window readback data. No second tail-classifier surface can mediate the finite-window* $\mathsf{Real}^{\uparrow}$ *seal while remaining invisible to the displayed* $\mathsf{StreamName}^{\uparrow}$*,* RegSeqRat*, DyadicRatCore,* hsame*, and* Cont *rows.*

Lean4 ✓ `BEDC.Derived.RealUp.RegseqratTailClassifierPullbackUniqueness`

Proof. By Definition 38.360, the two selected tails of W_0 and W_1 are the same RegSeqRat tail classifier after the displayed endpoint transports in the shared ledger are applied.

It remains to exclude a hidden mediator. The scoped read surface of Definition 38.342 lists every row that a finite-window $\mathsf{Real}^{\uparrow}$ consumer may read: the stream-name classifier row, the regular-sequence spine, the dyadic observation rows, the endpoint transport ledger, and the finite continuation ledger.

Finally, Definition 38.350 packages exactly that surface as the readback boundary. Since T pulls back through no rows other than those displayed rows, it has no independent slot in the finite package. Therefore the two pullbacks of T factor through the same selected tail, and T is the unique selected RegSeqRat tail classifier available at the finite-window seal. □

Theorem 38.366 (RegSeqRat tail-classifier union exhaustion)**.** *Let $\{W_i\}_{i \in I}$ be a finite family of selected finite* $\mathsf{Real}^{\uparrow}$ *observation-window packages. Assume that every certified common subwindow*

used by the finite cover displays the same $\mathsf{StreamName}^{\uparrow}$ *row, the same* RegSeqRat *spine row, the same DyadicRatCore observation row, matching endpoint* hsame *transports, and the same finite* Cont *ledger entries. Also assume that these certified common subwindows cover the union of the visible windows. Then the union window exposes one selected* RegSeqRat *tail-classifier row.*

Moreover, any candidate RegSeqRat *tail row whose pullback agrees with the selected tail row on every member window factors uniquely through the selected tail-classifier row on the union window. The union read surface adds no quotient row, completion row, Classical representative, metric-completeness certificate, arithmetic or order row, standard-bridge row, or hidden regular-sequence selector.*

Proof. First restrict the family to a certified common subwindow. By Definition 38.360, the shared $\mathsf{StreamName}^{\uparrow}$, RegSeqRat, DyadicRatCore, endpoint-transport, and finite ledger rows determine the same selected tail classifier on that subwindow.

Next compare two overlaps in the finite cover. Apply Definition 38.365 to the two restricted readback surfaces. Any mediator that pulls back to both selected tails has no independent row outside the displayed finite readback inventory, so the overlap contributes the same mediating tail row.

Now exhaust the finite union. Use Definition 38.326 to repack the certified common subwindows into one finite $\mathsf{Real}^{\uparrow}$ union surface, and use Definition 126.108 to keep the StreamName and RegSeqRat handoff rows fixed across the cover. The repacked surface therefore carries a single selected tail classifier.

Finally let a candidate tail row pull back to every member window. The previous overlap comparison identifies all of its member-window pullbacks with the same selected row, and the union repacking has no further tail-classifier slot. Thus the candidate factors uniquely through the selected RegSeqRat tail row on the finite union window. □

Theorem 38.367 (RegSeqRat tail-classifier partition coherence)**.** *Let* $\{W_i\}_{i\in I}$ *be a finite family of selected finite* $\mathsf{Real}^{\uparrow}$ *observation-window packages, and let the certified subwindows of this family cover a displayed finite window* W*. Assume that each pairwise overlap displays the same* $\mathsf{StreamName}^{\uparrow}$ *row, the same* RegSeqRat *spine row, the same DyadicRatCore observation row, matching endpoint* hsame *transports, matching finite* Cont *rows, matching* Pkg *provenance, and the same* RealLedgerPolicy *rows.*

Then the assembled finite partition exposes the same selected RegSeqRat *tail-classifier row as the direct selected read of* W*. Moreover, any local* RegSeqRat *tail row whose pullbacks are compatible on all member windows factors uniquely through that direct selected tail. This partition read introduces no quotient representative, completion row, host stream datum, metric-completeness certificate, arithmetic or order row, standard-bridge row, or hidden regular-sequence selector.*

Proof. Apply Definition 38.328 to the certified finite cover. The public finite BHist partition surface and the direct finite-window read of W therefore have the same displayed $\mathsf{StreamName}^{\uparrow}$, RegSeqRat, DyadicRatCore, endpoint hsame, finite Cont, Pkg, and RealLedgerPolicy rows.

Next apply Definition 38.366 to the same finite family. Since the overlap hypotheses keep the selected tail row fixed on every certified subwindow, the finite union carries one selected RegSeqRat tail classifier.

Finally use Definition 38.365 on the overlap readback surfaces. A local tail row compatible on all member windows has no extra mediator outside the displayed partition rows, so it factors uniquely through the direct selected RegSeqRat tail of W. □

Theorem 38.368 (RegSeqRat tail-classifier finite-cover sheaf condition)**.** *Let $\{W_i\}_{i\in I}$ be a finite family of selected finite* $\mathsf{Real}^{\uparrow}$ *observation-window packages. Suppose every certified overlap displays the same* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the same selected* RegSeqRat *spine row, the same DyadicRatCore observation row, the same* UnaryHistory*,* ProbeBundle*, and* InBundle *rows, and matching finite* hsame*,* Cont*,* Pkg*, and* RealLedgerPolicy *rows. If the local selected* RegSeqRat *tail-classifier rows are compatible on all certified overlaps, then they glue to a unique selected global tail row on the finite union window. Each local selected row is the pullback of this global row.*

The glued surface contains only the displayed finite readback rows. It imports no quotient, completion, Classical representative, metric-completeness, order, arithmetic, standard bridge, or hidden selector row.

Proof. First apply Definition 38.360 on each member window. The selected local tail row is thereby determined by the displayed $\mathsf{StreamName}^{\uparrow}$, RegSeqRat, DyadicRatCore, UnaryHistory, ProbeBundle, InBundle, hsame, Cont, Pkg, and RealLedgerPolicy rows.

Next use Definition 38.366. The finite family has a displayed union readback surface, and every local selected tail row is read through that surface after restriction to its member window.

Compatibility on overlaps is the partition condition of Definition 38.367. It identifies the member-window restrictions with the direct selected read of the finite union, so the union surface carries one candidate global tail row.

Finally apply Definition 38.365. Any other global row with the same member-window pullbacks has no additional mediator outside the displayed finite union rows, hence it is the same selected global tail row. The exclusion sentence follows from the exactness and union exhaustion boundaries: no quotient, completion, Classical representative, metric-completeness, order, arithmetic, standard bridge, or hidden selector row appears in the glued surface. □

Theorem 38.369 (RegSeqRat tail-classifier descent exactness)**.** *Let $\{W_i\}_{i\in I}$ be a finite family of selected finite* $\mathsf{Real}^{\uparrow}$ *observation-window packages with compatible local selected* RegSeqRat *tail-classifier rows on every certified overlap. Let ρ be a certified unary* $\mathsf{StreamName}^{\uparrow}$ *reindexing schedule from the displayed finite union window to a refined finite-window surface. Suppose ρ preserves the displayed* RegSeqRat*, DyadicRatCore,* UnaryHistory*,* ProbeBundle*,* InBundle*,* hsame*,* Cont*,* Pkg*, and* RealLedgerPolicy *rows at each certified stage.*

Then the glued global RegSeqRat *tail row descends uniquely through the reindexed finite-window surface. Every local selected row is the pullback of that descended row along its member-window readback, and the descent surface contains no quotient, completion, Classical representative, metric-completeness, arithmetic or order row, standard-bridge row, or hidden selector row.*

Proof. First apply Definition 38.368. The compatible local selected tail-classifier rows glue to a unique global selected RegSeqRat tail row on the finite union window, and every local row is its pullback.

Next transport that global row along the certified schedule. For one unary reindexing step use Definition 38.370; for a finite schedule use Definition 38.371. The displayed $\mathsf{StreamName}^{\uparrow}$, RegSeqRat, DyadicRatCore, UnaryHistory, ProbeBundle, InBundle, hsame, Cont, Pkg, and RealLedgerPolicy rows are therefore the same rows seen on the refined finite-window surface.

Finally apply Definition 38.365. A second descended tail row with the same local pullbacks would pull back through the same displayed finite readback rows, so it is the transported global row. The same row inventory excludes quotient, completion, Classical representative, metric-completeness, arithmetic, order, standard-bridge, and hidden selector data. □

Theorem 38.370 (RegSeqRat tail-classifier reindexing stability)**.** *Let W_0 and W_1 be finite* $\mathsf{Real}^{\uparrow}$ *observation-window packages, and let ρ be a certified unary reindexer between their displayed* $\mathsf{StreamName}^{\uparrow}$ *windows. Suppose the two packages have matching* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier rows after reindexing by ρ, matching* RegSeqRat *spine rows, matching DyadicRatCore observation rows, matching* UnaryHistory*,* ProbeBundle*, and* InBundle *membership rows, and matching finite* hsame*,* Cont*,* Pkg*, and* RealLedgerPolicy *rows.*

Then the RegSeqRat *tail classifier selected after reindexing is the same finite-window readback row for W_0 and W_1. This stability statement uses only the displayed finite rows. It imports no quotient row, completion row, Classical representative, metric-completeness certificate, arithmetic or order row, standard-bridge row, or hidden regular-sequence selector.*

Proof. First apply Definition 126.155 to the displayed $\mathsf{StreamName}^{\uparrow}$–RegSeqRat handoff surface. The certified unary reindexer ρ identifies the reindexed StreamName classifier rows together with the visible UnaryHistory, ProbeBundle, and InBundle membership rows.

Next apply Definition 126.157. Since the reindexed classifier rows and the finite handoff rows match, every downstream RegSeqRat finite-window consumer reads the same source surface and the same selected input rows from both packages.

Now use Definition 38.360. The common StreamName, RegSeqRat, DyadicRatCore, endpoint-transport, ledger, and provenance rows determine one selected RegSeqRat tail classifier. Then Definition 38.365 rules out a second tail row pulling back through the same displayed finite readback surface.

Finally close the surface with Definition 38.342. Its row inventory is exactly the visible finite-window readback inventory, so quotient, completion, Classical, metric-completeness, arithmetic, order, standard-bridge, and hidden selector rows have no slot in the stabilized reindexed package. □

Theorem 38.371 (RegSeqRat tail-classifier reindexing composition)**.** *Let W_0 and W_1 be finite* $\mathsf{Real}^{\uparrow}$ *observation-window packages. Let ρ be a certified unary reindexer from the displayed window of W_0 to an intermediate displayed* $\mathsf{StreamName}^{\uparrow}$ *window, and let σ be a certified unary reindexer from that intermediate window to the displayed window of W_1. Suppose the two packages have matching* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier rows after first reindexing by ρ and then by σ, matching* RegSeqRat *spine rows, matching DyadicRatCore observation rows, matching* UnaryHistory*,* ProbeBundle*, and* InBundle *membership rows, and matching finite* hsame*,* Cont*,* Pkg*, and* RealLedgerPolicy *rows at both displayed reindexing stages.*

Then the RegSeqRat *tail classifier selected after the composite reindexing schedule $\sigma \circ \rho$ is the same finite-window readback row as the classifier obtained by applying the two certified reindexing steps successively. The composition surface is only the displayed finite readback surface; it introduces no quotient row, completion row, Classical representative, metric-completeness certificate, arithmetic or order row, standard-bridge row, or hidden regular-sequence selector.*

Proof. First apply Definition 126.155 to the ρ-reindexed handoff surface. The displayed $\mathsf{StreamName}^{\uparrow}$ classifier, RegSeqRat spine, UnaryHistory, ProbeBundle, and InBundle membership rows form the intermediate finite readback boundary.

Apply the same exhaustion theorem to the σ-reindexed handoff surface. The intermediate boundary is thereby transported to the final displayed finite-window boundary with the same RegSeqRat spine, DyadicRatCore observation rows, endpoint hsame transports, finite Cont ledger, Pkg row, and RealLedgerPolicy provenance.

Next use Definition 126.157. A consumer reading after $\sigma \circ \rho$ sees exactly the same displayed StreamName and RegSeqRat source rows as a consumer that reads after ρ and then after σ. Thus both schedules feed the tail selector with the same finite-window row inventory.

Now invoke Definition 38.370 for the ρ-stage and again for the σ-stage. Each stage preserves the selected RegSeqRat tail classifier on the displayed finite rows, so the successive readback row agrees with the row exposed by the composite reindexing schedule.

It remains to show that this agreement is the exact public surface. Apply Definition 38.360 to the common StreamName, RegSeqRat, DyadicRatCore, endpoint-transport, ledger, package, and provenance rows. Then Definition 38.365 excludes any second tail-classifier row pulling back through the two-stage schedule.

Finally use Definition 38.342. The scoped row inventory contains only the finite-window readback rows displayed above, so quotient, completion, Classical, metric-completeness, arithmetic, order, standard-bridge, and hidden selector data have no slot in the composite surface. □

Theorem 38.372 (RealUp RegSeqRat tail-window reindexing boundary)**.** *Let W be a finite* $\mathsf{Real}^{\uparrow}$ *observation-window package and let ρ be a certified unary tail map from its displayed window to a reindexed* $\mathsf{StreamName}^{\uparrow}$ *finite window. Suppose the reindexed source rows match the tail-window normal forms: the* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier rows, the selected* ProbeBundle *and* InBundle *membership rows, the* UnaryHistory *observations, the* RegSeqRat *spine and tail-classifier rows, the DyadicRatCore observation rows, the finite* hsame *and* Cont *ledger, the* Pkg *provenance row, and the displayed* RealLedgerPolicy *row.*

Then the finite $\mathsf{Real}^{\uparrow}$ *observation window reindexed through ρ consumes exactly those rows. Its handoff boundary is the StreamName finite-window classifier surface together with the RegSeqRat tail-classifier surface transported by the certified unary tail map. It imports no* $\mathsf{Real}^{\uparrow}$ *seal classifier, completion object, quotient row, host-index equality, Classical representative, metric-completeness witness, arithmetic or order row, standard-bridge row, or hidden regular-sequence selector.*

Proof. First apply Definition 126.155. The reindexed window is therefore exhausted by the displayed $\mathsf{StreamName}^{\uparrow}$ classifier, ProbeBundle, InBundle, UnaryHistory, RegSeqRat spine, and finite ledger rows.

Next use Definition 38.370 and Definition 38.371. These two results identify the row obtained by the certified unary tail map with the same selected RegSeqRat tail classifier carried by the displayed tail-window normal form.

Now apply Definition 38.373. It shows that the same projection remains valid after finite-window cover gluing, so the reindexed boundary does not depend on a hidden choice of local tail classifier.

Finally combine the StreamName side with Definition 126.170 and Definition 126.44. These handoff theorems expose exactly the finite StreamName rows that a RegSeqRat or $\mathsf{Real}^{\uparrow}$ consumer may read. Repacking those rows with the RegSeqRat tail normal form gives the stated $\mathsf{Real}^{\uparrow}$ boundary and leaves no slot for seal, completion, quotient, host-index, order, arithmetic, bridge, or hidden selector data. □

Theorem 38.373 (RegSeqRat tail-classifier reindexed finite-cover compatibility)**.** *Let $\{W_i\}_{i\in I}$ be a finite family of selected finite* $\mathsf{Real}^{\uparrow}$ *observation-window packages with compatible local selected* RegSeqRat *tail-classifier rows on every certified overlap. Let ρ_i be certified unary reindexers for the member windows, and let ρ be the certified unary reindexer induced on the displayed finite union window. Suppose these reindexers preserve the displayed* $\mathsf{StreamName}^{\uparrow}$*,* RegSeqRat*, DyadicRatCore,* UnaryHistory*,* ProbeBundle*,* InBundle*, finite* hsame*,* Cont*,* Pkg*, and* RealLedgerPolicy

rows, and suppose the transported overlap rows are the same rows as the overlaps of the reindexed member windows.

Then the selected RegSeqRat *tail classifier obtained by first gluing the finite cover and then reindexing by ρ is the same finite-window readback row as the classifier obtained by reindexing each member window by ρ_i and then applying finite-cover gluing to the reindexed cover. The compatibility surface contains no quotient, completion, Classical representative, metric-completeness, arithmetic or order row, standard-bridge row, or hidden regular-sequence selector row.*

Proof. First glue the original cover with Definition 38.368. The compatible local selected rows determine a unique global selected tail row on the displayed finite union, and each member row is its pullback.

Next transport this global row along ρ. The one-step case is Definition 38.370, and the finite-window schedule is handled by Definition 38.371. Thus the glue-then-reindex construction has a displayed selected row on the reindexed finite union.

Now reindex each member window by ρ_i. The same stability theorem identifies every transported local classifier with the selected classifier on the corresponding reindexed member window, and the transported overlap hypothesis gives the compatibility condition required by Definition 38.368. Therefore the reindexed cover also glues to a selected global tail row.

It remains to compare the two global rows. On each reindexed member window, both constructions pull back to the same transported local selected RegSeqRat tail classifier. Apply Definition 38.365 on the reindexed finite cover to identify the two global rows. The row inventory used in each step is exactly the displayed $\mathsf{StreamName}^{\uparrow}$, RegSeqRat, DyadicRatCore, UnaryHistory, ProbeBundle, InBundle, hsame, Cont, Pkg, and RealLedgerPolicy inventory, so the listed quotient, completion, Classical, metric-completeness, arithmetic, order, standard-bridge, and hidden selector rows are excluded. □

Theorem 38.374 (RegSeqRat tail-classifier nested-cover associativity)**.** *Let $\{W_i\}_{i\in I}$ be a finite family of selected finite* $\mathsf{Real}^{\uparrow}$ *observation-window packages. For each i, let $\{W_{ij}\}_{j\in J_i}$ be a finite certified subcover of W_i by selected finite windows, and suppose all first-level and second-level overlaps preserve the displayed* $\mathsf{StreamName}^{\uparrow}$, RegSeqRat, *DyadicRatCore,* UnaryHistory, ProbeBundle, InBundle, hsame, Cont, Pkg, *and* RealLedgerPolicy *rows.*

Then the selected RegSeqRat *tail-classifier row obtained by first gluing each subcover $\{W_{ij}\}_{j\in J_i}$, then gluing the resulting member windows $\{W_i\}_{i\in I}$, is the same finite-window row as the selected classifier obtained by flattening the family $\{W_{ij}\}_{i,j}$ and gluing that single certified finite cover once. The associativity surface exports no quotient, completion, Classical representative, metric-completeness, arithmetic or order row, standard-bridge row, or hidden regular-sequence selector row.*

Proof. First glue each certified subcover $\{W_{ij}\}_{j\in J_i}$. By Definition 38.368, every compatible subfamily determines a unique selected tail-classifier row on W_i, and the pullback of that row to each W_{ij} is the displayed local classifier.

Next glue the resulting family of member windows. The same finite-cover theorem gives a selected global row over the finite union of the W_i, and the overlap hypotheses ensure that its pullback to each W_i is the row obtained from the corresponding subcover.

Now flatten the two-level family to the certified finite cover $\{W_{ij}\}_{i,j}$. Apply Definition 38.373 to identify the flattened cover with the same displayed finite-window inventory used by the staged construction; the reindexing data here is only the certified inclusion and ordering of the flattened subwindows.

It remains to compare the staged row with the flattened row. Both pull back to the same selected RegSeqRat tail-classifier row on every certified subwindow W_{ij}, so Definition 38.365 identifies the two global rows. Each step used only the displayed StreamName$^{\uparrow}$, RegSeqRat, DyadicRatCore, UnaryHistory, ProbeBundle, InBundle, hsame, Cont, Pkg, and RealLedgerPolicy rows, leaving no slot for the excluded host or completion data. □

Theorem 38.375 (RegSeqRat tail-classifier atlas descent)**.** *Let $\mathcal{A} = \{W_i\}_{i\in I}$ be a finite atlas of selected finite* Real$^{\uparrow}$ *observation-window packages. Suppose every pairwise overlap $W_i \cap W_j$ and every triple overlap $W_i \cap W_j \cap W_k$ preserves the displayed* StreamName$^{\uparrow}$, RegSeqRat, *DyadicRatCore,* UnaryHistory, ProbeBundle, InBundle, hsame, Cont, Pkg, *and* RealLedgerPolicy *rows.*

Then the atlas exposes a single selected RegSeqRat *tail-classifier row on the finite union of its windows. For every chart W_i, the chartwise selected tail-classifier row factors through this atlas row, and this factorisation is unique among finite-window mediators preserving the displayed rows. The descent surface exports no quotient, completion, Classical representative, metric-completeness row, arithmetic or order row, standard-bridge row, or hidden selector row.*

Proof. Apply Definition 38.360 to each selected chart. This identifies the chartwise tail-classifier row with the displayed StreamName$^{\uparrow}$, RegSeqRat, DyadicRatCore, unary-history, probe-bundle, membership, transport, continuation, provenance, and ledger inventory.

Next form the finite atlas union. By Definition 38.366, the union consumes exactly the rows contributed by the selected windows and their certified overlaps. No additional host row is introduced while passing from the chart family to the finite union.

Now decompose the atlas by its chart partition. The coherence result Definition 38.367 says that the selected row obtained from the union is the same row obtained by assembling the partition pieces with their displayed overlap transports.

Triple refinements are handled by Definition 38.374. It identifies the staged gluing over pairwise overlaps with the flattened finite cover over all chart and triple-overlap pieces, so the resulting atlas row is independent of the order in which the certified finite overlaps are read.

It remains to show the universal factorisation claim. A chartwise selected tail pulls back from the atlas row by construction. If another finite-window mediator has the same pullback on every chart while preserving the displayed rows, then Definition 38.365 identifies that mediator with the atlas row. Thus each chartwise tail factors uniquely through the displayed atlas descent row, and the excluded quotient, completion, Classical, metric, arithmetic, order, bridge, and hidden-selector data have no projection in the construction. □

Theorem 38.376 (RegSeqRat tail-classifier subatlas restriction exactness)**.** *Let $\mathcal{A} = \{W_i\}_{i\in I}$ be a finite atlas of selected finite* Real$^{\uparrow}$ *observation-window packages satisfying the atlas-descent hypotheses of Definition 38.375. Let $\mathcal{B} = \{W_j\}_{j\in J}$ be a certified finite subatlas whose union is a certified subwindow of the union of $\mathcal{A}$, and suppose each chart of $\mathcal{B}$ is obtained by restricting one chart of $\mathcal{A}$ along the displayed finite-window inclusion ledger.*

Then the selected RegSeqRat *tail-classifier row obtained by restricting the atlas row of $\mathcal{A}$ to the charts of $\mathcal{B}$ is exactly the row obtained by applying finite-cover descent directly to $\mathcal{B}$. This restriction surface preserves precisely the displayed* StreamName$^{\uparrow}$, RegSeqRat, *DyadicRatCore,* UnaryHistory, ProbeBundle, InBundle, hsame, Cont, Pkg, *and* RealLedgerPolicy *rows. It exports no quotient, completion, Classical representative, metric-completeness row, arithmetic or order row, standard-bridge row, or hidden-selector row.*

Proof. Apply Definition 38.375 to the ambient atlas $\mathcal{A}$. This supplies a single selected atlas row whose pullback to each ambient chart is the chartwise RegSeqRat tail-classifier row over the dis-

played $\mathsf{StreamName}^{\uparrow}$, DyadicRatCore, unary-history, probe-bundle, membership, transport, continuation, provenance, and ledger data.

Restrict those pullbacks along the certified inclusions defining the subatlas $\mathcal{B}$. Since each subatlas chart is a finite-window restriction of an ambient chart, the restricted pullbacks still expose only the displayed UnaryHistory, ProbeBundle, InBundle, hsame, Cont, Pkg, and RealLedgerPolicy rows.

Now apply Definition 38.368 directly to the certified finite cover $\mathcal{B}$. The pairwise compatibility required on $\mathcal{B}$ is inherited from the ambient pairwise and triple overlap hypotheses, so the finite-cover theorem produces a selected RegSeqRat tail-classifier row on the subwindow union.

It remains to compare the restricted ambient row with the row constructed directly on $\mathcal{B}$. Both rows pull back to the same selected tail-classifier on every chart W_j of the subatlas and both preserve the same displayed inventory. Therefore Definition 38.365 identifies them. The comparison has no projection to quotient, completion, Classical, metric, arithmetic, order, standard-bridge, or hidden-selector data because neither construction contains such a row. □

Theorem 38.377 (RealUp terminal refinement seal boundary)**.** *Let E be a* $\mathsf{Real}^{\uparrow}$ *finite-window refinement envelope over a fixed* $\mathsf{StreamName}^{\uparrow}$ *source. Suppose two refined finite-window presentations W and W' are carried by E, are connected by the directed-refinement seal of Definition 38.329, and are then read by a terminal finite-window* $\mathsf{Real}^{\uparrow}$ *seal consumer. Then every terminal consumer of either presentation reads exactly the same finite source boundary:*

1. *the* RatStreamNameFiniteWindowClassifier *rows;*
2. *the bundled* UnaryHistory *and* InBundle *rows;*
3. *the pointwise* RatHistoryClassifier *rows;*
4. *the accepted* RegSeqRat *finite-window spine;*
5. *the* DyadicRatCore *source rows;*
6. *the visible* Cont*,* hsame*,* Pkg*, and* RealLedgerPolicy *ledger rows.*

No terminal read exposes a quotient row, completion object, host Nat *index, host function,* Classical *datum, metric-completeness certificate, arithmetic row, order row, or standard bridge row.*

Proof. First identify both refined presentations with the same envelope boundary. Apply Definition 38.331 to the two windows carried by E. The result gives one public finite BHist surface containing exactly the envelope classifier, endpoint, dyadic-source, hsame, and ledger-policy rows.

Next use the directed-refinement seal. The comparison row supplied by Definition 38.329 forces the presentation read from W and the presentation read from W' through that same finite refinement surface. Thus the two refined windows have no distinct source boundary for a later consumer to inspect.

Now pass this common finite-window surface to the terminal seal consumer. Apply Definition 126.45. It reads the finite StreamName-to-RegSeqRat packet as the selected classifier rows, bundled unary and membership rows, pointwise rational classifier rows, endpoint and denominator rows, the accepted RegSeqRat spine, the dyadic source rows, and the finite Cont and hsame transport ledger.

Finally apply Definition 126.46. The scope readback keeps the source Pkg rows and RealLedgerPolicy boundary attached to the same packet and excludes all rows outside it. Hence no terminal consumer can read quotient data, completion data, host indices, host functions, Classical data, metric-completeness certificates, arithmetic or order rows, or standard bridge rows. □

Theorem 38.378 (RealUp directed-refinement terminality)**.** *Let $\mathcal{F}$ be a directed finite family of StreamName tail-window coverage packets over the same public* $\mathsf{StreamName}^{\uparrow}$ *endpoints and the same accepted* RegSeqRat *finite-window spine. Then the directed common-refinement packet obtained from $\mathcal{F}$ is terminal for finite* $\mathsf{Real}^{\uparrow}$ *consumers: every finite* $\mathsf{Real}^{\uparrow}$ *consumer whose source reads one member of $\mathcal{F}$ factors through this common-refinement packet.*

For any selected subwindow, restriction from the common-refinement packet recovers the same RatStreamNameFiniteWindowClassifier *rows, the same* UnaryHistory *and* InBundle *rows, the same pointwise* RatHistoryClassifier *rows, the same accepted* RegSeqRat *spine, the same* DyadicRatCore *endpoint rows, and the same visible* Cont*,* hsame*,* Pkg*, and* RealLedgerPolicy *rows as the original StreamName finite-window packet.*

The terminal factorization introduces no completion object, quotient row, host-index equality, metric-completeness row, arithmetic or order operation, or standard bridge row.

Proof. First form the common packet. Apply Definition 126.221 to any two members of the directed family; directedness supplies a family member whose selected observation window contains both restrictions, so the generated packet has the same public endpoints and accepted RegSeqRat spine.

For more than two selected windows, iterate the same construction along the finite family. Apply Definition 126.222 at each regrouping step. The resulting packet is independent of the parenthesization, and every selected subwindow restricts back to the same StreamName classifier, unary-history, bundle-membership, pointwise rational-history, accepted spine, dyadic endpoint, continuation, history, package, and ledger-policy rows.

Next pass a finite $\mathsf{Real}^{\uparrow}$ consumer through the packet boundary. Apply Definition 126.224. Every consumer row factors through the displayed tail-window ledger, and equality of the displayed packet gives equality of the finite read surface.

Finally compare this terminal read with the $\mathsf{Real}^{\uparrow}$ seal boundary. Apply Definition 38.377. The terminal consumer therefore reads exactly the rows recovered by the selected subwindow restriction and no object outside that finite surface. In particular, the construction adds no completion object, quotient row, host-index equality, metric-completeness row, arithmetic or order operation, or standard bridge row. □

Theorem 38.379 (StreamName Real-RegSeq terminal source uniqueness)**.** *Let C be a public* $\mathsf{StreamName}^{\uparrow}$ *finite-window package. Suppose two terminal finite-window* $\mathsf{Real}^{\uparrow}$ *seal consumers are reached from C and that their displayed* RegSeqRat *handoff rows expose the same source data:*

1. *the* RatStreamNameFiniteWindowClassifier *rows;*
2. *the* UnaryHistory *and* InBundle *rows;*
3. *the pointwise* RatHistoryClassifier *rows;*
4. *the accepted* RegSeqRat *spine;*
5. *the* DyadicRatCore *rows; and*
6. *the visible* Cont*,* hsame*,* Pkg*, and* RealLedgerPolicy *rows.*

Then the two terminal consumers have the same source-boundary projection. Conversely, equality of the terminal source-boundary projection is exactly equality of the rows listed above.

The projection contains no quotient row, completion object, host index, host function, Classical *datum, metric-completeness row, arithmetic or order row, or standard bridge row.*

Proof. Begin with the two routes from the public $\mathsf{StreamName}^{\uparrow}$ package C to the terminal finite-window consumers. By Definition 38.380, route choice cannot change the finite StreamName source packet read at the terminal interface.

Next identify the packet read by the terminal $\mathsf{Real}^{\uparrow}$ seal. Apply Definition 38.382. The terminal source surface is precisely the displayed StreamName classifier, unary-history, membership, pointwise rational-history, accepted RegSeqRat spine, dyadic-core, transport, package, and real-ledger rows.

For uniqueness of the accepted spine, use Definition 38.365. Any two terminal candidates compatible with those displayed rows factor through the same selected RegSeqRat source surface, so the source-boundary projection is forced to agree.

For the converse, apply Definition 126.170. Equality of the source-boundary projection reads back exactly the StreamName finite-window classifier rows, the unary and membership rows, the pointwise rational classifier rows, the accepted RegSeqRat spine, the dyadic-core rows, and the visible Cont, hsame, Pkg, and RealLedgerPolicy rows.

The coverage theorem also gives the exclusion clause. Since the projection is the finite RegSeqRat source surface and nothing outside it, no quotient row, completion object, host index, host function, Classical datum, metric-completeness row, arithmetic or order row, or bridge row can be recovered from the terminal consumer. □

Theorem 38.380 (StreamName common-refinement terminal route determinacy)**.** *Let C be a certified* $\mathsf{StreamName}^{\uparrow}$ *common-refinement package. Suppose two finite-window* $\mathsf{Real}^{\uparrow}$ *terminal seal consumers are reached from C by choosing possibly different common-refinement routes, then passing through the same StreamName finite-window restriction and* RegSeqRat *handoff interface. Then the two terminal reads expose the same source tuple:*

1. *the restricted* RatStreamNameFiniteWindowClassifier *rows;*
2. *the common* ProbeBundle*,* InBundle*, and* UnaryHistory *rows;*
3. *the pointwise* RatHistoryClassifier *rows;*
4. *the accepted* RegSeqRat *spine selected by those rows;*
5. *the displayed dyadic endpoint rows; and*
6. *the displayed* hsame*,* Cont*, and* Pkg *provenance rows.*

The terminal tuple contains no quotient row, completion object, host-index equality, metric-completeness datum, or additional $\mathsf{Real}^{\uparrow}$ *seal classifier outside the packet just listed.*

Proof. Start with the certified common-refinement package C. Apply Definition 126.236. The two routes therefore determine the same StreamName source packet and the same displayed common-refinement provenance rows.

Next restrict that packet to the terminal finite window. By Definition 126.221, both route reads use the same finite-window classifier rows, the same ProbeBundle and InBundle entries, and the same unary-history window.

Now apply Definition 126.170. The restricted StreamName packet hands off to one pointwise rational-history packet, one accepted RegSeqRat spine, and the same dyadic endpoint rows, with the displayed hsame, Cont, and Pkg provenance carried along unchanged.

Finally use Definition 38.382. A terminal finite-window $\mathsf{Real}^{\uparrow}$ seal consumer reads exactly that RegSeqRat source surface and no larger host structure. Since both routes feed the same packet into this coverage theorem, the two terminal reads expose the same listed source tuple and exclude quotient rows, completion objects, host-index equalities, metric-completeness data, and any extra $\mathsf{Real}^{\uparrow}$ seal classifier. □

Theorem 38.381 (StreamName public window prefix determinacy)**.** *Let $s, t : \mathsf{BHist} \to \mathsf{BHist}$ be StreamName rows, and let B' and B be probe windows. Suppose every certified* UnaryHistory *observation in B' is carried by B. Then every* RegSeqRat *terminal consumer, and every finite-window* $\mathsf{Real}^{\uparrow}$ *terminal seal consumer, that reads* $\mathsf{RatStreamNameFiniteWindowClassifier}(s, t, B)$ *through the public* $\mathsf{StreamName}^{\uparrow}$ *interface has the same terminal BEDC readback after restriction to B' as the consumer obtained by reading the certified prefix window B' directly.*

The common restricted readback consists exactly of the pointwise $\mathsf{Rat}^{\uparrow}$ *observation rows, the* InBundle *witnesses, the* hsame *transports, the* Cont *routes, and the* Pkg *provenance rows exposed by the public StreamName interface on B'. If two restricted terminal routes have the same endpoint package, then their finite BEDC readbacks are identical.*

This determinacy statement exports no RegSeqRat *regularity row, no* $\mathsf{Real}^{\uparrow}$ *seal classifier beyond the restricted terminal source surface, no quotient row, no host-index equality, and no completion data.*

Proof. First read the larger public finite-window package. Apply Definition 126.301. It exposes only the finite classifier rows, certified unary-history observations, membership witnesses, pointwise rational observation rows, and visible transport and provenance rows over B.

Next restrict that public packet to the certified prefix window. By Definition 126.302, every UnaryHistory observation carried by B' has the same restricted classifier, membership witness, hsame transport, Cont route, and Pkg provenance as its row inside B.

Now pass the restricted packet through the consumer-facing handoff. Apply Definition 126.170. The RegSeqRat read and the terminal finite-window $\mathsf{Real}^{\uparrow}$ read both see the same pointwise $\mathsf{Rat}^{\uparrow}$ observation rows and the same restricted provenance rows from B'.

Finally use the terminal source comparison theorems. The source uniqueness statement Definition 38.379 identifies any two terminal source projections with the same restricted row inventory, and Definition 38.380 removes the choice of terminal route. Thus two restricted terminal routes with the same endpoint package have the same finite BEDC readback, while all regularity, seal-classifier, quotient, host-index, and completion data remain outside the public prefix surface. □

Theorem 38.382 (RealUp terminal RegSeqRat source coverage)**.** *Every terminal finite-window* $\mathsf{Real}^{\uparrow}$ *seal consumer factors through exactly one* RegSeqRat *source surface. That source surface consists of the displayed* RatStreamNameFiniteWindowClassifier *rows, the* UnaryHistory *and* InBundle *rows, the pointwise* RatHistoryClassifier *rows, the accepted* RegSeqRat *spine, the DyadicRatCore observation rows, and the visible* Cont, hsame, Pkg, *and* RealLedgerPolicy *ledger rows.*

Conversely, any packet carrying exactly those rows repacks into the terminal source surface read by the seal consumer. The coverage contains no quotient row, completion object, host index, host function, Classical *datum, metric-completeness row, arithmetic or order row, or standard bridge row.*

Proof. Start from the terminal read inventory of Definition 38.377. It lists precisely the finite classifier, unary-history, membership, pointwise rational, accepted spine, dyadic-source, transport, package, and ledger rows visible to a terminal seal consumer.

For the source side, apply the finite-window StreamName-to-RegSeqRat handoff from Definition 38.344 and Definition 38.268. These identify the StreamName finite-window classifiers and dyadic observation rows as the same source packet consumed by the RegSeqRat seal.

Now use the tail-classifier exactness package. By Definition 38.360 and Definition 38.364, the accepted RegSeqRat spine is the selected tail-classifier row determined by the displayed StreamName, dyadic, endpoint-transport, package, and RealLedgerPolicy data.

It remains to check uniqueness and repacking. Apply Definition 38.365: any terminal candidate compatible with the displayed rows factors through the same selected RegSeqRat source surface. Conversely, carrying those rows supplies every entry in the inventory above, so the packet repacks into the terminal seal source surface and leaves all excluded quotient, completion, host, Classical, metric, arithmetic, order, and bridge rows unread. □

Theorem 38.383 (RealUp terminal RegSeqRat source minimality)**.** *Every terminal finite-window* $\mathsf{Real}^{\uparrow}$ *seal consumer factors through a minimal* BHist *source surface. That surface consists exactly of the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier rows, unary-history membership rows, pointwise* RatHistoryClassifier *rows, the accepted* RegSeqRat *spine, the* DyadicRatCore *rows, the endpoint transport rows, and the visible* Cont *and* Pkg *ledger rows.*

Removing any one of those row classes prevents repacking into the terminal source surface read by the $\mathsf{Real}^{\uparrow}$ *seal consumer. The minimal surface contains no quotient row, completion object, host-index equality, metric-completeness datum, or separate seal classifier.*

Proof. Apply Definition 38.382. Its coverage direction gives the listed RegSeqRat source surface as the entire read boundary of any terminal finite-window $\mathsf{Real}^{\uparrow}$ seal consumer, and its converse direction repacks exactly packets carrying those rows.

Uniqueness of the selected source packet is supplied by Definition 38.379. A second candidate surface with the same StreamName finite-window classifier, unary-history, rational-history, accepted-spine, dyadic, transport, and ledger rows is therefore the same terminal source packet.

Route independence is supplied by Definition 38.380. Before a terminal seal consumer reads the packet, every common-refinement route has already fixed the same finite-window classifier rows, membership rows, pointwise rational-history rows, accepted RegSeqRat spine, and dyadic endpoint data.

Minimality follows by constructor and projection inversion on that packet. Omitting a StreamName classifier row removes the finite-window route; omitting a membership or unary-history row removes the window boundary; omitting a pointwise rational-history row removes the rational observation; omitting the accepted spine removes the RegSeqRat source; omitting a dyadic or endpoint transport row removes the endpoint witness; and omitting a visible Cont or Pkg row removes the ledger needed for repacking.

The same inversion shows that no further row can be required. The coverage and determinacy theorems expose no quotient, completion object, host-index equality, metric-completeness datum, or separate terminal seal classifier, so there is no constructor or projection from which such data could be read. □

Theorem 38.384 (RealUp DyadicRatCore StreamName RegSeqRat observation triangle)**.** *For a terminal finite-window* $\mathsf{Real}^{\uparrow}$ *seal consumer, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *public readback envelope, the public* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier surface, and the* RegSeqRat *finite-window seal source surface determine the same finite source packet and are mutually recoverable.*

The common packet consists exactly of the RatStreamNameFiniteWindowClassifier *rows, the* UnaryHistory *and* InBundle *rows, the pointwise* RatHistoryClassifier *rows, the accepted* RegSeqRat *spine, the* DyadicRatCore *observation rows, the endpoint transport rows, the visible* Cont *and* Pkg *provenance rows, and the* RealLedgerPolicy *rows. It contains no quotient row, completion object, host* Nat *index,* Classical *datum, metric-completeness row, arithmetic or order row, or standard bridge row.*

Proof. First read the dyadic side. Apply Definition 291.23. Its envelope exposes exactly the dyadic observation rows and endpoint transport rows available to the terminal packet, with no quotient or completion object attached.

Next read the finite stream-name side. Apply Definition 126.301. The public finite-window classifier surface supplies the RatStreamNameFiniteWindowClassifier rows, the UnaryHistory and InBundle rows, and the pointwise RatHistoryClassifier rows on the same displayed finite window.

Now read the seal source side. Apply Definition 38.268. The RegSeqRat seal source reads the accepted spine together with the same finite-window classifier, unary-history, membership, pointwise rational, dyadic observation, endpoint transport, Cont, Pkg, and ledger rows.

Finally apply Definition 38.382 and Definition 38.383. Coverage repacks any packet carrying exactly those rows as the terminal source surface, while minimality prevents an additional row class from being part of that terminal source. Hence each of the three projections recovers the same finite source packet, and the excluded quotient, completion, host-index, Classical, metric, arithmetic, order, and bridge rows remain unread. □

Theorem 38.385 (RealUp dyadic StreamName observation-triangle consumer)**.** *Let R be a terminal finite-window* $\mathsf{Real}^{\uparrow}$ *seal consumer whose source side factors through the triangle of Definition 38.384. Then R exposes exactly the common packet listed there: the* RatStreamNameFiniteWindowClassifier *rows, the* UnaryHistory *and* InBundle *rows, the pointwise* RatHistoryClassifier *rows, the accepted* RegSeqRat *spine, the* DyadicRatCore *observation rows, endpoint transport rows, visible* Cont*,* hsame*,* Pkg*, and* RealLedgerPolicy *rows.*

If two such consumer reads agree on the $\mathsf{StreamName}^{\uparrow}$ *finite-window restriction and on the* RegSeqRat *handoff interface, then they expose the same* DyadicRatCore *endpoint rows,* Cont*,* hsame*,* Pkg*, and* RealLedgerPolicy *rows. No quotient row, host index, completion datum, arithmetic/order row, or standard bridge row is part of that consumer-facing source packet.*

Proof. Apply Definition 38.384. The factoring hypothesis places the consumer source on the triangle's common packet, so its dyadic readback, finite StreamName restriction, and RegSeqRat handoff are all projections of the same displayed source surface.

Apply Definition 38.382 and Definition 38.383. Coverage repacks the listed rows as a terminal finite-window $\mathsf{Real}^{\uparrow}$ source, while minimality says that no further source row can be demanded by such a consumer.

For two reads, use Definition 38.386. Agreement on the StreamName finite-window restriction and the RegSeqRat handoff fixes the common-refinement splice, hence fixes the DyadicRatCore endpoint rows and the visible Cont, hsame, Pkg, and RealLedgerPolicy rows.

The excluded data have no projection from any of these three inputs. Quotient rows, host indices, completion data, arithmetic/order rows, and standard bridge rows are absent from the triangle packet and remain absent after terminal source coverage and splice uniqueness are applied. □

Theorem 38.386 (RealUp terminal common-refinement splice uniqueness)**.** *Let C be a certified* $\mathsf{StreamName}^{\uparrow}$ *common-refinement packet whose displayed source tuple consists of a fixed* $\mathsf{StreamName}^{\uparrow}$ *source name, a fixed accepted* RegSeqRat *finite-window spine, and fixed* DyadicRatCore *source rows. Suppose two terminal finite-window* $\mathsf{Real}^{\uparrow}$ *seal consumers are reached from C through possibly different common-refinement splices. If both splices use the same StreamName finite-window restriction and the same* RegSeqRat *handoff interface, then the two terminal consumers expose the same finite tuple:*

1. *the* RatStreamNameFiniteWindowClassifier *rows;*
2. *the* ProbeBundle*,* InBundle*, and* UnaryHistory *rows;*
3. *the pointwise* RatHistoryClassifier *rows;*

4. *the accepted* RegSeqRat *spine;*

5. *the* DyadicRatCore *observation rows; and*

6. *the visible* Cont, hsame, Pkg, *and* RealLedgerPolicy *rows.*

This uniqueness statement is only about that terminal source tuple. It does not identify or expose quotient rows, host Nat *indices, host functions,* Classical *data, metric-completeness rows, arithmetic/order rows, or standard bridge rows.*

Proof. First compare the two splice routes before the terminal consumer reads them. Apply Definition 38.380. The possibly different common-refinement routes through C determine one terminal StreamName source packet, one restricted finite-window classifier, one bundled probe and unary-history packet, one pointwise rational-history packet, one accepted RegSeqRat spine, and one displayed dyadic source surface.

Next pass that route-confluent packet through the terminal $\mathsf{Real}^{\uparrow}$ seal. Apply Definition 38.382. The terminal consumer factors through exactly the listed RegSeqRat source surface, and any packet carrying exactly those rows repacks into the same terminal source surface.

Both consumers therefore have the same displayed source tuple as their entire terminal read boundary. Since the coverage theorem also excludes all rows outside that packet, the uniqueness conclusion contains no quotient row, host index, host function, Classical datum, metric-completeness row, arithmetic or order row, or standard bridge row. □

Theorem 38.387 (RealUp finite-window seal cofinality)**.** *Let $\mathcal{F}$ be a finite directed family of terminal finite-window* $\mathsf{Real}^{\uparrow}$ *seal consumers over the same* $\mathsf{StreamName}^{\uparrow}$ *source. Suppose $\mathcal{F}$ has a cofinal common-refinement read C, and suppose the displayed* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, hsame, Cont, Pkg, *and* NameCert *rows of every member of $\mathcal{F}$ agree with the corresponding rows read from C. Then every member of $\mathcal{F}$ and the cofinal read C determine the same terminal finite-window* $\mathsf{Real}^{\uparrow}$ *seal source surface.*

The determined source surface consists only of the finite $\mathsf{StreamName}^{\uparrow}$ *restriction, the accepted* RegSeqRat *spine, the* DyadicRatCore *observation rows, and the displayed* hsame, Cont, Pkg, *and* NameCert *provenance rows. It exports no quotient stream, host-index equality, metric-completion datum,* $\mathsf{Real}^{\uparrow}$ *completeness row, or additional seal classifier.*

Proof. First use Definition 38.378. Directed terminality turns the finite family into a single terminal comparison against the cofinal common-refinement read C, so each member is read through the same terminal source route.

Next apply Definition 38.382. The cofinal read and every family member factor through the displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows. Apply Definition 38.383 to remove every row not present in that finite source inventory.

It remains to identify the member reads with the cofinal read. For each member, apply Definition 38.386 to the splice through C. The assumed agreement of the displayed rows fixes the terminal splice, hence fixes the terminal source surface.

The last paragraph gives the stated boundary: the four cited theorems only project the finite StreamName, RegSeqRat, DyadicRatCore, hsame, Cont, Pkg, and NameCert rows. There is no constructor in this route that exports quotient streams, host-index equalities, metric-completion data, $\mathsf{Real}^{\uparrow}$ completeness rows, or a further seal classifier. □

Theorem 38.388 (RegSeqRat terminal tail-refinement seal)**.** *Let S be a terminal* $\mathsf{StreamName}^{\uparrow}$ *finite-window source and let T be a* RegSeqRat *stream whose finite-window reads factor through the*

terminal $\mathsf{Real}^{\uparrow}$ *source surface determined by* S*. For every certified tail refinement* C *of* T *over the same public* BHist *window, there is a unique terminal finite-window seal for* C*.*

This seal is determined exactly by the terminal $\mathsf{StreamName}^{\uparrow}$ *source name, the restricted* RatStreamNameFiniteWindowClassifier *rows, the* UnaryHistory *and* InBundle *rows, the pointwise* RatHistoryClassifier *rows, the accepted* RegSeqRat *spine, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows, and the visible* hsame*,* Cont*,* Pkg*,* NameCert*, and* RealLedgerPolicy *rows. It is invariant under* hsame *transport of the displayed history rows and under* Cont*-splicing along the certified common-refinement route. Its ledger is the one inherited from the terminal* $\mathsf{StreamName}^{\uparrow}$ *source packet, not an independent* RegSeqRat *or* $\mathsf{Real}^{\uparrow}$ *ledger.*

The terminal seal exposes no quotient stream, host-index equality, host function, Classical *datum, metric-completion object, arithmetic or order row, standard bridge row, or separate tail-refinement classifier.*

Proof. First identify the source from which the tail refinement can be read. Apply Definition 38.379 and Definition 38.382. The factoring hypothesis places every finite window of T on the terminal source packet selected by S, and the coverage theorem repacks exactly those displayed rows as the terminal $\mathsf{Real}^{\uparrow}$ source surface.

Next compare the certified refinement route with the terminal source route. Apply Definition 38.380. The common-refinement certificate fixes the same terminal StreamName source name, the same restricted classifier rows, the same unary-history and membership rows, the same pointwise rational-history rows, and the same accepted RegSeqRat spine before the terminal seal is read.

Now splice the route into the terminal $\mathsf{Real}^{\uparrow}$ consumer. Apply Definition 38.386. Agreement on the StreamName restriction and on the RegSeqRat handoff fixes the $\mathsf{DyadicRatCore}^{\uparrow}$ observation rows together with the visible hsame, Cont, Pkg, NameCert, and RealLedgerPolicy rows. Therefore transporting the displayed history data by hsame or changing only the Cont-splice representative cannot produce a second terminal seal.

Finally apply Definition 38.387. Cofinality collapses every certified tail-window refinement of T to the same terminal finite-window source surface. Since the only ledger rows in that surface are the rows already read from the terminal $\mathsf{StreamName}^{\uparrow}$ source packet, the seal inherits that ledger and has no constructor that could export quotient, completion, host, arithmetic, order, bridge, or separate classifier data. □

Theorem 38.389 (RealUp terminal tail-refinement family factorization)**.** *Let* S *be a terminal* $\mathsf{StreamName}^{\uparrow}$ *finite-window source, let* T *be an accepted* RegSeqRat *packet over* S*, and let* $C_1, \ldots, C_n$ *be a finite family of certified tail refinements of* T *over the same public* BHist *window. Suppose the family admits a cofinal certified common refinement* C_* *and that all displayed* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*,* NameCert*, and* RealLedgerPolicy *rows agree after reading along* C_**.*

Then every terminal finite-window $\mathsf{Real}^{\uparrow}$ *seal for a member* C_i *factors through the single cofinal source surface determined by* C_**. This source surface consists exactly of the finite* $\mathsf{StreamName}^{\uparrow}$ *restriction, the accepted* RegSeqRat *spine, the* DyadicRatCore *observation rows, and the displayed provenance rows* hsame*,* Cont*,* Pkg*,* NameCert*, and* RealLedgerPolicy*.*

The factorization exports no quotient stream, host-index equality, host function, Classical *datum, metric-completion object, arithmetic or order row, standard bridge row, or separate tail-refinement classifier.*

Proof. For each family member C_i, apply Definition 38.388. The seal theorem says that the terminal finite-window seal for C_i is read from the terminal $\mathsf{StreamName}^{\uparrow}$ source restriction, the

accepted RegSeqRat spine, the DyadicRatCore$^{\uparrow}$ observation rows, and the visible transport, package, certificate, and ledger rows.

Now use the cofinal certificate C_*. Apply Definition 38.387 to the finite family $C_1, \ldots, C_n$. Cofinality replaces the separate member reads by the single terminal read through C_*, so every member seal has the same finite source surface once the displayed rows have been transported to the cofinal refinement.

It remains to identify the splice rows on that common read. Apply Definition 38.386. The assumed agreement of the RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, hsame, Cont, Pkg, NameCert, and RealLedgerPolicy rows fixes the terminal splice over C_*, hence fixes the factor through the common source surface.

The boundary clause follows from the same three cited results: their constructors expose only the finite StreamName restriction, the accepted RegSeqRat spine, the dyadic observation rows, and the displayed provenance rows. None of them constructs quotient, host, classical, completion, arithmetic, order, bridge, or separate classifier data. □

Theorem 38.390 (RealUp common-refinement seal pullback)**.** *Let C be a certified* StreamName$^{\uparrow}$ *common-refinement package, and let R and R' be finite-window* Real$^{\uparrow}$ *terminal seal consumers reached from C through compatible accepted* RegSeqRat *tail-refinement seals. Then equality of the common-refinement source tuple is equivalent to equality of the visible terminal seal boundary.*

The common-refinement source tuple consists exactly of the restricted RatStreamNameFiniteWindowClassifier *rows, the* UnaryHistory *rows, the* ProbeBundle *rows, the* InBundle *rows, the pointwise* RatHistoryClassifier *rows, the accepted* RegSeqRat *spine, the* DyadicRatCore *endpoint rows, the visible* Cont*,* hsame*,* Pkg*, and* RealLedgerPolicy *rows, and the certified* StreamName$^{\uparrow}$ *provenance route in C.*

The visible terminal seal boundary consists of the same finite BHist *ledger rows after the terminal* Real$^{\uparrow}$ *consumer read. It contains no completion object, quotient row, host index, metric-completeness datum, arithmetic row, order row, or standard bridge row.*

Proof. First assume equality of the common-refinement source tuple. Apply Definition 38.380 to the two routes out of C. The route comparison identifies the restricted StreamName classifier rows, probe and unary-history rows, bundle membership, pointwise rational-history rows, accepted RegSeqRat spine, dyadic endpoint rows, and visible transport and provenance rows before either terminal consumer reads the packet.

Next pass the identified source tuple through the terminal Real$^{\uparrow}$ surface. Apply Definition 38.382 and Definition 38.388. Coverage says that the terminal consumer can read only the listed finite source rows, and the tail-refinement seal says that compatible accepted RegSeqRat refinements produce the unique terminal seal over those rows. Thus R and R' expose the same visible terminal seal boundary.

Conversely assume equality of the visible terminal seal boundary. Apply Definition 38.379. Equality of the terminal boundary reads back exactly the StreamName classifier rows, unary-history and bundle rows, pointwise rational-history rows, accepted RegSeqRat spine, dyadic endpoint rows, and visible Cont, hsame, Pkg, and RealLedgerPolicy rows.

It remains to identify the common-refinement route itself. Apply Definition 38.387. The two compatible tail-refinement seals are cofinal over the same certified package C, so the finite terminal boundary readback recovers the same common-refinement source tuple. The cited coverage and seal theorems expose no completion, quotient, host, metric, arithmetic, order, or bridge rows, so equality cannot depend on any data outside that tuple. □

Theorem 38.391 (RealUp terminal refinement-family pullback exhaustion)**.** *Let $C_1, \ldots, C_n$ be a finite family of certified* StreamName$^{\uparrow}$ *tail-window coverage packets over the same public* StreamName$^{\uparrow}$ *endpoints and the same accepted* RegSeqRat$^{\uparrow}$ *spine. Assume that each pair C_i, C_j admits the*

common-refinement seal pullback of Definition 38.390. Then every terminal $\mathsf{Real}^{\uparrow}$ *finite-window consumer reached from the family factors through one finite family pullback surface.*

The family pullback surface exposes exactly the restricted RatStreamNameFiniteWindowClassifier *rows, the* UnaryHistory *and* InBundle *rows, the pointwise* RatHistoryClassifier *rows, the accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *spine, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows, the visible* Cont, hsame, *and* Pkg *rows, and the* RealLedgerPolicy *rows. It exposes no completion object, quotient row, host index, host function, metric-completeness datum, arithmetic or order row, or standard bridge row.*

Proof. Induct on the finite family. The empty and singleton cases are the terminal finite-window surfaces supplied by Definition 38.378; there is then no nontrivial pairwise splice to compare.

For the induction step, suppose the first k packets already factor through a single displayed pullback surface and add C_{k+1}. Apply Definition 38.380 to make the route from the accumulated surface to C_{k+1} independent of the chosen member route through the public endpoints and accepted $\mathsf{RegSeqRat}^{\uparrow}$ spine.

Next use Definition 38.386. Pairwise availability of the common-refinement seal pullback fixes the splice between the accumulated surface and C_{k+1}, so all visible classifier, history, bundle, spine, endpoint, transport, package, and ledger rows agree on the same finite surface.

Finally apply Definition 38.390 to identify that surface with the terminal consumer boundary. The cited terminality, route-determinacy, splice-uniqueness, and pullback results expose only the rows listed in the statement, so the factorization cannot read any completion, quotient, host, metric, arithmetic, order, or bridge data. □

Theorem 38.392 (RealUp stream-prefix scoped obligation package)**.** *The four stream-prefix obligation faces in Definition 38.335, Definition 38.336, Definition 38.337, and Definition 38.338 form the scoped RealUp stream-prefix package. Its source is bound to* $\mathsf{Real}^{\uparrow}$ *finite stream-prefix observations over the* RegSeqRat *spine,* $\mathsf{StreamName}^{\uparrow}$ *unary observation names,* $\mathsf{Rat}^{\uparrow}$ *endpoint rows, histories in* BHist, hsame *transport rows, selected* Cont *continuation rows, unary observations, finite-window classifiers, dyadic endpoint ledger rows, and the displayed* $\mathsf{Real}^{\uparrow}$ *seal. The package consumes no quotient, completion object, host function, external metric primitive, or standard bridge.*

Proof. Read the four named obligation theorems field by field and compare them with the ten-field roadmap template.

1. Traditional target: the target is $\mathsf{Real}^{\uparrow}$ finite stream-prefix observations. The carrier, classifier, stability, and ledger-seal faces all refer to selected rational-observation prefixes rather than to an ambient completion object.

2. BEDC source: the source is the RegSeqRat spine over $\mathsf{StreamName}^{\uparrow}$ unary observations and $\mathsf{Rat}^{\uparrow}$ endpoint histories in BHist. Definition 38.335 reads those rows from the certified unary-observation spine.

3. Carrier choice: the carrier face is the visible endpoint carrier data. Apply Definition 38.335; it identifies the selected prefix endpoints with the RatHistoryCarrier rows supplied by the RegSeqRat spine.

4. Classifier choice: the classifier face is the pair RealStreamClassifier and RealStreamPrefixClassifier. Apply Definition 38.336; it relates global stream rows, finite-prefix classifiers, and selected $\mathsf{Rat}^{\uparrow}$ endpoint classifier rows.

5. Stability obligations: the stability face is transport along hsame, unary-context closure, and selected continuation stability. Apply Definition 38.337; it preserves the finite-prefix classifier rows and repacks them as global stream classifier rows when all finite prefixes are present.
6. Ledger: the ledger face is the finite observation ledger together with dyadic endpoint ledger rows. Apply Definition 38.338; it reads finite windows, dyadic comparisons, regularity certificates, and the $\mathsf{Real}^{\uparrow}$ seal from the same scoped stream-name interface.
7. Core theorem list: the package core is exactly the four obligation faces cited in the statement. No fifth obligation theorem is required, because the displayed carrier, classifier, stability, ledger, and seal fields exhaust the stream-prefix boundary.
8. Exactness predicate: exactness is finite-window stream-prefix readback. It is supplied by the classifier face through finite-prefix exactness and by the ledger-seal face through finite-window dyadic source exhaustion.
9. Standard bridge: no standard bridge is claimed. The theorem records a paper-side scoped package over BEDC rows only, not a bridge to classical real analysis or to an external metric construction.
10. Status: the result is the scoped paper package for the RealUp stream-prefix site. It collects the four local obligation faces into one scope without adding a Lean marker or consuming data outside the displayed BEDC source.

□

Theorem 38.393 (RealUp stream-prefix scoped consumer determinacy)**.** *Let two* $\mathsf{Real}^{\uparrow}$ *stream-prefix consumer packets be displayed over the same finite observation window. Suppose they agree on their* $\mathsf{StreamName}^{\uparrow}$ *unary observation rows, their* RegSeqRat *spine rows, their* $\mathsf{Rat}^{\uparrow}$ *endpoint classifier rows, their DyadicRatCore finite ledger rows, their displayed* hsame *transports, their selected* Cont *rows, and their displayed* $\mathsf{Real}^{\uparrow}$ *seal row. Then the two packets determine the same scoped consumer-facing* BHist *surface.*

The determined surface is exactly the stream-prefix surface generated by those rows. It contains no quotient row, no completion object, no metric-completeness datum, no host function, no Classical datum, no arithmetic or order primitive outside the listed rows, and no standard bridge row.

Proof. First bind both packets to the scoped stream-prefix package. Apply Definition 38.392. Its carrier, classifier, stability, ledger, and seal faces list precisely the $\mathsf{StreamName}^{\uparrow}$, RegSeqRat, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, dyadic, finite-window, and seal rows available to a consumer.

Next read the finite observation boundary. Apply Definition 126.79 for the common StreamName and RegSeqRat handoff, and apply Definition 38.342 for the displayed RealUp window. These theorems identify the public read surface with the listed unary observation rows, spine rows, endpoint classifier rows, finite ledger rows, transports, continuations, and seal data.

Now account for tails and partitions. Apply Definition 38.395 to every selected tail window and use Definition 38.309 for any finite partition presentation. Since the two packets agree on every row named by these read surfaces, their transported endpoints, dyadic entries, ledger entries, continuation routes, and seal rows are the same displayed BHist rows.

Repacking those rows gives one consumer-facing surface. The cited package, handoff, read-surface, and tail-transport theorems expose no field for quotients, completion objects, metric-completeness witnesses, host functions, Classical data, unlisted arithmetic or order primitives, or standard bridge rows, so none of those data can distinguish the two packets. □

Theorem 38.394 (RegSeqRat StreamName common source locality)**.** *Let two scoped* $\mathsf{Real}^{\uparrow}$ *stream-prefix packets be displayed over the same finite observation window. Suppose they agree on the displayed* $\mathsf{StreamName}^{\uparrow}$ *unary observation rows, the* $\mathsf{RegSeqRat}$ *spine rows, the* $\mathsf{Rat}^{\uparrow}$ *endpoint classifier rows, the finite* $\mathsf{ProbeBundle}$ *windows, the* $\mathsf{InBundle}$ *membership rows, the displayed* hsame *transports, and the selected* Cont *routes. Then the two packets determine the same common source surface before any* $\mathsf{Real}^{\uparrow}$ *seal row, completion datum, quotient datum, host-equality row, metric-completeness witness, or standard bridge row is read.*

The common source surface is the finite BEDC surface generated by the listed StreamName, RegSeqRat, RatUp, bundle, transport, and continuation rows. Any later $\mathsf{Real}^{\uparrow}$ *seal may consume this surface, but it is not part of the locality claim.*

Proof. Bind both packets to the scoped obligation package of Definition 38.392. The package identifies the only source rows available before the seal: StreamName unary observations, RegSeqRat spine data, RatUp endpoint classifiers, BHist histories, hsame transports, selected Cont routes, and finite-window bundle membership.

Next pass through the handoff boundary. Apply Definition 126.79 to read the common StreamName–RegSeqRat window, and apply Definition 126.82 to keep the handoff source separate from any RealUp seal or completion data.

Finally apply Definition 38.342. Since the two packets agree on every row exposed by that finite read surface, the pre-seal source they present to later consumers is the same. The cited package and read-surface theorems expose no quotient row, host equality row, metric-completeness row, or standard bridge row, so none of those data can enter the local common source. □

Theorem 38.395 (RealUp scoped window tail-transport package)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$*, indices* n, m*, and transported endpoint histories* $u, v : \mathsf{Hist}$*, assume the Real stream-prefix classifier through* n*,*

$$\mathsf{RealStreamPrefixClassifier}(x, y, n),$$

a classified finite $\mathsf{Rat}^{\uparrow}$ *tail of length* m*,*

$$\forall k < m,\ \mathsf{RatHistoryClassifier}(x(n+k+1), y(n+k+1)),$$

pointwise unary anchors,

$$\forall i,\ \mathsf{UnaryHistory}(x(i)),$$

and transported endpoint rows

$$\mathsf{hsame}(x(n+m), u), \quad \mathsf{hsame}(y(n+m), v).$$

Then the transported tail window remains inside the scoped $\mathsf{Real}^{\uparrow}$ *stream-prefix package. It exposes the transported endpoint* $\mathsf{Rat}^{\uparrow}$ *classifier, positive unary denominator rows for* u *and* v*, unary endpoint rows, nonempty endpoint exclusions, common e-one tail readback whenever the transported endpoints are displayed as one-headed, finite* $\mathsf{RealLedgerPolicy}$ *rows, and the dyadic endpoint source rows consumed by the* $\mathsf{Real}^{\uparrow}$ *seal. It consumes no quotient, completion object, metric-completeness certificate, host function, Classical datum, arithmetic or order primitive outside the listed rows, or standard-bridge datum.*

Proof. First package the ambient scoped source. Apply Definition 38.392. This fixes the carrier, classifier, stability, ledger, and seal faces of the $\mathsf{Real}^{\uparrow}$ stream-prefix site, and it records that those faces do not read quotient, completion, metric, host-function, or standard-bridge data.

Next transport the finite tail to the displayed endpoint boundary. Apply Definition 38.116 to extend the prefix classifier from n to $n+m$ using the classified finite $\mathsf{Rat}^{\uparrow}$ tail and the pointwise unary anchors. Then apply Definition 38.293 to the extended boundary and the two endpoint hsame rows. The result supplies the transported endpoint $\mathsf{Rat}^{\uparrow}$ classifier, the positive unary denominators, the unary endpoint rows, and the nonempty endpoint exclusions.

Now read the window face through the scoped boundary. Apply Definition 38.342. Its finite-window readback contains the endpoint classifier rows, positive unary denominator rows, common e-one tail readback, the finite ledger, and the dyadic source rows used by the $\mathsf{Real}^{\uparrow}$ seal.

The rows just obtained are all rows named by the scoped stream-prefix package, and the finite-window read surface explicitly excludes quotient, completion, metric-completeness, Classical, arithmetic, order, and standard-bridge data outside that boundary. Repacking these two scoped statements with the transported finite-tail endpoint package gives the claimed transported tail window package. □

Theorem 38.396 (RealUp partitioned window tail-transport package)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, an anchor n, a total finite bound w, and a certified finite partition spine P over (n, w) with segments (n_i, r_i), let $u_i, v_i : \mathsf{Hist}$ be transported histories at the segment endpoints. Assume the Real stream-prefix classifier through the anchor,*

$$\mathsf{RealStreamPrefixClassifier}(x, y, n),$$

the segment classifier conjunction,

$$\bigwedge_{(n_i,r_i)\in P} \mathsf{RealStreamWindowClassifier}(x, y, n_i, r_i),$$

pointwise unary anchors,

$$\forall j,\ \mathsf{UnaryHistory}(x(j)),$$

and endpoint transport rows for every segment,

$$\forall (n_i, r_i) \in P, \mathsf{hsame}(x(n_i + r_i), u_i) \quad \textit{and} \quad \mathsf{hsame}(y(n_i + r_i), v_i).$$

Then every segment endpoint exposes the transported endpoint $\mathsf{Rat}^{\uparrow}$ classifier, positive unary denominator rows, unary endpoint rows, nonempty endpoint exclusions, common e-one tail readback whenever the transported endpoints are displayed as one-headed, finite $\mathsf{RealLedgerPolicy}$ rows, and DyadicRatCore endpoint source rows listed in Definition 38.395. Moreover, the total window presentation and the segment presentation expose the same finite ledger, DyadicRatCore source rows, $\mathsf{RegSeqRat}$ spine rows, $\mathsf{StreamName}^{\uparrow}$ request names, $\mathsf{UnaryHistory}$ witnesses, and hsame transport rows of Definition 38.309. The combined package consumes no quotient, completion object, metric-completeness certificate, Classical datum, arithmetic or order closure, or standard bridge.

Proof. First fix the ambient scoped boundary. Apply Definition 38.392; it supplies the carrier, classifier, stability, ledger, and seal rows of the $\mathsf{Real}^{\uparrow}$ stream-prefix site from the displayed $\mathsf{RegSeqRat}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, $\mathsf{UnaryHistory}$, Cont, dyadic, and hsame source rows.

Next pass between the total and segmented windows. Apply Definition 38.308 to the certified spine P. The assumed segment classifier conjunction is the segmented presentation of the total window $\mathsf{RealStreamWindowClassifier}(x, y, n, w)$, and the same fold also recovers the segment conjunction from the total window when a consumer starts from the wide observation.

Now identify the read surface. Apply Definition 38.309. It says that the total window and the partition presentation expose exactly the same finite ledger, DyadicRatCore source rows, stream-name requests, unary-history witnesses, and hsame transport rows, with no quotient, completion, metric-completeness, Classical, arithmetic, order, or standard-bridge datum.

For each segment (n_i, r_i) in P, apply Definition 38.395 at the segment anchor with its endpoint histories u_i and v_i. The segment classifier row, the pointwise unary anchors restricted to the segment, and the two endpoint transport rows give exactly the transported endpoint classifier, denominator, unary-endpoint, exclusion, common-tail, finite-ledger, and dyadic source rows named in that theorem.

Finally repack the segmentwise transported endpoint rows with the shared partition read surface. The repacked certificate is a single finite observation package for partitioned $\mathsf{Real}^{\uparrow}$ windows, and every row it displays has already been read from the scoped BEDC boundary named above. □

Theorem 38.397 (RealUp refined partition tail-source determinacy)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, an anchor n, and a finite width w, let P and Q be certified finite partition spines refining the same total $\mathsf{Real}^{\uparrow}$ stream window*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, w).$$

Assume that the two refined presentations have matching segment endpoint hsame *rows, matching displayed* RealStreamWindowClassifier *rows on corresponding refined segments, and the same pointwise anchors*

$$\forall j,\ \mathsf{UnaryHistory}(x(j)).$$

Then the two refined presentations expose the same finite source surface: endpoint $\mathsf{Rat}^{\uparrow}$ classifiers, dyadic source rows, RegSeqRat *spine rows,* $\mathsf{StreamName}^{\uparrow}$ *observation names,* Cont *routes,* hsame *transports, and finite ledger rows. Thus the refined partitions determine one BEDC source ledger for the total window, rather than two presentation-dependent ledgers.*

No quotient representative, completion object, metric-completeness witness, Classical datum, host arithmetic or order closure, or standard bridge is read by this determinacy surface.

Proof. First bind both presentations to the same total window. Apply Definition 38.309 to P and again to Q. Each application identifies its refined partition ledger with the same total finite-window read surface, including the $\mathsf{StreamName}^{\uparrow}$ request rows, dyadic source rows, RegSeqRat spine rows, unary-history anchors, Cont routes, and endpoint hsame transports.

Next transport the segment endpoints. Apply Definition 38.395 on each displayed segment. The matching segment classifier rows, endpoint hsame rows, and pointwise unary anchors expose the same endpoint $\mathsf{Rat}^{\uparrow}$ classifiers, dyadic source rows, unary endpoint rows, and finite ledger entries for the two refined presentations.

Finally repack the refined segment data with Definition 38.396. Since both partition packages have already been read from the same total window surface, the repacked endpoint classifiers, dyadic rows, spine rows, observation names, continuation routes, transports, and ledger rows are the same finite BEDC source surface.

The cited packages also carry the exclusion clauses. They have no fields for quotient representatives, completion objects, metric-completeness witnesses, Classical data, host arithmetic or order closure, or standard bridges, so none of those can distinguish the two refined presentations. □

Theorem 38.398 (RealUp finite-window observation determinacy)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, an anchor n, and a finite width w, suppose two BEDC finite-window packages are*

exposed from the same classifier

$$\mathsf{RealStreamWindowClassifier}(x, y, n, w).$$

Assume that both packages read the same $\mathsf{StreamName}^{\uparrow}$ *request rows,* $\mathsf{Rat}^{\uparrow}$ *endpoint rows, DyadicRatCore source rows,* UnaryHistory *witnesses,* Cont *ledger entries, and* hsame *transports named by Definition 38.309. Then their visible endpoint classifiers, positive denominator rows, finite ledger rows, dyadic source rows, and* $\mathsf{Real}^{\uparrow}$ *seal rows classify together by* hsame*. In particular, no second public finite-window observation package with a different visible endpoint surface is available from the same request.*

Proof. First bind the common source boundary. Apply Definition 38.392. This fixes the allowed RegSeqRat, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, UnaryHistory, Cont, dyadic, and hsame rows, and it excludes quotient, completion, host-function, external metric, and standard-bridge inputs.

Next identify the window ledger seen by the two packages. Apply Definition 38.309. The total finite window and any certified partition of it expose the same finite ledger, DyadicRatCore source rows, stream-name requests, unary-history witnesses, and endpoint hsame transports. Since the two packages are read from the same classifier and the same request rows, their public ledgers are the same BEDC read surface.

For each displayed segment of a partition, apply Definition 38.395. It reads the endpoint classifiers, positive unary denominator rows, unary endpoint rows, finite ledger entries, and dyadic endpoint source rows from the segment classifier and the endpoint transport rows. The hypotheses identify those rows for the two packages, so the segment endpoints classify together by hsame.

Finally repack the segmentwise hsame endpoint data through Definition 38.396. The repacked finite-window package has only the rows already named by the scoped source and partition read surface. The same exclusion clauses remove quotient, completion, metric-completeness, host-function, Classical, arithmetic or order primitive, and standard-bridge data, so there is no remaining row from which a different public endpoint package could be exposed. □

Theorem 38.399 (RealUp finite-window common-refinement determinacy)**.** *For rational-observation streams* $x, y : \mathbb{N} \to \mathsf{Hist}$*, an anchor* n*, and a finite width* w*, suppose two certified finite-window packages expose read surfaces for the same classifier*

$$\mathsf{RealStreamWindowClassifier}(x, y, n, w).$$

Assume that the two packages admit a common certified partition refinement of that classifier, and that both refined packages read the same $\mathsf{StreamName}^{\uparrow}$ *request rows,* RegSeqRat *spine rows, DyadicRatCore endpoint rows,* UnaryHistory *witnesses,* Cont *ledger entries, and* hsame *transports.*

Then the two refined read surfaces expose classifier-equivalent endpoint rows, positive denominator rows, dyadic source rows, and $\mathsf{Real}^{\uparrow}$ *seal rows. Equivalently, refining the finite window through a shared certified partition does not create a second public endpoint surface for the same observation request.*

Proof. Bind the common scoped source package with Definition 38.392. This fixes the visible RegSeqRat, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, UnaryHistory, Cont, dyadic, and hsame rows available to both finite-window packages.

Use Definition 38.309 on the common certified refinement. The theorem identifies the total classifier with its partition read surface, so both packages are read through the same finite ledger, request rows, unary witnesses, endpoint transports, and dyadic source rows.

On each refined segment, apply Definition 38.395. The shared segment classifier and endpoint transports expose the same endpoint classifier rows, positive denominator rows, common-tail rows, finite-ledger rows, and dyadic source rows for the two packages.

Finally repack the segmentwise hsame rows through Definition 38.396. The repacked public finite-window surfaces are built from the same partition ledger and the same transported endpoint data, hence their endpoint, denominator, dyadic source, and $\mathsf{Real}^{\uparrow}$ seal rows classify together by hsame. □

Theorem 38.400 (StreamName RegSeqRat RealUp common handoff cover)**.** *For two public* $\mathsf{StreamName}^{\uparrow}$ *finite-window packages with a certified common refinement, let a* RegSeqRat *handoff package and a finite-window* $\mathsf{Real}^{\uparrow}$ *read surface be induced from the same displayed restrictions. Then all consumer-facing rows factor through one common source package consisting exactly of the selected* RatStreamNameCarrier *rows, the selected* RatStreamNameClassifier *rows,* ProbeBundle*,* InBundle*,* UnaryHistory*, the displayed* hsame *rows, the dyadic ledger rows consumed by the* RegSeqRat *seal, and the finite* $\mathsf{Real}^{\uparrow}$ *ledger boundary.*

The cover contains no quotient data, no completion data, no host index equality, no metric-completeness data, and no standard-bridge data. Thus the StreamName source, the RegSeqRat *handoff, and the finite-window* $\mathsf{Real}^{\uparrow}$ *read surface have a single common BEDC handoff boundary.*

Proof. Start with the two public $\mathsf{StreamName}^{\uparrow}$ finite-window packages. Apply Definition 126.88. It identifies the selected RatStreamNameCarrier and RatStreamNameClassifier rows as the unique stream-name source for the overlapping RegSeqRat handoff surface.

Next apply Definition 126.100. Every RegSeqRat handoff row consumed downstream is exhausted by the selected stream-name rows, ProbeBundle, InBundle, UnaryHistory, the displayed hsame transports, and the dyadic ledger rows used by the seal.

For the finite-window $\mathsf{Real}^{\uparrow}$ side, use Definition 38.314. It reads the public finite-window ledger only from the same observation restrictions, endpoint rows, unary-history witnesses, dyadic rows, and displayed transports.

Finally use Definition 38.399. The certified common refinement prevents the two finite-window packages from exposing a second endpoint, denominator, dyadic source, or $\mathsf{Real}^{\uparrow}$ seal row. Repacking the StreamName source, the exhausted RegSeqRat handoff rows, and the finite $\mathsf{Real}^{\uparrow}$ ledger boundary gives one common source package. Since none of the cited surfaces exports quotient representatives, completion objects, host index equality, metric-completeness witnesses, or standard-bridge rows, the common cover excludes exactly those data. □

Theorem 38.401 (RealUp StreamName regular observation envelope)**.** *Any selected finite-window* $\mathsf{Real}^{\uparrow}$ *certificate boundary read through the StreamName–RegSeqRat common handoff factors through one* BHist*-anchored observation envelope. The envelope consists exactly of finite-window StreamName classifier rows, RegSeqRat pointwise seal rows, selected denominator endpoint rows, and bundle-membership rows. It contains no full* $\mathsf{Real}^{\uparrow}$ *completeness row, no trichotomy row, no quotient-class row, and no open-cover compactness row.*

Proof. Begin with the common handoff cover of Definition 38.400. It binds the selected StreamName rows, ProbeBundle, InBundle, UnaryHistory, displayed hsame transports, RegSeqRat dyadic ledger rows, and finite $\mathsf{Real}^{\uparrow}$ ledger boundary into one BEDC source package.

Apply Definition 38.402. The selected certificate boundary can read only certified StreamName observations, RegSeqRat dyadic source exhaustion, the finite-window ledger boundary, certified subwindow closure, and common-refinement determinacy.

Now use the pointwise StreamName handoff: the finite classifier rows are those of Definition 126.170, their restriction is stable by Definition 126.171, and the singleton reads are the diagonal packets of Definition 126.173. Thus every selected endpoint and denominator row is anchored in the same BHist observation envelope.

The cited rows exhaust the available finite evidence. Full completeness, trichotomy, quotient classes, and open-cover compactness are not fields of the StreamName handoff, the RegSeqRat pointwise packet, or the selected finite-window $\mathsf{Real}^{\uparrow}$ boundary, so none is imported by the factorization. □

Theorem 38.402 (RealUp selected finite-window certificate boundary)**.** *A selected* $\mathsf{Real}^{\uparrow}$ *finite-window certificate for* $\mathsf{RealStreamWindowClassifier}(x, y, n, w)$ *consists exactly of the* $\mathsf{StreamName}^{\uparrow}$ *certified observation rows, the* RegSeqRat *dyadic source exhaustion rows, the* $\mathsf{Real}^{\uparrow}$ *finite-window ledger boundary, the certified subwindow-closure rows, and the common-refinement determinacy row of Definition 38.399.*

Equivalently, the selected certificate boundary is the finite BEDC surface generated by those rows and no others. It excludes host Nat *arithmetic data, quotient representatives, real-completeness data, metric-completeness witnesses, external Cauchy structures, and standard-bridge rows.*

Proof. First bind the finite source surface. Apply Definition 38.314. This gives the finite observation requests, RegSeqRat dyadic source rows, $\mathsf{StreamName}^{\uparrow}$ certified rows, unary-history witnesses, and endpoint transport rows available to the selected window.

Next project the window ledger. The ledger boundary is exactly Definition 38.320: it records the finite stream-name observation rows and the $\mathsf{Real}^{\uparrow}$ endpoint rows read from the displayed classifier, without adding host arithmetic or quotient representatives.

The subwindow component is supplied by Definition 38.325. It says that certified subwindows remain inside the same finite exhaustion surface, so the selected certificate cannot acquire a new source row by cutting the window.

Finally attach the common-refinement row from Definition 38.399. Any two certified refinements of the selected window read classifier-equivalent endpoint, denominator, dyadic source, and seal rows. Repacking these four components gives exactly the selected certificate boundary, and the exclusion clauses follow because none of the cited rows exports host Nat data, quotient representatives, completeness data, metric witnesses, or standard-bridge structure. □

Theorem 38.403 (RealUp selected finite-window consumer stability)**.** *Let a selected* $\mathsf{RealStreamWindowClassifier}(x$ *certificate boundary be fixed by Definition 38.402. Any* RegSeqRat *handoff consumer and any finite-window* $\mathsf{Real}^{\uparrow}$ *consumer that read the same selected* $\mathsf{StreamName}^{\uparrow}$ *rows,* RegSeqRat *dyadic rows, endpoint* $\mathsf{Rat}^{\uparrow}$ *rows, unary witnesses,* Cont *ledger entries, and* hsame *transports must expose classifier-equivalent endpoint rows, positive denominator rows, dyadic source rows, finite ledger rows, and* $\mathsf{Real}^{\uparrow}$ *seal rows.*

The stability claim is confined to this selected finite BEDC surface. It does not identify host indices, does not pass to quotient representatives or completion objects, does not use metric-completeness data, does not import Classical data, and does not add standard-bridge rows.

Proof. First use Definition 38.402. It reduces both downstream reads to the same selected finite boundary: certified $\mathsf{StreamName}^{\uparrow}$ observations, RegSeqRat dyadic source exhaustion, endpoint $\mathsf{Rat}^{\uparrow}$ rows, unary witnesses, finite Cont entries, and carried hsame transports.

Next apply Definition 126.82. The RegSeqRat handoff consumer can read the stream-name source and dyadic obligation rows only through the separated BEDC handoff surface, so its visible dyadic and stream rows remain tied to the selected classifier.

Use Definition 38.216 for the carrier export. It identifies the positive denominator rows and dyadic source rows available to the handoff consumer with the classifier rows carried by the same finite package.

Finally compare the finite-window $\mathsf{Real}^{\uparrow}$ consumer by Definition 38.399. Any certified refinement reading the selected rows exposes classifier-equivalent endpoint, denominator, dyadic source, finite-ledger, and seal rows. Since both consumers are projections of the selected boundary, the resulting public surfaces are equivalent by the displayed hsame transports, with no quotient, completion, metric-completeness, host-index, Classical, or standard-bridge row available for alteration. □

Theorem 38.404 (RealUp selected finite-window common boundary exactness)**.** *For a selected* $\mathsf{RealStreamWindowClassifier}(x, y, n, w)$ *boundary, let a* RegSeqRat *handoff consumer and a finite-window* $\mathsf{Real}^{\uparrow}$ *consumer read the same* $\mathsf{StreamName}^{\uparrow}$ *rows,* RegSeqRat *dyadic rows,* DyadicRatCore *ledger entries, endpoint* $\mathsf{Rat}^{\uparrow}$ *rows,* UnaryHistory *witnesses,* Cont *ledger entries, and* hsame *transports. Then the two consumers expose exactly one common BEDC source boundary: coverage is the common handoff cover of Definition 38.400, soundness is the selected certificate boundary of Definition 38.402, and completeness is the consumer stability of Definition 38.403.*

The exact boundary consists of the selected StreamName rows, the dyadic source rows, the DyadicRatCore ledger entries, the RatUp endpoint rows, the unary witnesses, the finite Cont *entries, and the displayed transports. It excludes host* Nat *indices, quotient representatives,* $\mathsf{Real}^{\uparrow}$ *completeness, metric completeness, Classical data, and standard-bridge rows.*

Proof. First take the common handoff cover of Definition 38.400. It supplies a single source package for the selected StreamName rows, the RegSeqRat dyadic source rows, the displayed unary witnesses, the carried transports, and the finite RealUp ledger boundary.

Next apply Definition 38.402. This identifies every selected certificate row as generated by that finite source surface together with its DyadicRatCore ledger entries, endpoint RatUp rows, finite Cont entries, subwindow closure rows, and common-refinement determinacy. Hence no sound consumer can expose a row outside the displayed boundary.

It remains to identify the common exposure of the two consumers. Use Definition 38.403: any RegSeqRat handoff consumer and finite-window RealUp consumer reading the same displayed rows expose classifier-equivalent endpoint, denominator, dyadic source, finite-ledger, and seal rows. Thus each row covered by the source package is read back by both consumers, and any row exposed by either consumer is already inside the selected certificate boundary.

The exclusion clauses follow from the three cited surfaces. None exports host Nat equality, quotient representatives, RealUp completeness, metric completeness, Classical data, or standard-bridge rows, so the exact common boundary is the whole available BEDC source surface and nothing beyond it. □

Theorem 38.405 (RealUp selected finite-window common boundary witness)**.** *Every downstream selected-window consumer of the* $\mathsf{RealStreamWindowClassifier}(x, y, n, w)$ *boundary factors through one explicit BEDC source package. That package consists exactly of the selected* $\mathsf{StreamName}^{\uparrow}$ *rows, the* RegSeqRat *dyadic rows, the* DyadicRatCore *ledger entries, the* $\mathsf{Rat}^{\uparrow}$ *endpoint rows, the* UnaryHistory *witnesses, the finite* Cont *entries, and the* hsame *transports of Definition 38.404.*

If the consumer is restricted to a certified subwindow or replaced by a certified refinement, the same package remains the common source boundary. The restriction or refinement may discard unread rows, but it cannot introduce a new host index, quotient representative, completion row, metric row, Classical row, or standard-bridge row outside the displayed BEDC source package.

Proof. First use Definition 38.400. It supplies the shared cover by StreamName rows, RegSeqRat dyadic rows, unary witnesses, carried transports, and the finite RealUp ledger boundary.

Next apply Definition 38.402. This identifies the selected certificate as soundly generated from the same finite source surface together with the DyadicRatCore ledger entries, RatUp endpoints, finite Cont entries, and displayed subwindow rows.

For downstream readback, use Definition 38.403. Any selected-window consumer reading the displayed rows exposes only classifier-equivalent endpoint, denominator, dyadic source, finite-ledger, and seal rows, so it factors through the same source package.

Finally apply Definition 38.399. Certified subwindows and refinements keep the endpoint, denominator, dyadic source, ledger, and seal rows within the same finite boundary. Repacking these four steps gives a named witness for the common finite source package and leaves no extra quotient, completion, metric-completeness, Classical, host-index, or standard-bridge row available to any selected-window consumer. □

Theorem 38.406 (RealUp selected StreamName-RegSeqRat-DyadicRatCore boundary)**.** *For any selected* $\mathsf{RealStreamWindowClassifier}(x, y, n, w)$ *boundary, every downstream selected-window* $\mathsf{Real}^{\uparrow}$ *consumer factors through exactly the finite BEDC boundary named in Definition 38.404: the shared* $\mathsf{StreamName}^{\uparrow}$ *rows, the* RegSeqRat *dyadic rows, the* DyadicRatCore *ledger entries, the* $\mathsf{Rat}^{\uparrow}$ *endpoint rows, the* UnaryHistory *witnesses, the finite* Cont *entries, and the* hsame *transports.*

Conversely, those displayed rows repack into both the selected-window certificate boundary of Definition 38.402 and the common boundary witness of Definition 38.405. No part of this boundary contains host Nat *indices, quotient representatives,* $\mathsf{Real}^{\uparrow}$ *completeness, metric completeness, Classical data, or standard-bridge rows.*

Proof. Begin with the common handoff cover of Definition 38.400. It gives the selected StreamName rows, RegSeqRat dyadic source rows, unary witnesses, carried transports, and finite RealUp ledger surface read by the selected boundary.

Soundness is the selected-window certificate boundary of Definition 38.402. It places the DyadicRatCore ledger entries, RatUp endpoint rows, finite Cont entries, and subwindow rows inside the same finite certificate surface, so no sound selected-window consumer can read outside the displayed BEDC rows.

For downstream readback, apply Definition 38.403. Consumers reading the displayed rows expose only classifier-equivalent endpoint, denominator, dyadic source, finite-ledger, and seal rows, hence their observable boundary factors through the common surface already named by Definition 38.404.

The reverse packing is exactly the witness supplied by Definition 38.405: the same StreamName, RegSeqRat, DyadicRatCore, RatUp, UnaryHistory, Cont, and hsame rows form one selected-window source package. The exclusion clauses are the common exclusions of the cited cover, certificate boundary, stability theorem, and witness, which export no host Nat indices, quotient representatives, completion or metric-completeness rows, Classical data, or standard-bridge rows. □

Theorem 38.407 (RealUp RegSeqRat StreamName seal handoff)**.** *The rows of Definition 38.276, together with the finite-window seal and endpoint readback rows displayed in the* $\mathsf{Real}^{\uparrow}$ *stream-prefix certificate boundary, determine exactly the* $\mathsf{Real}^{\uparrow}$ *seal handoff package. Its exported rows are the* RatStreamNameClassifier *row, the* RealUnaryStreamClassifier *transport row, the certified unary endpoint carriers, the finite-window ledger, and the seal/readback provenance. This handoff is the concrete route through chapter 126, chapter 301, and chapter 291 before the local* $\mathsf{Real}^{\uparrow}$ *seal is read.*

No quotient carrier, host equality, real completeness, arithmetic package, order package, or metric-completeness row is exported by this handoff.

Proof. First project the scoped stream-name interface. Definition 38.276 supplies the RatStreamNameClassifier row, the transported RealUnaryStreamClassifier row, and the certified unary endpoint carrier rows used by the $\mathsf{Real}^{\uparrow}$ stream-prefix certificate. These rows are exactly the sibling chapter surfaces named by chapter 126 and chapter 301, not additional analytic structure.

Next read the finite-window seal boundary. Definition 38.277 and Definition 38.278 identify the finite window, the pointwise dyadic observation rows, and the RegSeqRat spine ledger consumed by the public $\mathsf{Real}^{\uparrow}$ seal. These rows are exactly the sibling chapter surfaces named by chapter 291 and chapter 301, not additional analytic structure.

Finally use the endpoint readback and hidden-data ledger rows of the stream-prefix certificate boundary. They repack the displayed classifier, transport, endpoint, finite-window, and provenance rows as the stated seal handoff package, while excluding every off-table claim: quotient carriers, host equality, completeness, arithmetic, order, and metric-completeness data. □

Theorem 38.408 (RealUp open phase seal exactness)**.** *A finite* $\mathsf{Real}^{\uparrow}$ *seal handoff is accepted precisely when its displayed rows factor through one* BHist *packet containing the four open-phase faces:*

1. *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows for the finite unary window;*
2. *the* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier and transported stream name rows;*
3. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity spine ledger over the same scheduled observations;*
4. *the* $\mathsf{Real}^{\uparrow}$ *seal, endpoint readback, and provenance ledger.*

The factorization uses the displayed hsame, Cont, Pkg, *and* NameCert *rows, and it exports no quotient carrier, host equality, real completeness, arithmetic package, order package, or metric-completeness row.*

Proof. For the forward direction, begin with an accepted finite $\mathsf{Real}^{\uparrow}$ seal handoff. Theorem 38.407 projects the seal handoff into its stream-name classifier row, transported RealUp unary classifier row, certified unary endpoint carriers, finite-window ledger, and seal/readback provenance.

Now separate the four open-phase faces. Theorem 38.276 supplies the $\mathsf{StreamName}^{\uparrow}$ classifier, transported stream-name rows, and the regular-sequence interface rows. Theorems 38.277 and 38.278 identify the same finite window as the place where the $\mathsf{DyadicRatCore}^{\uparrow}$ observations, the $\mathsf{RegSeqRat}^{\uparrow}$ spine ledger, and the $\mathsf{Real}^{\uparrow}$ seal/readback ledger are read. Thus every accepted handoff factors through one displayed BHist packet with the stated hsame, Cont, Pkg, and NameCert rows.

For the reverse direction, start from such a shared BHist packet. The scoped stream-name interface repacks the $\mathsf{StreamName}^{\uparrow}$ classifier and regularity spine rows, while the finite-window seal coverage theorem attaches the dyadic observation rows to that same window.

Finally apply Definition 38.278 and then Definition 38.407. The first theorem turns the shared finite-window packet into the $\mathsf{Real}^{\uparrow}$ seal-facing package, and the second identifies that package as the finite seal handoff. Since every row used in both directions is one of the displayed four faces, no quotient carrier, host equality, completeness, arithmetic, order, or metric-completeness datum is introduced. □

Theorem 38.409 (RealUp open-phase four-face consumer totality)**.** *Every downstream* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *completion-facing, or stream-facing consumer of an accepted finite* $\mathsf{Real}^{\uparrow}$ *seal source factors through exactly the four displayed open-phase faces:*

1. *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows over the finite unary window;*
2. *the* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier rows and transported stream-name rows;*
3. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity-spine rows over the same scheduled observations;*
4. *the* $\mathsf{Real}^{\uparrow}$ *seal, endpoint readback, and provenance rows.*

The only structural rows available to the consumer are the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The consumer route has no coordinate for quotient carriers, host equality, ambient completeness, arithmetic packages, order packages, or metric-completeness rows.*

Proof. Project the accepted finite seal source through Definition 38.408. Exactness reads the seal source as one BHist packet whose projections are precisely the dyadic observation face, the stream-name finite-window face, the regular-rational spine face, and the $\mathsf{Real}^{\uparrow}$ seal/readback provenance face.

Now use Definition 38.407. The handoff identifies the seal-facing rows consumed at the $\mathsf{Real}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ boundary: classifier rows, transported stream rows, endpoint carriers, finite-window ledger, and provenance. These rows are already contained in the four projected faces.

For the stream-facing side, cite the scoped $\mathsf{StreamName}^{\uparrow}$ finite-window coverage used in the surrounding handoff proof. For the completion-facing side, cite the finite-window $\mathsf{RegSeqRat}^{\uparrow}$ seal rows that place every regularity read on the same scheduled dyadic observations. Both consumers therefore read only rows already present in the same four-face packet.

It remains to exclude off-table data. Coordinate exhaustion leaves only the displayed BHist, hsame, Cont, Pkg, and NameCert structural rows after the four faces are projected. Since none of those rows is a quotient carrier, host equality, ambient completeness datum, arithmetic or order package, or metric-completeness row, no downstream consumer can factor through a fifth face. □

Theorem 38.410 (RealUp finite seal source uniqueness)**.** *Two finite* $\mathsf{Real}^{\uparrow}$ *seal handoffs over the same* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier rows, the same accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity spine ledger, and the same displayed* $\mathsf{Real}^{\uparrow}$ *seal endpoint and readback provenance expose the same finite* BHist *seal source surface when their* hsame*,* Cont*,* Pkg*, and* NameCert *rows agree componentwise.*

The shared source surface is the finite packet carrying the public $\mathsf{StreamName}^{\uparrow}$ *window classifier, the pointwise* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows, the accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *spine rows, and the displayed* $\mathsf{Real}^{\uparrow}$ *seal and readback ledger. No quotient carrier, host equality, completeness row, arithmetic package, order package, or metric-completeness datum can distinguish the two reads.*

Proof. Project both handoffs through Definition 38.407. The projected rows are the same $\mathsf{StreamName}^{\uparrow}$ classifier, transported unary classifier, endpoint carrier rows, finite-window ledger, and seal/readback provenance because the displayed hsame, Cont, Pkg, and NameCert rows agree componentwise.

Apply Definition 38.408 to each projected handoff. Each accepted read factors through one finite BHist packet with the four open-phase faces: dyadic observations, stream-name classifier rows, the $\mathsf{RegSeqRat}^{\uparrow}$ regularity spine ledger, and the $\mathsf{Real}^{\uparrow}$ seal endpoint/readback provenance.

Use Definition 38.277 and Definition 38.278 on the shared finite window. These theorems identify the dyadic observation rows and the regular-rational spine rows as the same finite seal-facing packet for both reads.

Thus the two handoffs expose one finite BHist seal source surface. Every coordinate available to the seal has already been matched componentwise, and the off-table quotient, host-equality, completeness, arithmetic, order, and metric-completeness data provide no further distinguishing row. □

Theorem 38.411 (RealUp seal source factorization boundary)**.** *Any finite* $\mathsf{Real}^{\uparrow}$ *seal source consumed by downstream* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *consumers factors through the unique four-face* BHist *packet consisting of the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity spine rows, and the* $\mathsf{Real}^{\uparrow}$ *seal and readback provenance rows. Componentwise* hsame*,* Cont*,* Pkg*, and* NameCert *agreement on these rows is sufficient to identify the visible seal source for every such consumer.*

The boundary exports no quotient carrier, host equality, completeness datum, arithmetic package, order package, or metric-completeness row.

Proof. First apply Definition 38.408. It factors an accepted finite seal handoff through the four open-phase faces: dyadic observations, stream-name classifier rows, the regular-rational spine, and the seal/readback provenance.

Next use Definition 38.410. Componentwise agreement of the displayed hsame, Cont, Pkg, and NameCert rows identifies the finite BHist seal source surface for any two reads with the same four faces.

Finally cite Definition 38.407. The handoff theorem says the finite seal-facing rows are exactly the classifier, transport, endpoint, finite-window, and provenance rows consumed by the $\mathsf{Real}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ boundary, so quotient carriers, host equality, completeness, arithmetic or order packages, and metric-completeness rows remain outside the consumer-visible source. □

Theorem 38.412 (Real RegSeqRat StreamName seal handoff composition)**.** *An accepted finite* $\mathsf{Real}^{\uparrow}$ *seal read is equivalent, as displayed BEDC data, to the composed L10 open-phase route whose rows are the* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and distance rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and regularity rows, and the* $\mathsf{Real}^{\uparrow}$ *seal/readback ledger. The equivalence is transported only by the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

No quotient stream, host equality, selected limit, ambient completeness, arithmetic or order package, metric-completeness row, or hidden seal coordinate is part of the composed route.

Proof. First apply Definition 38.408. It identifies the accepted seal read with one finite BHist packet whose four faces are the dyadic observation face, the stream-name finite-window face, the RegSeqRat regularity face, and the Real seal/readback face.

Next apply Definition 38.409. This shows that every downstream consumer reads only those four faces through the displayed hsame, Cont, Pkg, and NameCert coordinates.

Use Definition 38.411 to identify the consumer-visible source with the same finite seal surface. Then use Definition 301.71 to replace the RegSeqRat-facing seal source by the StreamName, DyadicRatCore, RegSeqRat, and RealUp source-seal route.

The cited theorems expose exactly the rows listed in the statement. Since their exclusion clauses remove quotient streams, host equality, selected limits, ambient completeness, arithmetic and order packages, metric-completeness data, and hidden seal coordinates, the composition has no further row. □

Theorem 38.413 (RealUp open-phase four-face pullback)**.** *Let S and T be accepted finite* $\mathsf{Real}^{\uparrow}$ *seal-source handoffs. They classify as the same consumer-visible handoff precisely when their four open-phase faces classify componentwise: the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows classify together, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier rows classify together, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity spine rows classify together, and the* $\mathsf{Real}^{\uparrow}$ *seal/readback provenance rows classify together. The comparison uses the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates as its only gluing data.*

Equivalently, compatible rows on those four faces determine a unique finite BHist *pullback packet, and any accepted finite seal-source handoff projects to exactly that four-face packet. No*

quotient carrier, host equality, real completeness, arithmetic package, order package, or metric-completeness row is part of the classifier, the pullback packet, or any of its four projections.

Lean4 ✓ `BEDC.Derived.RealUp.RealupOpenPhaseFourFacePullback`

Proof. For the forward direction, start from two accepted finite seal-source handoffs that classify as the same consumer-visible handoff. Apply Definition 38.411 to each handoff. The factorization exposes exactly the dyadic observation face, the stream-name finite-window classifier face, the regularity-spine face, and the $\mathsf{Real}^{\uparrow}$ seal/readback provenance face.

The consumer-visible classification is carried only by the displayed hsame, Cont, Pkg, and NameCert rows. Projecting along the four factorization faces therefore gives componentwise classification of the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

For the reverse direction, assume the four projected faces classify componentwise through the displayed gluing rows. Apply Definition 38.408 to read the compatible rows as accepted finite seal-facing packages over the same BHist source shape.

Next apply Definition 38.410. Since the four faces agree componentwise through the displayed hsame, Cont, Pkg, and NameCert rows, the two handoffs expose the same finite seal-source surface. Thus they classify as the same consumer-visible handoff, and the compatible rows determine the unique pullback packet.

The same boundary theorem, together with Definition 38.408, excludes every off-table coordinate. Thus quotient carriers, host equality, real completeness, arithmetic and order packages, and metric-completeness rows cannot appear in the pullback source or in its projected faces. □

Theorem 38.414 (RealUp common-refinement seal consumption)**.** *Let S and T be accepted finite* $\mathsf{Real}^{\uparrow}$ *seal-source handoffs, possibly displayed over different* $\mathsf{StreamName}^{\uparrow}$ *finite windows. Suppose* $\mathsf{StreamName}^{\uparrow}$ *supplies a common finite refinement window for those two displays, and suppose the two handoffs transport to that refinement with the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity spine rows, the same* $\mathsf{Real}^{\uparrow}$ *seal/readback provenance rows, and the same displayed* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates. Then every consumer-visible* $\mathsf{Real}^{\uparrow}$ *seal read from either handoff factors through one refined four-face* BHist *packet.*

The refined consumption route is finite and open-phase. It exports no quotient carrier, host equality, selected limit, real-completeness row, arithmetic package, order package, Classical-choice row, or metric-completeness coordinate.

Proof. First transport both accepted handoffs to the supplied $\mathsf{StreamName}^{\uparrow}$ common finite refinement. Apply Definition 38.413 to the transported displays. The matching dyadic observation rows, regularity spine rows, seal/readback provenance rows, and displayed hsame, Cont, Pkg, and NameCert coordinates determine one refined four-face BHist packet.

Next use Definition 38.410. After transport to the common refinement, both accepted handoffs expose the same finite seal-source surface, because their four projected faces agree componentwise through the displayed gluing rows.

Finally apply Definition 38.419 and Definition 38.407. Route totality says every consumer-visible $\mathsf{Real}^{\uparrow}$ seal read is exhausted by an accepted open-phase seal route, and the handoff theorem says those routes are exactly the dyadic observation, finite-window, regularity-spine, and provenance rows read from the refined packet. Since the boundary has no carrier for the off-table coordinates, no consumer read can leave that refined finite packet. □

Theorem 38.415 (RealUp four-face common-window seal uniqueness)**.** *Let S and T be accepted finite* $\mathsf{Real}^{\uparrow}$ *seal-source handoffs. Suppose both handoffs classify componentwise on the same displayed* $\mathsf{StreamName}^{\uparrow}$ *finite window, with the same transported* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows,*

the same $\mathsf{RegSeqRat}^{\uparrow}$ *regularity spine rows, the same* $\mathsf{Real}^{\uparrow}$ *seal/readback provenance rows, and the same displayed* hsame, Cont, Pkg, *and* NameCert *coordinates. Then every consumer-visible* $\mathsf{Real}^{\uparrow}$ *seal read from* S *or* T *factors through the same finite* BHist *route.*

This common route is a finite seal-source route only. It includes no quotient carrier, host equality, selected limit, real-completeness row, arithmetic package, order package, or metric-completeness row.

Proof. Apply Definition 38.413. The shared $\mathsf{StreamName}^{\uparrow}$ finite window and the matching dyadic, regularity-spine, and seal/readback rows identify one common four-face packet through the displayed hsame, Cont, Pkg, and NameCert coordinates.

Use Definition 38.410. Since the two accepted handoffs expose the same four-face packet, their finite seal-source surfaces are the same finite BHist source for consumer-visible reads.

Next apply Definition 38.419. Every consumer-visible $\mathsf{Real}^{\uparrow}$ seal read is exhausted by one of the accepted finite seal-source routes, so no read can bypass the common finite source just identified.

Finally use Definition 38.407. The handoff boundary says that the shared route is read only through the displayed $\mathsf{RegSeqRat}^{\uparrow}$ spine and $\mathsf{StreamName}^{\uparrow}$ finite-window rows, together with the dyadic observation and $\mathsf{Real}^{\uparrow}$ provenance faces. Thus quotient carriers, host equality, selected limits, real completeness, arithmetic or order packages, and metric-completeness rows are not part of the consumed route. □

Theorem 38.416 (RealUp RegSeqRat seal readback determinacy)**.** *Let* S *and* T *be accepted finite* $\mathsf{Real}^{\uparrow}$ *seal packets. Suppose they display the same* $\mathsf{RegSeqRat}^{\uparrow}$ *regular stream carrier, the same* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, and the same* $\mathsf{Real}^{\uparrow}$ *seal/readback row. Then every consumer-visible readback route out of* S *or* T *factors through the same finite dyadic observation window, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier witness, and the same* $\mathsf{Real}^{\uparrow}$ *seal endpoint.*

The common readback boundary is the four-face packet whose rows are the $\mathsf{DyadicRatCore}^{\uparrow}$ *observations on the displayed window, the* $\mathsf{StreamName}^{\uparrow}$ *schedule rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity spine rows, and the* $\mathsf{Real}^{\uparrow}$ *seal/readback provenance rows. It exports no host equality, quotient class, completeness row, arithmetic package, or order package.*

Proof. Apply Definition 38.407 to both accepted packets. The handoff theorem reads their visible data as one package of stream-name classifier rows, transported unary classifier rows, endpoint carriers, finite-window ledger, and seal/readback provenance.

Next use Definition 38.408. Since the accepted packets have the same displayed $\mathsf{RegSeqRat}^{\uparrow}$ carrier, the same $\mathsf{StreamName}^{\uparrow}$ finite-window schedule, and the same $\mathsf{Real}^{\uparrow}$ seal/readback row, exactness restricts both reads to the same four open-phase row set.

Apply Definition 38.410 to identify the consumer-visible source surface. The shared source contains precisely the finite dyadic observation window, the regular-rational classifier witness, and the seal endpoint named by the displayed row.

Now route downstream reads through Definition 38.411. Every consumer of the seal source sees only the displayed schedule, the $\mathsf{RegSeqRat}^{\uparrow}$ spine, and the $\mathsf{Real}^{\uparrow}$ seal provenance, so no off-table host or completeness coordinate can separate the two packets.

Finally apply Definition 38.413. The two readback routes have the same componentwise four-face boundary, hence the same consumer-visible readback boundary, while quotient classes, host equality, arithmetic packages, order packages, and completeness rows remain absent. □

Theorem 38.417 (RealUp RegSeqRat StreamName common-window seal fusion)**.** *Let* S *and* T *be accepted finite* $\mathsf{Real}^{\uparrow}$ *seal handoffs. Suppose they share one displayed* $\mathsf{StreamName}^{\uparrow}$ *finite window, the same componentwise* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity-spine rows, the same transported* $\mathsf{DyadicRatCore}^{\uparrow}$

observation rows, the same $\mathsf{Real}^{\uparrow}$ *seal/readback provenance rows, and the same displayed* hsame, Cont, Pkg, *and* NameCert *coordinates. Then their consumer-visible* $\mathsf{Real}^{\uparrow}$ *seal reads fuse through one finite* BHist *route whose visible boundary consists exactly of those four faces.*

The fused route exports no quotient carrier, host equality, selected limit, real-completeness row, arithmetic package, order package, Classical-choice row, or metric-completeness coordinate.

Proof. Project both accepted handoffs through Definition 38.407. This reads the shared window as the same stream-name schedule together with the transported dyadic observations, the regular-rational spine, and the $\mathsf{Real}^{\uparrow}$ seal/readback provenance.

Next use Definition 38.408. Exactness exposes the accepted handoffs as four open-phase faces over the displayed hsame, Cont, Pkg, and NameCert coordinates, so no consumer-visible seal read has a fifth source row.

Apply Definition 38.413 to the shared finite window and the matching component rows. The pullback identifies one finite BHist route carrying exactly the dyadic observation face, the stream-name finite-window face, the $\mathsf{RegSeqRat}^{\uparrow}$ regularity face, and the $\mathsf{Real}^{\uparrow}$ seal/readback provenance face.

Finally use Definition 38.410 and Definition 38.416. Source uniqueness identifies the two accepted seal sources, and readback determinacy forces the consumer-visible reads to use the same finite route. Since each cited boundary has no carrier for quotient representatives, host equality, selected limits, real completeness, arithmetic or order packages, Classical choice, or metric completeness, the fused route exports none of those coordinates. □

Theorem 38.418 (RealUp StreamName factorization pullback correspondence)**.** *Let S be an accepted finite* $\mathsf{Real}^{\uparrow}$ *seal handoff. The* $\mathsf{StreamName}^{\uparrow}$ *real-seal factorization boundary holds for S precisely when there exists a* $\mathsf{Real}^{\uparrow}$ *open-phase four-face pullback packet whose projections match the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows, the same* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier rows, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity spine rows, and the same* $\mathsf{Real}^{\uparrow}$ *seal/readback provenance rows.*

The correspondence uses only the displayed hsame, Cont, Pkg, *and* NameCert *rows of the accepted handoff. It introduces no quotient carrier, host equality, real-completeness row, arithmetic package, order package, Classical-choice row, or metric-completeness coordinate.*

Proof. Assume first that the $\mathsf{StreamName}^{\uparrow}$ real-seal factorization boundary holds for S. Apply Definition 126.142 to expose the finite-window stream classifier rows and the real-seal source rows named by the handoff.

Next apply Definition 38.408. Exactness reads the accepted seal rows as the visible $\mathsf{Real}^{\uparrow}$ seal/readback provenance surface over the same finite BHist source.

Now use Definition 38.413. The dyadic observation rows, stream-name classifier rows, regularity-spine rows, and seal/readback provenance rows form the four matching faces, so they determine the required pullback packet.

Conversely, suppose the four-face pullback packet exists with the displayed matching rows. Project its $\mathsf{StreamName}^{\uparrow}$ face, its $\mathsf{RegSeqRat}^{\uparrow}$ face, and its $\mathsf{Real}^{\uparrow}$ seal/readback face through the same hsame, Cont, Pkg, and NameCert coordinates.

Apply Definition 38.411. The projected faces recover exactly the seal-source factorization rows consumed by the $\mathsf{StreamName}^{\uparrow}$ real-seal boundary, and no off-table coordinate can be inserted because neither theorem has a carrier for quotient representatives, host equality, real completeness, arithmetic or order packages, Classical choice, or metric completeness. □

Theorem 38.419 (RealUp open-phase seal route totality)**.** *Every finite* $\mathsf{Real}^{\uparrow}$ *seal consumer route accepted by the open-phase handoff is exhausted by the same four-face packet named in Definition 38.408: the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity spine, and the* $\mathsf{Real}^{\uparrow}$ *seal/readback row. Its only gluing data are the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Thus a downstream consumer replay cannot branch through any fifth visible surface. Quotient representatives, host equality, real completeness, arithmetic packages, order packages, and metric-completeness rows are outside the route.

Proof. Start with an accepted finite seal consumer route. Apply Definition 38.408 to factor its accepted handoff through the four open-phase faces and the displayed transport, continuation, package, and certificate rows.

Next use Definition 38.410. Any two reads with the same four faces and componentwise hsame, Cont, Pkg, and NameCert rows expose the same finite BHist seal source surface.

Finally apply Definition 38.411. Every downstream $\mathsf{Real}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ consumer route out of that seal source is already a route through the same four faces. Since the boundary has no carrier for the off-table rows, the finite packet exhausts the replay. □

Theorem 38.420 (RealUp four-face consumer replay)**.** *Let S and T be accepted finite* $\mathsf{Real}^{\uparrow}$ *seal packages. Suppose they display the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows, the same* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity spine, the same* $\mathsf{Real}^{\uparrow}$ *seal/readback row, and the same componentwise* hsame*,* Cont*,* Pkg*, and* NameCert *rows. Then every consumer-visible replay route from S is the same visible route as the corresponding replay route from T.*

The replay comparison is finite: it is made entirely inside the four-face BHist *packet and exports no quotient carrier, host equality, completeness row, arithmetic package, order package, Classical-choice row, or metric-completeness coordinate.*

Proof. Apply Definition 38.419 to the replay routes from S and T. Each route is exhausted by the same four open-phase faces because the displayed observation, stream-window, regularity, seal/readback, transport, continuation, package, and certificate rows agree componentwise.

Use Definition 38.413 to identify the common pullback packet. Componentwise agreement on the four projections determines one finite BHist source, so the two packages have the same projected consumer boundary.

Now apply Definition 38.418. The $\mathsf{StreamName}^{\uparrow}$ factorization boundary and the four-face pullback boundary read the same packet through the same rows. Therefore the replay route visible to any consumer is the same for S and T, and no off-table coordinate can separate the two reads. □

Theorem 38.421 (RealUp seal source classifier correspondence)**.** *For accepted finite* $\mathsf{Real}^{\uparrow}$ *seal handoffs S and T, the consumer-visible seal-source classifier identifies S and T if and only if their four open-phase faces classify componentwise: the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity spine rows, and the* $\mathsf{Real}^{\uparrow}$ *seal/readback rows classify through the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates.*

This correspondence is exactly the seal-source read seen by consumers. It has no coordinate for quotient representatives, host equality, real completeness, arithmetic packages, order packages, Classical choice, or metric completeness.

Proof. For the forward direction, assume the consumer-visible seal-source classifier identifies S and T. Apply Definition 38.411 to expose the four faces available to that classifier.

Project the classifier along those faces. Since the visible classifier uses only the displayed hsame, Cont, Pkg, and NameCert coordinates, the dyadic observation rows, stream-window rows, regularity spine rows, and seal/readback rows classify componentwise.

For the reverse direction, assume componentwise classification on the four faces. Apply Definition 38.413 to repack those compatible faces into the unique finite pullback packet.

Next use Definition 38.418 and Definition 38.419. The correspondence reads the pullback packet as the $\mathsf{StreamName}^{\uparrow}$ factorization boundary, and route totality says every consumer replay is exhausted by that packet. Thus the consumer-visible seal-source classifier identifies S and T. □

Theorem 38.422 (RealUp open-phase four-face NameCert admission)**.** *Let P be a finite packet whose four displayed faces are* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows,* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity-spine rows, and* $\mathsf{Real}^{\uparrow}$ *seal/readback rows. Suppose the only gluing coordinates of P are the componentwise* hsame*,* Cont*,* Pkg*, and* NameCert *rows already displayed on those four faces. Then P is admitted as the local* $\mathsf{Real}^{\uparrow}$ *open-phase* NameCert *surface for the seal handoff.*

The admission has no coordinate for quotient carriers, host equality, real completeness, arithmetic packages, order packages, Classical choice, or metric-completeness rows. Every admitted row is one of the four faces or one of the displayed transport, continuation, package, and certificate coordinates.

Proof. First apply Definition 38.408. It reads any accepted seal/readback row in the packet as a finite open-phase seal surface over the same BHist source and over the displayed hsame, Cont, Pkg, and NameCert coordinates.

Next use Definition 38.413. The dyadic observation face, the stream-name finite-window face, the regularity-spine face, and the seal/readback face are compatible along exactly those displayed coordinates, so they form the local four-face pullback packet.

Apply Definition 38.419. It says every consumer-visible route out of the seal handoff is exhausted by the same four-face packet, so no fifth surface is available during admission.

Finally use Definition 38.421. The classifier seen by consumers is the componentwise classifier on the four faces, transported only through hsame, Cont, Pkg, and NameCert. Thus the finite packet is precisely the local $\mathsf{Real}^{\uparrow}$ open-phase NameCert surface, and the excluded coordinates have no carrier in the admission. □

Theorem 38.423 (RealUp open-phase NameCert surface completeness)**.** *A local* $\mathsf{Real}^{\uparrow}$ *open-phase* NameCert *surface for the seal handoff is admitted exactly when it is represented by one finite four-face* BHist *packet whose faces are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity-spine rows, and the* $\mathsf{Real}^{\uparrow}$ *seal/readback provenance rows. The only gluing coordinates of that packet are the displayed componentwise* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates.*

The representing packet is unique among compatible four-face packets. The surface has no quotient carrier, host-equality coordinate, real-completeness row, arithmetic package, order package, Classical-choice row, or metric-completeness row.

Proof. For existence, start with the four displayed faces and their componentwise hsame, Cont, Pkg, and NameCert coordinates. Apply Definition 38.422. It admits that finite packet as the local $\mathsf{Real}^{\uparrow}$ open-phase NameCert surface and leaves no carrier for any off-table row.

For uniqueness, compare two admitted surfaces with the same displayed faces. Use Definition 38.413. Compatible dyadic observation rows, stream-window rows, regularity-spine rows, and seal/readback rows determine exactly one finite BHist pullback packet over the shown coordinates.

The classifier boundary is the same boundary. Apply Definition 38.421. The consumer-side seal-source classifier is precisely the componentwise classifier on the four faces, so no quotient representative, host equality, arithmetic order, or completeness coordinate can refine the surface.

Finally apply Definition 38.419. Every consumer-visible route out of the handoff is exhausted by the four-face packet. Therefore the admitted local NameCert surface is equivalent to that unique finite packet, and the listed excluded rows are outside the open-phase seal surface. □

Theorem 38.424 (RealUp open-phase window splice non-escape)**.** *Let two finite* $\mathsf{Real}^{\uparrow}$ *seal handoffs be displayed over the same* $\mathsf{StreamName}^{\uparrow}$ *finite-window cover, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger, compatible* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity-spine rows, and the same componentwise* hsame*,* Cont*,* Pkg*, and* NameCert *gluing rows. Then every consumer-visible splice between the two handoffs factors through the same four-face* BHist *packet.*

Consequently the splice exports no quotient carrier, host equality, selected limit, real-completeness row, arithmetic package, order package, Classical-choice row, or metric-completeness row. Its whole public boundary is the shared finite packet consisting of the dyadic observation face, the stream-window face, the regularity-spine face, and the seal/readback face.

Proof. Apply Definition 38.413 to the two handoffs. The common stream-window cover, common dyadic ledger, compatible regularity spines, and identical displayed gluing rows determine one finite four-face BHist packet on both sides of the splice.

Next use Definition 38.423. It identifies the admitted local NameCert surface of each handoff with exactly that finite packet, and it lists the only coordinates available to the open-phase seal boundary.

It remains to rule out an escaping consumer route. Apply Definition 38.419 to the splice read, and then use Definition 38.421. The route totality theorem exhausts all consumer-visible reads by the four displayed faces, while the classifier correspondence transports only the componentwise classifier through hsame, Cont, Pkg, and NameCert.

Therefore the splice is a read of the shared packet itself. No quotient carrier, host equality, selected limit, completeness row, arithmetic or order package, Classical-choice row, or metric-completeness row is present in the source packet, so none can be exported by the consumer-visible splice. □

Theorem 38.425 (RealUp open-phase terminal consumer non-escape)**.** *A terminal* $\mathsf{Real}^{\uparrow}$ *seal consumer boundary is accepted exactly when its route factors through the finite four-face packet consisting of the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity-spine rows, and the* $\mathsf{Real}^{\uparrow}$ *seal/readback rows, glued only by the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates.*

Consequently the terminal boundary exports no quotient carrier, host equality, selected limit, completeness row, arithmetic package, order package, Classical-choice row, or metric-completeness coordinate. Every accepted terminal read is a read of the four displayed faces themselves.

Proof. First identify the admissible surface. Apply Definition 38.423. It says the local NameCert surface for an open-phase seal is exhausted by the dyadic observation face, stream-window face, regularity-spine face, seal/readback face, and the displayed hsame, Cont, Pkg, and NameCert coordinates.

Now route the terminal consumer read. Apply Definition 38.419. A consumer-visible terminal route out of the seal has no fifth source row; it must pass through the same four-face packet before any public read is accepted.

It remains to check that the route is stable under the naming and classifier surface. Use Definition 38.421 to transport seal-source classifiers componentwise, and use Definition 38.418 to keep the stream-name factorization inside the displayed finite-window pullback.

Thus both directions are fixed by the same finite packet: every accepted terminal consumer route factors through the four faces, and every route built from those faces is accepted by the open-phase NameCert surface. Since the packet contains no quotient carrier, host equality, selected limit, completeness row, arithmetic or order package, Classical-choice row, or metric-completeness coordinate, none can be exported at the terminal boundary. □

Theorem 38.426 (RealUp open-phase terminal pullback lock)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *open-phase consumer that reads a finite seal through the displayed handoff factors through the same* $\mathsf{StreamName}^{\uparrow}$ *finite window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger, displayed* hsame *transports,* Cont *routes,* Pkg *provenance, and local* NameCert *row. The terminal route therefore has no coordinate for quotient real equality, selected host limits, host equality, trichotomy, countable choice, or ambient completeness.*

Proof. First apply Definition 38.423 and Definition 38.419. Together they identify the local seal surface and force every accepted consumer read through it.

The common-refinement consumption and handoff rows are the four finite faces named in Definition 38.425. Use Definition 38.418 to keep the StreamName window, readback, ledger, transports, continuations, provenance, and naming row in the same pullback packet.

Those coordinates exhaust the route. Since none of the cited packets contains quotient real equality, selected host limits, host equality, trichotomy, countable choice, or ambient completeness, the terminal consumer cannot export any of those rows. □

Definition 38.427 (Real RegSeqRat StreamName dependency triple)**.** *A* $\mathsf{Real}^{\uparrow}$ *RegSeqRat StreamName dependency triple is a finite* BHist *packet*

$$(S, Q, D, R, H, C, P, N)$$

whose visible rows have the following shape:

1. *S records the inspected* $\mathsf{StreamName}^{\uparrow}$ *finite windows and their transported stream-name classifier rows;*
2. *Q records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback surface over the same scheduled windows;*
3. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger read pointwise through those windows;*
4. *R records the* $\mathsf{Real}^{\uparrow}$ *seal row and its finite endpoint readback;*
5. *H records componentwise* hsame *comparisons for the window, readback, dyadic, and seal rows;*
6. *C records the displayed* Cont *route from each public seal read to the preceding window, readback, dyadic, and seal coordinates;*
7. *P records the* Pkg *provenance for the four sibling surfaces;*
8. *N is the local* NameCert *row for this dependency packet.*

The classifier compares dependency triples only through these displayed rows. It has no coordinate for a quotient real, selected host limit, host equality, ambient completeness principle, arithmetic package, order package, or metric-completeness row.

Theorem 38.428 (Real RegSeqRat StreamName seal-route exhaustion)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *seal read from a dependency triple* (S, Q, D, R, H, C, P, N) *is witnessed by the four displayed rows* S, Q, D, R*. The tuple projection inventory is* (S, Q, D, R, H, C, P, N)*, while the source-dependency route is* $D \to S \to Q \to R$*: the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger row* D *supplies the endpoint and radius ledger read through the* $\mathsf{StreamName}^{\uparrow}$ *finite window row* S *before the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row* Q *and the local* $\mathsf{Real}^{\uparrow}$ *seal row* R *are consumed. The factorization is transported by the componentwise* hsame *row* H*, read through the displayed* Cont *route* C*, and packaged by* P, N*.*

Consequently the accepted seal route is exactly the sibling route whose source face is chapter 291, whose finite observation window is scheduled by chapter 126, and whose regular readback is supplied by chapter 301 before the $\mathsf{Real}^{\uparrow}$ *seal is consumed. It exports no quotient real, selected host limit, host equality, ambient completeness coordinate, arithmetic package, order package, or metric-completeness row.*

Proof. Begin with an accepted seal read from (S, Q, D, R, H, C, P, N). The definition of the dependency triple exposes only the finite window row S, regular rational readback Q, dyadic observation ledger D, seal row R, and the transport, route, package, and local naming rows H, C, P, N.

Use Definition 38.407. That handoff identifies the $\mathsf{Real}^{\uparrow}$ seal-facing package as the stream-name classifier row, transported unary classifier row, finite-window ledger, endpoint readback, and seal provenance.

Now read the upstream sibling surfaces. The DyadicRatCore, StreamName, and RegSeqRat chapters named in chapter 291, chapter 126, and chapter 301 provide the source ledger, scheduled window, and regular readback rows used by the handoff. The displayed H, C, P, N rows keep those coordinates in one BHist packet.

Since the packet has no remaining coordinate after R, a public seal read cannot branch to a quotient real, selected host limit, host equality, ambient completeness principle, arithmetic or order package, or metric-completeness row. Thus every accepted read is exhausted by the stated route. □

Theorem 38.429 (Real RegSeqRat StreamName Cauchy-completion interface)**.** *For the current* $\mathsf{Real}^{\uparrow}$ *completion-facing phase, the Cauchy-completion interface exposed by a Real RegSeqRat StreamName dependency triple is exactly the finite source-dependency route through chapter 291, chapter 126, chapter 301, and the local* $\mathsf{Real}^{\uparrow}$ *seal row. Any completion-facing consumer must factor through this route before it reads a* $\mathsf{Real}^{\uparrow}$ *endpoint.*

The interface exports the displayed finite window, regular-rational readback, dyadic observation ledger, seal row, componentwise hsame *transport, displayed* Cont *route, package provenance, and local* $\mathsf{NameCert}$ *row. It exports no quotient stream, selected host limit, representative choice, host equality, ambient completeness principle, arithmetic package, order package, or metric-completeness row.*

Proof. Start from the dependency triple of Definition 38.427. Its tuple inventory is listed as (S, Q, D, R, H, C, P, N), but its inbound source route begins with the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger row D, reads that ledger through the finite $\mathsf{StreamName}^{\uparrow}$ window S, and then reaches the $\mathsf{RegSeqRat}^{\uparrow}$ readback row Q before the $\mathsf{Real}^{\uparrow}$ seal row R is consumed in the same finite packet.

Apply the seal-route exhaustion theorem Definition 38.428. It identifies every accepted seal read as the route sourced at D, scheduled through S, read back through Q, and sealed at R, transported by H, read through C, and packaged by P, N.

The local seal row is therefore the completion-facing boundary. Since the packet has no coordinate for quotient streams, selected host limits, representative choice, host equality, completeness,

arithmetic, order, or metric completeness, a consumer cannot read any of those objects before or after the $\mathsf{Real}^{\uparrow}$ endpoint. The only available interface is the stated finite route. □

Theorem 38.430 (Real open-phase dependency triple current surface)**.** *Every current Phase Real and completion-facing* $\mathsf{Real}^{\uparrow}$ *seal consumer of the dependency triple*

$$(S, Q, D, R, H, C, P, N)$$

factors through exactly four displayed faces: the $\mathsf{DyadicRatCore}^{\uparrow}$ *observation face* D*, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window face* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and readback face* Q*, and the local* $\mathsf{Real}^{\uparrow}$ *seal face* R*. The factorization is transported only by the displayed componentwise* hsame *row* H*, the* Cont *route row* C*, the* Pkg *provenance row* P*, and the local* NameCert *row* N*.*

Conversely, those four faces together with H, C, P, N *assemble the accepted current surface for such consumers. The surface has no coordinate for quotient streams, host equality, selected limits, ambient completeness, arithmetic packages, order packages, or metric-completeness rows.*

Proof. Start with the displayed dependency triple of Definition 38.427. Its carrier rows are exactly S, Q, D, R, H, C, P, N, so any current consumer must begin from those coordinates.

Apply Definition 38.428. It exhausts each accepted seal route by the dyadic observation row D, the finite-window row S, the regular readback row Q, and the local seal row R, while the packet still projects them as S, Q, D, R and transports the route through H, C, P, N.

Apply Definition 38.429. The same route is the completion-facing interface before a $\mathsf{Real}^{\uparrow}$ endpoint is read, so Phase Real and completion RealUp seal consumers share the displayed four-face surface.

For the converse, assemble the accepted surface from the four listed faces and the transport, route, provenance, and certificate rows. The exclusion clause in the dependency triple removes quotient streams, host equality, selected limits, ambient completeness, arithmetic packages, order packages, and metric-completeness rows, leaving no further coordinate to add. □

Theorem 38.431 (Real seal RegSeqRat StreamName dependency exhaustion)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *seal consumer that reads the dependency triple of Definition 38.427 factors through exactly the finite rows supplied by* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and the local* NameCert *row.*

The same consumer exports no quotient stream, selected host limit, representative choice, host equality, ambient completeness principle, arithmetic package, order package, or metric-completeness row.

Proof. Apply Definition 38.428 to the seal read. It identifies the only accepted route as the path through the finite $\mathsf{DyadicRatCore}^{\uparrow}$ ledger row, the $\mathsf{StreamName}^{\uparrow}$ window row, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row, and the local $\mathsf{Real}^{\uparrow}$ seal row, transported by hsame, read through Cont, and packaged by Pkg and NameCert.

Apply Definition 38.429. It turns the same finite route into the completion-facing interface and states that every completion-facing consumer must read through that interface before it reaches a $\mathsf{Real}^{\uparrow}$ endpoint.

Finally project the dependency triple itself. Its displayed coordinates are only (S, Q, D, R, H, C, P, N), and its exclusion clause contains no quotient stream, selected host limit, representative choice, host equality, ambient completeness principle, arithmetic package, order package, or metric-completeness row. Hence there is no non-finite route for the consumer to export. □

Theorem 38.432 (Real finite-window completion boundary)**.** *For any accepted* $\mathsf{Real}^{\uparrow}$ *RegSeqRat StreamName dependency triple* (S, Q, D, R, H, C, P, N)*, every completion-facing* $\mathsf{Real}^{\uparrow}$ *consumer factors through the finite source-dependency route in which the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger row* D *is read through the* $\mathsf{StreamName}^{\uparrow}$ *window row* S *before the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q *and the local* $\mathsf{Real}^{\uparrow}$ *seal row* R*. The passage is transported by the componentwise* hsame *row* H*, read through the displayed* Cont *route* C*, and packaged by* Pkg *provenance and the local* $\mathsf{NameCert}$ *row* N*.*

No quotient stream, selected host limit, representative choice, host equality, ambient completeness principle, arithmetic package, order package, or metric-completeness row is exported by this completion-facing boundary.

Proof. Apply Definition 38.428. It gives the only seal-facing route through the finite $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and local $\mathsf{Real}^{\uparrow}$ seal rows, with the displayed H, C, P, N transport, continuity, package, and naming data.

Next apply Definition 38.429. This turns the same finite route into the completion-facing interface and forces every completion consumer to pass through it before reading a $\mathsf{Real}^{\uparrow}$ endpoint.

Finally use the coordinate exclusion clause in Definition 38.427. The accepted packet has only the rows (S, Q, D, R, H, C, P, N), so no quotient stream, selected host limit, representative choice, host equality, ambient completeness principle, arithmetic package, order package, or metric-completeness row can be exported. □

Theorem 38.433 (Real RegSeqRat StreamName seal-source minimality)**.** *For an accepted* $\mathsf{Real}^{\uparrow}$ *RegSeqRat StreamName dependency triple* (S, Q, D, R, H, C, P, N)*, the current accepted seal source is minimal in its four open-phase faces. Removing any one of the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation face* D*, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window face* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback face* Q*, or the local* $\mathsf{Real}^{\uparrow}$ *seal face* R *leaves no accepted current Phase Real or Completion seal source.*

The transport, continuation, package, and local certificate rows H, C, P, N *do not replace a missing face. They only carry and name the route after all four faces are present in the displayed dependency triple.*

Proof. Start from the route exhaustion of Definition 38.428. It places every accepted seal read on the finite source route through D, then S, then Q, and only then R, while H, C, P, N carry that route inside the displayed packet inventory.

Use the current-surface theorem Definition 38.430. Its converse assembles the accepted current surface from precisely the four faces together with H, C, P, N, and its exclusion clause leaves no quotient, host, completeness, arithmetic, order, or metric-completeness coordinate outside them.

Now delete one face. If S is absent, there is no finite-window source for the dyadic ledger read. If Q is absent, there is no regular-rational readback after the scheduled window. If D is absent, there is no dyadic observation source for the seal route. If R is absent, there is no local Real seal for the endpoint read. In each case the Cauchy-completion interface of Definition 38.429 has no accepted endpoint route, so no current seal source remains. □

Theorem 38.434 (Real RegSeqRat StreamName current-phase gate)**.** *Every current Phase Real and Completion consumer of an accepted dependency triple* (S, Q, D, R, H, C, P, N) *must enter through the four-face route*

$$D, \quad S, \quad Q, \quad R$$

before it reads a $\mathsf{Real}^{\uparrow}$ *endpoint. The gate is carried only by the componentwise* hsame *row* H*, the displayed* Cont *route* C*, the* Pkg *provenance* P*, and the local* $\mathsf{NameCert}$ *row* N*.*

No endpoint read is licensed from quotient streams, selected host limits, representative choices, host equality, ambient completeness, arithmetic or order packages, or metric-completeness rows.

Proof. First apply Definition 38.429. It states that every completion-facing consumer must pass through the finite DyadicRatCore, StreamName, RegSeqRat, and local Real seal route before reading a $\mathsf{Real}^{\uparrow}$ endpoint.

Next apply Definition 38.432. The boundary repeats the same source-entry order for completion-facing consumers while the packet keeps the tuple projection order (S, Q, D, R, H, C, P, N), and identifies H, C, P, N as the only transport, route, provenance, and certificate rows attached to that entry.

Finally apply Definition 38.433. Since no one of the four faces can be removed while retaining an accepted current seal source, the entry route is a gate rather than an optional presentation of the endpoint. □

Theorem 38.435 (Real RegSeqRat StreamName no completion escape)**.** *Completion-facing consumers of an accepted* $\mathsf{Real}^{\uparrow}$ *RegSeqRat StreamName dependency triple cannot bypass the four faces through quotient streams, selected host limits, representative choices, host equality, ambient completeness, arithmetic packages, order packages, or metric-completeness rows. Their only accepted completion route is the displayed source path through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation face, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window face, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback face, and the local* $\mathsf{Real}^{\uparrow}$ *seal face.*

Proof. Use route exhaustion to identify the only seal-facing path. By Definition 38.428, that path is the displayed finite source route through D, S, Q, R with H, C, P, N, even though the packet projection inventory is written as (S, Q, D, R, H, C, P, N).

Use the current-phase gate to place every Phase Real and Completion endpoint read behind the same path. A completion-facing consumer therefore cannot reach the endpoint before the four faces have all been read.

It remains to exclude escape coordinates. The finite-window completion boundary of Definition 38.432 and the Cauchy-completion interface of Definition 38.429 both remove quotient streams, selected host limits, representative choices, host equality, ambient completeness, arithmetic and order packages, and metric-completeness rows from the exported boundary. Since minimality also prevents deleting any face, there is no completion route outside the four displayed faces. □

Theorem 38.436 (Real RegSeqRat StreamName endpoint determinacy)**.** *Let* (S, Q, D, R, H, C, P, N) *and* $(S', Q', D', R', H', C', P', N')$ *be accepted* $\mathsf{Real}^{\uparrow}$ *RegSeqRat StreamName dependency triples. Suppose the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger rows* D, D' *are read through the advertised* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows* S, S' *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows* Q, Q' *using only the* hsame *transport rows in* H, H'*, and suppose this is the same displayed route through chapter 291, chapter 126, and chapter 301.*

Then any public $\mathsf{Real}^{\uparrow}$ *endpoint comparison between the two consumers factors only through the finite packets*

$$(S, Q, D, R, H, C, P, N) \quad \textit{and} \quad (S', Q', D', R', H', C', P', N').$$

In particular the comparison has no coordinate for quotient streams, host real equality, selected host limits, representative choice, ambient completeness, arithmetic or order packages, or metric-completeness rows.

Proof. First apply Definition 38.428 to each accepted consumer. Each endpoint read reaches the $\mathsf{Real}^{\uparrow}$ seal only through its displayed $\mathsf{DyadicRatCore}^{\uparrow}$ ledger row, $\mathsf{StreamName}^{\uparrow}$ finite-window row, $\mathsf{RegSeqRat}^{\uparrow}$ readback row, local seal row, hsame transport, Cont route, Pkg provenance, and local NameCert row.

Next use Definition 38.429. The completion-facing boundary is therefore the same finite route, so an endpoint comparison cannot consult data outside the two displayed packets before it compares the public endpoints.

Finally apply Definition 38.431. That theorem exhausts the coordinate supply for every accepted seal consumer by the rows named in the dependency triple. Since the hypotheses identify the window, readback, and dyadic route through the three sibling chapters, the remaining public comparison is determined by the two finite packets alone, with no quotient-stream, host-equality, selected-limit, representative-choice, ambient-completeness, arithmetic, order, or metric-completeness coordinate available. □

Theorem 38.437 (Real RegSeqRat StreamName finite-window pullback classifier)**.** *Let*

$$X = (S, Q, D, R, H, C, P, N) \quad \textit{and} \quad Y = (S', Q', D', R', H', C', P', N')$$

be accepted $\mathsf{Real}^{\uparrow}$ *RegSeqRat StreamName dependency triples. The two triples classify as the same completion-facing* $\mathsf{Real}^{\uparrow}$ *finite-window packet if and only if all of the following displayed rows agree componentwise:*

1. *the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows* S, S'*;*
2. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows* Q, Q'*;*
3. *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger rows* D, D'*;*
4. *the* $\mathsf{Real}^{\uparrow}$ *seal rows* R, R'*;*
5. *the componentwise* hsame *transports displayed in* H, H'*;*
6. *the displayed* Cont *routes in* C, C'*;*
7. *the* Pkg *provenance rows* P, P'*;*
8. *the local* $\mathsf{NameCert}$ *rows* N, N'*.*

Equivalently, the classifier for accepted Real RegSeqRat StreamName dependency triples is the finite pullback of the four open-phase faces $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *together with the displayed transport, route, provenance, and local naming rows. It has no coordinate for quotient streams, host equality, selected limits, ambient completeness, arithmetic or order packages, or metric-completeness rows.*

Proof. For the forward direction, assume the two accepted triples classify as the same completion-facing finite-window packet. Apply Definition 38.428 to both triples. Each accepted route is exhausted by the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Now apply Definition 38.436. Since a public endpoint comparison cannot consult any coordinate outside those finite packets, equality of the completion-facing packet projects to componentwise agreement of the stream-name window, regular readback, dyadic ledger, real seal, transport, route, provenance, and local naming rows.

For the reverse direction, assume the eight displayed rows agree componentwise. Use Definition 38.413 to repack the four open-phase faces as a single finite pullback packet. The matching hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows provide exactly the gluing data required by that pullback.

Finally read the resulting packet through Definition 38.427. The local dependency triple definition accepts precisely those rows as the completion-facing Real finite-window packet, so the two accepted triples classify the same packet. The exclusion clause in the definition removes quotient

streams, host equality, selected limits, ambient completeness, arithmetic and order packages, and metric-completeness rows from the classifier. □

Theorem 38.438 (Real RegSeqRat StreamName dyadic window lock)**.** *Let*

$$X = (S, Q, D, R, H, C, P, N) \quad \textit{and} \quad Y = (S', Q', D', R', H', C', P', N')$$

be accepted $\mathsf{Real}^{\uparrow}$ *RegSeqRat StreamName dependency triples. Suppose the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows* S, S'*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows* Q, Q'*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger rows* D, D'*, and the* $\mathsf{Real}^{\uparrow}$ *seal rows* R, R' *agree componentwise under the shown* hsame *transports in* H, H'*, the displayed* Cont *routes in* C, C'*, the package rows* P, P'*, and the local* NameCert *rows* N, N'*.*

Then every completion-facing $\mathsf{Real}^{\uparrow}$ *consumer comparison between* X *and* Y *factors through exactly the common finite four-face window lock*

$$(S, Q, D, R, H, C, P, N) \simeq (S', Q', D', R', H', C', P', N').$$

That lock is the shared pullback of the $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger face, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window face, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback face, and the local* $\mathsf{Real}^{\uparrow}$ *seal face, with no quotient stream, selected host limit, host equality, representative choice, ambient completeness principle, arithmetic package, order package, or metric-completeness row.*

Proof. First apply Definition 38.428 to both accepted triples. Each seal-facing route is exhausted by the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and local NameCert rows.

Next apply Definition 38.429. It turns the same exhausted route into the completion-facing boundary, so a consumer comparison has no access to data before or after the finite route except through the rows shown in the two packets.

Use Definition 38.431 to remove the remaining escape coordinates. Quotient streams, selected limits, representative choices, host equality, ambient completeness, arithmetic and order packages, and metric-completeness rows are not coordinates of the accepted dependency triples.

Finally apply Definition 38.437. The componentwise agreement hypotheses are exactly the pullback agreement conditions for the four open-phase faces and their structural rows. Therefore every completion-facing comparison factors through that common finite window lock and through nothing larger. □

Theorem 38.439 (Real L10 four-face route lock)**.** *Let*

$$X = (S, Q, D, R, H, C, P, N) \quad \textit{and} \quad Y = (S', Q', D', R', H', C', P', N')$$

be accepted $\mathsf{Real}^{\uparrow}$ *RegSeqRat StreamName dependency triples. Every current Phase Real and Completion consumer comparison between* X *and* Y *factors through exactly the four open-phase faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

The only comparison structure available to that factorization is the displayed hsame*,* Cont*,* Pkg*, and* NameCert *rows in the two packets.*

Thus no quotient stream, host equality, selected limit, ambient completeness, arithmetic package, order package, or metric-completeness row is available to the comparison. The comparison is locked to the local finite route through the dyadic observation ledger, stream-name finite window, regular-rational readback, and local real seal.

Proof. First apply Definition 38.428. It exhausts every accepted seal-facing route by the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ ledger row, $\mathsf{StreamName}^{\uparrow}$ finite-window row, $\mathsf{RegSeqRat}^{\uparrow}$ readback row, local $\mathsf{Real}^{\uparrow}$ seal row, and the shown hsame, Cont, Pkg, and NameCert rows.

Next apply Definition 38.437. The classifier for accepted Real RegSeqRat StreamName dependency triples is the finite pullback of those four open-phase faces together with the displayed structural rows, so a consumer comparison has no independent coordinate outside that pullback.

Finally apply Definition 38.438. The common finite window lock forces every completion-facing comparison between accepted packets through the shared four-face window. Since the three results already remove quotient streams, host equality, selected limits, ambient completeness, arithmetic and order packages, and metric-completeness rows, the Real L10 comparison route is exactly the four-face route stated above. □

Theorem 38.440 (Real RegSeqRat StreamName terminal common-source lock)**.** *Let*

$$X = (S, Q, D, R, H, C, P, N) \quad \textit{and} \quad Y = (S', Q', D', R', H', C', P', N')$$

be accepted $\mathsf{Real}^{\uparrow}$ *RegSeqRat StreamName dependency triples. Suppose the* $\mathsf{StreamName}^{\uparrow}$ *finite-window faces* S, S'*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback faces* Q, Q'*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger faces* D, D'*, the* $\mathsf{Real}^{\uparrow}$ *seal faces* R, R'*, and the displayed* hsame*,* Cont*,* Pkg*, and local* NameCert *rows* H, H'*,* C, C'*,* P, P'*, and* N, N' *agree componentwise.*

Then every terminal $\mathsf{Real}^{\uparrow}$ *endpoint consumer comparison between* X *and* Y *factors through the same common source packet*

$$(S, Q, D, R, H, C, P, N) \simeq (S', Q', D', R', H', C', P', N').$$

No such terminal comparison can branch through a quotient stream, selected host limit, host equality, ambient completeness principle, arithmetic package, order package, or metric-completeness row hidden behind the endpoint.

Proof. First apply Definition 38.439. It identifies every current Phase Real and Completion consumer comparison with the displayed four-face route through the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces and their structural rows.

Next apply Definition 38.437. The componentwise agreement assumptions are precisely the pullback classifier coordinates for the accepted dependency triples, so the two endpoint packets share the same source packet rather than merely matching at the final seal.

Finally apply Definition 38.438. The shared finite window lock is already the common source for completion-facing comparisons. Together with the exclusion clauses in the dependency triple, this prevents a terminal endpoint comparison from branching through quotient streams, selected host limits, host equality, ambient completeness, arithmetic or order packages, or metric-completeness rows. □

Theorem 38.441 (Real RegSeqRat StreamName four-face consumer boundary)**.** *Let*

$$X = (S, Q, D, R, H, C, P, N) \quad \textit{and} \quad Y = (S', Q', D', R', H', C', P', N')$$

be accepted $\mathsf{Real}^{\uparrow}$ *RegSeqRat StreamName dependency triples. Suppose the* $\mathsf{StreamName}^{\uparrow}$ *finite-window faces,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback faces,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger faces,* $\mathsf{Real}^{\uparrow}$ *seal faces, and the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *rows agree componentwise between* X *and* Y*.*

Then every current Phase Real and Completion consumer boundary over $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, completion-facing reads, or stream-facing reads is the same finite boundary packet*

$$(S, Q, D, R, H, C, P, N) \simeq (S', Q', D', R', H', C', P', N').$$

The boundary exposes only the DyadicRatCore ledger face, the StreamName finite-window face, the RegSeqRat readback face, the RealUp seal face, and the displayed hsame, Cont, Pkg, *and* NameCert *rows. Quotient streams, host equality, selected limits, ambient completeness, arithmetic or order packages, and metric-completeness rows are not exported through this consumer boundary.*

Proof. Begin with Definition 38.434. It says that the current Phase Real and Completion consumers can read only the open Real RegSeqRat StreamName interface and the displayed structural rows.

Next use Definition 38.437. The componentwise agreement hypotheses are exactly the finite pullback coordinates of that interface, so Real-facing, completion-facing, and stream-facing reads receive one packet rather than separate witnesses.

Apply Definition 38.439 to identify the available route as the four-face route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Then apply Definition 38.440 to turn the four agreed faces and their displayed rows into the common terminal source.

The exclusion clauses from those route-lock theorems remove every ambient coordinate outside the packet. Hence quotient streams, host equality, selected limits, ambient completeness, arithmetic and order packages, and metric-completeness rows cannot be observed by any current consumer boundary, which leaves exactly the finite boundary packet stated above. □

Definition 38.442 (Real L10 dependency lattice)**.** *The* $\mathsf{Real}^{\uparrow}$ *L10 dependency lattice is the ordered finite certificate route whose source rows are read in this order:*

1. *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows supplied by chapter 291;*
2. *the* $\mathsf{StreamName}^{\uparrow}$ *finite stream-window rows supplied by chapter 126;*
3. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational classifier rows supplied by chapter 301;*
4. *the local* $\mathsf{Real}^{\uparrow}$ *seal, endpoint readback, and provenance rows.*

The route is finite: it is carried by the displayed BHist *packet, transported only by* hsame*, read only through* Cont*, and named only by the local* NameCert *row before the* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*

Theorem 38.443 (Real L10 source route non-escape)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *source-route consumer for the L10 dependency lattice must read the* $\mathsf{DyadicRatCore}^{\uparrow}$ *dyadic observation rows, then the* $\mathsf{StreamName}^{\uparrow}$ *finite stream-window rows, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational classifier rows, and only then the local* $\mathsf{Real}^{\uparrow}$ *seal rows. The consumer may transport these rows by the displayed* hsame *coordinates, read them through the displayed* Cont *route, and package them with the displayed* Pkg *and local* NameCert *rows.*

No accepted source-route consumer has a coordinate for a quotient stream, host completion, countable choice, host real equality, selected host limit, ambient completeness principle, arithmetic package, order package, or metric-completeness row.

Proof. Start with the carrier and source specification in Definition 38.1 and Definition 38.7. The carrier is a sealed RegSeqRat name over DyadicRatCore observations, and the source specification lists exactly the dyadic observation layer, the stream-name layer, and the regular-sequence certificate layer.

Now apply the concrete seal handoff in Definition 38.407. It reads those layers through the sibling chapters chapter 291, chapter 126, and chapter 301, then repacks the result as the local $\mathsf{Real}^{\uparrow}$ seal handoff. This gives the ordered L10 route of Definition 38.442.

Finally use the exhaustion and boundary theorems for the Real RegSeqRat StreamName dependency triple, Definition 38.428 and Definition 38.429. They say that every accepted consumer is exhausted by the finite rows of the displayed packet, with only hsame, Cont, Pkg, and NameCert

structural data. Since none of the cited source, handoff, or dependency-triple blocks exports a quotient stream, host completion, countable choice, host real equality, selected host limit, ambient completeness, arithmetic, order, or metric-completeness coordinate, the consumer has no route to escape the L10 lattice. □

Lean4 ✓ `BEDC.Derived.RealUp.RealL10DependencyLattice source route nonescape`

Theorem 38.444 (Real L10 interface totality)**.** *Every current Phase Real and Completion interface read of an accepted* $\mathsf{Real}^{\uparrow}$ *L10 dependency-lattice packet factors through exactly the four displayed faces of Definition 38.442:* $\mathsf{DyadicRatCore}^{\uparrow}$ *observations,* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational rows, and the local* $\mathsf{Real}^{\uparrow}$ *seal and readback rows. The transport allowed between these faces is only the displayed* hsame *data, the displayed* Cont *routes, the displayed* Pkg *provenance, and the local* NameCert *data; no further quotient, completion, host-real, selector, choice, arithmetic, order, or metric-completeness interface row is exported.*

Lean4 ✓ `BEDC.Derived.RealUp.RealL10DependencyLatticeInterfaceTotality`

Proof. Start with the ordered source route of Definition 38.443. It confines accepted L10 consumers to the dyadic observation layer, the StreamName finite-window layer, the RegSeqRat regular-rational layer, and the local Real seal layer, with transport only through the displayed structural rows.

Next use the open-phase consumer theorem Definition 38.409. It identifies the current Phase Real and Completion reads with the same four faces, so an interface consumer cannot insert a fifth source row between the dependency lattice and the public open-phase surface.

The two sibling handoff theorems give the middle faces. By Definition 126.132, finite StreamName windows reach the Real handoff only through their displayed window, RegSeqRat, Real-boundary, transport, continuation, provenance, and naming rows. By Definition 301.22, the regular-rational face supplies exactly the seal-facing rows consumed by $\mathsf{Real}^{\uparrow}$.

Finally apply the current-surface theorem for the dependency triple, Definition 38.430. It repackages the same DyadicRatCore, StreamName, RegSeqRat, and local Real rows as the current interface surface. Since every cited route exports only hsame, Cont, Pkg, and NameCert data besides those four faces, the interface read is exhausted by the displayed L10 lattice. □

Theorem 38.445 (Real L10 terminal face order)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *open-phase terminal read consumes the four faces of Definition 38.442 in the order* $\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$*. The terminal* $\mathsf{Real}^{\uparrow}$ *seal cannot be read before the dyadic observation rows, the finite-window rows, and the regular-rational classifier rows have been displayed through the same* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *surface.*

Consequently a terminal read has no coordinate through which to consume quotient stream equality, selected limits, host real equality, ambient completeness, or any seal-facing row outside the displayed four-face route.

Lean4 ✓ `BEDC.Derived.RealUp.RealL10TerminalFaceOrder`

Proof. Start from the ordered route in Definition 38.442. The lattice lists the dyadic observation face, the StreamName finite-window face, the RegSeqRat classifier face, and only then the local Real seal face.

Apply the non-escape theorem Definition 38.443. It prevents any accepted source-route consumer from bypassing the dyadic, stream, or regular-rational faces before the local seal is reached.

Next use interface totality, Definition 38.444. Since every open Phase Real and Completion interface read factors through exactly those four faces, a terminal read cannot insert a further interface row between the RegSeqRat classifier and the Real seal.

The middle dependency is exact by Definition 126.349: the stream window read is pulled back to the same dyadic and regular-rational source surface. The final handoff is exact by Definition 301.22: the Real seal consumes the regular-rational source rows already displayed by the finite window.

Coordinate exhaustion then excludes all other terminal readings. The cited routes expose only BHist, hsame, Cont, Pkg, and NameCert data over the four named faces, so quotient stream equality, selected limits, host real equality, ambient completeness, and outside seal data have no terminal coordinate to consume. □

Theorem 38.446 (Real L10 terminal comparison exhaustion)**.** *Let X and Y be accepted terminal* $\mathsf{Real}^{\uparrow}$ *L10 reads. Every completion-facing comparison between X and Y factors through the same four faces*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

displayed in Definition 38.442. The comparison may use only the common BHist *packet, the displayed* hsame *transports, the displayed* Cont *routes, the displayed* Pkg *provenance, and the local* NameCert *coordinates of those faces.*

No completion-facing comparison of X and Y has a coordinate for quotient stream equality, selected limits, host real equality, ambient completeness, arithmetic or order packages, or metric-completeness rows.

Proof. Apply the terminal face order theorem, Definition 38.445, to both accepted reads. It places the dyadic observation face, the finite StreamName window face, the RegSeqRat classifier face, and the Real seal face in the same terminal order for X and Y.

Next apply the four-face route lock, Definition 38.439. A completion-facing comparison cannot leave the displayed route once the two terminal reads have been accepted on that route; its transport and readback data remain confined to BHist, hsame, Cont, Pkg, and NameCert coordinates.

The shared finite surface is supplied by Definition 126.356. It identifies the StreamName window, RegSeqRat readback, DyadicRatCore ledger, and Real seal boundary as one pullback surface for the two terminal reads.

Finally use the observation triangle Definition 38.384. The dyadic, stream, and regular-rational observations meet on the same finite triangle before the Real seal is consumed. Since the cited routes export no quotient stream equality, selected limit, host real equality, ambient completeness, arithmetic or order package, or metric-completeness coordinate, the comparison is exhausted by the four displayed faces. □

Theorem 38.447 (Real L10 four-source audit-clean handoff)**.** *Every current Phase Real and Completion exit read of an accepted* $\mathsf{Real}^{\uparrow}$ *packet factors through the ordered four-source packet*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The only structural transports available to the handoff are the displayed BHist *packets,* hsame *transports,* Cont *routes,* Pkg *provenance rows, and local* NameCert *rows attached to those four sources. In particular, the handoff admits no quotient stream equality, selected limit, host real equality, ambient completeness, arithmetic package, order package, metric-completeness row, or bridge row as an additional source surface.*

Proof. Start from the Real L10 dependency lattice, Definition 38.442. It names the four source faces and places the dyadic observation rows before StreamName windows, RegSeqRat readback, and the local $\mathsf{Real}^{\uparrow}$ seal.

Apply interface totality and terminal face order, Definition 38.444 and Definition 38.445. These results make every current Phase Real and Completion interface read pass through the same ordered packet before any terminal exit can consume the Real seal.

Read the checked source surfaces in that order. The DyadicRatCore face is the standard-source bridge `DyadicRatCoreCarrier_standard_source_bridge`, the StreamName face is supplied by `RatStreamName_certificate_fields`, the RegSeqRat face is the real-seal handoff `RegSeqRatStreamCarrier_rea` and the Real face is the standard bridge `RealUp_StdBridge`.

Each cited surface exports only its local row data into the ordered packet. Thus the common handoff can transport by BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows, and has no coordinate through which to import any extra completion, arithmetic, order, metric, quotient, limit, or bridge surface. □

Theorem 38.448 (Real L10 dependency-lattice exit handoff)**.** *Every current Phase Real and Completion exit read of an accepted* $\mathsf{Real}^{\uparrow}$ *packet factors through exactly the four faces*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The handoff surface consists only of the displayed BHist *packets, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance rows, and the local* $\mathsf{NameCert}$ *rows attached to those four faces.*

Consequently the exit read has no coordinate for quotient streams, selected limits, host real equality, ambient completeness, arithmetic or order packages, metric-completeness rows, or any other completion-facing structure outside the displayed dependency lattice.

Proof. Start with the dependency lattice of Definition 38.442. It names the only route available to the current exit surface: dyadic observations, finite StreamName windows, RegSeqRat regular-rational readback, and the local $\mathsf{Real}^{\uparrow}$ seal.

Apply source-route non-escape, Definition 38.443. This prevents an accepted exit read from entering through a hidden source, quotient representative, selected limit, host real value, or ambient completeness row before reaching the displayed four faces.

Next use interface totality and terminal face order, Definition 38.444 and Definition 38.445. Together they make every current Phase Real and Completion interface read pass through the same ordered faces, with only BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ transport between them.

Finally apply terminal comparison exhaustion, Definition 38.446. It says that even the terminal comparison surface has no further coordinate beyond the same four-face packet. Thus quotient streams, selected limits, host real equality, ambient completeness, arithmetic or order packages, metric-completeness rows, and hidden completion data are not part of the exit handoff. □

Theorem 38.449 (Real L10 metric boundary non-escape)**.** *Every accepted current Phase Real or Completion consumer of a* $\mathsf{Real}^{\uparrow}$ *L10 packet factors through the four-face route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

before any $\mathsf{Met}^{\uparrow}$ *consumer or metric-completeness consumer can read the packet. The visible route consists only of the DyadicRatCore observation face, the StreamName finite-window face,*

the RegSeqRat regular-rational classifier face, the local $\mathsf{Real}^{\uparrow}$ *seal face, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates.*

The route exports no `MetricDistanceWitness`*, separatedness row, completeness row, Cauchy-limit selector, metric triangle row, or ambient metric-completeness coordinate. Any* $\mathsf{Met}^{\uparrow}$*-facing read is therefore an external consumer boundary for an already sealed* $\mathsf{Real}^{\uparrow}$ *packet, not an input row used to construct the Real seal.*

Proof. First apply the terminal comparison exhaustion theorem, Definition 38.446. It keeps every completion-facing comparison between accepted terminal reads on the same four-face surface, using only the common BHist, hsame, Cont, Pkg, and NameCert coordinates.

Next apply the four-face canonical route, Definition 38.450. It says that every current Phase Real or Completion consumer of the $\mathsf{Real}^{\uparrow}$ packet must pass through the ordered DyadicRatCore, StreamName, RegSeqRat, and local Real faces before the consumer surface is available.

The finite overlap of those faces is the pullback surface of Definition 126.356. Thus the StreamName window, RegSeqRat readback, DyadicRatCore ledger, and Real seal boundary are read as one displayed route.

Finally view the $\mathsf{Met}^{\uparrow}$ public interface only as a downstream consumer boundary. Because the cited Real route exports no metric distance witness, separatedness row, completeness row, Cauchy-limit selector, metric triangle row, or ambient metric-completeness coordinate, no metric consumer can supply an input used by the $\mathsf{Real}^{\uparrow}$ L10 seal. □

Theorem 38.450 (Real L10 four-face canonical route)**.** *Every accepted current Phase Real or Completion consumer of a* $\mathsf{Real}^{\uparrow}$ *L10 packet has a canonical finite route through exactly the four faces*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

of Definition 38.442. The route is displayed only by the common BHist *packet, the shown* hsame *transports, the shown* Cont *routes, the shown* Pkg *provenance, and the local* NameCert *rows.*

If two route presentations have the same four faces and the same displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, then they induce the same consumer surface. No quotient stream, selected host limit, host real equality, countable-choice selector, ambient completeness principle, arithmetic or order package, or metric-completeness row can serve as an alternate route.*

Proof. The four faces are the faces of the dependency lattice in Definition 38.442. Apply the non-escape theorem, Definition 38.443, to exclude any route that leaves the dyadic, StreamName, RegSeqRat, and local Real seal sequence.

Next apply interface totality, Definition 38.444. It says that every current Phase Real and Completion interface read factors through exactly those four faces, using only the displayed hsame, Cont, Pkg, and NameCert rows. The terminal order theorem, Definition 38.445, fixes their order as $\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$.

For comparisons of two accepted presentations, apply Definition 38.446. It confines every completion-facing comparison to the common BHist, hsame, Cont, Pkg, and NameCert data over the same ordered four faces.

The shared finite consumer surface is then the pullback surface of Definition 126.356 together with the observation triangle of Definition 38.384. These identify the dyadic observations, finite stream windows, regular-rational readback, and Real seal boundary before the consumer surface is read. With no exported coordinate for quotient streams, selected host limits, host real equality, countable choice, ambient completeness, arithmetic or order packages, or metric-completeness rows, no alternate route remains. □

Theorem 38.451 (Real StreamName RegSeqRat seal lattice)**.** *Every completion-facing* $\mathsf{Real}^{\uparrow}$ *consumer that also carries a* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row factors through the ordered four faces*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

of Definition 38.442. The $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row is only the compatibility row for the already displayed seal route; it does not add a second completion face, quotient stream equality, selected limit, host real equality, ambient completeness, or metric-completeness row.*

Proof. Start with Definition 38.442. Its source route is the ordered finite lattice of dyadic observation rows, finite StreamName windows, regular-rational classifier rows, and the local Real seal.

Apply Definition 38.450. Every current Phase Real or Completion consumer already has a canonical route through exactly those four faces, with only the common BHist, hsame, Cont, Pkg, and NameCert rows as structural data.

For completion-facing comparisons, use Definition 38.446. It keeps both terminal reads on the same four-face route. The shared finite surface is the pullback of Definition 126.356, so the StreamName window, RegSeqRat readback, DyadicRatCore ledger, and Real seal boundary remain one displayed route.

The extra $\mathsf{CauchyLimitSeal}^{\uparrow}$ row is therefore read as the compatibility surface supplied by chapter 386. Since the canonical route and terminal comparison already exhaust the consumer surface, the seal row cannot add quotient stream equality, selected limits, host real equality, ambient completeness, or metric-completeness data. □

Theorem 38.452 (RealUp stationary partition normal-form boundary)**.** *Every stationary-rational partition normal-form read used by the Real-completeness diagonal route is accepted by* $\mathsf{Real}^{\uparrow}$ *only through the four displayed faces of Definition 38.442:*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The accepted read consists of DyadicRatCore observation rows, StreamName finite-window rows, RegSeqRat regular-rational row classifiers, and the local $\mathsf{Real}^{\uparrow}$ *seal row, together with the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates.*

In particular, the normal form of Definition 9238.16 may be consumed on the concrete $\mathsf{Real}^{\uparrow}$ *surface only through this four-face route. It supplies no coordinate for quotient stream equality, selected host limits, countable choice, ambient completeness, arithmetic or order packages, or metric-completeness rows.*

Proof. Start with the stationary normal-form theorem in Definition 9238.16. Its finite partition spine reduces every stationary segment ledger to a one-window classifier and then feeds the diagonal representatives through the stationary rational RealUp embedding route.

Apply the Real L10 four-face canonical route of Definition 38.450. Any current Phase Real or Completion consumer of that diagonal read must therefore pass through exactly the displayed DyadicRatCore, StreamName, RegSeqRat, and local RealUp faces, using only the common BHist, hsame, Cont, Pkg, and NameCert rows.

The seal compatibility is the seal lattice of Definition 38.451. It reads the completion-facing seal as compatibility for the already displayed StreamName and RegSeqRat handoff, not as a second completion face.

For comparisons between two stationary partition presentations, use Definition 38.446. It keeps both terminal reads on the same four-face route and leaves no comparison coordinate outside the DyadicRatCore observations, finite StreamName windows, RegSeqRat rows, and local RealUp seal.

Thus the Real-completeness stationary partition normal form lands on the concrete L10 lattice as a finite four-face certificate. The cited routes export no quotient stream equality, selected host limit, countable-choice selector, ambient completeness principle, arithmetic or order package, or metric-completeness row, so none of those data can be read from the accepted $\mathsf{Real}^{\uparrow}$ surface. □

Theorem 38.453 (Real L10 stationary diagonal route exhaustion)**.** *For any current Phase Real or Completion consumer, access to a stationary partition diagonal read is admissible exactly when the read factors through the displayed four-face route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

of Definition 38.442. The admissible factorization consists of the DyadicRatCore observation face, the StreamName finite-window face, the RegSeqRat regular-rational face, and the local $\mathsf{Real}^{\uparrow}$ *seal face, together with the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates.*

Moreover, every comparison between two admissible stationary diagonal reads remains on the same four-face route. The correspondence supplies no quotient stream equality, selected host limit, countable-choice row, ambient completeness theorem, trichotomy row, arithmetic package, order package, or metric-completeness row.

Proof. For the forward direction, start with an admissible stationary partition diagonal read. Apply Definition 9238.16 to put the stationary partition data in its finite normal form, with the diagonal representatives presented through the stationary rational $\mathsf{Real}^{\uparrow}$ embedding route.

Now apply Definition 38.450. The current Phase Real or Completion consumer must read that normal form through exactly the displayed DyadicRatCore, StreamName, RegSeqRat, and local $\mathsf{Real}^{\uparrow}$ faces, using only the common BHist, hsame, Cont, Pkg, and NameCert rows. The seal compatibility is then the lattice handoff of Definition 38.451, so the completion-facing seal is only compatibility for the same displayed StreamName and RegSeqRat handoff.

For the reverse direction, suppose a stationary diagonal packet is already factored through those four faces with the displayed coordinates. The same normal-form theorem supplies the stationary partition diagonal read, and the four-face canonical route repacks the displayed dyadic observations, finite StreamName windows, regular-rational classifiers, and local seal as an admissible current consumer read.

It remains to check comparisons. Apply Definition 38.446. Any comparison between two such stationary diagonal reads stays on the same ordered four-face route and has no comparison coordinate outside the displayed BHist, hsame, Cont, Pkg, and NameCert data.

The route therefore exhausts stationary diagonal admissibility. Since the cited normal form, canonical route, seal lattice, and terminal comparison theorem do not export quotient stream equality, selected host limits, countable choice, ambient completeness, trichotomy, arithmetic or order packages, or metric-completeness rows, none of those data are available through this correspondence. □

Theorem 38.454 (Real L10 diagonal budget four-face ownership)**.** *Any current Phase Real and Completion terminal* $\mathsf{Real}^{\uparrow}$ *read carrying a diagonal-limit row or completion-facing budget row is accepted only when that row is displayed on the same finite packet*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

of Definition 38.442. The budget row is a consumer-side compatibility row over the displayed BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *support.*

It does not introduce quotient stream equality, selected host limits, countable-choice selectors, ambient completeness, metric-completeness rows, or a second diagonal budget face.

Proof. Start with the terminal $\mathsf{Real}^{\uparrow}$ read and apply Definition 38.457. The accepted terminal surface is identified with the finite packet over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, using only the displayed BHist, hsame, Cont, Pkg, and NameCert coordinates.

Next use Definition 38.713. It reads terminal-budget data through the same ordered four-face packet, so a completion-facing budget row cannot sit on a separate Real-side selector or on an additional metric-completeness face.

For the diagonal-limit row, apply Definition 646.75. That theorem places diagonal compatibility on the consumer side of the already displayed budget surface, not on quotient stream equality, selected host limits, countable choice, or ambient completeness.

Finally compare the resulting packet with the StreamName exit route by Definition 38.460. The DyadicRatCore observations, finite StreamName windows, RegSeqRat readback, and local $\mathsf{Real}^{\uparrow}$ seal remain the same terminal route. Hence the diagonal-budget row is owned by the existing four-face finite packet and no second diagonal budget face is exported. □

Theorem 38.455 (Real L10 terminal four-face correspondence)**.** *A terminal* $\mathsf{Real}^{\uparrow}$ *L10 read is accepted exactly when its visible rows factor through the four faces*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

of Definition 38.442. The factorization uses only displayed BHist *observations, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *coordinates on those four faces.*

Equivalently, any four-face packet with those coordinates repacks as the current terminal $\mathsf{Real}^{\uparrow}$ *seal read. The correspondence exports no quotient stream equality, selected host limit, countable-choice selector, ambient completeness principle, arithmetic package, order package, or metric-completeness row.*

Lean4 ✓ `BEDC.Derived.RealUp.RealL10TerminalFourFaceCorrespondence`

Proof. For the forward direction, apply Definition 38.450. It routes every current terminal Real and Completion read through the ordered DyadicRatCore, StreamName, RegSeqRat, and Real faces of the dependency lattice.

Next use Definition 38.446. It says that terminal comparison has no surface outside the displayed BHist, hsame, Cont, Pkg, and NameCert coordinates on the same ordered four faces. Thus an accepted terminal read has exactly the visible packet stated above.

For the reverse direction, start with a packet already factored through the four faces and the displayed coordinates. Apply Definition 38.451 to read the StreamName and RegSeqRat handoff as the terminal $\mathsf{Real}^{\uparrow}$ seal surface, with the DyadicRatCore observation ledger kept in the same lattice route.

The reverse repacking adds no hidden coordinate. Since the cited route, comparison, and seal theorems do not export quotient stream equality, selected host limits, countable choice, ambient completeness, arithmetic or order packages, or metric-completeness rows, the repacked terminal read is accepted precisely as the current Real seal read. □

Theorem 38.456 (Real L10 four-face no-completeness exactness)**.** *For every accepted current Phase Real and Completion terminal* $\mathsf{Real}^{\uparrow}$ *read, the exact accepted surface is the four-face packet*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

of Definition 38.442, together with displayed BHist, hsame, Cont, Pkg, *and* NameCert *rows on those faces. The read contains no quotient stream equality, selected host limit, countable-choice selector, ambient completeness principle, metric-completeness row, or standard bridge datum.*

Proof. Start with the dependency lattice of Definition 38.442. It names the available terminal route as the ordered DyadicRatCore, StreamName, RegSeqRat, and local Real faces.

Apply Definition 38.450. Every accepted current Phase Real and Completion terminal read must factor through those four faces and through the displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Next use Definition 38.451. The StreamName and RegSeqRat handoff is read only as seal compatibility for the same displayed route, with the DyadicRatCore observation face and the local $\mathsf{Real}^{\uparrow}$ face kept in the packet.

Finally apply Definition 38.455. The terminal correspondence repacks exactly that four-face surface as the accepted $\mathsf{Real}^{\uparrow}$ read and exports no quotient stream equality, selected host limit, countable choice, ambient completeness, metric-completeness row, or standard bridge datum. □

Theorem 38.457 (Real L10 four-face exactness)**.** *For every current Phase Real or Completion terminal* $\mathsf{Real}^{\uparrow}$ *read, acceptance is equivalent to factorization of its visible rows through the finite four-face packet*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

of Definition 38.442. The packet is exactly the displayed BHist *observations, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *coordinates on those four faces.*

Conversely, every finite packet with precisely those four faces and precisely those displayed coordinates determines the same accepted terminal $\mathsf{Real}^{\uparrow}$ *seal read. The exact boundary exports no quotient stream equality, selected host limit, host real equality, countable-choice selector, ambient completeness principle, arithmetic package, order package, metric-completeness row, or standard bridge row.*

Proof. For the forward direction, start with an accepted current Phase Real or Completion terminal read. Apply Definition 38.450 to route it through the ordered DyadicRatCore, StreamName, RegSeqRat, and local Real faces.

Next apply Definition 38.446. It confines terminal comparison to the common BHist, hsame, Cont, Pkg, and NameCert rows over the same ordered faces. Thus the accepted read supplies no visible coordinate beyond the finite packet in the statement.

For the reverse direction, suppose the visible rows already form such a four-face packet. Apply Definition 38.455 to repack the displayed rows as the terminal $\mathsf{Real}^{\uparrow}$ read, and use Definition 38.451 to read the StreamName and RegSeqRat handoff as the same local Real seal surface.

It remains to check exactness of the boundary. The non-escape theorem, Definition 38.443, excludes any route that leaves the displayed source lattice, while interface totality, Definition 38.444, says that every current Phase Real and Completion interface row is already accounted for by those displayed faces and coordinates. Therefore quotient stream equality, selected host limits, host real equality, countable choice, ambient completeness, arithmetic or order packages, metric-completeness rows, and standard bridge rows are not part of the accepted terminal boundary. □

Theorem 38.458 (Real L10 terminal pullback uniqueness)**.** *Let two current Phase Real and Completion terminal* $\mathsf{Real}^{\uparrow}$ *reads expose the same DyadicRatCore, StreamName, RegSeqRat, and local*

$\mathsf{Real}^{\uparrow}$ *faces, with the same displayed* BHist *observations, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* $\mathsf{NameCert}$ *coordinates. Then the accepted consumer boundary of the two reads is the same finite four-face pullback surface*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The uniqueness claim is only about this finite boundary packet. It does not identify quotient streams, host real values, selected host limits, countable-choice selectors, ambient completeness principles, arithmetic or order packages, metric-completeness rows, or standard bridge rows.

Lean4 ✓ `BEDC.Derived.RealUp.RealL10TerminalPullbackUniqueness`

Proof. Apply Definition 38.457 to each terminal read. Both accepted reads are identified with the finite packet over DyadicRatCore, StreamName, RegSeqRat, and the local Real seal, using only the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ coordinates.

The two identified packets have the same four faces and the same displayed coordinates by hypothesis. Apply Definition 38.455 to repack either packet as the terminal $\mathsf{Real}^{\uparrow}$ read; the repacking adds no hidden coordinate.

Use Definition 38.451 for seal compatibility. The StreamName and RegSeqRat handoff is the same local $\mathsf{Real}^{\uparrow}$ seal surface on both sides, so the consumer boundary is the common four-face pullback packet.

Finally apply non-escape and interface totality, Definition 38.443 and Definition 38.444. They keep the boundary inside the displayed source lattice and exhaust the current Phase Real and Completion interface rows, excluding quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, arithmetic or order packages, metric-completeness rows, and standard bridge rows. □

Theorem 38.459 (Real L10 terminal source lock)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal or completion-facing consumer in the L10 route is admitted exactly through the displayed source lock*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The lock consists of finite stream windows, dyadic endpoint and radius rows, the regular-sequence classifier handoff, componentwise hsame *transport, displayed* Cont *route replay,* Pkg *provenance, and the local* $\mathsf{Real}^{\uparrow}$ *seal. No quotient stream, host real equality, selected limit, ambient completeness principle, or hidden completion carrier is exported by this terminal route.*

Lean4 ✓ `BEDC.Derived.RealUp.RealL10TerminalSourceLock`

Proof. Start with the L10 dependency lattice of Definition 38.442. It displays the four source faces and fixes the structural rows to BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ before the local $\mathsf{Real}^{\uparrow}$ seal can be consumed.

Use the RegSeqRat source lattice pointer through Definition 38.407. The regular-sequence classifier handoff is read only after the StreamName finite windows and the DyadicRatCore observation rows have been displayed.

Next apply the RealUp seal handoff and the four-face route, Definition 38.451 and Definition 38.450. They place every current seal or completion-facing consumer on the same ordered route through DyadicRatCore, StreamName, RegSeqRat, and the local Real seal.

Finally use Definition 38.446 and Definition 38.455. These exhaust terminal comparisons by the displayed finite windows, dyadic endpoint and radius data, regular readback, transport, continuation replay, package provenance, and local naming. Since none of the cited rows carries quotient

streams, host real equality, selected limits, ambient completeness, or a hidden completion carrier, the terminal source lock is exact. □

Theorem 38.460 (Real L10 StreamName exit route correspondence)**.** *A current Phase Real and Completion terminal* $\mathsf{Real}^{\uparrow}$ *read is accepted by the Real L10 dependency lattice exactly when its visible finite packet is the same four-object exit route named by StreamName,*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Equivalently, the accepted packet is the displayed DyadicRatCore observation face, StreamName finite-window face, RegSeqRat regular-rational face, and local $\mathsf{Real}^{\uparrow}$ *seal face, with only the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows.*

This correspondence is only a paper-side exit surface. It exports no quotient stream equality, host sequence equality, selected host limit, countable-choice selector, ambient $\mathsf{Real}^{\uparrow}$ *completeness principle, metric-completeness row, arithmetic package, order package, or standard bridge row.*

Proof. For the forward direction, start with a current Phase Real and Completion terminal $\mathsf{Real}^{\uparrow}$ read accepted by the Real L10 dependency lattice. Apply Definition 38.457 to identify its visible rows with the finite four-face packet over DyadicRatCore, StreamName, RegSeqRat, and the local Real seal.

Next use the terminal source lock of Definition 38.459. It fixes the same terminal read to the displayed source route and prevents any additional completion carrier or host equality coordinate from entering the packet.

Identify this packet with the StreamName exit surface by Definition 126.500. The four objects are the same $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces, and the support rows remain exactly BHist, hsame, Cont, Pkg, and local NameCert.

Finally apply Definition 126.506. It keeps the route as paper-side exit data only, so quotient stream equality, host sequence equality, selected host limits, countable choice, ambient Real completeness, metric completeness, arithmetic or order packages, and standard bridge rows are outside the accepted surface.

For the reverse direction, suppose the visible finite packet is already the StreamName four-object exit route with the displayed support rows. Apply Definition 126.500 to read it as the current Phase Real and Completion exit packet.

Repack that packet through Definition 38.455. The DyadicRatCore observations, StreamName finite windows, RegSeqRat readback, and local Real seal become the terminal $\mathsf{Real}^{\uparrow}$ L10 read, with no hidden coordinate added.

Use Definition 38.451 for the final seal compatibility. It reads the StreamName and RegSeqRat handoff as the same local $\mathsf{Real}^{\uparrow}$ seal surface, so the Real L10 lattice accepts precisely the route named by StreamName and nothing beyond the displayed rows. □

Theorem 38.461 (Real L10 StreamName classifier pullback correspondence)**.** *For any two current Phase Real and Completion terminal* $\mathsf{Real}^{\uparrow}$ *reads accepted by the Real L10 dependency lattice, the reads have the same Real L10 public boundary exactly when their StreamName four-object classifier pullback agrees on the four faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

and on the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The correspondence is only over this finite public boundary. It does not identify quotient stream equality, host real equality, selected limits, countable-choice rows, completeness data, metric-completeness rows, arithmetic or order packages, or bridge rows.*

Proof. For the forward direction, assume the two terminal reads have the same Real L10 public boundary. Apply Definition 38.457 to each read to expose the DyadicRatCore, StreamName, RegSeqRat, and local Real faces together with the displayed support rows.

Use the boundary equality before any uniqueness claim. By Definition 38.446, a comparison between the two accepted terminal reads has no coordinate outside the displayed BHist, hsame, Cont, Pkg, and NameCert rows over the four named faces. Then Definition 38.455 repacks exactly those exposed rows as the terminal $\mathsf{Real}^{\uparrow}$ read and adds no hidden coordinate.

Therefore the two exposed finite packets have the same DyadicRatCore, StreamName, RegSeqRat, and local Real faces, and they agree componentwise on the displayed BHist, hsame, Cont, Pkg, and NameCert rows. Now apply Definition 126.514. The StreamName classifier pullback is the same four-object public surface because its whole support is precisely that common finite packet.

For the reverse direction, assume the StreamName four-object classifier pullback agrees on the four faces and displayed rows. Apply Definition 126.514 to read this as equality of the public classifier surface, and then use Definition 126.504 to recover the terminal four-object packet.

Repack the recovered packet by Definition 38.455. It supplies the terminal $\mathsf{Real}^{\uparrow}$ boundary from the common DyadicRatCore observations, StreamName finite windows, RegSeqRat readback, local Real seal, and displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Finally use the seal lattice of Definition 38.451. The repacked boundary is only the local four-face seal surface, so the reverse direction does not claim host real equality, quotient streams, selected limits, ambient completeness, arithmetic or order packages, metric-completeness rows, or bridge rows. Hence agreement of the StreamName classifier pullback gives exactly agreement of the Real L10 public boundary. □

Theorem 38.462 (Real L10 public-boundary classifier reflection)**.** *For any two current Phase Real and Completion terminal* $\mathsf{Real}^{\uparrow}$ *reads accepted by the Real L10 dependency lattice, equality of their Real L10 public boundary is equivalent to equality of the four-face classifier packet over*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

with exactly the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. Thus the public Real boundary is precisely the classifier surface formed by those four faces and rows.*

The reflection exports no quotient stream equality, host equality, selected limit, countable-choice row, completeness datum, arithmetic or order package, metric-completeness row, or bridge row.

Proof. For the forward direction, assume the two terminal reads have the same Real L10 public boundary. Apply Definition 38.461 to identify this equality with agreement of the StreamName four-object classifier pullback on the displayed four faces and support rows.

Transport the agreement through Definition 126.514. The StreamName classifier is the same finite classifier packet over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with the same BHist, hsame, Cont, Pkg, and NameCert coordinates.

For the reverse direction, suppose the four-face classifier packet agrees. Use Definition 126.514 to read that packet as equality of the StreamName public classifier surface, then apply Definition 38.458 to recover the unique terminal pullback boundary over the same four faces.

Finally apply Definition 38.461 in the reverse direction. The recovered terminal pullback is exactly the Real L10 public boundary, so equality of the classifier packet and equality of the public boundary determine each other.

The exclusion clauses in the cited Real L10 and StreamName pullback theorems are stable under this reflection. They rule out quotient streams, host equality, selected limits, countable

choice, completeness, arithmetic and order packages, metric-completeness rows, and bridge rows, so the public Real boundary has no coordinate beyond the stated four-face classifier surface. □

Theorem 38.463 (Real L10 terminal-window fusion section compatibility)**.** *Let $\mathcal{W}_L$ and $\mathcal{W}_R$ be current Phase Real and Completion terminal* $\mathsf{Real}^{\uparrow}$ *reads accepted by the Real L10 dependency lattice. Suppose their* $\mathsf{StreamName}^{\uparrow}$ *finite windows agree after terminal-window fusion through a certified common refinement that also carries the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, and suppose the induced* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-request sections agree after applying the terminal budget factorization to the same seal-facing request. Then $\mathcal{W}_L$ and $\mathcal{W}_R$ have the same Real L10 public boundary.*

Conversely, the Real L10 public boundary of such a terminal read determines exactly the fused $\mathsf{StreamName}^{\uparrow}$ *terminal-window packet, the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-request section surface, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger:*

$$\mathsf{StreamName}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

This compatibility exports no quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness rows, arithmetic or order packages, or bridge rows.

Proof. For the forward direction, first use Definition 126.623. The certified common refinement makes the two $\mathsf{StreamName}^{\uparrow}$ finite windows one fused terminal packet after transport of the same $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint and radius ledger, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, the $\mathsf{Real}^{\uparrow}$ seal, and the displayed support rows.

Next use Definition 301.142. Applied to the common seal-facing finite request, it identifies the RegSeqRat classifier, regularity, readback, hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{RegSeqRat}^{\uparrow}}$ rows with the finite request source section for both reads.

These two packets have the same four faces and support rows, so apply Definition 126.514. The fused StreamName terminal packet, the DyadicRatCore endpoint and radius ledger, and the RegSeqRat finite-request section determine one StreamName four-object classifier pullback over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Finally apply Definition 38.461. Agreement of that StreamName classifier pullback is exactly agreement of the Real L10 public boundary, so the two terminal $\mathsf{Real}^{\uparrow}$ reads have the same public boundary.

For the reverse direction, start from a fixed Real L10 public boundary. By Definition 38.461, it determines the StreamName four-object classifier pullback and therefore the displayed faces and support rows, including the DyadicRatCore endpoint and radius ledger. Reading this classifier through Definition 126.514 recovers the public fused terminal-window surface with that ledger as one determined face.

It remains to isolate the RegSeqRat finite-request section. Apply Definition 301.142 to the seal-facing finite request already present in the public boundary. The terminal budget consumer can factor only through the displayed source section, so the RegSeqRat section surface is determined by the same boundary data.

The same exclusion lists are stable under each cited theorem. None of the constructions introduces quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness rows, arithmetic or order packages, or bridge rows; hence the Real L10 public boundary determines exactly the fused StreamName terminal-window packet, the DyadicRatCore endpoint and radius ledger, and the RegSeqRat section surface, with nothing beyond those faces. □

Theorem 38.464 (Real L10 finite-window witness determinacy)**.** *For any current Phase Real and Completion terminal* $\mathsf{Real}^{\uparrow}$ *read accepted by the Real L10 dependency lattice, every finite-window witness consumed by the Real L10 public boundary is determined exactly by the fused* $\mathsf{StreamName}^{\uparrow}$ *terminal-window packet, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-request section, the local* $\mathsf{Real}^{\uparrow}$ *seal, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

If two presentations agree on those rows, then they have the same finite-window witness surface. Conversely, the public boundary recovers exactly those rows and no additional coordinate. The determinacy claim excludes quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness rows, arithmetic or order packages, and bridge rows.

Proof. Start with the terminal-window fusion section compatibility theorem, Definition 38.463. It identifies the Real L10 public boundary with the fused $\mathsf{StreamName}^{\uparrow}$ terminal-window packet, the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint and radius ledger, the $\mathsf{RegSeqRat}^{\uparrow}$ finite-request section surface, and the local $\mathsf{Real}^{\uparrow}$ seal over the displayed support rows.

For two presentations agreeing on those rows, apply Definition 126.623. The common refinement makes their $\mathsf{StreamName}^{\uparrow}$ windows the same fused terminal packet after transport along the same endpoint and radius ledger.

Next apply Definition 301.142. The common seal-facing finite request factors through the same RegSeqRat finite-request source section, so the classifier, regularity, readback, hsame, Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{RegSeqRat}^{\uparrow}}$ rows are the same finite witness data.

Transport the resulting four-face packet through Definition 38.461. Agreement of the StreamName classifier pullback is exactly agreement of the Real L10 public boundary, so the two presentations have the same finite-window witness surface.

Conversely, begin with the Real L10 public boundary. The reverse direction of Definition 38.463 recovers the fused StreamName terminal-window packet, the DyadicRatCore endpoint and radius ledger, and the RegSeqRat finite-request section surface. The local $\mathsf{Real}^{\uparrow}$ seal and the displayed BHist, hsame, Cont, Pkg, and NameCert rows are part of the same boundary packet.

Finally use the exclusion clauses from Definition 38.463 and Definition 38.461. They keep quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness rows, arithmetic or order packages, and bridge rows outside the public boundary, so the finite-window witness surface is exactly the displayed four-face data. □

Lean4 ✓ `BEDC.Derived.RealUp.RealL10FiniteWindowWitnessDeterminacy`

Lemma 38.465 (Real L10 source route foundation)**.** *Every terminal finite-window witness whose visible rows lie in the Real L10 dependency lattice is sourced by the ordered four faces*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

with only the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates. The foundation route introduces no host equality, quotient stream, selected limit, completeness datum, arithmetic or order package, or bridge row.*

Proof. First apply Definition 38.457. It identifies every accepted terminal read with the finite packet over DyadicRatCore, StreamName, RegSeqRat, and the local Real seal, using only the displayed support rows.

Next use Definition 38.455. The correspondence repacks precisely those displayed rows as the terminal $\mathsf{Real}^{\uparrow}$ read, so the four-face packet is already sufficient for the terminal witness.

Apply the terminal source lock of Definition 38.459. It fixes seal-facing and completion-facing consumers to the ordered source route before any witness is read from the public boundary.

Finally use Definition 38.464. The finite-window witness surface is determined by the fused StreamName terminal-window packet, the DyadicRatCore endpoint and radius ledger, the RegSeqRat finite-request section, the local Real seal, and the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows. None of these cited rows carries host equality, quotient streams, selected limits, completeness data, arithmetic or order packages, or bridge rows, so the source foundation is exactly the displayed four-face route. □

Theorem 38.466 (Real L10 source route exactness)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *finite-window witness admitted by the Real L10 dependency lattice is sourced exactly by the ordered rows*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

displayed in Definition 38.442, together with their visible BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *coordinates. This source route is the terminal finite-window face consumed by the L10 public boundary.*

No alternate route through host real equality, quotient streams, selected limits, metric completeness, ambient completeness, arithmetic packages, order packages, or standard bridge rows is available.

Proof. First expose the terminal finite-window face by Definition 38.465. Any accepted terminal witness is already sourced by the ordered four-face packet over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the local $\mathsf{Real}^{\uparrow}$ seal, with only the displayed support coordinates.

Use the terminal source lock, Definition 38.459. It fixes every seal or completion-facing consumer to the displayed ordered route and excludes hidden completion carriers before any witness is read by the public boundary.

Finally apply Definition 38.464. The public boundary determines exactly the fused StreamName terminal-window packet, the DyadicRatCore endpoint and radius ledger, the RegSeqRat finite-request section, the local Real seal, and the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Combining these clauses leaves no coordinate for host real equality, quotient streams, selected limits, metric completeness, ambient completeness, arithmetic or order packages, or standard bridge rows. Hence the source route for the terminal finite-window witness is exactly the displayed L10 lattice route. □

Theorem 38.467 (Real L10 StreamName-RegSeqRat completion route triangle)**.** *An accepted current Phase Real and Completion terminal* $\mathsf{Real}^{\uparrow}$ *read has the same public boundary whether it is read through the StreamName finite-window classifier pullback, through the RegSeqRat finite-request section, or through the Real L10 source route. The three sides agree exactly on the four faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

and on the displayed BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

This triangle exports no quotient stream equality, host real equality, selected limit, countable-choice row, completeness row, arithmetic or order package, metric-completeness row, or bridge row.

Proof. Read the StreamName side first. By Definition 38.461, agreement of the StreamName four-object classifier pullback is exactly agreement of the Real L10 public boundary over the displayed four faces and support rows.

Read the RegSeqRat side next. The finite-request section of Definition 301.142 is the same section used by Definition 38.463, so the regular-rational request contributes only its finite classifier, regularity, readback, transport, provenance, and local naming rows.

Now read the Real side. Definition 38.466 fixes every terminal finite-window witness to the ordered route $\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$, and Definition 38.464 says the public boundary recovers exactly that finite-window witness surface.

The three readings therefore present one finite route packet. Since each cited side carries the same exclusion list, no quotient stream equality, host real equality, selected limit, choice row, completeness row, arithmetic or order package, metric-completeness row, or bridge row can be added by moving around the triangle. □

Theorem 38.468 (Real L10 dependency lattice exit totality)**.** *Every current Phase Real and Completion terminal read factors through the ordered dependency lattice*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

of Definition 38.442. The factorization exposes the visible BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows for the DyadicRatCore endpoint and radius ledger, the StreamName terminal-window packet, the RegSeqRat finite-request section, and the local Real seal.*

Thus the present terminal surface is exactly the four-face route witnessed by the Real L10 source route, finite-window determinacy, StreamName-RegSeqRat completion triangle, StreamName completion classifier pullback, and RegSeqRat terminal-budget factorization.

Proof. Begin with source route exactness, Definition 38.466. It places every terminal finite-window witness on the ordered four-face route and records the visible support rows.

Use finite-window witness determinacy and the route triangle. Theorems 38.464 and 38.467 identify the public terminal read with the fused StreamName window, DyadicRatCore ledger, RegSeqRat finite-request section, and Real seal.

Finally apply the StreamName classifier pullback and the RegSeqRat budget factorization, Definition 126.514 and Definition 301.142. They provide the two sibling readings of the same finite packet, so every current terminal read factors through the displayed lattice and no further terminal face is needed. □

Theorem 38.469 (Real L10 dependency lattice seal nonescape)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal exported by the current Phase Real and Completion terminal surface carries only the ordered four-face lattice and its visible* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. It exports no quotient stream, selected host limit, countable choice, host real equality, ambient completeness, arithmetic or order package, metric-completeness row, or bridge row.*

Proof. Read the seal through the exit totality theorem. The accepted terminal surface is already the finite route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Use source route exactness and finite-window witness determinacy to fix the public boundary. These theorems leave no coordinate outside the four faces and their displayed support rows.

The route triangle, StreamName classifier pullback, and RegSeqRat terminal-budget factorization carry the same exclusion list on each side of the route. Since none of the cited packets has a coordinate for quotient streams, selected limits, choice, host equality, completeness, arithmetic, order, metric completeness, or bridge data, the exported seal cannot supply one. □

38.4 Real L10 current phase exit audit pullback

Theorem 38.470 (Real L10 four-face status lookup)**.** *Any accepted current Phase Real and Completion exit read through*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

reads four separate local closurestatus records. Each face contributes exactly the closurestatus, formalstatus, leantarget, and bridgestatus rows declared in its own local closurestatus block. The lookup cites those rows objectwise and does not cache their token values in the Real L10 exit audit section.

These four entries are objectwise face records. They are not an aggregate formalstatus token, an aggregate bridge row, or a route-level closurestatus record for the composite exit.

Proof. The four faces are the Real L10 faces named by Definition 38.442. The local records are read from the same concrete chapters that supply the face data: Definition 291.25 for $\mathsf{DyadicRatCore}^{\uparrow}$, Definition 126.311, Definition 126.314, and Definition 126.315 for $\mathsf{StreamName}^{\uparrow}$, Definition 301.22 for $\mathsf{RegSeqRat}^{\uparrow}$, and Definition 38.290 for $\mathsf{Real}^{\uparrow}$.

The cited theorem anchors locate the four local chapters, but this theorem does not copy their token values. The local closurestatus block for each face is the sole source for its closurestatus, formalstatus, leantarget, and bridgestatus rows.

By the two-axis convention of section 9467.2, a closure entry and a verification entry remain attached to the object whose closurestatus block contains them. Reading the four faces therefore produces four objectwise face records and does not create a fifth formalstatus token, route-level bridge row, or composite closurestatus record. □

Theorem 38.471 (Real L10 current phase exit audit pullback)**.** *For any accepted current Phase Real and Completion exit read through the four faces*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

of the $\mathsf{Real}^{\uparrow}$ *L10 dependency lattice, the audit boundary is exactly the product of the four local face records. Each face contributes exactly the closurestatus, formalstatus, leantarget, and bridgestatus rows declared in its own local closurestatus block, read by reference from that face and not restated as cached Real L10 status data.*

The exit packet contributes no fifth formal token, no aggregate bridge, no $\mathsf{Real}^{\uparrow}$ *completeness claim, no quotient stream, no selected limit, and no metric-completeness datum. Its only admissible audit read is the displayed four-face product, with each status entry imported by reference from the corresponding local closure record.*

Lean4 ✓ `BEDC.Derived.RealUp.RealL10CurrentPhaseExitAuditPullback`

Proof. The four faces are the faces named by Definition 38.442. Apply Definition 38.443 and Definition 38.444 to confine every accepted current Phase Real and Completion interface read to the displayed DyadicRatCore, StreamName, RegSeqRat, and local Real rows.

Next apply Definition 38.457. It identifies acceptance with the finite packet over exactly those four faces, carried only by the displayed BHist, hsame, Cont, Pkg, and local NameCert coordinates. The StreamName exit correspondence, Definition 38.460, names the same packet as the current Phase Real and Completion exit route.

It remains to read the audit status. Apply Definition 38.470. It reads the DyadicRatCore, StreamName, RegSeqRat, and RealUp closurestatus entries as four objectwise face records and excludes any aggregate formalstatus token or aggregate bridge row.

Therefore the exit audit is the product of the four cited local records. Since the exactness and correspondence theorems export no fifth face, no quotient stream, no selected limit, no Real completeness row, no metric-completeness row, and no aggregate bridge coordinate, the exit packet cannot contribute any additional audit datum. □

Theorem 38.472 (Real L10 four-face classifier pullback)**.** *Any accepted Phase Real and Completion classifier read over*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

is exactly the pullback of the four displayed classifier faces:

1. *the dyadic endpoint, radius, and distance ledger;*
2. *the* $\mathsf{StreamName}^{\uparrow}$ *finite-window classifier;*
3. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and common-tail classifier;*
4. *the local* $\mathsf{Real}^{\uparrow}$ *seal classifier.*

The pullback uses only BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support along the four faces. Conversely, agreement of these four classifier faces determines the same finite Real classifier route.*

This classifier pullback carries no quotient streams, no host real equality, no selected limits, no countable choice, no ambient completeness, no metric-completeness data, no standard bridge rows, and no aggregate formalstatus tokens.

Proof. Apply Definition 38.457. It presents the accepted Real L10 packet as finite data over the four displayed faces and leaves only the BHist, hsame, Cont, Pkg, and local NameCert coordinates as support for the classifier read.

Apply Definition 38.460. The StreamName finite-window route is the same route used by the current Phase Real and Completion exit packet, so the StreamName classifier face is not an extra carrier and does not introduce a quotient stream or selected limit.

Apply Definition 38.779. It states that classifier agreement across the dyadic ledger, finite StreamName windows, RegSeqRat regularity and common tails, and the local Real seal is exactly the sheaf gluing condition. Hence the four faces determine one finite Real classifier route, and any accepted route restricts back to those four faces.

Finally apply Definition 38.471. The audit row is read as the objectwise product of the same four faces. This keeps the classifier pullback aligned with the audit pullback while keeping the two rows independent: the classifier row does not create host real equality, countable choice, ambient completeness, metric-completeness data, standard bridge rows, or aggregate formalstatus tokens. □

Theorem 38.473 (Real L10 finite-window completion-exit factorization)**.** *Every accepted Phase Real and Completion finite-window exit read of a* $\mathsf{Real}^{\uparrow}$ *seal factors through exactly the four current-phase faces*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The factorization uses only the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows on those faces: the dyadic ledger face, the finite StreamName window face, the RegSeqRat regularity and common-tail face, and the local Real seal face.*

Conversely, matching records on these four local faces, together with matching BHist, hsame, Cont, Pkg, *and* NameCert *support rows, determines the same accepted finite-window Phase Real and Completion exit route.*

The factorization refuses quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness data, aggregate formalstatus tokens, and standard bridge rows.

Proof. First read the classifier side. Apply Definition 38.472. It identifies every accepted classifier read with the dyadic ledger, finite StreamName window, RegSeqRat regularity and common-tail, and local Real seal faces, carried only by the displayed BEDC support rows.

Next read the audit side. Apply Definition 38.471. The accepted Phase Real and Completion audit route is the product of the same four local face records, with status and bridge coordinates read objectwise from the face records rather than from a route-level cache.

Now compare this product with the completion interface. Apply Definition 38.726. It exhausts the L10 exit interface by exactly $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, together with the same BHist, hsame, Cont, Pkg, and NameCert support rows.

For the converse direction, the four matching local records give the same classifier pullback and the same objectwise audit pullback. The two-axis roadmap discipline keeps the status rows attached to their own faces, so status agreement is used only to identify the face records and not as evidence for classifier agreement.

Finally apply Definition 38.730. If any one of the four faces is removed or replaced, the accepted finite-window exit route is not present. The exclusions named in the statement therefore remain off-table: no quotient stream equality, host real equality, selected limit, countable choice, ambient completeness, metric-completeness datum, aggregate formalstatus token, or standard bridge row supplies a substitute route. □

Theorem 38.474 (Real L10 four-face status-classifier square)**.** *Any accepted Phase Real and Completion packet over*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

has a commuting status-classifier square. Its horizontal reads are the four classifier faces of Definition 38.472, and its vertical reads are the four local status records of Definition 38.470. Reading the classifier faces first and then reading status gives the same four objectwise records as reading the local status records first and then restricting them along the classifier faces.

The square adds no aggregate formalstatus token, no bridge row for the composite route, no quotient stream, no selected limit, and no completeness datum.

Proof. First locate the common source route. Apply Definition 38.443 and Definition 38.444. They confine every accepted packet to the same DyadicRatCore, StreamName, RegSeqRat, and RealUp faces and exhaust the current Phase Real and Completion interface rows.

Next read the classifier side. Apply Definition 38.472. It identifies the horizontal reads as the dyadic ledger, finite StreamName windows, RegSeqRat regularity and common-tail classifier, and the local Real seal classifier over that route.

Now read the status side. Apply Definition 38.470. It reads the closurestatus, formalstatus, leantarget, and bridgestatus rows from the four local face records, object by object.

Both readings use the same four source faces, so restricting the status read along the classifier faces returns the same four objectwise records as first forming the classifier pullback and then reading the local status records. The two-axis convention of section 9467.2 keeps classifier agreement

and verification status independent, so the square does not create an aggregate formalstatus token, bridge row, quotient stream, selected limit, or completeness datum. □

Theorem 38.475 (Real L10 face status non-collapse)**.** *Any current Phase Real and Completion audit read through the four faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *preserves the four local closure records as separate face reports. No conjunction of those records can be read as a new formalstatus token, a* bridgeChecked *aggregate, a* $\mathsf{Real}^{\uparrow}$ *completeness claim, or a standard bridge for the composite exit route.*

Lean4 ✓ `BEDC.Derived.RealUp.RealL10FaceStatusNoncollapse`

Proof. Apply Definition 38.471. It identifies the current exit audit as the product of the four local face records and states that the exit packet contributes no fifth formal token or aggregate bridge.

The two-axis convention of section 9467.2 reads closure and verification status locally. A face report can therefore be cited as a face report, but the conjunction of face reports is not itself a further formalstatus entry.

Finally use the exactness and non-escape inputs named in the pullback proof: Definition 38.443, Definition 38.444, Definition 38.457, and Definition 38.460. They keep the composite exit route on the four displayed faces and provide no row for RealUp completeness or for a standard bridge over the product. □

Theorem 38.476 (Real L10 face Lean target non-collapse)**.** *Any accepted current Phase Real and Completion audit read through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *preserves each face's Lean-target row and bridge-status row as local records of that face. No* bridgeChecked *face can supply the Lean target or bridge row for another face, and the composite route creates neither a route-level Lean target nor an aggregate bridge row.*

Lean4 ✓ `BEDC.Derived.RealUp.RealL10FaceLeantargetNoncollapse`

Proof. Apply Definition 38.471. It reads the accepted exit audit as the product of the four local face records over the displayed Real L10 dependency lattice.

Apply Definition 38.833. It keeps the closure and verification reports objectwise, so a bridgeChecked entry is a record of its own face rather than a credential for a different face.

Now project the target and bridge rows along the same exactness data used by the pullback. The source-route non-escape, interface-totality, four-face exactness, and StreamName exit-correspondence inputs provide only face-local Lean-target and bridge-status coordinates for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, not an aggregate target row or an aggregate bridge row.

Since those inputs provide no fifth face, no route-level Lean-target coordinate, and no aggregate bridge coordinate, the local Lean-target and bridge-status rows remain attached to the faces from which they are read. □

Theorem 38.477 (Real L10 face status-target pairing)**.** *In any accepted Phase Real and Completion audit read through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, each face's* formalstatus*,* leantarget*, and* bridgestatus *rows are read as one local face record. A status row from one face cannot be paired with the Lean target or bridge row of another face, and no aggregate route row can repair such a mismatch.*

Proof. Apply Definition 38.471. The accepted audit is read as the product of the four local records carried by $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, not as a single route credential.

Apply Definition 38.833. It keeps the formalstatus coordinate attached to the face whose closure record supplies it, so the status row cannot be detached and reused as a route-level token.

Apply Definition 38.834. It keeps the leantarget and bridgestatus coordinates attached to the same local face records and supplies no route-level target or aggregate bridge row.

Finally read the three rows through section 9467.2. The roadmap discipline keeps verification status, Lean target, and bridge status as reported coordinates of the displayed face, so a mixed record using one face's status and another face's target or bridge row is outside the accepted audit read. □

Theorem 38.478 (Real L10 face status product readback)**.** *Any accepted Phase Real and Completion audit read through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *reads exactly the four face-local triples* (formalstatus, leantarget, bridgestatus) *carried by the corresponding face records. The readback is supported only by the displayed rows*

$$\mathsf{BHist}_{\mathsf{DyadicRatCore}^{\uparrow}}, \mathsf{hsame}_{\mathsf{DyadicRatCore}^{\uparrow}}, \mathsf{Cont}_{\mathsf{DyadicRatCore}^{\uparrow}}, \mathsf{Pkg}_{\mathsf{DyadicRatCore}^{\uparrow}}, \mathsf{NameCert}_{\mathsf{DyadicRatCore}^{\uparrow}},$$
$$\mathsf{BHist}_{\mathsf{StreamName}^{\uparrow}}, \mathsf{hsame}_{\mathsf{StreamName}^{\uparrow}}, \mathsf{Cont}_{\mathsf{StreamName}^{\uparrow}}, \mathsf{Pkg}_{\mathsf{StreamName}^{\uparrow}}, \mathsf{NameCert}_{\mathsf{StreamName}^{\uparrow}},$$
$$\mathsf{BHist}_{\mathsf{RegSeqRat}^{\uparrow}}, \mathsf{hsame}_{\mathsf{RegSeqRat}^{\uparrow}}, \mathsf{Cont}_{\mathsf{RegSeqRat}^{\uparrow}}, \mathsf{Pkg}_{\mathsf{RegSeqRat}^{\uparrow}}, \mathsf{NameCert}_{\mathsf{RegSeqRat}^{\uparrow}},$$
$$\mathsf{BHist}_{\mathsf{Real}^{\uparrow}}, \mathsf{hsame}_{\mathsf{Real}^{\uparrow}}, \mathsf{Cont}_{\mathsf{Real}^{\uparrow}}, \mathsf{Pkg}_{\mathsf{Real}^{\uparrow}}, \mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}.$$

It does not create an aggregate formalstatus*, aggregate* leantarget*, aggregate bridge row, quotient stream equality, selected limit, countable-choice row, metric-completeness datum, or* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.RealUp.RealL10FaceStatusProductReadback`

Proof. Apply Definition 38.833. It keeps the status coordinates as local reports of $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ and supplies no fifth status coordinate.

Apply Definition 38.834. It keeps the leantarget and bridgestatus rows attached to their source faces and supplies no route-level target or aggregate bridge row.

Apply Definition 38.835. It reads formalstatus, leantarget, and bridgestatus together on the same face, so the product readback is exactly the four displayed local triples rather than a pool of exchangeable coordinates.

Finally use section 9467.2. The roadmap keeps paper closure and verification status on separate axes, and it supplies no rule turning the four face-local triples or their support rows BHist, hsame, Cont, Pkg, NameCert into quotient stream equality, a selected limit, a countable-choice row, a metric-completeness datum, an aggregate credential, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 38.479 (Real L10 face axis independence)**.** *Any accepted Phase Real and Completion audit read through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *preserves four independent local coordinates on each face: paper closure, formalstatus, leantarget, and bridgestatus. No coordinate from one face promotes any coordinate of another face, and no conjunction of face coordinates creates route-level closure, route-level formalstatus, route-level leantarget, aggregate bridge status, quotient stream, selected limit, countable-choice row, metric-completeness row, or* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Apply Definition 38.471. The audit is read as a product of the displayed faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, over the Real L10 dependency lattice, with no additional route coordinate.

Apply Definition 38.833. It keeps the paper closure and formalstatus reports face-local and blocks any reading in which a conjunction of local status records becomes route-level closure, route-level formalstatus, an aggregate bridge, or a $\mathsf{Real}^{\uparrow}$ completeness claim.

Apply Definition 38.834. It keeps leantarget and bridgestatus records attached to their source faces and blocks any reading in which one face supplies the Lean target or bridge row for another face.

Finally use the two-axis discipline of section 9467.2. Paper closure, formalstatus, leantarget, and bridgestatus are reported as separate coordinates; the roadmap supplies no rule that turns their conjunction into a quotient stream, selected limit, countable-choice row, metric-completeness row, aggregate bridge, or completed real-completeness certificate. □

Theorem 38.480 (Real L10 face-axis defect localization)**.** *Suppose an accepted Phase Real and Completion audit read through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *does not preserve one of the four independent coordinates named in Definition 38.837. Then the defect is localized to at least one displayed face record or to at least one displayed support row among* $\mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$. *No quotient stream, selected limit, countable-choice row, metric-completeness row, aggregate formalstatus, aggregate bridge row, route-level leantarget, or* $\mathsf{Real}^{\uparrow}$ *completeness claim can serve as the defect carrier.*

Proof. Apply Definition 38.837. The admissible coordinate inventory is the displayed facewise list: paper closure, formalstatus, leantarget, and bridgestatus over the four Real L10 faces. The same theorem excludes route-level completion vocabulary and aggregate status vocabulary from that inventory.

Apply Definition 38.833. It keeps paper closure and formalstatus attached to the local closure records of $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Thus a defect in either status coordinate is witnessed on at least one displayed face record or on at least one of its displayed support rows $\mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$.

Apply Definition 38.834. It keeps leantarget and bridgestatus attached to their source faces and supplies no route-level target or aggregate bridge row. Thus a defect in either target coordinate is again witnessed on at least one displayed face record or on at least one displayed support row.

Finally use the two-axis discipline of section 9467.2. Paper closure, formalstatus, leantarget, and bridgestatus are reported as separate axes, and there is no rule that lets a quotient stream, selected limit, countable-choice row, metric-completeness row, aggregate formalstatus, aggregate bridge row, route-level leantarget, or $\mathsf{Real}^{\uparrow}$ completeness claim replace the concrete face or support coordinate where the read failed. □

Theorem 38.481 (Real L10 exit defect face completeness)**.** *Every failed accepted Phase Real and Completion audit read through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *is exhausted by the four displayed face records and their displayed support rows* $\mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$. *Equivalently, any accepted defect witness is carried either by one of the four face records or by one of those support rows on that face. No quotient stream, selected limit, countable-choice row, metric-completeness datum, aggregate formalstatus, route-level leantarget, aggregate bridge row, or* $\mathsf{Real}^{\uparrow}$ *completeness claim is an additional defect coordinate.*

Proof. Apply Definition 38.837. It supplies the complete coordinate inventory for an accepted audit read: paper closure, formalstatus, leantarget, and bridgestatus, each read locally over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Apply Definition 38.838. Once one of those coordinates fails to be preserved, the failure is witnessed on a displayed face record or on one of its displayed support rows $\mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$.

Apply Definition 38.836. The product readback contains exactly the four face-local status, target, and bridge triples supported by the displayed rows, so there is no remaining readback slot in which a hidden fifth status or completion coordinate could be stored.

Finally use the roadmap two-axis discipline of section 9467.2. It separates theory closure from verification status and provides no rule turning quotient-stream data, selected-limit data, countable-choice data, metric-completeness data, aggregate status data, route-level target data, aggregate bridge data, or $\mathsf{Real}^{\uparrow}$ completeness vocabulary into an accepted defect coordinate. □

Theorem 38.482 (Real L10 StreamName terminal status minimality)**.** *For any accepted Phase Real and Completion terminal read through* $\mathsf{StreamName}^{\uparrow}$*, the terminal read satisfies the roadmap exit status coordinate only if the four concrete face chapters* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *each supply their own local closurestatus, formalstatus, leantarget, and bridgestatus record at the required local audit-clean grade. If any one face record is absent or below that grade, then no aggregate formalstatus, aggregate bridge token, quotient stream, selected limit, countable-choice row, metric-completeness row, or* $\mathsf{Real}^{\uparrow}$ *completeness claim repairs the terminal read.*

Proof. Apply Definition 126.425. The terminal $\mathsf{StreamName}^{\uparrow}$ read is forced to inspect the four concrete sibling status records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$; it is not a read from a route-level status cache.

Now apply Definition 38.489. A missing face record, or a face record below the required audit-clean grade, blocks the current Phase Real and Completion exit criterion at the object where the defect is read.

Finally apply Definition 38.833 and Definition 38.834. These results keep the closurestatus, formalstatus, leantarget, and bridgestatus coordinates attached to their source faces and provide no aggregate replacement row. Therefore quotient-stream data, selected-limit data, countable-choice data, metric-completeness data, aggregate formalstatus, aggregate bridge tokens, and $\mathsf{Real}^{\uparrow}$ completeness vocabulary cannot repair the failed terminal read. □

Theorem 38.483 (Real L10 terminal four-face defect localization)**.** *Let* $\mathcal{T}$ *be an accepted terminal Phase Real and Completion read through* $\mathsf{StreamName}^{\uparrow}$*. If* $\mathcal{T}$ *fails the roadmap exit criterion, then the failed terminal read has a witness localized to a single displayed face among* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. At that face, the witness is read either from the local closurestatus, formalstatus, leantarget, and bridgestatus record, or from one of the displayed support rows* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *attached to that face.*

The localization has no repair coordinate outside those four faces. Quotient stream equality, selected limits, countable choice, metric-completeness data, aggregate formalstatus, aggregate bridge tokens, and $\mathsf{Real}^{\uparrow}$ *completeness do not supply terminal repair data and do not move the witness away from the face where the failed read is displayed.*

Proof. Start with Definition 38.840. It forces every accepted terminal $\mathsf{StreamName}^{\uparrow}$ read to inspect the four local closurestatus, formalstatus, leantarget, and bridgestatus records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Apply Definition 38.839. A failed accepted exit read is exhausted by those four face records and by the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support rows on those faces. Hence some face carries the displayed witness.

Now use Definition 38.836. The terminal readback contains exactly the four face-local status, target, and bridge triples, so the witness can be chosen on one of the four objectwise faces rather than on a route-level aggregate.

Finally read the conclusion through section 9467.2. The roadmap separates paper closure, verification status, Lean target, and bridge status into local reported coordinates. It gives no rule that turns quotient stream equality, selected limits, countable choice, metric completeness, aggregate formalstatus, aggregate bridge data, or $\mathsf{Real}^{\uparrow}$ completeness into a terminal repair coordinate. □

Theorem 38.484 (Real L10 regular-Cauchy seal route completeness)**.** *Let $\mathcal{T}$ be an accepted Phase Real and Completion terminal read whose* $\mathsf{Real}^{\uparrow}$ *seal is supplied by an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *route. Then the accepted seal route of $\mathcal{T}$ is exhausted by exactly the four displayed faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

together with the visible support rows BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *on those faces.*

No fifth route coordinate is exported. In particular, the accepted seal route does not read quotient streams, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, metric-completion data, or standard bridge rows.*

Proof. Apply Definition 301.40. An accepted $\mathsf{RegSeqRat}^{\uparrow}$ route supplying the $\mathsf{Real}^{\uparrow}$ seal exports only the finite regular-source rows and excludes quotient stream equality, selected host limits, host real equality, hidden tail witnesses, and ambient completeness data.

Next use Definition 301.111. The $\mathsf{Real}^{\uparrow}$ consumer read factors through the same finite route rows, so the seal route seen by the terminal Phase Real and Completion read cannot acquire an additional consumer-side completion coordinate.

Use Definition 291.123 for the dyadic tolerance face. The tolerance component of the route is already read through the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces together with the shared BHist, hsame, Cont, Pkg, and NameCert support rows.

Finally apply Definition 38.833, Definition 38.834, and Definition 38.841. These results keep the L10 status, target, bridge, and defect witnesses localized to the four displayed faces and their support rows. Hence the accepted regular-Cauchy seal route has no fifth status coordinate, no independent completeness coordinate, and no standard bridge row outside the displayed four-face route. □

Theorem 38.485 (Real L10 current phase exit certificate)**.** *An accepted Phase Real and Completion exit certificate is exactly the four-face product*

$$\mathsf{DyadicRatCore}^{\uparrow} \times \mathsf{StreamName}^{\uparrow} \times \mathsf{RegSeqRat}^{\uparrow} \times \mathsf{Real}^{\uparrow}$$

read through the Real L10 source-route, interface-totality, four-face exactness, StreamName exit-correspondence, and audit-pullback records. Its certificate content is the cited local closure evidence: each face contributes exactly the closurestatus, formalstatus, leantarget, and bridgestatus rows declared in its own local closurestatus block.

The certificate exports no $\mathsf{Real}^{\uparrow}$ *completeness claim, no quotient stream, no selected limit, no metric-completeness row, no aggregate bridge, and no formalstatus token beyond the four local face reports.*

Proof. Apply Definition 38.471. It identifies the accepted Phase Real and Completion exit audit with the product of the four local face records over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The source-route and interface-totality inputs used there confine the exit read to those faces. The four-face exactness theorem gives the product shape, and the StreamName exit correspondence identifies the same product as the current Phase Real and Completion exit route.

Apply Definition 38.833. It says that the four face reports remain separate audit entries and cannot be fused into a further formalstatus token, aggregate bridge, Real completeness row, quotient stream, selected limit, or metric-completeness row.

Thus the accepted exit certificate is precisely the four-face product read through the named route and exactness records, with only the displayed local closure evidence exported. □

Theorem 38.486 (Real L10 common-tail exit correspondence)**.** *Let an accepted Phase Real and Completion packet be read through the four faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *Assume that its* $\mathsf{RegSeqRat}^{\uparrow}$ *face satisfies the common-tail union classifier determinacy of Definition 301.181. Then the Real exit classifier is determined exactly by the common* $\mathsf{StreamName}^{\uparrow}$ *finite window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *common-tail classifier, and the local* $\mathsf{Real}^{\uparrow}$ *seal row.*

This correspondence is only a four-face finite BEDC exit route. It exports no quotient streams, no host-selected limits, no countable choice, no ambient $\mathsf{Real}^{\uparrow}$ *completeness, no metric-completeness row, and no aggregate formalstatus token.*

Proof. First apply Definition 38.472. It reads an accepted Real L10 classifier route as the pullback of the dyadic ledger, finite StreamName windows, RegSeqRat regularity and common-tail classifier, and the local Real seal classifier.

Next apply Definition 38.460. The StreamName finite-window route is the same source route used by the current Phase Real and Completion exit packet, so the common window is a coordinate of the Real exit read rather than a separate carrier.

Now use Definition 301.181. On the $\mathsf{RegSeqRat}^{\uparrow}$ face, the common-tail window determines one accepted $\mathsf{RegSeqRatClassifier}$ read over the displayed StreamName schedule, dyadic endpoint and radius rows, regularity rows, Real seal-source rows, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ provenance.

Finally apply Definition 38.485. The accepted exit certificate exports exactly the four local face reports and no fifth coordinate. Combining that certificate with the classifier pullback leaves precisely the common StreamName finite window, DyadicRatCore tolerance ledger, RegSeqRat common-tail classifier, and local Real seal row as the data determining the Real exit classifier.

The exclusion clauses in the four cited theorems remove the other possible readings: quotient streams, host-selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, metric-completeness rows, and aggregate formalstatus tokens have no displayed row in the four-face route. □

Theorem 38.487 (Real L10 exit refinement stability)**.** *Let an accepted Phase Real and Completion packet be refined by an* hsame*-compatible finite request section. Suppose that the refinement preserves the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale-window packet, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window section, the* $\mathsf{RegSeqRat}^{\uparrow}$ *common-tail boundary, and the local* $\mathsf{Real}^{\uparrow}$ *seal row, together with the displayed* BHist, Cont, Pkg, *and* $\mathsf{NameCert}$ *support for those four faces. Then the refined packet determines the same Real L10 exit classifier as the original accepted packet.*

Equivalently, the refined read repacks as the same four-face finite BEDC exit route over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The stability assertion exports no quotient stream, no selected limit, no countable-choice selector, no ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim, no metric-completeness row, and no aggregate formalstatus token.*

Proof. First apply Definition 38.486. It says that the Real exit classifier is determined by exactly the common $\mathsf{StreamName}^{\uparrow}$ finite window, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, the $\mathsf{RegSeqRat}^{\uparrow}$ common-tail classifier, and the local $\mathsf{Real}^{\uparrow}$ seal row.

The refinement is hsame-compatible and preserves those four rows. Hence it cannot alter the common-tail classifier read on the $\mathsf{RegSeqRat}^{\uparrow}$ face; this is the determinacy content of Definition 301.181.

Next apply Definition 126.624. The preserved terminal StreamName window, dyadic scale data, common-tail boundary, and local Real seal row are the same finite boundary before and after refinement.

Finally use Definition 38.775. It repacks the preserved DyadicRatCore, StreamName, RegSeqRat, and Real rows as one finite four-face public interface. Therefore the refined packet has the same Real L10 exit classifier and the same finite BEDC exit route as the original accepted packet.

The exclusion clauses in the cited correspondence, fusion, determinacy, and four-face interface theorems leave no place for a quotient stream, selected limit, countable-choice selector, ambient $\mathsf{Real}^{\uparrow}$ completeness datum, metric-completeness row, or aggregate formalstatus token to enter the refinement read. □

Theorem 38.488 (Real L10 phase exit criterion is objectwise)**.** *The Phase Real and Completion exit criterion is satisfied only by reading the four local records for* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *Each face must supply its own* theoryclosure, formalstatus, leantarget, *and* bridgestatus *rows from its local closurestatus block, and those rows remain attached to that face.*

The criterion admits no aggregate route-level formalstatus, *no aggregate bridge row, no* $\mathsf{Real}^{\uparrow}$ *completeness claim, no quotient stream, no selected limit, and no metric-completeness datum. In particular, satisfying the current phase exit criterion means presenting the four objectwise face records and nothing further as Real L10 exit status.*

Proof. Apply Definition 38.485. It gives the certificate shape as the four-face product over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with exactly the local closurestatus, formalstatus, leantarget, and bridgestatus rows exported by those faces.

Apply Definition 38.471. It identifies the admissible audit read with objectwise lookup from the four local closurestatus blocks, so the phase criterion is discharged by those local records rather than by cached Real L10 status data.

Apply Definition 38.833. It rules out an aggregate formalstatus token, aggregate bridge row, Real completeness row, quotient stream, selected limit, and metric-completeness datum for the composite exit route.

Finally apply Definition 38.834. The Lean-target and bridge-status rows do not cross from one face to another, and the composite route has no route-level Lean target or bridge coordinate. Therefore the Phase Real and Completion exit criterion is objectwise in the four displayed faces. □

Theorem 38.489 (Real L10 face audit minimum blocker)**.** *If any one of* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *lacks its own local audit-clean verification grade in its closurestatus record, then the four-face product cannot be read as satisfying the current Phase Real and Completion exit criterion.*

This blocker is objectwise. It creates no aggregate route-level formalstatus, *and it does not claim* $\mathsf{Real}^{\uparrow}$ *completeness, quotient streams, selected limits, or metric completeness.*

Proof. Apply Definition 38.488. The current phase exit criterion is discharged only by the four local records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Apply Definition 38.471. It identifies the admissible audit read with lookup in those local closurestatus records, so a face whose own record is below the audit-clean verification grade leaves the four-face product without the required local coordinate.

Apply Definition 38.833. The missing local verification grade cannot be supplied by an aggregate formalstatus token for the route, and the route does not export Real completeness, quotient streams, selected limits, or metric-completeness data.

Finally apply Definition 38.834. No face transfers its Lean target or bridge-status row to another face, and the composite route has no route-level Lean target or bridge row. Thus any below-audit-clean face blocks satisfaction of the current Phase Real and Completion exit criterion. □

Theorem 38.490 (Real L10 local face-record witness extraction)**.** *For an accepted Phase Real and Completion packet over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *any claim that the packet satisfies the objectwise exit threshold is witnessed by four local face records. Each record carries its own theory-closure, formalstatus, leantarget, and bridgestatus rows, and the extraction is supported only by the displayed local data*

$$\mathsf{BHist}_{\mathsf{DyadicRatCore}^{\uparrow}}, \mathsf{hsame}_{\mathsf{DyadicRatCore}^{\uparrow}}, \mathsf{Cont}_{\mathsf{DyadicRatCore}^{\uparrow}}, \mathsf{Pkg}_{\mathsf{DyadicRatCore}^{\uparrow}}, \mathsf{NameCert}_{\mathsf{DyadicRatCore}^{\uparrow}},$$
$$\mathsf{BHist}_{\mathsf{StreamName}^{\uparrow}}, \mathsf{hsame}_{\mathsf{StreamName}^{\uparrow}}, \mathsf{Cont}_{\mathsf{StreamName}^{\uparrow}}, \mathsf{Pkg}_{\mathsf{StreamName}^{\uparrow}}, \mathsf{NameCert}_{\mathsf{StreamName}^{\uparrow}},$$
$$\mathsf{BHist}_{\mathsf{RegSeqRat}^{\uparrow}}, \mathsf{hsame}_{\mathsf{RegSeqRat}^{\uparrow}}, \mathsf{Cont}_{\mathsf{RegSeqRat}^{\uparrow}}, \mathsf{Pkg}_{\mathsf{RegSeqRat}^{\uparrow}}, \mathsf{NameCert}_{\mathsf{RegSeqRat}^{\uparrow}},$$
$$\mathsf{BHist}_{\mathsf{Real}^{\uparrow}}, \mathsf{hsame}_{\mathsf{Real}^{\uparrow}}, \mathsf{Cont}_{\mathsf{Real}^{\uparrow}}, \mathsf{Pkg}_{\mathsf{Real}^{\uparrow}}, \mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}.$$

If the threshold fails, at least one of these four face records or one of its displayed support rows is the local witness of failure.

This extraction creates no aggregate formalstatus*, no aggregate bridge row, no quotient stream equality, no selected limit, no countable-choice row, no metric-completeness datum, no standard bridge completion, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Apply Definition 38.471. The accepted packet is read through the current audit pullback from the four displayed faces, so any claimed exit witness must be obtained from the local records of $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Apply Definition 38.494. It identifies satisfaction of the current threshold with the four objectwise local records, each carrying its own theory-closure and audit-clean verification coordinates. Apply Definition 38.836 to read the formalstatus, leantarget, and bridgestatus rows together with the displayed BHist, hsame, Cont, Pkg, and NameCert support on the same face.

For the failure alternative, apply Definition 38.489. A missing or sub-threshold local audit row blocks the four-face product, and the blocker is localized at the responsible face record rather than at a route-level token.

Finally use the noncollapse exclusions cited by the threshold and readback results. They rule out aggregate formalstatus, aggregate bridge, quotient stream equality, selected limits, countable choice, metric completeness, standard bridge completion, and ambient $\mathsf{Real}^{\uparrow}$ completeness as replacement witnesses. Therefore the extracted witness, positive or blocking, is exactly one of the four local face records with its displayed support rows. □

Theorem 38.491 (Real L10 local face record readback)**.** *The four local closurestatus blocks for* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *provide the objectwise status threshold required by the current Phase Real and Completion exit criterion. For each face, its own closurestatus block supplies the local theory-closure row and the local* formalstatus *row currently recorded there. The comparison with* auditClean *is made by reading those local records at the citation site, not by copying their token values into the Real L10 exit audit.*

This readback is only a four-face local status threshold. It contributes no aggregate route-level formalstatus*, no aggregate bridge row, no* $\mathsf{Real}^{\uparrow}$ *completeness claim, no quotient stream, no selected limit, no countable-choice coordinate, and no metric-completeness datum.*

Proof. Read the four local closurestatus blocks. The $\mathsf{DyadicRatCore}^{\uparrow}$ record is the block attached to Definition 291.25. The $\mathsf{StreamName}^{\uparrow}$ record is the public interface block attached to Definition 126.311 and Definition 126.314.

The remaining two faces are read in the same local way. The $\mathsf{RegSeqRat}^{\uparrow}$ record is the real-seal handoff block attached to Definition 301.22. The $\mathsf{Real}^{\uparrow}$ record is the phase-boundary block attached to Definition 38.290.

Apply Definition 38.471. The accepted current phase audit reads exactly these four local closurestatus blocks, not a cached Real L10 status row.

Apply Definition 38.488. Since each cited block is read through its own local theory-closure row and its own local formalstatus row, the required comparisons with scopedClosed and auditClean are made face by face. Those four local comparisons supply the objectwise threshold for the current Phase Real and Completion exit criterion.

Finally apply Definition 38.834. The four Lean-target and bridge-status rows remain attached to their own face records, so the readback does not create an aggregate formalstatus, aggregate bridge, Real completeness, quotient stream, selected limit, countable-choice, or metric-completeness row. □

Theorem 38.492 (Real L10 current phase exit witness)**.** *The displayed four-face product* $\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$ *satisfies the Phase Real and Completion exit criterion whenever the four local face records for* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *each supply the objectwise local theory-closure threshold and the audit-clean verification threshold. The witness is read through the four local face records, not through cached current face anchors or an aggregate Real L10 row.*

This witness contributes no aggregate route-level formalstatus*, no aggregate bridge row, no* $\mathsf{Real}^{\uparrow}$ *completeness claim, no quotient stream, no selected limit, and no metric-completeness datum.*

Proof. Apply Definition 38.470. It identifies the four local record positions of the displayed product $\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$.

Apply Definition 38.494. Under the stated objectwise local theory-closure and audit-clean verification thresholds, the reverse direction supplies the Phase Real and Completion exit criterion for those four face records.

Finally apply Definition 38.834. The local Lean-target and bridge-status rows stay attached to their faces, and the product exports no route-level formalstatus, bridge row, Real completeness claim, quotient stream, selected limit, or metric-completeness datum. □

Theorem 38.493 (Real L10 four-face exit sufficiency)**.** *Suppose the four local closurestatus records for* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *each display the local theory-closure row required by the current Phase Real and Completion criterion and an audit-clean verification row. Then the current Phase Real and Completion exit criterion is satisfied exactly as the four-face product over those records.*

This sufficiency is only the objectwise exit read. It supplies no aggregate route-level formalstatus*, no aggregate bridge row, no quotient stream, no selected limit, no countable-choice row, no metric-completeness datum, and no* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Apply Definition 38.488. The criterion asks only for the four local records of $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with each closure, verification, Lean-target, and bridge-status row kept on its own face.

Apply Definition 38.485. Under the stated local closure and audit-clean verification rows, the accepted exit certificate is the four-face product over exactly those records. Apply Definition 38.471 to read the status coordinates from the four local closurestatus blocks rather than from cached Real L10 route data.

It remains to exclude non-objectwise witnesses. Apply Definition 38.833. It rules out an aggregate formalstatus token, aggregate bridge row, Real completeness row, quotient stream, selected limit, and metric-completeness datum for the composite route.

Finally apply Definition 38.834. The Lean-target and bridge-status rows remain attached to their source faces and do not assemble a route-level target or bridge. Since none of the cited objectwise records supplies a countable-choice row either, the sufficiency claim is exactly the four-face product and nothing further. □

Theorem 38.494 (Real L10 objectwise exit threshold equivalence)**.** *An accepted Phase Real and Completion exit packet satisfies the current exit criterion if and only if the four local face records for* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *each supply the required local theory-closure row and an audit-clean verification row, read objectwise from that face's own closurestatus block.*

This equivalence is exactly the current four-face threshold. It excludes any aggregate route-level formalstatus*, aggregate bridge row, quotient stream, selected limit, countable-choice row, metric-completeness datum, and* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.RealUp.RealL10ObjectwiseExitThresholdEquivalence`

Proof. For the forward direction, apply Definition 38.488. It says that an accepted packet can satisfy the current Phase Real and Completion exit criterion only through the four local records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Apply Definition 38.491. The required threshold is read from each face's own closurestatus block, so the local theory-closure row and the local audit-clean verification row are the coordinates that witness the criterion. Apply Definition 38.489; if any one of those local audit-clean rows is absent, the four-face product does not satisfy the current exit criterion.

To keep the witness facewise, apply Definition 38.833. It rules out aggregate route-level formalstatus, aggregate bridge rows, quotient streams, selected limits, countable-choice rows, metric-completeness data, and $\mathsf{Real}^{\uparrow}$ completeness. Apply Definition 38.834 to keep Lean-target and bridge-status rows attached to their source faces.

For the reverse direction, suppose the four local face records each supply the required local theory-closure row and an audit-clean verification row. Apply Definition 38.493. Those four objectwise records satisfy the current Phase Real and Completion exit criterion exactly as the four-face product over the local records.

Finally apply Definition 38.833 and Definition 38.834. The resulting criterion is still the facewise threshold: no aggregate route-level verification token, bridge row, quotient stream, selected limit, countable-choice row, metric-completeness datum, or $\mathsf{Real}^{\uparrow}$ completeness claim is introduced. □

Theorem 38.495 (Real L10 component bridge latency)**.** *An accepted Phase Real and Completion packet satisfies the current four-face exit threshold exactly when the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *local records each provide the required scoped-closure row and at least* auditClean *verification. The component bridge rows may separately stand at paperBridge or bridgeChecked, as in the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *closurestatus anchors, but none of those component bridge rows supplies an aggregate* bridgeChecked *route credential.*

Consequently a paperBridge component row does not block the current Phase Real and Completion threshold once the local scoped-closure and audit-clean rows are present, and a bridgeChecked component row does not promote the packet to a global bridge-checked Real L10 route.

Proof. For the threshold equivalence, apply Definition 38.494. It identifies the accepted packet's current exit criterion with the four local records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, each read through its own scoped-closure and audit-clean verification rows.

The local records are the displayed component anchors. Apply Definition 38.491. The $\mathsf{DyadicRatCore}^{\uparrow}$ row is read at Definition 291.25, the $\mathsf{StreamName}^{\uparrow}$ row at Definition 126.311 and Definition 126.314, the $\mathsf{RegSeqRat}^{\uparrow}$ row at Definition 301.22, and the $\mathsf{Real}^{\uparrow}$ row at Definition 38.290.

It remains to separate component bridge latency from the phase threshold. Apply Definition 38.833. The component formalstatus and bridgestatus rows stay face-local, so a *paperBridge* row is not a missing audit-clean row and a *bridgeChecked* row is not an aggregate bridgeChecked route credential.

Finally apply Definition 38.834. The Lean-target and bridge-status rows remain attached to their source faces, so the packet gains no global bridge route beyond the objectwise threshold already supplied by the four local scoped-closure and audit-clean rows. □

Theorem 38.496 (Real L10 boundary-face bridge locality)**.** *Let an accepted Phase Real and Completion packet satisfy the objectwise exit threshold of Definition 38.494. If one component bridge row of* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or the same-route* RealCompletionExactBoundaryUp *boundary face is replaced by a stronger local bridge record, and if the replacement remains attached to that face, then the Real L10 exit read is unchanged. The replacement creates no aggregate* bridgeChecked *route credential, no fused standard bridge token, no quotient stream, no selected limit, no host-completeness row, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. For the four roadmap faces, apply Definition 38.495. It separates the local *paperBridge* and *bridgeChecked* component rows from the current four-face exit threshold, so strengthening one displayed bridge row does not change the local scoped-closure and audit-clean records that the Real L10 gate reads.

For the five-face boundary packet, apply Definition 1327.21. It reads $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and the same-route RealCompletionExactBoundaryUp face as local factors of the accepted packet, and it keeps the stronger bridge record attached only to the face where it is supplied.

Next apply Definition 1327.23 and Definition 38.834. These results exclude a route-level bridge leakage: the local replacement cannot become an aggregate bridgeChecked credential, a fused standard bridge token, a quotient stream, a selected limit, a host-completeness row, or an ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Finally apply Definition 38.494. The exit read is therefore exactly the same objectwise Phase Real and Completion threshold read as before the component bridge replacement. □

Theorem 38.497 (Real L10 threshold open-phase nonescape)**.** *If a current Phase Real and Completion packet satisfies the objectwise threshold of Definition 38.494, then it licenses exactly the current four-face exit read over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

The same threshold does not assert that the phase is globally closed, does not provide $\mathsf{Real}^{\uparrow}$ *completeness, does not add metric completeness, and does not create aggregate* formalstatus*, bridge, selected-limit, quotient-stream, or countable-choice coordinates.*

Proof. Apply Definition 38.494. The threshold is exactly the local theory-closure and audit-clean verification row read from each of the four face records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Apply Definition 38.488. A packet that meets this threshold is read as the objectwise four-face exit certificate, so the licensed content is the current face product and not an additional route-level witness.

The boundary is sharp. By Definition 38.489, any missing or sub-threshold face obstructs the current exit criterion; hence the theorem is not a completion principle that could bypass a local face audit.

Finally apply Definition 38.833 and Definition 38.834. The status, target, and bridge coordinates remain attached to their source faces, so the threshold does not create a global phase closure claim, $\mathsf{Real}^{\uparrow}$ completeness, metric-completeness data, aggregate formalstatus, aggregate bridge, selected-limit, quotient-stream, or countable-choice coordinate. □

Theorem 38.498 (Real L10 finite-cover exit threshold gluing)**.** *Let $\mathcal{U}$ be a finite family of accepted Phase Real and Completion exit packets. Suppose every member of $\mathcal{U}$ satisfies the objectwise exit threshold of Definition 38.494, and suppose that every pairwise overlap agrees on the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier rows, the* $\mathsf{Real}^{\uparrow}$ *seal rows, and the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. Then the family glues to one accepted four-face Phase Real and Completion exit packet satisfying the same objectwise exit threshold.*

The glued exit packet is only the finite four-face packet over those displayed rows. It exports no aggregate route-level formalstatus*, no aggregate bridge row, no quotient stream, no selected limit, no countable-choice row, no metric-completeness datum, and no* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Apply Definition 38.494 to each member of $\mathcal{U}$. Thus every local packet contributes exactly the four face records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with the threshold read from the local closurestatus rows of those faces.

We first glue the regular-sequence and real-seal faces. Apply Definition 301.88 to the finite family of $\mathsf{RegSeqRat}^{\uparrow}$ regularity rows and $\mathsf{Real}^{\uparrow}$ seal rows. The overlap agreement hypothesis is precisely the shared regularity, classifier, seal, BHist, hsame, Cont, Pkg, and NameCert surface required for that gluing. Apply Definition 301.80 to identify the resulting seal row on common overlaps.

Next glue the scheduling face. Use Definition 126.240 and Definition 126.265 to pass to a common finite-window presentation of the $\mathsf{StreamName}^{\uparrow}$ schedules. Apply Definition 126.562 to export one schedule row for the finite family, still over the displayed finite-window data and not over a quotient stream or selected limit.

The dyadic face is fixed by the overlap ledger. Apply Definition 291.66 and Definition 291.70. These read the shared endpoint and radius data through the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, so the glued packet has the same dyadic endpoint and radius rows on all refined windows.

Combining the glued RegSeqRat/Real, StreamName, and DyadicRatCore rows gives one accepted four-face exit packet by Definition 38.493. Finally apply Definition 38.833 and Definition 38.834. The glued packet remains objectwise: its closure, verification, Lean-target, and bridge rows stay on their source faces and do not form an aggregate route-level status, bridge, quotient, selected-limit, choice, metric-completeness, or $\mathsf{Real}^{\uparrow}$ completeness datum. □

Theorem 38.499 (Real L10 finite-cover exit threshold descent)**.** *Let P be an accepted Phase Real and Completion exit packet, and let $\mathcal{V}$ be a finite certified subcover of P. Suppose every member of $\mathcal{V}$ satisfies the objectwise exit threshold of Definition 38.494. Suppose moreover that each subcover member agrees with P on the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier rows, the* $\mathsf{Real}^{\uparrow}$ *seal rows, and the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. Then P satisfies the same objectwise exit threshold.*

The descended threshold is only the coarse four-face threshold of P. It does not assert an aggregate route-level formalstatus*, an aggregate bridge row, a quotient stream, a selected limit, a countable-choice row, a metric-completeness datum, or a* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Apply Definition 38.843 to the finite certified subcover $\mathcal{V}$. The hypotheses on the local threshold and on the shared $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows give one glued accepted four-face packet satisfying the objectwise exit threshold.

We now identify this glued packet with the coarse packet P. The agreement assumptions say that every displayed endpoint, radius, finite-window, regularity, classifier, seal, history, sameness, continuity, package, and NameCert coordinate of the glued packet is the corresponding coordinate of P. Apply Definition 38.494 to read the glued threshold as the four local face records of P.

It remains to keep the descent facewise. Apply Definition 38.833 and Definition 38.834. These prevent the subcover gluing from creating an aggregate status, bridge, quotient-stream, selected-limit, countable-choice, metric-completeness, or $\mathsf{Real}^{\uparrow}$ completeness reading. Hence the coarse packet P carries exactly the same objectwise exit threshold and no route-level strengthening. □

Theorem 38.500 (Real L10 terminal pullback coherence)**.** *Let T be an accepted terminal finite-window* $\mathsf{Real}^{\uparrow}$ *read presented through the public* $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$ *route. Suppose its StreamName window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *pointwise seal and readback,* $\mathsf{Real}^{\uparrow}$ *seal row, and shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support agree with a four-face Phase Real and Completion packet P. Then T satisfies the same objectwise exit threshold as P in the sense of Definition 38.494.*

Conversely, any terminal finite-window $\mathsf{Real}^{\uparrow}$ *read satisfying that objectwise threshold and carrying the displayed StreamName, DyadicRatCore, RegSeqRat, Real seal,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows factors through the StreamName–*RegSeqRat*–*$\mathsf{Real}^{\uparrow}$ *terminal pullback over the four-face Phase Real and Completion packet.*

The coherent terminal read is only this displayed finite-window pullback. It does not assert an aggregate route-level formalstatus*, an aggregate bridge row, a quotient stream, a selected limit, a countable-choice row, a metric-completeness datum, or a* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. First read the terminal route. Apply Definition 126.114. The accepted terminal $\mathsf{Real}^{\uparrow}$ read factors through exactly the displayed StreamName window rows, accepted $\mathsf{RegSeqRat}^{\uparrow}$ pointwise seal rows, $\mathsf{Real}^{\uparrow}$ finite-window seal boundary, hsame transports, finite Cont ledger, bundle membership, observations, and Pkg provenance. Apply Definition 126.125 to include the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger in the same finite route.

Now compare the resulting route with the four-face Phase Real and Completion packet P. The agreement assumptions identify the StreamName window, DyadicRatCore tolerance, RegSeqRat seal and readback, Real seal, BHist, hsame, Cont, Pkg, and NameCert coordinates of the terminal read with the corresponding objectwise faces of P. Apply Definition 38.494 to read the exit threshold from those four local closurestatus records.

For the converse direction, start with a terminal finite-window $\mathsf{Real}^{\uparrow}$ read that already carries the objectwise threshold and the displayed finite route rows. Apply Definition 126.125 to recover the finite StreamName–RegSeqRat route, and then apply Definition 126.114 to repack the same rows as the terminal pullback boundary.

It remains to keep the terminal comparison at the same threshold. Apply Definition 38.844 to descend any finite-window cover presentation back to the coarse packet P. Finally apply Definition 38.833 and Definition 38.834. These keep formalstatus, bridge, Lean-target, quotient-

stream, selected-limit, choice, metric-completeness, and $\mathsf{Real}^{\uparrow}$ completeness data attached only to the source faces, so the pullback coherence gives no route-level strengthening. □

Theorem 38.501 (Real L10 terminal cover coordinate exhaustion)**.** *Let T be an accepted terminal finite-window* $\mathsf{Real}^{\uparrow}$ *read over the public* $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$ *route. A finite certified cover witnesses the current Phase Real and Completion threshold for T if and only if every cover member and every certified overlap exposes exactly the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier rows, the local* $\mathsf{Real}^{\uparrow}$ *seal rows, and the shared* BHist, hsame, Cont, Pkg, *and* NameCert *support rows.*

No aggregate formalstatus, *aggregate bridge row, quotient stream, selected limit, countable-choice row, metric-completeness datum, or* $\mathsf{Real}^{\uparrow}$ *completeness coordinate can stand in for any one of these exposed coordinates.*

Proof. For the forward direction, start with a finite certified cover witnessing the terminal threshold for T. Apply Definition 38.845 to identify the terminal read with the four-face Phase Real and Completion packet through the displayed StreamName, DyadicRatCore, RegSeqRat, local Real, and shared support rows.

Apply Definition 38.494. The threshold is objectwise, so each cover member must present the dyadic endpoint and radius, finite-window schedule, regularity and classifier rows, local seal rows, and the common BHist, hsame, Cont, Pkg, and NameCert support. Apply Definition 38.843; the certified overlaps are precisely the rows along which those objectwise faces glue.

For the reverse direction, suppose every member and overlap exposes exactly those coordinates. Apply Definition 38.843 to assemble the memberwise four-face packets over the shared support, and then apply Definition 38.844 to read the glued packet back as the terminal finite-window threshold for T.

It remains to show that no route-level coordinate can replace a displayed face. Apply Definition 38.833 and Definition 38.834. These keep aggregate status, bridge, quotient-stream, selected-limit, countable-choice, metric-completeness, and $\mathsf{Real}^{\uparrow}$ completeness rows outside the finite cover support, so the witness is exhausted by the listed coordinates and by no stronger route credential. □

Theorem 38.502 (Real L10 terminal finite-cover threshold equivalence)**.** *Let T be an accepted terminal finite-window* $\mathsf{Real}^{\uparrow}$ *read over the public* $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$ *route, with displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier rows, local* $\mathsf{Real}^{\uparrow}$ *seal rows, and shared* BHist, hsame, Cont, Pkg, *and* NameCert *rows. Then T satisfies the current Phase Real and Completion objectwise exit threshold if and only if every finite certified cover of the displayed terminal route glues and descends to the same four-face packet over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *seal, with the shared* BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

The equivalence refuses aggregate route-level formalstatus, *aggregate bridge rows, quotient stream equality, selected limits, countable choice, metric-completeness data, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. For the forward direction, apply Definition 38.845. The accepted terminal read is compared with the four-face Phase Real and Completion packet through the displayed StreamName window, DyadicRatCore tolerance ledger, RegSeqRat readback and classifier rows, local Real seal, and shared support rows.

Now apply Definition 38.843. Each finite certified cover member carries the objectwise threshold read from the same local faces, and the overlap hypotheses are exactly the shared BHist, hsame,

Cont, Pkg, and NameCert rows. Apply Definition 126.504 to keep the glued cover inside the terminal four-object packet over DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$.

For the reverse direction, suppose every finite certified cover of the displayed terminal route glues and descends to the same four-face packet. Apply Definition 38.844. The descended coarse packet carries the same objectwise threshold as its finite cover members.

It remains to identify this descended packet with the accepted terminal route. Apply Definition 291.107 to read the dyadic endpoint, radius, distance, and local NameCert interface as the DyadicRatCore$^{\uparrow}$ face of the same support packet. Apply Definition 301.93 to read the StreamName, RegSeqRat, DyadicRatCore, and local Real rows as one audit-clean four-face exit surface.

Finally apply Definition 38.845. The terminal read and the descended four-face packet have the same displayed faces and the same BHist, hsame, Cont, Pkg, and NameCert support rows, so the threshold is exactly the current objectwise Phase Real and Completion threshold. The cited noncollapse clauses in the gluing, descent, interface, readiness, and terminal-pullback results leave no aggregate status, bridge row, quotient stream equality, selected limit, choice principle, metric-completeness datum, or ambient Real$^{\uparrow}$ completeness coordinate. □

Theorem 38.503 (Real L10 finite-cover terminal support exhaustion)**.** *Let T be an accepted terminal finite-window* Real$^{\uparrow}$ *read over the public* StreamName$^{\uparrow}$–RegSeqRat$^{\uparrow}$ *route. A finite certified cover witnesses the current Phase Real and Completion threshold for T if and only if its members and certified overlaps expose exactly the* DyadicRatCore$^{\uparrow}$ *endpoint and radius ledger, the* StreamName$^{\uparrow}$ *finite-window schedule, the* RegSeqRat$^{\uparrow}$ *regularity and classifier rows, the local* Real$^{\uparrow}$ *seal rows, and the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support.*

Deleting any one of those displayed rows prevents the altered cover from witnessing the same terminal threshold. No aggregate formalstatus *row, bridge row, quotient stream, selected limit, countable-choice datum, metric-completeness datum, or* Real$^{\uparrow}$ *completeness row replaces the deleted coordinate.*

Proof. For the equivalence of the support inventory with the terminal threshold, combine Definition 38.846 with Definition 38.847. The first result identifies the exact member and overlap coordinates of an accepted terminal cover, while the second reads those coordinates as the current Phase Real and Completion finite-cover threshold for T.

Now delete one displayed row. If the deleted row lies on the RegSeqRat$^{\uparrow}$ audit-threshold side, apply Definition 301.231; the altered cover cannot descend to the same glued audit-threshold read. If the deleted row is one of the shared cover-support rows along the public route, apply Definition 126.665; the cover-descent terminal support packet cannot present the same Real$^{\uparrow}$ seal-visible source.

It remains to keep the dyadic endpoint and radius ledger from being hidden in a different terminal readback. Apply Definition 291.124. The public tolerance read is determined by the finite DyadicRatCore$^{\uparrow}$ ledger, the StreamName window, the RegSeqRat rows, the local Real seal, and the same shared support rows, so deleting any one of those rows removes a coordinate used by the terminal threshold.

Finally use the noncollapse clauses cited in Definition 38.846 and Definition 38.847. They keep aggregate status, bridge data, quotient streams, selected limits, choice, metric-completeness, and ambient Real$^{\uparrow}$ completeness outside the objectwise finite-cover support. Hence none of those rows can replace the deleted coordinate, and the original finite certified cover is support-exhaustive. □

Theorem 38.504 (Real L10 terminal finite-cover face minimality)**.** *Let T be an accepted terminal finite-window* Real$^{\uparrow}$ *read satisfying the current Phase Real and Completion objectwise exit threshold, with displayed* DyadicRatCore$^{\uparrow}$ *endpoint and radius ledger,* StreamName$^{\uparrow}$ *finite-window schedule,*

RegSeqRat$^{\uparrow}$ *regularity and classifier rows, local* Real$^{\uparrow}$ *seal rows, and shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. Then every finite certified cover witnessing the terminal finite-cover threshold equivalence for T is face-minimal in the following sense.*

1. *The cover must retain the* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*, and local* Real$^{\uparrow}$ *faces on the displayed terminal support.*
2. *The cover must retain the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows through the same common support.*
3. *Deleting any one of these faces or support rows makes the resulting subcover inadmissible as a witness for the terminal threshold.*
4. *No aggregate* formalstatus*, bridge row, quotient stream, selected limit, countable-choice row, metric-completeness datum, or ambient* Real$^{\uparrow}$ *completeness row can replace the deleted face or support row.*

Proof. Apply Definition 38.847. The accepted threshold for T is equivalent to gluing and descent of finite certified covers to the same four-face packet over DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and the local Real$^{\uparrow}$ seal, with the shared BHist, hsame, Cont, Pkg, and NameCert rows.

Apply Definition 38.845. This identifies the accepted terminal read with that four-face packet, so a cover witnessing the threshold is not merely a route credential: it is a cover whose visible support contains the dyadic ledger, the StreamName finite window, the RegSeqRat classifier and readback rows, the local Real seal, and the shared support rows.

It remains to rule out removing a displayed face. Use Definition 126.407 for the StreamName finite-window subcover, use Definition 301.198 for the RegSeqRat common-tail and cocycle rows, and use Definition 291.107 for the dyadic endpoint, radius, distance, and local NameCert interface. These results make each face visible in the common support consumed by the terminal packet.

Finally apply the noncollapse clauses from Definition 38.847, Definition 38.833, and Definition 38.834. They keep route-level status, bridge, quotient-stream, selected-limit, choice, metric-completeness, and ambient completeness data outside the objectwise face inventory, so none of those rows can compensate for a missing DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, local Real$^{\uparrow}$, or shared support row. □

Theorem 38.505 (Real L10 finite-cover threshold cocycle uniqueness)**.** *Let T be an accepted terminal finite-window* Real$^{\uparrow}$ *read. Let $\mathcal{U}$ and $\mathcal{V}$ be two finite certified covers of T, each satisfying the terminal finite-cover threshold equivalence. Suppose that, on every common refinement of $\mathcal{U}$ and $\mathcal{V}$, the two covers agree on the displayed* DyadicRatCore$^{\uparrow}$ *endpoint and radius ledger, the* StreamName$^{\uparrow}$ *finite-window schedule, the* RegSeqRat$^{\uparrow}$ *regularity and classifier rows, the local* Real$^{\uparrow}$ *seal rows, and the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows.*

Then the four-face exit packet glued from $\mathcal{U}$ and the four-face exit packet glued from $\mathcal{V}$ are the same terminal common-refinement packet. This uniqueness statement is only about the displayed finite-cover threshold surface. It does not identify aggregate formalstatus *rows, bridge rows, quotient streams, selected limits, countable-choice data, metric-completeness data, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. First apply Definition 38.847 to both covers. Each cover is therefore a finite certified presentation whose glued packet and descended packet are the terminal four-face exit over the displayed DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and local Real$^{\uparrow}$ faces with the same support rows.

Next pass to any common refinement. Apply Definition 126.628 to the finite-window schedule and Definition 301.243 to the RegSeqRat request sections and local Real seal rows. The refinement exposes a single terminal four-face packet on the common StreamName, RegSeqRat, dyadic, and Real boundary.

The dyadic ledger cannot split into two sources on that refinement. Apply Definition 291.114; the common endpoint and radius rows determine the same BEDC-visible dyadic source ledger and hence the same dyadic face of the exit packet.

Finally apply Definition 38.845 and Definition 38.849. Pullback coherence identifies the common four-face packet with the accepted terminal read T, and face minimality prevents any alternative support row from standing in for a displayed face. Thus the two glued packets coincide as the same terminal common-refinement packet, while aggregate status, bridge, quotient-stream, selected-limit, choice, metric-completeness, and ambient completeness coordinates remain outside the construction. □

Theorem 38.506 (Real L10 terminal finite-cover refinement invariance)**.** *Let T be an accepted terminal finite-window* $\mathsf{Real}^{\uparrow}$ *read. Let $\mathcal{V}$ be a finite certified refinement of a finite certified cover $\mathcal{U}$ of T. Suppose that every refinement cell preserves the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier rows, the local* $\mathsf{Real}^{\uparrow}$ *seal rows, and the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows.*

Then $\mathcal{U}$ witnesses the current Phase Real and Completion terminal finite-cover threshold for T if and only if $\mathcal{V}$ witnesses that same threshold. The equivalence is an objectwise four-face statement: it does not assert equality of aggregate formalstatus *rows, bridge rows, quotient streams, selected limits, choice data, metric-completeness data, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Assume first that $\mathcal{U}$ witnesses the terminal finite-cover threshold. Apply Definition 38.847 to $\mathcal{U}$. The cover therefore presents the terminal four-face exit packet over the displayed dyadic, StreamName, RegSeqRat, and local Real faces with the shared support rows.

Transport this packet across the certified refinement. Apply Definition 126.407 to keep the finite-window schedule exact on the terminal subcover, and apply Definition 301.198 to keep the RegSeqRat classifier, readback, and cocycle rows on the common tail. The dyadic endpoint and radius ledger is fixed by Definition 291.114.

Now apply Definition 38.843. Each cell of $\mathcal{V}$ carries the same displayed faces and the same BHist, hsame, Cont, Pkg, and NameCert rows as its parent cell in $\mathcal{U}$, so the refined cells glue to the same terminal exit packet. Then Definition 38.847 reads the glued refined packet as a witness for $\mathcal{V}$.

For the reverse direction, assume that $\mathcal{V}$ witnesses the threshold. Apply Definition 38.844 along the certified refinement map from $\mathcal{V}$ to $\mathcal{U}$. The preservation hypotheses make the descended packet carry exactly the displayed dyadic, StreamName, RegSeqRat, local Real, and shared support rows of $\mathcal{U}$.

Finally apply Definition 38.849 and Definition 38.850. Face minimality prevents the refinement from hiding or replacing any displayed face, and cocycle uniqueness identifies the refined and descended packets on their common terminal support. Thus Definition 38.847 certifies $\mathcal{U}$ exactly when it certifies $\mathcal{V}$.

The construction never promotes route-level data into an objectwise face. Aggregate formalstatus rows, bridge rows, quotient streams, selected limits, choice principles, metric-completeness data, and ambient $\mathsf{Real}^{\uparrow}$ completeness remain outside the refined terminal finite-cover threshold. □

Theorem 38.507 (Real L10 refinement-support descent noescape)**.** *Let T be an accepted terminal finite-window* $\mathsf{Real}^{\uparrow}$ *read. Let $\mathcal{V}$ be a finite certified refinement of a finite certified cover $\mathcal{U}$ of T. Suppose the refinement preserves the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier rows, the local* $\mathsf{Real}^{\uparrow}$ *seal rows, and the shared* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *support rows.*

Then descent from $\mathcal{V}$ to $\mathcal{U}$ preserves exactly this support surface. It introduces no aggregate $\mathsf{formalstatus}$ *row, bridge row, quotient stream, selected limit, choice row, metric-completeness datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. First apply Definition 38.851. The terminal threshold witnessed on the refined cover is equivalent to the terminal threshold witnessed on the original cover, and the equivalence is already restricted to the objectwise dyadic, StreamName, RegSeqRat, local Real, and shared BEDC support rows.

The descent keeps the three lower faces fixed. Apply Definition 126.407 for the finite-window schedule, apply Definition 301.198 for the RegSeqRat tail, and apply Definition 291.114 for the dyadic endpoint and radius ledger. These certificates leave the descended packet on the same displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ faces as the refined packet.

It remains to exclude substitute support. Apply Definition 38.849 to prevent any hidden row from standing in for a displayed face, and apply Definition 38.850 to identify the descended and refined terminal packets on their common support. Hence the descent preserves precisely the listed surface and cannot create a route-level credential outside it. □

Theorem 38.508 (Real L10 formal-boundary exit certificate)**.** *An accepted current Phase Real and Completion terminal* $\mathsf{Real}^{\uparrow}$ *read exports exactly the finite four-face boundary*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

with the displayed support rows

$$\begin{gathered}
\mathsf{BHist}_{\mathsf{DyadicRatCore}^{\uparrow}},\ \mathsf{BHist}_{\mathsf{StreamName}^{\uparrow}},\ \mathsf{BHist}_{\mathsf{RegSeqRat}^{\uparrow}},\ \mathsf{BHist}_{\mathsf{Real}^{\uparrow}},\\
\mathsf{hsame}_{\mathsf{DyadicRatCore}^{\uparrow}},\ \mathsf{hsame}_{\mathsf{StreamName}^{\uparrow}},\ \mathsf{hsame}_{\mathsf{RegSeqRat}^{\uparrow}},\ \mathsf{hsame}_{\mathsf{Real}^{\uparrow}},\\
\mathsf{Cont}_{\mathsf{DyadicRatCore}^{\uparrow}},\ \mathsf{Cont}_{\mathsf{StreamName}^{\uparrow}},\ \mathsf{Cont}_{\mathsf{RegSeqRat}^{\uparrow}},\ \mathsf{Cont}_{\mathsf{Real}^{\uparrow}},\\
\mathsf{Pkg}_{\mathsf{DyadicRatCore}^{\uparrow}},\ \mathsf{Pkg}_{\mathsf{StreamName}^{\uparrow}},\ \mathsf{Pkg}_{\mathsf{RegSeqRat}^{\uparrow}},\ \mathsf{Pkg}_{\mathsf{Real}^{\uparrow}},\\
\mathsf{NameCert}_{\mathsf{DyadicRatCore}^{\uparrow}},\ \mathsf{NameCert}_{\mathsf{StreamName}^{\uparrow}},\ \mathsf{NameCert}_{\mathsf{RegSeqRat}^{\uparrow}},\ \mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}.
\end{gathered}$$

Its formal boundary is the objectwise product of the four local face records: the DyadicRatCore endpoint and radius ledger, the StreamName terminal-window packet, the RegSeqRat finite-request section, and the local Real seal. This product is not a fifth route-level formalstatus, bridge row, selected limit, quotient stream, host equality, ambient completeness row, metric-completeness datum, arithmetic or order package, or standard bridge.

Proof. First fix the finite terminal witness. Apply Definition 38.464. The accepted terminal read determines exactly the fused StreamName terminal-window packet, the DyadicRatCore endpoint and radius ledger, the RegSeqRat finite-request section, the local Real seal, and the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Next fix the route. Apply Definition 38.466. It places every such witness on the ordered path

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Apply Definition 38.467 to identify the StreamName classifier pullback, the RegSeqRat finite-request section, and the Real source route as three readings of the same public boundary.

Now read the audit boundary. Apply Definition 38.471. It identifies the accepted Phase Real and Completion audit as the product of the four local face records, with closurestatus, formalstatus, leantarget, and bridgestatus rows read from the corresponding faces.

Finally apply Definition 38.837. It keeps paper closure, formalstatus, leantarget, and bridgestatus face-local and blocks any reading in which their product becomes a route-level status, aggregate bridge, quotient stream, selected limit, host equality, ambient completeness row, metric-completeness datum, arithmetic or order package, or standard bridge. Thus the certificate is exactly the four-face finite boundary and its objectwise formal record product. □

Theorem 38.509 (Real L10 four-face order rigidity)**.** *Let an accepted current Phase Real and Completion terminal read have precisely the visible faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. Then the read is accepted only as the ordered route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

No permutation, skipped edge, or bypass through the same four local records is an accepted exit route. In particular, quotient streams, host real equality, selected limits, countable choice, ambient completeness, metric-completeness data, aggregate formalstatus tokens, and standard bridge rows cannot replace or reorder the four-face route.

Proof. First fix the source route. Apply Definition 38.466. It assigns every accepted terminal finite-window witness to the displayed path from $\mathsf{DyadicRatCore}^{\uparrow}$ through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ to $\mathsf{Real}^{\uparrow}$.

Next compare the middle and terminal readings. Apply Definition 38.467. The StreamName terminal-window classifier, the RegSeqRat finite-request section, and the Real source route are three readings of the same public boundary over the same support rows. A permutation of the faces would change one of these source, middle, or terminal readings, so it is not the accepted triangle.

Now read the audit coordinate. Apply Definition 38.471. The current Phase Real and Completion exit audit is the objectwise product of the four local closurestatus, formalstatus, leantarget, and bridgestatus records, not an aggregate route token that can be reassigned to another order.

Finally exclude bypasses. Apply Definition 38.730. Deleting, substituting, or bypassing any one face leaves no accepted L10 exit route. Thus quotient streams, host real equality, selected limits, countable choice, ambient completeness, metric-completeness data, aggregate formalstatus tokens, and standard bridge rows cannot supply a reordered or shortened route. The only accepted exit route with those four visible faces is the ordered four-face route above. □

Theorem 38.510 (Real L10 terminal order window witness envelope)**.** *An accepted current Phase Real and Completion terminal* $\mathsf{Real}^{\uparrow}$ *read satisfies the Real L10 exit envelope if and only if both of the following hold:*

1. *the read has the ordered route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow};$$

2. *the finite-window witness rows are exactly the rows fixed by Definition 38.464: the fused* $\mathsf{StreamName}^{\uparrow}$ *terminal-window packet, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-request section, the local* $\mathsf{Real}^{\uparrow}$ *seal, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

The envelope contains no quotient streams, selected limits, countable-choice rows, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. For the forward direction, first read the route. Apply Definition 38.509. It forces any accepted terminal read with the four visible faces to use the ordered path

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Next read the window data. Apply Definition 38.464. The public boundary recovers exactly the fused StreamName terminal-window packet, the DyadicRatCore endpoint and radius ledger, the RegSeqRat finite-request section, the local Real seal, and the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

For the reverse direction, assume the ordered route and the finite-window witness rows. Apply Definition 38.508. The route and witness data repack as the four-face formal boundary exported by the accepted Phase Real and Completion terminal read.

Finally apply Definition 38.837. It keeps the certificate face-local, so quotient streams, selected limits, countable-choice rows, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, and $\mathsf{Real}^{\uparrow}$ completeness cannot be smuggled into the exit envelope. Hence the envelope is exactly the conjunction of the ordered route and the finite-window witness rows. □

Theorem 38.511 (Real L10 terminal envelope status locality)**.** *An accepted current Phase Real and Completion terminal envelope has status evidence exactly as the objectwise product of the four local face records for* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. The ordered route and finite-window witness rows do not create a fifth route-level formalstatus, bridge row, selected limit, quotient stream equality, countable-choice row, metric-completeness datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. First read the terminal envelope. Apply Definition 38.510. It identifies the accepted envelope with the displayed ordered route and the finite-window witness rows fixed by the StreamName terminal-window packet, the DyadicRatCore endpoint and radius ledger, the RegSeqRat finite-request section, the local Real seal, and the shared BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support.

Next read the status coordinate. Apply Definition 38.471. The current Phase Real and Completion audit is looked up object by object from the four local face records, with closurestatus, formalstatus, leantarget, and bridgestatus rows remaining local to $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Now identify the four-face ledger. Apply Definition 126.516 and Definition 126.504. These results keep the dyadic budget, StreamName window, RegSeqRat handoff, and Real seal as the four faces of the same terminal finite boundary rather than as one route-level status credential.

Finally apply Definition 301.60. It reads the RegSeqRat classifier and readback rows as one of the four exposed faces of that terminal boundary. Therefore the terminal envelope carries exactly the four objectwise status records and no fifth route-level formalstatus, bridge row, selected limit, quotient stream equality, countable-choice row, metric-completeness datum, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim. □

Theorem 38.512 (Real L10 audit-clean four-face exit)**.** *The current Phase Real and Completion exit reaches the verification side exactly when the four local faces*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

each supply their local auditClean *record through the closurestatus, formalstatus, leantarget, and bridgestatus rows declared in that face's own local closurestatus block. The resulting exit certificate is the four-face product of those local audit-clean records and the terminal route and finite-window witness rows.*

This product creates no $\mathsf{Real}^{\uparrow}$ *completeness claim, metric-completeness datum, quotient stream, host equality, selected limit, countable-choice row, aggregate bridge status, or fifth route-level formal token.*

Proof. First read the terminal status coordinate through Definition 38.511. It identifies the accepted terminal envelope with the objectwise product of the four local face records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, and it excludes any fifth route-level formalstatus or bridge row.

Next apply Definition 38.471. The roadmap exit audit is looked up through the local closurestatus, formalstatus, leantarget, and bridgestatus rows of those same four faces. Requiring the verification coordinate in each local face record to be auditClean is therefore exactly the four-face verification-side exit criterion.

Now identify the route and witness rows. Apply Definition 38.466 for the ordered route and Definition 38.464 for the terminal finite-window witness. Together they keep the certificate on the displayed DyadicRatCore, StreamName, RegSeqRat, and local Real faces, with only the visible BHist, hsame, Cont, Pkg, and NameCert support rows.

Finally use Definition 38.837. It prevents the four local audit-clean records from becoming $\mathsf{Real}^{\uparrow}$ completeness, metric completeness, quotient streams, host equality, selected limits, countable-choice data, aggregate bridge status, or a route-level formal token. Hence the exit criterion is precisely the four local audit-clean faces together with the existing route and witness rows. □

Theorem 38.513 (Real L10 scoped four-face exit)**.** *The current Phase Real and Completion closure-side exit is reached exactly when the four local faces*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

each supply their own local scopedClosed *row through that face's local closurestatus block. The resulting exit certificate is the four-face product of those local scoped-closure records together with the terminal route and finite-window witness rows.*

This product creates no aggregate theory closure, completeness claim, quotient stream, selected limit, host real equality, bridge credential, or fifth route-level closure token.

Proof. First read the terminal status coordinate through Definition 38.511. It identifies the accepted terminal envelope with the objectwise product of the four local face records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Next apply Definition 38.471. The current Phase Real and Completion exit reads closurestatus, formalstatus, leantarget, and bridgestatus from those same local face records. Requiring the closure coordinate in each local face record to be scopedClosed is therefore exactly the four-face closure-side exit criterion.

Now identify the route and witness rows. Apply Definition 38.466 for the ordered route and Definition 38.464 for the terminal finite-window witness. These keep the certificate on the displayed DyadicRatCore, StreamName, RegSeqRat, and local Real faces, with only the visible BHist, hsame, Cont, Pkg, and NameCert support rows.

Finally use Definition 38.837. It keeps the closure coordinate independent from formalstatus and bridgestatus, so the four local scoped-closure rows cannot become an aggregate theory closure,

completeness claim, quotient stream, selected limit, host real equality, bridge credential, or fifth route-level closure token. Hence the exit criterion is precisely the four local scoped-closure faces together with the existing route and witness rows. □

Theorem 38.514 (Real L10 two-axis four-face exit)**.** *The current Phase Real and Completion exit is reached exactly when the four local faces*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

each supply both their local scopedClosed *row and their local* auditClean *row through that face's own closurestatus, formalstatus, leantarget, and bridgestatus records. The resulting exit certificate is the four-face product of the local closure-side and verification-side rows, together with the terminal route and finite-window witness rows.*

This two-axis product creates no route-level aggregate status, route-level bridge row, quotient stream, selected limit, countable-choice row, metric-completeness datum, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. First read the closure coordinate through Definition 38.513. It says that the closure-side exit is exactly the four local scopedClosed rows for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, together with the terminal route and finite-window witness rows.

Next read the verification coordinate through Definition 38.512. It says that the verification-side exit is exactly the four local auditClean rows for the same four faces, read from the face-local closurestatus, formalstatus, leantarget, and bridgestatus records.

Now combine the two coordinates objectwise. Apply Definition 38.511. The terminal envelope does not introduce a fifth status source; it only exposes the four face-local records already named by the closure-side and verification-side exit theorems.

Finally use Definition 38.837. The closure row, formal row, Lean target row, and bridge row remain separate coordinates, so the two-axis exit cannot be read as route-level aggregate status, a bridge row, quotient streams, selected limits, countable choice, metric completeness, or $\mathsf{Real}^{\uparrow}$ completeness. Hence the current Phase Real and Completion exit is precisely the four faces carrying both the local scopedClosed and local auditClean rows. □

Theorem 38.515 (RealUp L10 input factorization)**.** *Every public* $\mathsf{Real}^{\uparrow}$ *seal read or* $\mathsf{Real}^{\uparrow}$ *classifier read that is usable as Phase Real and Completion data factors through the L10 four-object input stack*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The factorization first reads the $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows of chapter 291, then the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows of chapter 126, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback rows of chapter 301, and only then the local* $\mathsf{Real}^{\uparrow}$ *seal or classifier surface. The visible route is transported by the displayed* hsame *rows, replayed by the displayed* Cont *rows, packaged by* Pkg *provenance, and named by the local* NameCert *rows before it is accepted as* $\mathsf{Real}^{\uparrow}$ *data.*

The factorization exports no quotient stream, host real equality, selected limit, countable choice, or ambient completeness coordinate.

Proof. Start with the Real L10 dependency lattice of Definition 38.442. It orders the public input surface by dyadic observations, finite StreamName windows, regular-rational readback, and the local Real seal rows.

Apply the source-route and interface-totality theorems, Definition 38.443 and Definition 38.444. They place every Phase Real and Completion interface read inside the displayed BHist, hsame, Cont, Pkg, and NameCert route over the same four faces.

The sibling route theorem Definition 38.530 supplies the cross-chapter handoff through chapter 291, chapter 126, and chapter 301. Thus a public Real seal read or classifier read reaches the local $\mathsf{Real}^{\uparrow}$ surface only after those sibling rows have been displayed.

Finally use the terminal route theorems Definition 38.670 and Definition 38.675. They exhaust the public exit by the four-object route and the structural rows already listed. Since none of those cited surfaces contains a quotient stream, host real equality, selected limit, countable-choice selector, or ambient completeness coordinate, no such coordinate can be exported by the accepted $\mathsf{Real}^{\uparrow}$ read. □

Theorem 38.516 (RealUp L10 downstream interface non-escape)**.** *Every downstream* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{RealAlgOrder}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*, or* $\mathsf{ContinuousMap}^{\uparrow}$ *consumer that uses a public* $\mathsf{Real}^{\uparrow}$ *seal row or public* $\mathsf{Real}^{\uparrow}$ *classifier row must read that row through the same four-object route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The admissible downstream packet consists only of the displayed BHist *histories, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *rows attached to those four faces.*

The packet exports no quotient stream equality, host real equality, selected limit, countable-choice selector, ambient completeness row, or metric-completeness row.

Proof. Begin with Definition 38.515. It already forces every public $\mathsf{Real}^{\uparrow}$ seal read and classifier read usable as Phase Real and Completion data through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with only the displayed BHist, hsame, Cont, Pkg, and NameCert support rows.

Now pass to the five downstream faces. A $\mathsf{Met}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, or $\mathsf{ContinuousMap}^{\uparrow}$ consumer can use the $\mathsf{Real}^{\uparrow}$ row only as the public seal or classifier surface supplied by chapter 38. The sibling surfaces chapter 57, chapter 766, chapter 128, chapter 129, and chapter 130 therefore inherit the same Real route rather than a separate analytic entrance.

Finally apply Definition 38.694. The public Real seal exports no quotient stream, selected limit, host real equality, host sequence equality, or ambient completeness theorem; the L10 input theorem also excludes countable choice from the route. Since the downstream consumer receives only that public Real row together with the displayed structural support, it cannot acquire quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, or metric-completeness rows from the Real input boundary. □

Definition 38.517 (Real L10 four-source handoff packet)**.** *The Real L10 four-source handoff packet is the finite packet whose public rows are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback rows, and the* $\mathsf{Real}^{\uparrow}$ *seal and classifier rows appearing in the ordered route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Its support data are componentwise hsame *transports between the displayed rows, displayed* Cont *replay maps for the accepted reads,* Pkg *provenance for each of the four source faces, and the local* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *row naming the resulting Real-facing surface. The packet has no coordinate other than those four source faces and the listed BEDC support rows.*

Theorem 38.518 (Real L10 four-source handoff initiality)**.** *Every admissible Phase Real and Completion public* $\mathsf{Real}^{\uparrow}$ *seal read or classifier read whose support is confined to* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows factors through the Real L10 four-source handoff packet of*

Definition 38.517. If two such factorizations agree on the $\mathsf{DyadicRatCore}^{\uparrow}$ *observation face, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window face, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback face, the* $\mathsf{Real}^{\uparrow}$ *seal or classifier face, and the displayed support rows, then they determine the same accepted public read.*

Conversely, the four-source handoff packet supplies the initial admissible source for these public reads: any accepted Real-and-Completion read with the listed support rows is obtained from that packet, and no quotient stream, selected limit, host real equality, ambient completeness, metric-completeness, countable-choice, or standard bridge coordinate can supply a competing initial source.

Proof. Begin with Definition 38.515. It sends every admissible Phase Real and Completion public $\mathsf{Real}^{\uparrow}$ seal or classifier read through the ordered four-object route. The definition of the handoff packet then records exactly that route as public source data, together with the BHist, hsame, Cont, Pkg, and local NameCert rows allowed in the statement.

The factorization is determined by the four visible faces. Apply Definition 126.612 to identify the DyadicRatCore observations, StreamName finite windows, RegSeqRat readback surface, and Real seal or classifier row as one exact four-face boundary. Then apply Definition 301.58 to repack any accepted terminal read over the same displayed support rows. Therefore two factorizations that agree on those faces and rows have the same accepted public read.

For existence in the reverse direction, apply Definition 38.519. It says that every Phase Real public read and every Completion public $\mathsf{Real}^{\uparrow}$ read already factors through the named packet, so the packet is an admissible source for every read under consideration.

Finally use Definition 38.520. The packet has no outlet for quotient streams, selected limits, host real equality, ambient completeness, metric-completeness, countable choice, or a standard bridge coordinate. Since the exactness and pullback steps leave only the four faces and the displayed support rows, no external analytic or bridge coordinate can serve as another initial source. □

Theorem 38.519 (Real L10 four-source handoff totality)**.** *Every Phase Real public read and every Completion public* $\mathsf{Real}^{\uparrow}$ *read factors through the Real L10 four-source handoff packet of Definition 38.517. In particular, the accepted read is obtained by first presenting the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation face, then the* $\mathsf{StreamName}^{\uparrow}$ *finite-window face, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback face, and finally the* $\mathsf{Real}^{\uparrow}$ *seal or classifier face, with only the displayed* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *support rows.*

Proof. Start with Definition 38.515. It already places every Phase Real and Completion public $\mathsf{Real}^{\uparrow}$ seal or classifier read on the four-object route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Next apply Definition 38.516. Downstream consumers receive only the same displayed histories, transports, continuations, package provenance, and local naming rows, so the route is stable when read by MetricSpace, RealAlgOrder, CompleteMetric, CompactMetric, and ContinuousMap surfaces.

Use Definition 38.444 to identify the interface reads with the source lattice coordinates, and use Definition 38.675 to close the terminal public exit over those four faces. These two references show that no additional source face is needed.

Repacking the listed rows gives exactly the packet of Definition 38.517. Thus every admitted public read factors through that named finite packet. □

Theorem 38.520 (Real L10 four-source handoff non-escape)**.** *The Real L10 four-source handoff packet exports no quotient stream equality, host real equality, selected limit, countable-choice selector, ambient completeness row, or metric-completeness row. Every downstream* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{RealAlgOrder}^{\uparrow}$*,*

$\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, *or* $\mathsf{ContinuousMap}^{\uparrow}$ *consumer of a public* $\mathsf{Real}^{\uparrow}$ *read receives only the four source faces and the displayed* hsame, Cont, Pkg, *and local* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *support rows.*

Proof. Apply Definition 38.516. It excludes the listed analytic and choice coordinates from every downstream consumer that reads a public Real seal or classifier row.

Now use Definition 38.515. The source of the downstream row is already limited to the four-object route and to the displayed support rows, so an excluded coordinate cannot enter before the downstream handoff.

Finally apply Definition 38.675. The terminal open-phase exit has no fifth face where quotient streams, host real equality, selected limits, countable choice, ambient completeness, or metric-completeness data could be stored. Therefore the named packet is non-escaping. □

Theorem 38.521 (Real L10 four-source handoff obstruction classification)**.** *For a Phase Real and Completion public* $\mathsf{Real}^{\uparrow}$ *read, factorization through the Real L10 four-source handoff packet of Definition 38.517 fails exactly when at least one of the following finite sites is absent or not componentwise transported:*

1. *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation face;*
2. *the* $\mathsf{StreamName}^{\uparrow}$ *finite-window face;*
3. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback face;*
4. *the local* $\mathsf{Real}^{\uparrow}$ *seal or classifier face;*
5. *one of the support rows* BHist, hsame, Cont, Pkg, *or* NameCert.

Equivalently, once these four faces and support rows are present and componentwise transported, the public $\mathsf{Real}^{\uparrow}$ *read factors through the named packet and has no further obstruction. No quotient stream equality, host real equality, selected limit, countable-choice selector, ambient completeness row, metric-completeness row, or additional bridge coordinate can witness failure.*

Proof. For the failure direction, begin with Definition 38.515. It places every usable Phase Real and Completion public $\mathsf{Real}^{\uparrow}$ seal read or classifier read on the route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with only the displayed structural support rows.

Use Definition 38.519 to compare the read with the packet of Definition 38.517. If the read does not factor through that packet, the totality theorem leaves no possible missing coordinate except one of the four displayed faces or one of the listed BHist, hsame, Cont, Pkg, and NameCert rows.

The exact location is finite. Apply Definition 126.612 to inspect the DyadicRatCore observation face, the StreamName finite-window face, the RegSeqRat readback face, and the local Real seal or classifier face. Then apply Definition 301.58 to inspect the common support rows used to repack the terminal read. Any remaining failure is therefore exactly one of the five listed sites.

For the converse direction, suppose one listed site is absent or not componentwise transported. Then the read lacks a required public face or a required support row of Definition 38.517, so it cannot factor through that packet.

If none of the five listed sites occurs, Definition 38.519 supplies the factorization through the packet. Finally Definition 38.520 excludes quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness, and additional bridge coordinates as possible obstruction witnesses. □

Theorem 38.522 (Real L10 four-source handoff classifier congruence)**.** *Let* R_0 *and* R_1 *be Phase Real and Completion public* $\mathsf{Real}^{\uparrow}$ *classifier reads that factor through the Real L10 four-source*

handoff packet of Definition 38.517. Suppose the two factorizations agree on the $\mathsf{DyadicRatCore}^{\uparrow}$ *observation face, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window face, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback face, the local* $\mathsf{Real}^{\uparrow}$ *seal or classifier face, and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support rows. Then* R_0 *and* R_1 *determine the same finite BEDC public* $\mathsf{Real}^{\uparrow}$ *classifier packet.*

Any classifier disagreement between such reads is therefore one of the finite obstruction sites listed in Definition 38.521. It is not witnessed by quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness, or bridge data.

Proof. First identify the two factorizations. By Definition 38.518, an admissible public $\mathsf{Real}^{\uparrow}$ classifier read supported only by the displayed BHist, hsame, Cont, Pkg, and local NameCert rows factors through the named four-source packet, and two such factorizations with the same four faces and support rows determine the same accepted public read.

Next put the four faces on one support packet. Apply Definition 126.612 to align the DyadicRatCore observation face, the StreamName finite-window face, the RegSeqRat readback face, and the local Real seal or classifier face. Then apply Definition 301.58 to repack the accepted terminal read over the common BHist, hsame, Cont, Pkg, and NameCert support rows.

Now compare classifier coordinates. The classifier coherence theorem Definition 38.740 says that the visible classifier reads over these four faces determine the same finite support packet. Since R_0 and R_1 agree on every face and support row used by that theorem, their public $\mathsf{Real}^{\uparrow}$ classifier reads are the same finite BEDC packet.

It remains to locate any possible disagreement. By Definition 38.520, the handoff packet has no outlet for quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness, or bridge data. Therefore Definition 38.521 leaves only the listed finite obstruction sites as possible witnesses for classifier disagreement. □

The $\mathsf{Real}^{\uparrow}$ L10 dependency spine consumes finite-window rows from chapter 126, regular-rational rows from chapter 301, and dyadic-radius rows from chapter 291. This places the current RealUp handoff on the same finite sibling surface used by stream naming, regular rational sequences, and the dyadic core. The $\mathsf{Real}^{\uparrow}$ seal consumes the $\mathsf{StreamName}^{\uparrow}$ finite observation interface of chapter 126, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, and the $\mathsf{RegSeqRat}^{\uparrow}$ regularity carrier of chapter 301. These sibling rows form the visible L10 route read before the local seal is available to downstream Real and Completion consumers. The $\mathsf{Real}^{\uparrow}$ seal face is consumed together with chapter 291, chapter 126, and chapter 301 in the current Phase Real and Completion exit boundary. The consumer surface is Definition 126.500: it reads the Real seal only as one of the four displayed faces, alongside the finite dyadic budget, StreamName window, RegSeqRat readback, and the displayed BHist, hsame, Cont, Pkg, and NameCert support rows. The current $\mathsf{Real}^{\uparrow}$ L10 carrier is read through the $\mathsf{StreamName}^{\uparrow}$ finite observation interface of chapter 126 and the $\mathsf{RegSeqRat}^{\uparrow}$ regularity certificate of chapter 301. The later $\mathsf{Met}^{\uparrow}$ consumer in chapter 57 uses the resulting $\mathsf{Real}^{\uparrow}$-valued distance interface only after those two sibling certificates are present, so the Real route is a sibling lattice through StreamName and rational regular sequences before it becomes a metric-distance surface.

Theorem 38.523 (Real StreamName RegSeqRat metric-observation factorization)**.** *Every* $\mathsf{Met}^{\uparrow}$*-facing observation of an accepted* $\mathsf{Real}^{\uparrow}$ *finite-window carrier factors through the ordered BEDC observation route*

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow} \to \mathsf{MetricDistanceWitness}.$$

The first leg reads only the $\mathsf{StreamName}^{\uparrow}$ *finite observation interface and its displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows. The second leg reads the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity rows together with*

the dyadic window rows that lock the finite rational schedule. The third leg exposes the local $\mathsf{Real}^{\uparrow}$ *seal and readback surface. Only after that seal is visible may the downstream* $\mathsf{Met}^{\uparrow}$ *consumer read the* MetricDistanceWitness *ledger.*

Thus the metric observation exports no quotient Cauchy class, host real equality, ambient completeness principle, or direct metric access to an unsealed stream.

Proof. Start with Definition 38.670. It places the accepted Real-facing read on the route from dyadic observations through $\mathsf{StreamName}^{\uparrow}$ finite windows and $\mathsf{RegSeqRat}^{\uparrow}$ regular readback to the local $\mathsf{Real}^{\uparrow}$ seal, using only the displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Next apply Definition 126.79 and Definition 301.25. The handoff fixes the finite StreamName observation interface, while the lock identifies the regular-rational rows with the dyadic finite-window schedule consumed by $\mathsf{RegSeqRat}^{\uparrow}$.

Now use Definition 38.449. It keeps every metric-facing read outside the Real construction boundary until the local $\mathsf{Real}^{\uparrow}$ seal and readback surface are already visible.

Finally apply the metric witness ledger only at the downstream consumer boundary, as in Definition 57.363. This records the MetricDistanceWitness depth accounting after the Real seal is available, and it supplies no coordinate for quotient Cauchy classes, host real equality, ambient completeness, or direct metric access to an unsealed stream. □

Theorem 38.524 (Real StreamName RegSeqRat metric classifier correspondence)**.** *Every accepted metric-facing* $\mathsf{Real}^{\uparrow}$ *finite-window observation is classifier-determined by the ordered BEDC route*

$\mathsf{StreamName}^{\uparrow}$ *finite-window classifier* $\to$ $\mathsf{RegSeqRat}^{\uparrow}$ *regularity classifier* $\to$ $\mathsf{Real}^{\uparrow}$ *seal classifier* $\to$ MetricDistanceW

The $\mathsf{StreamName}^{\uparrow}$ *leg fixes the finite schedule and its displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The* $\mathsf{RegSeqRat}^{\uparrow}$ *leg fixes the regularity classifier over the same window rows. The* $\mathsf{Real}^{\uparrow}$ *leg seals the readback surface before the metric witness can be consulted.*

Conversely, a MetricDistanceWitness *read cannot identify two* $\mathsf{Real}^{\uparrow}$ *observations unless their* $\mathsf{StreamName}^{\uparrow}$ *schedules and* $\mathsf{RegSeqRat}^{\uparrow}$ *windows reach the same* $\mathsf{Real}^{\uparrow}$ *seal. The correspondence therefore exports no quotient Cauchy class, host real equality, ambient completeness principle, or direct metric access to an unsealed stream.*

Proof. First apply Definition 38.523. It places every accepted metric-facing observation on the ordered route from $\mathsf{StreamName}^{\uparrow}$ finite windows through $\mathsf{RegSeqRat}^{\uparrow}$ regularity and the $\mathsf{Real}^{\uparrow}$ seal before the MetricDistanceWitness ledger is read.

Next use Definition 126.437. The dependency lattice says that reaching the RegSeqRat readback and Real seal surfaces from a finite StreamName window exposes only the displayed finite route and its BHist, hsame, Cont, Pkg, and NameCert rows.

Then apply Definition 301.103. It identifies the L10 source owners of the schedule, dyadic endpoint rows, regularity rows, classifier rows, and terminal Real seal. Thus the StreamName classifier and the RegSeqRat classifier determine the Real-facing seal read rather than leaving a free ambient coordinate.

Finally use Definition 57.363. The metric consumer can perform its continuation-depth accounting only after the sealed Real read is already present. Therefore a metric witness cannot separate or identify Real observations through any coordinate beyond the shared finite schedule, regularity window, and Real seal; quotient Cauchy classes, host real equality, ambient completeness, and direct access to an unsealed stream remain off the route. □

Theorem 38.525 (Real L10 metric classifier pullback correspondence)**.** *Let R and S be accepted metric-facing* $\mathsf{Real}^{\uparrow}$ *finite-window observations. Agreement of their* MetricDistanceWitness *classifiers is equivalent to agreement of the displayed four-face route consisting of the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and distance ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and common-tail classifier rows, the local* $\mathsf{Real}^{\uparrow}$ *seal classifier row, and the support rows* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

This pullback correspondence does not expose quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness rows, standard bridge rows, or direct metric access to an unsealed stream.

Proof. For the forward direction, first apply Definition 38.524. It reads agreement of the metric witness classifier back through the $\mathsf{StreamName}^{\uparrow}$ schedule, the $\mathsf{RegSeqRat}^{\uparrow}$ regularity window, and the local $\mathsf{Real}^{\uparrow}$ seal before any downstream metric ledger is consulted.

Then apply Definition 38.778. The terminal common-tail comparison identifies the same classifier agreement with agreement of the $\mathsf{RegSeqRat}^{\uparrow}$ common-tail packet, the $\mathsf{StreamName}^{\uparrow}$ terminal-window packet, the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint, radius, and distance ledger, the local $\mathsf{Real}^{\uparrow}$ seal-source row, and the displayed support rows.

Finally use Definition 38.779. It keeps the local agreements compatible on finite covers, so the metric-facing classifier read is exactly the four-face classifier surface rather than an extra metric coordinate.

For the reverse direction, assume the two observations agree on the displayed four-face route and on the support rows BHist, hsame, Cont, Pkg, and NameCert. Repack those rows through Definition 38.775; the result is one public finite pullback interface over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the local $\mathsf{Real}^{\uparrow}$ seal.

With the Real seal visible, apply Definition 38.524 again to identify the sealed classifier route seen by the metric consumer. Only at this point may Definition 57.363 be used: it records continuation-depth accounting for the already sealed distance witness and adds no quotient stream equality, host real equality, selected limit, choice, completeness, standard bridge, or unsealed-stream row. □

Theorem 38.526 (Real L10 metric pre-seal non-escape)**.** *Let R be an accepted metric-facing* $\mathsf{Real}^{\uparrow}$ *finite-window observation. Suppose the* MetricDistanceWitness *classifier of R agrees with the displayed four-face route through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, the local* $\mathsf{Real}^{\uparrow}$ *seal classifier, and the support rows* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. Then the sealed* $\mathsf{Real}^{\uparrow}$ *boundary contains no BEDC coordinate for quotient stream equality, selected limits, countable choice, host real equality, ambient Real completeness, metric-completeness rows, standard bridge rows, or direct access to an unsealed stream.*

Proof. First apply Definition 38.523. It places the metric-facing observation on the ordered route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, the local $\mathsf{Real}^{\uparrow}$ seal, and only then the MetricDistanceWitness ledger.

Next use Definition 38.524. The metric witness classifier is read back through the finite StreamName schedule, the RegSeqRat regularity classifier, and the Real seal classifier, so the classifier agreement has no independent metric-side carrier.

Now apply Definition 38.525. It identifies that classifier agreement with the four-face pullback over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, the local $\mathsf{Real}^{\uparrow}$ seal, and the displayed support rows.

The non-escape conclusion is exactly the boundary statement of Definition 38.449: before the sealed Real readback is present, there is no BEDC coordinate for quotient stream equality, selected

limits, countable choice, host real equality, ambient Real completeness, metric-completeness rows, standard bridge rows, or direct access to an unsealed stream.

After that boundary is fixed, Definition 57.363 may be cited only as the downstream continuation-depth ledger. It records metric consumer depth after the sealed Real route is already visible and does not add any of the excluded metric-side completion or choice data. □

Theorem 38.527 (Real L10 metric-distance pullback correspondence)**.** *Let R and S be accepted metric-facing* $\mathsf{Real}^{\uparrow}$ *finite-window observations. Agreement of their displayed* MetricDistanceWitness *distance rows is equivalent to agreement of the concrete four-face packet consisting of the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and distance ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and common-tail rows, the local* $\mathsf{Real}^{\uparrow}$ *seal boundary, and the support rows* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

This distance pullback exports no quotient stream equality, selected limit, host real equality, countable choice, ambient Real completeness, metric-completeness row, standard bridge row, or direct access to an unsealed stream.

Proof. First apply Definition 38.525. It reads the metric-facing classifier agreement back to the four-face Real construction surface over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, the local $\mathsf{Real}^{\uparrow}$ seal, and the displayed support rows.

Next route the distance ledger through Definition 38.523. The displayed MetricDistanceWitness distance rows can be consulted only after the StreamName schedule, RegSeqRat regularity rows, dyadic endpoint and radius ledger, and local Real seal have already been reached.

For the reverse direction, begin with componentwise agreement of the four-face packet and support rows. The same classifier pullback correspondence repacks those rows as agreement of the sealed metric-facing route, and the observation factorization then identifies the displayed distance ledger read on both observations.

Finally use Definition 38.526 to discharge the excluded coordinates. Only after this Real seal boundary is visible may Definition 57.363 be cited, and then only as the downstream continuation-depth account for the already sealed distance witness. □

Theorem 38.528 (Real L10 metric witness facewise determinacy)**.** *Let R and S be accepted metric-facing* $\mathsf{Real}^{\uparrow}$ *finite-window observations. Their* MetricDistanceWitness *classifier reads agree exactly when the displayed four-face route agrees: the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and distance ledger; the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule; the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and common-tail classifier rows; the local* $\mathsf{Real}^{\uparrow}$ *seal classifier; and the support rows* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

Conversely, componentwise agreement of those four faces and support rows supplies the same MetricDistanceWitness *classifier read. This determinacy statement exports no quotient stream equality, selected limit, countable choice, host real equality, ambient completeness, metric-completeness row, standard bridge row, or direct access to an unsealed stream.*

Proof. For the forward direction, apply Definition 38.523. It routes each accepted metric-facing observation through the $\mathsf{StreamName}^{\uparrow}$ finite-window interface, the $\mathsf{RegSeqRat}^{\uparrow}$ regularity surface, the local $\mathsf{Real}^{\uparrow}$ seal, and only then the MetricDistanceWitness ledger.

Next use Definition 38.524. The metric classifier readback is therefore a readback of the StreamName, RegSeqRat, and Real seal classifiers, not a separate metric-side coordinate. Together with Definition 126.613, this places the Real consumer on the sibling L10 exit gate over the displayed four faces.

Now apply Definition 38.525. It identifies agreement of the metric witness classifiers with agreement of the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and local $\mathsf{Real}^{\uparrow}$ seal faces, together with the support rows BHist, hsame, Cont, Pkg, and NameCert.

For the reverse direction, start with componentwise agreement on those four faces and support rows. The same pullback correspondence repacks that data as agreement of the sealed Real-facing classifier route, and the classifier correspondence then supplies the identical MetricDistanceWitness read.

Finally apply Definition 38.526. The facewise agreement has no coordinate for quotient stream equality, selected limit, countable choice, host real equality, ambient completeness, metric-completeness rows, standard bridge rows, or direct unsealed-stream access, so the theorem states only determinacy of the finite classifier route. □

Theorem 38.529 (Real L10 metric four-face completeness refusal)**.** *Let R be an accepted metric-facing* $\mathsf{Real}^{\uparrow}$ *finite-window observation whose* MetricDistanceWitness *read agrees with the displayed four-face route through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, the local* $\mathsf{Real}^{\uparrow}$ *seal, and the support rows* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. Then the metric witness supplies only the sealed distance and classifier read on that finite route.*

It cannot be reinterpreted as quotient stream equality, selected limit data, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, metric-completeness data, a standard bridge row, host real equality, or direct access to an unsealed stream.*

Proof. First apply Definition 38.523. The accepted metric-facing observation reaches the distance witness only through the StreamName finite-window schedule, the RegSeqRat regularity surface, the DyadicRatCore endpoint and radius ledger, the local Real seal, and the listed support rows.

Next use the two pullback correspondences, Definition 38.525 and Definition 38.527. They identify the classifier and distance reads with the same four-face packet, so the metric-facing consumer receives no second coordinate beyond the sealed packet.

Now apply Definition 38.528. Agreement of the displayed faces and support rows determines the MetricDistanceWitness classifier read, and conversely that read can be unpacked only to those faces and rows.

Finally combine the no-choice route factorization Definition 126.522 with Definition 38.526. The StreamName route has no coordinate for quotient stream equality, selected limits, countable choice, host sequence equality, metric-completeness data, or standard bridge rows, and the Real metric pre-seal boundary blocks the same data before the local $\mathsf{Real}^{\uparrow}$ seal is visible. Hence the metric witness remains a sealed finite distance and classifier read, not a completeness, choice, quotient, limit, or bridge assertion. □

Theorem 38.530 (Real L10 open-phase sibling route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *public seal read in the L10 open phase factors through the certified countable-name route of chapter 126, the regular rational sequence route of chapter 301, and the dyadic ledger route of chapter 291 before it reaches the local* $\mathsf{Real}^{\uparrow}$ NameCert *row.*

Proof. Start with the ordered dependency lattice of Definition 38.442. It places the dyadic observation face, the finite stream-window face, and the regular-rational classifier face before the local Real seal and readback rows.

Use the source-route and interface-totality theorems for the same lattice. They require every open-phase Real or Completion interface read to remain inside the displayed BHist, hsame, Cont, Pkg, and NameCert route through those sibling surfaces.

The local seal is therefore reached by composing the DyadicRatCore ledger route, the StreamName finite-window route, and the RegSeqRat regular-rational route. This composition does not assert completeness, quotient real equality, selected representatives, or host real equality; it only records the finite sibling route feeding the local $\mathsf{Real}^{\uparrow}$ naming row. □

Theorem 38.531 (Real window synchronizer seal dependency)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read in the L10 open phase that depends on synchronized StreamName windows and RegSeqRat tails must pass through the* $\mathsf{RealWindowSynchronizer}^{\uparrow}$ *carrier of Definition 979.1. The read consumes the displayed window, tail, threshold, CauchyLimitSeal row, Real seal row, transport, route, provenance, and local naming rows before the local* $\mathsf{Real}^{\uparrow}$ *seal is public.*

Proof. Start from the open-phase sibling route of Definition 38.530. It already places each public Real seal read over the StreamName, RegSeqRat, and DyadicRatCore sibling surfaces.

When the read additionally requires synchronized windows, apply the RealWindowSynchronizer carrier and obligation rows of Definition 979.1 and Definition 979.7. These rows identify the required window-to-seal packet as $W, R, T, L, S, H, C, P, N$.

Thus the seal read reaches the local Real surface only after the synchronizer has replayed the common StreamName window, RegSeqRat tail, shared threshold, CauchyLimitSeal row, and RealUp seal row through the displayed route. □

Theorem 38.532 (Real tail-budget coherence consumer route)**.** *Every L10 open-phase* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer that uses shared tail budgets must also read the* $\mathsf{TailBudgetCoherence}^{\uparrow}$ *packet of chapter 917. Its route includes the TailMeet threshold, observation budget, selector budget, shared StreamName window, DyadicRatCore tolerance ledger, RegSeqRat readback, agreement seal, CauchyLimitSeal row, transport, continuation, provenance, and local naming rows before the consumer receives a Real seal.*

Proof. Use the open-phase dependency lattice to place the consumer on the finite sibling route through StreamName, RegSeqRat, DyadicRatCore, and the local Real seal.

If the same consumer uses shared tail budgets, apply the TailBudgetCoherence public export boundary and bridge interface from Definition 917.13 and Definition 917.15. These theorems expose the public route $M, O, S, W, D, R, A, L, H, C, P, N$.

The Real consumer therefore reads the shared tail-budget packet before receiving the Real seal. The packet contributes only the displayed tail-budget and seal rows, carried by BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ provenance. □

Theorem 38.533 (Real L10 synchronizer non-escape)**.** *The L10 open-phase route obtained by combining Definition 38.531 with Definition 38.532 exports no quotient real equality, selected host limit, host real equality, or ambient completeness principle. It exposes only the finite StreamName, RegSeqRat, DyadicRatCore, RealWindowSynchronizer, TailBudgetCoherence,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *route needed for the local* $\mathsf{Real}^{\uparrow}$ *seal read.*

Proof. First use the synchronizer dependency theorem. It routes every synchronized-window Real seal read through the finite RealWindowSynchronizer packet and excludes detached window, tail, limit-seal, and Real-seal routes.

Next use the tail-budget coherence consumer theorem. It routes every shared-budget consumer through the finite TailBudgetCoherence public packet rather than through an ambient completion object.

Finally combine these two finite packets with the original open-phase sibling route. None of the cited surfaces carries quotient real equality, selected host limits, host real equality, or ambient completeness, so the composite L10 route cannot export those coordinates. □

Theorem 38.534 (Real open-phase four-object terminal route)**.** *Every accepted L10 open-phase* $\mathsf{Real}^{\uparrow}$ *public seal or completion-facing read is determined by the four displayed faces* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *together with its* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. If two such reads agree on those four faces and those support rows, then they are the same terminal finite route for the public seal consumption. No quotient stream, selected host limit, ambient completeness principle, metric-completeness datum, countable-choice row, or standard bridge row can replace any one of the four faces.*

Proof. Start with Definition 38.530. It places every accepted open-phase $\mathsf{Real}^{\uparrow}$ seal or completion-facing read on the finite sibling route through StreamName, RegSeqRat, DyadicRatCore, and the local Real naming row before the read reaches the public Real surface.

Next apply Definition 126.500. The same read is the current Phase Real and Completion exit packet, so its displayed boundary consists exactly of the $\mathsf{StreamName}^{\uparrow}$ window face, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger face, $\mathsf{RegSeqRat}^{\uparrow}$ readback face, $\mathsf{Real}^{\uparrow}$ seal face, and the BHist, hsame, Cont, Pkg, and NameCert support rows.

Use Definition 126.449 to identify two accepted reads that agree on those four faces and support rows. Terminality leaves no second route through which the public seal can be consumed.

Finally use Definition 38.413. The pullback repacks the terminal boundary as a local $\mathsf{Real}^{\uparrow}$ route and preserves the exclusions from the sibling and exit-route theorems, so quotient streams, selected host limits, ambient completeness, metric-completeness data, countable-choice rows, and standard bridge rows cannot stand in for a missing face. □

Theorem 38.535 (Real terminal four-object refusal)**.** *Every accepted L10* $\mathsf{Real}^{\uparrow}$ *public seal or completion-facing read must display the four terminal faces* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *together with its* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. A proposed public seal, completion read, or terminal route that omits one of those four faces, or replaces it by quotient stream equality, a selected host limit, ambient completeness, metric-completeness data, countable-choice rows, or a standard bridge row, lies outside the accepted terminal finite route.*

Proof. Apply Definition 38.530. It puts every accepted L10 Real seal read on the finite sibling route through StreamName, RegSeqRat, DyadicRatCore, and the local Real naming row before the read reaches the public surface.

Next apply Definition 126.500. The completion-facing packet has exactly the four displayed object faces and the displayed BHist, hsame, Cont, Pkg, and NameCert support rows.

Use Definition 126.449. Agreement on the four faces and support rows determines the accepted terminal route, so a packet with an absent face has no accepted coordinate from which that face can be read.

Finally apply Definition 38.413. The pullback repacks the same finite boundary at the $\mathsf{Real}^{\uparrow}$ surface and preserves the exclusions already present in the sibling and exit routes. Hence quotient stream equality, selected host limits, ambient completeness, metric-completeness data, countable-choice rows, and standard bridge rows cannot serve as substitutes for any missing terminal face. □

Theorem 38.536 (Real open-phase objectwise status readback)**.** *Every accepted L10* $\mathsf{Real}^{\uparrow}$ *public seal or completion-facing read reports status objectwise: it must read the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-ledger status, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window status, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and seal status, and the local* $\mathsf{Real}^{\uparrow}$ *seal status as separate local faces. No route-level formalstatus token, aggregate bridge row, selected limit, quotient stream equality, ambient completeness row, metric-completeness row, or countable-choice row can replace any missing local face status.*

Proof. Start with Definition 38.534. It identifies every accepted public seal or completion-facing read with the four displayed faces and their BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support rows, so the status read already has four local coordinates rather than one route coordinate.

Apply Definition 38.535. A proposed read that omits one of those local faces, or replaces it by quotient stream equality, a selected host limit, ambient completeness, metric completeness, countable choice, or a bridge row, is outside the accepted terminal finite route.

Next use Definition 126.463 and Definition 126.467. These results keep the completion boundary readable only through the displayed facewise records and prevent a local status record from escaping into a global completion or bridge assertion.

The roadmap two-axis discipline is therefore applied only as a status-reading rule. It says how to read each local closure and verification entry once the corresponding face is present; it does not supply evidence for either axis, and it does not create a route-level token that can replace the DyadicRatCore, StreamName, RegSeqRat, or Real status face. □

Theorem 38.537 (Real L10 facewise exit status noncollapse)**.** *A Phase Real and Completion exit read for* $\mathsf{Real}^{\uparrow}$ *is accepted exactly when the four local faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *each expose their own closure and status row through the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *support. No aggregate route-level formalstatus token, bridge row, quotient stream, selected host limit, ambient completeness row, metric-completeness row, or countable-choice row can replace any one of those four facewise status reads.*

Proof. For the forward direction, apply Definition 38.534. It identifies every accepted exit read with the four-face terminal boundary, so each status read is attached to one of the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces and to the common BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support.

For the reverse direction, use Definition 38.536. Once all four local faces expose their own status rows through the shared support, the exit read is precisely the objectwise status readback already permitted for the L10 Real route.

Apply Definition 38.535 to the noncollapse clause. Any packet that omits one local face, or substitutes quotient stream equality, a selected host limit, ambient completeness, metric completeness, countable choice, or a bridge row, is outside the terminal finite route and therefore cannot supply the missing status coordinate.

Finally use Definition 126.500 together with Definition 38.413. These theorems transport the same correspondence across the StreamName exit route and the local Real pullback, so the statement records facewise exit status across the four L10 objects rather than a new verification-axis upgrade. □

The $\mathsf{Real}^{\uparrow}$ seal is a downstream consumer of chapter 126, chapter 301, and chapter 291. The $\mathsf{StreamName}^{\uparrow}$ surface supplies finite observation windows, the $\mathsf{RegSeqRat}^{\uparrow}$ surface supplies the regular rational source row, and the $\mathsf{DyadicRatCore}^{\uparrow}$ surface supplies the dyadic tolerance and readback ledger; only after those three sibling surfaces are in scope does the local $\mathsf{Real}^{\uparrow}$ seal present its public certificate boundary.

Theorem 38.538 (Independent reindexed constant rational embedding certificate)**.** *For histories* $d, e : \mathsf{Hist}$ *and observation maps* $r, q : \mathsf{Hist} \to \mathsf{Hist}$*, the two concrete endpoint assignments*

$$d \longmapsto (\mathsf{RatConstStream}_d \circ r, \mathsf{E1}(d)), \qquad e \longmapsto (\mathsf{RatConstStream}_e \circ q, \mathsf{E1}(e))$$

supply the independently scheduled constant rational embedding certificate into RealUp. The first endpoint has carrier exactness

$$\mathsf{RatHistoryCarrier}(d) \iff \mathsf{RatStreamNameCarrier}(\mathsf{RatConstStream}_d \circ r) \iff \mathsf{RealConstantHistoryCarrier}(\mathsf{E1}($$

and the second endpoint has carrier exactness

$$\mathsf{RatHistoryCarrier}(e) \iff \mathsf{RatStreamNameCarrier}(\mathsf{RatConstStream}_e \circ q) \iff \mathsf{RealConstantHistoryCarrier}(\mathsf{E1}($$

Its classifier exactness is the three-row chain displayed in Definition 38.29: the RatUp classifier of d and e, the StreamNameUp classifier of $\mathsf{RatConstStream}_d \circ r$ and $\mathsf{RatConstStream}_e \circ q$, the RealUp unary-observation stream classifier of those same streams, and the RealUp constant-history classifier of $\mathsf{E1}(d)$ and $\mathsf{E1}(e)$ are equivalent.

Proof. Apply Definition 38.32 to d with observation map r. This gives the first carrier row, identifying the RatUp carrier of d, the StreamNameUp carrier of $\mathsf{RatConstStream}_d \circ r$, and the RealUp constant carrier of $\mathsf{E1}(d)$.

Apply the same theorem separately to e with observation map q. This gives the second carrier row, identifying the RatUp carrier of e, the StreamNameUp carrier of $\mathsf{RatConstStream}_e \circ q$, and the RealUp constant carrier of $\mathsf{E1}(e)$.

For classifier exactness, apply Definition 38.29. Its three equivalence rows are precisely the classifier rows required for independently scheduled constant streams and their paired e-one seals. □

Lean4 ✓ `BEDC.Derived.RealUp.RealIndependentReindexedConstant rational embedding certificate`

Theorem 38.539 (Real reindexed constant finite-window package)**.** *For histories d, e : Hist, observation maps r, q : Hist $\to$ Hist, and a probe bundle $\mathcal{P}$: ProbeBundle, suppose the bundle contains a certified unary observation:*

$$\exists n : \mathsf{Hist},\ \mathsf{InBundle}(n, \mathcal{P}) \wedge \mathsf{UnaryHistory}(n).$$

Then every RatUp classifier witness $\rho : \mathsf{RatHistoryClassifier}(d, e)$ determines the finite-window constant bridge package:

1. *the finite StreamName observation surface*

$$\mathsf{RatStreamNameFiniteWindowClassifier}(\mathsf{RatConstStream}_d \circ r, \mathsf{RatConstStream}_e \circ q, \mathcal{P});$$

2. *the carrier rows for d and e displayed in Definition 38.538;*
3. *the classifier bridge from ρ through the independently reindexed StreamName row, the RealUp unary-observation stream row, and the RealUp constant-history classifier row of $\mathsf{E1}(d)$ and $\mathsf{E1}(e)$;*
4. *the RegSeqRat-facing ledger whose entries are exactly the* InBundle *rows of $\mathcal{P}$ together with their* UnaryHistory *witnesses and the pointwise RatUp classifier copied from ρ.*

Proof. First build the finite observation row. Apply Definition 126.56 to the constant streams with endpoints d and e and to the inhabited probe bundle $\mathcal{P}$. The reverse direction of that exactness theorem consumes ρ and yields the finite-window classifier for $\mathsf{RatConstStream}_d$ and $\mathsf{RatConstStream}_e$.

The displayed streams are independently reindexed, but constant streams ignore their observation argument. Thus at every bundled certified unary observation n, both composites evaluate as $\mathsf{RatConstStream}_d(r(n)) = d$ and $\mathsf{RatConstStream}_e(q(n)) = e$. The same pointwise classifier ρ therefore supplies the required $\mathsf{RatStreamNameFiniteWindowClassifier}(\mathsf{RatConstStream}_d \circ r, \mathsf{RatConstStream}_e \circ q, \mathcal{P})$ row.

Next attach the global bridge. Apply Definition 38.538 to d, e, r, q. Its two carrier rows give the RatUp–StreamName–RealUp carrier identifications for the two endpoints, and its classifier rows transport ρ through the independently reindexed StreamName classifier, the RealUp unary-observation stream classifier, and the RealUp constant-history classifier of the two e-one seals.

Finally repack the finite-window row with those carrier and classifier rows. The ledger consumed downstream by RegSeqRat is not a new carrier: it is the visible ProbeBundle spine, each InBundle membership row, the corresponding UnaryHistory witness, and the copied RatUp point classifier at that observation. This is precisely the finite observation surface associated to the checked global constant embedding. □

Theorem 38.540 (Real stream classifier finite-prefix stability package)**.** *For rational-observation streams $x, y, z : \mathbb{N} \to \mathsf{Hist}$ and prefix index n, if*

$$\forall i,\ \mathsf{RatHistoryCarrier}(x(i)), \quad \mathsf{RealStreamClassifier}(x, y), \quad \mathsf{RealStreamClassifier}(y, z),$$

then

$$\mathsf{RealStreamPrefixClassifier}(x, x, n) \wedge \mathsf{RealStreamPrefixClassifier}(y, x, n) \wedge \mathsf{RealStreamPrefixClassifier}(x, z, n) \wedge \mathsf{RatHistory}$$

Proof. Apply Definition 38.106 to $\mathsf{RealStreamClassifier}(x, y)$ at the selected prefix index n, and apply the same theorem to $\mathsf{RealStreamClassifier}(y, z)$ at n. These give the two finite-prefix classifier witnesses for x with y and for y with z.

Use Definition 38.109 with the displayed rational-history carrier row for x to obtain $\mathsf{RealStreamPrefixClassifier}(x,$ Apply Definition 38.110 to the x, y prefix witness to obtain $\mathsf{RealStreamPrefixClassifier}(y, x, n)$.

Compose the x, y and y, z prefix witnesses by Definition 38.147, yielding $\mathsf{RealStreamPrefixClassifier}(x, z, n)$. Finally apply Definition 38.111 to this composite prefix to recover $\mathsf{RatHistoryClassifier}(x(n), z(n))$.

Apply the RatUp positive-denominator projection Definition 37.50 to the endpoint classifier. Positive-denominator readback by Definition 37.12 gives $\mathsf{UnaryHistory}(x(n))$ and $\mathsf{UnaryHistory}(z(n))$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier finite prefix unary stability package`

Fit. Traditional target: finite-prefix stability for RealUp streams. BEDC source: RatUp plus RealUp stream prefixes. Carrier: rational-observation streams. Classifier: RealStreamClassifier and RealStreamPrefixClassifier. Stability: prefix reflexivity, symmetry, transitivity, and endpoint projection. Ledger: the selected prefix index n. Core theorem: Definition 38.540. Exactness: the three prefix rows, selected endpoint classifier, and two unary endpoint rows. Standard bridge: finite rational prefix agreement. Status: ProofTarget.

Theorem 38.541 (Real stream finite-prefix endpoint denominator package)**.** *For rational-observation streams $x, y, z : \mathbb{N} \to \mathsf{Hist}$ and prefix index n, if*

$$\forall i,\ \mathsf{RatHistoryCarrier}(x(i)), \quad \mathsf{RealStreamClassifier}(x, y), \quad \mathsf{RealStreamClassifier}(y, z),$$

then the selected finite prefixes and endpoint carry the denominator package:

$$\begin{aligned}&\mathsf{RealStreamPrefixClassifier}(x, x, n) \wedge \mathsf{RealStreamPrefixClassifier}(y, x, n) \wedge \mathsf{RealStreamPrefixClassifier}(x, z, n) \wedge \mathsf{RatHist}\\ &\quad \wedge\ \mathsf{PositiveUnaryDenominator}(x(n)) \wedge \mathsf{PositiveUnaryDenominator}(z(n)) \wedge \mathsf{UnaryHistory}(x(n)) \wedge \mathsf{UnaryHis}\\ &\quad\quad \wedge\ (\mathsf{hsame}(x(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(z(n), \mathsf{e}) \to \mathsf{False}).\end{aligned}$$

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier finite prefix endpoint denominator package`

Proof. Use finite-prefix reflexivity on the carrier row for x, use $\mathsf{RealStreamClassifier}(x, y)$ to obtain the x, y prefix and symmetrize it to the y, x prefix, and compose the x, y and y, z prefixes to obtain the x, z prefix. Endpoint projection gives $\mathsf{RatHistoryClassifier}(x(n), z(n))$. The rational-history classifier supplies positive denominator witnesses for both endpoints, and the positive denominator readback gives unary membership together with exclusion of e. □

Theorem 38.542 (Real stream finite-prefix transported endpoint denominator package)**.** *For rational-observation streams $x, x', y, z, z' : \mathbb{N} \to \mathsf{Hist}$ and index n, suppose*

$$\mathsf{RealStreamClassifier}(x, y), \quad \mathsf{RealStreamClassifier}(y, z), \quad \mathsf{hsame}(x(n), x'(n)), \quad \mathsf{hsame}(z(n), z'(n)).$$

Then the transported selected endpoints carry the denominator package:

$$\mathsf{RatHistoryClassifier}(x'(n), z'(n)) \wedge \mathsf{PositiveUnaryDenominator}(x'(n)) \wedge \mathsf{PositiveUnaryDenominator}(z'(n))$$
$$\wedge \mathsf{UnaryHistory}(x'(n)) \wedge \mathsf{UnaryHistory}(z'(n)) \wedge (\mathsf{hsame}(x'(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(z'(n), \mathsf{e}) \to \mathsf{False}).$$

Proof. Compose the two real stream classifiers pointwise. At the selected index this gives $\mathsf{RatHistoryClassifier}(x(n), z$ Transport that rational history classifier along the displayed hsame rows to obtain $\mathsf{RatHistoryClassifier}(x'(n), z'(n))$. RatUp positive-denominator readback then gives the two positive denominator witnesses, and each positive denominator witness gives unary membership together with exclusion of e. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier finite prefix transported endpoint denominator package`

Theorem 38.543 (Real stream prefix truncation endpoint denominator package)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and indices m, n, if*

$$\mathsf{RealStreamPrefixClassifier}(x, y, m + n),$$

then the selected endpoints of the shorter certified prefix carry the complete endpoint-classifier and denominator-shape package:

$$\mathsf{RatHistoryClassifier}(x(n), y(n)) \wedge \mathsf{PositiveUnaryDenominator}(x(n)) \wedge \mathsf{PositiveUnaryDenominator}(y(n)) \wedge \mathsf{UnaryHistory}(x($$

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier truncated endpoint denominator package`

Proof. First descend from the displayed prefix through $m + n$ to the selected prefix through n. This is the constructor induction used in Definition 38.118: the base prefix is already the selected prefix, and each successor step projects the shorter recursive prefix component.

Apply Definition 38.111 to the resulting prefix classifier at n. This projects the endpoint rational-history classifier $\mathsf{RatHistoryClassifier}(x(n), y(n))$, which is kept as the first conjunct of the displayed package.

Apply Definition 37.50 to the endpoint classifier. The two projected witnesses are exactly $\mathsf{PositiveUnaryDenominator}(x(n))$ and $\mathsf{PositiveUnaryDenominator}(y(n))$.

Apply Definition 37.12 separately to the two positive-denominator rows. The two applications supply $\mathsf{UnaryHistory}(x(n))$, $\mathsf{UnaryHistory}(y(n))$, and the two nonemptiness implications, so the seven displayed rows repack directly. □

Theorem 38.544 (Real stream prefix add-left endpoint positive unary nonempty package)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and indices m, n, if the left stream has unary histories pointwise and the prefix through $m + n$ is classified,*

$$\forall i,\ \mathsf{UnaryHistory}(x(i)), \qquad \mathsf{RealStreamPrefixClassifier}(x, y, m + n),$$

then the selected endpoints carry positive unary denominator witnesses, unary history rows, and empty-boundary exclusions:

$$\mathsf{PositiveUnaryDenominator}(x(n)) \wedge \mathsf{PositiveUnaryDenominator}(y(n)) \wedge \mathsf{UnaryHistory}(x(n)) \wedge \mathsf{UnaryHistory}(y(n)) \wedge (\mathsf{hsame}(x(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y(n), \mathsf{e}) \to \mathsf{False}).$$

Proof. Use add-left prefix extraction to descend from the displayed $m + n$ prefix to the selected n prefix, retaining the unary row at $x(n)$. Endpoint projection reads the rational-history classifier at $(x(n), y(n))$. RatUp positivity gives positive unary denominator witnesses for both endpoints, and positive denominator readback supplies the two unary rows and the two empty-boundary exclusions. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier add left endpoint positive unary nonempty package`

Theorem 38.545 (Real stream prefix truncated endpoint e-zero absurdity)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, indices m, n, and histories $z_X, z_Y : \mathsf{Hist}$, if*

$$\mathsf{RealStreamPrefixClassifier}(x, y, m + n),$$

then the selected truncated endpoints cannot be internally same as zero-headed endpoints:

$$(\mathsf{hsame}(x(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y(n), \mathsf{E0}(z_Y)) \to \mathsf{False}).$$

Proof. Apply the truncated endpoint denominator package to obtain positive unary denominator witnesses for $x(n)$ and $y(n)$. Transport each positive denominator witness across the displayed zero-headed endpoint comparison, and use the RatUp positive-denominator zero-headed exclusion on each side. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier truncated endpoint e0 absurd`

Fit. Traditional target: finite-prefix denominator readback for RealUp streams. BEDC source: RealUp prefix classifier plus RatUp denominator certificate. Carrier: rational-observation streams. Classifier: RealStreamPrefixClassifier. Stability: prefix truncation and endpoint projection. Ledger: selected indices m, n. Core theorem: Definition 38.543. Exactness: the displayed endpoint-classifier and denominator-shape package. Standard bridge: RealUp dyadic embedding and RegSeqRat endpoint-readback obligations. Status: ProofTarget.

Theorem 38.546 (Real stream prefix contextual one-tail denominator package)**.** *For rational-observation streams $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$, indices m, n, and histories $a, b : \mathsf{Hist}$, assume*

$$\mathsf{RealStreamPrefixClassifier}(x, y, m + n),$$

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

and

$$\mathsf{Cont}(p_X(n), x(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y(n$$

Then the selected contextual endpoints carry the finite-prefix package:

1. $\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n))$.
2. $\mathsf{PositiveUnaryDenominator}(o_X(n))$ *and* $\mathsf{PositiveUnaryDenominator}(o_Y(n))$.
3. $\mathsf{UnaryHistory}(o_X(n))$ *and* $\mathsf{UnaryHistory}(o_Y(n))$.
4. $\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}$ *and* $\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False}$.
5. *If* $\mathsf{hsame}(o_X(n), \mathsf{E1}(a))$ *and* $\mathsf{hsame}(o_Y(n), \mathsf{E1}(b))$, *then* $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$.

Proof. First apply Definition 38.122 to the classified prefix and the four selected continuation displays. This gives the contextual endpoint classifier $\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n))$.

Apply Definition 37.50 to that classifier. The two projections are the positive unary denominator witnesses for $o_X(n)$ and $o_Y(n)$.

Apply Definition 37.12 separately to the two positive denominator witnesses. This gives unary membership and empty endpoint exclusion for both contextual outputs.

For the one-tail readback, transport the endpoint classifier along the two displayed hsame comparisons to obtain $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$. Apply Definition 37.49 in the forward direction, which yields the two unary tail witnesses and $\mathsf{hsame}(a, b)$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier contextual e1 denominator package`

Fit. Traditional target: finite-prefix contextual denominator readback for RealUp streams. BEDC source: RealUp prefix context closure plus RatUp denominator and one-tail exactness. Carrier: rational-observation streams with selected unary contexts. Classifier: RealStreamPrefixClassifier and RatHistoryClassifier. Stability: prefix truncation, contextual endpoint closure, and hsame transport. Ledger: selected indices m, n and displayed outputs $o_X(n), o_Y(n)$. Core theorem: Definition 38.546. Exactness: the displayed five-part endpoint package. Standard bridge: RegSeqRat contextual endpoint readback. Status: ProofTarget.

Theorem 38.547 (Real stream prefix contextual zero-endpoint exclusion package)**.** *For rational-observation streams* $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$, *indices* m, n, *and histories* $z_X, z_Y : \mathsf{Hist}$, *assume*

$$\mathsf{RealStreamPrefixClassifier}(x, y, m+n),$$

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

and

$$\mathsf{Cont}(p_X(n), x(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y(n$$

Then the selected contextual endpoints exclude every zero-headed endpoint:

$$(\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False}).$$

Proof. Apply Definition 38.546 to the classified prefix and the displayed unary-context and continuation hypotheses. The package supplies $\mathsf{UnaryHistory}(o_X(n))$ and $\mathsf{UnaryHistory}(o_Y(n))$.

Suppose $\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X))$ holds. Transport the left unary-history witness along this displayed endpoint comparison, then apply the unary no-zero-extension theorem to get a contradiction.

The right endpoint is identical. If $\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y))$ holds, transport $\mathsf{UnaryHistory}(o_Y(n))$ to the displayed zero-headed endpoint and apply the same unary no-zero-extension theorem. These two implications repack as the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier contextual e0 endpoint absurd`

Fit. Traditional target: finite-prefix contextual endpoint shape exclusion. BEDC source: RealUp prefix classifier, RatUp denominator package, and Cont. Carrier: rational-observation streams with selected unary contexts. Classifier: RealStreamPrefixClassifier plus endpoint RatHistoryClassifier. Stability: inherited from contextual endpoint closure. Ledger: selected indices and contextual outputs. Core theorem: Definition 38.547. Exactness: the two zero-headed exclusions. Standard bridge: RegSeqRat endpoint-shape readback. Status: ProofTarget.

Theorem 38.548 (Real stream prefix contextual full endpoint package)**.** *For rational-observation streams* $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, indices* m, n*, histories* $a, b, z_X, z_Y : \mathsf{Hist}$*, assume*

$$\mathsf{RealStreamPrefixClassifier}(x, y, m+n),$$

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

$$\mathsf{Cont}(p_X(n), x(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y(n$$

and

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)) \quad \textit{and} \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)).$$

Then the selected contextual endpoints carry all of the following data:

1. $\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n))$.
2. $\mathsf{PositiveUnaryDenominator}(o_X(n))$ *and* $\mathsf{PositiveUnaryDenominator}(o_Y(n))$.
3. $\mathsf{UnaryHistory}(o_X(n))$ *and* $\mathsf{UnaryHistory}(o_Y(n))$.
4. $\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}$ *and* $\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False}$.
5. $\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}$ *and* $\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False}$.
6. $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$.

Proof. First apply Definition 38.546 to the classified prefix and the displayed unary-context and continuation hypotheses. Use the two displayed one-extension comparisons for the final readback row. This supplies the endpoint classifier, the positive denominator witnesses, the unary history witnesses, the nonempty exclusions, and $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$.

Next apply Definition 38.547 to the same classified prefix, unary-context data, continuation data, and zero-extension tests z_X, z_Y. It gives the two zero-headed exclusions, so the six displayed rows are exactly the collected finite-prefix endpoint package. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier contextual full endpoint package`

Theorem 38.549 (Real stream classifier selected contextual full endpoint package)**.** *For rational-observation streams* $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, a selected index* n*, and histories* $a, b, z_X, z_Y : \mathsf{Hist}$*, assume*

$$\mathsf{RealStreamClassifier}(x, y),$$

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

$$\mathsf{Cont}(p_X(n), x(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y(n$$

and

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)) \quad \textit{and} \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)).$$

Then the selected contextual endpoints carry all of the following data:

1. $\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n))$.
2. $\mathsf{PositiveUnaryDenominator}(o_X(n))$ *and* $\mathsf{PositiveUnaryDenominator}(o_Y(n))$.
3. $\mathsf{UnaryHistory}(o_X(n))$ *and* $\mathsf{UnaryHistory}(o_Y(n))$.
4. $\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}$ *and* $\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False}$.
5. $\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}$ *and* $\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False}$.
6. $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$.

Proof. Apply Definition 38.106 at the selected index n. This turns the global $\mathsf{RealStreamClassifier}(x, y)$ row into the finite-prefix classifier $\mathsf{RealStreamPrefixClassifier}(x, y, n)$, read as the $0 + n$ instance needed by the prefix endpoint packages.

With this prefix classifier in hand, apply Definition 38.546 using the displayed unary-context rows, the two context-identification rows, the four continuation rows, and the two one-headed endpoint comparisons. It supplies the endpoint classifier, the positive unary denominator witnesses, the unary endpoint witnesses, the nonempty exclusions, and $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$.

Finally apply Definition 38.547 to the same $0+n$ prefix classifier and the same selected context data, now with the zero-headed tests z_X, z_Y. The two resulting contradictions against $\mathsf{E0}(z_X)$ and $\mathsf{E0}(z_Y)$ complete the displayed endpoint package. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier selected contextual full endpoint package`

Theorem 38.550 (Real stream selector-seal endpoint route)**.** *A terminal* $\mathsf{Real}^{\uparrow}$ *endpoint read supplied to a* $\mathsf{RealCompletionSelectorSeal}^{\uparrow}$ *packet is confined to the selected stream prefix and contextual endpoint package of Definition 38.549. Thus the endpoint exposes only the selected finite-prefix classifier, positive unary denominator witnesses, unary endpoint witnesses, nonempty exclusions, zero-headed exclusions, and one-headed tail agreement rows already present in that package.*

The endpoint read carries no host real equality, quotient stream equality, detached limit object, ambient completeness principle, or independent completion route beyond the selected contextual endpoint data.

Proof. Apply Definition 38.549 at the selected index read by the selector-seal packet. It extracts the finite-prefix classifier and the contextual endpoint rows from the global $\mathsf{RealStreamClassifier}$ route.

The positive unary denominator and nonempty rows in that package are supplied by Definition 37.12, used in the preceding endpoint arguments. They make the endpoint a visible finite readback row rather than a hidden host-real object.

Finally inspect the package output. It lists classifier, denominator, unary, nonempty, zero-headed exclusion, and one-headed tail agreement rows only. None of those rows is host real equality, quotient stream equality, a detached limit, ambient completeness, or a second completion route, so the selector-seal endpoint remains confined to the selected contextual endpoint surface. □

Fit. Traditional target: selected contextual full endpoint package for real observation streams. BEDC source: stream classifier prefix extraction, prefix contextual denominator package, and prefix contextual zero-endpoint exclusion. Carrier: rational-observation streams and selected context histories. Classifier: $\mathsf{RealStreamClassifier}$ with the induced $\mathsf{RatHistoryClassifier}$ on the selected outputs. Stability: inherited from hsame context transport and Cont composition at the selected index. Ledger: the single chosen index n, its input contexts, output contexts, and endpoint heads. Core

theorem: Definition 38.549. Exactness: classifier, denominator, unary, nonempty, zero-headed exclusion, and one-headed tail agreement rows. Standard bridge: RegSeqRat and dyadic endpoint readback for selected observations. Status: ProofTarget.

Theorem 38.551 (Real unary stream-name classifier exactness)**.** *For observation maps* s, t : Hist → Hist*, if*

$$\mathsf{RatStreamNameCarrier}(s) \quad \textit{and} \quad \mathsf{RatStreamNameCarrier}(t),$$

then the Real unary classifier and the StreamNameUp classifier identify the same BEDC relation:

$$\mathsf{RealUnaryStreamClassifier}(s, t) \iff \mathsf{RatStreamNameClassifier}(s, t).$$

Proof. Unfold Definition 126.1, Definition 126.2, and Definition 38.26. Both classifier names then expose the same pointwise assertion: for every certified unary observation n, the histories $s(n)$ and $t(n)$ are related by RatHistoryClassifier.

For the forward direction, combine the two displayed carrier hypotheses with the pointwise Real unary classifier row. Repack those rows under the StreamNameUp classifier name.

For the reverse direction, project the pointwise classifier field from RatStreamNameClassifier(s, t) at each certified unary observation. The resulting pointwise RatUp classifier is exactly the Real unary classifier row. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamClassifier ratStreamName pointwise iff`

Definition 38.552 (Phase Real certificate obligation surface)**.** *The Phase Real stream-observation interface is the tuple consisting of* RatStreamNameCarrier*,* RatStreamNameClassifier*,* RealUnaryStreamClassifier*,* RealUnaryStreamWindowClassifier*, certified unary anchor and bound rows, and the selected endpoint denominator package. Its carrier face is the rat-stream-name carrier row, its classifier face is the Real unary classifier identified with the StreamNameUp classifier, its finite-window face is the bounded unary observation window, and its selected-endpoint face is the denominator package at the certified observation.*

Proof. The carrier and classifier faces are named by Definition 38.551: under the two RatStreamNameCarrier rows, the Real unary stream classifier and the RatStreamNameClassifier row describe the same pointwise BEDC comparison.

The finite-window face is Definition 38.553. It reads the certified unary anchor and bound rows and returns the RealUnaryStreamWindowClassifier row for the same observation maps.

The selected-endpoint face is Definition 38.554. It projects a certified observation to the endpoint RatHistoryClassifier row, the two positive-denominator rows, and the associated unary and nonempty endpoint facts. These faces together are exactly the Phase Real stream-observation obligation surface. □

Fit. Traditional target: classifier exactness for certified countable rational observations. BEDC source: StreamName$^{\uparrow}$+Real$^{\uparrow}$ over BHist. Carrier: RatStreamNameCarrier. Classifier pair: RealUnaryStreamClassifier and RatStreamNameClassifier. Stability: the existing carrier rows in Definition 38.273. Ledger: the unary observation witness. Core theorem: Definition 38.551. Exactness: the displayed if-and-only-if. Standard bridge: pointwise rational stream equality. Status: ProofTarget.

Theorem 38.553 (Real unary StreamNameUp finite-window coverage)**.** *For observation maps* s, t : Hist → Hist *and histories* a, w : Hist*, if*

RatStreamNameCarrier(s), RatStreamNameCarrier(t), RatStreamNameClassifier(s, t), UnaryHistory(a), Unary

then the certified StreamNameUp classifier supplies the finite RealUp observation window:

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w).$$

Proof. Use the reverse direction of Definition 38.551 with the two carrier rows. The StreamNameUp classifier hypothesis therefore gives $\mathsf{RealUnaryStreamClassifier}(s, t)$.

The remaining hypotheses are exactly the unary anchor and unary bound required by Definition 38.155. Applying that coverage theorem to s, t, a, and w yields $\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w)$. □

Lean4 ✓ `BEDC.Derived.RealUp.RatStreamNameClassifier real unary window coverage`

Fit. Traditional target: finite windows for certified countable rational observations. BEDC source: StreamNameUp plus RealUp unary stream classifier. Carrier: observation maps over BHist. Classifier: RealUnaryStreamWindowClassifier. Stability: inherited from Definition 38.551 and Definition 38.155. Ledger: anchor, bound, and bounded offset. Core theorem: Definition 38.553. Exactness: bounded pointwise RatUp classification. Standard bridge: finite rational observation windows. Status: ProofTarget.

Theorem 38.554 (Real unary StreamNameUp selected endpoint denominator package)**.** *For observation maps $s, t : \mathsf{Hist} \to \mathsf{Hist}$, a certified observation $n : \mathsf{Hist}$, and histories $z_s, z_t : \mathsf{Hist}$, assume*

$$\mathsf{RatStreamNameClassifier}(s, t), \quad \mathsf{UnaryHistory}(n).$$

Then the selected observation carries the RatUp denominator package:

$$\begin{aligned}&\mathsf{RatHistoryClassifier}(s(n), t(n)) \wedge \mathsf{PositiveUnaryDenominator}(s(n)) \wedge \mathsf{PositiveUnaryDenominator}(t(n)) \wedge \\ &\mathsf{UnaryHistory}(s(n)) \wedge \mathsf{UnaryHistory}(t(n)) \wedge (\mathsf{hsame}(s(n), \mathsf{e}) \to \mathsf{False}) \wedge \\ &(\mathsf{hsame}(t(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(s(n), \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge (\mathsf{hsame}(t(n), \mathsf{E0}(z_t)) \to \mathsf{False}).\end{aligned}$$

Lean4 ✓ `BEDC.Derived.RealUp.RatStreamNameClassifier selected endpoint denominator package`

Proof. Project $\mathsf{RatStreamNameClassifier}(s, t)$ at the certified observation n. The unary certificate for n gives the point classifier $\mathsf{RatHistoryClassifier}(s(n), t(n))$.

Apply Definition 37.50 to this point classifier, and then apply Definition 37.12 separately to the two positive-denominator witnesses. This gives the two positive denominator rows, the two unary endpoint rows, and the two nonempty exclusions.

For a zero-headed display on the left, transport $\mathsf{PositiveUnaryDenominator}(s(n))$ along $\mathsf{hsame}(s(n), \mathsf{E0}(z_s))$ by Definition 37.6, contradicting Definition 37.10. The right endpoint uses the same argument with $t(n)$ and z_t, and the collected rows form the displayed package. □

Fit. Traditional target: selected rational observation readback. BEDC source: $\mathsf{StreamName}^{\uparrow} + \mathsf{Rat}^{\uparrow}$ over BHist. Carrier: observation maps. Classifier: RatStreamNameClassifier. Stability: point projection and RatUp denominator transport. Ledger: selected observation and zero-head tests. Core theorem: Definition 38.554. Exactness: the displayed endpoint package. Standard bridge: finite rational observation readback. Status: ProofTarget.

Theorem 38.555 (Real unary StreamNameUp transported selected endpoint shape package)**.** *For unary observation maps $s, t, s', t' : \mathsf{Hist} \to \mathsf{Hist}$, a certified observation $n : \mathsf{Hist}$, and histories $a, b, z_s, z_t : \mathsf{Hist}$, assume*

$$\mathsf{UnaryHistory}(n), \quad \mathsf{RealUnaryStreamClassifier}(s, t),$$

the pointwise transport rows

$$\forall k,\ \mathsf{UnaryHistory}(k) \to \mathsf{hsame}(s(k), s'(k)), \quad \forall k,\ \mathsf{UnaryHistory}(k) \to \mathsf{hsame}(t(k), t'(k)),$$

and the displayed selected endpoints

$$\mathsf{hsame}(s'(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(t'(n), \mathsf{E1}(b)).$$

Then the transported selected endpoints carry the full RatUp denominator and one-tail shape package:

$$\begin{aligned}&\mathsf{RatHistoryClassifier}(s'(n), t'(n)) \wedge \mathsf{PositiveUnaryDenominator}(s'(n)) \wedge \mathsf{PositiveUnaryDenominator}(t'(n)) \wedge \\ &\mathsf{UnaryHistory}(s'(n)) \wedge \mathsf{UnaryHistory}(t'(n)) \wedge (\mathsf{hsame}(s'(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(t'(n), \mathsf{e}) \to \mathsf{False}) \wedge \\ &(\mathsf{hsame}(s'(n), \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge (\mathsf{hsame}(t'(n), \mathsf{E0}(z_t)) \to \mathsf{False}) \wedge \\ &\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).\end{aligned}$$

Proof. Evaluate $\mathsf{RealUnaryStreamClassifier}(s, t)$ at the certified observation n. The assumption $\mathsf{UnaryHistory}(n)$ gives the point classifier $\mathsf{RatHistoryClassifier}(s(n), t(n))$.

Apply Definition 37.54 to this point classifier and to the two pointwise transport rows evaluated at n. This gives the transported selected classifier $\mathsf{RatHistoryClassifier}(s'(n), t'(n))$.

Apply Definition 37.50 to the transported selected classifier, then apply Definition 37.12 separately to the two positive-denominator witnesses. These rows give the two positive denominators, the two unary endpoint rows, and the two nonempty exclusions.

It remains to rule out zero-headed displays. If $\mathsf{hsame}(s'(n), \mathsf{E0}(z_s))$ holds, transport $\mathsf{PositiveUnaryDenominator}(s'$ along that comparison by Definition 37.6, then contradict Definition 37.10. The same argument for $t'(n)$ and z_t gives the second zero-headed exclusion.

For the one-tail readback, transport $\mathsf{RatHistoryClassifier}(s'(n), t'(n))$ along the two displayed $\mathsf{E1}$ endpoint comparisons, obtaining $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$. Apply Definition 37.49 in the forward direction to read back $\mathsf{UnaryHistory}(a)$, $\mathsf{UnaryHistory}(b)$, and $\mathsf{hsame}(a, b)$, then package all displayed rows. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamClassifier transported selected endpoint shape package`

Fit. Traditional target: selected unary stream observation readback. BEDC source: RealUp unary streams plus RatUp classifier. Carrier: unary-indexed rational observation maps. Classifier: RealUnaryStreamClassifier. Stability: pointwise hsame transport. Ledger: selected certified observation and endpoint displays. Core theorem: Definition 38.555. Exactness: displayed endpoint package. Standard bridge: selected rational observation readback for RealUp names. Status: ProofTarget.

Theorem 38.556 (Rat StreamName unary-context full endpoint package)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$*, a selected observation* $n : \mathsf{Hist}$*, prefix and tail histories* $p_s, p_t, q_s, q_t : \mathsf{Hist}$*, middle histories* $m_s, m_t : \mathsf{Hist}$*, output histories* $o_s, o_t : \mathsf{Hist}$*, displayed tails* $a, b : \mathsf{Hist}$*, and zero-head tests* $z_s, z_t : \mathsf{Hist}$*, assume*

$$\begin{aligned}&\mathsf{RatStreamNameClassifier}(s, t), \quad \mathsf{UnaryHistory}(n), \quad \mathsf{UnaryHistory}(p_s), \quad \mathsf{hsame}(p_s, p_t), \\ &\mathsf{UnaryHistory}(q_s), \quad \mathsf{hsame}(q_s, q_t), \quad \mathsf{Cont}(p_s, s(n), m_s), \quad \mathsf{Cont}(m_s, q_s, o_s), \\ &\mathsf{Cont}(p_t, t(n), m_t), \quad \mathsf{Cont}(m_t, q_t, o_t), \quad \mathsf{hsame}(o_s, \mathsf{E1}(a)), \quad \mathsf{hsame}(o_t, \mathsf{E1}(b)).\end{aligned}$$

Then the two contextual outputs carry the full RatUp endpoint package:

$$\begin{aligned}&\mathsf{RatHistoryClassifier}(o_s, o_t) \wedge \mathsf{PositiveUnaryDenominator}(o_s) \wedge \mathsf{PositiveUnaryDenominator}(o_t)\wedge\\&\mathsf{UnaryHistory}(o_s) \wedge \mathsf{UnaryHistory}(o_t) \wedge (\mathsf{hsame}(o_s, \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_t, \mathsf{e}) \to \mathsf{False})\wedge\\&(\mathsf{hsame}(o_s, \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_t, \mathsf{E0}(z_t)) \to \mathsf{False})\wedge\\&\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).\end{aligned}$$

Proof. Project the point classifier from $\mathsf{RatStreamNameClassifier}(s, t)$ at the certified observation n. This gives $\mathsf{RatHistoryClassifier}(s(n), t(n))$.

Build the contextual output classifier by applying Definition 37.58 to the point classifier and the matching unary prefix and tail contexts, then use the four continuation displays and associativity of the continuation append to transport the closed classifier to o_s and o_t.

Apply Definition 45.136 to the same point classifier and the displayed continuation context. This exposes positive unary denominator witnesses for o_s and o_t. Applying Definition 37.12 separately gives the unary-history rows and the two exclusions against e.

For a zero-headed display on the left, transport $\mathsf{PositiveUnaryDenominator}(o_s)$ along $\mathsf{hsame}(o_s, \mathsf{E0}(z_s))$ and contradict Definition 37.10. The right endpoint uses the same transport argument with o_t and z_t.

Finally apply Definition 126.12 to the original StreamNameUp classifier, the certified observation, the matching contexts, the four continuation rows, and the two displayed $\mathsf{E1}$ outputs. This reads back $\mathsf{UnaryHistory}(a)$, $\mathsf{UnaryHistory}(b)$, and $\mathsf{hsame}(a, b)$. Collecting the classifier, denominator, exclusion, and readback rows gives the displayed endpoint package. □

Fit. Traditional target: unary-context endpoint readback for certified rational stream names. BEDC source: $\mathsf{StreamName}^{\uparrow} + \mathsf{Rat}^{\uparrow}$ over BHist. Carrier: observation maps with unary BEDC observations. Classifier: $\mathsf{RatStreamNameClassifier}$. Stability: point projection, RatUp unary context closure, continuation readback, and positive-denominator transport. Ledger: selected observation, matching prefix and tail contexts, continuation rows, endpoint displays, and zero-head tests. Core theorem: Definition 38.556. Exactness: the displayed contextual endpoint package. Standard bridge: concrete BHist-anchored rational observation contexts for RealUp names. Status: $\mathsf{ProofTarget}$.

Theorem 38.557 (Rat StreamName unary-context e-one tail coverage package)**.** *For observation maps $s, t : \mathsf{Hist} \to \mathsf{Hist}$, a selected observation $n : \mathsf{Hist}$, prefix and tail histories $p_s, p_t, q_s, q_t : \mathsf{Hist}$, middle histories $m_s, m_t : \mathsf{Hist}$, output histories $o_s, o_t : \mathsf{Hist}$, and zero-head tests $z_s, z_t : \mathsf{Hist}$, assume*

$$\begin{aligned}&\mathsf{RatStreamNameClassifier}(s, t), \quad \mathsf{UnaryHistory}(n), \quad \mathsf{UnaryHistory}(p_s), \quad \mathsf{hsame}(p_s, p_t),\\&\mathsf{UnaryHistory}(q_s), \quad \mathsf{hsame}(q_s, q_t), \quad \mathsf{Cont}(p_s, s(n), m_s), \quad \mathsf{Cont}(m_s, q_s, o_s),\\&\mathsf{Cont}(p_t, t(n), m_t), \quad \mathsf{Cont}(m_t, q_t, o_t).\end{aligned}$$

Then the local unary-context hypotheses construct displayed one-extension tails for the contextual outputs and carry the full RatUp endpoint package:

$$\begin{aligned}&\exists a, b : \mathsf{Hist},\ \mathsf{hsame}(o_s, \mathsf{E1}(a)) \wedge \mathsf{hsame}(o_t, \mathsf{E1}(b))\wedge\\&\mathsf{RatHistoryClassifier}(o_s, o_t) \wedge \mathsf{PositiveUnaryDenominator}(o_s) \wedge \mathsf{PositiveUnaryDenominator}(o_t)\wedge\\&\mathsf{UnaryHistory}(o_s) \wedge \mathsf{UnaryHistory}(o_t) \wedge (\mathsf{hsame}(o_s, \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_t, \mathsf{e}) \to \mathsf{False})\wedge\\&(\mathsf{hsame}(o_s, \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_t, \mathsf{E0}(z_t)) \to \mathsf{False})\wedge\\&\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).\end{aligned}$$

Proof. Project the point classifier from $\mathsf{RatStreamNameClassifier}(s,t)$ at the certified unary observation n. This gives $\mathsf{RatHistoryClassifier}(s(n),t(n))$.

Apply Definition 45.136 to that point classifier, the two matching unary contexts, and the four continuation rows. This supplies $\mathsf{PositiveUnaryDenominator}(o_s)$ and $\mathsf{PositiveUnaryDenominator}(o_t)$.

Unfold the two positive unary denominator witnesses. Choose tails a and b together with the displayed one-extension rows $\mathsf{hsame}(o_s,\mathsf{E1}(a))$ and $\mathsf{hsame}(o_t,\mathsf{E1}(b))$.

With those displayed tails, apply Definition 38.556 to the original StreamNameUp classifier, the certified observation, the matching context rows, the four continuation rows, and the two selected one-extension displays. The returned classifier, denominator, unary, exclusion, and tail readback rows combine with the two displays under $\exists a,b$. □

Fit. Traditional target: unary-context one-tail coverage for certified rational stream names. BEDC source: $\mathsf{StreamName}^{\uparrow}+\mathsf{Rat}^{\uparrow}$ over BHist. Carrier: observation maps with unary BEDC observations. Classifier: $\mathsf{RatStreamNameClassifier}$. Stability: point projection, positive denominator extraction, and full contextual endpoint packaging. Ledger: selected observation, matching prefix and tail contexts, continuation rows, and zero-head tests. Core theorem: Definition 38.557. Exactness: existential one-extension tails with the displayed contextual endpoint package. Standard bridge: RegSeqRat/RealUp selected contextual observation readback. Status: $\mathsf{ProofTarget}$.

Theorem 38.558 (Rat StreamName unary-context e-one tail determinacy)**.** *For observation maps $s,t:\mathsf{Hist}\to\mathsf{Hist}$, a selected observation $n:\mathsf{Hist}$, prefix and tail histories $p_s,p_t,q_s,q_t:\mathsf{Hist}$, middle histories $m_s,m_t:\mathsf{Hist}$, output histories $o_s,o_t:\mathsf{Hist}$, and displayed tails $a,a',b,b':\mathsf{Hist}$, assume*

$$\begin{aligned}&\mathsf{RatStreamNameClassifier}(s,t),\quad \mathsf{UnaryHistory}(n),\quad \mathsf{UnaryHistory}(p_s),\quad \mathsf{hsame}(p_s,p_t),\\&\mathsf{UnaryHistory}(q_s),\quad \mathsf{hsame}(q_s,q_t),\quad \mathsf{Cont}(p_s,s(n),m_s),\quad \mathsf{Cont}(m_s,q_s,o_s),\\&\mathsf{Cont}(p_t,t(n),m_t),\quad \mathsf{Cont}(m_t,q_t,o_t),\end{aligned}$$

and the four e-one displays

$$\mathsf{hsame}(o_s,\mathsf{E1}(a)),\quad \mathsf{hsame}(o_s,\mathsf{E1}(a')),\quad \mathsf{hsame}(o_t,\mathsf{E1}(b)),\quad \mathsf{hsame}(o_t,\mathsf{E1}(b')).$$

Then all of the following data hold:

1. $\mathsf{UnaryHistory}(a)$;
2. $\mathsf{UnaryHistory}(a')$;
3. $\mathsf{UnaryHistory}(b)$;
4. $\mathsf{UnaryHistory}(b')$;
5. $\mathsf{hsame}(a,a')$;
6. $\mathsf{hsame}(a,b)$;
7. $\mathsf{hsame}(a,b')$;
8. $\mathsf{hsame}(a',b)$;
9. $\mathsf{hsame}(a',b')$;
10. $\mathsf{hsame}(b,b')$.

Proof. Apply Definition 38.556 to the displays $\mathsf{hsame}(o_s,\mathsf{E1}(a))$ and $\mathsf{hsame}(o_t,\mathsf{E1}(b))$. Its tail rows supply $\mathsf{UnaryHistory}(a)$, $\mathsf{UnaryHistory}(b)$, and $\mathsf{hsame}(a,b)$.

Apply the same full endpoint package again to the displays $\mathsf{hsame}(o_s, \mathsf{E1}(a'))$ and $\mathsf{hsame}(o_t, \mathsf{E1}(b'))$. This supplies $\mathsf{UnaryHistory}(a')$, $\mathsf{UnaryHistory}(b')$, and $\mathsf{hsame}(a', b')$.

For the left-output tail comparison, compose the first display of o_s with the symmetry of the second display. The resulting $\mathsf{hsame}(\mathsf{E1}(a), \mathsf{E1}(a'))$ is inverted by BEDC.FKernel.Hist.hsame_e1_inversion_iff, giving $\mathsf{hsame}(a, a')$.

The same composition and e-one inversion applied to the two displays of o_t gives $\mathsf{hsame}(b, b')$. Transitivity of hsame, using $\mathsf{hsame}(a, b)$ together with symmetry of $\mathsf{hsame}(a', b')$ and the two same-side comparisons, gives the remaining mixed rows $\mathsf{hsame}(a, b')$ and $\mathsf{hsame}(a', b)$. Package the four unary rows with the six displayed tail comparisons. □

Fit. Traditional target: selected contextual rational-stream tail determinacy. BEDC source: $\mathsf{StreamName}^{\uparrow}$+$\mathsf{Rat}^{\uparrow}$+BHist. Carrier: observation maps over Hist. Classifier: RatStreamNameClassifier. Stability: unary context closure, e-one no-confusion, and hsame transitivity. Ledger: selected observation, context rows, continuation rows, and endpoint displays. Core theorem: Definition 38.558. Exactness: uniqueness of displayed e-one tails. Standard bridge: RegSeqRat selected observation canonicalization. Status: ProofTarget.

Theorem 38.559 (Rat StreamName unary-context bundled tail determinacy)**.** *Let* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *be public rational* $\mathsf{StreamName}^{\uparrow}$ *rows with* $\mathsf{RatStreamNameClassifier}(s, t)$*. Let* $\mathcal{P} : \mathsf{ProbeBundle}$ *be a finite bundle of unary observation requests. Suppose that every bundled request* n *with* $\mathsf{InBundle}(n, \mathcal{P})$ *carries* $\mathsf{UnaryHistory}(n)$*, shared prefix rows* $p_s(n), p_t(n) : \mathsf{Hist}$*, shared tail-context rows* $q_s(n), q_t(n) : \mathsf{Hist}$*, middle rows* $m_s(n), m_t(n) : \mathsf{Hist}$*, output rows* $o_s(n), o_t(n) : \mathsf{Hist}$*, and displayed tails* $a(n), a'(n), b(n), b'(n) : \mathsf{Hist}$ *satisfying*

$$\begin{aligned}\mathsf{UnaryHistory}(p_s(n)),\quad \mathsf{hsame}(p_s(n), p_t(n)),\quad \mathsf{UnaryHistory}(q_s(n)),\quad \mathsf{hsame}(q_s(n), q_t(n)),\\ \mathsf{Cont}(p_s(n), s(n), m_s(n)),\quad \mathsf{Cont}(m_s(n), q_s(n), o_s(n)),\\ \mathsf{Cont}(p_t(n), t(n), m_t(n)),\quad \mathsf{Cont}(m_t(n), q_t(n), o_t(n)).\end{aligned}$$

and the four e-one endpoint displays

$$\mathsf{hsame}(o_s(n), \mathsf{E1}(a(n))),\quad \mathsf{hsame}(o_s(n), \mathsf{E1}(a'(n))),\quad \mathsf{hsame}(o_t(n), \mathsf{E1}(b(n))),\quad \mathsf{hsame}(o_t(n), \mathsf{E1}(b'(n))).$$

Then the bundled displayed tail rows are unary and pairwise hsame *across all source and target endpoint reads. More explicitly, for every bundled* n*, the four rows* $a(n), a'(n), b(n), b'(n)$ *are unary, and the six comparisons*

$$\begin{aligned}\mathsf{hsame}(a(n), a'(n)),\quad \mathsf{hsame}(a(n), b(n)),\quad \mathsf{hsame}(a(n), b'(n)),\\ \mathsf{hsame}(a'(n), b(n)),\quad \mathsf{hsame}(a'(n), b'(n)),\quad \mathsf{hsame}(b(n), b'(n))\end{aligned}$$

hold inside the same finite bundle surface. This surface is exactly the finite source surface consumed by the $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff: the bundled unary rows, their* InBundle *witnesses, the shared prefix–tail context, the continuation rows, the endpoint displays, the pointwise rational-stream handoff rows, and the support rows* hsame, Cont, Pkg, NameCert*. It contains no quotient stream equality, selected limit, host real equality, metric-completion point, or* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Fix a bundled observation n and its membership row $\mathsf{InBundle}(n, \mathcal{P})$. Apply Definition 38.558 to the displayed prefix, tail-context, continuation, output, and e-one rows attached to n. This gives the four unary tail rows and the six pairwise hsame comparisons for that bundled request.

Repeat this pointwise over the finite ProbeBundle. The InBundle membership witnesses keep each selected observation inside $\mathcal{P}$, so the collected rows are one finite family rather than a hidden choice of endpoint tails.

Finally apply Definition 126.547. Its cofinal packet identifies the collected unary observations, membership rows, shared tail-compatible context, pointwise $\mathsf{RegSeqRat}^{\uparrow}$ handoff rows, and support rows as the finite bundled handoff surface. The non-escape clauses in that lock exclude quotient stream equality, selected limits, host real equality, metric-completion data, and ambient $\mathsf{Real}^{\uparrow}$ completeness from the surface just constructed. □

Fit. Traditional target: finite contextual rational-stream tail determinacy. BEDC source: $\mathsf{StreamName}^{\uparrow} + \mathsf{Rat}^{\uparrow} + \mathsf{ProbeBundle} + \mathsf{BHist}$. Carrier: public rational StreamName rows over Hist with bundled unary requests. Classifier: RatStreamNameClassifier together with InBundle membership. Stability: pointwise unary-context closure, e-one no-confusion, finite-bundle collection, and tail-compatible cofinal locking. Ledger: bundled observation rows, shared prefix and tail-context rows, continuation rows, endpoint displays, pointwise rational handoff rows, and Pkg/NameCert support. Core theorem: Definition 38.559. Exactness: all displayed source and target e-one tails in the bundle are unary and pairwise hsame. Standard bridge: finite $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ handoff surface. Status: ProofTarget.

Definition 38.560 (Real unary selected denominator row)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and a certified unary observation* $n : \mathsf{Hist}$*, the selected denominator row records the complete RatUp denominator data at that observation:*

$$\begin{aligned}
&\mathsf{RealUnarySelectedDenominatorRow}(s,t,n) \iff \\
&\mathsf{RatHistoryClassifier}(s(n),t(n)) \wedge \mathsf{PositiveUnaryDenominator}(s(n)) \wedge \mathsf{PositiveUnaryDenominator}(t(n)) \wedge \\
&\mathsf{UnaryHistory}(s(n)) \wedge \mathsf{UnaryHistory}(t(n)) \wedge (\mathsf{hsame}(s(n),\mathsf{e}) \to \mathsf{False}) \wedge \\
&(\mathsf{hsame}(t(n),\mathsf{e}) \to \mathsf{False}) \wedge \forall z : \mathsf{Hist}, ((\mathsf{hsame}(s(n),\mathsf{E0}(z)) \to \mathsf{False}) \wedge \\
&\qquad\qquad (\mathsf{hsame}(t(n),\mathsf{E0}(z)) \to \mathsf{False})).
\end{aligned}$$

Theorem 38.561 (Real unary StreamNameUp pointwise denominator coverage)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$*, assume*

$$\mathsf{RatStreamNameCarrier}(s) \quad \textit{and} \quad \mathsf{RatStreamNameCarrier}(t).$$

Then the following three clauses are equivalent, in the sense that any one of them constructs the other two:

1. $\mathsf{RatStreamNameClassifier}(s,t)$.
2. $\mathsf{RealUnaryStreamClassifier}(s,t)$.
3. $\forall n,\ \mathsf{UnaryHistory}(n) \to \mathsf{RealUnarySelectedDenominatorRow}(s,t,n)$.

Lean4 ✓ `BEDC.Derived.RealUp.RealUnarySelectedDenominatorRow streamName equivalence`

Proof. The StreamNameUp and Real unary classifier clauses are the same pointwise RatUp classifier under the two carrier assumptions. Apply Definition 38.551 to identify them.

Assume the Real unary classifier and fix a certified unary observation n. Evaluating the classifier at n gives $\mathsf{RatHistoryClassifier}(s(n),t(n))$. Apply Definition 37.50 to this row, then apply Definition 37.12 separately to the two positive denominator witnesses. This supplies the classifier, both positive unary denominators, both unary endpoint rows, and both nonempty exclusions.

It remains to fill the zero-headed exclusions. For an arbitrary history z, transport the positive unary denominator witness for $s(n)$ along $\mathsf{hsame}(s(n), \mathsf{E0}(z))$ by Definition 37.6, then contradict Definition 37.10. The same argument for $t(n)$ gives the right endpoint exclusion, so the selected denominator row is constructed.

Conversely, assume the pointwise selected denominator rows. For each certified unary observation n, project the first conjunct of $\mathsf{RealUnarySelectedDenominatorRow}(s, t, n)$ to obtain $\mathsf{RatHistoryClassifier}(s(n), t(n$ Repack this pointwise classifier with the two carrier assumptions as $\mathsf{RatStreamNameClassifier}(s, t)$, and use the exactness theorem again to recover the Real unary classifier clause. □

Fit. Traditional target: certified rational observation streams for RealUp. BEDC source: $\mathsf{StreamName}^{\uparrow}$+$\mathsf{Real}^{\uparrow}$+$\mathsf{Rat}^{\uparrow}$. Carrier: RatStreamNameCarrier. Classifier pair: RatStreamNameClassifier and RealUnaryStreamClassifier. Stability: pointwise RatUp denominator transport. Ledger: unary observation index and zero-headed probes. Core theorem: Definition 38.561. Exactness: the three-way equivalence. Standard bridge: finite rational observation windows for RegSeqRat/RealUp. Status: ProofTarget.

Theorem 38.562 (RegSeqRat finite-window dyadic observation coverage)**.** *For observation maps $s, t : \mathsf{Hist} \to \mathsf{Hist}$, histories $a, w, k : \mathsf{Hist}$, and RegSeqRat stream certificate spines for s and t, assume*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameClassifier}(s, t), \quad \mathsf{UnaryHistory}(a), \quad \mathsf{Unary}$$

Let $n = \mathsf{append}(a, k)$. Then the selected bounded observation supplies the finite RealUp window and the dyadic endpoint rows:

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w) \wedge \mathsf{RatHistoryClassifier}(s(n), t(n)) \wedge \\ \mathsf{DyadicRatCoreObservationRow}(s(n)) \wedge \mathsf{DyadicRatCoreObservationRow}(t(n)).$$

Here DyadicRatCoreObservationRow *is the package described in Definition 38.219.*

Proof. Apply Definition 38.553 to the two carrier rows, the displayed StreamNameUp classifier, and the unary anchor and bound. This constructs $\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w)$.

Project the window at the selected offset k by Definition 38.157. The witness $\mathsf{UnaryOffsetLe}(k, w)$ supplies the bounded row, so the selected observation $n = \mathsf{append}(a, k)$ carries $\mathsf{RatHistoryClassifier}(s(n), t(n))$.

Unfolding the offset witness gives $\mathsf{UnaryHistory}(k)$. Unary append closure with $\mathsf{UnaryHistory}(a)$ gives $\mathsf{UnaryHistory}(n)$, the certified observation index needed by the two RegSeqRat spines.

Apply Definition 38.246 to the spine for s at n, and apply the same theorem to the spine for t at n. These two applications supply the DyadicRatCore observation rows for $s(n)$ and $t(n)$. Together with the selected classifier and the finite window, these are exactly the displayed package. □

Lean4 ✓ `BEDC.Derived.RealUp.RegseqratFiniteWindowDyadicObservationCoverage`

Theorem 38.563 (RegSeqRat finite-window dyadic classifier stability package)**.** *For observation maps $s, t, u, s', t' : \mathsf{Hist} \to \mathsf{Hist}$, histories $a, w, k : \mathsf{Hist}$, and RegSeqRat stream certificate spines for s, t, u, s', t', assume*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameCarrier}(u), \quad \mathsf{RatStreamNameCarrier}(s'),$$

$$\mathsf{RatStreamNameClassifier}(s, t), \quad \mathsf{RatStreamNameClassifier}(t, u), \quad \mathsf{UnaryHistory}(a), \quad \mathsf{UnaryHistory}(w), \quad \mathsf{UnaryOffse}$$

Let $n = \mathsf{append}(a, k)$, and assume the selected pointwise transport rows

$$\mathsf{hsame}(s(n), s'(n)) \quad \textit{and} \quad \mathsf{hsame}(t(n), t'(n)).$$

Then the finite-window dyadic classifier package selected at n contains exactly the four classifier-stability faces needed by the RealUp finite-window seal:

1. *the diagonal face* $\mathsf{RatHistoryClassifier}(s(n), s(n))$ *together with* $\mathsf{DyadicRatCoreObservationRow}(s(n))$*;*
2. *the symmetry face* $\mathsf{RatHistoryClassifier}(t(n), s(n))$ *together with the swapped dyadic observation rows at* $t(n)$ *and* $s(n)$*;*
3. *the transitivity face* $\mathsf{RatHistoryClassifier}(s(n), u(n))$ *together with the dyadic observation rows at* $s(n)$ *and* $u(n)$*;*
4. *the* hsame *transport face* $\mathsf{RatHistoryClassifier}(s'(n), t'(n))$ *together with the transported dyadic observation rows at* $s'(n)$ *and* $t'(n)$*.*

The package has no additional diagonal classifier-stability constructor beyond the RatUp reflexive face and the selected RegSeqRat dyadic observation row.

Proof. First obtain the selected forward observation by Definition 38.562. It gives the $\mathsf{Real}^{\uparrow}$ finite window, the pointwise $\mathsf{RatHistoryClassifier}(s(n), t(n))$, and the endpoint $\mathsf{DyadicRatCoreObservationRow}$ witnesses at $s(n)$ and $t(n)$.

For the diagonal face, project the rational carrier at $s(n)$ from the RegSeqRat spine and the selected unary index. Apply Definition 37.37 to that carrier witness. The dyadic row at the same endpoint is the one supplied by the selected observation coverage theorem, so the diagonal face is present without a separate RegSeqRat classifier reflexivity package.

For symmetry, use Definition 38.565. For transitivity, use Definition 38.566 with the two displayed StreamNameUp classifier rows. These two rows provide the reversed and composed pointwise RatUp classifiers together with the corresponding DyadicRatCore observation rows.

For transport, use Definition 38.567 with the displayed hsame rows. It preserves the original finite $\mathsf{Real}^{\uparrow}$ window and transports the selected RatUp classifier to $s'(n)$ and $t'(n)$ while exposing the DyadicRatCore rows at the transported endpoints.

Thus the package is assembled from $\mathsf{StreamName}^{\uparrow} + \mathsf{Rat}^{\uparrow} + \mathsf{Real}^{\uparrow} + \mathsf{DyadicRatCore}$: StreamNameUp supplies the stream classifier rows, RatUp supplies the pointwise reflexive, symmetric, transitive, and transported classifiers, RealUp supplies the bounded unary window, and DyadicRatCore supplies the endpoint observation rows. These are the carrier, classifier, stability, ledger, core theorem, exactness, bridge, and downstream-use faces of the roadmap template, with no extra diagonal classifier-stability source. □

Fit. Traditional target: finite-window dyadic classifier stability for RegSeqRat. BEDC source: $\mathsf{StreamName}^{\uparrow}+\mathsf{Rat}^{\uparrow}+\mathsf{Real}^{\uparrow}+\mathsf{DyadicRatCore}$. Carrier/classifier: $\mathsf{RatStreamNameCarrier}$ rows for the participating streams, the source and composed $\mathsf{RatStreamNameClassifier}$ rows, and the selected pointwise $\mathsf{RatHistoryClassifier}$ faces. Stability: RatUp reflexivity, symmetry, transitivity, and hsame transport at the selected endpoint. Ledger: the unary observation index $n = \mathsf{append}(a, k)$ and the finite $\mathsf{Real}^{\uparrow}$ window. Core theorem: Definition 38.563. Exactness: the diagonal face is read from Definition 37.37 and Definition 38.562; the other faces are read from the finite-window symmetry, transitivity, and transport rows. Standard bridge: the RealUp finite-window seal. Status: $\mathsf{ProofTarget}$.

Theorem 38.564 (RegSeqRat finite-window dyadic source exhaustion)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$*, histories* $a, w, k : \mathsf{Hist}$*, and RegSeqRat stream certificate spines for* s *and* t*, assume*

$\mathsf{RatStreamNameCarrier}(s)$, $\mathsf{RatStreamNameCarrier}(t)$, $\mathsf{RatStreamNameClassifier}(s, t)$, $\mathsf{UnaryHistory}(a)$, Unary

Let $n = \mathsf{append}(a, k)$. Then the selected bounded observation exhausts the scoped DyadicRatCore source package at the two endpoints $s(n)$ and $t(n)$:

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w) \wedge \mathsf{RatHistoryClassifier}(s(n), t(n)) \wedge \mathsf{DyadicRatCoreObservationRow}(s(n)) \wedge \mathsf{DyadicRatCoreObservationRow}(t(n)).$$

Moreover, the carrier, classifier, stability, and finite ledger faces read at $s(n)$ and $t(n)$ are exactly the faces named by Definition 38.221.

Proof. Apply Definition 38.562. It supplies the finite $\mathsf{Real}^{\uparrow}$ window, the selected pointwise $\mathsf{RatHistoryClassifier}(s(n)$, and the two $\mathsf{DyadicRatCoreObservationRow}$ witnesses at $s(n)$ and $t(n)$.

Next identify the source faces. Apply Definition 38.221 to the two endpoint rows. Its carrier face is the rational-history carrier together with positive unary denominator and dyadic-radius data; its classifier face is the displayed $\mathsf{RatHistoryClassifier}$ row together with hsame transport; its stability and finite ledger faces are the ones already recorded by the RegSeqRat spine.

No further package data are read. The selected index $n = \mathsf{append}(a, k)$ comes from the finite RealUp window, and the endpoint source data are exactly the two DyadicRatCore observation rows identified with the scoped package faces. Thus the bounded RegSeqRat spine and the DyadicRatCore observation row exhaust the scoped source package at both endpoints. □

Theorem 38.565 (RegSeqRat finite-window dyadic classifier symmetry coverage)**.** *For observation maps $s, t : \mathsf{Hist} \to \mathsf{Hist}$, histories $a, w, k : \mathsf{Hist}$, and RegSeqRat stream certificate spines for s and t, assume*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameClassifier}(s, t), \quad \mathsf{UnaryHistory}(a), \quad \mathsf{Unary}$$

Let $n = \mathsf{append}(a, k)$. Then the reversed selected bounded observation supplies

$$\mathsf{RealUnaryStreamWindowClassifier}(t, s, a, w) \wedge \mathsf{RatHistoryClassifier}(t(n), s(n)) \wedge \mathsf{DyadicRatCoreObservationRow}(t(n)) \wedge \mathsf{DyadicRatCoreObservationRow}(s(n)).$$

Moreover, the carrier, classifier, stability, and finite ledger faces read at $t(n)$ and $s(n)$ are exactly the faces named by Definition 38.221.

Proof. Apply Definition 38.562 to the pair (s, t). It supplies the forward $\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w)$, the selected classifier $\mathsf{RatHistoryClassifier}(s(n), t(n))$, and the two endpoint dyadic rows at $s(n)$ and $t(n)$.

Reverse the StreamNameUp classifier by the symmetry clause of Definition 126.13. Apply Definition 38.553 to this reversed classifier, the carrier rows for t and s, and the same unary anchor and bound. This gives $\mathsf{RealUnaryStreamWindowClassifier}(t, s, a, w)$.

For the selected point, apply Definition 37.55 to the pointwise classifier obtained from the forward package. The result is exactly $\mathsf{RatHistoryClassifier}(t(n), s(n))$.

The two $\mathsf{DyadicRatCoreObservationRow}$ witnesses are reused in swapped order. Applying Definition 38.221 to those two rows identifies the carrier, classifier, stability, and finite ledger faces with the same scoped source package, now read at the reversed endpoints $t(n)$ and $s(n)$. □

Theorem 38.566 (RegSeqRat finite-window dyadic classifier transitivity coverage)**.** *For observation maps $s, t, u : \mathsf{Hist} \to \mathsf{Hist}$, histories $a, w, k : \mathsf{Hist}$, and RegSeqRat stream certificate spines for s, t, and u, assume*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameCarrier}(u), \quad \mathsf{RatStreamNameClassifier}(s, t$$

$$\mathsf{UnaryHistory}(a), \quad \mathsf{UnaryHistory}(w), \quad \mathsf{UnaryOffsetLe}(k, w).$$

Let $n = \mathsf{append}(a, k)$*. Then the composed selected bounded observation supplies*

$$\mathsf{RealUnaryStreamWindowClassifier}(s, u, a, w) \wedge \mathsf{RatHistoryClassifier}(s(n), u(n)) \wedge \\ \mathsf{DyadicRatCoreObservationRow}(s(n)) \wedge \mathsf{DyadicRatCoreObservationRow}(u(n)).$$

Moreover, the carrier, classifier, stability, and finite ledger faces read at $s(n)$ *and* $u(n)$ *are exactly the faces named by Definition 38.221.*

Proof. Apply the transitivity clause of Definition 126.13 to the two displayed classifier rows. This composes $\mathsf{RatStreamNameClassifier}(s, t)$ and $\mathsf{RatStreamNameClassifier}(t, u)$ into $\mathsf{RatStreamNameClassifier}(s, u)$.

Now apply Definition 38.562 to the pair (s, u), the RegSeqRat spines for s and u, the carrier rows for s and u, the composed StreamNameUp classifier, and the unary anchor, bound, and offset. This yields the finite $\mathsf{RealUnaryStreamWindowClassifier}(s, u, a, w)$, the selected pointwise $\mathsf{RatHistoryClassifier}(s(n), u(n))$, and the endpoint dyadic rows for $s(n)$ and $u(n)$.

Finally identify the source package faces. Apply Definition 38.221 to the two endpoint rows. The selected unary offset supplies the finite ledger index $n = \mathsf{append}(a, k)$, while the two endpoint RegSeqRat spines supply the carrier, classifier, and stability faces already named by the dyadic scoped source package. Hence the composed finite-window observation carries exactly the DyadicRatCore source package at the endpoints $s(n)$ and $u(n)$. □

Theorem 38.567 (RegSeqRat finite-window dyadic transport package)**.** *For observation maps* $s, t, s', t' : \mathsf{Hist} \to \mathsf{Hist}$ *and histories* $a, w, k : \mathsf{Hist}$*, assume RegSeqRat stream certificate spines for all four streams and*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameCarrier}(s'), \quad \mathsf{RatStreamNameCarrier}(t'),$$

$$\mathsf{RatStreamNameClassifier}(s, t), \quad \mathsf{UnaryHistory}(a), \quad \mathsf{UnaryHistory}(w), \quad \mathsf{UnaryOffsetLe}(k, w).$$

Let $n = \mathsf{append}(a, k)$*, and assume the selected pointwise transport rows*

$$\mathsf{hsame}(s(n), s'(n)) \quad \textit{and} \quad \mathsf{hsame}(t(n), t'(n)).$$

Then the transported selected endpoints carry the finite-window dyadic package

$$\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w) \wedge \\ \mathsf{RatHistoryClassifier}(s'(n), t'(n)) \wedge \\ \mathsf{DyadicRatCoreObservationRow}(s'(n)) \wedge \mathsf{DyadicRatCoreObservationRow}(t'(n)).$$

Here DyadicRatCoreObservationRow *is the package described in Definition 38.219.*

Proof. First apply Definition 38.562 to the untransported streams s, t, their RegSeqRat spines, the two RatStreamNameCarrier rows, the displayed StreamNameUp classifier, and the unary anchor, bound, and offset. This supplies the original $\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w)$, the selected $\mathsf{RatHistoryClassifier}(s(n), t(n))$, and the DyadicRatCore observation rows at $s(n)$ and $t(n)$.

Transport the selected classifier next. Apply Definition 37.54 to the selected $\mathsf{RatHistoryClassifier}(s(n), t(n))$ and to the two pointwise hsame rows. The result is the transported selected classifier $\mathsf{RatHistoryClassifier}(s'(n), t'(n))$

It remains to expose the transported DyadicRatCore rows. The offset witness gives the certified unary row for k, and unary append closure with $\mathsf{UnaryHistory}(a)$ gives $\mathsf{UnaryHistory}(n)$. Apply Definition 38.246 to the RegSeqRat spine for s' at n, and apply the same theorem to the spine for

t' at n. These two applications provide the dyadic-radius ledger tokens and endpoint carrier faces for $s'(n)$ and $t'(n)$.

The denominator face is stable under the selected pointwise transports. From the untransported DyadicRatCore rows, project the positive unary denominator rows at $s(n)$ and $t(n)$, then transport them along Definition 37.6 using $\mathsf{hsame}(s(n), s'(n))$ and $\mathsf{hsame}(t(n), t'(n))$. These transported denominator rows agree with the denominator components of the s' and t' DyadicRatCore packages supplied by the previous paragraph.

Repack the original finite window, the transported selected classifier, and the two transported DyadicRatCore observation rows. This is exactly the displayed finite-window dyadic transport package. □

Theorem 38.568 (RegSeqRat finite-window transported dyadic source exhaustion)**.** *For observation maps $s, t, s', t' : \mathsf{Hist} \to \mathsf{Hist}$ and histories $a, w, k : \mathsf{Hist}$, assume RegSeqRat stream certificate spines for all four streams and*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameCarrier}(s'), \quad \mathsf{RatStreamNameCarrier}(t'),$$

$$\mathsf{RatStreamNameClassifier}(s, t), \quad \mathsf{UnaryHistory}(a), \quad \mathsf{UnaryHistory}(w), \quad \mathsf{UnaryOffsetLe}(k, w).$$

Let $n = \mathsf{append}(a, k)$, and assume the selected pointwise transport rows

$$\mathsf{hsame}(s(n), s'(n)) \quad \textit{and} \quad \mathsf{hsame}(t(n), t'(n)).$$

Then the transported selected observation exhausts the scoped DyadicRatCore source package at the endpoints $s'(n)$ and $t'(n)$:

$$\begin{aligned}&\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w) \wedge \\ &\mathsf{RatHistoryClassifier}(s'(n), t'(n)) \wedge \\ &\mathsf{DyadicRatCoreObservationRow}(s'(n)) \wedge \mathsf{DyadicRatCoreObservationRow}(t'(n)).\end{aligned}$$

Moreover, the carrier, classifier, stability, and finite ledger faces read at $s'(n)$ and $t'(n)$ are exactly the faces named by Definition 38.221.

Proof. First apply Definition 38.567. It supplies the transported finite-window dyadic package: the original $\mathsf{Real}^{\uparrow}$ window, the transported selected classifier $\mathsf{RatHistoryClassifier}(s'(n), t'(n))$, and the two transported $\mathsf{DyadicRatCoreObservationRow}$ witnesses at $s'(n)$ and $t'(n)$.

Now identify the scoped source reads. Apply Definition 38.221 to the endpoint rows $s'(n)$ and $t'(n)$. The carrier face is the rational-history carrier, positive unary denominator, and dyadic-radius token stored in each transported DyadicRatCore observation row. The classifier face is the transported $\mathsf{RatHistoryClassifier}(s'(n), t'(n))$ together with the selected hsame stability rows.

The ledger is finite for the same reason as in the transport package. The index $n = \mathsf{append}(a, k)$ is selected by the unary anchor and bounded offset, and the dyadic-radius token read at each transported endpoint is the token carried by the corresponding RegSeqRat spine. Thus the transported classifier and endpoint rows read no data beyond the scoped DyadicRatCore carrier, classifier, stability, and finite ledger faces. □

Theorem 38.569 (RegSeqRat finite-window dyadic transport composition)**.** *For observation maps $s, t, s', t', s'', t'' : \mathsf{Hist} \to \mathsf{Hist}$ and histories $a, w, k : \mathsf{Hist}$, assume RegSeqRat stream certificate spines for all six streams and*

$$\begin{aligned}&\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameCarrier}(s'), \\ &\mathsf{RatStreamNameCarrier}(t'), \quad \mathsf{RatStreamNameCarrier}(s''), \quad \mathsf{RatStreamNameCarrier}(t''),\end{aligned}$$

$$\mathsf{RatStreamNameClassifier}(s,t),\quad \mathsf{UnaryHistory}(a),\quad \mathsf{UnaryHistory}(w),\quad \mathsf{UnaryOffsetLe}(k,w).$$

Let $n = \mathsf{append}(a,k)$*, and assume the selected pointwise transport rows*

$$\mathsf{hsame}(s(n),s'(n)),\quad \mathsf{hsame}(t(n),t'(n)),\quad \mathsf{hsame}(s'(n),s''(n)),\quad \mathsf{hsame}(t'(n),t''(n)).$$

Then the twice-transported selected endpoints carry the finite-window dyadic package and exhaust the scoped DyadicRatCore source package at $s''(n)$ *and* $t''(n)$*:*

$$\begin{aligned}&\mathsf{RealUnaryStreamWindowClassifier}(s,t,a,w)\wedge\\&\mathsf{RatHistoryClassifier}(s''(n),t''(n))\wedge\\&\mathsf{DyadicRatCoreObservationRow}(s''(n))\wedge\mathsf{DyadicRatCoreObservationRow}(t''(n)).\end{aligned}$$

Moreover, the carrier, classifier, stability, and finite ledger faces read at $s''(n)$ *and* $t''(n)$ *are exactly the faces named by Definition 38.221.*

Proof. First compose the selected endpoint transports. Apply Definition 3.8 to $\mathsf{hsame}(s(n),s'(n))$ and $\mathsf{hsame}(s'(n),s''(n))$, and apply the same theorem to $\mathsf{hsame}(t(n),t'(n))$ and $\mathsf{hsame}(t'(n),t''(n))$. This gives direct rows $\mathsf{hsame}(s(n),s''(n))$ and $\mathsf{hsame}(t(n),t''(n))$ at the selected index.

Next apply Definition 38.567 with target streams s'' and t''. The six-stream hypotheses contain the four rows it needs for s,t,s'',t'', the source classifier, the unary anchor and bound, the bounded offset, and the composed selected hsame rows. Hence it supplies the original $\mathsf{Real}^{\uparrow}$ finite window, the selected $\mathsf{RatHistoryClassifier}(s''(n),t''(n))$, and the two DyadicRatCoreObservationRow witnesses at $s''(n)$ and $t''(n)$.

Finally identify the package faces. Apply Definition 38.221 to the two endpoint rows at $s''(n)$ and $t''(n)$. The carrier face is read from the transported DyadicRatCore rows, the classifier face is the twice-transported selected RatUp classifier, the stability face is the composed hsame transport, and the finite ledger is the unary selected index together with the dyadic-radius tokens stored by the RegSeqRat spines. □

Theorem 38.570 (RegSeqRat finite-window dyadic classifier determinacy)**.** *Let* $s,t:\mathsf{Hist}\to\mathsf{Hist}$ *be carried RegSeqRat streams, let* $a,w,k:\mathsf{Hist}$ *satisfy* $\mathsf{UnaryHistory}(a)$*,* $\mathsf{UnaryHistory}(w)$*, and* $\mathsf{UnaryOffsetLe}(k,w)$*, and put* $n=\mathsf{append}(a,k)$*. Suppose two selected finite-window records have the same unary window, the same RegSeqRat stream certificate spines, the DyadicRatCore observation rows at* $s(n)$ *and* $t(n)$*, and two finite-window dyadic classifier packages selecting the same* $\mathsf{RatHistoryClassifier}(s(n),t(n))$*. Then the selected* $\mathsf{Real}^{\uparrow}$ *finite observation endpoints and their ledger provenance are classified by the same displayed* hsame *row. No quotient of rational histories, host real equality, or external comparison of reals is exported.*

Proof. Apply Definition 38.562 to the shared unary window. It supplies the two pointwise DyadicRatCore observation rows and identifies their finite ledger with the selected index n and the denominator tokens stored in the RegSeqRat spines.

Next apply Definition 38.563. The two dyadic classifier packages name the same $\mathsf{RatHistoryClassifier}(s(n),t(n))$, so their classifier readbacks have the same displayed stability row over the selected endpoints.

Transport each package through Definition 38.567, using the identity endpoint rows supplied by the shared observation records. Then use Definition 38.569 to compose the two readback routes.

The composed route is a single hsame comparison between the selected $\mathsf{Real}^{\uparrow}$ finite observation endpoints. Its provenance is exactly the shared finite-window ledger, so determinacy is internal to the displayed classifier package and exports no ambient equality of real numbers. □

Theorem 38.571 (RegSeqRat finite-window dyadic closure package)**.** *For observation maps* $s, t, s', t', s'', t'' : \mathsf{Hist} \to \mathsf{Hist}$ *and histories* $a, w, k : \mathsf{Hist}$*, assume RegSeqRat stream certificate spines for* s, t, s', t', s'', t''*, the source classifier* $\mathsf{RatStreamNameClassifier}(s, t)$*, and*

$$\mathsf{UnaryHistory}(a), \quad \mathsf{UnaryHistory}(w), \quad \mathsf{UnaryOffsetLe}(k, w).$$

Let $n = \mathsf{append}(a, k)$*, and assume two-step selected endpoint transports*

$$\mathsf{hsame}(s(n), s'(n)), \quad \mathsf{hsame}(t(n), t'(n)), \quad \mathsf{hsame}(s'(n), s''(n)), \quad \mathsf{hsame}(t'(n), t''(n)).$$

Then the selected finite-window surface at the final endpoints simultaneously contains the $\mathsf{Real}^{\uparrow}$ *window* $\mathsf{RealUnaryStreamWindowClassifier}(s, t, a, w)$*, the final selected classifier* $\mathsf{RatHistoryClassifier}(s''(n), t''(n))$*, the two endpoint observation rows* $\mathsf{DyadicRatCoreObservationRow}(s''(n))$ *and* $\mathsf{DyadicRatCoreObservationRow}(t''(n))$*, and the four stability faces needed by the* $\mathsf{Real}^{\uparrow}$ *finite-window seal: source endpoint classifier stability, target endpoint classifier stability, transported source observation stability, and transported target observation stability.*

Proof. First read the finite observation rows. Apply Definition 38.562. The RegSeqRat spines provide the stream-side rational histories, while $\mathsf{StreamName}^{\uparrow}$ supplies the finite unary window selected by a, w, k.

Next read the classifier faces. Apply Definition 38.563. The source $\mathsf{RatStreamNameClassifier}(s, t)$ and the first selected hsame endpoint transports give the RatUp classifier stability rows at the intermediate endpoints.

Now assemble the endpoint rows. Apply Definition 38.567 to the first selected transport step, and then apply Definition 38.569 to compose the second selected transport step. These theorems supply the final selected $\mathsf{RatHistoryClassifier}(s''(n), t''(n))$ and the two $\mathsf{DyadicRatCoreObservationRow}$ witnesses.

Thus $\mathsf{StreamName}^{\uparrow}$ contributes the finite window, $\mathsf{Rat}^{\uparrow}$ contributes the classifier faces, $\mathsf{DyadicRatCore}$ contributes the endpoint observation rows, and RegSeqRat contributes the four stream spines. Repacking these rows gives a single BHist-anchored package for the finite-window seal. □

Fit. Traditional target: composed finite-window dyadic endpoint transport for RegSeqRat. BEDC source: $\mathsf{StreamName}^{\uparrow}+\mathsf{Rat}^{\uparrow}+\mathsf{Real}^{\uparrow}+\mathsf{DyadicRatCore}$. Carrier/classifier: six $\mathsf{RatStreamNameCarrier}$ rows, the source $\mathsf{RatStreamNameClassifier}(s, t)$, and the twice-transported selected $\mathsf{RatHistoryClassifier}(s''(n), t''(n))$. Stability: composed hsame endpoint transport through the intermediate presentation. Ledger: the selected unary offset and the dyadic-radius token at each final endpoint. Core theorem: Definition 38.569. Exactness: the final endpoint package is the scoped DyadicRatCore source read at $s''(n)$ and $t''(n)$. Standard bridge: finite RealUp observation windows. Downstream use: the RealUp finite-window seal. Status: $\mathsf{ProofTarget}$.

Fit. Traditional target: transported finite-window dyadic endpoint source coverage for RegSeqRat. BEDC source: $\mathsf{StreamName}^{\uparrow} + \mathsf{Rat}^{\uparrow} + \mathsf{Real}^{\uparrow} + \mathsf{DyadicRatCore}$. Carrier/classifier: four $\mathsf{RatStreamNameCarrier}$ rows, the source $\mathsf{RatStreamNameClassifier}(s, t)$, and the transported selected $\mathsf{RatHistoryClassifier}(s'(n), t'(n))$. Stability: selected hsame transport of the two endpoints. Ledger: unary offset together with the dyadic-radius token at each transported endpoint. Core theorem: Definition 38.568. Exactness: the transported endpoint package is the scoped DyadicRatCore source read at $s'(n)$ and $t'(n)$. Standard bridge: finite rational observation windows for RealUp. Downstream use: the RealUp finite-window seal. Status: $\mathsf{ProofTarget}$.

Fit. Traditional target: finite-window dyadic endpoint transport for RegSeqRat. BEDC source: $\mathsf{StreamName}^{\uparrow} + \mathsf{Rat}^{\uparrow} + \mathsf{Real}^{\uparrow} + \mathsf{DyadicRatCore}$ over BHist. Carrier: four $\mathsf{RatStreamNameCarrier}$ rows

with RegSeqRat stream certificate spines. Classifier: $\mathsf{RatStreamNameClassifier}(s,t)$ and the transported selected $\mathsf{RatHistoryClassifier}$. Stability: selected pointwise hsame transport plus positive-denominator transport. Ledger: the selected unary offset and dyadic-radius token. Core theorem: Definition 38.567. Exactness: transported selected endpoint coverage. Standard bridge: finite RealUp observation windows for RegSeqRat streams. Downstream use: RealUp finite-window seal and later RegSeqRat formalization. Status: $\mathsf{ProofTarget}$.

Theorem 38.572 (Real unary StreamNameUp classifier selected endpoint shape package)**.** *For unary observation maps* $s,t,s',t' : \mathsf{Hist} \to \mathsf{Hist}$*, a certified observation* $n : \mathsf{Hist}$*, and histories* $a,b,z_s,z_t : \mathsf{Hist}$*, assume*

$$\mathsf{RatStreamNameClassifier}(s,t), \quad \mathsf{UnaryHistory}(n),$$

the pointwise transport rows

$$\forall k,\ \mathsf{UnaryHistory}(k) \to \mathsf{hsame}(s(k),s'(k)), \quad \forall k,\ \mathsf{UnaryHistory}(k) \to \mathsf{hsame}(t(k),t'(k)),$$

and the displayed selected endpoints

$$\mathsf{hsame}(s'(n),\mathsf{E1}(a)), \quad \mathsf{hsame}(t'(n),\mathsf{E1}(b)).$$

Then pointwise transport carries the StreamNameUp classifier to the transported maps, and the selected endpoints obtained from that classifier carry the full RatUp denominator and one-tail shape package:

$$\begin{aligned}
&\mathsf{RatStreamNameClassifier}(s',t')\wedge\\
&\mathsf{RatHistoryClassifier}(s'(n),t'(n)) \wedge \mathsf{PositiveUnaryDenominator}(s'(n)) \wedge \mathsf{PositiveUnaryDenominator}(t'(n))\wedge\\
&\mathsf{UnaryHistory}(s'(n)) \wedge \mathsf{UnaryHistory}(t'(n)) \wedge (\mathsf{hsame}(s'(n),\mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(t'(n),\mathsf{e}) \to \mathsf{False})\wedge\\
&(\mathsf{hsame}(s'(n),\mathsf{E0}(z_s)) \to \mathsf{False}) \wedge (\mathsf{hsame}(t'(n),\mathsf{E0}(z_t)) \to \mathsf{False})\wedge\\
&\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a,b).
\end{aligned}$$

Proof. First convert the StreamNameUp classifier into the Real unary classifier. Apply Definition 38.551 with the two carrier fields projected from $\mathsf{RatStreamNameClassifier}(s,t)$, then use the reverse implication on the same classifier row.

Next apply Definition 38.275 to the same two carrier fields, the converted Real unary classifier, and the two pointwise transport rows. This gives $\mathsf{RatStreamNameClassifier}(s',t')$.

Now apply Definition 38.555 to that Real unary classifier, the selected certified observation n, the two pointwise transport rows, and the two displayed $\mathsf{E1}$ endpoint comparisons. The conclusion is exactly the displayed selected endpoint package. Repack it with the transported StreamNameUp classifier row. □

Fit. Traditional target: selected unary stream observation readback from a certified StreamNameUp classifier. BEDC source: $\mathsf{StreamName}^{\uparrow}+\mathsf{Real}^{\uparrow}+\mathsf{Rat}^{\uparrow}$ over BHist. Carrier: $\mathsf{RatStreamNameCarrier}$. Classifier: $\mathsf{RatStreamNameClassifier}$ transported through $\mathsf{RealUnaryStreamClassifier}$. Ledger: selected unary observation and endpoint displays. Core theorem: Definition 38.572. Exactness: transported StreamNameUp classifier and displayed selected endpoint package. Standard bridge: pointwise rational stream observation readback. Status: $\mathsf{ProofTarget}$.

Theorem 38.573 (Real unary StreamNameUp classifier selected endpoint tail pairwise coherence)**.** *For unary observation maps* $s,t,s',t' : \mathsf{Hist} \to \mathsf{Hist}$*, a certified observation* $n : \mathsf{Hist}$*, and*

histories $a, a', b, b' : \mathsf{Hist}$*, assume* $\mathsf{RatStreamNameClassifier}(s, t)$*,* $\mathsf{UnaryHistory}(n)$*, the two pointwise transport rows of Definition 38.572, and the four displayed endpoints*

$$\mathsf{hsame}(s'(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(s'(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(t'(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(t'(n), \mathsf{E1}(b')).$$

Then $\mathsf{UnaryHistory}(a)$*,* $\mathsf{UnaryHistory}(a')$*,* $\mathsf{UnaryHistory}(b)$*,* $\mathsf{UnaryHistory}(b')$*, and all six tail comparisons hold:*

$$\mathsf{hsame}(a, a'), \quad \mathsf{hsame}(a, b), \quad \mathsf{hsame}(a, b'), \quad \mathsf{hsame}(a', b), \quad \mathsf{hsame}(a', b'), \quad \mathsf{hsame}(b, b').$$

Proof. Apply Definition 38.572 twice, first to the displayed pair (a, b) and then to (a', b'), instantiating the zero-headed display parameters by endpoint tails. This supplies the four unary-history rows together with $\mathsf{hsame}(a, b)$ and $\mathsf{hsame}(a', b')$.

For the same-side comparisons, compose the two displays of $s'(n)$ to obtain $\mathsf{hsame}(\mathsf{E1}(a), \mathsf{E1}(a'))$ and use BEDC.FKernel.Hist.hsame_e1_inversion_iff to read back $\mathsf{hsame}(a, a')$. The same composition and e-one inversion applied to the two displays of $t'(n)$ gives $\mathsf{hsame}(b, b')$.

It remains to fill the two mixed comparisons. Compose $\mathsf{hsame}(a, b)$ with $\mathsf{hsame}(b, b')$ by BEDC.FKernel.Hist.hsame_trans to obtain $\mathsf{hsame}(a, b')$; compose the symmetry of $\mathsf{hsame}(a, a')$ with $\mathsf{hsame}(a, b)$ to obtain $\mathsf{hsame}(a', b)$. Package the four unary rows and the six comparisons. □

Lean4 ✓ `BEDC.Derived.RealUp.RatStreamNameClassifier selected endpoint tail pairwise coherence`

Fit. Traditional target: selected unary stream observation readback. BEDC source: RealUp unary streams plus RatUp classifier. Carrier: unary-indexed rational observation maps. Classifier: RealUnaryStreamClassifier. Stability: pointwise hsame transport. Ledger: selected certified observation and endpoint displays. Core theorem: Definition 38.555. Exactness: displayed endpoint package. Standard bridge: selected rational observation readback for RealUp names. Status: ProofTarget.

Theorem 38.574 (Real unary StreamNameUp finite-window selected denominator package)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and histories* $\alpha, \omega, k, z_s, z_t : \mathsf{Hist}$*, assume*

$$\mathsf{RatStreamNameClassifier}(s, t),$$

$$\mathsf{UnaryHistory}(\alpha), \quad \mathsf{UnaryHistory}(\omega), \quad \mathsf{UnaryOffsetLe}(k, \omega).$$

Then the selected endpoints carry the finite-window denominator package:

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(s(\mathsf{append}(\alpha, k)), t(\mathsf{append}(\alpha, k)))\wedge \\
&\mathsf{PositiveUnaryDenominator}(s(\mathsf{append}(\alpha, k))) \wedge \mathsf{PositiveUnaryDenominator}(t(\mathsf{append}(\alpha, k)))\wedge \\
&\mathsf{UnaryHistory}(s(\mathsf{append}(\alpha, k))) \wedge \mathsf{UnaryHistory}(t(\mathsf{append}(\alpha, k)))\wedge \\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{e}) \to \mathsf{False})\wedge \\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge (\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E0}(z_t)) \to \mathsf{False}).
\end{aligned}$$

Proof. Apply Definition 38.553 to the two carrier fields projected from $\mathsf{RatStreamNameClassifier}(s, t)$, the StreamNameUp classifier, and the unary anchor and bound. This gives $\mathsf{RealUnaryStreamWindowClassifier}(s, t, \alpha,$

Project this window classifier at the selected offset k by Definition 38.157. The offset witness $\mathsf{UnaryOffsetLe}(k, \omega)$ gives

$$\mathsf{RatHistoryClassifier}(s(\mathsf{append}(\alpha, k)), t(\mathsf{append}(\alpha, k))).$$

Apply Definition 37.50 to this selected endpoint classifier. This supplies positive unary denominator witnesses for both selected endpoints.

Apply Definition 37.12 separately to the two positive-denominator rows. These projections give the two unary-history rows and the two nonempty endpoint exclusions.

It remains to rule out selected zero heads. For the left endpoint, transport the positive denominator witness along $\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E0}(z_s))$ by Definition 37.6; the transported witness contradicts Definition 37.10.

The right endpoint is identical, using the displayed comparison with $\mathsf{E0}(z_t)$. The same transport and zero-head absurdity theorem give the second zero-head exclusion, and all rows together form the displayed package. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamWindowClassifier selected denominator package`

Theorem 38.575 (Real unary StreamNameUp finite-window selected shape package)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and histories* $\alpha, \omega, k, u, v, z_s, z_t : \mathsf{Hist}$*, assume*

$$\mathsf{RatStreamNameClassifier}(s, t),$$

$$\mathsf{UnaryHistory}(\alpha), \quad \mathsf{UnaryHistory}(\omega), \quad \mathsf{UnaryOffsetLe}(k, \omega),$$

and the displayed selected window endpoints

$$\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(u)), \quad \mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E1}(v)).$$

Then the selected endpoints carry the finite-window RatUp readback package:

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(s(\mathsf{append}(\alpha, k)), t(\mathsf{append}(\alpha, k)))\wedge\\
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(u), \mathsf{E1}(v)) \wedge \mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsame}(u, v)\wedge\\
&\mathsf{PositiveUnaryDenominator}(s(\mathsf{append}(\alpha, k))) \wedge \mathsf{PositiveUnaryDenominator}(t(\mathsf{append}(\alpha, k)))\wedge\\
&\mathsf{UnaryHistory}(s(\mathsf{append}(\alpha, k))) \wedge \mathsf{UnaryHistory}(t(\mathsf{append}(\alpha, k)))\wedge\\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{e}) \to \mathsf{False})\wedge\\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge (\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E0}(z_t)) \to \mathsf{False}).
\end{aligned}$$

Proof. Apply Definition 38.574 to the StreamNameUp classifier, the unary anchor and bound, the selected offset, and the two zero-head tests. Inside that package, the carrier rows are the two fields projected from $\mathsf{RatStreamNameClassifier}(s, t)$. This supplies the selected RatUp classifier, the positive-denominator rows, the unary endpoint rows, the nonempty exclusions, and the two zero-head exclusions.

The selected RatUp classifier is the first row of the selected shape package. Transport the selected RatUp classifier across the two displayed $\mathsf{E1}$ endpoint comparisons by Definition 37.54. The transported classifier is $\mathsf{RatHistoryClassifier}(\mathsf{E1}(u), \mathsf{E1}(v))$.

Apply Definition 37.49 in the forward direction to the transported $\mathsf{E1}$ classifier. This reads back $\mathsf{UnaryHistory}(u)$, $\mathsf{UnaryHistory}(v)$, and $\mathsf{hsame}(u, v)$. Together with the denominator package rows, these are exactly the displayed finite-window selected shape package. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamWindowClassifier selected shape package`

Fit. Traditional target: selected finite-window rational readback for RealUp StreamNameUp classifiers. BEDC source: $\mathsf{StreamName}^{\uparrow} + \mathsf{Real}^{\uparrow} + \mathsf{Rat}^{\uparrow}$ over BHist. Carrier: $\mathsf{RatStreamNameCarrier}$. Classifier: $\mathsf{RatStreamNameClassifier}$ through $\mathsf{RealUnaryStreamWindowClassifier}$. Stability: hsame transport of selected endpoints and positive-denominator transport. Ledger: anchor, bound, offset, selected endpoint displays, and zero-head tests. Core theorem: Definition 38.575. Exactness: selected source RatUp classifier, displayed RatUp one-tail classifier, denominator, unary, nonempty, and zero-headed exclusion rows. Standard bridge: finite rational observation windows. Status: $\mathsf{ProofTarget}$.

Theorem 38.576 (Real unary StreamNameUp finite-window selected common e-one tail readback)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and histories* $\alpha, \omega, k : \mathsf{Hist}$*, assume*

$$\mathsf{RatStreamNameClassifier}(s, t),$$

$$\mathsf{UnaryHistory}(\alpha), \quad \mathsf{UnaryHistory}(\omega), \quad \mathsf{UnaryOffsetLe}(k, \omega).$$

Then the selected endpoints admit common one-headed unary readback:

$$\exists u, v : \mathsf{Hist},\ \mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(u)) \wedge \mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E1}(v)) \wedge \mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsam}$$

Proof. Apply Definition 38.574 to the StreamNameUp classifier, the unary anchor and bound, the selected offset, and arbitrary zero-head tests. This supplies the selected RatUp classifier, the positive-denominator rows, the unary endpoint rows, and the nonempty endpoint exclusions.

Use Definition 18.45 separately on the two selected endpoints. The left endpoint yields a tail u with $\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(u))$ and $\mathsf{UnaryHistory}(u)$. The right endpoint yields a tail v with $\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E1}(v))$ and $\mathsf{UnaryHistory}(v)$.

Transport the selected RatUp classifier across these two displayed endpoint rows by Definition 37.54. The transported classifier is $\mathsf{RatHistoryClassifier}(\mathsf{E1}(u), \mathsf{E1}(v))$.

Apply Definition 37.49 in the forward direction to the transported classifier. This reads back the common tail row $\mathsf{hsame}(u, v)$. Package u and v with the two displayed endpoint rows, the two unary-tail rows, and the common-tail row. □

Fit. Traditional target: selected finite-window RealUp endpoint witness readback without displayed endpoint assumptions. BEDC source: $\mathsf{StreamName}^{\uparrow} + \mathsf{Real}^{\uparrow} + \mathsf{Rat}^{\uparrow}$ over BHist. Carrier: $\mathsf{RatStreamNameCarrier}$. Classifier: $\mathsf{RatStreamNameClassifier}$ through selected $\mathsf{RatHistoryClassifier}$. Stability: hsame endpoint transport from selected endpoints to e-one displays. Ledger: anchor, bound, selected offset, positive denominator rows, unary endpoint rows, and nonempty exclusions. Core theorem: Definition 38.576. Exactness: existential one-headed endpoints with unary tails and common tail comparison. Standard bridge: finite rational observation windows. Status: $\mathsf{ProofTarget}$.

Theorem 38.577 (Real unary StreamNameUp finite-window selected full endpoint package)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and histories* $\alpha, \omega, k, u, v, z_s, z_t : \mathsf{Hist}$*, assume*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameClassifier}(s, t),$$

$$\mathsf{UnaryHistory}(\alpha), \quad \mathsf{UnaryHistory}(\omega), \quad \mathsf{UnaryOffsetLe}(k, \omega),$$

and the displayed selected window endpoints

$$\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(u)), \quad \mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E1}(v)).$$

Then the selected endpoints carry the full finite-window endpoint package:

$$\begin{aligned}
&\mathsf{RealUnaryStreamWindowClassifier}(s, t, \alpha, \omega) \wedge \\
&\mathsf{RatHistoryClassifier}(s(\mathsf{append}(\alpha, k)), t(\mathsf{append}(\alpha, k))) \wedge \\
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(u), \mathsf{E1}(v)) \wedge \\
&\mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsame}(u, v) \wedge \\
&\mathsf{PositiveUnaryDenominator}(s(\mathsf{append}(\alpha, k))) \wedge \mathsf{PositiveUnaryDenominator}(t(\mathsf{append}(\alpha, k))) \wedge \\
&\mathsf{UnaryHistory}(s(\mathsf{append}(\alpha, k))) \wedge \mathsf{UnaryHistory}(t(\mathsf{append}(\alpha, k))) \wedge \\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{e}) \to \mathsf{False}) \wedge \\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge (\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E0}(z_t)) \to \mathsf{False}).
\end{aligned}$$

Proof. Apply Definition 38.553 to the two carrier rows, the StreamNameUp classifier, and the unary anchor and bound. This produces $\mathsf{RealUnaryStreamWindowClassifier}(s, t, \alpha, \omega)$.

Apply Definition 38.157 to that window classifier and the displayed offset witness $\mathsf{UnaryOffsetLe}(k, \omega)$. This gives the selected source classifier

$$\mathsf{RatHistoryClassifier}(s(\mathsf{append}(\alpha, k)), t(\mathsf{append}(\alpha, k))).$$

Apply Definition 38.575 to the same hypotheses. It supplies the transported $\mathsf{E1}$ classifier, the unary tail readback, the two positive-denominator rows, the two unary endpoint rows, the nonempty exclusions, and the zero-head exclusions.

Combining the window classifier, the projected selected classifier, and the selected shape package gives exactly the displayed full endpoint package. □

Fit. Traditional target: RealUp finite-window selected full endpoint readback. BEDC source: $\mathsf{StreamName}^{\uparrow}+\mathsf{Real}^{\uparrow}+\mathsf{Rat}^{\uparrow}$. Carrier: $\mathsf{RatStreamNameCarrier}$. Classifier: $\mathsf{RealUnaryStreamWindowClassifier}$. Stability: hsame endpoint transport with positive-denominator transport. Ledger: carrier, classifier, unary anchor, unary bound, selected offset, endpoint displays, and zero-head tests. Core theorem: Definition 38.577. Exactness: selected classifier plus the displayed endpoint package. Standard bridge: downstream finite rational observation windows. Status: $\mathsf{ProofTarget}$.

Theorem 38.578 (Real unary StreamNameUp finite-window selected classifier appended-tail package)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and histories* $\alpha, \omega, k, u, v, z_s, z_t, d_s, d_t : \mathsf{Hist}$*, assume*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameClassifier}(s, t),$$

$$\mathsf{UnaryHistory}(\alpha), \quad \mathsf{UnaryHistory}(\omega), \quad \mathsf{UnaryOffsetLe}(k, \omega),$$

and the displayed selected window endpoints

$$\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(u)), \quad \mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E1}(v)).$$

Then the selected endpoints carry the selected-shape endpoint package and the appended e-zero-tail exclusions:

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(s(\mathsf{append}(\alpha, k)), t(\mathsf{append}(\alpha, k)))\wedge\\
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(u), \mathsf{E1}(v))\wedge\\
&\mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsame}(u, v)\wedge\\
&\mathsf{PositiveUnaryDenominator}(s(\mathsf{append}(\alpha, k))) \wedge \mathsf{PositiveUnaryDenominator}(t(\mathsf{append}(\alpha, k)))\wedge\\
&\mathsf{UnaryHistory}(s(\mathsf{append}(\alpha, k))) \wedge \mathsf{UnaryHistory}(t(\mathsf{append}(\alpha, k)))\wedge\\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{e}) \to \mathsf{False})\wedge\\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge (\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E0}(z_t)) \to \mathsf{False})\wedge\\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), d_s \cdot \mathsf{E0}(z_s)) \to \mathsf{False})\wedge\\
&(\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), d_t \cdot \mathsf{E0}(z_t)) \to \mathsf{False}).
\end{aligned}$$

Proof. Apply Definition 38.575 to the two carrier rows, the StreamNameUp classifier, the unary anchor and bound, the selected offset, and the displayed one-headed endpoint comparisons. This gives every selected endpoint row through the zero-head exclusions, including the two selected positive-denominator witnesses.

For the left endpoint, suppose $\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), d_s \cdot \mathsf{E0}(z_s))$. Transport the positive denominator witness for $s(\mathsf{append}(\alpha, k))$ across this displayed sameness by Definition 37.6. The

transported witness is a positive unary denominator witness for $d_s \cdot \mathsf{E0}(z_s)$, contradicting Definition 37.15.

The right endpoint is identical. A display $\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), d_t \cdot \mathsf{E0}(z_t))$ transports the positive denominator witness for $t(\mathsf{append}(\alpha, k))$ to $d_t \cdot \mathsf{E0}(z_t)$, and the same appended e-zero-tail absurdity theorem contradicts that transported witness.

Repack the original selected-shape rows with the two appended-tail exclusions. This is exactly the displayed selected classifier appended-tail package. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamWindowClassifier selected classifier appended tail package`

Fit. Traditional target: selected finite-window rational readback with appended-tail endpoint exclusion for RealUp StreamNameUp classifiers. BEDC source: $\mathsf{StreamName}^{\uparrow} + \mathsf{Real}^{\uparrow} + \mathsf{Rat}^{\uparrow}$ over BHist. Carrier: $\mathsf{RatStreamNameCarrier}$. Classifier: $\mathsf{RatStreamNameClassifier}$ through $\mathsf{RealUnaryStreamWindowClassifier}$. Stability: hsame transport of selected endpoints and positive-denominator transport to appended tails. Ledger: carrier, classifier, unary anchor, unary bound, selected offset, one-headed endpoint displays, zero-head tests, and appended-tail displays. Core theorem: Definition 38.578. Exactness: the full selected endpoint package plus the two appended e-zero-tail exclusion rows. Standard bridge: finite rational observation windows. Status: $\mathsf{ProofTarget}$.

Theorem 38.579 (Real unary StreamNameUp finite-window selected e-one tail coverage package)**.** *For observation maps $s, t : \mathsf{Hist} \to \mathsf{Hist}$ and histories $\alpha, \omega, k, z_s, z_t, d_s, d_t : \mathsf{Hist}$, assume*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameClassifier}(s, t),$$

$$\mathsf{UnaryHistory}(\alpha), \quad \mathsf{UnaryHistory}(\omega), \quad \mathsf{UnaryOffsetLe}(k, \omega).$$

Then there exist histories $u, v : \mathsf{Hist}$ such that the selected endpoints are displayed as e-one endpoints and, for those witnesses, the full endpoint rows and appended e-zero-tail exclusions hold:

$$\begin{aligned}
&\exists u, v,\ \mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(u)) \wedge \mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E1}(v)) \wedge \\
&\mathsf{RealUnaryStreamWindowClassifier}(s, t, \alpha, \omega) \wedge \\
&\mathsf{RatHistoryClassifier}(s(\mathsf{append}(\alpha, k)), t(\mathsf{append}(\alpha, k))) \wedge \\
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(u), \mathsf{E1}(v)) \wedge \\
&\mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsame}(u, v) \wedge \\
&\mathsf{PositiveUnaryDenominator}(s(\mathsf{append}(\alpha, k))) \wedge \mathsf{PositiveUnaryDenominator}(t(\mathsf{append}(\alpha, k))) \wedge \\
&\mathsf{UnaryHistory}(s(\mathsf{append}(\alpha, k))) \wedge \mathsf{UnaryHistory}(t(\mathsf{append}(\alpha, k))) \wedge \\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{e}) \to \mathsf{False}) \wedge \\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge (\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E0}(z_t)) \to \mathsf{False}) \wedge \\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), d_s \cdot \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge \\
&(\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), d_t \cdot \mathsf{E0}(z_t)) \to \mathsf{False}).
\end{aligned}$$

Proof. Apply Definition 38.574 to the StreamNameUp classifier, the unary anchor and bound, the selected offset, and the two zero-head tests. The package supplies the selected RatUp classifier, the two positive unary denominator rows, the two unary selected endpoint rows, the two nonempty endpoint exclusions, and the two zero-head exclusions.

Apply Definition 18.45 to the left unary endpoint row and its nonempty exclusion. This chooses a tail u, and the constructor equality supplies the hsame display from $s(\mathsf{append}(\alpha, k))$ to $\mathsf{E1}(u)$. The same theorem applied to the right unary endpoint row and nonempty exclusion chooses a tail v and supplies the hsame display from $t(\mathsf{append}(\alpha, k))$ to $\mathsf{E1}(v)$.

Feed the two e-one endpoint displays, together with the carrier rows, classifier row, unary anchor and bound, selected offset, zero-head tests, and appended-tail tests, into Definition 38.578. That theorem returns the full selected endpoint package and the two appended e-zero-tail exclusions for the chosen witnesses u and v.

Package u and v as the existential witnesses. Prepending their two selected endpoint displays to the returned appended-tail package gives exactly the displayed coverage package. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamWindowClassifier selected e1 tail coverage package`

Fit. Traditional target: finite RealUp observation-window readback without endpoint display hypotheses. BEDC source: $\mathsf{StreamName}^{\uparrow}$ plus $\mathsf{Real}^{\uparrow}$ finite windows plus $\mathsf{Rat}^{\uparrow}$ denominator readback. Carrier: RatStreamNameCarrier. Classifier: RatStreamNameClassifier through RealUnaryStreamWindowClassifi Stability: hsame transport plus unary nonempty e-one-tail decomposition. Ledger: anchor, bound, offset, zero-head tests, and appended-tail tests. Core theorem: Definition 38.579. Exactness: existential e-one tails plus the full selected endpoint package. Standard bridge: finite rational observation windows. Status: ProofTarget.

Theorem 38.580 (Real unary StreamNameUp finite-window transported selected appended-tail package)**.** *For observation maps* $s, t, s', t' : \mathsf{Hist} \to \mathsf{Hist}$ *and histories* $\alpha, \omega, k, u, v, z_s, z_t, d_s, d_t : \mathsf{Hist}$*, assume*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameClassifier}(s,t),$$

$$\mathsf{UnaryHistory}(\alpha), \quad \mathsf{UnaryHistory}(\omega), \quad \mathsf{UnaryOffsetLe}(k,\omega),$$

and the pointwise transported rows

$$\forall n : \mathsf{Hist},\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(s(n), s'(n)), \quad \forall n : \mathsf{Hist},\ \mathsf{UnaryHistory}(n) \to \mathsf{hsame}(t(n), t'(n)).$$

Assume also the displayed transported selected window endpoints

$$\mathsf{hsame}(s'(\mathsf{append}(\alpha,k)), \mathsf{E1}(u)), \quad \mathsf{hsame}(t'(\mathsf{append}(\alpha,k)), \mathsf{E1}(v)).$$

Then the transported selected endpoints carry the selected-shape endpoint package and the appended e-zero-tail exclusions:

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(s'(\mathsf{append}(\alpha,k)), t'(\mathsf{append}(\alpha,k)))\wedge\\
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(u), \mathsf{E1}(v))\wedge\\
&\mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsame}(u,v)\wedge\\
&\mathsf{PositiveUnaryDenominator}(s'(\mathsf{append}(\alpha,k))) \wedge \mathsf{PositiveUnaryDenominator}(t'(\mathsf{append}(\alpha,k)))\wedge\\
&\mathsf{UnaryHistory}(s'(\mathsf{append}(\alpha,k))) \wedge \mathsf{UnaryHistory}(t'(\mathsf{append}(\alpha,k)))\wedge\\
&(\mathsf{hsame}(s'(\mathsf{append}(\alpha,k)), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(t'(\mathsf{append}(\alpha,k)), \mathsf{e}) \to \mathsf{False})\wedge\\
&(\mathsf{hsame}(s'(\mathsf{append}(\alpha,k)), \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge (\mathsf{hsame}(t'(\mathsf{append}(\alpha,k)), \mathsf{E0}(z_t)) \to \mathsf{False})\wedge\\
&(\mathsf{hsame}(s'(\mathsf{append}(\alpha,k)), d_s \cdot \mathsf{E0}(z_s)) \to \mathsf{False})\wedge\\
&(\mathsf{hsame}(t'(\mathsf{append}(\alpha,k)), d_t \cdot \mathsf{E0}(z_t)) \to \mathsf{False}).
\end{aligned}$$

Proof. First derive the selected RatUp classifier at $\mathsf{append}(\alpha,k)$. Apply Definition 38.574 to the StreamNameUp classifier, the unary anchor and bound, and the selected offset. This supplies the untransported selected RatHistoryClassifier row, positive denominator rows, unary endpoint rows, nonempty exclusions, and zero-head exclusions.

The selected index $\mathsf{append}(\alpha,k)$ is unary by the finite-window offset construction, so the two pointwise rows give $\mathsf{hsame}(s(\mathsf{append}(\alpha,k)), s'(\mathsf{append}(\alpha,k)))$ and $\mathsf{hsame}(t(\mathsf{append}(\alpha,k)), t'(\mathsf{append}(\alpha,k)))$.

Transport the selected RatUp classifier across these two comparisons by Definition 37.54. Transport the two positive denominator rows by Definition 37.6.

Apply Definition 37.49 to the transported classifier and the two displayed one-headed endpoint comparisons. This gives $\mathsf{RatHistoryClassifier}(\mathsf{E1}(u), \mathsf{E1}(v))$, the two unary tail rows, and $\mathsf{hsame}(u, v)$. Apply Definition 37.12 to the transported positive-denominator rows; this gives the unary transported endpoint rows and the two empty endpoint exclusions.

For the zero-head exclusions, suppose first $\mathsf{hsame}(s'(\mathsf{append}(\alpha, k)), \mathsf{E0}(z_s))$. Transport the left positive-denominator witness across that comparison by Definition 37.6, contradicting Definition 37.10. The right zero-head exclusion is the same argument using $t'(\mathsf{append}(\alpha, k))$ and $\mathsf{E0}(z_t)$.

It remains to rule out the appended e-zero tails. For the left endpoint, suppose $\mathsf{hsame}(s'(\mathsf{append}(\alpha, k)), d_s \cdot \mathsf{E0}(z_s))$. Transport the positive denominator witness for $s'(\mathsf{append}(\alpha, k))$ across this comparison by Definition 37.6. The transported witness contradicts Definition 37.15.

The right endpoint is identical. A display $\mathsf{hsame}(t'(\mathsf{append}(\alpha, k)), d_t \cdot \mathsf{E0}(z_t))$ transports the positive denominator witness for $t'(\mathsf{append}(\alpha, k))$ to $d_t \cdot \mathsf{E0}(z_t)$, and the same appended e-zero-tail obstruction contradicts that transported witness.

Repack the transported classifier, displayed e-one readback rows, denominator rows, endpoint exclusions, and appended-tail contradictions. These rows are exactly the transported selected endpoint package. □

Fit. Traditional target: transported finite-window rational readback with appended-tail endpoint obstruction for RealUp StreamNameUp classifiers. BEDC source: $\mathsf{StreamName}^{\uparrow}+\mathsf{Real}^{\uparrow}+\mathsf{Rat}^{\uparrow}$ over BHist. Carrier: $\mathsf{RatStreamNameCarrier}$. Classifier: $\mathsf{RatStreamNameClassifier}$ transported to the selected $\mathsf{RatHistoryClassifier}$. Stability: pointwise hsame transport of StreamNameUp endpoints and positive-denominator transport to appended tails. Ledger: carrier, classifier, unary anchor, unary bound, selected offset, pointwise transport rows, one-headed endpoint displays, zero-head tests, and appended-tail displays. Core theorem: Definition 38.580. Exactness: transported selected endpoint package plus the two appended e-zero-tail exclusion rows. Standard bridge: finite rational observation windows. Status: $\mathsf{ProofTarget}$.

Theorem 38.581 (Real unary StreamNameUp finite-window selected e-one tail pairwise coherence)**.** *For observation maps $s, t : \mathsf{Hist} \to \mathsf{Hist}$ and histories $\alpha, \omega, k, a, a', b, b' : \mathsf{Hist}$, assume*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameClassifier}(s, t),$$

$$\mathsf{UnaryHistory}(\alpha), \quad \mathsf{UnaryHistory}(\omega), \quad \mathsf{UnaryOffsetLe}(k, \omega),$$

and the four displayed selected e-one endpoint comparisons

$$\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(a)), \quad \mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(a')),$$

$$\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E1}(b)), \quad \mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E1}(b')).$$

Then the displayed tails form one pairwise selected-tail class:

1. $\mathsf{UnaryHistory}(a)$.
2. $\mathsf{UnaryHistory}(a')$.
3. $\mathsf{UnaryHistory}(b)$.
4. $\mathsf{UnaryHistory}(b')$.

5. $\mathsf{hsame}(a, a')$.
6. $\mathsf{hsame}(b, b')$.
7. $\mathsf{hsame}(a, b)$.
8. $\mathsf{hsame}(a', b')$.
9. $\mathsf{hsame}(a, b')$.
10. $\mathsf{hsame}(a', b)$.

Proof. Apply Definition 38.575 to the first left and right endpoint displays, together with the StreamNameUp classifier, the unary anchor and bound, and the selected offset. This gives $\mathsf{UnaryHistory}(a)$, $\mathsf{UnaryHistory}(b)$, and $\mathsf{hsame}(a, b)$.

Apply the same selected shape package to the primed left and right endpoint displays. This gives $\mathsf{UnaryHistory}(a')$, $\mathsf{UnaryHistory}(b')$, and $\mathsf{hsame}(a', b')$.

For the left selected endpoint, compose the symmetry of $\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(a))$ with $\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(a'))$. The kernel transitivity theorem BEDC.FKernel.Hist.hsame_trans gives $\mathsf{hsame}(\mathsf{E1}(a), \mathsf{E1}(a'))$, and BEDC.FKernel.Hist.hsame_e1_iff inverts the common e-one head to give $\mathsf{hsame}(a, a')$.

The right selected endpoint is identical. Compose the symmetry of the displayed comparison with $\mathsf{E1}(b)$ and the displayed comparison with $\mathsf{E1}(b')$, then invert the common e-one head by BEDC.FKernel.Hist.hsame_e1_iff to get $\mathsf{hsame}(b, b')$.

It remains to fill the two off-diagonal rows. Transitivity sends $\mathsf{hsame}(a, a')$ and $\mathsf{hsame}(a', b')$ to $\mathsf{hsame}(a, b')$, while symmetry of $\mathsf{hsame}(a, a')$ followed by $\mathsf{hsame}(a, b)$ gives $\mathsf{hsame}(a', b)$. Together with the four unary rows and the two direct cross rows, these are exactly the ten displayed claims. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamWindowClassifier selected e1 tail pairwise coherence`

Theorem 38.582 (Real unary StreamNameUp finite-window selected canonical e-one tail witness)**.** *For observation maps $s, t : \mathsf{Hist} \to \mathsf{Hist}$ and histories $\alpha, \omega, k : \mathsf{Hist}$, assume*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameClassifier}(s, t),$$

$$\mathsf{UnaryHistory}(\alpha), \quad \mathsf{UnaryHistory}(\omega), \quad \mathsf{UnaryOffsetLe}(k, \omega).$$

Then there exist histories $u, v : \mathsf{Hist}$ such that the selected endpoints have canonical e-one tail displays and every other selected e-one display is coherent with them:

$$\begin{aligned}
&\exists u, v : \mathsf{Hist}, \mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(u)) \wedge \mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E1}(v)) \wedge \\
&\mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsame}(u, v) \wedge \\
&\forall u', v' : \mathsf{Hist}, \ (\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(u')) \wedge \mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E1}(v'))) \to \\
&\qquad \mathsf{UnaryHistory}(u') \wedge \mathsf{UnaryHistory}(v') \wedge \mathsf{hsame}(u, u') \wedge \mathsf{hsame}(v, v') \wedge \\
&\qquad \mathsf{hsame}(u', v) \wedge \mathsf{hsame}(u, v').
\end{aligned}$$

Proof. Instantiate Definition 38.579 with the harmless choices $z_s = z_t = d_s = d_t = \mathsf{e}$. The returned witnesses u and v carry the two selected endpoint displays, $\mathsf{UnaryHistory}(u)$, $\mathsf{UnaryHistory}(v)$, and $\mathsf{hsame}(u, v)$.

Now fix arbitrary histories u', v' with the same selected endpoint displays. Apply Definition 38.581 with $a = u$, $a' = u'$, $b = v$, and $b' = v'$. The hypotheses are the carrier, classifier, unary

anchor, unary bound, selected offset, the chosen endpoint displays, and the arbitrary endpoint displays.

Project the ten rows returned by pairwise coherence. They give $\mathsf{UnaryHistory}(u')$, $\mathsf{UnaryHistory}(v')$, $\mathsf{hsame}(u, u')$, $\mathsf{hsame}(v, v')$, $\mathsf{hsame}(u', v)$, and $\mathsf{hsame}(u, v')$. Repack these rows under the universal clause and then package the chosen u and v as the displayed canonical selected-tail witnesses. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamWindowClassifier selected canonical e1 tail witness`

Fit. Traditional target: canonical finite rational observation tail. BEDC source: $\mathsf{StreamName}^{\uparrow}$ plus $\mathsf{Real}^{\uparrow}$ plus $\mathsf{Rat}^{\uparrow}$ plus $\mathsf{FKernel}$ e-one inversion. Carrier: $\mathsf{RatStreamNameCarrier}$. Classifier: $\mathsf{RatStreamNameClassifier}$ through $\mathsf{RealUnaryStreamWindowClassifier}$. Stability: endpoint hsame and pairwise tail coherence. Ledger: anchor, bound, offset, and selected endpoint displays. Core theorem: Definition 38.582. Exactness: existence plus uniqueness up to hsame. Standard bridge: finite rational observation windows for RegSeqRat. Status: $\mathsf{ProofTarget}$.

Theorem 38.583 (Real unary StreamNameUp finite-window selected canonical e-one tail full package)**.** *For observation maps $s, t : \mathsf{Hist} \to \mathsf{Hist}$ and histories $\alpha, \omega, k, z_s, z_t, d_s, d_t : \mathsf{Hist}$, assume*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameClassifier}(s, t),$$

$$\mathsf{UnaryHistory}(\alpha), \quad \mathsf{UnaryHistory}(\omega), \quad \mathsf{UnaryOffsetLe}(k, \omega).$$

Then there exist histories $u, v : \mathsf{Hist}$ such that the selected endpoints carry the complete displayed e-one certificate and every other selected e-one display is coherent with those witnesses:

$$\begin{aligned}
&\exists u, v : \mathsf{Hist}, \mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(u)) \wedge \mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E1}(v)) \wedge \\
&\mathsf{RealUnaryStreamWindowClassifier}(s, t, \alpha, \omega) \wedge \\
&\mathsf{RatHistoryClassifier}(s(\mathsf{append}(\alpha, k)), t(\mathsf{append}(\alpha, k))) \wedge \\
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(u), \mathsf{E1}(v)) \wedge \\
&\mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsame}(u, v) \wedge \\
&\mathsf{PositiveUnaryDenominator}(s(\mathsf{append}(\alpha, k))) \wedge \mathsf{PositiveUnaryDenominator}(t(\mathsf{append}(\alpha, k))) \wedge \\
&\mathsf{UnaryHistory}(s(\mathsf{append}(\alpha, k))) \wedge \mathsf{UnaryHistory}(t(\mathsf{append}(\alpha, k))) \wedge \\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{e}) \to \mathsf{False}) \wedge \\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge (\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E0}(z_t)) \to \mathsf{False}) \wedge \\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), d_s \cdot \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge \\
&(\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), d_t \cdot \mathsf{E0}(z_t)) \to \mathsf{False}) \wedge \\
&\forall u', v' : \mathsf{Hist}, (\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(u')) \wedge \mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E1}(v'))) \to \\
&\qquad \mathsf{UnaryHistory}(u') \wedge \mathsf{UnaryHistory}(v') \wedge \mathsf{hsame}(u, u') \wedge \mathsf{hsame}(v, v') \wedge \\
&\qquad \mathsf{hsame}(u', v) \wedge \mathsf{hsame}(u, v').
\end{aligned}$$

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamWindowClassifier selected canonical e1 tail full package`

Proof. Apply Definition 38.579 with the displayed histories z_s, z_t, d_s, d_t. The resulting witnesses u and v carry the two selected endpoint displays, the RealUp window classifier row, the selected RatHistoryClassifier rows, the unary tail rows, the denominator rows, the endpoint unary rows, the nonempty exclusions, the zero-head exclusions, and the appended e-zero-tail exclusions.

Now fix arbitrary histories u', v' with the same selected e-one endpoint displays. Apply Definition 38.581 with $a = u$, $a' = u'$, $b = v$, and $b' = v'$. The required displayed endpoint comparisons are exactly the two chosen displays and the two arbitrary displays.

Project the rows supplied by pairwise coherence. They give $\mathsf{UnaryHistory}(u')$, $\mathsf{UnaryHistory}(v')$, $\mathsf{hsame}(u, u')$, $\mathsf{hsame}(v, v')$, $\mathsf{hsame}(u', v)$, and $\mathsf{hsame}(u, v')$. Repack this universal coherence clause after the full coverage rows and package u, v as the displayed canonical full witnesses. □

Fit. Traditional target: canonical finite-window selected rational endpoint certificate for RealUp StreamNameUp classifiers. BEDC source: $\mathsf{StreamName}^{\uparrow} + \mathsf{Real}^{\uparrow} + \mathsf{Rat}^{\uparrow}$ over BHist. Carrier: $\mathsf{RatStreamNameCarrier}$. Classifier: $\mathsf{RatStreamNameClassifier}$ through $\mathsf{RealUnaryStreamWindowClassifier}$. Stability: selected endpoint hsame transport plus pairwise e-one tail coherence. Ledger: carrier, classifier, unary anchor, unary bound, selected offset, selected endpoint displays, RatHistoryClassifier rows, positive denominator rows, endpoint unary rows, and endpoint exclusion rows. Core theorem: Definition 38.583. Exactness: existence, selected endpoint exactness, denominator exclusions, appended-tail exclusions, and uniqueness up to hsame. Standard bridge: finite RegSeqRat observation windows. Status: $\mathsf{ProofTarget}$.

Theorem 38.584 (Real unary StreamNameUp finite-window selected tail-class exactness)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and histories* $\alpha, \omega, k : \mathsf{Hist}$*, assume*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameClassifier}(s, t),$$

$$\mathsf{UnaryHistory}(\alpha), \quad \mathsf{UnaryHistory}(\omega), \quad \mathsf{UnaryOffsetLe}(k, \omega).$$

Then the selected finite-window tail class is exact:

$$\begin{aligned}
&\exists u, v : \mathsf{Hist}, \mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(u)) \wedge \mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E1}(v)) \wedge \\
&\mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsame}(u, v) \wedge \\
&\forall u', v' : \mathsf{Hist}, \ (\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(u')) \wedge \mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E1}(v'))) \iff \\
&\qquad (\mathsf{UnaryHistory}(u') \wedge \mathsf{UnaryHistory}(v') \wedge \mathsf{hsame}(u, u') \wedge \mathsf{hsame}(v, v')).
\end{aligned}$$

Proof. Apply Definition 38.582 to the carrier rows, the StreamNameUp classifier, the unary anchor and bound, and the selected offset. This gives witnesses u and v with the two selected endpoint displays, their unary rows, $\mathsf{hsame}(u, v)$, and the universal coherence package for every displayed selected e-one tail pair.

For the forward direction of the displayed if-and-only-if, fix u' and v' with the two selected endpoint displays. The universal coherence clause of the canonical witness theorem gives $\mathsf{UnaryHistory}(u')$, $\mathsf{UnaryHistory}(v')$, $\mathsf{hsame}(u, u')$, and $\mathsf{hsame}(v, v')$.

For the reverse direction, assume $\mathsf{UnaryHistory}(u')$, $\mathsf{UnaryHistory}(v')$, $\mathsf{hsame}(u, u')$, and $\mathsf{hsame}(v, v')$. Apply BEDC.FKernel.Hist.hsame_e1_congr to the two tail comparisons to obtain $\mathsf{hsame}(\mathsf{E1}(u), \mathsf{E1}(u'))$ and $\mathsf{hsame}(\mathsf{E1}(v), \mathsf{E1}(v'))$.

Compose the selected display $\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(u))$ with $\mathsf{hsame}(\mathsf{E1}(u), \mathsf{E1}(u'))$ by BEDC.FKernel.Hist.hs and do the same for the right endpoint. The two composed comparisons are exactly the selected endpoint displays for u' and v', completing the reverse direction and the exact tail-class package. □

Lean4 ✓ `BEDC.Derived.RealUp.RealUnaryStreamWindowClassifier selected tail class exactness`

Fit. Traditional target: exact selected finite rational observation tails. BEDC source: $\mathsf{StreamName}^{\uparrow}$ plus $\mathsf{Real}^{\uparrow}$ plus $\mathsf{Rat}^{\uparrow}$ plus $\mathsf{FKernel}$ e-one congruence and transitivity. Carrier: $\mathsf{RatStreamNameCarrier}$. Classifier: $\mathsf{RatStreamNameClassifier}$ through $\mathsf{RealUnaryStreamWindowClassifier}$. Stability: endpoint hsame transport inside the selected e-one tail class. Ledger: anchor, bound, offset, selected endpoint displays, and canonical tail witnesses. Core theorem: Definition 38.584. Exactness: displayed selected e-one tails are exactly the canonical hsame classes of u and v. Downstream consumer: RegSeqRat finite observation canonicalization. Status: $\mathsf{ProofTarget}$.

Theorem 38.585 (Real unary StreamNameUp finite-window selected full tail-class certificate)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and histories* $\alpha, \omega, k, z_s, z_t, d_s, d_t : \mathsf{Hist}$*, assume*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameClassifier}(s, t),$$

$$\mathsf{UnaryHistory}(\alpha), \quad \mathsf{UnaryHistory}(\omega), \quad \mathsf{UnaryOffsetLe}(k,\omega).$$

Then there exist histories $u, v : \mathsf{Hist}$ such that the selected endpoints carry the full endpoint certificate and the selected tail class is exact:

$$\begin{aligned}
&\exists u, v : \mathsf{Hist}, \mathsf{hsame}(s(\mathsf{append}(\alpha,k)), \mathsf{E1}(u)) \wedge \mathsf{hsame}(t(\mathsf{append}(\alpha,k)), \mathsf{E1}(v)) \wedge \\
&\mathsf{RealUnaryStreamWindowClassifier}(s,t,\alpha,\omega) \wedge \\
&\mathsf{RatHistoryClassifier}(s(\mathsf{append}(\alpha,k)), t(\mathsf{append}(\alpha,k))) \wedge \\
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(u), \mathsf{E1}(v)) \wedge \\
&\mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsame}(u,v) \wedge \\
&\mathsf{PositiveUnaryDenominator}(s(\mathsf{append}(\alpha,k))) \wedge \mathsf{PositiveUnaryDenominator}(t(\mathsf{append}(\alpha,k))) \wedge \\
&\mathsf{UnaryHistory}(s(\mathsf{append}(\alpha,k))) \wedge \mathsf{UnaryHistory}(t(\mathsf{append}(\alpha,k))) \wedge \\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha,k)), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(t(\mathsf{append}(\alpha,k)), \mathsf{e}) \to \mathsf{False}) \wedge \\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha,k)), \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge (\mathsf{hsame}(t(\mathsf{append}(\alpha,k)), \mathsf{E0}(z_t)) \to \mathsf{False}) \wedge \\
&(\mathsf{hsame}(s(\mathsf{append}(\alpha,k)), d_s \cdot \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge \\
&(\mathsf{hsame}(t(\mathsf{append}(\alpha,k)), d_t \cdot \mathsf{E0}(z_t)) \to \mathsf{False}) \wedge \\
&\forall u', v' : \mathsf{Hist}, \big(\mathsf{hsame}(s(\mathsf{append}(\alpha,k)), \mathsf{E1}(u')) \wedge \mathsf{hsame}(t(\mathsf{append}(\alpha,k)), \mathsf{E1}(v'))\big) \iff \\
&\qquad \big(\mathsf{UnaryHistory}(u') \wedge \mathsf{UnaryHistory}(v') \wedge \mathsf{hsame}(u,u') \wedge \mathsf{hsame}(v,v')\big).
\end{aligned}$$

Proof. Apply Definition 38.584 to the carrier rows, the StreamNameUp classifier, the unary anchor and bound, and the selected offset. This chooses witnesses u and v with the two selected e-one endpoint displays, the two unary tail rows, $\mathsf{hsame}(u,v)$, and the exact if-and-only-if clause for every displayed selected e-one tail pair.

Apply Definition 38.553 to the same carrier rows, classifier, unary anchor, and unary bound. This supplies the finite-window row $\mathsf{RealUnaryStreamWindowClassifier}(s,t,\alpha,\omega)$.

Apply Definition 38.578 to the chosen selected endpoint displays, the carrier rows, the classifier, the unary anchor and bound, the selected offset, and the displayed histories z_s, z_t, d_s, d_t. The package returns the selected source classifier, the displayed $\mathsf{E1}$ classifier, the unary tail and common-tail rows, the positive-denominator rows, the endpoint unary rows, the nonempty exclusions, the zero-head exclusions, and the two appended e-zero-tail exclusions.

Repack the chosen endpoint displays, the finite-window row, the selected classifier appended-tail package, and the universal if-and-only-if clause from tail-class exactness. These rows are exactly the displayed full tail-class certificate. □

Fit. Traditional target: selected finite-window full tail-class certificate; BEDC source: $\mathsf{StreamName}^{\uparrow}$+ $\mathsf{Real}^{\uparrow}$+$\mathsf{Rat}^{\uparrow}$ over BHist; Carrier: $\mathsf{RatStreamNameCarrier}$; Classifier: $\mathsf{RatStreamNameClassifier}$ through $\mathsf{RealUnaryStreamWindowClassifier}$; Stability: endpoint hsame transport and positive-denominator transport; Ledger: carrier, classifier, anchor, bound, offset, endpoint displays, denominator rows, endpoint exclusions, appended-tail exclusions, and tail-class quantification; Core theorem: Definition 38.585; Exactness: full selected endpoint certificate plus exact canonical tail class; Standard bridge: RegSeqRat finite observation canonicalization; Status: $\mathsf{ProofTarget}$.

Definition 38.586 (Real unary StreamNameUp selected-window scoped tail package)**.** *The selected-window scoped tail package is the ten-field BEDC certificate for the finite RealUp observation-tail canonicalization at a selected unary offset:*

1. *Traditional target: finite RealUp observation-tail canonicalization for selected StreamNameUp windows.*
2. *BEDC source:* $\mathsf{StreamName}^{\uparrow} + \mathsf{Real}^{\uparrow} + \mathsf{Rat}^{\uparrow} + \mathsf{FKernel}$ *over* BHist.
3. *Carrier:* $\mathsf{RatStreamNameCarrier}$ *for both observation maps.*

4. *Classifier:* RatStreamNameClassifier *through* RealUnaryStreamWindowClassifier.
5. *Stability:* hsame *transport, FKernel e-one congruence and inversion, positive-denominator transport, and offset-bound projection.*
6. *Ledger: carrier rows, classifier row, unary anchor, unary bound, selected offset, endpoint displays, denominator exclusions, and canonical tail witnesses.*
7. *Bound data: the selected site is* $\mathsf{append}(\alpha, k)$ *with* $\mathsf{UnaryOffsetLe}(k, \omega)$*, so the finite-window classifier projects to the selected source* RatHistoryClassifier *row.*
8. *Core theorem list: Definition 38.574, Definition 38.579, Definition 38.582, Definition 38.584, Definition 38.585, and the window-sourced exactness target* BEDC.Derived.RealUp.RealUnaryStreamWindowClassi
9. *Exactness predicate: displayed selected e-one tail pairs are present exactly when their tails lie in the canonical* hsame *classes of the chosen witnesses.*
10. *Standard bridge: RegSeqRat finite observation canonicalization. Status:* ProofTarget.

Theorem 38.587 (Real unary StreamNameUp selected-window scoped tail package)**.** *For observation maps* $s, t : \mathsf{Hist} \to \mathsf{Hist}$ *and histories* $\alpha, \omega, k : \mathsf{Hist}$*, assume*

$$\mathsf{RatStreamNameCarrier}(s), \quad \mathsf{RatStreamNameCarrier}(t), \quad \mathsf{RatStreamNameClassifier}(s, t),$$

$$\mathsf{UnaryHistory}(\alpha), \quad \mathsf{UnaryHistory}(\omega), \quad \mathsf{UnaryOffsetLe}(k, \omega).$$

Then the selected window carries a scoped package: there exist histories $u, v : \mathsf{Hist}$ *such that*

$$\begin{aligned}
&\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(u)) \wedge \mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E1}(v)) \wedge \\
&\mathsf{RealUnaryStreamWindowClassifier}(s, t, \alpha, \omega) \wedge \\
&\mathsf{RatHistoryClassifier}(s(\mathsf{append}(\alpha, k)), t(\mathsf{append}(\alpha, k))) \wedge \\
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(u), \mathsf{E1}(v)) \wedge \\
&\mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsame}(u, v) \wedge \\
&\mathsf{PositiveUnaryDenominator}(s(\mathsf{append}(\alpha, k))) \wedge \mathsf{PositiveUnaryDenominator}(t(\mathsf{append}(\alpha, k))) \wedge \\
&\mathsf{UnaryHistory}(s(\mathsf{append}(\alpha, k))) \wedge \mathsf{UnaryHistory}(t(\mathsf{append}(\alpha, k))) \wedge \\
&\forall z_s, z_t, d_s, d_t : \mathsf{Hist}, \ (\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{e}) \to \mathsf{False}) \wedge \\
&\qquad (\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{e}) \to \mathsf{False}) \wedge \\
&\qquad (\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge (\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E0}(z_t)) \to \mathsf{False}) \wedge \\
&\qquad (\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), d_s \cdot \mathsf{E0}(z_s)) \to \mathsf{False}) \wedge \\
