&\qquad (\mathsf{hsame}(t(\mathsf{append}(\alpha, k)), d_t \cdot \mathsf{E0}(z_t)) \to \mathsf{False}) \wedge \\
&\forall u', v' : \mathsf{Hist}, \ \big(\mathsf{hsame}(s(\mathsf{append}(\alpha, k)), \mathsf{E1}(u')) \wedge \mathsf{hsame}(t(\mathsf{append}(\alpha, k)), \mathsf{E1}(v'))\big) \iff \\
&\qquad \big(\mathsf{UnaryHistory}(u') \wedge \mathsf{UnaryHistory}(v') \wedge \mathsf{hsame}(u, u') \wedge \mathsf{hsame}(v, v')\big).
\end{aligned}$$

Proof. Apply Definition 38.584 to the carrier rows, the StreamNameUp classifier, the unary anchor and bound, and the selected offset. This chooses canonical tails u and v with the two selected e-one endpoint displays, the unary tail rows, $\mathsf{hsame}(u, v)$, and the exact if-and-only-if clause for every displayed selected e-one tail pair.

Apply Definition 38.553 to the same carrier rows, classifier, unary anchor, and unary bound. This gives $\mathsf{RealUnaryStreamWindowClassifier}(s, t, \alpha, \omega)$. Projecting that window at the selected offset is the selected source RatHistoryClassifier row at $\mathsf{append}(\alpha, k)$.

The displayed selected endpoints for u and v transport the selected source classifier to $\mathsf{RatHistoryClassifier}(\mathsf{E1}(u)$, by Definition 37.54. FKernel e-one inversion, as used in the canonical tail-class theorem, reads this transported row as the canonical common-tail relation.

For the denominator and endpoint-exclusion ledger, fix arbitrary histories z_s, z_t, d_s, d_t. Apply Definition 38.574 to the classifier, the unary anchor and bound, the selected offset, and the zero-head tests. This returns the selected positive-denominator rows, endpoint unary rows, nonempty exclusions, and zero-head exclusions.

Apply Definition 38.578 to the chosen e-one endpoint displays and the same displayed histories z_s, z_t, d_s, d_t. Positive-denominator transport supplies the two appended e-zero-tail exclusions, while the earlier selected source row and endpoint rows remain unchanged.

Repack the finite-window row, selected source row, endpoint classifier, positive-denominator ledger, endpoint exclusions, canonical tails, and exact tail-class predicate. These fields are precisely the scoped package described in Definition 38.586. □

Theorem 38.588 (Real stream classifier selected e-one pair readback)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, every selected observation index n, and histories $a, b : \mathsf{Hist}$, if*

$$\mathsf{RealStreamClassifier}(x, y), \quad \mathsf{hsame}(x(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(y(n), \mathsf{E1}(b)),$$

then

$$\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).$$

Proof. Apply Definition 38.106 to the stream classifier at the selected index n. This produces the finite-prefix classifier witness needed at that index.

Apply Definition 38.148 to that prefix witness and to the two displayed e-one endpoint equalities. The readback theorem returns the two unary tail witnesses and the internal sameness relation $\mathsf{hsame}(a, b)$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier selected e1 pair readback`

Theorem 38.589 (Real stream classifier transported selected e-one rational classifier readback)**.** *For rational-observation streams $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$, every selected observation index n, and histories $a, b : \mathsf{Hist}$, if*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(y'(n), \mathsf{E}$$

then

$$\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)).$$

Proof. Use the forward direction of Definition 38.135 on $\mathsf{RealStreamClassifier}(x, y)$ and select the finite prefix at n. Transport this prefix witness along the two pointwise hsame hypotheses by Definition 38.107, obtaining a classified prefix for x' and y' at the same selected index.

Project the selected endpoint classifier with Definition 38.111. It gives $\mathsf{RatHistoryClassifier}(x'(n), y'(n))$.

Finally apply Definition 37.54 to move this endpoint classifier along $\mathsf{hsame}(x'(n), \mathsf{E1}(a))$ and $\mathsf{hsame}(y'(n), \mathsf{E1}(b))$, producing $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier transported selected e1 rat classifier readback`

Fit: traditional target selected rational endpoint readback for RealUp streams; BEDC source RatUp plus RealUp; carrier rational-observation streams; classifier RealStreamClassifier and RatHistoryClassifier; stability prefix exactness, hsame transport, and endpoint projection; ledger selected observation index and displayed e-one seals; core theorem Definition 38.589; exactness the displayed implication; standard bridge rational equality read from equal real observations; status ProofTarget.

Theorem 38.590 (Real stream classifier transported selected e-one pair readback)**.** *For rational-observation streams* $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$*, every selected observation index* n*, and histories* $a, b : \mathsf{Hist}$*, if*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(y'(n), \mathsf{E}$$

then

$$\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).$$

Proof. Apply Definition 38.589 to obtain the endpoint classifier $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$.

Apply Definition 37.49 in the forward direction. The one-tail exactness theorem returns $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier transported selected e1 pair readback`

Theorem 38.591 (Real stream classifier transported selected e-one full readback package)**.** *For rational-observation streams* $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$*, every selected observation index* n*, and histories* $a, b : \mathsf{Hist}$*, if*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(y'(n), \mathsf{E}$$

then

$$\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).$$

Proof. Apply Definition 38.589 under the displayed transport, classifier, and e-one seal hypotheses. This gives the first conjunct $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$.

Apply Definition 38.590 under the same hypotheses. This gives $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$.

Package the endpoint classifier together with the unary-tail readback triple. The resulting conjunction is exactly the selected transported e-one readback package displayed in the statement. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier transported selected e1 full readback package`

Fit: traditional target selected sealed rational endpoint package for RealUp streams; BEDC source RatUp plus RealUp finite-prefix exactness; carrier rational-observation streams; classifier RealStreamClassifier and RatHistoryClassifier; stability prefix hsame transport and RatUp one-tail exactness; ledger selected index and two e-one seals; core theorem this block; exactness the displayed conjunction; standard bridge rational equality read from equal transported real observations; status ProofTarget.

Theorem 38.592 (Real stream classifier transported selected e-one tail determinacy)**.** *For rational-observation streams* $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$*, every selected index* n*, and histories* $a, a', b, b' : \mathsf{Hist}$*, assume*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

If the transported selected endpoints satisfy the four e-one displays

$$\mathsf{hsame}(x'(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(y'(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(y'(n), \mathsf{E1}(b')),$$

then all of the following data hold:

1. $\mathsf{UnaryHistory}(a)$;
2. $\mathsf{UnaryHistory}(a')$;
3. $\mathsf{UnaryHistory}(b)$;
4. $\mathsf{UnaryHistory}(b')$;
5. $\mathsf{hsame}(a, a')$;
6. $\mathsf{hsame}(b, b')$;
7. $\mathsf{hsame}(a, b)$;
8. $\mathsf{hsame}(a', b')$.

Proof. Apply Definition 38.590 to the displays $\mathsf{hsame}(x'(n), \mathsf{E1}(a))$ and $\mathsf{hsame}(y'(n), \mathsf{E1}(b))$. This supplies $\mathsf{UnaryHistory}(a)$, $\mathsf{UnaryHistory}(b)$, and $\mathsf{hsame}(a, b)$.

Apply the same transported pair readback theorem again to the displays $\mathsf{hsame}(x'(n), \mathsf{E1}(a'))$ and $\mathsf{hsame}(y'(n), \mathsf{E1}(b'))$. This supplies $\mathsf{UnaryHistory}(a')$, $\mathsf{UnaryHistory}(b')$, and $\mathsf{hsame}(a', b')$.

For the x'-tail comparison, compose the first selected endpoint display with the symmetry of the second display. The resulting $\mathsf{hsame}(\mathsf{E1}(a), \mathsf{E1}(a'))$ is inverted by BEDC.FKernel.Hist.hsame_e1_iff, giving $\mathsf{hsame}(a, a')$.

The same composition and e-one inversion applied to the two y' endpoint displays gives $\mathsf{hsame}(b, b')$. Package these same-side comparisons with the two cross-tail rows from transported pair readback. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier transported selected e1 tail determinacy`

Fit: traditional target canonical selected transported rational observation tails; BEDC source RealUp streams, RatUp e-one readback, and FKernel e-one no-confusion; carrier rational-observation streams; classifier RealStreamClassifier; stability pointwise hsame transport plus e-one inversion; ledger selected index and four e-one seals; core theorem Definition 38.592; exactness unique tails for transported selected endpoints; standard bridge RegSeqRat selected denominator tails; status ProofTarget.

Theorem 38.593 (Real stream classifier transported selected positive denominator package)**.** *For rational-observation streams $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$ and every selected observation index n, if*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y),$$

then

$$\mathsf{RatHistoryClassifier}(x'(n), y'(n)) \wedge \mathsf{PositiveUnaryDenominator}(x'(n)) \wedge \mathsf{PositiveUnaryDenominator}(y'(n)).$$

Proof. Apply Definition 38.140 to the two pointwise hsame hypotheses and the source stream classifier. The endpoint field of that package gives $\mathsf{RatHistoryClassifier}(x'(n), y'(n))$ at the selected index n.

Apply Definition 37.50 to this selected endpoint classifier. It exposes $\mathsf{PositiveUnaryDenominator}(x'(n))$ and $\mathsf{PositiveUnaryDenominator}(y'(n))$.

Package the endpoint classifier with the two positive-denominator witnesses. The result is exactly the displayed transported selected denominator readback conjunction. □

Theorem 38.594 (Real stream classifier transported selected positive unary nonempty package)**.** *For rational-observation streams $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$ and a selected observation index n, assume*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

Then the transported selected endpoints carry the complete rational endpoint package

$$\mathsf{RatHistoryClassifier}(x'(n), y'(n)) \wedge \mathsf{PositiveUnaryDenominator}(x'(n)) \wedge \mathsf{PositiveUnaryDenominator}(y'(n)) \\ \wedge\ \mathsf{UnaryHistory}(x'(n)) \wedge \mathsf{UnaryHistory}(y'(n)) \wedge (\mathsf{hsame}(x'(n), \mathsf{e}) \to \bot) \wedge (\mathsf{hsame}(y'(n), \mathsf{e}) \to \bot).$$

Proof. Transport the selected rational-history classifier from $\mathsf{RatHistoryClassifier}(x(n), y(n))$ to $\mathsf{RatHistoryClassifier}(x'(n), y'(n))$ along the two pointwise hsame hypotheses.

Rational classifier positivity exposes positive unary denominator witnesses at both transported endpoints. Each positive unary denominator witness gives a unary-history row and separates that endpoint from e. Packaging these rows with the transported classifier gives the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier transport selected positive unary nonempty package`

Fit: traditional target selected positive denominator readback for transported RealUp rational observations; BEDC source RealUp plus RatUp; carrier rational-observation streams; classifier RealStreamClassifier and RatHistoryClassifier; stability prefix hsame transport plus RatUp denominator exposure; ledger selected observation index and transported endpoint displays; core theorem this block; exactness the displayed conjunction; standard bridge positivity of rational denominators inside equal transported real observations; status ProofTarget.

Theorem 38.595 (Real stream classifier selected positive unary nonempty package)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and a selected index n, if*

$$\mathsf{RealStreamClassifier}(x, y),$$

then the selected endpoints carry positive unary denominator witnesses, unary history witnesses, and nonempty boundary exclusions:

$$\mathsf{PositiveUnaryDenominator}(x(n)) \wedge \mathsf{PositiveUnaryDenominator}(y(n)) \wedge \mathsf{UnaryHistory}(x(n)) \wedge \mathsf{UnaryHistory}(y(n)) \wedge \\ (\mathsf{hsame}(x(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y(n), \mathsf{e}) \to \mathsf{False}).$$

Proof. Select the point classifier $\mathsf{RatHistoryClassifier}(x(n), y(n))$ from the stream classifier. RatUp positive-denominator projection gives the two positive denominator witnesses. Apply positive unary denominator readback to each endpoint, yielding the unary history witness and the empty-boundary contradiction for that endpoint. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier selected positive unary nonempty package`

Theorem 38.596 (Real stream classifier selected endpoint e-one shapes)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and a selected index n, if $\mathsf{RealStreamClassifier}(x, y)$ holds, then both selected endpoints are visibly one-headed with unary tails:*

$$(\exists x_t,\ x(n) = \mathsf{E1}(x_t) \wedge \mathsf{UnaryHistory}(x_t)) \wedge (\exists y_t,\ y(n) = \mathsf{E1}(y_t) \wedge \mathsf{UnaryHistory}(y_t)).$$

Proof. Apply selected positive unary nonempty readback at the chosen index. The package supplies unary-history evidence and empty-boundary exclusion for both selected endpoints.

For the x endpoint, unary nonempty one-tail readback chooses a tail x_t with $\mathsf{UnaryHistory}(x_t)$ and gives the constructor equality $x(n) = \mathsf{E1}(x_t)$ directly. Pair this equality with the unary-tail witness.

The y endpoint is treated in the same way, producing a tail y_t, its unary history witness, and the constructor equality $y(n) = \mathsf{E1}(y_t)$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier selected endpoint e1 shapes`

Theorem 38.597 (Real stream classifier selected endpoint common e-one tail readback)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and a selected index n, if $\mathsf{RealStreamClassifier}(x, y)$ holds, then*

$$\exists a, b,\ \mathsf{hsame}(x(n), \mathsf{E1}(a)) \wedge \mathsf{hsame}(y(n), \mathsf{E1}(b)) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).$$

Proof. Apply Definition 38.596 at the selected index. This gives a tail a for the x endpoint and a tail b for the y endpoint, together with the two displayed e-one rows $\mathsf{hsame}(x(n), \mathsf{E1}(a))$ and $\mathsf{hsame}(y(n), \mathsf{E1}(b))$ and the two unary-tail witnesses.

Apply Definition 38.588 to the same stream classifier and to those two displayed rows. The readback theorem returns the shared-tail row $\mathsf{hsame}(a, b)$ while preserving the unary-history evidence for both tails.

Package the two tails as the existential witnesses and combine the two displayed endpoint rows, the two unary-tail witnesses, and the common-tail row. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier selected endpoint common e1 tail readback`

Fit: traditional target selected rational observation readback for RealUp streams; BEDC source RatUp plus RealUp; carrier rational-observation streams; classifier RealStreamClassifier with selected RatHistoryClassifier readback; stability selected endpoint e-one coverage and e-one pair readback; ledger selected observation index and the two endpoint histories; core theorem Definition 38.597; exactness the existential package of one-headed endpoints, unary tails, and tail sameness; standard bridge rational equality read from the common unary tail; status ProofTarget.

Theorem 38.598 (Real stream classifier transported selected full shape readback package)**.** *For rational-observation streams $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$, every selected observation index n, and histories $a, b, z_X, z_Y : \mathsf{Hist}$, if*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(y'(n), \mathsf{E}$$

then

$$\begin{aligned}&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b) \wedge \\ &\mathsf{PositiveUnaryDenominator}(x'(n)) \wedge \mathsf{PositiveUnaryDenominator}(y'(n)) \wedge \mathsf{UnaryHistory}(x'(n)) \wedge \mathsf{UnaryHistory}(y'(n)) \wedge \\ &(\mathsf{hsame}(x'(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{e}) \to \mathsf{False}) \wedge \\ &(\mathsf{hsame}(x'(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{E0}(z_Y)) \to \mathsf{False}).\end{aligned}$$

Proof. Apply Definition 38.591 under the two pointwise transport rows, the source RealUp stream classifier, and the two selected e-one seals. This gives the endpoint classifier $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$ together with the unary tail readback $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$.

Apply Definition 38.594 under the same two pointwise transport rows and the same source RealUp stream classifier. This gives the selected transported endpoint classifier, the positive-denominator witnesses for $x'(n)$ and $y'(n)$, the unary-history rows, and the two nonempty exclusions.

It remains to exclude displayed zero-extensions. Suppose $\mathsf{hsame}(x'(n), \mathsf{E0}(z_X))$ holds. Transport $\mathsf{PositiveUnaryDenominator}(x'(n))$ along this comparison by Definition 37.6, and contradict Definition 37.10.

The y' endpoint is identical: transport $\mathsf{PositiveUnaryDenominator}(y'(n))$ along $\mathsf{hsame}(y'(n), \mathsf{E0}(z_Y))$ and apply the same zero-extension exclusion.

Package the e-one classifier row, the unary-tail readback, the positive endpoint rows, the unary and nonempty endpoint rows, and the two zero-extension contradictions. The result is exactly the displayed selected full shape readback package. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier transported selected full shape readback package`

Fit: traditional target selected transported endpoint-shape readback package for RealUp; BEDC source RatUp plus StreamNameUp-shaped RealUp streams; carrier rational-observation streams; classifiers RealStreamClassifier and RatHistoryClassifier; stability transported prefix readback, positive-denominator exposure, positive denominator hsame transport, and zero-extension exclusion; ledger selected observation index, two transport rows, two e-one seals, and two zero-extension tests; core theorem Definition 38.598; exactness the displayed classifier, tail, positive-denominator, unary, nonempty, and zero-extension package; downstream use by the RealUp dyadic embedding certificate; status ProofTarget.

Theorem 38.599 (Real stream classifier transported contextual full endpoint package)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, a selected index* n*, and histories* $a, b, z_X, z_Y : \mathsf{Hist}$*, assume*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

Assume also the selected transported context rows

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

the four selected continuation rows

$$\mathsf{Cont}(p_X(n), x'(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y'(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y($$

and the two one-headed endpoint seals

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)) \quad \textit{and} \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)).$$

Then the transported selected contextual endpoints carry all of the following data:

1. $\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n))$.
2. $\mathsf{PositiveUnaryDenominator}(o_X(n))$ *and* $\mathsf{PositiveUnaryDenominator}(o_Y(n))$.
3. $\mathsf{UnaryHistory}(o_X(n))$ *and* $\mathsf{UnaryHistory}(o_Y(n))$.
4. $\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}$ *and* $\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False}$.
5. $\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}$ *and* $\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False}$.

6. $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$.

Proof. First take the forward implication from Definition 38.139 and apply it to the two pointwise hsame rows and the source classifier $\mathsf{RealStreamClassifier}(x, y)$. This gives the transported classifier $\mathsf{RealStreamClassifier}(x', y')$.

With that classifier in hand, apply Definition 38.549 at the selected index n to the displayed unary context rows, the two context-identification rows, the four continuation rows, and the two one-headed endpoint seals. The theorem returns exactly the six displayed endpoint rows for $o_X(n)$ and $o_Y(n)$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier transported contextual full endpoint package`

Fit: traditional target transported contextual endpoint readback for RealUp; BEDC source RealUp stream hsame transport plus RatUp contextual endpoint readback; carrier rational-observation streams; classifiers RealStreamClassifier and selected RatHistoryClassifier; stability pointwise hsame transport, Cont context closure, and endpoint readback; ledger selected index, pointwise transport rows, contextual continuation outputs, one-headed and zero-headed tests; core theorem Definition 38.599; exactness the six-row endpoint package; standard bridge transported RegSeqRat selected contextual observation readback; status ProofTarget.

Theorem 38.600 (Real stream classifier transported contextual displayed e-one classifier package)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, a selected index* n*, and histories* $a, b, z_X, z_Y : \mathsf{Hist}$*, assume*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

Assume also the selected transported context rows

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

the four selected continuation rows

$$\mathsf{Cont}(p_X(n), x'(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y'(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y($$

and the two one-headed endpoint seals

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)) \quad \textit{and} \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)).$$

Then the transported selected contextual endpoints and their displayed e-one readbacks carry all of the following data:

1. $\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n))$.
2. $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$.
3. $\mathsf{UnaryHistory}(a)$ *and* $\mathsf{UnaryHistory}(b)$.
4. $\mathsf{hsame}(a, b)$.
5. $\mathsf{PositiveUnaryDenominator}(o_X(n))$ *and* $\mathsf{PositiveUnaryDenominator}(o_Y(n))$.
6. $\mathsf{UnaryHistory}(o_X(n))$ *and* $\mathsf{UnaryHistory}(o_Y(n))$.
7. $\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}$ *and* $\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False}$.
8. $\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}$ *and* $\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False}$.

Proof. Apply Definition 38.599 under the displayed pointwise transport rows, selected context rows, continuation rows, and one-headed endpoint seals. This returns the classifier for $o_X(n)$ and $o_Y(n)$, the positive-denominator rows, the endpoint unary rows, the two nonempty exclusions, the two zero-headed exclusions, and the tail readback $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$.

Now transport the first classifier row across the two displayed e-one seals by Definition 37.54. The source classifier is $\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n))$, and the endpoint comparisons are $\mathsf{hsame}(o_X(n), \mathsf{E1}(a))$ and $\mathsf{hsame}(o_Y(n), \mathsf{E1}(b))$; the transported row is $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$.

Finally project the three tail readback components from the returned conjunction and repack them with the transported displayed e-one classifier and the remaining endpoint rows already supplied by Definition 38.599. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier transported contextual displayed e1 classifier package`

Theorem 38.601 (Real stream classifier transported contextual e-one tail determinacy)**.** *For rational-observation streams $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$, a selected index n, and histories $a, a', b, b' : \mathsf{Hist}$, assume*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

Assume also the selected transported context rows

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

the four selected continuation rows

$$\mathsf{Cont}(p_X(n), x'(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y'(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y($$

and the four e-one displays

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')).$$

Then all of the following data hold:

1. $\mathsf{UnaryHistory}(a)$;
2. $\mathsf{UnaryHistory}(a')$;
3. $\mathsf{UnaryHistory}(b)$;
4. $\mathsf{UnaryHistory}(b')$;
5. $\mathsf{hsame}(a, a')$;
6. $\mathsf{hsame}(b, b')$;
7. $\mathsf{hsame}(a, b)$;
8. $\mathsf{hsame}(a', b')$.

Proof. Apply Definition 38.599 to the displays $\mathsf{hsame}(o_X(n), \mathsf{E1}(a))$ and $\mathsf{hsame}(o_Y(n), \mathsf{E1}(b))$. Its tail row supplies $\mathsf{UnaryHistory}(a)$, $\mathsf{UnaryHistory}(b)$, and $\mathsf{hsame}(a, b)$.

Apply the same transported contextual endpoint package to the displays $\mathsf{hsame}(o_X(n), \mathsf{E1}(a'))$ and $\mathsf{hsame}(o_Y(n), \mathsf{E1}(b'))$. This gives $\mathsf{UnaryHistory}(a')$, $\mathsf{UnaryHistory}(b')$, and $\mathsf{hsame}(a', b')$.

For the X-tail comparison, compose the first display of $o_X(n)$ with the symmetry of the second display. The resulting $\mathsf{hsame}(\mathsf{E1}(a), \mathsf{E1}(a'))$ is inverted by BEDC.FKernel.Hist.hsame_e1_inversion_iff to obtain $\mathsf{hsame}(a, a')$.

The same composition and e-one inversion applied to the two displays of $o_Y(n)$ gives $\mathsf{hsame}(b, b')$. Package these two internal tail comparisons with the two endpoint-package tail rows. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier transported contextual e1 tail determinacy`

Fit: traditional target transported contextual RealUp selected-tail determinacy; BEDC source RealUp streams, RatUp point classifiers, Cont, and FKernel history sameness; carrier rational-observation streams; classifier RealStreamClassifier with selected contextual endpoint displays; stability pointwise representative transport and context closure; ledger selected index, two transport rows, context continuations, and four e-one displays; core theorem Definition 38.601; exactness canonical e-one tails under transported contexts; standard bridge RegSeqRat and dyadic selected endpoint readback; status ProofTarget.

Theorem 38.602 (Real stream classifier transported contextual cross e-one tails)**.** *Under the assumptions of Definition 38.601, the off-diagonal selected tails satisfy*

$$\mathsf{hsame}(a, b') \wedge \mathsf{hsame}(a', b).$$

Proof. Apply Definition 38.601. It gives $\mathsf{hsame}(a, a')$, $\mathsf{hsame}(b, b')$, and $\mathsf{hsame}(a, b)$ among the selected tail rows. Compose $\mathsf{hsame}(a, b)$ with $\mathsf{hsame}(b, b')$ to obtain $\mathsf{hsame}(a, b')$. Compose the symmetry of $\mathsf{hsame}(a, a')$ with $\mathsf{hsame}(a, b)$ to obtain $\mathsf{hsame}(a', b)$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier transported contextual e1 tail cross hsame`

Theorem 38.603 (Real stream prefix transported selected full shape readback package)**.** *For rational-observation streams $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$, indices m, n, and histories $a, b, z_X, z_Y : \mathsf{Hist}$, if*

$$\mathsf{RealStreamPrefixClassifier}(x, y, m + n),$$

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(y'(n), \mathsf{E1}(b)),$$

then the transported selected finite-prefix endpoints carry the full readback package

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b) \wedge \\
&\mathsf{PositiveUnaryDenominator}(x'(n)) \wedge \mathsf{PositiveUnaryDenominator}(y'(n)) \wedge \mathsf{UnaryHistory}(x'(n)) \wedge \mathsf{UnaryHistory}(y'(n)) \wedge \\
&(\mathsf{hsame}(x'(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{e}) \to \mathsf{False}) \wedge \\
&(\mathsf{hsame}(x'(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{E0}(z_Y)) \to \mathsf{False}).
\end{aligned}$$

Proof. First truncate the displayed prefix classifier from length $m+n$ to the selected prefix through n by Definition 38.118. Transport this shorter prefix along the two pointwise hsame rows by Definition 38.107, obtaining a classified prefix for x' and y' at index n.

Project the selected endpoint by Definition 38.111. This gives $\mathsf{RatHistoryClassifier}(x'(n), y'(n))$. Transport that endpoint classifier across the displayed e-one seals with Definition 37.54, giving $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$.

Apply Definition 37.50 to the transported endpoint classifier before the e-one seals. The two projected rows are $\mathsf{PositiveUnaryDenominator}(x'(n))$ and $\mathsf{PositiveUnaryDenominator}(y'(n))$.

Apply Definition 37.12 separately to the two positive-denominator rows. This gives $\mathsf{UnaryHistory}(x'(n))$, $\mathsf{UnaryHistory}(y'(n))$, and the two empty-endpoint exclusions.

For the e-one tails, use Definition 37.49 in the forward direction on $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$. It supplies $\mathsf{UnaryHistory}(a)$, $\mathsf{UnaryHistory}(b)$, and $\mathsf{hsame}(a, b)$.

It remains to exclude displayed zero-headed endpoints. If $\mathsf{hsame}(x'(n), \mathsf{E0}(z_X))$ holds, transport $\mathsf{PositiveUnaryDenominator}(x'(n))$ along this comparison with Definition 37.6, then contradict Definition 37.10. The same argument for $y'(n)$ and z_Y gives the right zero-headed exclusion.

Collect the transported e-one classifier, the e-one tail rows, the positive denominator witnesses, the unary and nonempty endpoint rows, and the two zero-headed exclusions. These are exactly the displayed finite-prefix readback package. □

Fit: traditional target finite-prefix transported selected endpoint-shape readback package for RealUp; BEDC source RatUp plus RealUp stream prefixes; carrier rational-observation streams; classifiers RealStreamPrefixClassifier and RatHistoryClassifier; stability prefix truncation, prefix hsame transport, endpoint projection, positive-denominator hsame transport, and zero-extension exclusion; ledger selected observation index, prefix surplus index, two transport rows, two e-one seals, and two zero-extension tests; core theorem Definition 38.603; exactness the displayed classifier, tail, positive-denominator, unary, nonempty, and zero-extension package; standard bridge finite-prefix selected endpoint readback for transported RealUp rational observations; status ProofTarget.

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier transported selected full shape readback package`

Theorem 38.604 (Real stream transported selected endpoint common e-one tail readback)**.** *For rational-observation streams $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$ and index n, if x and y are pointwise transported to x' and y' and $\mathsf{RealStreamClassifier}(x, y)$ holds, then the transported selected endpoints have common e-one tail readback:*

$$\exists a, b,\ \mathsf{hsame}(x'(n), \mathsf{E1}(a)) \wedge \mathsf{hsame}(y'(n), \mathsf{E1}(b)) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).$$

Proof. The selected positive unary nonempty package exposes one-headed endpoint witnesses for $x(n)$ and $y(n)$. Transport the two displayed endpoint seals along the pointwise hsame rows to obtain the corresponding seals for $x'(n)$ and $y'(n)$. The selected e-one pair readback theorem supplies the two unary tail rows and their common hsame comparison, giving the displayed existential package. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier transport selected endpoint common e1 tail readback`

Theorem 38.605 (Real stream selected appended e-one tail cancellation)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, index n, and histories $d, e, tail_D, tail_E$, if the selected stream endpoints display as appended e-one tails, then tail equality cancels the displayed tails and recovers the denominator head comparison:*

$$\begin{aligned}&\mathsf{RealStreamClassifier}(x, y) \Longrightarrow \mathsf{hsame}(x(n), \mathsf{E1}(d \cdot \mathsf{E1}(tail_D))) \Longrightarrow \\ &\quad \mathsf{hsame}(y(n), \mathsf{E1}(e \cdot \mathsf{E1}(tail_E))) \Longrightarrow \mathsf{hsame}(tail_D, tail_E) \Longrightarrow \mathsf{hsame}(d, e).\end{aligned}$$

Proof. Evaluate the stream classifier at the selected index to obtain the RatUp history classifier for $x(n)$ and $y(n)$. Transport this classifier across the two displayed e-one endpoint comparisons. RatUp e-one tail readback gives the comparison between $d \cdot \mathsf{E1}(tail_D)$ and $e \cdot \mathsf{E1}(tail_E)$. The tail comparison identifies the e-one suffixes, and BEDC append right cancellation leaves exactly $\mathsf{hsame}(d, e)$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier selected append e1 tail hsame cancel`

Theorem 38.606 (Real stream classifier transported contextual displayed e-one appended-tail package)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, a selected index* n*, and histories* $a, b, d_X, d_Y, z_X, z_Y : \mathsf{Hist}$*, assume*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

Assume also the selected transported context rows

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

the four selected continuation rows

$$\mathsf{Cont}(p_X(n), x'(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y'(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y($$

and the two one-headed endpoint seals

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)) \quad \textit{and} \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)).$$

Then the transported selected contextual displayed e-one package also carries the appended e-zero-tail exclusions:

1. $\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n))$.
2. $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$.
3. $\mathsf{UnaryHistory}(a)$ *and* $\mathsf{UnaryHistory}(b)$.
4. $\mathsf{hsame}(a, b)$.
5. $\mathsf{PositiveUnaryDenominator}(o_X(n))$ *and* $\mathsf{PositiveUnaryDenominator}(o_Y(n))$.
6. $\mathsf{UnaryHistory}(o_X(n))$ *and* $\mathsf{UnaryHistory}(o_Y(n))$.
7. $\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}$ *and* $\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False}$.
8. $\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}$ *and* $\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False}$.
9. $(\mathsf{hsame}(o_X(n), d_X \cdot \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), d_Y \cdot \mathsf{E0}(z_Y)) \to \mathsf{False})$.

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier transported contextual displayed e1 appended tail exclusion package`

Proof. Apply Definition 38.600 under the same pointwise transport rows, selected context rows, continuation rows, and one-headed endpoint seals. This supplies the classifier rows, the displayed e-one tail readback, the positive-denominator rows, the unary endpoint rows, and the nonempty and zero-headed exclusions.

For the left appended-tail test, suppose $\mathsf{hsame}(o_X(n), d_X \cdot \mathsf{E0}(z_X))$. Transport $\mathsf{PositiveUnaryDenominator}(o_X(n))$ across this displayed equality by Definition 37.6. The transported positive-denominator row for $d_X \cdot \mathsf{E0}(z_X)$ contradicts Definition 37.15.

The right appended-tail test is the same argument applied to $\mathsf{hsame}(o_Y(n), d_Y \cdot \mathsf{E0}(z_Y))$ and the projected positive-denominator row for $o_Y(n)$. Transport gives a positive denominator for $d_Y \cdot \mathsf{E0}(z_Y)$, contradicting the same appended e-zero-tail obstruction.

Repackage the rows from the transported contextual displayed e-one classifier package with the two appended-tail contradictions. The result is the stated displayed classifier package together with the appended e-zero-tail exclusions. □

Fit: traditional target transported RegSeqRat contextual endpoint classifier with appended-tail exclusion; BEDC source RealUp streams, RatUp classifier, Cont, and positive denominator obstruction; carrier rational-observation streams; classifier RealStreamClassifier plus selected RatHistoryClassifier; stability pointwise transport, context closure, e-one display transport, and positive-denominator appended-tail contradiction; ledger selected index, transport rows, context continuations, e-one seals, zero-headed and appended-tail tests; core theorem Definition 38.606; exactness displayed classifier package plus appended-tail exclusions; standard bridge dyadic endpoint normalization; status ProofTarget.

Theorem 38.607 (Real stream classifier transported selected common e-one certified shape envelope)**.** *For rational-observation streams* $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$*, an index* n*, and histories* $z_X, z_Y : \mathsf{Hist}$*, assume*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

Then there exist histories $a, b : \mathsf{Hist}$ *such that*

$$\begin{aligned}
&\mathsf{hsame}(x'(n), \mathsf{E1}(a)) \wedge \mathsf{hsame}(y'(n), \mathsf{E1}(b)) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)\\
&\wedge\ \mathsf{RatHistoryClassifier}(x'(n), y'(n))\\
&\wedge\ \mathsf{PositiveUnaryDenominator}(x'(n)) \wedge \mathsf{PositiveUnaryDenominator}(y'(n))\\
&\wedge\ \mathsf{UnaryHistory}(x'(n)) \wedge \mathsf{UnaryHistory}(y'(n))\\
&\wedge\ (\mathsf{hsame}(x'(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{e}) \to \mathsf{False})\\
&\wedge\ (\mathsf{hsame}(x'(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{E0}(z_Y)) \to \mathsf{False}).
\end{aligned}$$

Proof. Apply Definition 38.604 under the pointwise transport rows and the stream classifier. This supplies histories a and b, the two displayed e-one endpoint rows, the two unary tail rows, and the common tail comparison $\mathsf{hsame}(a, b)$.

Next apply Definition 38.594 under the same hypotheses. This gives the transported RatUp classifier, the two positive unary denominator rows, the unary endpoint rows, and the two nonempty endpoint exclusions.

Finally apply Definition 38.141 with the displayed histories z_X and z_Y. Repack the tail readback, endpoint classifier, denominator rows, nonempty exclusions, and zero-headed exclusions into the displayed existential envelope. □

Theorem 38.608 (RealUp StreamName-RegSeqRat common e-one window envelope)**.** *Let* $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$ *be rational-observation streams, let* $n : \mathsf{Hist}$ *be a certified unary index, and let* $\mathcal{P} : \mathsf{ProbeBundle}$ *be a finite bundle with* $\mathsf{InBundle}(n, \mathcal{P})$*. Suppose the pointwise transport rows and stream classifier hypotheses of Definition 38.607 hold at the selected observation, and suppose the finite-window* $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}$ *handoff rows over* $\mathcal{P}$ *are present. Then the extracted common e-one witnesses* $a, b : \mathsf{Hist}$ *form exactly the finite consumer packet*

1. $\mathsf{UnaryHistory}(n)$ *and* $\mathsf{InBundle}(n, \mathcal{P})$*;*
2. *the transported* $\mathsf{RatHistoryClassifier}(x'(n), y'(n))$ *row;*
3. *positive unary denominator rows for* $x'(n)$ *and* $y'(n)$*;*
4. *the endpoint exclusions* $\mathsf{hsame}(x'(n), \mathsf{e}) \to \mathsf{False}$*,* $\mathsf{hsame}(y'(n), \mathsf{e}) \to \mathsf{False}$*,* $\mathsf{hsame}(x'(n), \mathsf{E0}(a)) \to \mathsf{False}$*, and* $\mathsf{hsame}(y'(n), \mathsf{E0}(b)) \to \mathsf{False}$*;*
5. *the endpoint readbacks* $\mathsf{hsame}(x'(n), \mathsf{E1}(a))$ *and* $\mathsf{hsame}(y'(n), \mathsf{E1}(b))$*, the unary tail rows* $\mathsf{UnaryHistory}(a)$ *and* $\mathsf{UnaryHistory}(b)$*, and the shared tail comparison* $\mathsf{hsame}(a, b)$*.*

The packet exports no quotient, completion, Classical representative, metric-completeness row, arithmetic or order row, standard bridge row, or hidden selector.

Proof. First apply Definition 38.607. It supplies the witnesses a and b, their e-one endpoint readbacks, their unary tail rows, the shared $\mathsf{hsame}(a, b)$ comparison, the transported rational classifier, positive unary denominator rows, unary endpoint rows, and the empty and zero-headed endpoint exclusions.

Next read the same selected observation through Definition 126.170. The handoff contributes only the bundled unary-history row, the displayed $\mathsf{InBundle}(n, \mathcal{P})$ membership, and the pointwise rational classifier row consumed by RegSeqRat.

Finally apply Definition 38.342 to the selected $\mathsf{Real}^{\uparrow}$ finite window. Its read surface identifies the listed finite packet as a boundary over BHist, ProbeBundle, UnaryHistory, $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, RegSeqRat, and hsame. The exclusion clauses supplied by the envelope rule out empty and zero-headed endpoints, so the repacked packet has no slot for quotient, completion, Classical representative, metric completeness, arithmetic, order, standard bridge, or hidden selection data. □

Theorem 38.609 (Real stream classifier transported selected appended e-one tail cancellation)**.** *For rational-observation streams $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$, index n, and histories $d, e, tail_D, tail_E$, if the source stream endpoints are classified and the transported selected endpoints display as appended e-one tails, then tail equality cancels the transported displayed tails and recovers the denominator head comparison:*

$$\begin{aligned}&(\forall i,\ \mathsf{hsame}(x(i), x'(i))) \Longrightarrow (\forall i,\ \mathsf{hsame}(y(i), y'(i))) \Longrightarrow \\ &\quad \mathsf{RealStreamClassifier}(x, y) \Longrightarrow \mathsf{hsame}(x'(n), \mathsf{E1}(d \cdot \mathsf{E1}(tail_D))) \Longrightarrow \\ &\quad \mathsf{hsame}(y'(n), \mathsf{E1}(e \cdot \mathsf{E1}(tail_E))) \Longrightarrow \mathsf{hsame}(tail_D, tail_E) \Longrightarrow \mathsf{hsame}(d, e).\end{aligned}$$

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier transported selected append e1 tail hsame cancel`

Proof. Evaluate $\mathsf{RealStreamClassifier}(x, y)$ at the selected index n to obtain the RatUp point classifier for $x(n)$ and $y(n)$. Use the two pointwise hsame rows to transport that classifier to the endpoints $x'(n)$ and $y'(n)$.

Transport the RatUp point classifier again across the two displayed appended e-one seals. This gives a RatUp classifier between $\mathsf{E1}(d \cdot \mathsf{E1}(tail_D))$ and $\mathsf{E1}(e \cdot \mathsf{E1}(tail_E))$.

Apply RatUp e-one tail readback to compare $d \cdot \mathsf{E1}(tail_D)$ with $e \cdot \mathsf{E1}(tail_E)$. The supplied tail comparison identifies the two e-one suffixes, and Definition 4.50 cancels the common suffix to leave exactly $\mathsf{hsame}(d, e)$. □

Fit: traditional target transported selected denominator-tail agreement readback for RealUp streams; BEDC source RealUp streams, RatUp classifier transport, RatUp e-one tail readback, and BEDC append cancellation; carrier rational-observation streams; classifier RealStreamClassifier plus selected RatHistoryClassifier; stability pointwise stream transport, endpoint hsame transport, e-one constructor transport, and append right-context cancellation; ledger selected index, two stream transport rows, two displayed appended e-one endpoint seals, and the supplied tail comparison; core theorem Definition 38.609; exactness the displayed implication to $\mathsf{hsame}(d, e)$; standard bridge RegSeqRat and dyadic endpoint normalization readback; status ProofTarget.

Theorem 38.610 (Real stream classifier transported selected certified e-one tail cancellation envelope)**.** *For rational-observation streams $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$, an index n, and histories $d, e, tail_D, tail_E, z_X, z_Y : \mathsf{Hist}$, assume*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y),$$

and assume the transported selected endpoints display as appended e-one tails:

$$\mathsf{hsame}(x'(n), \mathsf{E1}(d \cdot \mathsf{E1}(tail_D))), \quad \mathsf{hsame}(y'(n), \mathsf{E1}(e \cdot \mathsf{E1}(tail_E))), \quad \mathsf{hsame}(tail_D, tail_E).$$

Then the same transported selected observation carries the endpoint certificate and the denominator-head cancellation package

$$\begin{aligned}
&\mathsf{PositiveUnaryDenominator}(x'(n)) \wedge \mathsf{PositiveUnaryDenominator}(y'(n)) \\
&\wedge\ \mathsf{UnaryHistory}(x'(n)) \wedge \mathsf{UnaryHistory}(y'(n)) \\
&\wedge\ (\mathsf{hsame}(x'(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{e}) \to \mathsf{False}) \\
&\wedge\ (\mathsf{hsame}(x'(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{E0}(z_Y)) \to \mathsf{False}) \\
&\wedge\ \mathsf{hsame}(d, e).
\end{aligned}$$

Proof. Evaluate $\mathsf{RealStreamClassifier}(x, y)$ at the selected index n. Transport the resulting RatUp point classifier along the two pointwise stream rows to obtain a classifier for $x'(n)$ and $y'(n)$.

Project positive unary denominators from the transported RatUp classifier. Apply positive-denominator readback to the two projected rows; this gives the unary endpoint rows and separates both selected endpoints from e.

For the displayed zero-headed exclusions, transport each positive-denominator row across a proposed comparison with $\mathsf{E0}(z_X)$ or $\mathsf{E0}(z_Y)$ and apply the RatUp zero-headed contradiction.

Finally transport the RatUp classifier across the two displayed appended e-one endpoint seals. RatUp e-one tail readback compares $d \cdot \mathsf{E1}(tail_D)$ with $e \cdot \mathsf{E1}(tail_E)$; the supplied tail comparison identifies the two e-one suffixes, and Definition 4.50 cancels that right context to give $\mathsf{hsame}(d, e)$. Repack the endpoint certificate rows with this denominator head comparison. □

Fit: traditional target transported selected denominator-tail agreement with certified endpoint readback for RealUp streams; BEDC source RealUp streams, RatUp classifier transport, RatUp positive denominator readback, RatUp e-one tail readback, zero-headed denominator exclusion, and BEDC append cancellation; carrier rational-observation streams; classifier RealStreamClassifier plus selected RatHistoryClassifier; stability pointwise stream transport, endpoint hsame transport, e-one constructor transport, positive denominator hsame transport, and append right-context cancellation; ledger selected index, two stream transport rows, two displayed appended e-one endpoint seals, the supplied tail comparison, and two zero-extension tests; core theorem Definition 38.610; exactness the displayed endpoint certificate and $\mathsf{hsame}(d, e)$ package; standard bridge RegSeqRat and dyadic endpoint normalization readback; status ProofTarget.

Theorem 38.611 (Real stream classifier transported selected tail-class exactness)**.** *For rational-observation streams $x, x', y, y' : \mathbb{N} \to \mathsf{Hist}$, an index n, and chosen tails $a, b : \mathsf{Hist}$, assume*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y),$$

and the transported selected e-one displays

$$\mathsf{hsame}(x'(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(y'(n), \mathsf{E1}(b)).$$

Then the chosen transported selected e-one tail class satisfies

$$\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b),$$

and for all histories $a', b' : \mathsf{Hist}$,

$$\begin{aligned}
&\big(\mathsf{hsame}(x'(n), \mathsf{E1}(a')) \wedge \mathsf{hsame}(y'(n), \mathsf{E1}(b'))\big) \iff \\
&\qquad \big(\mathsf{UnaryHistory}(a') \wedge \mathsf{UnaryHistory}(b') \wedge \mathsf{hsame}(a, a') \wedge \mathsf{hsame}(b, b')\big).
\end{aligned}$$

Proof. Apply Definition 38.590 to the two pointwise representative-transport rows, the source stream classifier, and the chosen displays. This gives the selected readback triple $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$.

For the forward direction of the displayed if-and-only-if, fix histories a', b' with displays $\mathsf{hsame}(x'(n), \mathsf{E1}(a'))$ and $\mathsf{hsame}(y'(n), \mathsf{E1}(b'))$. Apply Definition 38.592 to the chosen displays and the two new displays. The determinacy theorem gives $\mathsf{UnaryHistory}(a')$, $\mathsf{UnaryHistory}(b')$, $\mathsf{hsame}(a, a')$, and $\mathsf{hsame}(b, b')$ among its returned rows.

For the reverse direction, assume $\mathsf{UnaryHistory}(a')$, $\mathsf{UnaryHistory}(b')$, $\mathsf{hsame}(a, a')$, and $\mathsf{hsame}(b, b')$. Apply BEDC.FKernel.Hist.hsame_e1_congr to $\mathsf{hsame}(a, a')$ and compose the result with $\mathsf{hsame}(x'(n), \mathsf{E1}(a))$ by BEDC.FKernel.Hist.hsame_trans. This transports the chosen left display to $\mathsf{hsame}(x'(n), \mathsf{E1}(a'))$.

Apply the same e-one congruence and transitivity chain to $\mathsf{hsame}(b, b')$ and $\mathsf{hsame}(y'(n), \mathsf{E1}(b))$. This transports the chosen right display to $\mathsf{hsame}(y'(n), \mathsf{E1}(b'))$, so the two transported displays give the reverse membership implication. □

Fit: traditional target transported selected rational endpoint tail classes; BEDC source RealUp stream classifier, StreamName-style pointwise representative transport, RatUp selected endpoint readback, and FKernel e-one congruence; carrier rational-observation streams; classifier RealStreamClassifier; stability selected e-one determinacy, e-one congruence, and hsame transitivity; ledger selected index, two pointwise transport rows, source stream classifier, chosen transported e-one displays, and arbitrary candidate transported e-one displays; core theorem Definition 38.611; exactness the displayed selected tail class is precisely the pair of hsame classes of a and b; standard bridge and downstream consumer RegSeqRat selected observation canonicalization; status ProofTarget.

Theorem 38.612 (RealUp RegSeqRat terminal seal functoriality)**.** *Let $x, y, x', y', x'', y'' : \mathbb{N} \to \mathsf{Hist}$ be rational-observation streams, let n be a selected finite-window index, and let $a, b : \mathsf{Hist}$ be selected tails. Suppose that x, y satisfy $\mathsf{RealStreamClassifier}(x, y)$, that the first representative transport carries x, y to x', y', and that the second representative transport carries x', y' to x'', y'':*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \forall i,\ \mathsf{hsame}(x'(i), x''(i)), \quad \forall i,\ \mathsf{hsame}(y'(i), y''(i)).$$

Assume also that both stages preserve the selected e-one displays used by the RegSeqRat finite-window consumer:

$$\mathsf{hsame}(x'(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(y'(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(x''(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(y''(n), \mathsf{E1}(b)).$$

Then the terminal $\mathsf{Real}^{\uparrow}$ seal reads the same selected tail class through the staged route $x, y \to x', y' \to x'', y''$ as through the composed route $x, y \to x'', y''$. In particular, for every candidate pair $a', b' : \mathsf{Hist}$, the RegSeqRat terminal consumer accepts the terminal displays $\mathsf{hsame}(x''(n), \mathsf{E1}(a'))$ and $\mathsf{hsame}(y''(n), \mathsf{E1}(b'))$ exactly when a' and b' lie in the selected hsame classes of a and b.

Proof. Apply Definition 38.611 to the first-stage transport and the selected displays at $x'(n)$ and $y'(n)$. This identifies the selected tail class seen by the staged route after the first transport.

For the composed route, use BEDC.FKernel.Hist.hsame_trans to compose the two pointwise representative transports, obtaining $\mathsf{hsame}(x(i), x''(i))$ and $\mathsf{hsame}(y(i), y''(i))$ for each index i. Apply Definition 38.611 again to the composed transport and the selected terminal displays at $x''(n)$ and $y''(n)$.

It remains only to compare candidate terminal displays. If the staged read uses a candidate a', b' at the terminal seal, the selected-tail exactness theorem places a' and b' in the hsame classes

of a and b. Conversely, BEDC.FKernel.Hist.hsame_e1_congr lifts $\mathsf{hsame}(a, a')$ and $\mathsf{hsame}(b, b')$ to e-one displays, and BEDC.FKernel.Hist.hsame_trans composes those lifted displays with the terminal displays for a and b.

The argument uses only the displayed hsame transports, e-one congruence, and selected-tail exactness. It introduces no quotient sequence, completion object, host index equality, or host real equality. □

Theorem 38.613 (Real selected transport readback functoriality)**.** *Let W_0 be a finite* $\mathsf{Real}^{\uparrow}$ *observation window with finite probe bundle $\mathcal{P}$:* ProbeBundle *and selected bundled observation n :* Hist *with* $\mathsf{InBundle}(n, \mathcal{P})$*. Suppose two displayed unary-context transports*

$$\mathcal{T}_{01} : W_0 \to W_1, \qquad \mathcal{T}_{12} : W_1 \to W_2$$

are composable over the same selected $\mathsf{StreamName}^{\uparrow}$ *source, and suppose their composite transport $\mathcal{T}_{02}$ is the displayed unary-context composition of $\mathcal{T}_{01}$ and $\mathcal{T}_{12}$. Assume each of $\mathcal{T}_{01}$, $\mathcal{T}_{12}$, and $\mathcal{T}_{02}$ preserves the visible* $\mathsf{StreamName}^{\uparrow}$*,* RegSeqRat*, DyadicRatCore,* UnaryHistory*,* ProbeBundle*,* InBundle*,* hsame*,* Cont*,* Pkg*, and* RealLedgerPolicy *rows at the selected finite window.*

Then the selected readback after $\mathcal{T}_{02}$ is the same finite RegSeqRat *tail-classifier row as the stagewise readback obtained by first reading after $\mathcal{T}_{01}$ and then reading after $\mathcal{T}_{12}$. Equivalently, the following two displayed packets expose one selected tail-classifier row:*

1. *the endpoint package, contextual package, appended e-one tail package, common e-one certified-shape envelope, cancellation envelope, and selected tail-class exactness read after $\mathcal{T}_{02}$;*
2. *the same six readback packages read after $\mathcal{T}_{01}$ and then transported through $\mathcal{T}_{12}$.*

The common row is determined only by the displayed $\mathsf{StreamName}^{\uparrow}$/RegSeqRat*/DyadicRatCore finite-window surface, the* UnaryHistory *and* ProbeBundle *membership rows, the* hsame/Cont/Pkg *ledger, and the finite* RealLedgerPolicy *row. It exports no quotient, completion, Classical representative, metric-completeness, arithmetic or order, standard-bridge, or hidden selector row.*

Proof. First read the selected endpoints through the composite transport. Apply the selected endpoint package Definition 38.604 and the transported contextual package Definition 38.599 to $\mathcal{T}_{02}$. These give the transported selected endpoint rows, the contextual continuation rows, and the common e-one tail comparison at W_2.

Next enrich that composite readback with the displayed endpoint certificates. Use Definition 38.606 and Definition 38.607 to attach the appended-tail exclusions, positive-denominator rows, unary endpoint rows, and the common certified-shape envelope. Apply Definition 38.610 to identify the displayed appended e-one denominator heads.

Now perform the same read in two stages. The first transport $\mathcal{T}_{01}$ supplies the same endpoint and contextual rows at W_1. The second transport $\mathcal{T}_{12}$ preserves exactly the same $\mathsf{StreamName}^{\uparrow}$, RegSeqRat, DyadicRatCore, UnaryHistory, ProbeBundle, InBundle, hsame, Cont, Pkg, and RealLedgerPolicy rows, so the stagewise packet has the same six certificate faces as the composite packet.

Finally apply Definition 38.611 to both packets. Tail-class exactness says that a selected readback is classified only by the displayed e-one tail class and its finite RegSeqRat classifier row. Since the endpoint, contextual, appended-tail, common-shape, cancellation, and selected-tail exactness faces agree under the preserved ledger, the composite readback and the stagewise readback expose the same finite tail-classifier row.

The exclusion clause follows from the same readback surface. None of the cited packages contains a quotient carrier, completion object, Classical representative, metric-completeness certificate, arithmetic or order operation, standard-bridge datum, or hidden selector row, and the composite transport is formed inside the displayed unary-context ledger. □

Theorem 38.614 (Real selected transport readback identity)**.** *Let W be a finite* $\mathsf{Real}^{\uparrow}$ *observation window with finite probe bundle* $\mathcal{P} : \mathsf{ProbeBundle}$ *and selected bundled observation* $n : \mathsf{Hist}$ *with* $\mathsf{InBundle}(n, \mathcal{P})$*. Suppose the displayed unary-context transport*

$$\mathcal{I}_W : W \to W$$

is identity on the visible $\mathsf{StreamName}^{\uparrow}$*,* RegSeqRat*, DyadicRatCore,* UnaryHistory*,* ProbeBundle*,* InBundle*,* hsame*,* Cont*,* Pkg*, and* RealLedgerPolicy *rows at this selected finite window.*

Then the selected readback through $\mathcal{I}_W$ exposes exactly the original finite RegSeqRat *tail-classifier row attached to n in W. The readback exports no quotient, completion, metric-completeness, standard bridge, arithmetic or order structure, hidden selector, or additional endpoint row beyond the displayed finite-window ledger.*

Proof. Specialize Definition 38.613 to the identity composite $\mathcal{I}_W = \mathcal{I}_W \circ \mathcal{I}_W$. The identity hypotheses make the composite packet and the stagewise packet use the same visible $\mathsf{StreamName}^{\uparrow}$/RegSeqRat/DyadicRatC surface and the same UnaryHistory, ProbeBundle, InBundle, hsame, Cont, Pkg, and RealLedgerPolicy rows.

The endpoint package, contextual package, common-shape envelope, cancellation envelope, and selected-tail exactness rows cited in the functoriality theorem therefore read back the endpoint package already present at W. Since selected-tail exactness identifies a selected readback only through the displayed e-one tail class and its finite RegSeqRat classifier, the identity transport cannot change the tail-classifier row.

The exclusion clause is inherited from the same finite ledger projections. Each cited package is a projection of the finite observation window and none contains a quotient carrier, completion object, metric-completeness certificate, standard bridge, arithmetic or order operation, hidden selector, or additional endpoint row. □

Theorem 38.615 (Real selected transport readback pullback uniqueness)**.** *Let K be a certified common finite* $\mathsf{Real}^{\uparrow}$ *source window with finite probe bundle* $\mathcal{P} : \mathsf{ProbeBundle}$ *and selected bundled observation* $n : \mathsf{Hist}$ *with* $\mathsf{InBundle}(n, \mathcal{P})$*. Let*

$$\mathcal{T}_1 : K \to W_1, \qquad \mathcal{T}_2 : K \to W_2$$

be two selected unary-context transports into observation windows W_1 and W_2. Suppose their restrictions over K expose the same $\mathsf{StreamName}^{\uparrow}$ *classifier rows, the same* RegSeqRat *tail-classifier rows, the same DyadicRatCore endpoint rows, and the same* ProbeBundle*,* InBundle*,* UnaryHistory*,* hsame*,* Cont*,* Pkg*, and* RealLedgerPolicy *ledger.*

Then the selected readback packets in W_1 and W_2 expose one common finite RegSeqRat *tail-classifier row on K. The row is determined by the shared finite source surface alone: the two readbacks may be viewed as pullbacks of the same selected source readback, and their endpoint, contextual, appended-tail, common-shape, cancellation, and selected-tail exactness faces agree after restriction to K.*

No quotient carrier, completion object, Classical representative, metric-completeness certificate, arithmetic or order structure, standard bridge, or hidden selector is part of this uniqueness statement.

Proof. First restrict both transported packets to the certified finite source window K. The hypothesis identifies the visible $\mathsf{StreamName}^{\uparrow}$ classifier rows, the RegSeqRat tail classifiers, the DyadicRatCore endpoint rows, and the ProbeBundle/InBundle/UnaryHistory membership surface used by the selected readback.

Next apply Definition 38.614 on K. It says that the identity readback over the shared source surface exposes exactly the original finite RegSeqRat tail-classifier row attached to n.

Now apply Definition 38.613 separately to the identity transport on K followed by $\mathcal{T}_1$, and to the identity transport on K followed by $\mathcal{T}_2$. Since the two restrictions carry the same hsame/Cont/Pkg ledger and the same RealLedgerPolicy row, the two transported packets read back the same row as the identity packet when pulled to K.

Finally use Definition 38.611 on the two selected packets. Tail-class exactness leaves only the displayed e-one tail class and its finite RegSeqRat classifier row. Those rows are the same by the common-source hypotheses, so the two selected readbacks expose one finite tail-classifier row on K.

The exclusions follow because every cited result is stated inside the finite-window readback ledger. None introduces quotient representatives, completion, Classical choice, metric completeness, arithmetic or order operations, or bridge data. □

Theorem 38.616 (Real selected transport readback boundary certificate)**.** *Let W be a certified finite selected* Real$^{\uparrow}$ *observation window, and let the selected unary-context readback diagram over W be either composable or obtained from a common-source pullback. Suppose every leg of the diagram preserves exactly the visible* StreamName$^{\uparrow}$ *classifier rows, the finite* RegSeqRat *tail-classifier rows, the DyadicRatCore endpoint rows, and the displayed* UnaryHistory*,* ProbeBundle*,* InBundle*,* hsame*,* Cont*,* Pkg*, and* RealLedgerPolicy *rows.*

Then the selected readback boundary of the diagram is a single finite RegSeqRat *tail-classifier row. This row is stable under the identity diagram, under unary-context composition, and under common-source pullback: all three presentations expose the same selected tail class and the same finite readback ledger over the visible window.*

The boundary certificate contains no quotient carrier, no completion object, no metric-completeness datum, no arithmetic or order structure, no standard bridge data, no Classical representative, and no hidden selector.

Proof. For a composable diagram, apply Definition 38.613. The displayed finite ledger rows are preserved along each unary-context leg, so the stagewise and composite readbacks expose the same finite RegSeqRat tail-classifier row.

For the unit diagram, apply Definition 38.614. The selected readback over W is unchanged by the identity transport, and the visible StreamName$^{\uparrow}$, DyadicRatCore, membership, continuation, package, and ledger rows are exactly the rows already present in the certified window.

For a common-source pullback, apply Definition 38.615. Agreement of the two restrictions on the displayed source rows forces the same selected tail class and hence the same finite RegSeqRat classifier row on the pullback window.

These three cases exhaust the boundary operations named in the statement. Exactness is therefore the finite ledger inventory itself: the only row left at the selected readback boundary is the visible RegSeqRat tail-classifier row, and none of the excluded carriers, representatives, completions, metric, order, arithmetic, bridge, or hidden-selection data is introduced by the cited finite-window results. □

Fit: traditional target functoriality of selected finite-window readback for RealUp transports; BEDC source Real$^{\uparrow}$ selected transport, RatUp endpoint readback, StreamNameUp finite-window rows, RegSeqRat tail classifiers, and DyadicRatCore source rows; carrier BHist histories with UnaryHistory, ProbeBundle, and InBundle; classifier selected RegSeqRat tail-classifier row; stability displayed unary-context composition through hsame, Cont, Pkg, and RealLedgerPolicy rows; ledger selected finite observation, two stagewise transports, their composite transport, endpoint packages,

contextual packages, appended-tail exclusions, common-shape envelope, cancellation envelope, and selected-tail exactness; core theorem Definition 38.613; exactness the composite and stagewise selected readbacks expose the same finite RegSeqRat tail-classifier row; standard bridge none; status ProofTarget. Fit: traditional target transported contextual endpoint readback for RealUp; BEDC source RealUp stream hsame transport plus RatUp contextual endpoint readback; carrier rational-observation streams; classifiers RealStreamClassifier and selected RatHistoryClassifier; stability pointwise hsame transport, Cont context closure, and endpoint readback; ledger selected index, pointwise transport rows, contextual continuation outputs, one-headed and zero-headed tests; core theorem Definition 38.599; exactness the six-row endpoint package; standard bridge transported RegSeqRat selected contextual observation readback; status ProofTarget.

Fit: traditional target transported contextual RealUp selected-tail determinacy; BEDC source RealUp streams, RatUp point classifiers, Cont, and FKernel history sameness; carrier rational-observation streams; classifier RealStreamClassifier with selected contextual endpoint displays; stability pointwise representative transport and context closure; ledger selected index, two transport rows, context continuations, and four e-one displays; core theorem Definition 38.601; exactness canonical e-one tails under transported contexts; standard bridge RegSeqRat and dyadic selected endpoint readback; status ProofTarget.

Fit: traditional target finite-prefix transported selected endpoint-shape readback package for RealUp; BEDC source RatUp plus RealUp stream prefixes; carrier rational-observation streams; classifiers RealStreamPrefixClassifier and RatHistoryClassifier; stability prefix truncation, prefix hsame transport, endpoint projection, positive-denominator hsame transport, and zero-extension exclusion; ledger selected observation index, prefix surplus index, two transport rows, two e-one seals, and two zero-extension tests; core theorem Definition 38.603; exactness the displayed classifier, tail, positive-denominator, unary, nonempty, and zero-extension package; standard bridge finite-prefix selected endpoint readback for transported RealUp rational observations; status ProofTarget.

Theorem 38.617 (Real selected transport fit certificate)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y$ $\mathbb{N} \to \mathsf{Hist}$*, indices* m, n*, and histories* $a, a', b, b', z_X, z_Y : \mathsf{Hist}$*, assume the pointwise transport rows and the two source classifier rows*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y), \quad \mathsf{RealStreamPrefixClassifier}(x, y, m{+}n).$$

Assume also the selected transported context rows

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

the selected continuation rows

$$\mathsf{Cont}(p_X(n), x'(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y'(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y($$

and the selected e-one displays

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a$$

Then the selected-transport fit carries the displayed package

$$\Big(\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n)) \wedge \mathsf{PositiveUnaryDenominator}(o_X(n)) \wedge \mathsf{PositiveUnaryDenominator}(o_Y(n)) \wedge$$
$$\mathsf{UnaryHistory}(o_X(n)) \wedge \mathsf{UnaryHistory}(o_Y(n)) \wedge (\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False}) \wedge$$
$$(\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False}) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a$$
$$\wedge \Big(\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(a') \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{UnaryHistory}(b') \wedge$$
$$\mathsf{hsame}(a, a') \wedge \mathsf{hsame}(b, b') \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(a', b')\Big)$$
$$\wedge \Big(\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b) \wedge$$
$$\mathsf{PositiveUnaryDenominator}(x'(n)) \wedge \mathsf{PositiveUnaryDenominator}(y'(n)) \wedge \mathsf{UnaryHistory}(x'(n)) \wedge \mathsf{UnaryHistory}(y'(n)) \wedge$$
$$(\mathsf{hsame}(x'(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{e}) \to \mathsf{False}) \wedge$$
$$(\mathsf{hsame}(x'(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{E0}(z_Y)) \to \mathsf{False})\Big).$$

Proof. We build the three displayed conjuncts separately and then conjoin them.

For the first conjunct, apply Definition 38.599 to the two pointwise transport rows, the stream classifier row, the displayed context rows, the four continuation rows, and the endpoint displays $\mathsf{hsame}(o_X(n), \mathsf{E1}(a))$ and $\mathsf{hsame}(o_Y(n), \mathsf{E1}(b))$. Its six enumerated rows project to the classifier row, the two positive-denominator rows, the two endpoint-unary rows, the two empty exclusions, the two zero-headed exclusions using z_X and z_Y, and the tail rows $\mathsf{UnaryHistory}(a)$, $\mathsf{UnaryHistory}(b)$, and $\mathsf{hsame}(a, b)$.

For the second conjunct, apply Definition 38.601 to the same transport, classifier, context, and continuation rows, now using all four displayed e-one endpoints. The eight displayed rows of that theorem project directly to the four unary tail rows and the four hsame tail rows.

For the third conjunct, apply Definition 38.603 to the prefix classifier row, the two pointwise transport rows, and the selected endpoint displays $\mathsf{hsame}(x'(n), \mathsf{E1}(a))$ and $\mathsf{hsame}(y'(n), \mathsf{E1}(b))$. Its displayed readback package projects to the e-one classifier, tail, positive-denominator, endpoint-unary, empty-exclusion, and zero-headed exclusion rows for $x'(n)$ and $y'(n)$.

The three row packages just obtained are exactly the three displayed conjuncts, and their conjunction is the stated selected-transport fit certificate. □

Lean4 ✓ `BEDC.Derived.RealUp.RealSelectedTransportFit certificate`

Theorem 38.618 (Real selected transport fit appended-tail certificate)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, indices* m, n*, and histories* $a, a', b, b', d_X, d_Y, e_X, e_Y, u$ Hist*, assume the pointwise transport rows and the two source classifier rows*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y), \quad \mathsf{RealStreamPrefixClassifier}(x, y, m{+}n).$$

Assume also the selected transported context rows

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

the selected continuation rows

$$\mathsf{Cont}(p_X(n), x'(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y'(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y($$

and the selected e-one displays

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a)$$

Then the three displayed conjuncts of Definition 38.617 hold, and the same selected-transport fit carries the appended e-zero-tail exclusions

$$\Big(\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n)) \wedge \mathsf{PositiveUnaryDenominator}(o_X(n)) \wedge \mathsf{PositiveUnaryDenominator}(o_Y(n)) \wedge$$
$$\mathsf{UnaryHistory}(o_X(n)) \wedge \mathsf{UnaryHistory}(o_Y(n)) \wedge (\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False}) \wedge$$
$$(\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False}) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a$$
$$\wedge \Big(\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(a') \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{UnaryHistory}(b') \wedge$$
$$\mathsf{hsame}(a, a') \wedge \mathsf{hsame}(b, b') \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(a', b')\Big)$$
$$\wedge \Big(\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b) \wedge$$
$$\mathsf{PositiveUnaryDenominator}(x'(n)) \wedge \mathsf{PositiveUnaryDenominator}(y'(n)) \wedge \mathsf{UnaryHistory}(x'(n)) \wedge \mathsf{UnaryHistory}(y'(n)) \wedge$$
$$(\mathsf{hsame}(x'(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{e}) \to \mathsf{False}) \wedge$$
$$(\mathsf{hsame}(x'(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{E0}(z_Y)) \to \mathsf{False})\Big)$$
$$\wedge (\mathsf{hsame}(o_X(n), d_X \cdot \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), d_Y \cdot \mathsf{E0}(z_Y)) \to \mathsf{False}) \wedge$$
$$(\mathsf{hsame}(x'(n), e_X \cdot \mathsf{E0}(w_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), e_Y \cdot \mathsf{E0}(w_Y)) \to \mathsf{False}).$$

Proof. First invoke Definition 38.617 with the displayed transport, classifier, context, continuation, and e-one rows. This gives the contextual endpoint package, contextual e-one determinacy package, and finite-prefix selected endpoint-shape package used below.

Next invoke Definition 38.606 on the same pointwise transport rows, source stream classifier, selected context rows, continuation rows, and contextual displays $\mathsf{hsame}(o_X(n), \mathsf{E1}(a))$ and $\mathsf{hsame}(o_Y(n), \mathsf{E1}(b))$. Its appended-tail clause gives the two contextual output exclusions for $o_X(n)$ and $o_Y(n)$ with prefixes d_X and d_Y.

It remains to exclude appended e-zero tails for the selected endpoints. Project $\mathsf{PositiveUnaryDenominator}(x'(n))$ and $\mathsf{PositiveUnaryDenominator}(y'(n))$ from the finite-prefix conjunct already supplied by Definition 38.617.

For $x'(n)$, suppose $\mathsf{hsame}(x'(n), e_X \cdot \mathsf{E0}(w_X))$. Transport the positive-denominator row across this history sameness by Definition 37.6; the resulting positive denominator for $e_X \cdot \mathsf{E0}(w_X)$ contradicts Definition 37.15.

For $y'(n)$, the same argument applied to $\mathsf{hsame}(y'(n), e_Y \cdot \mathsf{E0}(w_Y))$ transports the positive-denominator row to $e_Y \cdot \mathsf{E0}(w_Y)$ and contradicts the appended e-zero-tail obstruction. Combining the three fit conjuncts with these four exclusions gives the displayed certificate. □

Fit: traditional target selected RealUp transport certificate with appended-tail endpoint exclusion; BEDC source RealUp streams, RatUp contextual readback, and finite-prefix selected endpoint shape; carrier rational-observation streams; classifiers RealStreamClassifier, RealStreamPrefixClassifier, and selected RatHistoryClassifier; stability pointwise hsame transport, contextual continuation, e-one display transport, positive-denominator hsame transport, and appended e-zero-tail obstruction; ledger selected index, transport rows, contextual output tails, selected endpoint tails, and denominator tests; core theorem Definition 38.618; exactness original fit package plus four appended-tail exclusions; standard bridge RealUp dyadic/RegSeqRat selected endpoint normalization row; status ProofTarget.

Lean4 ✓ `BEDC.Derived.RealUp.RealSelectedTransportFit appended tail certificate`

Theorem 38.619 (Real selected transport fit from stream classifier)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, indices* m, n*, and histories* $a, a', b, b', z_X, z_Y : \mathsf{Hist}$*, assume the pointwise transport rows and the source stream classifier row*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

Assume also the selected transported context rows

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

the selected continuation rows

$$\mathsf{Cont}(p_X(n), x'(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y'(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y($$

and the selected e-one displays

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a$$

Then the selected-transport fit carries all four certificate packages:

1. *the contextual endpoint package of Definition 38.599 for $o_X(n)$ and $o_Y(n)$ with tails a and b;*
2. *the contextual displayed e-one classifier package of Definition 38.600 for the displayed endpoints $\mathsf{E1}(a)$ and $\mathsf{E1}(b)$;*
3. *the contextual e-one tail determinacy package of Definition 38.601 for the four tails a, a', b, b';*
4. *the finite-prefix selected full-shape readback package of Definition 38.603 for $x'(n)$ and $y'(n)$ with tails a and b.*

Proof. Apply Definition 38.106 to $\mathsf{RealStreamClassifier}(x, y)$ at the finite length $m + n$. This gives the derived row $\mathsf{RealStreamPrefixClassifier}(x, y, m + n)$ needed by the finite-prefix package.

Apply Definition 38.599 to the two pointwise transport rows, the source stream classifier, the selected context rows, the four continuation rows, and the two contextual displays $\mathsf{hsame}(o_X(n), \mathsf{E1}(a))$ and $\mathsf{hsame}(o_Y(n), \mathsf{E1}(b))$. This gives the contextual endpoint package.

Apply Definition 38.600 to the same transported contextual data and the same two contextual displays. This supplies the displayed e-one classifier row together with the endpoint readback rows carried by that package.

Apply Definition 38.601 to the same transported contextual data and all four contextual e-one displays. This yields the tail-determinacy package for a, a', b, b'.

Finally apply Definition 38.603 to the derived prefix classifier row, the two pointwise transport rows, and the selected endpoint displays $\mathsf{hsame}(x'(n), \mathsf{E1}(a))$ and $\mathsf{hsame}(y'(n), \mathsf{E1}(b))$. Conjoining the finite-prefix readback package with the three contextual packages gives the four-package selected-transport fit. □

Lean4 ✓ `BEDC.Derived.RealUp.RealSelectedTransport fit from stream classifier`

Fit: traditional target transported contextual RealUp selected-transport readback without an external prefix classifier; BEDC source RealUp stream classifier prefix closure plus transported contextual endpoint readback; carrier rational-observation streams; classifier RealStreamClassifier with the derived RealStreamPrefixClassifier row; stability obligations pointwise hsame transport, contextual continuation closure, e-one readback, and finite-prefix transport; ledger selected index, prefix surplus index, two transport rows, contextual continuation outputs, and six e-one displays; core theorem Definition 38.619; exactness predicate the four-package selected endpoint and contextual readback certificate; standard bridge selected RegSeqRat and dyadic contextual endpoint readback; status ProofTarget.

Theorem 38.620 (Real selected transport synchronized e-one endpoints)**.** *For rational-observation streams $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$, indices m, n, and histories $a, a', b, b', z_X, z_Y : \mathsf{Hist}$, assume the pointwise transport rows and the source stream classifier row*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

Assume also the selected transported context rows

$$\mathsf{UnaryHistory}(p_X(n)),\quad \mathsf{UnaryHistory}(t_X(n)),\quad \mathsf{hsame}(p_X(n), p_Y(n)),\quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

the selected continuation rows

$$\mathsf{Cont}(p_X(n), x'(n), m_X(n)),\quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)),\quad \mathsf{Cont}(p_Y(n), y'(n), m_Y(n)),\quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y($$

and the selected e-one displays

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)),\quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')),\quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)),\quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')),\quad \mathsf{hsame}(x'(n), \mathsf{E1}(a$$

Then the selected transported endpoints satisfy the synchronized classifier and tail rows

$$\begin{aligned}&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(b'))\wedge\\ &\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(a') \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{UnaryHistory}(b')\wedge\\ &\mathsf{hsame}(a, a') \wedge \mathsf{hsame}(b, b') \wedge \mathsf{hsame}(a, b)\wedge\\ &\mathsf{hsame}(a', b') \wedge \mathsf{hsame}(a, b') \wedge \mathsf{hsame}(a', b).\end{aligned}$$

Proof. First apply Definition 38.599 to the displayed pointwise transport rows, the source stream classifier, the selected context rows, the continuation rows, and the contextual displays for a and b.

This supplies the contextual endpoint package and, in particular, the tail row $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$.

Next apply Definition 38.601 to the same transported contextual data and all four contextual e-one displays. This supplies $\mathsf{UnaryHistory}(a')$, $\mathsf{UnaryHistory}(b')$, $\mathsf{hsame}(a, a')$, $\mathsf{hsame}(b, b')$, and $\mathsf{hsame}(a', b')$, while retaining the a, b tail rows already identified above.

The off-diagonal tail rows are constructive consequences of these rows. Compose $\mathsf{hsame}(a, b)$ with $\mathsf{hsame}(b, b')$ to obtain $\mathsf{hsame}(a, b')$; compose the symmetry of $\mathsf{hsame}(a, a')$ with $\mathsf{hsame}(a, b)$ to obtain $\mathsf{hsame}(a', b)$.

Apply Definition 38.106 to $\mathsf{RealStreamClassifier}(x, y)$ at the finite length $m + n$. This gives the derived row $\mathsf{RealStreamPrefixClassifier}(x, y, m + n)$ used by the selected finite-prefix package.

Apply Definition 38.603 to the derived prefix classifier row, the two pointwise transport rows, and the selected prefix endpoint displays $\mathsf{hsame}(x'(n), \mathsf{E1}(a))$ and $\mathsf{hsame}(y'(n), \mathsf{E1}(b))$. The returned finite-prefix readback package includes $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$.

Finally use the reverse direction of Definition 37.49 on $\mathsf{UnaryHistory}(a')$, $\mathsf{UnaryHistory}(b')$, and $\mathsf{hsame}(a', b')$. It gives $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(b'))$, which combines with the first displayed classifier, the four unary tail rows, and the six pairwise synchronized tail rows. □

Lean4 ✓ `BEDC.Derived.RealUp.RealSelectedTransport synchronized e1 endpoints`

Fit: traditional target synchronized selected RealUp observation readback; BEDC source RatUp, StreamNameUp-shaped RealUp streams, Cont, and FKernel hsame; carrier rational-observation streams; classifiers RealStreamClassifier plus RatHistoryClassifier on displayed e-one endpoints; stability pointwise transport, stream-classifier finite-prefix closure, contextual continuation, and e-one tail inversion/congruence; ledger selected index, prefix surplus, four endpoint histories, two contextual outputs, and prefix endpoint rows; core theorem Definition 38.620; exactness the two displayed RatHistoryClassifier rows and all six pairwise synchronized tail rows; standard bridge selected RegSeqRat dyadic observation readback; status ProofTarget.

Theorem 38.621 (Real selected transport synchronized fit package)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, indices* m, n*, and histories* $a, a', b, b', z_X, z_Y : \mathsf{Hist}$*, assume the pointwise transport rows and the source stream classifier row*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

Assume also the selected transported context rows

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

the selected continuation rows

$$\mathsf{Cont}(p_X(n), x'(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y'(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y($$

and the selected e-one displays

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a)$$

Then the selected transport carries the following packages simultaneously.

1. *The contextual endpoint package of Definition 38.599:*

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n)),\\
&\mathsf{PositiveUnaryDenominator}(o_X(n)) \wedge \mathsf{PositiveUnaryDenominator}(o_Y(n)),\\
&\mathsf{UnaryHistory}(o_X(n)) \wedge \mathsf{UnaryHistory}(o_Y(n)),\\
&(\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False}),\\
&(\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False}),\\
&\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).
\end{aligned}$$

2. *The contextual e-one tail determinacy package of Definition 38.601 together with the off-diagonal rows of Definition 38.602:*

$$\begin{aligned}
&\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(a') \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{UnaryHistory}(b') \wedge\\
&\mathsf{hsame}(a, a') \wedge \mathsf{hsame}(b, b') \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(a', b') \wedge \mathsf{hsame}(a, b') \wedge \mathsf{hsame}(a', b).
\end{aligned}$$

3. *The finite-prefix selected full-shape readback package of Definition 38.603:*

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b) \wedge\\
&\mathsf{PositiveUnaryDenominator}(x'(n)) \wedge \mathsf{PositiveUnaryDenominator}(y'(n)) \wedge \mathsf{UnaryHistory}(x'(n)) \wedge \mathsf{UnaryHistory}(y'(n\\
&(\mathsf{hsame}(x'(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{e}) \to \mathsf{False}) \wedge\\
&(\mathsf{hsame}(x'(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{E0}(z_Y)) \to \mathsf{False}).
\end{aligned}$$

4. *The synchronized displayed rows*

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(b')) \wedge\\
&\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(a') \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{UnaryHistory}(b') \wedge\\
&\mathsf{hsame}(a, a') \wedge \mathsf{hsame}(b, b') \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(a', b') \wedge \mathsf{hsame}(a, b') \wedge \mathsf{hsame}(a', b).
\end{aligned}$$

Proof. First apply Definition 38.599 to the two pointwise transport rows, the source stream classifier, the transported context rows, the continuation rows, and the displayed endpoints for a and b. This gives the contextual endpoint package.

Next apply Definition 38.601 to the same transported contextual data and all four displayed e-one endpoints. This gives the contextual e-one tail determinacy package, including the primed tail rows used below.

The two off-diagonal rows are the same constructive consequences: compose $\mathsf{hsame}(a, b)$ with $\mathsf{hsame}(b, b')$ for $\mathsf{hsame}(a, b')$, and compose the symmetry of $\mathsf{hsame}(a, a')$ with $\mathsf{hsame}(a, b)$ for $\mathsf{hsame}(a', b)$.

Apply Definition 38.106 to $\mathsf{RealStreamClassifier}(x, y)$ at the finite length $m + n$. This gives the derived row $\mathsf{RealStreamPrefixClassifier}(x, y, m + n)$ used by the selected finite-prefix package.

Apply Definition 38.603 to the derived prefix classifier row, the two pointwise transport rows, and the selected endpoint displays $\mathsf{hsame}(x'(n), \mathsf{E1}(a))$ and $\mathsf{hsame}(y'(n), \mathsf{E1}(b))$. This gives the finite-prefix selected full-shape readback package and the row $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$.

Finally use the reverse direction of Definition 37.49 with $\mathsf{UnaryHistory}(a')$, $\mathsf{UnaryHistory}(b')$, and $\mathsf{hsame}(a', b')$. It gives $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(b'))$, and the remaining synchronized rows are exactly the six pairwise tail rows supplied by the determinacy package and its off-diagonal consequences. □

Theorem 38.622 (Real selected transport synchronized appended-tail package from stream classifier)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, indices* m, n*, and histories* $a, a', b, b', d_X, d_Y, e_X, e_Y, w_X, w_Y, z_X, z_Y : \mathsf{Hist}$*, assume the pointwise transport rows and the source stream classifier row*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

Assume also the selected transported context rows

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

the selected continuation rows

$$\mathsf{Cont}(p_X(n), x'(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y'(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y($$

and the selected e-one displays

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a$$

Then the four synchronized packages of Definition 38.865 hold together with the appended e-zero-tail exclusions

$$(\mathsf{hsame}(o_X(n), d_X \cdot \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), d_Y \cdot \mathsf{E0}(z_Y)) \to \mathsf{False}) \wedge$$
$$(\mathsf{hsame}(x'(n), e_X \cdot \mathsf{E0}(w_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), e_Y \cdot \mathsf{E0}(w_Y)) \to \mathsf{False}).$$

Proof. Apply Definition 38.106 to $\mathsf{RealStreamClassifier}(x, y)$ at the finite length $m + n$. This produces the derived row $\mathsf{RealStreamPrefixClassifier}(x, y, m + n)$.

Invoke Definition 38.865 with the source stream classifier row and all displayed transport, context, continuation, and e-one rows. This gives the four synchronized packages.

Invoke Definition 38.618 with the derived prefix row and the same displayed hypotheses. Its appended-tail conjunct gives exactly the four displayed exclusions.

Conjoin these outputs. □

Fit: traditional target RealUp selected-transport synchronized appended-tail package from stream classifier; BEDC source RealUp stream classifier plus RatUp denominator obstruction; carrier rational-observation streams; classifier $\mathsf{RealStreamClassifier}$; stability pointwise hsame, Cont,

prefix closure, positive-denominator transport; ledger selected index and appended-tail probes; exactness synchronized package plus four exclusions; downstream RegSeqRat/dyadic endpoint normalization; status ProofTarget.

Fit: traditional target synchronized transported RealUp selected-observation certificate; BEDC source RealUp stream transport plus RatUp and FKernel Cont; carrier rational-observation streams; classifier RealStreamClassifier plus displayed RatHistoryClassifier rows; stability pointwise hsame, context closure, stream-classifier finite-prefix closure, e-one inversion; ledger selected index, prefix surplus, four tail histories, contexts; core theorem Definition 38.621; exactness package plus synchronized classifiers and six pairwise synchronized tail rows; standard bridge selected RegSeqRat dyadic observation readback; status ProofTarget.

Theorem 38.623 (Real selected transport constant real classifier package)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, indices* m, n*, and histories* $a, a', b, b', z_X, z_Y : \mathsf{Hist}$*, assume the pointwise transport rows and the source stream classifier row*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

Assume also the selected transported context rows

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

the selected continuation rows

$$\mathsf{Cont}(p_X(n), x'(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y'(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y($$

and the selected e-one displays

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a$$

Then the selected transport carries the constant-real displayed classifier rows and the synchronized tail rows

$$\begin{aligned}&\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(\mathsf{E1}(a)), \mathsf{E1}(\mathsf{E1}(b)))\wedge\\ &\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(\mathsf{E1}(a')), \mathsf{E1}(\mathsf{E1}(b')))\wedge\\ &\mathsf{hsame}(a, a') \wedge \mathsf{hsame}(b, b') \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(a', b') \wedge \mathsf{hsame}(a, b') \wedge \mathsf{hsame}(a', b).\end{aligned}$$

Proof. Invoke Definition 38.865 with the two pointwise transport rows, the source stream classifier row, and the displayed context, continuation, and e-one hypotheses. The synchronized displayed package gives $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$, $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(b'))$, and the six pairwise tail rows.

Apply the reverse direction of Definition 38.11 with $(d, e) = (\mathsf{E1}(a), \mathsf{E1}(b))$. This turns the first rational classifier row into $\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(\mathsf{E1}(a)), \mathsf{E1}(\mathsf{E1}(b)))$.

Apply the same reverse direction with $(d, e) = (\mathsf{E1}(a'), \mathsf{E1}(b'))$. This turns the second rational classifier row into $\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(\mathsf{E1}(a')), \mathsf{E1}(\mathsf{E1}(b')))$. Conjoin these two constant-real rows with the six synchronized tail rows. □

Lean4 ✓ `BEDC.Derived.RealUp.RealSelectedTransport constant real classifier package`

Fit: traditional target RealUp selected observation sealing; BEDC source RealStreamClassifier plus RatUp e-one endpoints; carrier rational-observation streams; classifier RealStreamClassifier with selected RatHistoryClassifier endpoint rows; stability pointwise hsame transport, contextual continuation closure, synchronized tail determinacy, and constant-real e-one sealing; ledger selected

index, prefix surplus index, two transport rows, context continuations, four selected context tails, and two displayed stream tails; core theorem Definition 38.623; exactness predicate the two selected constant-real classifier rows together with the six synchronized tail rows; standard bridge dyadic embedding and RegSeqRat selected endpoint sealing; status ProofTarget.

Theorem 38.624 (Real selected transport fit carrier obligation)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, indices* m, n*, and histories* $a, a', b, b', d_X, d_Y, e_X, e_Y, w_X, w_Y, z$ Hist*, assume the pointwise transport rows, source stream classifier row, selected context rows, continuation rows, and selected e-one displays of Definition 38.619. Then the selected transport supplies the RealUp carrier boundary*

$$\begin{aligned}
&\mathsf{PositiveUnaryDenominator}(o_X(n)) \wedge \mathsf{PositiveUnaryDenominator}(o_Y(n)) \wedge \mathsf{PositiveUnaryDenominator}(x'(n)) \wedge \mathsf{Positiv}\\
&\mathsf{UnaryHistory}(o_X(n)) \wedge \mathsf{UnaryHistory}(o_Y(n)) \wedge \mathsf{UnaryHistory}(x'(n)) \wedge \mathsf{UnaryHistory}(y'(n)) \wedge\\
&\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(a') \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{UnaryHistory}(b') \wedge\\
&(\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(x'(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{e}) \to \mathsf{False}) \wedge\\
&(\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False}) \wedge (\mathsf{hsame}(x'(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'\\
&(\mathsf{hsame}(o_X(n), d_X \cdot \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), d_Y \cdot \mathsf{E0}(z_Y)) \to \mathsf{False}) \wedge\\
&(\mathsf{hsame}(x'(n), e_X \cdot \mathsf{E0}(w_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), e_Y \cdot \mathsf{E0}(w_Y)) \to \mathsf{False}).
\end{aligned}$$

Proof. Apply Definition 38.106 to the source $\mathsf{RealStreamClassifier}(x, y)$ row at length $m + n$. This supplies the prefix classifier row required by Definition 38.617 and Definition 38.618.

Invoke Definition 38.617 with the derived prefix row and the displayed selected-transport hypotheses. Its contextual endpoint component gives the carrier rows for $o_X(n)$ and $o_Y(n)$, and its finite-prefix component gives the carrier rows for $x'(n)$ and $y'(n)$.

The tail rows for a and b are projected from both the contextual endpoint component and the finite-prefix component. The tail rows for a' and b' are projected from the contextual e-one tail determinacy component.

Finally invoke Definition 38.618. Its appended-tail component gives the four displayed e-zero-tail exclusions. These projections are exactly the displayed carrier boundary. □

Theorem 38.625 (Real selected transport fit classifier obligation)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, indices* m, n*, and histories* $a, a', b, b', z_X, z_Y : \mathsf{Hist}$*, assume the pointwise transport rows, source stream classifier row, selected context rows, continuation rows, and selected e-one displays of Definition 38.619. Then the selected transport supplies the RealUp classifier boundary*

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n)) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(b')) \wedge\\
&\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(\mathsf{E1}(a)), \mathsf{E1}(\mathsf{E1}(b))) \wedge\\
&\mathsf{RealConstantHistoryClassifier}(\mathsf{E1}(\mathsf{E1}(a')), \mathsf{E1}(\mathsf{E1}(b'))).
\end{aligned}$$

Proof. Apply Definition 38.619 to the displayed selected-transport hypotheses. The contextual endpoint package projects to $\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n))$, and the finite-prefix package projects to $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$.

Apply Definition 38.620 to the same selected-transport hypotheses. This supplies $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}($ together with the synchronized tail rows used by the constant-real package.

Apply Definition 38.623 to the same hypotheses. It supplies the two displayed RealConstantHistoryClassifier rows. Conjoining the three rational classifier rows with the two constant-real classifier rows gives the stated classifier boundary. □

Theorem 38.626 (Real selected transport fit ledger obligation)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, indices* m, n*, and histories* $a, a', b, b', d_X, d_Y, e_X, e_Y, w_X, w_Y, z$ Hist*, assume the pointwise transport rows, source stream classifier row, selected context rows, continuation rows, and selected e-one displays of Definition 38.619. Then the ledger consumed by the carrier and classifier obligations is exactly the selected index* n*, the prefix surplus* m*, the pointwise transport rows* $\forall i,\ \mathsf{hsame}(x(i), x'(i))$ *and* $\forall i,\ \mathsf{hsame}(y(i), y'(i))$*, the contextual continuations*

$$\mathsf{Cont}(p_X(n), x'(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)),$$
$$\mathsf{Cont}(p_Y(n), y'(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y(n)),$$

the displayed e-one tails

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')),$$
$$\mathsf{hsame}(x'(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(y'(n), \mathsf{E1}(b)),$$

and the appended-tail probes $d_X, d_Y, e_X, e_Y, w_X, w_Y, z_X, z_Y$*.*

Proof. Apply Definition 38.624 and Definition 38.625 to the same selected-transport data. The former consumes the selected index, the prefix surplus, the transport rows, the contextual continuations, the six e-one displays, and the appended-tail probes; the latter consumes the same selected index, transport, context, continuation, and displayed-tail rows without the extra appended-tail probes.

The four-package theorem Definition 38.619 accounts for the contextual endpoint package, displayed e-one classifier package, tail determinacy package, and finite-prefix readback package. Its certificate strengthening Definition 38.618 accounts for the appended-tail tests.

Projecting these packages lists no further inputs: the rows consumed are exactly the selected index, prefix surplus, pointwise transport rows, contextual continuations, displayed e-one tails, and appended-tail probes named in the statement. □

Theorem 38.627 (Real selected transport fit stability and seal obligation)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, indices* m, n*, and histories* $a, a', b, b', d_X, d_Y, e_X, e_Y, u$ Hist*, assume the pointwise transport rows, source stream classifier row, selected context rows, continuation rows, and selected e-one displays of Definition 38.619. Then the carrier, classifier, and ledger package of Definition 38.624, Definition 38.625, and Definition 38.626 is stable under the pointwise* hsame *transports, consumes only the selected index* n*, prefix surplus* m*, contextual* Cont *rows, displayed e-one tails, and appended-tail probes already listed there, and is accepted by the* $\mathsf{Real}^{\uparrow}$ *seal through Definition 38.285.*

Proof. First collect the selected-transport package. Apply Definition 38.624, Definition 38.625, and Definition 38.626 to the same selected-transport hypotheses. These three faces supply the carrier, classifier, and finite ledger rows while naming exactly the selected index, prefix surplus, context rows, displayed e-one tails, and appended-tail probes.

Next read the stability and ledger face through the RealUp obligation boundary. Apply Definition 38.283; the pointwise hsame transports and selected finite ledger rows are precisely the stability and ledger entries required by Definition 38.285.

Finally attach the seal. Apply Definition 38.284; it accepts the same package through the $\mathsf{Real}^{\uparrow}$ seal and records that the $\mathsf{RegSeqRat}$ consumption reads no source outside the displayed carrier, classifier, stability, and ledger rows. Thus the theorem is the stability and seal face of the selected-transport obligation package, not a separate source presentation. □

Theorem 38.628 (Real selected transport fit scoped boundary package)**.** *For the selected-transport data of Definition 38.619, the carrier obligation Definition 38.624, classifier obligation Definition 38.625, and ledger obligation Definition 38.626 together form the scoped RealUp selected-transport fit package. Its source side is made of RealUp streams, RatUp rational observations, StreamNameUp selected contexts,* Cont *rows, pointwise* hsame *transport, selected e-one displays, and appended-tail probes. Its carrier choices are the rational-observation streams and selected endpoints. Its classifier choices are the* RatHistoryClassifier *row together with the* RealConstantHistoryClassifier *rows.*

The package binds the stability obligations to pointwise hsame *transport, contextual continuation closure, selected e-one tail determinacy, and positive-denominator transport. Its ledger is exactly the selected index, prefix surplus, transport rows, continuation rows, e-one displays, and appended-tail probes enumerated in Definition 38.626. Its exactness boundary is precisely the displayed carrier and classifier boundary supplied by Definition 38.624 and Definition 38.625. The standard bridge clause is the transported RegSeqRat selected endpoint normalization already carried by the same selected-transport certificates.*

Proof. Start from the four-package selected-transport certificate Definition 38.619. It fixes the RealUp stream source, RatUp observation stream, StreamNameUp selected context, pointwise hsame rows, contextual Cont rows, selected e-one displays, and finite-prefix readback surface used by the scoped package.

Apply Definition 38.617 and Definition 38.618. The first certificate supplies the displayed carrier and classifier readback data, while the second supplies the appended-tail probes that keep the endpoint exclusions inside the same selected ledger.

Apply Definition 38.620 and Definition 38.623. These identify the synchronized selected e-one endpoints and the constant-real classifier rows that turn the rational endpoint package into the stated RealUp and Completion boundary.

Now project the three obligation theorems. The carrier obligation gives the rational-observation streams, selected endpoints, unary and positive denominator rows, and endpoint exclusions. The classifier obligation gives the RatHistoryClassifier and RealConstantHistoryClassifier rows. The ledger obligation states that the selected index, prefix surplus, transport rows, continuation rows, e-one displays, and appended-tail probes are exactly the consumed resources.

No object outside Cont, hsame, RatUp, StreamNameUp, and RealUp is used in these projections. Therefore the three obligations bind the selected-transport fit site as a scoped package, with exactness given by the displayed carrier and classifier boundary and with the standard bridge supplied by the transported RegSeqRat selected endpoint normalization. □

Theorem 38.629 (Real selected transport synchronized package from stream classifier)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, indices* m, n*, and histories* $a, a', b, b', z_X, z_Y : \mathsf{Hist}$*, assume the pointwise transport rows and the source stream classifier row*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

Assume also the selected transported context rows

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

the selected continuation rows

$$\mathsf{Cont}(p_X(n), x'(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y'(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y($$

and the selected e-one displays

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a$$

Then the selected transport carries the following packages simultaneously.

1. *The contextual endpoint package of Definition 38.599:*

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n)),\\
&\mathsf{PositiveUnaryDenominator}(o_X(n)) \wedge \mathsf{PositiveUnaryDenominator}(o_Y(n)),\\
&\mathsf{UnaryHistory}(o_X(n)) \wedge \mathsf{UnaryHistory}(o_Y(n)),\\
&(\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False}),\\
&(\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False}),\\
&\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).
\end{aligned}$$

2. *The contextual e-one tail determinacy package of Definition 38.601:*

$$\begin{aligned}
&\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(a') \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{UnaryHistory}(b') \wedge\\
&\mathsf{hsame}(a, a') \wedge \mathsf{hsame}(b, b') \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(a', b').
\end{aligned}$$

3. *The finite-prefix selected full-shape readback package of Definition 38.603:*

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b) \wedge\\
&\mathsf{PositiveUnaryDenominator}(x'(n)) \wedge \mathsf{PositiveUnaryDenominator}(y'(n)) \wedge \mathsf{UnaryHistory}(x'(n)) \wedge \mathsf{UnaryHistory}(y'(n\\
&(\mathsf{hsame}(x'(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{e}) \to \mathsf{False}) \wedge\\
&(\mathsf{hsame}(x'(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{E0}(z_Y)) \to \mathsf{False}).
\end{aligned}$$

4. *The synchronized displayed rows*

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(b')) \wedge\\
&\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(a') \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{UnaryHistory}(b') \wedge\\
&\mathsf{hsame}(a, a') \wedge \mathsf{hsame}(b, b') \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(a', b').
\end{aligned}$$

Proof. Apply Definition 38.106 to $\mathsf{RealStreamClassifier}(x, y)$ at the finite length $m + n$. This produces the derived row $\mathsf{RealStreamPrefixClassifier}(x, y, m + n)$.

Apply Definition 38.621 with the derived prefix row, the source stream classifier row, the two pointwise transport rows, and the remaining context, continuation, and displayed e-one hypotheses. The four returned packages are exactly the four packages displayed above. □

Fit: traditional target selected RealUp observation synchronization from a stream classifier; BEDC source RealUp stream classifier plus RatUp, StreamNameUp, and Cont; carrier rational-observation streams; classifier RealStreamClassifier with derived finite-prefix row; stability pointwise hsame transport, contextual continuation, and e-one inversion; ledger selected index, prefix length, transport rows, contexts, and four tails; core theorem Definition 38.865; exactness the four synchronized packages; standard bridge selected RegSeqRat dyadic observation readback; status ProofTarget.

Fit: traditional target synchronized transported RealUp selected-observation certificate; BEDC source RealUp stream transport plus RatUp and FKernel Cont; carrier rational-observation streams; classifier RealStreamClassifier plus displayed RatHistoryClassifier rows; stability pointwise hsame, context closure, stream-classifier finite-prefix closure, e-one inversion; ledger selected index, prefix surplus, four tails, contexts; core theorem Definition 38.621; exactness package plus synchronized classifiers; standard bridge selected RegSeqRat dyadic observation readback; status ProofTarget.

Theorem 38.630 (Real selected transport synchronized fit from stream classifier)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, indices* m, n*, and histories* $a, a', b, b', z_X, z_Y : \mathsf{Hist}$*, assume the pointwise transport rows and the source stream classifier row*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

Assume also the selected transported context rows

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

the selected continuation rows

$$\mathsf{Cont}(p_X(n), x'(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y'(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y($$

and the selected e-one displays

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a$$

Then the selected transport carries the following packages simultaneously.

1. *The contextual endpoint package of Definition 38.599:*

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n)),\\
&\mathsf{PositiveUnaryDenominator}(o_X(n)) \wedge \mathsf{PositiveUnaryDenominator}(o_Y(n)),\\

&\mathsf{hsame}(a, a') \wedge \mathsf{hsame}(b, b') \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(a', b').
\end{aligned}$$

Proof. Apply Definition 38.106 to $\mathsf{RealStreamClassifier}(x, y)$ at the finite length $m + n$. This gives the prefix row $\mathsf{RealStreamPrefixClassifier}(x, y, m + n)$.

Apply Definition 38.621 to the two pointwise transport rows, the source stream classifier row, the derived prefix row, the selected context rows, the selected continuation rows, and the six selected e-one display rows. Its conclusion is exactly the four packages listed above. □

Fit: traditional target stream-classifier-closed synchronized transported RealUp selected-observation certificate; BEDC source Definition 38.106 plus Definition 38.621; carrier rational-observation streams; classifier RealStreamClassifier with the finite-prefix row derived internally; stability pointwise hsame, context closure, e-one inversion, and selected full-shape readback; ledger selected index, prefix surplus, four tails, contexts, and derived prefix row; core theorem Definition 38.866 in future Lean namespace `BEDC.Derived.RealUp`; exactness predicate the four synchronized selected-transport packages; standard bridge RealUp selected RegSeqRat endpoint synchronization; status ProofTarget. Fit: traditional target selected RealUp observation synchronization from a stream classifier; BEDC source RealUp stream classifier plus RatUp, StreamNameUp, and Cont; carrier rational-observation streams; classifier RealStreamClassifier with derived finite-prefix row; stability pointwise hsame transport, contextual continuation, and e-one inversion; ledger selected index, prefix length, transport rows, contexts, and four tails; core theorem Definition 38.865; exactness the four synchronized packages; standard bridge selected RegSeqRat dyadic observation readback; status ProofTarget.

Fit: traditional target synchronized transported RealUp selected-observation certificate; BEDC source RealUp stream transport plus RatUp and FKernel Cont; carrier rational-observation streams; classifier RealStreamClassifier plus displayed RatHistoryClassifier rows; stability pointwise hsame, context closure, stream-classifier finite-prefix closure, e-one inversion; ledger selected index, prefix surplus, four tails, contexts; core theorem Definition 38.621; exactness package plus synchronized classifiers; standard bridge selected RegSeqRat dyadic observation readback; status ProofTarget.

Theorem 38.631 (Real selected transport synchronized e-one classifier clique)**.** *Under the hypotheses of Definition 38.866, the four displayed tails a, a', b, b' form a complete displayed rational-classifier clique:*

$$\begin{aligned}&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(a')) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \\ &\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b')) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(b)) \wedge \\ &\mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(b')) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(b), \mathsf{E1}(b')).\end{aligned}$$

Lean4 ✓ `BEDC.Derived.RealUp.RealSelectedTransport common rational classifier class`

Proof. Apply Definition 38.866 to the displayed hypotheses and project the synchronized displayed rows. This gives unary rows for a, a', b, b' and the four tail rows $\mathsf{hsame}(a, a')$, $\mathsf{hsame}(b, b')$, $\mathsf{hsame}(a, b)$, and $\mathsf{hsame}(a', b')$.

The two remaining tail rows come from Definition 3.8. Compose $\mathsf{hsame}(a, b)$ with $\mathsf{hsame}(b, b')$ to obtain $\mathsf{hsame}(a, b')$. Compose the symmetry of $\mathsf{hsame}(a, a')$ with $\mathsf{hsame}(a, b)$ to obtain $\mathsf{hsame}(a', b)$.

For each displayed pair among (a, a'), (a, b), (a, b'), (a', b), (a', b'), and (b, b'), use the corresponding two unary rows and tail hsame row. The reverse direction of Definition 37.49 lifts that data to the six displayed RatHistoryClassifier rows, which are exactly the complete clique. □

Lean4 ✓ `BEDC.Derived.RealUp.RealSelectedTransport synchronized e1 classifier clique`

Fit: traditional target synchronized RegSeqRat selected-observation classifier completion; BEDC source RealUp stream classifier plus RatUp e-one classifier exactness plus FKernel hsame; carrier rational-observation streams with selected displayed e-one tails; classifier RealStreamClassifier feeding RatHistoryClassifier through E1 displays; stability pointwise hsame and tail-level symmetry and transitivity; ledger selected index, contexts, transported endpoints, unary tails, and six pairwise classifier rows; core theorem Definition 38.862 in future Lean namespace `BEDC.Derived.RealUp`; exactness predicate complete displayed e-one rational-classifier clique; downstream use RealUp dyadic endpoint normalization; status ProofTarget.

Theorem 38.632 (Real selected transport synchronized appended-tail classifier clique)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, indices* m, n*, and histories* $a, a', b, b', d_X, d_Y, e_X, e_Y, w_X, w_Y, z_X, z_Y : \mathsf{Hist}$*, assume the pointwise transport rows and the source stream classifier row*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

Assume also the selected transported context rows

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

the selected continuation rows

$$\mathsf{Cont}(p_X(n), x'(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y'(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y($$

and the selected e-one displays

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a$$

Then the selected transport supplies the displayed classifier clique together with the appended-tail exclusions:

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(a')) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \\
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b')) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(b)) \wedge \\
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(b')) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(b), \mathsf{E1}(b')) \wedge \\
&(\mathsf{hsame}(o_X(n), d_X \cdot \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), d_Y \cdot \mathsf{E0}(z_Y)) \to \mathsf{False}) \wedge \\
&(\mathsf{hsame}(x'(n), e_X \cdot \mathsf{E0}(w_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), e_Y \cdot \mathsf{E0}(w_Y)) \to \mathsf{False}).
\end{aligned}$$

Proof. Apply Definition 38.862 to the selected-transport hypotheses. This yields the six displayed RatHistoryClassifier rows as a single clique package.

Apply Definition 38.622 to the same selected-transport hypotheses. Project its appended-tail component to obtain the four exclusions for $o_X(n)$, $o_Y(n)$, $x'(n)$, and $y'(n)$.

Conjoin the six classifier projections with the four appended-tail projections. The resulting ten conjuncts are exactly the displayed conclusion. □

Fit: traditional target selected RegSeqRat endpoint normalization; BEDC source RealStreamClassifier, RatHistoryClassifier, Cont, and hsame; carrier rational-observation streams; classifier RealStreamClassifier feeding displayed RatHistoryClassifier rows; stability pointwise transport, context closure, e-one inversion, and positive-denominator obstruction; ledger selected index, four displayed tails, context outputs, and appended-tail probes; core theorem Definition 38.863; exactness classifier clique plus malformed-tail exclusion; standard bridge dyadic selected endpoint normalization; status ProofTarget.

Theorem 38.633 (Real selected transport common rational classifier class)**.** *Under the hypotheses of Definition 38.866, the displayed selected representative* $\mathsf{E1}(a)$ *is a RatUp classifier hub for the contextual outputs and the transported selected source endpoints:*

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(o_X(n), \mathsf{E1}(a)) \wedge \mathsf{RatHistoryClassifier}(o_Y(n), \mathsf{E1}(a)) \wedge \\
&\mathsf{RatHistoryClassifier}(x'(n), \mathsf{E1}(a)) \wedge \mathsf{RatHistoryClassifier}(y'(n), \mathsf{E1}(a)) \wedge \\
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(a)) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(b), \mathsf{E1}(a)) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(b'), \mathsf{E1}(a)).
\end{aligned}$$

Proof. Apply Definition 38.866 to the displayed hypotheses. Project the displayed endpoint rows $\mathsf{hsame}(o_X(n), \mathsf{E1}(a))$, $\mathsf{hsame}(o_Y(n), \mathsf{E1}(b))$, $\mathsf{hsame}(x'(n), \mathsf{E1}(a))$, and $\mathsf{hsame}(y'(n), \mathsf{E1}(b))$, together with the selected displayed classifier row $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$.

Apply Definition 38.862 under the same hypotheses. This supplies the complete displayed e-one classifier clique. Use Definition 37.55 to orient the rows through the chosen center, giving $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(a))$, $\mathsf{RatHistoryClassifier}(\mathsf{E1}(b), \mathsf{E1}(a))$, and $\mathsf{RatHistoryClassifier}(\mathsf{E1}(b'), \mathsf{E1}(a))$.

The self-row $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(a))$ follows by composing $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$ with its symmetric row using Definition 37.53. Transport this self-row along $\mathsf{hsame}(o_X(n), \mathsf{E1}(a))$ and $\mathsf{hsame}(x'(n), \mathsf{E1}(a))$ by Definition 37.54, with FKernel hsame symmetry and reflexivity supplying the needed endpoint orientations. This gives the $o_X(n)$ and $x'(n)$ classifier rows centered at $\mathsf{E1}(a)$.

Finally transport $\mathsf{RatHistoryClassifier}(\mathsf{E1}(b), \mathsf{E1}(a))$ along $\mathsf{hsame}(o_Y(n), \mathsf{E1}(b))$ and $\mathsf{hsame}(y'(n), \mathsf{E1}(b))$, again using Definition 37.54 with the appropriate FKernel hsame orientations. The four transported endpoint rows together with the three oriented displayed-tail rows are exactly the stated common classifier class. □

Fit: traditional target common selected rational observation representative; BEDC source RealUp selected transport plus RatUp classifier transport plus FKernel hsame; carrier rational-observation streams; classifier RatHistoryClassifier centered at $\mathsf{E1}(a)$; stability selected endpoint hsame transport and classifier symmetry; ledger selected index, contextual outputs, transported source endpoints, and displayed e-one tails; core theorem Definition 38.864; exactness all selected endpoints read through the same rational classifier class; standard bridge RegSeqRat selected dyadic representative; status ProofTarget. Fit: traditional target selected RealUp observation synchronization from a stream classifier; BEDC source RealUp stream classifier plus RatUp, StreamNameUp, and Cont; carrier rational-observation streams; classifier RealStreamClassifier with derived finite-prefix row; stability pointwise hsame transport, contextual continuation, and e-one inversion; ledger selected index, prefix length, transport rows, contexts, and four tails; core theorem Definition 38.865; exactness the four synchronized packages; standard bridge selected RegSeqRat dyadic observation readback; status ProofTarget.

Fit: traditional target synchronized transported RealUp selected-observation certificate; BEDC source RealUp stream transport plus RatUp and FKernel Cont; carrier rational-observation streams; classifier RealStreamClassifier plus displayed RatHistoryClassifier rows; stability pointwise hsame, context closure, stream-classifier finite-prefix closure, e-one inversion; ledger selected index, prefix surplus, four tails, contexts; core theorem Definition 38.621; exactness package plus synchronized classifiers; standard bridge selected RegSeqRat dyadic observation readback; status ProofTarget.

Fit: traditional target stream-classifier-closed synchronized transported RealUp selected-observation certificate; BEDC source Definition 38.106 plus Definition 38.621; carrier rational-observation streams; classifier RealStreamClassifier with the finite-prefix row derived internally; stability pointwise hsame, context closure, e-one inversion, and selected full-shape readback; ledger selected index, prefix surplus, four tails, contexts, and derived prefix row; core theorem Definition 38.866 in future Lean namespace `BEDC.Derived.RealUp`; exactness predicate the four synchronized selected-transport packages; standard bridge RealUp selected RegSeqRat endpoint synchronization; status ProofTarget.

Theorem 38.634 (Real stream classifier unary denominator context closure)**.** *For rational-observation streams* $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, if*

$$\mathsf{RealStreamClassifier}(x, y),$$

and for every observation index n the contexts and continuation outputs satisfy

$$\mathsf{UnaryHistory}(p_X(n)),\quad \mathsf{UnaryHistory}(t_X(n)),\quad \mathsf{hsame}(p_X(n), p_Y(n)),\quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

$$\mathsf{Cont}(p_X(n), x(n), m_X(n)),\quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)),$$
$$\mathsf{Cont}(p_Y(n), y(n), m_Y(n)),\quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y(n)),$$

then

$$\mathsf{RealStreamClassifier}(o_X, o_Y).$$

Proof. Fix an observation index n. The stream classifier supplies $\mathsf{RatHistoryClassifier}(x(n), y(n))$ at that index.

Apply Definition 37.58 to this point classifier, the two unary-context hypotheses on $p_X(n)$ and $t_X(n)$, and the two displayed context comparisons $\mathsf{hsame}(p_X(n), p_Y(n))$ and $\mathsf{hsame}(t_X(n), t_Y(n))$. This gives the rational history classifier on the associativity-normal context endpoints.

The four continuation witnesses identify those normal endpoints with $o_X(n)$ and $o_Y(n)$, using associativity of append as in Definition 38.21. Transport the point classifier along these endpoint identifications.

Since n was arbitrary, repack the transported pointwise witnesses as $\mathsf{RealStreamClassifier}(o_X, o_Y)$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier unary denominator context closed`

Theorem 38.635 (Real stream classifier transported unary denominator context closure)**.** *For rational-observation streams $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$, assume*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)),\quad \forall i,\ \mathsf{hsame}(y(i), y'(i)),$$

and

$$\mathsf{RealStreamClassifier}(x, y).$$

If for every observation index i the contexts and continuation outputs satisfy

$$\mathsf{UnaryHistory}(p_X(i)),\quad \mathsf{UnaryHistory}(t_X(i)),\quad \mathsf{hsame}(p_X(i), p_Y(i)),\quad \mathsf{hsame}(t_X(i), t_Y(i)),$$

$$\mathsf{Cont}(p_X(i), x'(i), m_X(i)),\quad \mathsf{Cont}(m_X(i), t_X(i), o_X(i)),$$
$$\mathsf{Cont}(p_Y(i), y'(i), m_Y(i)),\quad \mathsf{Cont}(m_Y(i), t_Y(i), o_Y(i)),$$

then

$$\mathsf{RealStreamClassifier}(o_X, o_Y).$$

Proof. Fix an observation index n. The source stream classifier supplies $\mathsf{RatHistoryClassifier}(x(n), y(n))$, and the two pointwise representative rows give $\mathsf{hsame}(x(n), x'(n))$ and $\mathsf{hsame}(y(n), y'(n))$.

Apply Definition 37.54 to this point classifier and the two endpoint comparisons. This produces $\mathsf{RatHistoryClassifier}(x'(n), y'(n))$.

Since n was arbitrary, repack these transported pointwise witnesses as $\mathsf{RealStreamClassifier}(x', y')$. Applying Definition 38.634 to that stream classifier and to the displayed contexts with middle observations x' and y' gives $\mathsf{RealStreamClassifier}(o_X, o_Y)$. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier transported unary denominator context closed`

Fit: traditional target representative-stable RealUp contextual closure; BEDC source RealUp streams, RatUp hsame transport, and Cont; carrier rational-observation streams; classifier RealStreamClassifier; stability pointwise representative transport followed by unary context closure; ledger pointwise transport rows and context outputs; core theorem Definition 38.635; exactness preservation of the stream classifier; standard bridge RegSeqRat representative-stable contextual observations; status ProofTarget.

Theorem 38.636 (Real stream classifier selected continuation rational classifier)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, a selected index n, a shared unary suffix q, and continuation outputs xq, yq, if*

$$\mathsf{RealStreamClassifier}(x, y), \quad \mathsf{UnaryHistory}(q), \quad \mathsf{Cont}(x(n), q, xq), \quad \mathsf{Cont}(y(n), q, yq),$$

then

$$\mathsf{RatHistoryClassifier}(xq, yq).$$

Proof. At the selected index, the stream classifier gives $\mathsf{RatHistoryClassifier}(x(n), y(n))$. Rational unary-denominator closure extends this classifier along the shared unary suffix q, using reflexive suffix sameness. The two displayed continuation witnesses identify the closed append endpoints with xq and yq, and rational classifier transport along these endpoint displays gives the stated classifier. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier selected continuation rat classifier`

Theorem 38.637 (Real stream classifier selected continuation e-one pair readback)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, a selected index n, a shared unary suffix q, continuation outputs xq, yq, and histories $a, b : \mathsf{Hist}$, if*

$$\mathsf{RealStreamClassifier}(x, y), \quad \mathsf{UnaryHistory}(q), \quad \mathsf{Cont}(x(n), q, xq), \quad \mathsf{Cont}(y(n), q, yq),$$

and

$$\mathsf{hsame}(xq, \mathsf{E1}(a)), \quad \mathsf{hsame}(yq, \mathsf{E1}(b)),$$

then

$$\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).$$

Proof. At the selected index, the stream classifier gives $\mathsf{RatHistoryClassifier}(x(n), y(n))$. Close this rational classifier under the shared unary suffix q by rational unary-denominator continuation closure, using reflexive sameness of the suffix on the two sides. The two continuation displays identify the closed endpoints with xq and yq. Transport the closed rational classifier across those displays and then across the two e-one endpoint seals. Rational one-tail classifier exactness reads back the unary tails and their hsame relation. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier selected continuation e1 pair readback`

Fit: traditional target streamwise rational-denominator context stability; BEDC source RealUp streams plus RatUp classifier plus Cont; carrier rational-observation streams; classifier RealStreamClassifier; stability pointwise unary context closure; ledger pointwise prefix and tail context witnesses with continuation outputs; core theorem Definition 38.634; exactness pointwise RealStreamClassifier preservation; standard bridge denominator/context stability of rational real names; status ProofTarget.

Theorem 38.638 (Real stream classifier unary context closure)**.** *For rational-observation streams x, y and pointwise unary contexts $pref_X, pref_Y, tail_X, tail_Y$, if* $\mathsf{RealStreamClassifier}(x, y)$ *and each prefix and tail is matched by* hsame*, then the stream obtained by placing every observation inside its matched prefix and tail context is again classified by* $\mathsf{RealStreamClassifier}$*.*

Proof. At each index, apply rational history unary-denominator context closure to the point classifier supplied by the real stream classifier and to the matched unary prefix and tail histories. These pointwise classifiers assemble into the contextual stream classifier. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier unary context closed`

Theorem 38.639 (Real stream classifier unary denominator context selected positive denominators)**.** *For rational-observation streams $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$ and a selected index n, assume*

$$\mathsf{RealStreamClassifier}(x, y),$$

and for every observation index the unary contexts, context comparisons, and continuation displays satisfy the hypotheses of Definition 38.634. Then

$$\mathsf{PositiveUnaryDenominator}(o_X(n)) \wedge \mathsf{PositiveUnaryDenominator}(o_Y(n)).$$

Proof. At the selected index n, the stream classifier gives $\mathsf{RatHistoryClassifier}(x(n), y(n))$. Apply the rational unary denominator context closure to the two unary contexts and their hsame comparisons. The continuation displays identify the normalized contextual endpoints with $o_X(n)$ and $o_Y(n)$ by associativity of continuation append.

Transport the rational classifier to these displayed outputs and apply Definition 37.50. This yields the two positive-denominator witnesses in the displayed conclusion. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier unary denominator context selected positive denominators`

Theorem 38.640 (Real stream classifier unary denominator context selected shape package)**.** *For rational-observation streams $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$ and a selected index n, assume* $\mathsf{RealStreamClassifier}(x, y)$ *and the pointwise unary-context and continuation hypotheses of Definition 38.634. Then the selected contextual outputs $o_X(n)$ and $o_Y(n)$ are unary histories, are disjoint from* e*, and are disjoint from every zero-extension endpoint:*

1. $\mathsf{UnaryHistory}(o_X(n)) \wedge \mathsf{UnaryHistory}(o_Y(n))$*;*
2. $(\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False})$*;*
3. $(\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False})$*.*

Proof. Apply unary-denominator context closure to obtain $\mathsf{RealStreamClassifier}(o_X, o_Y)$. At the selected index, the classifier gives a rational-history classifier between $o_X(n)$ and $o_Y(n)$, hence positive unary denominator witnesses for both outputs. Each positive denominator gives unary membership and nonempty exclusion, and transport of positive denominators across a displayed zero-extension contradicts the zero-extension exclusion for positive denominators. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier unary denominator context selected shape package`

Theorem 38.641 (Real stream classifier unary denominator context appended e-zero tail exclusion)**.** *For rational-observation streams* $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, a selected index* n*, and histories* $d_X, d_Y, z_X, z_Y : \mathsf{Hist}$*, assume* $\mathsf{RealStreamClassifier}(x, y)$ *and the pointwise unary-context and continuation hypotheses of Definition 38.634. Then the selected contextual endpoints cannot be displayed as denominators with an appended e-zero tail:*

$$(\mathsf{hsame}(o_X(n), d_X \cdot \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), d_Y \cdot \mathsf{E0}(z_Y)) \to \mathsf{False}).$$

Proof. Apply Definition 38.639 to the same selected index and pointwise context hypotheses. This gives positive unary denominator witnesses for both $o_X(n)$ and $o_Y(n)$.

For the left endpoint, suppose $\mathsf{hsame}(o_X(n), d_X \cdot \mathsf{E0}(z_X))$. Transport the positive denominator witness across this displayed hsame to obtain a positive denominator witness for $d_X \cdot \mathsf{E0}(z_X)$. This contradicts Definition 37.15.

The right endpoint is identical: a display $\mathsf{hsame}(o_Y(n), d_Y \cdot \mathsf{E0}(z_Y))$ transports the positive denominator witness for $o_Y(n)$ to the appended e-zero-tail denominator $d_Y \cdot \mathsf{E0}(z_Y)$, again contradicting Definition 37.15. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier unary denominator context appended e0 tail absurd`

Theorem 38.642 (Real stream classifier unary denominator context selected classifier shape package)**.** *For rational-observation streams* $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, a selected index* n*, and zero-extension tests* $z_X, z_Y : \mathsf{Hist}$*, assume* $\mathsf{RealStreamClassifier}(x, y)$ *and the pointwise unary-context and continuation hypotheses of Definition 38.634. Then the selected contextual endpoints carry the classifier-and-shape package*

1. $\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n))$*;*
2. $\mathsf{PositiveUnaryDenominator}(o_X(n)) \wedge \mathsf{PositiveUnaryDenominator}(o_Y(n))$*;*
3. $\mathsf{UnaryHistory}(o_X(n)) \wedge \mathsf{UnaryHistory}(o_Y(n))$*;*
4. $(\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False})$*;*
5. $(\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False})$.

Proof. First apply Definition 38.634 to the given RealUp stream classifier and the pointwise context-closure hypotheses. This gives $\mathsf{RealStreamClassifier}(o_X, o_Y)$, and evaluating it at the selected index n gives $\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n))$.

Next apply Definition 38.639 to the same selected instance. This supplies the two positive unary denominator rows for $o_X(n)$ and $o_Y(n)$.

Finally apply Definition 38.640 with the same hypotheses and the two zero-extension tests. This supplies the unary-history rows, the nonempty exclusions, and the two zero-headed exclusions, which together with the selected rational classifier and positivity rows are exactly the displayed package. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier unary denominator context selected classifier shape package`

Theorem 38.643 (Real stream classifier unary denominator context one-tail pair readback)**.** *For rational-observation streams* $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$ *and a selected index* n*,*

assume $\mathsf{RealStreamClassifier}(x, y)$ *and the pointwise unary-context and continuation hypotheses of Definition 38.634. If the displayed contextual outputs satisfy*

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)) \quad \textit{and} \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)),$$

then

$$\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).$$

Proof. First apply Definition 38.634 to obtain $\mathsf{RealStreamClassifier}(o_X, o_Y)$. At the selected index, transport the point classifier to the displayed one-extension endpoints and apply the selected RealUp one-tail pair readback theorem. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier unary denominator context e1 pair readback`

Theorem 38.644 (Real stream classifier unary denominator context selected full endpoint package)**.** *For rational-observation streams* $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, a selected index* n*, histories* $a, b : \mathsf{Hist}$*, and zero-extension tests* $z_X, z_Y : \mathsf{Hist}$*, assume* $\mathsf{RealStreamClassifier}(x, y)$ *and the pointwise unary-context and continuation hypotheses of Definition 38.634. If the selected contextual outputs also satisfy*

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)) \quad \textit{and} \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)),$$

then the selected contextual endpoints carry all of the following data:

1. $\mathsf{PositiveUnaryDenominator}(o_X(n)) \wedge \mathsf{PositiveUnaryDenominator}(o_Y(n))$*;*
2. $\mathsf{UnaryHistory}(o_X(n)) \wedge \mathsf{UnaryHistory}(o_Y(n))$*;*
3. $(\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False})$*;*
4. $(\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False})$*;*
5. $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$*.*

Proof. First apply Definition 38.639 under the selected instance of the context-closure hypotheses. This supplies the two positive unary denominator witnesses for $o_X(n)$ and $o_Y(n)$.

Next apply Definition 38.640 under the same context-closure hypotheses and the displayed zero-extension tests. This supplies the unary-history witnesses, the nonempty exclusions, and the zero-extension exclusions for the two selected outputs.

Finally apply Definition 38.643 to the same context-closure hypotheses together with the two one-extension seals. The readback row gives the unary tails and their hsame relation, and the five displayed conclusions are exactly the collected endpoint data. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier unary denominator context selected full endpoint package`

Theorem 38.645 (Real stream classifier iterated unary context selected full endpoint package)**.** *For rational-observation streams* $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, u_X, u_Y, q_X, q_Y, s_X, s_Y, v_X, v_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, a selected index* n*, histories* $a, b : \mathsf{Hist}$*, and zero-extension tests* $z_X, z_Y : \mathsf{Hist}$*, assume* $\mathsf{RealStreamClassifier}(x, y)$*. Assume also that for every observation index* k *the first context layer satisfies*

$$\mathsf{UnaryHistory}(p_X(k)), \quad \mathsf{UnaryHistory}(t_X(k)), \quad \mathsf{hsame}(p_X(k), p_Y(k)), \quad \mathsf{hsame}(t_X(k), t_Y(k)),$$

$$\mathsf{Cont}(p_X(k), x(k), m_X(k)), \quad \mathsf{Cont}(m_X(k), t_X(k), u_X(k)),$$
$$\mathsf{Cont}(p_Y(k), y(k), m_Y(k)), \quad \mathsf{Cont}(m_Y(k), t_Y(k), u_Y(k)),$$

and that for every observation index k the second context layer satisfies

$$\mathsf{UnaryHistory}(q_X(k)), \quad \mathsf{UnaryHistory}(s_X(k)), \quad \mathsf{hsame}(q_X(k), q_Y(k)), \quad \mathsf{hsame}(s_X(k), s_Y(k)),$$
$$\mathsf{Cont}(q_X(k), u_X(k), v_X(k)), \quad \mathsf{Cont}(v_X(k), s_X(k), o_X(k)),$$
$$\mathsf{Cont}(q_Y(k), u_Y(k), v_Y(k)), \quad \mathsf{Cont}(v_Y(k), s_Y(k), o_Y(k)).$$

If the selected second-layer outputs satisfy

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)) \quad \textit{and} \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)),$$

then the selected contextual endpoints carry all of the following data:

1. $\mathsf{PositiveUnaryDenominator}(o_X(n)) \wedge \mathsf{PositiveUnaryDenominator}(o_Y(n))$;
2. $\mathsf{UnaryHistory}(o_X(n)) \wedge \mathsf{UnaryHistory}(o_Y(n))$;
3. $(\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False})$;
4. $(\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False})$;
5. $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$.

Proof. First apply Definition 38.634 to the given RealUp stream classifier and the first-layer unary context and continuation rows. This produces $\mathsf{RealStreamClassifier}(u_X, u_Y)$.

Next apply Definition 38.644 to this intermediate stream classifier, using the second-layer unary context and continuation rows, the selected one-extension seals, and the two zero-extension tests. The resulting five rows are exactly the displayed endpoint package for $o_X(n)$ and $o_Y(n)$. □

Fit: traditional target RealUp iterated contextual endpoint readback; BEDC source RealUp streams plus RatUp classifier plus Cont; carrier rational-observation streams; classifier RealStreamClassifier; stability consecutive unary context closure; ledger two context layers and selected e-one seals; core theorem Definition 38.645; exactness the displayed endpoint package; standard bridge RegSeqRat iterated observation readback; status ProofTarget.

Theorem 38.646 (Real stream classifier unary denominator context selected classifier full endpoint package)**.** *For rational-observation streams $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$, a selected index n, histories $a, b : \mathsf{Hist}$, and zero-extension tests $z_X, z_Y : \mathsf{Hist}$, assume* $\mathsf{RealStreamClassifier}(x, y)$ *and the pointwise unary-context and continuation hypotheses of Definition 38.634. If the selected contextual outputs also satisfy*

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)) \quad \textit{and} \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)),$$

then the selected contextual endpoints carry all of the following data:

1. $\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n))$;
2. $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$;
3. $\mathsf{PositiveUnaryDenominator}(o_X(n)) \wedge \mathsf{PositiveUnaryDenominator}(o_Y(n))$;
4. $\mathsf{UnaryHistory}(o_X(n)) \wedge \mathsf{UnaryHistory}(o_Y(n))$;

5. $(\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False})$;

6. $(\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False})$;

7. $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$.

Proof. First apply Definition 38.634 to the given RealUp stream classifier and the pointwise context-closure hypotheses. This supplies $\mathsf{RealStreamClassifier}(o_X, o_Y)$.

By the definition of RealStreamClassifier, evaluating the closed stream classifier at the selected index n gives $\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n))$.

Transport this endpoint classifier across the two one-extension seals using Definition 37.54. This gives $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$.

Next apply Definition 38.644 to the same hypotheses, the two displayed one-extension seals, and the zero-extension tests. This gives the positivity, unary-shape, nonempty, zero-headed exclusion, and e-one tail readback rows.

Package the selected rational-history classifier and its sealed transported classifier as the first two rows, then append the five rows supplied by the full endpoint package. □

Fit: traditional target RealUp contextual endpoint classifier readback; BEDC source RealUp streams, RatUp classifier, Cont, and unary contexts; carrier rational-observation streams; classifier RealStreamClassifier with selected and sealed RatHistoryClassifier; stability context closure and endpoint selection; ledger selected index, contexts, continuation outputs, e-one and zero-headed tests; core theorem Definition 38.646; exactness selected and sealed RatUp classifiers, denominator/shape rows, and tail exclusions; standard bridge RegSeqRat selected endpoint classifier readback; status ProofTarget.

Theorem 38.647 (Real stream classifier unary denominator context selected classifier appended-tail package)**.** *For rational-observation streams $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$, a selected index n, histories $a, b, d_X, d_Y, z_X, z_Y : \mathsf{Hist}$, assume $\mathsf{RealStreamClassifier}(x, y)$ and the pointwise unary-context and continuation hypotheses of Definition 38.634. If the selected contextual outputs also satisfy the one-extension seals*

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)) \quad \textit{and} \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)),$$

then the selected contextual endpoints carry all of the following data:

1. $\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n))$;

2. $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$;

3. $\mathsf{PositiveUnaryDenominator}(o_X(n)) \wedge \mathsf{PositiveUnaryDenominator}(o_Y(n))$;

4. $\mathsf{UnaryHistory}(o_X(n)) \wedge \mathsf{UnaryHistory}(o_Y(n))$;

5. $(\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False})$;

6. $(\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False})$;

7. $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$;

8. $(\mathsf{hsame}(o_X(n), d_X \cdot \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), d_Y \cdot \mathsf{E0}(z_Y)) \to \mathsf{False})$.

Proof. First apply Definition 38.646 to the same RealUp stream classifier, pointwise context-closure hypotheses, and one-extension seals. This supplies the selected rational-history classifier, the sealed

transported rational-history classifier, the positivity rows, the unary-shape rows, the nonempty and zero-headed exclusions, and the e-one tail readback row.

Next apply Definition 38.641 to the same selected contextual instance. This gives the two exclusions against displays of $o_X(n)$ and $o_Y(n)$ as denominators with appended e-zero tails.

Repack the seven rows from the selected classifier full endpoint package with the sealed classifier preceding the appended-tail exclusions. The resulting tuple is exactly the displayed package for the selected contextual endpoints. □

Fit: traditional target RealUp contextual endpoint classifier readback; BEDC source RealUp streams, RatUp classifier, Cont, unary contexts, and appended e-zero-tail obstruction; carrier rational-observation streams; classifier RealStreamClassifier and selected RatHistoryClassifier together with its sealed endpoint transport; stability context closure and endpoint selection; ledger selected index, contexts, continuation outputs, e-one seals, zero-headed tests, and appended-tail displays; core theorem Definition 38.647; exactness selected and sealed RatUp classifiers, denominator/shape rows, and tail exclusions; standard bridge RegSeqRat selected endpoint classifier readback; status ProofTarget.

Theorem 38.648 (Real stream classifier contextual appended e-one tail cancellation)**.** *For rational-observation streams* $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, a selected index* n*, and histories* $d, e, tail_D, tail_E : \mathsf{Hist}$*, assume*

$$\mathsf{RealStreamClassifier}(x, y),$$

and for every observation index i *the contexts and continuation outputs satisfy*

$$\mathsf{UnaryHistory}(p_X(i)), \quad \mathsf{UnaryHistory}(t_X(i)), \quad \mathsf{hsame}(p_X(i), p_Y(i)), \quad \mathsf{hsame}(t_X(i), t_Y(i)),$$

$$\mathsf{Cont}(p_X(i), x(i), m_X(i)), \quad \mathsf{Cont}(m_X(i), t_X(i), o_X(i)),$$
$$\mathsf{Cont}(p_Y(i), y(i), m_Y(i)), \quad \mathsf{Cont}(m_Y(i), t_Y(i), o_Y(i)).$$

If the selected contextual outputs display as appended e-one tails,

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(d \cdot \mathsf{E1}(tail_D))), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(e \cdot \mathsf{E1}(tail_E))),$$

and the displayed tails agree by $\mathsf{hsame}(tail_D, tail_E)$*, then*

$$\mathsf{hsame}(d, e).$$

Proof. First apply Definition 38.634 to the source stream classifier and the pointwise unary-context and continuation hypotheses. This supplies the contextual stream classifier $\mathsf{RealStreamClassifier}(o_X, o_Y)$.

Apply Definition 38.605 to the contextual streams o_X, o_Y at the selected index n, using the two displayed appended e-one tail rows and the comparison $\mathsf{hsame}(tail_D, tail_E)$. The conclusion is exactly the denominator-head comparison $\mathsf{hsame}(d, e)$. □

Fit: traditional target contextual RegSeqRat endpoint cancellation; BEDC source RealUp streams, RatUp classifier readback, Cont, and BEDC append cancellation; carrier rational-observation streams; classifier RealStreamClassifier; stability unary denominator context closure; ledger selected index plus context witnesses and e-one tail displays; core theorem Definition 38.648; exactness denominator-head comparison after tail cancellation; standard bridge contextual rational observation tail cancellation; status ProofTarget.

Theorem 38.649 (Real stream classifier unary denominator context selected e-one tail determinacy)**.** *For rational-observation streams* $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, a selected index* n*, and histories* $a, a', b, b' : \mathsf{Hist}$*, assume* $\mathsf{RealStreamClassifier}(x, y)$ *and the pointwise unary-context plus continuation hypotheses of Definition 38.634. If the selected contextual outputs satisfy the four e-one displays*

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')),$$

then all of the following data hold:

1. $\mathsf{UnaryHistory}(a)$*;*
2. $\mathsf{UnaryHistory}(a')$*;*
3. $\mathsf{UnaryHistory}(b)$*;*
4. $\mathsf{UnaryHistory}(b')$*;*
5. $\mathsf{hsame}(a, a')$*;*
6. $\mathsf{hsame}(b, b')$*;*
7. $\mathsf{hsame}(a, b)$*;*
8. $\mathsf{hsame}(a', b')$*.*

Proof. Apply Definition 38.643 to the displays $\mathsf{hsame}(o_X(n), \mathsf{E1}(a))$ and $\mathsf{hsame}(o_Y(n), \mathsf{E1}(b))$. This supplies $\mathsf{UnaryHistory}(a)$, $\mathsf{UnaryHistory}(b)$, and $\mathsf{hsame}(a, b)$.

Apply the same readback theorem again to the displays $\mathsf{hsame}(o_X(n), \mathsf{E1}(a'))$ and $\mathsf{hsame}(o_Y(n), \mathsf{E1}(b'))$. This supplies $\mathsf{UnaryHistory}(a')$, $\mathsf{UnaryHistory}(b')$, and $\mathsf{hsame}(a', b')$.

For the X-tail comparison, compose the first display of $o_X(n)$ with the symmetry of the second display. The resulting $\mathsf{hsame}(\mathsf{E1}(a), \mathsf{E1}(a'))$ is inverted by the history constructor characterization, equivalently BEDC.FKernel.Hist.hsame_e1_inversion_iff, to get $\mathsf{hsame}(a, a')$.

The same composition and e-one inversion applied to the two displays of $o_Y(n)$ gives $\mathsf{hsame}(b, b')$. Package these two tail comparisons with the two readback rows. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier unary denominator context selected e1 tail determinacy`

Fit: traditional target RealUp contextual endpoint tail determinacy; BEDC source RealUp streams, RatUp classifier, Cont, unary contexts, and selected e-one displays; carrier rational-observation streams; classifier RealStreamClassifier and selected endpoint displays; stability context closure and selected continuation transport; ledger selected index, contexts, continuation outputs, and paired e-one seals; core theorem Definition 38.649; exactness canonical selected denominator tails; standard bridge RegSeqRat and dyadic selected-tail consumers; status ProofTarget.

Theorem 38.650 (Real stream classifier unary denominator context selected e-one tail pairwise coherence)**.** *For rational-observation streams* $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, a selected index* n*, and histories* $a, a', b, b' : \mathsf{Hist}$*, assume* $\mathsf{RealStreamClassifier}(x, y)$ *and the pointwise unary-context plus continuation hypotheses of Definition 38.634. If the selected contextual outputs satisfy the four e-one displays*

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')),$$

then all of the following data hold:

1. $\mathsf{UnaryHistory}(a)$;
2. $\mathsf{UnaryHistory}(a')$;
3. $\mathsf{UnaryHistory}(b)$;
4. $\mathsf{UnaryHistory}(b')$;
5. $\mathsf{hsame}(a, a')$;
6. $\mathsf{hsame}(a, b)$;
7. $\mathsf{hsame}(a, b')$;
8. $\mathsf{hsame}(a', b)$;
9. $\mathsf{hsame}(a', b')$;
10. $\mathsf{hsame}(b, b')$.

Proof. Apply Definition 38.649 to the same RealUp stream classifier, selected index, pointwise unary-context and continuation hypotheses, and four e-one displays. This supplies the four unary-history rows together with $\mathsf{hsame}(a, a')$, $\mathsf{hsame}(b, b')$, $\mathsf{hsame}(a, b)$, and $\mathsf{hsame}(a', b')$.

For the first cross-tail comparison, compose $\mathsf{hsame}(a, a')$ with $\mathsf{hsame}(a', b')$ by BEDC.FKernel.Hist.hsame_trans. The resulting row is $\mathsf{hsame}(a, b')$.

For the second cross-tail comparison, apply BEDC.FKernel.Hist.hsame_symm to $\mathsf{hsame}(a, a')$ and compose the result with $\mathsf{hsame}(a, b)$ by BEDC.FKernel.Hist.hsame_trans. This gives $\mathsf{hsame}(a', b)$.

Package the four unary-history witnesses, the four tail rows supplied by Definition 38.649, and the two cross-tail rows just obtained. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier unary denominator context selected e1 tail pairwise coherence`

Fit: traditional target canonical selected denominator-tail class for contextual RealUp observations; BEDC source RealUp streams, RatUp readback, Cont contexts, and FKernel hsame transitivity; carrier rational-observation streams; classifier RealStreamClassifier; stability selected context closure plus e-one no-confusion; ledger selected index, context witnesses, continuation outputs, and four e-one seals; core theorem Definition 38.650; exactness pairwise selected-tail coherence; standard bridge RegSeqRat selected dyadic-tail canonicalization; status ProofTarget.

Theorem 38.651 (Real stream classifier unary denominator context selected e-one tail-class exactness)**.** *For rational-observation streams $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$, a selected index n, and histories $a, b : \mathsf{Hist}$, assume $\mathsf{RealStreamClassifier}(x, y)$ and the pointwise unary-context plus continuation hypotheses of Definition 38.634. If the selected contextual outputs satisfy the displayed endpoint seals*

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)),$$

then for all histories $u, v : \mathsf{Hist}$,

$$(\mathsf{hsame}(o_X(n), \mathsf{E1}(u)) \wedge \mathsf{hsame}(o_Y(n), \mathsf{E1}(v))) \iff (\mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsame}(a, u) \wedge \mathsf{hsame}(b, v)).$$

Proof. For the forward direction, assume the two additional displays $\mathsf{hsame}(o_X(n), \mathsf{E1}(u))$ and $\mathsf{hsame}(o_Y(n), \mathsf{E1}(v))$. Apply Definition 38.650 with $(a, a', b, b') = (a, u, b, v)$ to the two endpoint seals and the two additional displays. The resulting ten rows include $\mathsf{UnaryHistory}(u)$, $\mathsf{UnaryHistory}(v)$, $\mathsf{hsame}(a, u)$, and $\mathsf{hsame}(b, v)$.

For the reverse direction, assume $\mathsf{UnaryHistory}(u)$, $\mathsf{UnaryHistory}(v)$, $\mathsf{hsame}(a, u)$, and $\mathsf{hsame}(b, v)$. Apply BEDC.FKernel.Hist.hsame_e1_congr to $\mathsf{hsame}(a, u)$ and compose the result with the endpoint seal $\mathsf{hsame}(o_X(n), \mathsf{E1}(a))$ by BEDC.FKernel.Hist.hsame_trans. This gives $\mathsf{hsame}(o_X(n), \mathsf{E1}(u))$.

Apply the same e-one congruence and transitivity chain to $\mathsf{hsame}(b, v)$ and the endpoint seal $\mathsf{hsame}(o_Y(n), \mathsf{E1}(b))$. This gives $\mathsf{hsame}(o_Y(n), \mathsf{E1}(v))$, and the two displays form the selected tail-class membership pair. □

Fit: traditional target contextual selected denominator-tail classes; BEDC source RealUp streams, RatUp readback, Cont, UnaryHistory, and FKernel e-one congruence; carrier rational-observation streams; classifier RealStreamClassifier; stability pairwise coherence plus e-one congruence; ledger selected index, context witnesses, continuation outputs, and selected e-one seals; core theorem Definition 38.651; exactness the displayed selected e-one tails are exactly the canonical hsame classes; standard bridge RegSeqRat selected dyadic-tail canonicalization; status ProofTarget.

Theorem 38.652 (Real stream classifier transported contextual e-one tail pairwise coherence)**.** *For rational-observation streams $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$, a selected index n, and histories $a, a', b, b' : \mathsf{Hist}$, assume*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)),$$

and

$$\mathsf{RealStreamClassifier}(x, y).$$

Assume also that for every observation index i the transported unary contexts and continuation outputs satisfy

$$\mathsf{UnaryHistory}(p_X(i)), \quad \mathsf{UnaryHistory}(t_X(i)), \quad \mathsf{hsame}(p_X(i), p_Y(i)), \quad \mathsf{hsame}(t_X(i), t_Y(i)),$$

$$\mathsf{Cont}(p_X(i), x'(i), m_X(i)), \quad \mathsf{Cont}(m_X(i), t_X(i), o_X(i)),$$
$$\mathsf{Cont}(p_Y(i), y'(i), m_Y(i)), \quad \mathsf{Cont}(m_Y(i), t_Y(i), o_Y(i)).$$

If the selected contextual outputs satisfy the four e-one displays

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')),$$

then all of the following data hold:

1. $\mathsf{UnaryHistory}(a)$;
2. $\mathsf{UnaryHistory}(a')$;
3. $\mathsf{UnaryHistory}(b)$;
4. $\mathsf{UnaryHistory}(b')$;
5. $\mathsf{hsame}(a, a')$;
6. $\mathsf{hsame}(a, b)$;
7. $\mathsf{hsame}(a, b')$;
8. $\mathsf{hsame}(a', b)$;
9. $\mathsf{hsame}(a', b')$;
10. $\mathsf{hsame}(b, b')$.

Proof. Apply Definition 38.635 to the pointwise representative rows, the source RealUp stream classifier, and the displayed transported unary-context hypotheses. This gives $\mathsf{RealStreamClassifier}(o_X, o_Y)$.

Apply Definition 38.588 to this endpoint classifier with the displays $\mathsf{hsame}(o_X(n), \mathsf{E1}(a))$ and $\mathsf{hsame}(o_Y(n), \mathsf{E1}(b))$. This supplies $\mathsf{UnaryHistory}(a)$, $\mathsf{UnaryHistory}(b)$, and $\mathsf{hsame}(a, b)$.

Apply the same selected pair readback theorem to the displays $\mathsf{hsame}(o_X(n), \mathsf{E1}(a'))$ and $\mathsf{hsame}(o_Y(n), \mathsf{E1}(b'))$. This supplies $\mathsf{UnaryHistory}(a')$, $\mathsf{UnaryHistory}(b')$, and $\mathsf{hsame}(a', b')$.

For the left representative comparison, compose the two $o_X(n)$ displays with the symmetry of the second display and invert the resulting $\mathsf{hsame}(\mathsf{E1}(a), \mathsf{E1}(a'))$ by e-one no-confusion. This gives $\mathsf{hsame}(a, a')$.

The same composition and e-one inversion applied to the two $o_Y(n)$ displays gives $\mathsf{hsame}(b, b')$.

Finally compose $\mathsf{hsame}(a, b)$ with $\mathsf{hsame}(b, b')$ by BEDC.FKernel.Hist.hsame_trans to obtain $\mathsf{hsame}(a, b')$. Compose the symmetry of $\mathsf{hsame}(a, a')$ with $\mathsf{hsame}(a, b)$ by the same transitivity theorem to obtain $\mathsf{hsame}(a', b)$, and package these rows with the two readback triples and the two same-side representative comparisons. □

Theorem 38.653 (Real stream classifier transported iterated unary context selected e-one tail pairwise coherence)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, u_X, u_Y, q_X, q_Y, s_X, s_Y, v_X,$ $\mathbb{N} \to \mathsf{Hist}$*, a selected index* n*, and histories* $a, a', b, b' : \mathsf{Hist}$*, assume*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)),$$

and

$$\mathsf{RealStreamClassifier}(x, y).$$

Assume also that for every observation index i *the transported first context layer satisfies*

$$\mathsf{UnaryHistory}(p_X(i)), \quad \mathsf{UnaryHistory}(t_X(i)), \quad \mathsf{hsame}(p_X(i), p_Y(i)), \quad \mathsf{hsame}(t_X(i), t_Y(i)),$$

$$\mathsf{Cont}(p_X(i), x'(i), m_X(i)), \quad \mathsf{Cont}(m_X(i), t_X(i), u_X(i)),$$

$$\mathsf{Cont}(p_Y(i), y'(i), m_Y(i)), \quad \mathsf{Cont}(m_Y(i), t_Y(i), u_Y(i)),$$

and that for every observation index i *the second context layer satisfies*

$$\mathsf{UnaryHistory}(q_X(i)), \quad \mathsf{UnaryHistory}(s_X(i)), \quad \mathsf{hsame}(q_X(i), q_Y(i)), \quad \mathsf{hsame}(s_X(i), s_Y(i)),$$

$$\mathsf{Cont}(q_X(i), u_X(i), v_X(i)), \quad \mathsf{Cont}(v_X(i), s_X(i), o_X(i)),$$

$$\mathsf{Cont}(q_Y(i), u_Y(i), v_Y(i)), \quad \mathsf{Cont}(v_Y(i), s_Y(i), o_Y(i)).$$

If the selected second-layer outputs satisfy the four e-one displays

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')),$$

then all of the following data hold:

1. $\mathsf{UnaryHistory}(a)$*;*
2. $\mathsf{UnaryHistory}(a')$*;*
3. $\mathsf{UnaryHistory}(b)$*;*
4. $\mathsf{UnaryHistory}(b')$*;*
5. $\mathsf{hsame}(a, a')$*;*

6. $\mathsf{hsame}(a, b)$;
7. $\mathsf{hsame}(a, b')$;
8. $\mathsf{hsame}(a', b)$;
9. $\mathsf{hsame}(a', b')$;
10. $\mathsf{hsame}(b, b')$.

Proof. First apply Definition 38.635 to the pointwise representative rows, the source RealUp stream classifier, and the displayed first-layer context and continuation hypotheses. This produces $\mathsf{RealStreamClassifier}(u_X, u_Y)$.

Next apply Definition 38.650 to this transported intermediate classifier, using the second-layer context and continuation rows together with the four selected e-one displays. The resulting ten rows are exactly the unary-history and pairwise tail-coherence package displayed above. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamClassifier transported iterated unary context selected e1 tail pairwise coherence`

Fit: traditional target RegSeqRat representative-stable iterated selected-tail canonicalization; BEDC source RealUp streams plus RatUp classifier plus Cont; carrier rational-observation streams; classifier RealStreamClassifier; stability representative transport followed by two context closures; ledger two context layers and four selected e-one seals; core theorem Definition 38.653; exactness the selected-tail equivalence class; standard bridge dyadic selected-tail canonicalization; status ProofTarget.

Theorem 38.654 (Real stream classifier iterated unary denominator context appended e-zero tail exclusion)**.** *For rational-observation streams* $x, y, p_X, p_Y, t_X, t_Y, m_X, m_Y, u_X, u_Y, q_X, q_Y, s_X, s_Y, v_X, v_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, a selected index* n*, and histories* $d_X, d_Y, z_X, z_Y : \mathsf{Hist}$*, assume*

$$\mathsf{RealStreamClassifier}(x, y).$$

Assume also that for every observation index k *the first context layer satisfies*

$$\mathsf{UnaryHistory}(p_X(k)), \quad \mathsf{UnaryHistory}(t_X(k)), \quad \mathsf{hsame}(p_X(k), p_Y(k)), \quad \mathsf{hsame}(t_X(k), t_Y(k)),$$
$$\mathsf{Cont}(p_X(k), x(k), m_X(k)), \quad \mathsf{Cont}(m_X(k), t_X(k), u_X(k)),$$
$$\mathsf{Cont}(p_Y(k), y(k), m_Y(k)), \quad \mathsf{Cont}(m_Y(k), t_Y(k), u_Y(k)),$$

and that for every observation index k *the second context layer satisfies*

$$\mathsf{UnaryHistory}(q_X(k)), \quad \mathsf{UnaryHistory}(s_X(k)), \quad \mathsf{hsame}(q_X(k), q_Y(k)), \quad \mathsf{hsame}(s_X(k), s_Y(k)),$$
$$\mathsf{Cont}(q_X(k), u_X(k), v_X(k)), \quad \mathsf{Cont}(v_X(k), s_X(k), o_X(k)),$$
$$\mathsf{Cont}(q_Y(k), u_Y(k), v_Y(k)), \quad \mathsf{Cont}(v_Y(k), s_Y(k), o_Y(k)).$$

Then the selected second-layer outputs cannot be displayed as denominators with an appended e-zero tail:

$$(\mathsf{hsame}(o_X(n), d_X \cdot \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), d_Y \cdot \mathsf{E0}(z_Y)) \to \mathsf{False}).$$

Proof. First apply Definition 38.634 to the source RealUp stream classifier and the first-layer unary context and continuation rows. This produces the intermediate stream classifier $\mathsf{RealStreamClassifier}(u_X, u_Y)$.

Next apply Definition 38.641 to this intermediate stream classifier, using the second-layer unary context and continuation rows at the same selected index. The resulting two contradictions are exactly the displayed exclusions for $o_X(n)$ and $o_Y(n)$. □

Fit: traditional target RegSeqRat iterated observation denominator sanity; BEDC source RealUp plus RatUp plus Cont; carrier rational-observation streams; classifier RealStreamClassifier; stability two unary-context closures; ledger two context layers and appended e-zero displays; core theorem Definition 38.654; exactness selected appended-tail impossibility; standard bridge finite rational observation windows; status ProofTarget.

Theorem 38.655 (Real stream classifier transported iterated unary context selected e-one tail–class exactness)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, u_X, u_Y, q_X, q_Y, s_X, s_Y, v_X, v_Y, \mathbb{N} \to \mathsf{Hist}$*, a selected index* n*, and histories* $a, b : \mathsf{Hist}$*, assume*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)),$$

and

$$\mathsf{RealStreamClassifier}(x, y).$$

Assume also that for every observation index i *the transported first context layer satisfies*

$$\mathsf{UnaryHistory}(p_X(i)), \quad \mathsf{UnaryHistory}(t_X(i)), \quad \mathsf{hsame}(p_X(i), p_Y(i)), \quad \mathsf{hsame}(t_X(i), t_Y(i)),$$
$$\mathsf{Cont}(p_X(i), x'(i), m_X(i)), \quad \mathsf{Cont}(m_X(i), t_X(i), u_X(i)),$$
$$\mathsf{Cont}(p_Y(i), y'(i), m_Y(i)), \quad \mathsf{Cont}(m_Y(i), t_Y(i), u_Y(i)),$$

and that for every observation index i *the second context layer satisfies*

$$\mathsf{UnaryHistory}(q_X(i)), \quad \mathsf{UnaryHistory}(s_X(i)), \quad \mathsf{hsame}(q_X(i), q_Y(i)), \quad \mathsf{hsame}(s_X(i), s_Y(i)),$$
$$\mathsf{Cont}(q_X(i), u_X(i), v_X(i)), \quad \mathsf{Cont}(v_X(i), s_X(i), o_X(i)),$$
$$\mathsf{Cont}(q_Y(i), u_Y(i), v_Y(i)), \quad \mathsf{Cont}(v_Y(i), s_Y(i), o_Y(i)).$$

If the selected second-layer outputs satisfy

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)),$$

then for all histories $u, v : \mathsf{Hist}$*,*

$$\big(\mathsf{hsame}(o_X(n), \mathsf{E1}(u)) \wedge \mathsf{hsame}(o_Y(n), \mathsf{E1}(v))\big) \iff \big(\mathsf{UnaryHistory}(u) \wedge \mathsf{UnaryHistory}(v) \wedge \mathsf{hsame}(a, u) \wedge \mathsf{hsame}(b, v)\big).$$

Proof. For the forward direction, assume the two additional displays $\mathsf{hsame}(o_X(n), \mathsf{E1}(u))$ and $\mathsf{hsame}(o_Y(n), \mathsf{E1}(v))$. Apply Definition 38.653 with $(a, a', b, b') = (a, u, b, v)$ to the two selected endpoint seals and the two additional displays. The resulting ten rows include $\mathsf{UnaryHistory}(u)$, $\mathsf{UnaryHistory}(v)$, $\mathsf{hsame}(a, u)$, and $\mathsf{hsame}(b, v)$.

For the reverse direction, assume $\mathsf{UnaryHistory}(u)$, $\mathsf{UnaryHistory}(v)$, $\mathsf{hsame}(a, u)$, and $\mathsf{hsame}(b, v)$. Apply BEDC.FKernel.Hist.hsame_e1_congr to $\mathsf{hsame}(a, u)$ and compose the result with the endpoint seal $\mathsf{hsame}(o_X(n), \mathsf{E1}(a))$ by BEDC.FKernel.Hist.hsame_trans. This gives $\mathsf{hsame}(o_X(n), \mathsf{E1}(u))$.

Apply the same e-one congruence and transitivity chain to $\mathsf{hsame}(b, v)$ and the endpoint seal $\mathsf{hsame}(o_Y(n), \mathsf{E1}(b))$. This gives $\mathsf{hsame}(o_Y(n), \mathsf{E1}(v))$, and the two displays form the selected tail-class membership pair. □

Fit: traditional target RegSeqRat selected denominator-tail class; BEDC source RealUp streams, RatUp readback, Cont contexts, and FKernel e-one congruence; carrier rational-observation streams; classifier RealStreamClassifier; stability representative transport plus two unary context layers; ledger selected index, context witnesses, continuation outputs, and e-one seals; core theorem Definition 38.655; exactness canonical selected-tail class; standard bridge dyadic selected-tail canonicalization; status ProofTarget.

Theorem 38.656 (Real stream classifier transported iterated unary context selected classifier full endpoint package)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, u_X, u_Y, q_X, q_Y, s_X, s_Y, v_X,$ $\mathbb{N} \to \mathsf{Hist}$*, a selected index* n*, histories* $a, b, z_X, z_Y : \mathsf{Hist}$*, assume*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)),$$

and

$$\mathsf{RealStreamClassifier}(x, y).$$

Assume also that for every observation index i *the transported first unary-context layer satisfies*

$$\mathsf{UnaryHistory}(p_X(i)), \quad \mathsf{UnaryHistory}(t_X(i)), \quad \mathsf{hsame}(p_X(i), p_Y(i)), \quad \mathsf{hsame}(t_X(i), t_Y(i)),$$

$$\mathsf{Cont}(p_X(i), x'(i), m_X(i)), \quad \mathsf{Cont}(m_X(i), t_X(i), u_X(i)),$$
$$\mathsf{Cont}(p_Y(i), y'(i), m_Y(i)), \quad \mathsf{Cont}(m_Y(i), t_Y(i), u_Y(i)),$$

and that for every observation index i *the second unary-context layer satisfies*

$$\mathsf{UnaryHistory}(q_X(i)), \quad \mathsf{UnaryHistory}(s_X(i)), \quad \mathsf{hsame}(q_X(i), q_Y(i)), \quad \mathsf{hsame}(s_X(i), s_Y(i)),$$

$$\mathsf{Cont}(q_X(i), u_X(i), v_X(i)), \quad \mathsf{Cont}(v_X(i), s_X(i), o_X(i)),$$
$$\mathsf{Cont}(q_Y(i), u_Y(i), v_Y(i)), \quad \mathsf{Cont}(v_Y(i), s_Y(i), o_Y(i)).$$

If the selected second-layer outputs satisfy

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)) \quad \textit{and} \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)),$$

then the selected transported contextual endpoints carry all of the following data:

1. $\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n))$*;*
2. $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$*;*
3. $\mathsf{PositiveUnaryDenominator}(o_X(n)) \wedge \mathsf{PositiveUnaryDenominator}(o_Y(n))$*;*
4. $\mathsf{UnaryHistory}(o_X(n)) \wedge \mathsf{UnaryHistory}(o_Y(n))$*;*
5. $(\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False})$*;*
6. $(\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False})$*;*
7. $\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b)$*.*

Proof. First apply Definition 38.635 to the pointwise representative rows, the source RealUp stream classifier, and the displayed transported first-layer context and continuation hypotheses. This produces $\mathsf{RealStreamClassifier}(u_X, u_Y)$.

Next apply Definition 38.646 to this intermediate stream classifier, the second-layer context and continuation rows, the selected one-extension seals, and the two zero-extension tests. The resulting seven rows are exactly the selected transported classifier full endpoint package displayed above. □

Fit: traditional target RealUp selected transported observation readback; BEDC source RealStreamClassifier, RatHistoryClassifier, Cont, UnaryHistory, and FKernel hsame; carrier rational-observation streams; classifier RealStreamClassifier with selected sealed RatHistoryClassifier; stability representative transport followed by two unary context layers; ledger selected index, context witnesses, continuation outputs, e-one seals, and zero-headed tests; core theorem Definition 38.656; exactness selected and sealed RatUp classifiers, denominator and unary-shape rows, nonempty exclusions, zero-headed exclusions, and e-one tail readback; standard bridge RegSeqRat selected transported observation readback; status ProofTarget. The $\mathsf{Real}^{\uparrow}$ carrier is consumed only after the finite-window $\mathsf{StreamName}^{\uparrow}$ surface of chapter 126 and the regular-rational readback surface of chapter 301 are both available. In this dependency row, a real seal is a downstream consumer of the visible stream window and regular rational approximation ledgers; it does not create a quotient-real equality row, selected host limit, or ambient completeness principle before those two finite surfaces have been displayed.

Theorem 38.657 (Real StreamName RegSeqRat pointwise seal composition)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *seal-facing read whose source includes a* $\mathsf{StreamName}^{\uparrow}$ *finite-window row and whose readback includes a* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational row factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite-window ledger, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *pointwise handoff, and then the local* RealUnaryStreamClassifier *row. The route is transported only by the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows already present in the Real carrier and seal material of this chapter.*

The composed route exports no quotient-real equality, selected host limit, ambient completeness principle, or direct $\mathsf{Real}^{\uparrow}$ *seal edge bypassing the StreamName and RegSeqRat surfaces.*

Proof. Start with an accepted seal-facing read at the $\mathsf{Real}^{\uparrow}$ boundary. The Real carrier and seal material already input in this chapter exposes the read only through the local finite-window seal package, endpoint readback, and provenance rows.

First project the StreamName source. By chapter 126 and Definition 126.170, the finite source contributes exactly the visible StreamName window ledger, bundle membership, unary-history observations, and pointwise hsame comparisons. These are the only source rows available before the regular-rational readback is consumed.

Next project the RegSeqRat readback. The RegSeqRat surface of chapter 301, together with Definition 38.407, reads the same finite window as the regular-rational handoff and keeps the readback on the displayed BHist route.

Finally transport the result into the Real unary stream classifier. The local Real seal package reads the already assembled StreamName and RegSeqRat rows as the classifier-facing input, so the seal-facing route has no remaining coordinate from which to obtain quotient-real equality, a selected host limit, an ambient completeness principle, or a direct seal edge around those two surfaces. □

Theorem 38.658 (RealUp StreamName RegSeqRat dyadic window exhaustion)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *seal-facing finite-window read whose source is a* $\mathsf{StreamName}^{\uparrow}$ *window and whose spine is a* $\mathsf{RegSeqRat}^{\uparrow}$ *row is exhausted by the route*

StreamName finite-window ledger → *RegSeqRat pointwise handoff* → *DyadicRatCore observation row* → RealUnar

The route reads only the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows carried by the StreamName, RegSeqRat, DyadicRatCore, and Real finite-window surfaces. No quotient-real equality, selected host limit, ambient completeness row, or off-ledger dyadic sample can determine the* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Begin with the pointwise seal composition of Definition 38.657. It already forces the seal-facing read to pass through the displayed StreamName finite-window ledger and the RegSeqRat pointwise handoff before it reaches the local real classifier.

The handoff is exhaustive by Definition 126.100. Thus the source window contributes only its visible finite ledger, unary-history observations, bundle membership, and pointwise hsame comparisons; it cannot add a second stream source or a hidden real equality row.

The dyadic part is then read through the public DyadicRatCore observation and source-boundary surface. That surface supplies the observation row used by the real finite-window classifier, while the RealUp finite-window coverage rows identify the classifier-facing input with $\mathsf{RealUnaryStreamClassifier}$.

Composing these four displayed routes leaves no unused coordinate in the seal-facing packet. A host limit, ambient completeness row, quotient-real equality, or off-ledger dyadic sample is absent from the route and therefore cannot determine the accepted $\mathsf{Real}^{\uparrow}$ seal. □

Theorem 38.659 (Real StreamName RegSeqRat terminal seal exhaustion)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing consumer whose source is a* $\mathsf{StreamName}^{\uparrow}$ *finite-window row and whose regularity witness is a* $\mathsf{RegSeqRat}^{\uparrow}$ *row factors through exactly the route*

StreamName finite-window ledger → *RegSeqRat pointwise handoff* → *DyadicRatCore observation row* → $\mathsf{RealUnar}$

before the local $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *row can be read. The terminal packet has no additional carrier coordinate for quotient-real equality, a selected host limit, ambient completeness, an off-ledger dyadic sample, or a direct* $\mathsf{Real}^{\uparrow}$ *seal edge bypassing either the StreamName source surface or the RegSeqRat regularity surface.*

Proof. Apply the pointwise seal composition of Definition 38.657. It sends any accepted seal-facing read with a StreamName source and RegSeqRat readback through the StreamName finite-window ledger, the RegSeqRat pointwise handoff, and the local real classifier-facing row.

Next apply the dyadic-window exhaustion of Definition 38.658. This identifies the only remaining classifier input as the DyadicRatCore observation row feeding $\mathsf{RealUnaryStreamClassifier}$, with no off-ledger dyadic sample and no ambient real-completion coordinate.

It remains only to read the terminal seal packet itself. Its carrier coordinates are the Real finite-window seal rows and the local $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ rows displayed in this chapter, so the preceding two exhaustion routes consume every available source, regularity, dyadic, and classifier coordinate before the local certificate is opened. Hence a quotient-real equality, selected host limit, ambient completeness row, or direct Real seal edge around StreamName or RegSeqRat has no coordinate from which to determine the terminal consumer. □

Theorem 38.660 (Real StreamName RegSeqRat common-refinement consumer lock)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing consumer whose source is a common-refinement* $\mathsf{StreamName}^{\uparrow}$ *window and whose regularity witness is* $\mathsf{RegSeqRat}^{\uparrow}$ *factors through the common-refinement terminal packet, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, then the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, and finally the local* $\mathsf{RealUnaryStreamClassifier}$ *row. The route exports no quotient-real equality, host sequence equality, selected host limit, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, independent* $\mathsf{Real}^{\uparrow}$ *carrier row, or metric-completeness datum.*

Proof. Begin with Definition 38.657. It sends any accepted Real seal-facing read with a StreamName source and RegSeqRat readback through the finite StreamName window, the regular-rational handoff, and the local Real classifier-facing row.

Next apply Definition 38.658. The dyadic observation row is the only classifier input left after the StreamName and RegSeqRat surfaces have been read.

Use Definition 38.659 to lock this route at the terminal seal boundary. The local $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$ row can be read only after the source, regularity, dyadic, and classifier coordinates have been consumed.

Now apply Definition 126.403. The common-refinement terminal packet supplies the StreamName window accepted by the terminal Real seal read. Then Definition 126.404 keeps the RegSeqRat readback on that same common window, and Definition 126.405 identifies the resulting seal route with the common-refinement handoff.

The assembled route therefore reaches the Real classifier only through the common-refinement packet, the RegSeqRat readback, and the DyadicRatCore observation row. None of the cited packets contains a coordinate for quotient-real equality, host sequence equality, selected host limits, ambient Real completeness, independent Real carrier rows, or metric-completeness data, so no terminal consumer can read one from this handoff. □

Theorem 38.661 (Real StreamName RegSeqRat common-refinement seal uniqueness)**.** *Let C_0 and C_1 be accepted terminal* $\mathsf{Real}^\uparrow$ *seal-facing consumers. Suppose C_i is read through a* $\mathsf{StreamName}^\uparrow$ *common-refinement window W_i with a* $\mathsf{RegSeqRat}^\uparrow$ *readback row, a* $\mathsf{DyadicRatCore}^\uparrow$ *observation row, and a local* RealUnaryStreamClassifier *endpoint, all carried by the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support. Suppose further that W_0 and W_1 both transport to one shared common-refinement packet W_*, and that after this transport their* $\mathsf{RegSeqRat}^\uparrow$ *readbacks and* $\mathsf{DyadicRatCore}^\uparrow$ *observation rows agree on W_*.*

Then the two local RealUnaryStreamClassifier *endpoints are* hsame*-equal at the shared refinement boundary, and C_0 and C_1 determine one terminal finite* $\mathsf{Real}^\uparrow$ *seal route. The assertion is only this common-refinement uniqueness statement. It excludes quotient-real equality, host sequence equality, selected host limits, ambient completeness, independent* $\mathsf{Real}^\uparrow$ *carrier rows, metric-completeness data, and standard-bridge rows.*

Proof. Apply Definition 38.663 to C_0 and C_1. This sends each terminal consumer through the same four types of displayed faces: its StreamName finite-window ledger, its RegSeqRat pointwise handoff, its DyadicRatCore observation row, and its local RealUnaryStreamClassifier endpoint with the local $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$ row.

Next use Definition 38.660. It forces both terminal reads to pass through the common-refinement terminal packet before the RegSeqRat readback, DyadicRatCore observation, and local Real classifier rows are consumed.

Transport the two factorizations along the displayed maps from W_0 and W_1 to W_*. By hypothesis the transported RegSeqRat readbacks and DyadicRatCore observation rows agree on this shared StreamName window, so the only remaining local Real boundary coordinate is the transported RealUnaryStreamClassifier endpoint.

Now apply Definition 38.664. With the StreamName common-refinement window, RegSeqRat readback, DyadicRatCore observation, and local $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$ support fixed on W_*, the two classifier endpoints are hsame-equal at the shared boundary.

Finally apply Definition 38.662. The hsame-identified classifier endpoints, together with the shared StreamName, RegSeqRat, DyadicRatCore, Cont, Pkg, and NameCert rows, determine one terminal finite $\mathsf{Real}^\uparrow$ seal route. The cited pullback separation also rules out any appeal to quotient-real equality, host sequence equality, selected limits, ambient completeness, independent Real carrier rows, metric-completeness data, or standard-bridge rows. □

Theorem 38.662 (Real StreamName RegSeqRat terminal pullback separation)**.** *Let C_0 and C_1 be terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing consumers whose sources are common-refinement* $\mathsf{StreamName}^{\uparrow}$ *windows and whose readbacks are* $\mathsf{RegSeqRat}^{\uparrow}$ *rows. Suppose that C_0 and C_1 share the same common-refinement* $\mathsf{StreamName}^{\uparrow}$ *window, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, and the same local* RealUnaryStreamClassifier *row, with the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support carried by those four faces. Then C_0 and C_1 determine the same terminal finite* $\mathsf{Real}^{\uparrow}$ *seal route.*

Conversely, any equality of terminal finite $\mathsf{Real}^{\uparrow}$ *seal routes between such consumers factors back through those four faces: the common-refinement StreamName window, the RegSeqRat readback row, the DyadicRatCore observation row, and the local Real classifier row with its displayed history, continuity, package, and local-name support. The separation statement asserts only this terminal finite route. It does not identify quotient-real equalities, host sequence equalities, selected host limits, ambient completeness rows, independent Real carrier rows, metric-completeness data, or standard-bridge rows.*

Proof. Apply Definition 38.659 to each consumer. This sends both terminal reads through the four displayed faces before the local $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ row is inspected, so the two consumers have no terminal seal coordinate outside the StreamName, RegSeqRat, DyadicRatCore, and local Real classifier surfaces.

Next use Definition 126.403. The shared common-refinement StreamName window supplies the same finite terminal packet for both consumers, including the visible history rows, transports, package provenance, and local names that feed the downstream Real seal.

Then apply Definition 126.404 and Definition 126.405. These two results lock the RegSeqRat readback, the DyadicRatCore observation row, and the Real seal route to the same common-refinement pullback. Hence equality at the terminal Real seal boundary is witnessed by equality on the four displayed faces, and every equality of such terminal finite seal routes pulls back to those faces.

Finally apply Definition 38.660. It rules out bypass coordinates for quotient-real equality, host sequence equality, selected host limits, ambient completeness, independent Real carrier rows, metric-completeness data, or standard-bridge rows. The terminal pullback therefore separates precisely the finite Real seal route and nothing outside the displayed handoff. □

Theorem 38.663 (StreamName RegSeqRat RealUp finite-window factorization)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *L10 finite-window seal read whose source is a* $\mathsf{StreamName}^{\uparrow}$ *window and whose regularity witness is a* $\mathsf{RegSeqRat}^{\uparrow}$ *row factors through exactly the four displayed faces*

StreamName finite-window ledger → RegSeqRat pointwise handoff → DyadicRatCore observation and tolerance ro

The factorization is finite and uses only the displayed BHist, hsame, Cont, Pkg, *and* NameCert *coordinates on those faces. It exports no quotient stream, host sequence equality, selected limit, ambient completeness, metric-completion datum, off-ledger dyadic sample, or direct* $\mathsf{Real}^{\uparrow}$ *seal edge outside the four-face route.*

Proof. Start with the pointwise seal composition of Definition 38.657. It puts the accepted seal-facing read on the StreamName finite-window ledger, then on the RegSeqRat pointwise handoff, and only then on the local Real classifier-facing row.

Next apply the dyadic-window exhaustion theorem, Definition 38.658. This identifies the remaining classifier input with the DyadicRatCore observation and tolerance row and rules out any off-ledger dyadic sample before the Real classifier is read.

Use the terminal seal exhaustion theorem, Definition 38.659, to attach the local $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$ row after the source, regularity, dyadic, and classifier coordinates have been consumed. The terminal packet therefore has no unused coordinate from which to read quotient stream data, host sequence equality, selected limits, ambient completeness, or metric-completion data.

Finally compare this packet with the ordered L10 dependency lattice of Definition 38.442. The open-phase sibling route, Definition 38.530, reads the same StreamName, RegSeqRat, DyadicRatCore, and local Real faces and no other source surface. Repacking the three seal-exhaustion results along that route gives the claimed finite-window factorization. □

Theorem 38.664 (Real finite-window classifier endpoint determinacy)**.** *For every accepted* $\mathsf{Real}^\uparrow$ *finite-window seal read whose source is a* $\mathsf{StreamName}^\uparrow$ *window and whose regularity witness is a* $\mathsf{RegSeqRat}^\uparrow$ *row, the displayed classifier endpoint is unique up to* hsame *once the four faces of Definition 38.663 are fixed: the StreamName finite-window ledger, the RegSeqRat pointwise handoff, the DyadicRatCore observation and tolerance row, and the local* RealUnaryStreamClassifier *row with* $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$.

Equivalently, any two endpoint reads using those same four displayed faces are related by the same finite BHist*,* Cont*,* Pkg*, and* NameCert *rows, and their endpoint witnesses are* hsame*-equal at the classifier boundary. No quotient-real equality, host sequence equality, selected host limit, ambient completeness row, or metric-completion datum can separate the two endpoints.*

Proof. Apply Definition 38.663 to the two endpoint reads. Both reads are sent to the same four displayed faces, so their finite StreamName ledger rows, RegSeqRat handoff rows, and local $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$ rows are compared inside the displayed BHist, Cont, and Pkg coordinates rather than through an ambient Real carrier.

Next use Definition 38.658. It fixes the dyadic classifier input by the shared DyadicRatCore observation and tolerance row, leaving no off-ledger dyadic sample that could distinguish one classifier endpoint from the other.

Finally use Definition 38.659 to lock the terminal seal boundary. Repacking the shared finite rows through the local RealUnaryStreamClassifier gives the same displayed endpoint up to hsame, and the terminal packet contains no coordinate for quotient-real equality, host sequence equality, selected limits, ambient completeness, or metric-completion data. □

Theorem 38.665 (Real terminal common-tail cocycle boundary)**.** *Let P be an accepted* $\mathsf{RegSeqRat}^\uparrow$ *packet, and let T_0, T_1, and T_2 be three certified cofinal tail shifts of the* $\mathsf{StreamName}^\uparrow$ *schedule carried by P. Suppose each shifted pair (T_i, T_j) lands in a common-tail window packet and that the three pairwise packets restrict to one triple* $\mathsf{StreamName}^\uparrow$ *refinement W_* carrying the displayed* $\mathsf{StreamName}^\uparrow$*,* $\mathsf{DyadicRatCore}^\uparrow$*,* $\mathsf{RegSeqRat}^\uparrow$*,* $\mathsf{Real}^\uparrow$*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Then the terminal $\mathsf{Real}^\uparrow$ *seal boundaries induced by the three pairwise common-tail packets agree exactly when those displayed rows satisfy Definition 301.190 on W_*. The boundary statement is only this finite terminal seal comparison. It excludes quotient streams, host sequence equality, selected limits, countable choice, ambient completeness, metric-completeness rows, and extra seal coordinates.*

Proof. Apply Definition 38.663 to each pairwise common-tail packet. Every terminal boundary read is thereby sent through the same four displayed faces: the StreamName finite-window ledger, the RegSeqRat pointwise handoff, the DyadicRatCore observation and tolerance row, and the local Real classifier row with its $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$ provenance.

Next use Definition 38.664. Once those four faces agree on the triple refinement W_*, the Real classifier endpoint at each pairwise boundary is determined up to the displayed hsame row and

cannot be separated by host sequence equality, selected limits, ambient completeness, or metric-completion data.

Now apply Definition 38.662. Any agreement of terminal finite $\mathsf{Real}^{\uparrow}$ seal routes pulls back to the same common-refinement StreamName window, RegSeqRat readback row, DyadicRatCore observation row, and local Real classifier row, with the displayed Cont, Pkg, and NameCert support.

Finally invoke Definition 301.190. Its triple-overlap criterion is exactly the equality of the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows on W_*. Therefore the three terminal $\mathsf{Real}^{\uparrow}$ seal boundaries agree exactly in the cocycle case, and the absence of quotient streams, host sequence equality, selected limits, countable choice, ambient completeness, metric-completeness rows, and extra seal coordinates follows from the same displayed-row inventory. □

Theorem 38.666 (RealUp StreamName RegSeqRat source lattice)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *source-lattice read used by a Phase Real or Completion consumer factors through the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule of chapter 126, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row of chapter 301, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger of chapter 291 before the Real seal is public. The read exposes only the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *coordinates carried by those sibling surfaces and the local* $\mathsf{Real}^{\uparrow}$ *seal package.*

In particular, the accepted source lattice contains no quotient real equality, selected representative, ambient completeness coordinate, or direct public Real seal edge bypassing the StreamName, RegSeqRat, and DyadicRatCore rows.

Proof. Start with an accepted $\mathsf{Real}^{\uparrow}$ source-lattice read. The local Real boundary only accepts the finite-window package already routed through the displayed stream, regular-rational, dyadic-tolerance, transport, continuation, provenance, and naming rows.

First read the source schedule through chapter 126. This fixes the visible finite-window row and its unary-history observations before any regular readback or Real seal row can be consumed.

Next read the regular-rational spine through chapter 301. The RegSeqRat row uses the same displayed window and supplies the regular readback surface on the common BHist, hsame, Cont, Pkg, and NameCert route.

Finally attach the tolerance ledger through chapter 291. The dyadic row is the only tolerance surface available to the Real seal package, so the public Real seal is reached only after the StreamName schedule, RegSeqRat readback, and DyadicRatCore ledger have all been displayed.

The composed source lattice therefore has no remaining coordinate from which to read quotient real equality, a selected representative, ambient completeness, or a direct seal edge around the sibling surfaces. □

Theorem 38.667 (Real StreamName RegSeqRat terminal budget stability)**.** *Let a terminal* $\mathsf{Real}^{\uparrow}$ *seal-facing consumer read its source as a common-refinement* $\mathsf{StreamName}^{\uparrow}$ *window, let its regularity witness be the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row on that same window, and let its precision request be served through* $\mathsf{RealObservationBudget}^{\uparrow}$*. Then restricting the request to a smaller finite observation budget, or enlarging it to a larger finite observation budget, preserves the same public finite source surface:*

$$\mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

The budget operation may change only which displayed finite observations are queried. It cannot add quotient-real equality, host sequence equality, a selected host limit, ambient Real completeness, an independent Real carrier, or metric-completeness data.

Proof. Start with the common-refinement source. The consumer lock Definition 38.660 fixes the terminal read on the shared StreamName, RegSeqRat, DyadicRatCore, and Real seal rows before the seal-facing consumer can inspect the packet.

Now attach the observation-budget route. The StreamName Real observation-budget factorization Definition 126.363 routes every accepted $\mathsf{RealObservationBudget}^{\uparrow}$ precision request through the same visible finite-window, dyadic, regular readback, and Real seal chain.

Finally use the carrier and non-escape rows of chapter 611. They make budget restriction or enlargement a change of displayed finite request rows, not a change of source carrier. Since the cited routes expose only the finite BEDC rows listed in the statement, none of the excluded analytic or host-level objects can enter the terminal seal-facing surface. □

Theorem 38.668 (Real StreamName RegSeqRat Dyadic source exhaustion)**.** *Every Phase Real and Completion* $\mathsf{Real}^{\uparrow}$ *source read of the accepted dependency lattice factors through exactly the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the local* $\mathsf{Real}^{\uparrow}$ *seal row. The factorization exposes only the finite packet coordinates already carried by those four surfaces and their shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *routes.*

Consequently the completion-facing source route contains no quotient stream, selected host limit, ambient completeness theorem, or hidden endpoint equality.

Proof. Begin with the accepted source-lattice route of Definition 38.666. It already decomposes the Real source read into the StreamName finite-window schedule, the RegSeqRat regular readback row, and the DyadicRatCore tolerance ledger before the local Real seal is public.

Next apply the terminal budget stability statement Definition 38.667. Changing the finite observation budget changes only which displayed source observations are queried; it does not add a carrier row outside the StreamName, RegSeqRat, DyadicRatCore, and Real seal packet.

It remains to exhaust the packet coordinates. The nearby source-route clauses give the visible BHist, hsame, Cont, Pkg, and NameCert rows for each of the four surfaces, while the Real seal row is reached only after those sibling rows have been displayed.

Thus every completion-facing source read is a coordinate projection of that finite packet. Since the packet has no coordinate for quotient streams, selected host limits, ambient completeness theorems, or hidden endpoint equalities, none of those objects can be read from the accepted source route. □

Theorem 38.669 (Real L10 source-lattice four-face equivalence)**.** *For a Phase Real and Completion* $\mathsf{Real}^{\uparrow}$ *source read, acceptance by the current source lattice is equivalent to exposing exactly the four local faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

together with their shared BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support. In this equivalence the* $\mathsf{DyadicRatCore}^{\uparrow}$ *face is the dyadic tolerance ledger, the* $\mathsf{StreamName}^{\uparrow}$ *face is the finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *face is the regular-rational readback row, and the local* $\mathsf{Real}^{\uparrow}$ *face is the seal row reached after those sibling faces.*

Both directions exclude quotient streams, selected limits, countable choice, metric completeness, aggregate formal status, bridge rows, and ambient $\mathsf{Real}^{\uparrow}$ *completeness as source-surface data.*

Proof. For the forward direction, start with an accepted Phase Real and Completion $\mathsf{Real}^{\uparrow}$ source read. The source-lattice theorem Definition 38.666 places the read on the StreamName finite-window schedule, the RegSeqRat readback row, and the DyadicRatCore tolerance ledger before the local Real seal is public.

Next apply terminal budget stability, Definition 38.667. It says that changing the finite observation request changes only displayed finite rows, so no additional source carrier or classifier can appear at the seal-facing boundary. The dyadic source exhaustion theorem Definition 38.668 then identifies the accepted read with exactly the four faces and shared BHist, hsame, Cont, Pkg, and NameCert support named in the statement.

For the reverse direction, assume exactly those four local faces and shared support are exposed. Apply Definition 291.83 to read the dyadic scale-window ledger as the same four-face pullback through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the local $\mathsf{Real}^{\uparrow}$ seal. Then apply Definition 301.175 to put the regular-rational exit consumer in the corresponding four-face normal form.

The local source-lattice route Definition 38.666 repacks that pullback and normal-form data as the accepted Real source read. Since the four exposed faces provide all displayed BHist, hsame, Cont, Pkg, and NameCert coordinates, the reconstructed read has the same source surface as the accepted Phase Real and Completion lattice.

The exclusion clause follows in both directions from the cited non-escape statements. None of the four-face pullback, the RegSeqRat normal form, or the local Real source-lattice route contains a coordinate for quotient streams, selected limits, countable choice, metric completeness, aggregate formal status, bridge rows, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 38.670 (Real dyadic StreamName RegSeqRat route)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *open-phase seal read whose source is presented to an L10 consumer as a* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation ledger, a* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, a* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row, and the local* $\mathsf{Real}^{\uparrow}$ *seal factors through one ordered finite route:*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The route is transported only by the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows of those four surfaces.*

No accepted read on this route exports quotient real equality, host limits, countable choice, ambient completeness, an independent host completion surface, or a direct local seal edge bypassing the dyadic, stream, and regular-rational rows.

Lean4 ✓ `BEDC.Derived.RealUp.RealDyadicStreamRegseqRoute`

Proof. Begin with the L10 interface totality theorem Definition 38.444. It already places every accepted Phase Real or Completion interface read on exactly the four visible faces of the Real L10 dependency lattice: DyadicRatCore observations, StreamName finite-window rows, RegSeqRat regular-rational rows, and the local Real seal.

Next apply the source lattice theorem Definition 38.666. It identifies the StreamName, RegSeqRat, and DyadicRatCore handoff as one source lattice before the Real seal is public, with only the displayed BHist, hsame, Cont, Pkg, and NameCert coordinates available for transport and packaging.

Finally use terminal budget stability, Definition 38.667. Changing the finite observation budget changes only which displayed finite rows are queried, not the carrier of the route. Thus the open-phase seal read remains on the single ordered finite route and has no coordinate for quotient real equality, host limits, countable choice, ambient completeness, host completion, or a direct seal bypass. □

Theorem 38.671 (Real dyadic StreamName RegSeqRat budget exactness)**.** *Let two accepted current Phase Real and Completion* $\mathsf{Real}^{\uparrow}$ *seal reads be presented on the ordered route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Suppose their finite observation budgets expose the same displayed $\mathsf{DyadicRatCore}^{\uparrow}$ *observations,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, local* $\mathsf{Real}^{\uparrow}$ *seal rows, and structural* BHist, hsame, Cont, Pkg, *and* NameCert *rows on their overlap. Then replacing one budget by the other, or refining either budget, changes only the displayed finite request rows. The accepted read remains the same four-face route from dyadic observations through finite stream windows and regular-rational readback to the local Real seal.*

In particular, this budget operation is not a quotient stream equality, host real equality, selected limit, countable-choice selector, ambient completeness principle, metric-completeness row, or direct $\mathsf{Real}^{\uparrow}$ *seal bypass.*

Proof. Apply Definition 38.670. Both accepted reads are already placed on the ordered finite route from $\mathsf{DyadicRatCore}^{\uparrow}$ through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ to $\mathsf{Real}^{\uparrow}$, and the only transport rows available on the route are the displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Next apply Definition 38.444. It says that the current Phase Real and Completion interface has exactly the four visible faces listed in the statement. Since the two budgets agree on those faces and on the structural rows over their overlap, every common exposed request row projects to the same place in the L10 lattice.

Finally use Definition 38.667. Refining or replacing a finite observation budget changes the finite row display but does not add a new carrier, classifier, package row, or naming certificate. Row projection therefore preserves the same four-face acceptance route.

The exclusion clause is the non-escape part of the same three inputs. None of the displayed route, interface-totality, or terminal-budget rows contains a coordinate for quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric completeness, or a direct Real seal bypass, so a budget change cannot certify any of those routes. □

Theorem 38.672 (Real dyadic StreamName RegSeqRat seal equivalence)**.** *For a current Phase Real and Completion* $\mathsf{Real}^{\uparrow}$ *seal read, agreement of the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows,* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback rows, and local* $\mathsf{Real}^{\uparrow}$ *seal row, together with the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *coordinates, is equivalent to acceptance of the ordered four-face route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

This equivalence is internal to the finite dyadic-stream-regseq seal route. It does not assert quotient stream equality, host real equality, a selected limit, countable choice, metric completeness, ambient completion coordinates, or any direct seal edge outside the four displayed faces.

Proof. For the forward direction, start from agreement of the displayed dyadic, finite-window, regular-readback, and local seal rows, with the displayed BHist, hsame, Cont, Pkg, and NameCert coordinates fixed. Apply Definition 38.444 to restrict the current Phase Real and Completion read to the four visible L10 faces.

Next use Definition 38.666. It identifies the DyadicRatCore, StreamName, and RegSeqRat rows as the source lattice available before the local Real seal is accepted. The row agreement therefore has exactly the finite source data needed by the seal route.

Apply Definition 38.670. The matched source and seal rows are repacked as the ordered route

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

For the reverse direction, assume acceptance of the ordered four-face route. The route theorem exposes precisely the dyadic observations, finite stream windows, regular-rational readback rows, local seal row, and structural transport and package coordinates named in the statement.

Finally apply Definition 38.671. It says that replacing or refining the finite budget changes only the displayed request rows, so agreement on those rows is exactly the classifier agreement carried by the accepted finite dyadic-stream-regseq seal route.

The exclusion clause follows because the four cited inputs have no coordinate for quotient stream equality, host real equality, selected limits, countable choice, metric completeness, ambient completion, or a direct $\mathsf{Real}^{\uparrow}$ seal bypass. □

Theorem 38.673 (Real Cauchy window transducer seal route)**.** *Any* $\mathsf{Real}^{\uparrow}$ *seal read exported by an accepted* $\mathsf{CauchyWindowTransducer}^{\uparrow}$ *packet factors through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and then* $\mathsf{Real}^{\uparrow}$. *The transducer rows* $S, D, W, R, E, L, H, C, P, N$ *provide only finite route replay, and they provide no direct seal bypass.*

Proof. Apply Definition 38.670. It places the relevant Real-facing read on the ordered route from DyadicRatCore observations through StreamName finite windows and RegSeqRat regular readback to the Real seal.

Use Definition 1020.4. In an accepted Cauchy window transducer packet, the seal row E is public only after the RegSeqRat readback row R has been displayed.

Finally apply Definition 1020.5. The remaining rows S, D, W, L, H, C, P, N replay the finite route and bind transport, provenance, and local naming. They do not add a quotient Real equality, host limit, countable-choice row, ambient completeness row, or direct edge to the seal. □

Theorem 38.674 (Real StreamName RegSeqRat sibling nonorphan route)**.** *The Real seal route consumes the sibling chapter surfaces chapter 291, chapter 126, chapter 301, and chapter 1020 before the local* $\mathsf{Real}^{\uparrow}$ *seal is public. Thus the local Real route is a horizontal L10 dependency through dyadic observations, finite stream windows, regular-rational readback, and the Cauchy window transducer, not a self-reference and not a host-completion shortcut.*

Proof. Apply Definition 38.670. It places the Real-facing route on the ordered dyadic, StreamName, RegSeqRat, and Real seal surfaces, with only displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ coordinates available for transport.

Then apply Definition 38.673. The Cauchy window transducer seal read factors through the same dyadic, stream, and regular-rational route before the local Real seal is exposed.

These two routes cite sibling chapter surfaces rather than the local Real chapter as their source. The dependency is therefore horizontal in the L10 lattice and cannot be replaced by a Real self-reference, selected host limit, ambient completion object, or direct seal bypass. □

Theorem 38.675 (Real terminal four-face open-phase exit)**.** *Every current Phase Real and Completion terminal* $\mathsf{Real}^{\uparrow}$ *seal read is accepted exactly when its visible rows factor through the ordered four-face route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

displayed by the Real L10 dependency lattice. The visible coordinates of the exit read are only the displayed BHist *packet, the displayed* hsame *transports, the displayed* Cont *routes, the displayed* Pkg *provenance rows, and the displayed* $\mathsf{NameCert}$ *rows on those four faces.*

Thus no terminal exit read is accepted by quotient stream equality, countable choice, host limits, metric completeness, ambient completion, host real equality, or any direct edge to the $\mathsf{Real}^{\uparrow}$ *seal outside the displayed four-face route.*

Proof. Suppose first that a current Phase Real or Completion terminal $\mathsf{Real}^{\uparrow}$ seal read is accepted. Apply Definition 38.670. It places the accepted seal read on the ordered dyadic, StreamName,

RegSeqRat, and Real route and restricts transport to the displayed BHist, hsame, Cont, Pkg, and NameCert coordinates.

Next apply Definition 38.674. The route is therefore sourced by the sibling DyadicRatCore, StreamName, RegSeqRat, and Cauchy-window-transducer surfaces before the local Real seal is public. This rules out a local self-reference or a host-completion shortcut as the source of acceptance.

Now read the same terminal packet through the Real L10 dependency lattice, using Definition 38.442 and Definition 38.444. The lattice gives exactly the four displayed faces, and interface totality says that current Phase Real and Completion reads have no fifth visible coordinate.

Conversely, suppose that the visible rows of a terminal read factor through that ordered four-face route with only the displayed BHist, hsame, Cont, Pkg, and NameCert coordinates. The route theorem supplies the accepted Real seal handoff, and the sibling nonorphan route supplies the horizontal source through the dyadic, stream, regular-rational, and transducer surfaces. The Real L10 interface totality theorem then repacks that handoff as the current Phase Real and Completion terminal surface.

The exclusion clause follows from the same three inputs. None of the route, sibling, or L10 lattice rows exports quotient stream equality, countable choice, host limits, metric completeness, ambient completion, host real equality, or a direct seal bypass, so none of those data can certify a terminal exit read. □

Theorem 38.676 (Real current-phase four-face exit certificate)**.** *A current Phase Real and Completion public read of the* $\mathsf{Real}^{\uparrow}$ *seal is accepted if and only if its visible rows factor through the four-face route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

using exactly the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows on that route.*

Any purported completion-facing read that uses quotient stream equality, countable choice, host limits, metric completeness, ambient completion, host real equality, or a direct $\mathsf{Real}^{\uparrow}$ *seal bypass is rejected by the current Phase Real and Completion surface.*

Proof. For the forward direction, apply Definition 38.675. It sends every accepted terminal $\mathsf{Real}^{\uparrow}$ seal read to the ordered four-face route and restricts the visible coordinates to the displayed BHist, hsame, Cont, Pkg, and NameCert rows.

For the converse direction, use the same theorem in the reverse direction: visible rows on the ordered four-face route, with no extra coordinate, repack as the current Phase Real and Completion terminal surface.

Now apply Definition 38.670. It identifies the route as the finite handoff from DyadicRatCore observations through StreamName finite windows and RegSeqRat regular readback to the local $\mathsf{Real}^{\uparrow}$ seal. Apply Definition 38.674 to record that the handoff is horizontal through the sibling surfaces, not a local Real self-reference and not a host-completion shortcut.

Finally use Definition 38.444. The Real L10 interface has no fifth public coordinate beyond the displayed faces. Hence a purported read using quotient stream equality, countable choice, host limits, metric completeness, ambient completion, host real equality, or a direct Real seal bypass has no accepting coordinate on the current Phase Real and Completion surface. □

Theorem 38.677 (Real four-face terminal cover pullback)**.** *Let a finite family of current Phase Real and Completion terminal* $\mathsf{Real}^{\uparrow}$ *seal reads be displayed over one terminal cover. Suppose that on every pairwise overlap the visible rows agree on the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational classifier rows, and the local*

$\mathsf{Real}^{\uparrow}$ *seal rows, together with the displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *coordinates. Assume also that on every triple overlap the two restriction routes from each local read to the common section coincide:*

$$(\mathcal{R}_i|_{ij})|_{ijk} = (\mathcal{R}_i|_{ik})|_{ijk}, \qquad (\mathcal{R}_i|_{ij})|_{ijk} = (\mathcal{R}_j|_{ij})|_{ijk}.$$

Then the whole family pulls back to one ordered terminal four-face route

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The resulting terminal surface has no coordinate for quotient stream equality, host real equality, countable choice, ambient completion, metric-completeness rows, or a direct $\mathsf{Real}^{\uparrow}$ *seal bypass.*

Proof. Apply Definition 38.676 to each member of the finite terminal cover. Each accepted seal read is therefore already presented by the ordered dyadic, stream, regular-rational, and local Real faces, with only the displayed structural rows available.

The pairwise overlap agreement and the triple-overlap route coherence are the cocycle data required by Definition 38.821. Applying that theorem pastes the finite family to a unique public $\mathsf{Real}^{\uparrow}$ terminal-seal read whose restrictions are the displayed local reads. Reading this pasted seal through the preceding normal-form certificate presents it as the ordered terminal four-face route

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Finally apply Definition 38.444. The dependency lattice supplies no fifth route beside the four displayed faces, so the cover repackages as one terminal four-face surface and excludes quotient stream equality, host real equality, countable choice, ambient completion, metric-completeness rows, and direct seal bypasses. □

Theorem 38.678 (Real four-face terminal cover overlap compatibility)**.** *Let* C_0 *and* C_1 *be two finite families of current Phase Real and Completion terminal* $\mathsf{Real}^{\uparrow}$ *seal reads. Suppose each family satisfies the hypotheses of Definition 38.677. Suppose further that on a shared subcover the two families agree on the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational classifier rows, the local* $\mathsf{Real}^{\uparrow}$ *seal rows, and the same* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *support coordinates. Then the two pulled-back terminal four-face routes have the same public* $\mathsf{Real}^{\uparrow}$ *seal classifier surface on that shared subcover.*

This compatibility is only a finite four-face statement. It does not identify quotient streams, host reals, selected limits, countable-choice witnesses, ambient completions, metric-completeness witnesses, or any direct bypass of the local $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Apply Definition 38.677 to C_0 and C_1. This presents both terminal covers over ordered routes

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

with only the displayed structural rows available.

On the shared subcover, use Definition 126.108. Agreement of the $\mathsf{DyadicRatCore}^{\uparrow}$ observation rows and the $\mathsf{StreamName}^{\uparrow}$ finite-window rows identifies the same finite-window source for both pulled-back routes.

Next transport the classifier surface through the shared rows. Apply Definition 38.672 to pass between the dyadic, stream, regular-rational, and local Real seal presentations, and apply Definition 38.671 to keep the BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ coordinates exact on the same subcover.

Finally apply Definition 38.444. Since the current Phase Real and Completion interface has no fifth public coordinate, there is no additional route through quotient stream equality, host real equality, selected limits, countable choice, ambient completion, metric-completeness witnesses, or a direct Real seal bypass. The transported classifier agreement is therefore exactly equality of the public $\mathsf{Real}^{\uparrow}$ seal classifier surface on the shared subcover. □

Theorem 38.679 (Real four-face terminal cover classifier finality)**.** *Let C_0 be a finite terminal cover of current Phase Real and Completion* $\mathsf{Real}^{\uparrow}$ *seal reads satisfying the hypotheses of Definition 38.677. Let C_1 be a second finite terminal presentation of the same terminal read support. Suppose that C_1 also satisfies those hypotheses, and that C_0 and C_1 agree on the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and readback rows, the local* $\mathsf{Real}^{\uparrow}$ *seal rows, and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support coordinates. Then C_0 and C_1 determine one and the same public* $\mathsf{Real}^{\uparrow}$ *seal classifier surface.*

This finality is only over the terminal four-face cover

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

It excludes quotient stream equality, host real equality, selected limits, countable choice, ambient completion, metric-completeness rows, and any direct $\mathsf{Real}^{\uparrow}$ *seal bypass from the data that can affect the public classifier surface.*

Proof. Apply Definition 38.677 separately to C_0 and C_1. The two presentations therefore pull back to terminal four-face routes with the same displayed dyadic, stream, regular-rational, local Real, and structural support rows.

On every common part of the cover, use Definition 38.678. The agreement of the DyadicRatCore observations, StreamName windows, RegSeqRat classifier and readback rows, local Real seal rows, and displayed support coordinates identifies the public $\mathsf{Real}^{\uparrow}$ seal classifier surface on each overlap.

Next pass through the four named faces. Apply Definition 38.672 to identify the classifier surface obtained from the dyadic, stream, regular-rational, and local Real presentations.

Finally apply Definition 38.444. The current Phase Real and Completion dependency lattice exposes no fifth public coordinate, so quotient stream equality, host real equality, selected limits, countable choice, ambient completion, metric-completeness rows, and direct Real seal bypasses have no classifier input. The overlap-compatible four-face surface is therefore the unique public $\mathsf{Real}^{\uparrow}$ seal classifier surface determined by the two presentations. □

Theorem 38.680 (Real four-face terminal subcover localization)**.** *Let C be a finite terminal cover of current Phase Real and Completion* $\mathsf{Real}^{\uparrow}$ *seal reads satisfying the hypotheses of Definition 38.677. Let D be any displayed finite subcover whose local rows, overlap rows, and triple-overlap restriction routes are inherited from C. Then D pulls back to the same ordered terminal four-face route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Its public $\mathsf{Real}^{\uparrow}$ *seal classifier surface is the restriction of the classifier surface determined by C to the displayed subcover rows. In particular, the localized cover still has no coordinate for quotient stream equality, host real equality, selected limits, countable choice, ambient completion, metric-completeness rows, or a direct* $\mathsf{Real}^{\uparrow}$ *seal bypass.*

Proof. Apply Definition 38.677 to the ambient cover C. This presents every accepted row of C on the ordered dyadic, stream, regular-rational, and local Real route, with only the displayed BHist, hsame, Cont, Pkg, and NameCert support coordinates.

Because D inherits its rows and restriction routes from C, its pairwise overlap agreement and triple-overlap coherence are just the corresponding ambient equalities restricted to the chosen finite subcover. Applying Definition 38.677 to those inherited data pastes D to the same ordered route

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Now use Definition 38.678 with the ambient cover and the displayed subcover. Their rows agree on the subcover by inheritance, so the public $\mathsf{Real}^{\uparrow}$ seal classifier surface for D is exactly the restriction of the classifier surface obtained from C.

Finally apply Definition 38.679 and Definition 38.444. Finality makes the restricted classifier independent of the chosen terminal presentation, and interface totality rules out any fifth coordinate. Hence quotient stream equality, host real equality, selected limits, countable choice, ambient completion, metric-completeness rows, and direct Real seal bypasses remain outside the localized terminal surface. □

Theorem 38.681 (Real dyadic tail-radius ledger dependency)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *seal-facing consumer that uses the dyadic tail-radius route first factors through chapter 757 before the local* $\mathsf{Real}^{\uparrow}$ *seal row is consumed. When the same consumer is completion-facing and reads a witness ledger, it also factors through chapter 902 before the completion-facing* $\mathsf{Real}^{\uparrow}$ *seal row is consumed.*

Equivalently, the admitted finite route is confined to the displayed chain

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicTailRadiusLedger}^{\uparrow} \to \mathsf{CauchyWitnessLedger}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

with the $\mathsf{CauchyWitnessLedger}^{\uparrow}$ *row present only for completion-facing witness reads. The route exports no quotient stream equality, host real equality, selected external limit, countable choice, or ambient completeness principle.*

Proof. Begin with the Real dyadic StreamName RegSeqRat route of Definition 38.670. It places every accepted open-phase seal read whose source is presented through dyadic observations, finite StreamName windows, and regular-rational readback on the ordered route $\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$.

Next apply the DyadicTailRadiusLedger finite route package from Definition 757.14. Its carrier inserts the finite precision request, tail-window ledger, StreamName windows, dyadic readback, RegSeqRat handoff, and Real seal row into one ledger route. Thus a seal-facing consumer using the dyadic tail-radius route cannot reach the Real seal before that ledger has been consumed.

For completion-facing witness reads, apply the CauchyWitnessLedger budget factorization and Real completion handoff, Definition 902.5 and Definition 902.9. These force the consumer through the finite witness ledger before the completion-seal classifier and the Real-facing completion read are available.

Finally combine the non-escape boundaries of the three routes: Definition 38.670, Definition 757.7, and Definition 902.18. Since none of the composed carriers has a coordinate for quotient stream equality, host real equality, selected external limits, countable choice, or ambient completeness, the composed Real dependency route exports none of them. □

Theorem 38.682 (Real dyadic tail-radius seal determinacy)**.** *Let two accepted* $\mathsf{Real}^{\uparrow}$ *seal-facing consumers use the dyadic tail-radius route. If they expose the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius rows, the same* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff rows, the same* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *route, the same* $\mathsf{CauchyWitnessLedger}^{\uparrow}$ *witness row whenever the read is completion-facing, and the same displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *support rows, then they determine the same finite* $\mathsf{Real}^{\uparrow}$ *seal boundary.*

Conversely, every admitted $\mathsf{Real}^{\uparrow}$ *seal boundary that uses this dyadic tail-radius route is read through exactly those rows: dyadic endpoint and radius data, finite StreamName windows, regular-rational handoff, tail-radius ledger route, the completion-facing witness row when present, and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support. The statement does not assert* $\mathsf{Real}^{\uparrow}$ *completeness, quotient-stream equality, host real equality, selected external limits, countable choice, or metric-completion equality.*

Proof. First apply Definition 38.681. It fixes the ordered dependency route

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{DyadicTailRadiusLedger}^{\uparrow} \to \mathsf{CauchyWitnessLedger}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

with the witness-ledger row present only for completion-facing reads. Thus two accepted consumers with the same displayed rows have the same ordered route to the Real seal.

Next use Definition 38.670. The initial segment of the route is already determined by the dyadic observations, finite StreamName windows, RegSeqRat regular readback, and the structural BHist, hsame, Cont, Pkg, and NameCert rows. Hence the two consumers cannot differ before the tail-radius ledger is reached.

Now apply Definition 757.14 together with Definition 757.7. The package fixes the finite tail-radius packet on the route, and non-escape prevents an additional quotient, host-equality, selected-limit, unbounded-search, independent-ledger, or ambient-completeness coordinate from entering the seal boundary.

For completion-facing reads, apply Definition 902.5, Definition 902.9, and Definition 902.18. These place the witness row behind the finite budget route, hand it to the Real completion-facing consumer through the displayed support rows, and exclude quotient streams, host Real equality, selected external limits, countable choice, and ambient completeness from the read.

The forward determinacy follows because every row on the seal-facing route has been fixed componentwise. The converse follows by reading any admitted boundary through the same factorization and non-escape results: there is no public coordinate outside the listed finite dyadic, StreamName, RegSeqRat, tail-radius, witness-ledger, and structural support rows, so the listed rows are exactly the finite $\mathsf{Real}^{\uparrow}$ seal boundary for this route. □

Theorem 38.683 (RealUp RegSeqRat StreamName sibling route)**.** *Every public* $\mathsf{Real}^{\uparrow}$ *seal read that uses the regular-Cauchy presentation first consumes the sibling surfaces of chapter 126 and chapter 301, together with the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance surface of chapter 291, before the RealUp name is public. The route is transported only through the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows carried by those sibling surfaces and the local* $\mathsf{Real}^{\uparrow}$ *seal packet.*

The public seal read exports no quotient-real equality, selected host limit, ambient completeness coordinate, hidden dyadic tolerance sample, or direct $\mathsf{Real}^{\uparrow}$ *name edge bypassing StreamName and RegSeqRat.*

Proof. Begin with the Real StreamName-RegSeqRat crosslink of Definition 38.657. It routes any seal-facing read with a StreamName source and a RegSeqRat readback through the visible StreamName finite-window ledger and the RegSeqRat pointwise handoff before the local real classifier is consumed.

Next use Definition 38.666. This places the StreamName and RegSeqRat rows inside a common source lattice and attaches the DyadicRatCore tolerance ledger before the Real seal becomes public.

Finally apply Definition 38.670. The ordered route

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

is the only open-phase seal route available to the L10 consumer. Since the cited packets expose only the displayed finite carrier, classifier, transport, packaging, and certificate rows, the public RealUp name has no coordinate for quotient-real equality, selected host limits, ambient completeness, hidden dyadic samples, or a direct seal bypass. □

Theorem 38.684 (Real RegSeqRat StreamName lattice route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *finite-window seal route used by Phase Real and Completion consumes a* $\mathsf{StreamName}^{\uparrow}$ *finite window, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger through the sibling chapters chapter 126, chapter 301, and chapter 291 before the local* $\mathsf{Real}^{\uparrow}$ *seal row is public. The route is a horizontal lattice edge through those sibling surfaces and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, not a quotient stream, selected limit, host sequence equality, or* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with Definition 38.530. It already places every public $\mathsf{Real}^{\uparrow}$ seal read in the open phase after the StreamName, RegSeqRat, and DyadicRatCore sibling surfaces.

Next apply Definition 38.666. The lattice identifies the finite StreamName schedule, regular-rational readback, and dyadic tolerance ledger as the source rows that must be consumed before the local Real seal is exposed.

Use Definition 38.670 to align those rows into one route. The dyadic observations, StreamName finite window, RegSeqRat readback, and Real seal remain a single finite BEDC path rather than independent analytic witnesses.

Finally apply Definition 38.674. It confirms that the Real route is read through the same sibling chapters and exports no quotient stream, selected host limit, host sequence equality, ambient completeness row, or direct seal bypass. □

Definition 38.685 (Real name seal carrier)**.** *A* $\mathsf{Real}^{\uparrow}$ *name-seal carrier is a finite* BHist *packet*

$$R = (D, S, Q, L, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row recording the endpoint, radius, and finite tolerance data available to the read;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule that exposes the requested observations;*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row that records the pointwise regular-rational readback;*
4. *L is the finite ledger tying the selected windows, dyadic observations, radius rows, and regularity checks to one request surface;*
5. *E is the local* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after D, S, Q, L have been displayed;*
6. *H records the componentwise* hsame *transports for D, S, Q, L, E, C, P, N;*
7. *C records the displayed* Cont *routes from the finite-window schedule through the dyadic and regularity rows to the seal row;*
8. *P records* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *row for this name-seal packet.*

The carrier has no coordinate for a quotient stream, a selected host limit, host real equality, host sequence equality, or an ambient completeness theorem.

Lean4 (definition) `BEDC.Derived.RealUp.RealNameSealCarrier`

Theorem 38.686 (Real name seal source factorization)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read accepted through the carrier of Definition 38.685 factors through the displayed source route*

$$S, D, Q, L \longmapsto E$$

together with the visible BHist, hsame, Cont, Pkg, *and* NameCert *rows. Equivalently, the seal may be read only after the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row, and the finite ledger have all been consumed through the same packet.*

Lean4 ✓ `BEDC.Derived.RealUp.RealNameSeal source factorization`

Proof. Project the accepted packet through Definition 38.685. The only seal coordinate is E, and the only source rows that lead to it are S, D, Q, L with the transport, continuation, package, and naming rows H, C, P, N.

The route is the local RealUp form of Definition 38.684. That theorem places the Phase Real and Completion seal path behind the StreamName, RegSeqRat, and DyadicRatCore sibling surfaces before the local seal is public.

The RegularCauchyName seal results provide the readback discipline used by the same boundary. Apply Definition 371.15, Definition 371.18, and Definition 371.24: a real-seal consumer is downstream of the displayed finite window, dyadic observation, regularity ledger, package provenance, and local NameCert rows. Repacking those rows as $D, S, Q, L, E, H, C, P, N$ gives the stated factorization. □

Theorem 38.687 (Real name seal four-face coverage)**.** *For every accepted* $\mathsf{Real}^{\uparrow}$ *name-seal packet*

$$R = (D, S, Q, L, E, H, C, P, N)$$

of Definition 38.685, all public seal reads are exhausted by exactly the four finite faces

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The exhaustive route consists of the following displayed rows:

1. *the* BHist *packet rows* D, S, Q, L, E*;*
2. *the componentwise* hsame *transports in* H*;*
3. *the* Cont *routes in* C *from finite windows through dyadic observations and regular-rational rows to the local seal;*
4. *the* Pkg *provenance row* P *over the four faces and the structural rows;*
5. *the local* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *row* N *for this packet.*

No public read through R *has a coordinate for quotient stream equality, selected host limits, host real equality, host sequence equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, metric-completeness data, choice rows, or standard bridge rows.*

Proof. Project the packet through Definition 38.685. The carrier exposes exactly the dyadic observation row D, the finite-window row S, the regular-rational row Q, the finite ledger L, the local seal row E, and the structural rows H, C, P, N.

Apply Definition 38.686. Every public seal read must pass through $S, D, Q, L \longmapsto E$, with only the visible BHist, hsame, Cont, Pkg, and NameCert support rows.

The lattice and consumer-scope results identify the four faces of that route. Use Definition 38.684 and Definition 371.15 to place the accepted read behind the StreamName, RegSeqRat, DyadicRatCore, and local Real surfaces.

The face rows are the existing handoffs: Definition 126.301, Definition 291.18, Definition 301.22, and Definition 38.135. They account for the finite window, dyadic observation, regular-rational readback, and local seal faces.

Since Definition 38.685 has no fifth analytic coordinate, the listed four faces exhaust the accepted seal route. The excluded quotient, host-limit, host-equality, completeness, metric-completeness, choice, and standard-bridge rows are therefore not public reads of R. □

Theorem 38.688 (Real StreamName-RegSeqRat seal route)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *name-seal packet*

$$R = (D, S, Q, L, E, H, C, P, N)$$

of Definition 38.685 consumes the $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule* S*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row* Q*, and the ledger* L *before exposing the local seal row* E*. The resulting Phase Real and Completion exit route is the four-face route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

carried only by the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

The route exports no quotient stream equality, selected host limit, host real equality, host sequence equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness principle, metric-completeness datum, or choice row.*

Proof. Start with the carrier definition and the source factorization theorem, Definition 38.685 and Definition 38.686. They identify D, S, Q, L as the only source rows through which the accepted packet can reach E, with H, C, P, N as structural transport, replay, provenance, and naming rows.

Next apply the Real L10 sibling lattice summary. The ordered lattice of Definition 38.442, together with Definition 38.443 and Definition 38.444, places Phase Real and Completion consumers on the same DyadicRatCore, StreamName, RegSeqRat, and Real faces.

The four public faces provide the component rows. The StreamName face is the public finite-window interface of Definition 126.301; the DyadicRatCore face is the real-phase source coverage of Definition 291.18; the RegSeqRat face is the real-seal handoff of Definition 301.22; and the local Real face is finite-prefix exactness through Definition 38.135.

Composing those rows with the source factorization repacks the accepted read as the displayed route to E. Since each cited interface exposes only finite packet rows and the same structural support, no quotient stream equality, selected host limit, host real equality, host sequence equality, ambient Real completeness principle, metric-completeness datum, or choice row is exported. □

Theorem 38.689 (Real name seal NameCert obligations)**.** *For the carrier of Definition 38.685, the local* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the finite packet* $R = (D, S, Q, L, E, H, C, P, N)$*;*
2. *classifier transport by the displayed* hsame *rows over the dyadic observation, finite-window schedule, regularity row, finite ledger, and seal row;*
3. *stability of the same route under the displayed* Cont *rows;*
4. *ledger exhaustion by* D, S, Q, L *before the seal row* E *is public;*
5. *source factorization through Definition 38.686.*

Proof. Carrier admission is projection from the displayed tuple. The packet lists every public row available to the local RealUp name-seal read, so the carrier and classifier have no hidden coordinate beyond $D, S, Q, L, E, H, C, P, N$.

Transport and stability are componentwise. The H row moves the displayed source and seal rows, while the C row replays the same finite route from the StreamName schedule through the dyadic observation, RegSeqRat readback, ledger, and seal.

Ledger exhaustion is supplied by Definition 38.686 together with the RegularCauchyName exhaustion theorems cited there. Thus the local $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$ obligations are exactly carrier, classifier, stability, ledger, and source-factorization obligations. □

Theorem 38.690 (Real name seal classifier stability)**.** *Let*

$$R = (D, S, Q, L, E, H, C, P, N) \qquad \textit{and} \qquad R' = (D', S', Q', L', E', H', C', P', N')$$

be accepted $\mathsf{Real}^\uparrow$ *name-seal packets for the carrier of Definition 38.685. Suppose the displayed source rows* D, S, Q, L *and* D', S', Q', L' *and the seal rows* E, E' *are related componentwise by the* hsame *transports recorded in* H *and* H'*. Suppose also that the displayed* Cont *routes in* C *and* C' *preserve the same source reads from the finite-window schedule through the dyadic observation row, the regularity row, and the finite ledger. Then the local* $\mathsf{Real}^\uparrow$ *seal classifier presents the same public seal row for* R *and* R' *after passing through the* $\mathsf{DyadicRatCore}^\uparrow$ *observation, the* $\mathsf{StreamName}^\uparrow$ *schedule, the* $\mathsf{RegSeqRat}^\uparrow$ *regularity row, the finite ledger, and the local* $\mathsf{Real}^\uparrow$ *seal.*

This classifier equality has no coordinate for quotient streams, selected host limits, host equality, ambient completeness, metric-completeness data, or choice rows.

Proof. Project both accepted packets through Definition 38.685. The only analytic coordinates available to the classifier are the dyadic observation rows D, D', the finite-window schedules S, S', the regularity rows Q, Q', the ledgers L, L', and the seal rows E, E'; the rows $H, H', C, C', P, P', N, N'$ supply transport, replay, provenance, and naming data.

Apply Definition 38.686 to both packets. Each public seal read factors through the displayed route from the StreamName window, DyadicRatCore observation, RegSeqRat regularity row, and finite ledger before reaching the local seal. Apply Definition 38.689 to read the same route as the NameCert classifier-transport and route-stability surface.

Now compose the sibling faces of Definition 38.688. The StreamName face is fixed by Definition 126.301; the DyadicRatCore face is fixed by Definition 291.18; the RegSeqRat face is fixed by Definition 301.22; and the local Real face is fixed by Definition 38.135. The componentwise hsame rows identify the corresponding displayed rows, and the Cont rows replay the same source reads through those faces.

The two accepted packets therefore present the same finite public route to the seal classifier, hence the same public seal row. Since the carrier and the cited faces expose only those finite BEDC rows, no quotient stream, selected host limit, host equality, ambient completeness theorem, metric-completeness datum, or choice row can enter the classifier comparison. □

Theorem 38.691 (Real name seal classifier transitivity)**.** *Let*

$$R = (D, S, Q, L, E, H, C, P, N), \qquad R' = (D', S', Q', L', E', H', C', P', N'), \qquad R'' = (D'', S'', Q'', L'', E'', H'', C'',$$

be accepted $\mathsf{Real}^\uparrow$ *name-seal packets for the carrier of Definition 38.685. Suppose* R *and* R' *classify by the displayed Real name-seal route of Definition 38.690, and suppose* R' *and* R'' *classify by the same displayed route. Then* R *and* R'' *present the same public* $\mathsf{Real}^\uparrow$ *seal row through the common* $\mathsf{DyadicRatCore}^\uparrow$*,* $\mathsf{StreamName}^\uparrow$*,* $\mathsf{RegSeqRat}^\uparrow$*, finite-ledger,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

This composed classifier comparison exports no quotient stream, selected host limit, host equality, ambient completeness principle, metric-completeness data, or choice row.

Proof. Project the three accepted packets through Definition 38.685. The projection exposes only the displayed source rows D, S, Q, L, D', S', Q', L', D'', S'', Q'', L'', the seal rows E, E', E'', and the corresponding structural rows H, H', H'', C, C', C'', P, P', P'', and N, N', N''.

Apply Definition 38.686 to each packet and then apply Definition 38.689. Both accepted comparisons are forced onto the same source route: the finite-window schedule, dyadic observation row, regularity row, and finite ledger are consumed before the local seal row is public, and the NameCert surface records only carrier admission, classifier transport, route stability, ledger exhaustion, and source factorization.

Now use Definition 38.688. The two comparisons identify the same four public faces, namely $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The first comparison transports the displayed rows from R to R', and the second transports the displayed rows from R' to R''.

Compose the componentwise hsame transports along the shared middle packet and replay the two Cont routes through the same finite source reads. The package and naming rows remain on the same displayed route, so the comparison from R to R'' is again a comparison of the public Real seal classifier.

Finally apply Definition 38.690 to the composed comparison. The classifier therefore presents the same public seal row for R and R'', and every step stayed inside the finite carrier and the four public faces. No quotient stream, selected host limit, host equality, ambient completeness theorem, metric-completeness datum, or choice row is introduced. □

Theorem 38.692 (Real name seal terminal source uniqueness)**.** *Let*

$$R = (D, S, Q, L, E, H, C, P, N) \qquad \textit{and} \qquad R' = (D', S', Q', L', E', H', C', P', N')$$

be accepted $\mathsf{Real}^{\uparrow}$ *name-seal packets for the carrier of Definition 38.685. Suppose the two packets agree componentwise on the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row, the finite ledger, the local seal row, and the displayed* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows. Then every downstream* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer that reads through either accepted packet reads the same terminal finite* BHist *source surface*

$$(S, D, Q, L, E, H, C, P, N).$$

The terminal surface is only this displayed finite packet. It is not a quotient stream, a selected host limit, a host equality witness, an ambient completeness principle, metric-completeness data, or a choice row.

Proof. Project both accepted packets through Definition 38.685. The projection exposes exactly the source rows S, D, Q, L, the seal row E, and the structural rows H, C, P, N; the primed packet exposes the corresponding primed rows and no additional analytic coordinate.

Apply Definition 38.686 to each packet. Any $\mathsf{Real}^{\uparrow}$ seal read, and hence any $\mathsf{RegSeqRat}^{\uparrow}$ consumer entering the local Real seal route, must pass through the displayed source rows before the seal row is public.

Next compose the four public faces of Definition 38.688. The $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces carry the same finite BHist route because the two packets agree on the corresponding source, ledger, transport, continuation, package, and naming rows.

Finally use Definition 38.690. The stability theorem identifies the visible seal row presented by the two accepted packets, so every downstream consumer sees the same terminal finite source

surface. Since each step was taken inside the carrier and the four public faces, no quotient stream, selected host limit, host equality, ambient completeness principle, metric-completeness datum, or choice row is introduced. □

Theorem 38.693 (Real finite-prefix readback uniqueness)**.** *Let*

$$R = (D, S, Q, L, E, H, C, P, N) \qquad \textit{and} \qquad R' = (D', S', Q', L', E', H', C', P', N')$$

be accepted $\mathsf{Real}^{\uparrow}$ *name-seal packets for the carrier of Definition 38.685. Suppose the packets expose the same finite* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-radius-tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and readback row, finite ledger row, local* $\mathsf{Real}^{\uparrow}$ *seal row, and the same displayed* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. Then every public finite-prefix readback through either packet presents the same public* $\mathsf{Real}^{\uparrow}$ *seal row.*

This readback has no coordinate for quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness data, or a second seal coordinate.

Proof. Project both accepted packets through Definition 38.685. The projection exposes exactly the displayed rows $D, S, Q, L, E, H, C, P, N$ and their primed counterparts, so the finite-prefix readback can only inspect the StreamName window, dyadic observation, RegSeqRat regularity read, ledger, local seal, and structural support rows.

Apply Definition 38.686 to both packets. Each public read must pass through the route $S, D, Q, L \longmapsto E$ before a Real seal row is visible, and the same hypothesis identifies the corresponding source rows on the primed packet.

Next apply Definition 38.690 to the displayed source comparison and Definition 38.691 to compose any intermediate classifier presentation. The hsame and Cont rows replay the same finite route, while the Pkg and NameCert rows keep the readback on the same local seal classifier.

Finally use Definition 38.692. Since both packets have the same terminal finite BHist source surface, every downstream public finite-prefix readback sees the same terminal Real seal row. The carrier contains no quotient stream equality, host real equality, selected limit, countable-choice principle, ambient completeness theorem, metric-completeness datum, or second seal coordinate, so none can be introduced by the readback. □

Theorem 38.694 (Real name seal non-completeness boundary)**.** *An accepted* $\mathsf{Real}^{\uparrow}$ *name-seal carrier exports only the finite packet rows* $D, S, Q, L, E, H, C, P, N$ *of Definition 38.685. It exports no quotient stream, no selected limit, no host real equality, no host sequence equality, and no ambient completeness theorem.*

Proof. Inspect the carrier definition. Its analytic rows are the DyadicRatCore observation, StreamName schedule, RegSeqRat regularity readback, finite ledger, and RealUp seal; its structural rows are BHist, hsame, Cont, Pkg, and local NameCert evidence.

Apply Definition 38.686. Every seal read is forced through the displayed source route before E is public, so a consumer cannot enter through a quotient stream, selected host limit, host equality test, or ambient completeness principle.

Finally use Definition 38.689. The obligation surface records carrier admission, classifier transport, route stability, ledger exhaustion, and the same source factorization, leaving no remaining exported coordinate from which any of the excluded analytic objects could be obtained. □

Theorem 38.695 (Real name seal open-phase status readback)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *name-seal packet* $R = (D, S, Q, L, E, H, C, P, N)$ *of Definition 38.685 reads the Phase Real and Completion*

boundary only through the four public faces

$$\mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

together with the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. Consequently every downstream user of the packet must read closurestatus, Lean target, bridge status, and completeness claims separately from the four chapters* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

The packet itself exports no quotient stream, selected limit, host equality, ambient Real completeness, metric-completeness data, countable-choice principle, or standard bridge row.

Proof. Apply Definition 38.686. It projects the accepted packet to the source route $S, D, Q, L \longmapsto E$ and leaves only the visible BHist, hsame, Cont, Pkg, and NameCert rows as structural support.

Apply Definition 38.688. That route identifies the public faces available to a Phase Real and Completion read as $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with no additional analytic coordinate in the packet.

Use Definition 38.692 to make the readback boundary objectwise. Any downstream $\mathsf{Real}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ consumer that enters through the packet sees the same terminal finite BHist source surface, so it cannot replace the four chapter surfaces by a single global verification or completeness row.

Finally apply Definition 38.694. The packet has no coordinate for quotient streams, selected limits, host equality, ambient Real completeness, metric-completeness data, countable choice, or standard bridge evidence. The status rows for closure, Lean target, bridge status, and completeness therefore remain chapter-local obligations of the four public faces. □

Theorem 38.696 (Real constant dyadic name-seal exhaustion)**.** *Let C be a* $\mathsf{RegSeqRat}^{\uparrow}$ *constant dyadic source packet over a displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint d, and let*

$$R = (D, S, Q, L, E, H, C_R, P, N)$$

be an induced accepted $\mathsf{Real}^{\uparrow}$ *name-seal packet for the carrier of Definition 38.685. Then every public read of R factors through exactly the constant* $\mathsf{StreamName}^{\uparrow}$ *schedule of C, the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row d, the requested dyadic-radius rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier ledger of C, the finite ledger L, and the local* $\mathsf{Real}^{\uparrow}$ *seal rows of Definition 38.685.*

Equivalently, the induced packet is exhausted by the route

$$\mathsf{StreamName}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

together with the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. It exports no quotient stream, selected limit, host real equality, ambient completeness row, metric-completeness datum, choice principle, or standard bridge row.*

Proof. Project the induced packet through Definition 38.685. The projection exposes the finite-window schedule row S, the dyadic observation row D, the RegSeqRat row Q, the finite ledger L, the local seal row E, and the structural rows H, C_R, P, N.

Apply Definition 301.131 to the constant source packet. Every requested finite window is therefore represented by the same displayed $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint d, the requested radius rows, the equal-endpoint dyadic-distance row, the regularity ledger, and the componentwise transport, continuation, package, and naming rows.

Next apply Definition 301.132 and Definition 301.136. These results say that every $\mathsf{Real}^{\uparrow}$-facing request made of the constant source reaches the seal only through the constant $\mathsf{StreamName}^{\uparrow}$

schedule, the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint and radius rows, the $\mathsf{RegSeqRat}^{\uparrow}$ regularity and classifier ledger, the cofinal finite window, and the same finite BEDC structural rows.

Now repack that source description through the local Real seal route. Use Definition 38.686 to force any public read of R through $S, D, Q, L \longmapsto E$, and use Definition 38.688 to identify the only public faces of that route as $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Finally apply Definition 38.694. Since neither the constant RegSeqRat source nor the Real name-seal carrier has a coordinate for quotient streams, selected limits, host real equality, ambient completeness, metric-completeness data, choice, or a standard bridge, the induced packet has no remaining public row beyond the listed constant-source and local seal rows. □

Theorem 38.697 (Real dyadic constant classifier handoff)**.** *Let C and C' be* $\mathsf{RegSeqRat}^{\uparrow}$ *constant dyadic source packets over displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoints d and d', and let*

$$R = (D, S, Q, L, E, H, C_R, P, N), \qquad R' = (D', S', Q', L', E', H', C_{R'}, P', N')$$

be the induced accepted $\mathsf{Real}^{\uparrow}$ *name-seal packets for the carrier of Definition 38.685. Any public* $\mathsf{Real}^{\uparrow}$ *classifier read comparing R and R' may be exposed only after the following rows have been displayed on both sides:*

1. *the constant* $\mathsf{StreamName}^{\uparrow}$ *schedules of C and C';*
2. *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, tolerance, and equal-endpoint request rows;*
3. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity rows and classifier ledgers of the constant sources;*
4. *the finite ledgers L and L' tying the requested windows to the local packets;*
5. *the local* $\mathsf{Real}^{\uparrow}$ *seal rows E and E' with their displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support.*

Thus a Real equality or order consumer reading the induced constant dyadic names receives only the displayed constant-source route and the local Real seal rows. It receives no quotient stream, selected limit, host real equality test, ambient completeness row, metric-completeness datum, choice principle, or standard bridge row.

Proof. Apply Definition 38.696 to both induced packets. Each public read of R and R' is already exhausted by the constant StreamName schedule, the DyadicRatCore endpoint and radius rows, the RegSeqRat regularity and classifier ledger, the finite ledger, and the local Real seal rows.

Next use the local carrier route. The source factorization of Definition 38.686 forces every Real seal read through $S, D, Q, L \longmapsto E$ and $S', D', Q', L' \longmapsto E'$, while Definition 38.688 identifies the only public faces of those routes as $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The constant-source side supplies the classifier handoff. Apply Definition 301.131 to obtain the equal-endpoint dyadic request rows and the regularity ledger for each requested finite window. Then apply Definition 301.132 and Definition 301.136 to show that any Real-facing request from the constant source has already consumed the constant StreamName schedule, the dyadic endpoint and tolerance rows, the RegSeqRat classifier ledger, and the finite BEDC structural rows.

Finally repack the two induced packets through the Real name-seal classifier surface. Since all cited routes expose only the displayed finite rows and the local seal support, a Real equality or order consumer has no remaining coordinate for quotient streams, selected limits, host equality, ambient completeness, metric-completeness data, choice, or standard bridge evidence. □

Theorem 38.698 (RealUp RegSeqRat finite-request fusion)**.** *Let R be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet and let S be a public finite request to a* $\mathsf{Real}^{\uparrow}$ *seal over R. Then the request factors through one finite* BHist *packet whose visible source rows are exactly the following data:*

1. *the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule row selected by the request;*
2. *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and finite distance rows read at that schedule;*
3. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier row and regularity rows that certify the accepted packet;*
4. *the componentwise* hsame *transports tying the schedule, dyadic rows, regularity rows, and local seal row to the same request packet;*
5. *the displayed* Cont *routes from the schedule through the dyadic and regularity rows to the seal read;*
6. *the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
7. *the local* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *row for the finite seal request.*

Every downstream consumer of the public seal request reads through this same packet. The fusion exports no quotient stream equality, no host real equality, no selected limit, no ambient completeness principle, no choice data, and no second $\mathsf{Real}^{\uparrow}$ *seal coordinate.*

Lean4 ✓ `BEDC.Derived.RealUp.RealRegseqratFiniteRequestFusion`

Proof. First apply Definition 38.417. It places the public seal request on one common finite window with the displayed $\mathsf{StreamName}^{\uparrow}$ schedule, transported $\mathsf{DyadicRatCore}^{\uparrow}$ observations, $\mathsf{RegSeqRat}^{\uparrow}$ regularity spine, and local $\mathsf{Real}^{\uparrow}$ seal provenance.

Next use Definition 301.69. The accepted $\mathsf{RegSeqRat}^{\uparrow}$ packet can reach the real seal only through the StreamName schedule rows, dyadic endpoint and radius ledgers, finite dyadic-distance rows, classifier rows, and regularity rows named by the same finite handoff.

Now apply Definition 301.113. The tail-budget window pulls the seal read back to the same finite rows, so later consumers cannot substitute an off-packet tail selector, host limit, or second seal coordinate.

Finally use Definition 38.686. Repacking the common-window handoff, the RegSeqRat exactness route, and the tail-budget pullback gives one BHist source packet with exactly the schedule, dyadic, classifier, regularity, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows listed above. Since each cited boundary lacks quotient stream equality, host real equality, selected limits, ambient completeness, choice data, and duplicate Real-seal coordinates, the fused request exports none of them. □

Theorem 38.699 (RealUp RegSeqRat finite-request selector-budget lock)**.** *Let Q be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet and let S be a public finite request to a* $\mathsf{Real}^{\uparrow}$ *seal over Q. Suppose the finite request fusion is displayed over the rows (W, D, R, H, C, P, N), where W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius row family, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and readback row, H is the componentwise* hsame *provenance, C is the displayed* Cont *route, P is the* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *row. Then any downstream selector-budget consumer or completion-facing consumer of the same* $\mathsf{Real}^{\uparrow}$ *seal must reuse exactly these rows. In particular it cannot introduce a second selector budget, an off-packet tail selector, quotient stream equality, host real equality, a selected limit, choice data, or an ambient completeness row.*

Proof. Apply Definition 38.698. The public finite request has already been repacked into one BHist packet whose displayed rows are the window row W, the dyadic endpoint and radius rows D, the classifier and readback row R, and the provenance rows H, C, P, and N.

Apply Definition 38.417. This identifies every seal read in the packet with the same $\mathsf{StreamName}^{\uparrow}$ finite-window row, so a later selector-budget consumer has no second window coordinate through which to read the seal.

Apply Definition 301.113. The tail-budget route is pulled back to the displayed finite window and its dyadic and regularity rows, ruling out an off-packet tail selector or a second selector budget.

Finally apply Definition 38.686. The final $\mathsf{Real}^{\uparrow}$ seal source is the same finite source packet with its $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ row, so completion-facing consumers inherit the listed W, D, R, H, C, P, and N rows and gain no quotient stream equality, host real equality, selected limit, choice data, or ambient completeness row. □

Theorem 38.700 (RealUp RegSeqRat finite-request triangle)**.** *Let Q be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet and let S be a public finite request to a* $\mathsf{Real}^{\uparrow}$ *seal over Q. The following four displayed BEDC routes mutually determine one another:*

1. *S is the* $\mathsf{Real}^{\uparrow}$ *finite-request fusion packet displayed by Definition 38.698;*
2. *S lands in one* $\mathsf{StreamName}^{\uparrow}$ *finite-window row carrying the scheduled unary observation read by the request;*
3. *that same finite-window row carries the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, finite-distance ledger, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and readback row;*
4. *the local* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *seal read is reached only through those StreamName, dyadic-ledger, classifier, readback,* hsame, Cont, *and* Pkg *rows.*

Thus any one of the four route descriptions reconstructs the other three inside the same finite BHist *packet. The triangle exports no quotient stream equality, no host real equality, no selected limit, no choice data, and no ambient completeness principle.*

Proof. Start with the fusion packet route. By Definition 38.698, the public request is already repacked as one finite BHist packet whose visible rows include the $\mathsf{StreamName}^{\uparrow}$ schedule, the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint and radius family, the $\mathsf{RegSeqRat}^{\uparrow}$ classifier and regularity rows, the componentwise hsame transports, the displayed Cont routes, the Pkg provenance, and the local $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ row.

The StreamName corner is determined by Definition 38.417. It places the seal request and the scheduled unary observation on a single common finite window, so the fusion packet determines the window route and the window route recovers the seal-facing source row of the packet.

The dyadic and classifier corner is determined by Definition 301.69. The same finite handoff carries the dyadic endpoint, radius, finite-distance ledger, classifier row, and readback row, and the handoff admits no off-window replacement for those rows.

It remains to identify the seal corner. Apply Definition 301.113 to pull the seal read back to the displayed window and ledger rows, then apply Definition 38.686 to factor the local $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ seal source through exactly that finite packet.

Each direction of the triangle is therefore a repackaging of the same source rows: fusion packet, StreamName window, dyadic-RegSeqRat ledger, and local Real seal. Since the cited routes carry only finite BHist, hsame, Cont, Pkg, and NameCert provenance, the correspondence introduces no quotient stream equality, no host real equality, no selected limit, no choice data, and no ambient completeness principle. □

Theorem 38.701 (RealUp RegSeqRat completion-consumer section exactness)**.** *Let Q be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet, let S be a public finite request to a* $\mathsf{Real}^{\uparrow}$ *seal over Q, and let (W, D, R, H, C, P, N) be the finite request section displayed by Definition 38.699. A completion-facing or* $\mathsf{Real}^{\uparrow}$*-facing*

consumer of S is accepted exactly when its visible rows factor through that section: W is the $\mathsf{StreamName}^{\uparrow}$ *finite-window row, D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and distance row family, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and readback row family, H is the componentwise* hsame *provenance, C is the displayed* Cont *route, P is the* Pkg *provenance, and N is the local* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *row. Thus the consumer boundary exports no quotient stream equality, no host real equality, no selected limit, no choice data, no ambient completeness principle, and no second* $\mathsf{Real}^{\uparrow}$ *seal coordinate.*

Proof. For the forward direction, apply Definition 38.698. The accepted seal request is represented by one finite BHist packet whose visible rows are the StreamName window, dyadic endpoint, radius, and distance rows, RegSeqRat classifier and readback rows, componentwise hsame rows, displayed Cont routes, Pkg provenance, and local $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ row.

Next apply Definition 38.699. Any completion-facing or selector-budget consumer of the same seal must reuse the displayed (W, D, R, H, C, P, N) rows, so an accepted consumer has no remaining visible coordinate outside the finite section.

For the reverse direction, assume the visible rows of the completion-facing or $\mathsf{Real}^{\uparrow}$-facing consumer factor through (W, D, R, H, C, P, N). Apply Definition 301.140 to identify this section as the entire RegSeqRat source section seen by a Real seal, with no escaping source coordinate.

Finally apply Definition 126.546. The StreamName finite-window row is terminal among accepted finite-window consumers with the same observation, tail-selector route, budget surface, pointwise handoff, and support rows. Repacking the terminal window with the dyadic, classifier, readback, transport, route, package, and local naming rows gives exactly the accepted finite section above, and the exclusions from the cited nonescape and terminality theorems rule out quotient stream equality, host real equality, selected limits, choice data, ambient completeness, and a second $\mathsf{Real}^{\uparrow}$ seal coordinate. □

Theorem 38.702 (RealUp RegSeqRat finite-request four-face source exhaustion)**.** *Let Q be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet and let S be a public finite request to a* $\mathsf{Real}^{\uparrow}$ *seal over Q. Then S is accepted exactly through the following four displayed source faces:*

1. *the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule face;*
2. *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and finite-distance face;*
3. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier, readback, and regularity face;*
4. *the local* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *seal face.*

The only transport between these faces is the componentwise hsame *family, the displayed* Cont *routes, and the* Pkg *provenance already present in the finite request section. Consequently the accepted source of S is exhausted by those four faces, and no quotient stream equality, host real equality, selected limit, choice data, ambient completeness principle, or second* $\mathsf{Real}^{\uparrow}$ *seal coordinate is exported.*

Proof. Apply Definition 38.698. It supplies the finite BHist packet whose visible rows are the StreamName schedule, DyadicRatCore endpoint, radius, and distance data, RegSeqRat classifier and regularity data, componentwise hsame, displayed Cont, Pkg provenance, and the local $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ seal row.

Next apply Definition 38.699. The displayed finite request section is the unique section available to selector-budget and completion-facing consumers of the same seal request, so none of the four faces can be replaced by a second section.

Apply Definition 38.700. The fusion packet, StreamName window, DyadicRatCore-RegSeqRat ledger, and local Real seal face mutually determine one another inside the same finite packet.

Finally use Definition 38.701. Its accepted-consumer boundary says that every completion-facing or $\mathsf{Real}^{\uparrow}$-facing consumer is accepted precisely when its visible rows factor through this same section. The four displayed faces therefore give the complete accepted source for S, while the exclusions recorded by the cited results rule out quotient stream equality, host real equality, selected limits, choice data, ambient completeness, and a second Real seal coordinate. □

Theorem 38.703 (StreamName-RegSeqRat-Real finite-request seal coherence)**.** *Let W be a public* $\mathsf{StreamName}^{\uparrow}$ *finite-window package, let Q be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet whose finite-window seal consumes the selected rows of W, and let S be a public finite request to a* $\mathsf{Real}^{\uparrow}$ *seal over Q. Suppose the finite request displays the same* $\mathsf{StreamName}^{\uparrow}$ *window, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and distance rows, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and readback rows, the same componentwise* hsame *family, the same displayed* Cont *routes, the same* Pkg *provenance, and the same local* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *rows. Then the StreamName-RegSeqRat seal-composition route and the* $\mathsf{Real}^{\uparrow}$ *four-face source-exhaustion route determine the same finite* BHist *packet. This coherence exports no quotient stream equality, no host real equality, no selected limit, no countable-choice schedule, no ambient completeness row, and no second* $\mathsf{Real}^{\uparrow}$ *seal coordinate.*

Proof. First apply Definition 126.79. The public finite-window package W supplies the StreamName source rows consumed by the accepted $\mathsf{RegSeqRat}^{\uparrow}$ packet, and those rows are the displayed window rows of the request.

Next apply Definition 126.83. The seal route from the StreamName window through the accepted RegSeqRat packet reaches the Real-facing seal only through the selected window rows, the RegSeqRat classifier and readback rows, and their displayed provenance.

Now apply Definition 38.698 and Definition 38.700. These results repack the displayed StreamName, dyadic, RegSeqRat, hsame, Cont, Pkg, and local naming rows as one finite BHist packet, and they identify the StreamName window route, the dyadic-RegSeqRat ledger route, and the Real seal route as mutually determining faces of that packet.

Finally use Definition 38.702. Its four-face source exhaustion says that the accepted source of S has no visible face beyond the StreamName window, DyadicRatCore endpoint-radius-distance data, RegSeqRat classifier-readback data, and local $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ seal row. Hence the StreamName-RegSeqRat seal-composition route and the RealUp four-face route name the same finite BHist packet, with none of the excluded quotient, host-real, selected-limit, countable-choice, completeness, or duplicate-seal data exported. □

Theorem 38.704 (RealUp RegSeqRat finite-request section terminality)**.** *Let Q be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet and let S be a public finite request to a* $\mathsf{Real}^{\uparrow}$ *seal over Q. Suppose two accepted completion-facing or* $\mathsf{Real}^{\uparrow}$*-facing finite-request sections over S display the same* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and finite-distance rows, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and readback rows, the same componentwise* hsame *family, the same displayed* Cont *routes, the same* Pkg *provenance, and the same local* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *rows. Then the two sections determine the same finite* BHist *packet. This terminal section exports no quotient stream equality, no host real equality, no selected limit, no choice data, no ambient completeness row, and no second* $\mathsf{Real}^{\uparrow}$ *seal coordinate.*

Proof. First apply Definition 38.698. Each accepted finite request is represented by one finite BHist packet whose visible rows are exactly the StreamName window, dyadic endpoint-radius-distance

data, RegSeqRat classifier-readback data, componentwise hsame transports, displayed Cont routes, Pkg provenance, and local $\mathsf{NameCert}_{\mathsf{Real}^\uparrow}$ rows.

Next apply Definition 38.699. A completion-facing or $\mathsf{Real}^\uparrow$-facing consumer of the same seal cannot replace the displayed window, dyadic, classifier, readback, transport, route, package, or local naming rows by a second selector-budget section.

The StreamName coordinate is terminal by Definition 126.546. Since the two sections display the same finite window and the same compatible tail-budget surface, both StreamName faces collapse to the same window packet.

Now use Definition 38.701. Acceptance of either completion-facing or $\mathsf{Real}^\uparrow$-facing section is exactly factorization through the displayed (W, D, R, H, C, P, N) rows, so the two sections have no visible coordinate outside those rows.

Finally apply Definition 38.702. The StreamName, DyadicRatCore, RegSeqRat, and local Real naming faces exhaust the accepted source of S. Since the two sections agree on all four faces and on the only permitted hsame, Cont, and Pkg transports between them, they determine the same finite BHist packet, and none of the excluded quotient, host-real, selected-limit, choice, completeness, or duplicate-seal data is exported. □

Theorem 38.705 (RealUp StreamName finite-request terminal bridge)**.** *Let Q be an accepted* $\mathsf{RegSeqRat}^\uparrow$ *packet, let S be an accepted* $\mathsf{Real}^\uparrow$ *finite-request terminal section over Q, and let P be the* $\mathsf{StreamName}^\uparrow$ *finite-section pullback for the finite window used by S. Then S and P determine the same finite* BHist *packet exactly when they display the same* $\mathsf{StreamName}^\uparrow$ *window row, the same* $\mathsf{DyadicRatCore}^\uparrow$ *endpoint and radius ledger, the same* $\mathsf{RegSeqRat}^\uparrow$ *classifier and readback rows, the same componentwise* hsame *rows, the same displayed* Cont *route, the same* Pkg *provenance, and the same local* NameCert *rows. This bridge exports no quotient streams, no selected limits, no host equality, no ambient completeness row, no countable-choice schedule, and no standard bridge rows.*

Proof. For the Real-facing direction, apply Definition 38.704. The accepted terminal section over S is already exhausted by the displayed StreamName window, DyadicRatCore endpoint-radius ledger, RegSeqRat classifier and readback rows, componentwise hsame, displayed Cont, Pkg provenance, and local NameCert rows.

For the StreamName-facing direction, apply Definition 126.586 together with Definition 126.577. The pullback section has no visible source beyond the finite window rows and the finite request rows transported through the same BHist packet.

If the displayed window, endpoint-radius ledger, classifier and readback rows, hsame rows, Cont route, Pkg provenance, and local NameCert rows agree, the two cited terminal descriptions have the same four visible faces and the same permitted transports between them. Hence the Real terminal section and the StreamName pullback name one finite BHist packet.

Conversely, if they name the same finite BHist packet, equality of the visible packet rows forces agreement of each displayed row listed in the statement: the StreamName window, dyadic ledger, RegSeqRat classifier and readback data, componentwise transport rows, continuation route, package provenance, and local naming rows.

Finally apply Definition 126.453. The correspondence remains on the four-object finite exit route, so it does not add quotient streams, selected limits, host equality, ambient completeness, countable-choice schedules, or standard bridge rows. □

Theorem 38.706 (RealUp RegSeqRat finite-request pullback determinacy)**.** *Let Q be an accepted* $\mathsf{RegSeqRat}^\uparrow$ *packet and let S be a public finite request to a* $\mathsf{Real}^\uparrow$ *seal over Q. Suppose two accepted completion-facing or* $\mathsf{Real}^\uparrow$*-facing finite-request sections over S display the same* $\mathsf{StreamName}^\uparrow$ *finite-section pullback, the same* $\mathsf{DyadicRatCore}^\uparrow$ *endpoint, radius, and finite-distance rows, the*

same $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and readback rows, the same local* $\mathsf{Real}^{\uparrow}$ *seal row, and the same* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. Then the two sections determine the same finite* BHist *Real seal packet. This determinacy exports no quotient stream equality, no host real equality, no selected limit, no choice data, no ambient completeness row, and no second* $\mathsf{Real}^{\uparrow}$ *seal coordinate.*

Proof. First use Definition 126.586. The shared $\mathsf{StreamName}^{\uparrow}$ finite-section pullback identifies the StreamName-facing part of both accepted sections with the same finite four-face route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Next apply Definition 38.702. Once the StreamName pullback is fixed, the accepted source of the request has only the StreamName schedule face, the DyadicRatCore endpoint-radius-distance face, the RegSeqRat classifier-readback face, and the local Real naming face.

Now use Definition 38.701. Each accepted completion-facing or $\mathsf{Real}^{\uparrow}$-facing section must factor through those visible rows together with the displayed hsame, Cont, Pkg, and NameCert support rows, so neither section has an additional consumer coordinate.

Finally apply Definition 38.704. The two sections agree on the StreamName pullback and on every visible dyadic, classifier, readback, local seal, transport, route, package, and naming row; terminality therefore identifies the displayed finite BHist Real seal packet. The cited boundaries keep quotient stream equality, host real equality, selected limits, choice data, ambient completeness, and a second Real seal coordinate outside the packet. □

Theorem 38.707 (RealUp RegSeqRat finite-request route equivalence)**.** *Let Q be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet and let S be a public finite request to a* $\mathsf{Real}^{\uparrow}$ *seal over Q. A completion-facing or* $\mathsf{Real}^{\uparrow}$*-facing finite-request read over S is accepted exactly when it factors through the same four displayed L10 source faces:*

1. *the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selected by the request;*
2. *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and finite-distance ledger read at that window;*
3. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier, readback, and regularity rows of the accepted packet;*
4. *the local* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *seal row.*

The factorization includes precisely the displayed BHist*,* hsame*,* Cont*, and* Pkg *support tying those four faces to one finite packet. The displayed packet is unique among accepted completion-facing and* $\mathsf{Real}^{\uparrow}$*-facing reads with these rows, and the equivalence exports no quotient stream equality, no host real equality, no selected limit, no choice data, no ambient completeness, no metric-completeness row, no standard bridge row, and no second* $\mathsf{Real}^{\uparrow}$ *seal coordinate.*

Proof. For the forward direction, apply Definition 38.702. Any accepted read over S has no visible source beyond the StreamName finite window, the DyadicRatCore endpoint-radius-distance ledger, the RegSeqRat classifier-readback-regularity surface, and the local Real naming row.

For the reverse direction, assume the read factors through these four faces together with the displayed BHist, hsame, Cont, and Pkg support. Apply Definition 38.701. Its section criterion accepts exactly the completion-facing and $\mathsf{Real}^{\uparrow}$-facing consumers whose visible rows factor through the displayed finite section, so the factored read is accepted.

It remains to identify the packet. Apply Definition 38.706 to any two accepted reads displaying the same four faces and support rows. Then use Definition 38.705 to identify the StreamName-facing pullback with the Real-facing terminal section on the same finite BHist packet.

Thus accepted reads are precisely the four-object L10 finite route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the local $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ seal row. Since the cited boundaries carry only the listed finite support, the route does not add quotient stream equality, host real

equality, selected limits, choice data, ambient completeness, metric-completeness rows, standard bridge rows, or a second Real seal coordinate. □

Theorem 38.708 (RealUp RegSeqRat terminal four-face acceptance equivalence)**.** *Let Q be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet and let S be a public finite request to a* $\mathsf{Real}^{\uparrow}$ *seal over Q. Acceptance of a completion-facing or* $\mathsf{Real}^{\uparrow}$*-facing terminal read over S is equivalent to factorization through exactly the four L10 faces:*

1. *the selected* $\mathsf{StreamName}^{\uparrow}$ *finite-window row;*
2. *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and finite-distance ledger;*
3. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier, readback, and regularity rows;*
4. *the local* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *seal row.*

The factorization uses only the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support tying those faces to one finite packet. Among accepted terminal reads displaying this support, the packet is unique. The equivalence exports no quotient stream equality, no host real equality, no selected limit, no choice data, no ambient completeness, no metric-completeness row, no standard bridge row, and no second Real seal coordinate.*

Proof. For the forward direction, apply Definition 38.707. An accepted terminal read over S is accepted only through the selected StreamName window, the DyadicRatCore endpoint-radius-distance ledger, the RegSeqRat classifier-readback-regularity surface, and the local Real seal row, with the displayed BHist, hsame, Cont, Pkg, and NameCert support.

For the reverse direction, suppose a terminal read factors through exactly these four faces with the displayed support. Apply Definition 301.239. Its four-face exactness repacks the StreamName, DyadicRatCore, RegSeqRat, and Real seal rows as the accepted terminal packet for the public finite request.

It remains to identify uniqueness. First use Definition 38.706: two accepted terminal reads with the same four faces and support rows determine the same finite Real seal packet.

Then apply Definition 38.705 to identify the StreamName-facing pullback with the Real-facing terminal section on that packet. Finally use Definition 38.458; no second completion-facing or Real-facing terminal read can display the same four L10 faces while naming a different finite BHist packet.

The cited route, exactness, bridge, and pullback-uniqueness statements expose only the listed finite rows. Therefore the equivalence carries no quotient stream equality, host real equality, selected limit, choice data, ambient completeness, metric-completeness row, standard bridge row, or second Real seal coordinate. □

Theorem 38.709 (RealUp RegSeqRat Cauchy-witness budget projection)**.** *Let Q be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet, let S be a public finite request to a* $\mathsf{Real}^{\uparrow}$ *seal over Q, and let $L = (Q_L, B_L, S_L, K_L, H_L, C_L, P_L, N_L)$ be an accepted* $\mathsf{CauchyWitnessLedger}^{\uparrow}$ *budget row whose visible* $\mathsf{StreamName}^{\uparrow}$ *finite window is the same window read by S. Then the visible budget projection of the combined read is exactly the displayed packet consisting of the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and finite-distance rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and readback rows, the local* $\mathsf{Real}^{\uparrow}$ *seal row, and the supporting* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. Equivalently, the Cauchy-witness ledger consumes the same finite packet through its diagonal-budget, observation-budget, synchronizer, and completion-seal rows before any completion-facing classifier is visible.*

The projection exports no quotient streams, no host real equality, no selected limits, no choice data, no ambient completeness, no metric-completion rows, no standard bridge rows, and no second $\mathsf{Real}^{\uparrow}$ *seal coordinate.*

Proof. First apply Definition 38.698 and Definition 38.699. They place the public request on one finite packet and force every selector-budget or completion-facing consumer of S to reuse the displayed StreamName, dyadic, RegSeqRat, Real seal, and support rows.

Next use Definition 38.702. The visible source has exactly four faces: the StreamName finite window, the dyadic endpoint-radius-distance ledger, the RegSeqRat classifier-readback surface, and the local Real seal row. There is no fifth face from which a quotient stream, selected limit, ambient completeness row, metric-completion row, or bridge row could be read.

Now apply the terminal bridge Definition 38.705. Since the ledger row and the Real request display the same finite StreamName window, the StreamName-facing pullback and the Real-facing terminal section name the same finite BHist packet with the same hsame, Cont, Pkg, and $\mathsf{NameCert}$ support.

Finally read the witness-ledger side through Definition 902.5, Definition 902.7, and Definition 902.49. These rows order every accepted completion-facing read through the same diagonal-budget, observation-budget, synchronizer, and completion-seal route, and they identify the ledger's $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ source surface with the one already fixed by the finite request. Thus all budget consumers reuse the same finite packet, and the excluded quotient, host, selected-limit, choice, completeness, metric-completion, bridge, and duplicate-seal data remain outside the projection. □

Theorem 38.710 (RealUp RegSeqRat StreamName dyadic tail-budget pullback)**.** *Let Q be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet, let S be a public finite request to a* $\mathsf{Real}^{\uparrow}$ *seal over Q, and let $L = (E, T, W, D, R, A, H, C, P, N)$ be an accepted* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *row whose visible* $\mathsf{StreamName}^{\uparrow}$ *finite window W is the same window selected by S. Then the* $\mathsf{Real}^{\uparrow}$ *finite-request packet pulls back exactly to the shared finite packet consisting of the* $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and finite-distance rows in D, the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier, readback, and regularity rows of Q and R, the local* $\mathsf{Real}^{\uparrow}$ *seal row A, and the supporting* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows H, C, P, N.*

Equivalently, every completion-facing or $\mathsf{Real}^{\uparrow}$*-facing read of S that is mediated by the tail-radius ledger L is accepted exactly through the same four L10 faces: the selected StreamName window, the DyadicRatCore endpoint-radius-distance ledger, the RegSeqRat classifier and readback surface, and the local Real seal row. The pullback exports no quotient streams, no host real equality, no selected limits, no choice data, no ambient completeness, no metric-completion rows, no standard bridge rows, and no duplicate* $\mathsf{Real}^{\uparrow}$ *seal coordinates.*

Proof. Start with the Real finite request. By Definition 38.702, the accepted source of S has exactly the StreamName window face, the DyadicRatCore endpoint-radius-distance face, the RegSeqRat classifier-readback-regularity face, and the local $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ seal face.

Next apply Definition 38.707. A completion-facing read over S is accepted precisely when it factors through those four faces together with the displayed BHist, hsame, Cont, and Pkg support. Thus the Real-facing section has no coordinate outside the finite L10 packet.

Now use Definition 38.709. Its budget projection identifies the Cauchy-witness budget surface with the same StreamName, DyadicRatCore, RegSeqRat, Real seal, and support rows already fixed by the finite request.

Finally apply the DyadicTailRadiusLedger handoff, namely Definition 757.3 and Definition 757.6. Since L displays the same finite StreamName window W selected by S, tail-budget coverage places

the precision, tail-window, StreamName-window, and dyadic readback rows on the same finite route, and the handoff carries that route through the RegSeqRat and Real seal rows. Repacking these rows gives exactly the shared packet $W, D, Q, R, A, H, C, P, N$, with no quotient stream, host equality, selected limit, choice, completeness, metric-completion, bridge, or duplicate Real-seal coordinate available to the pullback. □

Theorem 38.711 (RealUp RegSeqRat reindexed finite-request descent)**.** *Let Q_0 and Q_1 be accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packets, and let S_0 and S_1 be accepted finite requests to* $\mathsf{Real}^{\uparrow}$ *seals over them. Suppose the selected* $\mathsf{StreamName}^{\uparrow}$ *finite windows of S_0 and S_1 are related by a certified public reindex route. Suppose also that the route preserves the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and finite-distance ledger, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and readback rows, the same local* $\mathsf{Real}^{\uparrow}$ *seal row, and the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. Then S_0 and S_1 determine the same finite* $\mathsf{Real}^{\uparrow}$ *seal packet.*

Conversely, equality of the accepted finite $\mathsf{Real}^{\uparrow}$ *seal packet recovers exactly that reindexed four-face data: the transported StreamName window, the DyadicRatCore endpoint-radius-distance ledger, the RegSeqRat classifier and readback rows, the local Real seal row, and the displayed support rows* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. The descent exports no quotient stream equality, no host real equality, no selected limits, no choice data, no ambient completeness, no metric-completeness rows, no standard bridge rows, and no duplicate* $\mathsf{Real}^{\uparrow}$ *seal coordinates.*

Proof. First apply Definition 126.642. The certified public reindex route carries the selected StreamName finite window to the same terminal four-face exit route, with the displayed BHist, hsame, Cont, Pkg, and NameCert rows transported componentwise.

Next use Definition 38.705. The StreamName-facing pullback and the Real-facing finite request therefore read one finite BHist packet whenever they display the same StreamName window, dyadic ledger, RegSeqRat readback, Real seal row, and support rows.

Now apply Definition 38.707. Acceptance of either request is exactly factorization through the four L10 faces: the selected StreamName window, the DyadicRatCore endpoint-radius-distance ledger, the RegSeqRat classifier-readback surface, and the local Real seal row, together with the displayed finite support.

Finally use Definition 38.710. The preserved dyadic tail-budget ledger identifies the Real-facing finite packet with the same StreamName, DyadicRatCore, RegSeqRat, Real seal, and support rows on both sides of the reindex route. Thus the two accepted requests determine the same finite $\mathsf{Real}^{\uparrow}$ seal packet.

For the converse, read equality of the accepted finite Real seal packet through the route equivalence just cited. Since the packet has no hidden coordinate beyond the four faces and displayed support, equality recovers exactly the transported StreamName window, dyadic ledger, RegSeqRat classifier and readback rows, local seal row, and BHist/hsame/Cont/Pkg/NameCert support rows. The same boundary exclusions keep quotient stream equality, host real equality, selected limits, choice data, ambient completeness, metric-completeness rows, standard bridge rows, and duplicate Real seal coordinates outside the conclusion. □

Theorem 38.712 (RealUp RegSeqRat tail-witness budget agreement)**.** *Let Q be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet, let S be a public finite request to a* $\mathsf{Real}^{\uparrow}$ *seal over Q, let L be an accepted* $\mathsf{CauchyWitnessLedger}^{\uparrow}$ *budget row, and let T be an accepted* $\mathsf{DyadicTailRadiusLedger}^{\uparrow}$ *row. Suppose that the visible* $\mathsf{StreamName}^{\uparrow}$ *finite window read by L is the same finite window selected by S, and that the visible* $\mathsf{StreamName}^{\uparrow}$ *finite window read by T is the same selected window. Then the Cauchy-witness budget projection and the dyadic tail-budget pullback determine one and the same finite four-face* $\mathsf{Real}^{\uparrow}$ *packet: the selected* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint,*

radius, and finite-distance rows, the $\mathsf{RegSeqRat}^{\uparrow}$ *classifier, readback, and regularity rows, the local* $\mathsf{Real}^{\uparrow}$ *seal row, and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support.*

Conversely, equality of that finite four-face packet recovers agreement of the two displayed budget routes on precisely those rows. The agreement exports no quotient stream equality, no host real equality, no selected limit, no choice data, no ambient completeness, no metric-completeness row, no standard bridge row, and no duplicate $\mathsf{Real}^{\uparrow}$ *seal coordinate.*

Proof. First apply Definition 38.709. The accepted CauchyWitnessLedger row L projects to the selected StreamName window, the dyadic endpoint-radius-distance rows, the RegSeqRat classifier and readback surface, the local Real seal row, and the displayed finite support rows.

Next apply Definition 38.710. Since T displays the same selected StreamName window, its tail-radius route pulls the Real finite request back to the identical StreamName, DyadicRatCore, RegSeqRat, local seal, and BHist/hsame/Cont/Pkg/NameCert support surface.

Now use Definition 38.707. Acceptance through either budget route is exactly acceptance through the four L10 faces, so neither route contributes a fifth coordinate or any completion-facing row outside the finite packet.

It remains to identify the two budget descriptions. Apply Definition 38.711 with the identity public reindex route on the shared selected StreamName window. The descent theorem identifies the two accepted finite Real seal packets because their StreamName, dyadic, RegSeqRat, local seal, and support rows agree.

For the converse, read equality of the shared packet back through the same descent and route-equivalence statements. Since the packet contains only the four displayed faces and support rows, equality recovers exactly the Cauchy-witness projection route and the dyadic tail-budget pullback route on those rows, while the listed quotient, host, limit, choice, completeness, metric-completion, standard bridge, and duplicate-seal data remain outside the conclusion. □

Theorem 38.713 (Real RegSeqRat terminal budget exhaustion)**.** *Let Q be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet and let S be a finite RegSeqRat request accepted by the* $\mathsf{Real}^{\uparrow}$ *seal over Q. A terminal-budget consumer of S is accepted exactly when its visible rows factor through the ordered four-face packet*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The packet consists of the $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and distance ledgers; the* $\mathsf{StreamName}^{\uparrow}$ *finite schedules; the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity, classifier, and provenance rows; and the local* $\mathsf{Real}^{\uparrow}$ *terminal seal row, all transported by the displayed* BHist, *componentwise* hsame, *displayed* Cont, Pkg, *and local* NameCert *coordinates.*

Conversely, any packet with exactly these four faces and exactly these support rows repacks as the accepted $\mathsf{Real}^{\uparrow}$ *terminal-budget read of S. The exhaustion exports no quotient stream equality, host real equality, selected limit, countable-choice selector, ambient completeness principle, arithmetic package, order package, or metric-completeness row.*

Proof. For the forward direction, begin with an accepted terminal-budget consumer of the finite RegSeqRat request. Apply Definition 301.142 to place the request on its finite terminal-budget section, with the RegSeqRat classifier, regularity, readback, and provenance rows already tied to a finite source packet.

Next apply Definition 38.699. The $\mathsf{Real}^{\uparrow}$ seal over the accepted RegSeqRat packet must reuse the same finite request section, so the StreamName schedule, DyadicRatCore endpoint, radius, and distance ledgers, RegSeqRat rows, componentwise hsame transports, displayed Cont routes, Pkg provenance, and local $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ row cannot be replaced by a second terminal-budget surface.

Now use Definition 38.457. It identifies the visible rows of the accepted terminal $\mathsf{Real}^{\uparrow}$ read with the finite four-face packet over DyadicRatCore, StreamName, RegSeqRat, and the local Real seal. Thus the terminal-budget consumer has no visible coordinate outside the ordered packet in the statement.

For the reverse direction, suppose the displayed DyadicRatCore ledgers, StreamName schedules, RegSeqRat regularity and classifier rows, and local $\mathsf{Real}^{\uparrow}$ terminal seal row are already present with the listed support coordinates. Apply Definition 38.455 to repack those rows as the terminal $\mathsf{Real}^{\uparrow}$ read.

It remains to match that terminal read with the original finite request. The finite-request factorization and selector-budget lock identify the RegSeqRat source section and the $\mathsf{Real}^{\uparrow}$ seal section as the same packet, so the repacked four-face read is exactly the accepted terminal-budget read of S. Since the cited routes do not export quotient stream equality, host real equality, selected limits, countable-choice selectors, ambient completeness, arithmetic or order packages, or metric-completeness rows, none of those data are available through this exhaustion. □

Lean4 ✓ `BEDC.Derived.RealUp.RealRegseqratTerminalBudgetExhaustion`

Theorem 38.714 (Real RegSeqRat terminal budget seal uniqueness)**.** *Let Q be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet and let S be a finite RegSeqRat request accepted by the* $\mathsf{Real}^{\uparrow}$ *seal over Q. Suppose two accepted terminal-budget reads of S display the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and distance ledgers, the same* $\mathsf{StreamName}^{\uparrow}$ *finite schedules, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity, classifier, and provenance rows, the same local* $\mathsf{Real}^{\uparrow}$ *seal row, and the same displayed* BHist*, componentwise* hsame*, displayed* Cont*,* Pkg*, and local* NameCert *support rows.*

Then the two public finite $\mathsf{Real}^{\uparrow}$ *seal rows coincide. This equality is only the equality of the visible terminal-budget seal row; it does not assert quotient stream equality, host real equality, selected limits, countable-choice selectors, ambient completeness, arithmetic or order packages, metric-completeness rows, standard bridge rows, or any equality of hidden completion carriers.*

Proof. Apply Definition 38.713 to each accepted terminal-budget read. Both reads factor through the ordered four-face packet

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The hypotheses identify every displayed face of these two packets: the dyadic endpoint, radius, and distance ledgers, the StreamName schedules, the RegSeqRat regularity, classifier, and provenance rows, and the local Real seal row. They also identify the support rows BHist, componentwise hsame, displayed Cont, Pkg, and local NameCert.

Next use Definition 38.459 and Definition 38.455. The source lock keeps both terminal reads on the same L10 source route, while the four-face correspondence reads the identified packet as the terminal $\mathsf{Real}^{\uparrow}$ seal read. Thus neither read can obtain a second terminal source after the four visible faces and support rows have been fixed.

It remains to check that both reads are attached to the same finite request section. Apply Definition 301.142 to the RegSeqRat request and Definition 38.699 to the Real seal over it. These two locks identify the RegSeqRat source section and the Real selector-budget section as the same terminal-budget packet for S.

Finally invoke Definition 126.500 and Definition 126.449. The exit route names the same four public objects, and terminality says that agreement on those objects and the displayed support rows determines a single terminal finite route. Hence the visible public $\mathsf{Real}^{\uparrow}$ seal row of the first read is the visible public $\mathsf{Real}^{\uparrow}$ seal row of the second read.

All equalities used above are equalities of the finite displayed packet. The cited routes export no quotient stream equality, host real equality, selected limit, countable-choice selector, ambient completeness, arithmetic or order package, metric-completeness row, standard bridge row, or hidden completion carrier, so the uniqueness conclusion has exactly the public finite seal-row scope stated above. □

Theorem 38.715 (Real RegSeqRat terminal budget four-face naturality)**.** *Let Q be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet and let S be a finite RegSeqRat request accepted by the* $\mathsf{Real}^{\uparrow}$ *seal over Q. Suppose an accepted terminal-budget read of S is transported through the displayed* BHist*, componentwise* hsame*, displayed* Cont*,* Pkg*, and local* NameCert *support rows, while preserving the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and distance ledgers, the* $\mathsf{StreamName}^{\uparrow}$ *finite schedules, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity, classifier, and provenance rows, and the local* $\mathsf{Real}^{\uparrow}$ *seal row.*

Then the transported read has the same public $\mathsf{Real}^{\uparrow}$ *terminal-budget seal row as the original read, and it is the same four-face read through*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The transported read exports no quotient stream equality, selected limit, choice selector, ambient completeness, arithmetic or order package, metric-completeness row, standard bridge row, or hidden completion carrier.

Proof. Apply terminal-budget exhaustion to the original read. The accepted read is exhausted by the four displayed faces, together with the DyadicRatCore ledgers, StreamName schedules, RegSeqRat rows, local Real seal row, and the listed support rows.

Apply the same exhaustion theorem to the transported read. The transport hypotheses preserve exactly those visible rows and support coordinates, so the transported read factors through the same ordered four-face packet and has no additional terminal-budget coordinate.

Now use terminal-budget seal uniqueness. Since the two accepted reads display the same dyadic, schedule, regularity, classifier, provenance, Real seal, transport, continuation, package, and naming rows, their public finite $\mathsf{Real}^{\uparrow}$ seal rows coincide.

The non-escape conclusion is inherited from the two preceding results. Exhaustion supplies no hidden completion data, and uniqueness identifies only the visible finite seal row, so the transported read cannot export quotient stream equality, selected limits, choice selectors, ambient completeness, arithmetic or order packages, metric-completeness rows, standard bridge rows, or hidden completion carriers. □

Theorem 38.716 (Real terminal-budget pasting exactness)**.** *Let Q be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet under a fixed* $\mathsf{Real}^{\uparrow}$ *seal, and let S_0 and S_1 be accepted finite RegSeqRat requests with an accepted overlap S_{01}. Suppose their terminal-budget reads agree on S_{01} in the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and distance ledgers, the* $\mathsf{StreamName}^{\uparrow}$ *finite schedules, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity, classifier, and provenance rows, the local* $\mathsf{Real}^{\uparrow}$ *seal row, and the displayed* BHist*, componentwise* hsame*,* Cont*,* Pkg*, and local* NameCert *support rows. Then the pasted terminal-budget read has the same public* $\mathsf{Real}^{\uparrow}$ *seal row as the two restrictions on the overlap and factors through the same ordered four-face route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The pasted read exports no quotient stream equality, host real equality, selected limit, countable-choice selector, ambient completeness principle, arithmetic package, order package, metric-completeness row, standard bridge row, or hidden completion carrier.

Proof. Apply Definition 38.713 to the two accepted reads. Each restriction is exhausted by the DyadicRatCore endpoint, radius, and distance ledgers, the StreamName schedules, the RegSeqRat regularity, classifier, and provenance rows, the local Real seal row, and the displayed support rows.

On the overlap S_{01}, use Definition 38.714. The agreement hypotheses identify every visible terminal-budget row, so the public $\mathsf{Real}^{\uparrow}$ seal row is single on the overlap.

Paste the two terminal-budget reads along this common seal row. The pasted read has exactly the displayed dyadic, StreamName, RegSeqRat, Real seal, and support coordinates inherited from its restrictions, with no extra terminal coordinate at the gluing boundary.

Finally apply Definition 38.715. Naturality transports the pasted read along the same support rows and keeps it on the ordered four-face route. The non-escape clauses are inherited from exhaustion, seal uniqueness, and naturality, so the pasted terminal-budget read does not claim quotient, host-real, selected-limit, choice, completeness, arithmetic, order, metric-completion, bridge, or hidden-completion data. □

Theorem 38.717 (Real terminal-budget finite-cover descent)**.** *Let Q be an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *packet under a fixed* $\mathsf{Real}^{\uparrow}$ *seal, and let $\{S_i\}_{i\in I}$ be a finite cover of accepted finite RegSeqRat requests over Q. Suppose each S_i carries an accepted terminal-budget read, and suppose every nonempty overlap in the cover satisfies the* $\mathsf{StreamName}^{\uparrow}$ *terminal-fusion finite-cover cocycle and the* $\mathsf{RegSeqRat}^{\uparrow}$ *shared-window triple-overlap cocycle while preserving the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and distance ledgers, the* $\mathsf{StreamName}^{\uparrow}$ *finite schedules, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity, classifier, and provenance rows, the local* $\mathsf{Real}^{\uparrow}$ *seal row, and the displayed* BHist*, componentwise* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}$ *support rows.*

Then the local terminal-budget reads descend to one public $\mathsf{Real}^{\uparrow}$ *terminal-budget seal row over the same ordered four-face route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The descended seal row exports no quotient stream equality, host real equality, selected limit, countable-choice selector, ambient completeness principle, arithmetic package, order package, metric-completeness row, standard bridge row, or hidden completion carrier.

Proof. First fuse the finite StreamName windows. Apply Definition 126.628 to the overlap cocycle data; the result is a single finite schedule carrying the same displayed BHist, componentwise hsame, Cont, Pkg, and local $\mathsf{NameCert}$ support rows on every member of the cover.

Next identify the RegSeqRat sections over that fused schedule. The hypotheses give the shared-window triple-overlap cocycle, so Definition 301.163 keeps the regularity, classifier, and provenance rows on one finite RegSeqRat section while preserving the DyadicRatCore endpoint, radius, and distance ledgers.

Now paste the Real terminal-budget reads over the finite cover. On each pairwise overlap, Definition 38.716 applies to the identified dyadic, StreamName, RegSeqRat, Real seal, and support rows, so the overlap has a single public $\mathsf{Real}^{\uparrow}$ seal row. Repeating this finite pasting along the fused schedule gives one candidate terminal-budget seal row for the whole cover.

It remains to check that the candidate is the public terminal-budget read and not a hidden completion object. Use Definition 38.715 to keep the pasted read on the displayed ordered route, and then apply Definition 38.713. Exhaustion says the route has only the four visible faces and the listed support rows, so the descent cannot export quotient stream equality, host real equality, selected limits, choice, ambient completeness, metric-completeness, standard bridge rows, or hidden completion carriers. □

Theorem 38.718 (Real finite-window seal exhaustion)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *seal read used by a Real-completion consumer factors through the displayed* $\mathsf{StreamName}^{\uparrow}$ *finite window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{Real}^{\uparrow}$ *seal row. Equivalently, the terminal read is exhausted by the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

together with the visible BHist, hsame, Cont, Pkg, *and* NameCert *support rows.*

The read cannot add quotient stream equality, host real equality, selected host limits, ambient completeness, countable-choice selectors, metric-completeness data, or a standard bridge row.

Proof. Project the terminal seal through the existing $\mathsf{Real}^{\uparrow}$ finite-window rows. The name-seal carrier of Definition 38.685 displays the finite-window schedule, dyadic observation, RegSeqRat regularity row, finite ledger, local seal row, and the support rows H, C, P, N.

Apply Definition 38.686. It forces every public seal read to pass through the displayed source route from the $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{DyadicRatCore}^{\uparrow}$ observation to the $\mathsf{RegSeqRat}^{\uparrow}$ readback and then to the local $\mathsf{Real}^{\uparrow}$ seal.

Use the sibling routes already present in the hub. The StreamName finite-window face is the public interface of Definition 126.301, the RegSeqRat handoff is Definition 301.22, and the DyadicRatCore tolerance source is Definition 291.18. Together with Definition 38.688, these rows repack the read as the four-face route in the statement.

Finally apply the local non-escape and readback surface supplied by Definition 38.687 and Definition 38.713. Those theorems expose no quotient stream equality, host real equality, selected host limits, ambient completeness, choice selector, metric-completeness row, or standard bridge row, so a terminal Real-completion consumer cannot acquire any of those objects from the finite seal read. □

Theorem 38.719 (Real finite-window seal refinement monotonicity)**.** *Let* $\mathcal{R}$ *be an accepted public* $\mathsf{Real}^{\uparrow}$ *terminal seal read whose finite boundary factors through the four faces*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Suppose $\mathcal{R}'$ *is a second finite request whose* $\mathsf{StreamName}^{\uparrow}$ *window refines the displayed window of* $\mathcal{R}$*, while preserving the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and distance ledger, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and readback rows, the same local* $\mathsf{Real}^{\uparrow}$ *seal row, and the same support rows*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

Then $\mathcal{R}'$ *is again an accepted finite-window* $\mathsf{Real}^{\uparrow}$ *seal read. Moreover,* $\mathcal{R}'$ *exports no coordinate outside the same four-face packet and the displayed support rows.*

Proof. Start with the accepted read $\mathcal{R}$. By Definition 38.718, its public terminal seal surface is exhausted by the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces together with the displayed BHist, hsame, Cont, Pkg, and NameCert support rows.

Now restrict the refined request to the same four-face cover. The cover normal form of Definition 38.819 says that finite refinements of the displayed $\mathsf{StreamName}^{\uparrow}$ windows remain in the same terminal seal packet when the dyadic ledger, RegSeqRat classifier and readback rows, Real seal row, and support rows are preserved.

Next apply terminality from Definition 126.504. Since the refined request exposes exactly the same four faces and the same support rows after restriction, it factors through the terminal finite BEDC pullback available to Real-seal-facing consumers.

Finally transport the accepted status along the unchanged support rows using Definition 38.715. Naturality keeps the RegSeqRat budget and local Real seal readback on the same accepted four-face route, so $\mathcal{R}'$ is an accepted finite-window seal read. The non-escape clauses in the cited exhaustion, normal-form, pullback, and naturality results leave no coordinate outside the four faces and the displayed support rows. □

Theorem 38.720 (Real terminal finite-section pullback exactness)**.** *Let $\mathcal{S}$ be a finite section of a terminal* $\mathsf{Real}^{\uparrow}$ *seal read. Then $\mathcal{S}$ is accepted exactly when its visible pullback is the ordered four-face packet*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

with the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. The* $\mathsf{DyadicRatCore}^{\uparrow}$ *face is the terminal scale-window packet, the* $\mathsf{StreamName}^{\uparrow}$ *face is the tail-compatible finite-window request, the* $\mathsf{RegSeqRat}^{\uparrow}$ *face is the common-tail finite-request readback surface, and the* $\mathsf{Real}^{\uparrow}$ *face is the local terminal seal row.*

Thus a finite section is accepted by the terminal seal precisely through this visible BEDC pullback. It has no accepted coordinate for quotient streams, host real equality, selected limits, countable choice, ambient completeness, metric-completeness rows, standard bridge rows, or hidden completion carriers.

Proof. For the forward direction, start with an accepted finite section $\mathcal{S}$. By Definition 38.718, the terminal seal read is exhausted by the four displayed faces and by the BHist, hsame, Cont, Pkg, and NameCert support rows.

Refine the section inside that cover. The refinement monotonicity theorem Definition 38.719 keeps any visible finite refinement on the same four-face route, so the accepted section cannot leave the displayed terminal packet while preserving its support rows.

Now identify the three source faces. The StreamName tail-compatible request, Definition 126.542, supplies the finite window row. The RegSeqRat common-tail finite-request pullback, Definition 301.184, identifies the common-tail readback with the same finite Real seal boundary. The DyadicRatCore scale-window monotonicity and terminal fusion theorems, Definition 291.41 and Definition 291.46, force the dyadic entry face onto one terminal scale-window packet.

For the reverse direction, suppose the visible pullback is exactly this ordered four-face packet with the displayed support rows. The StreamName request, RegSeqRat pullback, and DyadicRatCore terminal fusion results assemble the section as a finite route into the local $\mathsf{Real}^{\uparrow}$ seal row. Applying Definition 38.719 to that route gives an accepted finite-window terminal seal section.

The exclusion clauses are inherited from the same cited routes and from Definition 38.718. Quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness rows, standard bridge rows, and hidden completion carriers are not rows of the pullback, so they cannot be used to accept another finite section of the terminal seal. □

Theorem 38.721 (Real terminal finite-section classifier determinacy)**.** *Let $\mathcal{S}$ and $\mathcal{T}$ be accepted finite sections of terminal* $\mathsf{Real}^{\uparrow}$ *seal reads. Suppose their visible* $\mathsf{DyadicRatCore}^{\uparrow}$ *faces carry the same endpoint, radius, and distance ledger, their* $\mathsf{StreamName}^{\uparrow}$ *faces display the same finite window, their* $\mathsf{RegSeqRat}^{\uparrow}$ *faces display the same common-tail classifier and readback rows, their local* $\mathsf{Real}^{\uparrow}$ *faces display the same terminal seal row, and their support rows*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}$$

are the same displayed rows. Then $\mathcal{S}$ and $\mathcal{T}$ determine the same public $\mathsf{Real}^{\uparrow}$ *classifier route.*

Conversely, every public $\mathsf{Real}^{\uparrow}$ *classifier route accepted at this terminal finite-section boundary is determined by exactly the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-radius ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *common-tail readback surface, the local* $\mathsf{Real}^{\uparrow}$ *seal row, and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support rows. The route carries no quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness data, standard bridge row, or hidden completion carrier.*

Proof. First compare two accepted sections. By Definition 38.720, each accepted finite section is represented by the same ordered four-face pullback whenever its dyadic ledger, StreamName window, RegSeqRat common-tail readback, local Real seal row, and displayed support rows agree.

Now refine both representatives to the common finite window. The preservation clause in Definition 38.719 keeps the accepted status and forbids any extra coordinate from entering during this finite-window comparison.

Terminal uniqueness supplies the classifier route. Apply Definition 126.504 to the common $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces with the displayed support rows; the terminal pullback admits only one public Real classifier route over those faces.

Finally transport that route along the RegSeqRat budget boundary using Definition 38.715. This gives the same public classifier route for $\mathcal{S}$ and $\mathcal{T}$.

For the converse, start with an accepted public classifier route at the terminal finite-section boundary. Pullback exactness identifies its accepted boundary with the four displayed faces and support rows, and terminality makes that representation unique. Naturality then transports the route back to the RegSeqRat common-tail readback without adding quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness data, a standard bridge row, or a hidden completion carrier. □

Theorem 38.722 (Real terminal finite-cover seal descent)**.** *Let $\{\mathcal{S}_i\}_{i\in I}$ be a finite family of accepted terminal* $\mathsf{Real}^{\uparrow}$ *finite sections. Suppose the visible* $\mathsf{StreamName}^{\uparrow}$ *windows of the family satisfy the finite-cover pasted source hypotheses, the induced* RegSeqRat *handoff packages consume one shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *finite ledger on every displayed overlap, and the local* $\mathsf{Real}^{\uparrow}$ *seal classifier rows agree on all pairwise overlaps and satisfy the displayed triple-overlap cocycle. Suppose also that the support rows*

$$\mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}$$

restrict compatibly on the same finite cover.

Then the family descends to one public $\mathsf{Real}^{\uparrow}$ *classifier route over the finite union of the windows. This descended route is exhausted by the pasted* $\mathsf{StreamName}^{\uparrow}$ *source surface, the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *finite ledger, the pasted* RegSeqRat *handoff surface, the local* $\mathsf{Real}^{\uparrow}$ *seal row, and the displayed support rows. It exports no quotient stream equality, selected limit, countable-choice selector, ambient completeness theorem, metric-completeness row, standard bridge row, or hidden completion carrier.*

Proof. First paste the finite source surface. Apply Definition 126.551 to the certified $\mathsf{StreamName}^{\uparrow}$ windows, their displayed overlaps, their triple-overlap cocycles, and the shared DyadicRatCore finite ledger. This produces one RegSeqRat and finite-window Real source surface over the finite union.

Next paste the seal rows. The overlap agreement of the local $\mathsf{Real}^{\uparrow}$ classifier rows and the triple-overlap seal cocycle are exactly the hypotheses of Definition 126.552, so the local seal classifiers form one finite-window Real seal surface over the same finite union.

Now identify each local section with the terminal four-face packet. Use Definition 38.720 on every accepted $\mathcal{S}_i$. The only visible rows of each local section are the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces together with the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

The shared dyadic ledger is the same finite-tail input consumed by Definition 291.61. That route places the pasted source and pasted seal surfaces on the displayed

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

packet and leaves no auxiliary equality, selected-limit, completeness, or bridge coordinate.

Finally apply Definition 38.721. Since the pasted finite union has one dyadic ledger, one StreamName source surface, one RegSeqRat handoff surface, one local Real seal row, and compatible support rows, the public terminal classifier route is determined uniquely over that finite union. The non-escape clauses of the cited pasted-source, pasted-seal, pullback, determinacy, and finite-tail factorization routes give exactly the exclusions in the statement. □

Theorem 38.723 (RealUp RealCompleteness exit route)**.** *Let S be an accepted* $\mathsf{Real}^{\uparrow}$ *seal consumed as a Phase Real and Completion endpoint, and suppose the endpoint read is supplied by an accepted* $\mathsf{RealCompleteness}^{\uparrow}$ *diagonal packet*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N).$$

Every completion-facing read of S factors through exactly the displayed $\mathsf{RealCompleteness}^{\uparrow}$ *diagonal packet, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row Q, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, and the BEDC support rows* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *carried by H, C, P, N.*

The route exports no quotient stream, host real equality, selected external limit, countable-choice row, ambient completeness theorem, standard bridge row, or completion-facing coordinate outside that finite packet.

Proof. Start with the $\mathsf{RealCompleteness}^{\uparrow}$ public seal export. Theorem 450.12 identifies the endpoint consumed by $\mathsf{Real}^{\uparrow}$ and completion-facing readers with the seal row S reached through the displayed rows D, W, Q, H, C, P, N of the accepted diagonal packet.

Next apply the diagonal-limit candidate theorem and the non-escape boundary from chapter 450. The diagonal-limit candidate theorem routes the candidate through the explicit selector, the dyadic ledger, the StreamName windows, the RegSeqRat readback row, and the support rows, while the non-escape boundary rules out quotient streams, selected host limits, countable choice, host real equality, and ambient completeness as exported coordinates.

Now compare this packet with the local $\mathsf{Real}^{\uparrow}$ terminal route. By Definition 38.713, a terminal-budget Real read is exhausted by the ordered four-face packet over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ with the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows. By Definition 38.534, the same four faces determine the Phase Real and Completion endpoint route.

Finally use the consumer-side consistency check Definition 646.75. It pins the completion-facing consumer to the same four-face budget surface, so the $\mathsf{RealCompleteness}^{\uparrow}$ diagonal packet and the local $\mathsf{Real}^{\uparrow}$ seal read have one finite exit route. Since all cited boundaries expose only the listed rows, no quotient stream, host equality, selected external limit, countable-choice row, ambient completeness theorem, standard bridge row, or separate completion-facing coordinate can be read from the endpoint. □

Theorem 38.724 (RealCompleteness consumer direction)**.** *Let S be a displayed* $\mathsf{Real}^{\uparrow}$ *seal and let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *diagonal packet consuming that seal as a Phase Real and Completion endpoint. The packet is only a completion-facing consumer route for the already displayed* $\mathsf{Real}^{\uparrow}$ *seal: it agrees with the four-face route through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *exactly along the exposed rows D, W, Q, S, H, C, P, N.*

This direction does not assert that every $\mathsf{Real}^{\uparrow}$ *seal carries such a diagonal packet, does not supply* $\mathsf{Real}^{\uparrow}$ *completeness, does not change any face status, and does not add a standard bridge row.*

Proof. First apply Definition 38.723. It identifies any completion-facing read of the displayed seal with the $\mathsf{RealCompleteness}^{\uparrow}$ diagonal packet and with the StreamName, RegSeqRat, DyadicRatCore, and support rows exposed by D, W, Q, S, H, C, P, N.

Next compare that packet with the Phase Real terminal route. Theorem 38.713 exhausts terminal Real reads by the four-face budget over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, and Definition 38.534 reads the same four objects as the Phase Real and Completion endpoint route.

Finally use Definition 646.75. It keeps the diagonal-limit consumer on the same four-face budget surface, so the only agreement being recorded is the consumer-side agreement along the displayed rows.

The roadmap two-axis discipline then supplies the refusal of the opposite reading. A consumer route for one exposed diagonal packet is not a quantified existence theorem for all $\mathsf{Real}^{\uparrow}$ seals, not a completeness theorem for $\mathsf{Real}^{\uparrow}$, not a face-status change, and not a standard bridge row. □

Theorem 38.725 (Real L10 single completion packet is not completeness)**.** *Let S be a displayed* $\mathsf{Real}^{\uparrow}$ *seal and let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be an accepted $\mathsf{RealCompleteness}^{\uparrow}$ *diagonal packet consuming that seal as a Phase Real and Completion endpoint. The existence of this one accepted packet gives only the finite four-face consumer route over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and the local* $\mathsf{Real}^{\uparrow}$ *seal, with the displayed rows D, W, Q, S, H, C, P, N and the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *support.*

It does not imply the quantified claim that every accepted $\mathsf{Real}^{\uparrow}$ *seal has such a packet, does not add a selected-limit operation, and does not certify* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First apply Definition 38.724. It records only the consumer direction for the displayed packet R and the displayed seal S, so its conclusion is a one-packet route rather than a universal existence principle over all accepted $\mathsf{Real}^{\uparrow}$ seals.

Next use Definition 38.732. The admissible endpoint read is exactly the ordered four-face packet through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the local $\mathsf{Real}^{\uparrow}$ seal, together with the local records and shared support rows named in the statement.

The possible substitute readings are excluded by Definition 38.730. Replacing the four-face route by a host equality row, quotient row, selected-limit row, or completeness row leaves no accepted L10 exit route.

Finally apply Definition 38.736. Since completeness and selected external limits are not consequences of the seal handoff, the single accepted $\mathsf{RealCompleteness}^{\uparrow}$ consumer packet cannot certify $\mathsf{Real}^{\uparrow}$ completeness or supply a selected-limit operation. □

Theorem 38.726 (RealCompleteness L10 exit interface exhaustion)**.** *Let S be an accepted* $\mathsf{Real}^{\uparrow}$ *seal consumed by a Phase Real and Completion interface read, and suppose that this read reaches the public* $\mathsf{RealCompleteness}^{\uparrow}$ *seal through an accepted diagonal packet*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N).$$

Then the interface read factors through exactly the four L10 boundary faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The only transport and support rows available along the route are the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows carried by* D, W, Q, S, H, C, P, N.

The interface exports no quotient stream, host real equality, selected external limit, countable-choice row, ambient completeness theorem, metric-completion row, or separate StandardBridge *coordinate.*

Proof. Begin with the exit route of Definition 38.723. It identifies any completion-facing read of S reached through the public $\mathsf{RealCompleteness}^{\uparrow}$ packet with the displayed diagonal rows D, W, Q, S, H, C, P, N and rules out every coordinate not exposed by that finite packet.

Next apply the Real L10 interface-totality theorem, Definition 38.444. This places the same Phase Real and Completion read inside the ordered four-face lattice $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with no additional quotient, host-real, selector, choice, arithmetic, order, or metric-completeness interface row.

The RegSeqRat handoff supplies the regular-rational boundary face. By Definition 301.154, the public RealUp consumer is unblocked only by the finite StreamName–RegSeqRat–RealUp scope row and the dyadic tail-budget surface, preserving hsame, Cont, Pkg, and NameCert provenance across the downstream handoff.

Finally use the four-face ownership theorem, Definition 646.75. It identifies the completion-facing consumer boundary with the same StreamName, DyadicRatCore, RegSeqRat, and Real faces and treats H, C, P, N only as shared support rows. Thus the public $\mathsf{RealCompleteness}^{\uparrow}$ seal can be read at the L10 boundary exactly through those four faces and the displayed BEDC support rows, and none of the excluded quotient, host, choice, completeness, metric-completion, or StandardBridge coordinates is exported. □

Theorem 38.727 (RealCompleteness finite diagonal induction)**.** *Let S be an accepted* $\mathsf{Real}^{\uparrow}$ *seal consumed by a Phase Real and Completion interface read, and let*

$$R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$$

be the accepted $\mathsf{RealCompleteness}^{\uparrow}$ *diagonal packet that supplies the read. Finite induction over the displayed packet extracts, in order, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance face D, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window face W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback face Q, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal face S. At every induction stage the only transport and support rows are* BHist, *componentwise* hsame, Cont *replay,* Pkg *provenance, and the local* NameCert *rows carried by* D, W, Q, S, H, C, P, N.

Consequently the diagonal induction exports no quotient stream, selected host limit, countable choice, ambient completeness, metric-completeness, aggregate formalstatus, aggregate bridge, or $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. For the base case, read the displayed seal row from Definition 38.723. That theorem identifies the accepted consumer endpoint with the diagonal packet $R = (X, \mu, \Delta, D, W, Q, S, H, C, P, N)$ and keeps all exported coordinates inside the finite route named by the packet.

For the induction step, peel one displayed packet coordinate at a time. The first projection exposes the dyadic tolerance face D; the next exposes the StreamName finite-window face W; the

next exposes the RegSeqRat readback face Q; the terminal projection exposes the local Real seal face S. Each peel preserves the route already extracted because the only transport data available are the componentwise hsame rows, the Cont replay rows, the Pkg provenance rows, and the local NameCert support rows.

The extracted route is then exhausted by Definition 38.726. It identifies the same consumer read with exactly the four L10 boundary faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, and it rules out every coordinate not carried by the finite packet.

Finally invoke Definition 38.731. It orders the extracted faces as the dyadic ledger, the finite-window StreamName rows, the regular-rational readback rows, and the terminal Real seal. Since no other row appears in either the induction or the exhaustion theorem, quotient streams, selected host limits, countable choice, ambient completeness, metric-completeness, aggregate formalstatus, aggregate bridge, and $\mathsf{Real}^{\uparrow}$ completeness remain unavailable. □

Theorem 38.728 (Real L10 four-face audit-clean handoff)**.** *Let S be an accepted* $\mathsf{Real}^{\uparrow}$ *seal consumed by a Phase Real and Completion L10 exit packet. The packet is a valid audit-clean handoff only when the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic face, the* $\mathsf{StreamName}^{\uparrow}$ *countable-name face, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy face, and the local* $\mathsf{Real}^{\uparrow}$ *seal face are each read through their own closurestatus and formalstatus records. The paper-closure grade of one face never promotes the Lean-verification grade of another face, and a Lean audit token never promotes a paper-closure grade.*

Consequently the handoff exports only the four named faces and the shared BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows already displayed by the route. It does not certify that* $\mathsf{Real}^{\uparrow}$ *is complete.*

Proof. Start with Definition 38.726. It exhausts the L10 interface by the four boundary faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with only the displayed BEDC support rows.

Read the four faces separately. The dyadic arithmetic face is governed by its own closurestatus and formalstatus record, the StreamName face by its finite-window name record, the RegSeqRat face by its regular-Cauchy handoff record, and the Real face by the local seal record. These records are inputs to the handoff, not consequences of one another.

The no-promotion claim is just the two-axis discipline applied componentwise. A theory-closure row states a paper-side scope boundary, while a formalstatus row states the Lean-side verification grade of the named target. Since the L10 exit theorem only projects the route through the four faces, it has no constructor that turns either axis into the other.

Finally use the off-table exclusions in the exit interface. Completeness is not among the exported rows, so the handoff can be audit-clean as a route while still refusing the statement that $\mathsf{Real}^{\uparrow}$ is complete. □

Theorem 38.729 (Real L10 facewise audit obstruction)**.** *A Phase Real and Completion L10 exit read of an accepted* $\mathsf{Real}^{\uparrow}$ *seal is audit-admissible only as a componentwise four-face product. On the displayed route, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic face, the* $\mathsf{StreamName}^{\uparrow}$ *countable-name face, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy face, and the local* $\mathsf{Real}^{\uparrow}$ *seal face must each provide its own closurestatus and formalstatus record.*

If any one of these four local face records is absent, the exit packet has no aggregate audit token, fifth face, completeness row, bridge row, or shared BHist*,* hsame*,* Cont*,* Pkg*, or* NameCert *support row that can compensate for the missing record.*

Proof. First apply Definition 38.726. It restricts the L10 exit interface to the four boundary faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$ and to the displayed BEDC support rows.

Next apply Definition 38.728. The audit-clean handoff reads the four closurestatus and formalstatus records separately: dyadic arithmetic, finite-window name, regular-Cauchy readback, and local Real seal. These records are independent inputs to the route, so omitting one face leaves that component with no local audit witness.

Finally use Definition 38.736. Completeness, selected external limits, countable choice, host equality, quotient construction, and standard bridge data are not consequences of the seal handoff. Since the exhausted interface contains no fifth face and no aggregate replacement token, none of those excluded rows can supply the missing local face record. □

Theorem 38.730 (Real L10 incomplete face exit obstruction)**.** *An accepted Phase Real and Completion terminal* $\mathsf{Real}^{\uparrow}$ *exit requires all four source faces displayed by the L10 route: the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic face, the* $\mathsf{StreamName}^{\uparrow}$ *countable-name face, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy face, and the local* $\mathsf{Real}^{\uparrow}$ *seal face. Each face must appear with its own* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows and with its local closurestatus and formalstatus record.*

If any one of the four faces is absent, replaced by a host equality row, a quotient row, a selected-limit row, or a completeness row, or detached from its local closurestatus and formalstatus record, then the packet has no accepted L10 exit route.

Proof. Use Definition 38.726 to identify the terminal interface. It admits only the four boundary faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, together with the displayed BEDC support rows.

Apply Definition 38.728 and Definition 38.729. They make the audit token componentwise: each face is read through its own closurestatus and formalstatus record, and no aggregate row can compensate for a missing local face.

The ordered source route is fixed by Definition 38.731. Therefore deleting or replacing any one source face breaks one of the four route positions rather than producing another admissible terminal path.

Finally apply Definition 38.736. Host equality, quotient construction, selected external limits, completeness, and standard bridge data are off-table for the seal handoff, so none of them supplies the missing face or its local audit record. □

Theorem 38.731 (Real StreamName-RegSeqRat-Dyadic audit route)**.** *Every accepted Phase Real and Completion L10 exit read of a* $\mathsf{Real}^{\uparrow}$ *seal follows the ordered source route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The route begins with the $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic tolerance ledger, exposes the* $\mathsf{StreamName}^{\uparrow}$ *countable-name finite-window rows, passes through the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy readback rows, and ends at the local* $\mathsf{Real}^{\uparrow}$ *seal. At every step the only shared support rows are* BHist*, componentwise* hsame*,* Cont *replay,* Pkg *provenance, and the local* NameCert *rows.*

Proof. Apply Definition 38.726. It already identifies the L10 exit interface with the four boundary faces and with the support rows carried by D, W, Q, S, H, C, P, N.

The source route is then read by projection. The dyadic row D supplies the arithmetic tolerance face, the StreamName row W supplies the finite-window name face, the RegSeqRat row Q supplies the regular-Cauchy readback face, and the seal row S supplies the local Real face.

The remaining rows are structural. The BHist rows name the source histories, hsame transports componentwise agreement, Cont records replay of the same route, Pkg records provenance, and NameCert records the local certificate surfaces. No further carrier or classifier is used. □

Theorem 38.732 (Real L10 four-face exit criterion)**.** *An accepted Phase Real and Completion endpoint read of a* $\mathsf{Real}^{\uparrow}$ *seal is admissible exactly when it is supplied by the ordered four-face packet*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Each face must expose its own local closurestatus and formalstatus record, and the only shared route support rows are BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

Equivalently, the current L10 exit route accepts precisely the packets whose dyadic arithmetic face, finite-window StreamName face, regular-rational readback face, and local Real seal face all appear in that order with those local records and shared support rows. It accepts no quotient row, host equality row, selected external limit, completeness row, choice row, metric-completion row, or StandardBridge *reading in place of one of the four faces.*

Proof. For the forward direction, begin with Definition 38.726. It restricts every accepted Phase Real and Completion endpoint read to the four L10 boundary faces and to the displayed BEDC support rows.

Apply Definition 38.728 to read the closurestatus and formalstatus records face by face. Then apply Definition 38.731 to order the faces as the dyadic ledger, the StreamName finite-window rows, the RegSeqRat readback rows, and the local Real seal.

For the reverse direction, use Definition 38.534. A packet that supplies exactly the ordered four faces, their local records, and the shared BHist, hsame, Cont, Pkg, and NameCert rows has the terminal route data read by the Phase Real and Completion endpoint.

It remains to exclude substitute readings. The incomplete-face obstruction Definition 38.730 rules out deleting or replacing any one face, and Definition 38.736 rules out quotient construction, host equality, selected limits, completeness, choice, metric-completion, and StandardBridge consequences from the seal handoff. Thus the four-face packet is both necessary and sufficient for the admissible L10 endpoint read. □

Theorem 38.733 (Real L10 four-object phase exit certificate)**.** *A Phase Real and Completion endpoint read of an accepted* $\mathsf{Real}^{\uparrow}$ *seal is accepted exactly as the four-object certificate over*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The certificate consists only of the dyadic tolerance ledger, the finite-window StreamName rows, the RegSeqRat readback rows, the local Real seal row, and the shared BEDC support rows BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

Thus the current Phase Real and Completion exit surface is precisely the displayed four-object certificate. It contains no quotient stream, host real equality, selected limit, countable-choice row, completeness row, metric-completion row, or StandardBridge *row.*

Proof. First apply Definition 38.726. It exhausts every Phase Real and Completion interface read of the accepted seal by the four L10 boundary faces and the displayed support rows.

Next apply Definition 38.728. It keeps the four boundary faces componentwise audit-clean and prevents a closurestatus row for one face from supplying the formalstatus row of another face.

The source order is fixed by Definition 38.731. The endpoint certificate therefore starts at the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, passes through the $\mathsf{StreamName}^{\uparrow}$ finite-window name rows and the $\mathsf{RegSeqRat}^{\uparrow}$ regular-rational readback rows, and terminates at the local $\mathsf{Real}^{\uparrow}$ seal.

Finally apply Definition 38.732. It gives the exact acceptance criterion for this ordered packet: the packet is admissible exactly when the four faces appear with their local records and the shared BHist, hsame, Cont, Pkg, and NameCert support rows.

The off-table coordinates are excluded by the same criterion together with the exit interface exhaustion. Quotient streams, host real equality, selected limits, countable choice, completeness, metric-completion, and StandardBridge rows are not among the certificate rows, so none can be read from the Phase Real and Completion endpoint. □

Theorem 38.734 (Real L10 four-object phase exit no-collapse)**.** *The four-object L10 phase-exit certificate over*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

cannot be reread as a bridge-axis row, an aggregate formalstatus row, a selected-limit operation, a quotient construction, or a completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

It remains exactly the finite BEDC exit certificate whose data are the dyadic tolerance ledger, the finite-window StreamName rows, the RegSeqRat readback rows, the local Real seal row, and the shared BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows.*

Proof. First apply Definition 38.726. It exhausts the L10 exit interface by the four displayed boundary faces and the stated BEDC support rows, so no fifth carrier or bridge-axis coordinate is available inside the endpoint read.

Next apply Definition 38.728. The handoff keeps the closurestatus and formalstatus records face-local: the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows each supply their own audit coordinate, and no aggregate formalstatus row can replace that componentwise route.

The route order is fixed by Definition 38.731. Hence a selected-limit operation or quotient construction cannot be inserted between the dyadic ledger, finite-window name rows, regular-rational readback rows, and the local Real seal without leaving the certified source route.

Finally use Definition 38.732. It accepts precisely the ordered four-face packet with the shared BHist, hsame, Cont, Pkg, and NameCert rows. The excluded completeness consequences are then exactly those named in Definition 38.736, so the certificate does not collapse into $\mathsf{Real}^{\uparrow}$ completeness or any standard bridge reading. □

Theorem 38.735 (Real L10 terminal route pullback square)**.** *An accepted Phase Real and Completion endpoint read of a* $\mathsf{Real}^{\uparrow}$ *seal is the pullback square whose four boundary maps are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *terminal tolerance exhaustion, the* $\mathsf{StreamName}^{\uparrow}$ *terminal pullback factorization, the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-cover audit-threshold gluing, and the local* $\mathsf{Real}^{\uparrow}$ *seal route:*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow},$$
$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow},$$
$$\mathsf{StreamName}^{\uparrow} \to \mathsf{Real}^{\uparrow},$$
$$\mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The square is determined only by the visible BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows carried by those four faces. No quotient stream, selected limit, countable-choice row, metric-completion datum, aggregate formalstatus row, bridge row, or* $\mathsf{Real}^{\uparrow}$ *completeness theorem can fill a missing face of the square.*

Proof. First read the dyadic boundary through Definition 291.123. Its terminal tolerance exhaustion supplies the finite dyadic ledger and exposes the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and local $\mathsf{Real}^{\uparrow}$ faces with only the shared support rows.

Next apply Definition 126.115 and Definition 301.227. The StreamName factorization identifies the upstream terminal route through the StreamName, RegSeqRat, DyadicRatCore, and

Real faces, while the RegSeqRat gluing reads compatible finite-cover audit-threshold data as one terminal section over those faces.

The local endpoint is fixed by Definition 38.732. It accepts exactly the ordered four-face packet and its visible BHist, hsame, Cont, Pkg, and NameCert support rows, so the three upstream maps and the local Real seal route form one pullback square rather than four unrelated claims.

Finally use Definition 38.734. It excludes bridge-axis rows, aggregate formalstatus rows, selected limits, quotient constructions, and completeness theorems from the certificate. Therefore none of the excluded rows can replace a missing boundary map or supply an additional face of the square. □

Theorem 38.736 (RealUp seal handoff has no completeness consequence)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal handoff supplied by the L10 exit route does not imply that* $\mathsf{Real}^{\uparrow}$ *is complete. It also does not imply Dedekind-cut completeness, trichotomy, quotient-by-equivalence-class construction of reals, selected external limits, host real equality, countable choice, or any standard bridge consequence not explicitly present in the four-face route.*

Proof. Use Definition 38.728. The handoff is valid only as a four-face route whose inputs are the displayed closurestatus and formalstatus records. Those inputs name route acceptance and audit status, not analytic completeness.

Next use Definition 38.731. Its data are exactly the DyadicRatCore ledger, StreamName finite-window rows, RegSeqRat readback rows, the local Real seal, and the shared BHist, hsame, Cont, Pkg, and NameCert rows.

The listed completeness and order principles require additional public rows: a completeness carrier, a Dedekind-cut interface, a trichotomy classifier, a quotient construction, a selected limit operator, host equality, choice, or a bridge schema. None appears in the route. Therefore none is projected from the seal handoff. □

38.5 StreamName and RegSeqRat dependency route

Theorem 38.737 (Real seal StreamName-RegSeqRat dependency route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read consumes the finite* $\mathsf{StreamName}^{\uparrow}$ *window rows of chapter 126 before it reads the regularity and seal rows supplied by chapter 301. Thus the real-name carrier is routed through finite scheduled observations and regular rational-source ledgers before any completion-facing consumer can use the* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. The Real carrier of Definition 38.1 is specified as a sealed regular rational stream name. Its observations are StreamName rows, and its regularity certificate is exposed through the RegSeqRat source surface.

Project the StreamName surface first. A finite observation request fixes the scheduled window through chapter 126, so the later seal read cannot introduce an unnamed observation stream.

Then project the RegSeqRat surface. The regularity and classifier rows of chapter 301 supply the rational-source ledger consumed by the Real seal, so a completion-facing Real read is downstream of both sibling packets. □

Theorem 38.738 (Real seal DyadicRatCore-StreamName-RegSeqRat dependency route)**.** *Every accepted current-phase* $\mathsf{Real}^{\uparrow}$ *seal read factors through the ordered finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The DyadicRatCore endpoint and radius ledger is read before the StreamName finite-window schedule, the RegSeqRat regularity and classifier rows, and the local Real seal. The route exports no quotient streams, selected limits, host real equality, ambient completeness, metric-completeness rows, countable choice, or Real completeness coordinate.

Proof. Start from the Real carrier of Definition 38.1. The preceding dependency route, Definition 38.737, places every Real seal read downstream of the StreamName finite-window rows and the RegSeqRat regular-rational source rows.

Insert the DyadicRatCore face before those rows. The RegSeqRat bridge handoff exactness of Definition 291.28 says that the RegSeqRat finite-window handoff consumes the displayed DyadicRatCore endpoint and radius ledger, while the StreamName four-object terminal pullback of Definition 126.504 keeps the DyadicRatCore, StreamName, RegSeqRat, and local Real faces in one finite terminal packet.

Finally apply Real L10 finite-window witness determinacy, Definition 38.464. It identifies the public seal boundary with exactly the fused StreamName terminal-window packet, the DyadicRatCore endpoint and radius ledger, the RegSeqRat finite-request section, the local Real seal, and the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows. Hence the accepted current-phase seal read has the stated ordered route and none of the excluded quotient, selected-limit, host-equality, completeness, metric-completeness, choice, or Real-completeness coordinates. □

Theorem 38.739 (Real L10 four-face route order uniqueness)**.** *Every current-phase terminal* $\mathsf{Real}^{\uparrow}$ *seal section whose displayed rows are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier, regularity, and transport rows, and the public* $\mathsf{Real}^{\uparrow}$ *seal row has*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

as its unique BEDC route. Any attempted route omitting or permuting one face either loses one of the displayed rows or introduces an off-table coordinate, namely quotient stream equality, a selected limit, host real equality, ambient completeness, metric-completeness, countable choice, or a second $\mathsf{Real}^{\uparrow}$ *seal coordinate.*

Proof. The forward order is the route of Definition 38.738. It already reads the DyadicRatCore endpoint and radius ledger before the StreamName finite-window schedule, then the RegSeqRat regularity and classifier rows, and finally the local Real seal.

The order of the first three faces cannot be permuted without dropping a displayed row. The DyadicRatCore handoff exactness of Definition 291.28 makes the endpoint and radius ledger the finite handoff read by RegSeqRat, while the StreamName four-object terminal pullback of Definition 126.504 keeps the DyadicRatCore, StreamName, RegSeqRat, and Real faces in one terminal packet.

The public seal boundary is fixed by Real L10 finite-window witness determinacy, Definition 38.464. RegSeqRat terminal-section exhaustion, Definition 301.94, rules out a fifth-face witness or a shortcut witness between the regular rational section and the Real seal. Therefore every alternative route either omits one of the four displayed faces or leaves the table by adding one of the excluded quotient, selected-limit, host-equality, completeness, choice, or duplicate-seal coordinates. □

Theorem 38.740 (Real L10 four-face classifier coherence)**.** *Let S be an accepted current-phase terminal* $\mathsf{Real}^{\uparrow}$ *seal section whose displayed rows are exactly the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius*

ledger, the $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier, regularity, and transport rows, and the public* $\mathsf{Real}^{\uparrow}$ *seal row. Then the four visible classifier reads of* S *determine the same finite packet*

$$(\mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}).$$

Any classifier disagreement either drops one of the four displayed faces or leaves the table by adding an off-table coordinate: quotient stream equality, a selected limit, host real equality, ambient completeness, metric-completeness, countable choice, or a duplicate $\mathsf{Real}^{\uparrow}$ *seal coordinate.*

Proof. Start with the ordered route of Definition 38.739. It fixes the only current-phase terminal order as $\mathsf{DyadicRatCore}^{\uparrow}$ to $\mathsf{StreamName}^{\uparrow}$ to $\mathsf{RegSeqRat}^{\uparrow}$ to $\mathsf{Real}^{\uparrow}$, so a visible classifier comparison must be read on those four faces and on no independent route.

The endpoint and radius classifier compatibility comes from Definition 291.28. The finite-window packet shared by the four faces is supplied by Definition 126.504. Together these two results place the DyadicRatCore ledger, StreamName schedule, RegSeqRat classifier rows, and local Real seal row on one finite BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support packet.

It remains to exclude extra classifier sources. RegSeqRat terminal-section exhaustion, Definition 301.94, rules out a shortcut from the regular rational section to the Real seal and rules out a fifth classifier face. Real L10 finite-window witness determinacy, Definition 38.464, then fixes the public seal boundary to the same finite-window witness. Hence any classifier mismatch is visible as the loss of one of the four displayed faces, or else it requires one of the listed off-table coordinates. □

Theorem 38.741 (Real L10 route face deletion obstruction)**.** *Let* S *be an accepted current-phase terminal* $\mathsf{Real}^{\uparrow}$ *seal section with public seal boundary displayed on*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Then no route presenting the same public boundary may delete any one of these four faces. Deleting $\mathsf{DyadicRatCore}^{\uparrow}$ *loses the endpoint and radius ledger rows, deleting* $\mathsf{StreamName}^{\uparrow}$ *loses the finite-window schedule, deleting* $\mathsf{RegSeqRat}^{\uparrow}$ *loses the regularity and classifier rows, and deleting* $\mathsf{Real}^{\uparrow}$ *loses the seal row itself. Any purported route retaining the boundary after such a deletion must leave the permitted current-phase surface by adding quotient stream equality, a selected limit, host real equality, ambient completeness, metric-completeness, countable choice, or a duplicate* $\mathsf{Real}^{\uparrow}$ *seal coordinate.*

Proof. The accepted boundary first has the ordered route of Definition 38.738. Its unique current-phase order is fixed by Definition 38.739, so any route with the same public boundary must read the four displayed faces in the same finite order.

Now compare the four deletions. Without $\mathsf{DyadicRatCore}^{\uparrow}$ the route has no endpoint and radius ledger feeding the rational source rows. Without $\mathsf{StreamName}^{\uparrow}$ it has no finite-window schedule. Without $\mathsf{RegSeqRat}^{\uparrow}$ it has no regularity and classifier surface between the scheduled observations and the seal. Without $\mathsf{Real}^{\uparrow}$ it has no public seal row.

The terminal packet cannot hide these losses in another current-phase coordinate. The StreamName terminal pullback of Definition 126.504 keeps the four faces in one finite terminal packet, while Definition 301.94 rules out a shortcut or fifth face between the regular rational section and the Real seal.

Finally apply the classifier coherence theorem, Definition 38.740. It says the visible classifier reads determine the same finite BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ packet exactly on these faces; hence a route that claims the same boundary after deleting one face must supply the missing row by one of the excluded off-table coordinates. □

Theorem 38.742 (Real L10 four-face local-threshold descent)**.** *Let $\mathcal{E}$ be a finite Phase* $\mathsf{Real}^{\uparrow}$ *and Completion packet displayed exactly on the four faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

with support rows BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. If $\mathcal{E}$ satisfies the current-phase local threshold, then every accepted projection of the four-face route carries the same objectwise local threshold records on the DyadicRatCore endpoint and radius ledger, the StreamName finite-window schedule, the RegSeqRat classifier and regularity rows, and the local Real seal row.*

Conversely, any accepted four-face route projection carrying those four local threshold records together with the same displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support repacks as the current-phase Phase* $\mathsf{Real}^{\uparrow}$ *and Completion exit certificate of Definition 38.796. The descent and repacking use no quotient streams, selected limits, host real equality, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First put all classifier reads on one finite packet. By Definition 38.740, the visible classifier coordinates of an accepted route projection over the four displayed faces determine the same finite BHist, hsame, Cont, Pkg, and NameCert support packet.

For descent, apply Definition 38.796. It identifies the current Phase Real and Completion exit criterion with the objectwise product of the four local threshold records on $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the local $\mathsf{Real}^{\uparrow}$ face, supported by exactly those finite rows. Hence every accepted projection of that same packet reads the same four local threshold records.

The projection order does not add a second certificate. Use Definition 38.739 to fix the terminal route and use Definition 38.801 to compare support-row-preserving projections of the displayed packet. Thus the descended local threshold is independent of the accepted projection order.

For the converse direction, start with an accepted four-face route projection carrying the four local threshold records and the same displayed support rows. The local-threshold theorem repacks these rows as the current-phase exit certificate, and the classifier coherence theorem keeps the repacked certificate on the same finite four-face packet.

Finally apply Definition 38.793. Each face record and each displayed support row is indispensable, so no shortened route or off-table coordinate can present the same exit certificate. Therefore the repacking uses exactly the stated four faces and excludes the listed quotient, selected-limit, host-equality, choice, metric-completeness, aggregate-status, aggregate-bridge, standard-bridge, and completeness data. □

Theorem 38.743 (Real L10 tail-budget projection nonescape)**.** *Let S be an accepted current-phase terminal* $\mathsf{Real}^{\uparrow}$ *seal section whose public seal is read by a* $\mathsf{RegSeqRat}^{\uparrow}$ *tail-budget consumer. Then every support-row-preserving projection of that consumer remains on the displayed four-face route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The projection preserves the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows, and it may read only the DyadicRatCore endpoint and tolerance ledger, the StreamName finite-window schedule, the RegSeqRat tail-budget classifier and regularity rows, and the terminal Real seal. No such projection may introduce quotient stream equality, selected limits, host real equality, countable choice, ambient completeness, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, or a* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. First lock the tail-budget consumer to its source route. Apply Definition 301.112. The consumer can read the Real seal only through the StreamName schedule, the DyadicRatCore tolerance row, the RegSeqRat classifier, and the terminal $\mathsf{Real}^{\uparrow}$ seal. Thus the read has no source for quotient stream equality, selected limits, host real equality, choice, completeness data, or a separate Real completeness coordinate.

Next identify the local threshold records on the same four faces. Apply Definition 38.742. The accepted projection is therefore read objectwise on the DyadicRatCore endpoint and tolerance ledger, the StreamName finite-window schedule, the RegSeqRat classifier and regularity rows, and the local Real seal row, while preserving the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support packet.

It remains to exclude alternative projections of that packet. Use Definition 38.801 to compare support-row-preserving reads of the displayed route, and then apply Definition 38.793. The first result prevents a reordered projection from changing the certificate, and the second makes every listed face and support row indispensable. Hence a projection that is shortened or enlarged cannot present the same current-phase Real seal read, so the only surviving route is the displayed four-face route with exactly the support rows named in the statement. □

Theorem 38.744 (Real L10 four-face support exhaustion)**.** *Every accepted current-phase terminal* $\mathsf{Real}^{\uparrow}$ *seal section on the route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

has exactly the visible support inventory consisting of the DyadicRatCore endpoint and tolerance ledger, the StreamName finite-window schedule, the RegSeqRat classifier, regularity, and transport rows, the terminal Real seal, and the shared BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

Conversely, that inventory repacks as the same current-phase Phase $\mathsf{Real}^{\uparrow}$ *and Completion exit certificate. It contains no quotient streams, selected limits, host real equality, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, or* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. First read the objectwise threshold rows. Apply Definition 38.742: the accepted terminal section carries the DyadicRatCore endpoint and tolerance ledger, the StreamName finite-window schedule, the RegSeqRat classifier and regularity rows, and the local Real seal row over the common BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support packet.

Next lock that packet to the route. By Definition 38.743, every support-row-preserving projection remains on

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The route therefore has no available coordinate outside the four construction faces and the displayed support rows.

Now identify the endpoint and schedule inventories. Apply Definition 291.118 to read the DyadicRatCore endpoint and tolerance ledger, and apply Definition 126.657 to read the StreamName-side finite-window support surface. These two inventories sit inside the same RegSeqRat classifier, regularity, and transport rows and the same terminal Real seal.

For the converse, use Definition 38.793. The listed four face records and the shared BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows are indispensable, so the inventory repacks as the same current-phase Phase $\mathsf{Real}^{\uparrow}$ and Completion exit certificate. The same minimality statement excludes quotient streams, selected limits, host real equality, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, and $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 38.745 (Real L10 four-face exit criterion equivalence)**.** *An accepted current-phase terminal* $\mathsf{Real}^{\uparrow}$ *seal section satisfies the Phase* $\mathsf{Real}^{\uparrow}$ *and Completion exit criterion if and only if the same finite support packet exposes exactly the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier, regularity, and transport rows, the local* $\mathsf{Real}^{\uparrow}$ *seal row, and the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows.*

Equivalently, the exit criterion is the four-face packet

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

with no quotient streams, selected limits, host real equality, countable choice, ambient completeness, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, or separate $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. For the forward direction, apply Definition 38.744. It identifies every accepted terminal seal section on the displayed route with the visible inventory consisting of the DyadicRatCore endpoint and tolerance ledger, the StreamName finite-window schedule, the RegSeqRat classifier, regularity, and transport rows, the terminal Real seal, and the shared BHist, hsame, Cont, Pkg, and NameCert rows.

For the reverse direction, first read the objectwise exit ledger through Definition 291.110. Then use Definition 126.657 for the finite-window schedule and support surface, Definition 301.239 for the RegSeqRat terminal classifier and regularity rows, and Definition 301.246 for the finite-cover normal form joining the four faces.

These ingredients repack the displayed support inventory as the current-phase Phase $\mathsf{Real}^{\uparrow}$ and Completion exit certificate. Finally, Definition 38.746 separates that certificate from aggregate formalstatus, leantarget, bridge, metric-completeness, selected-limit, quotient-stream, and separate $\mathsf{Real}^{\uparrow}$ completeness coordinates, so the equivalence has exactly the exclusion list stated above. □

Theorem 38.746 (Real L10 dependency route axis independence)**.** *For any accepted current-phase terminal* $\mathsf{Real}^{\uparrow}$ *seal section on the route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow},$$

the dependency route determines only the construction faces, the classifier faces, and the support rows BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*. It does not determine or aggregate any* formalstatus*,* leantarget*, or* bridgestatus *row, nor any standard bridge row, metric-completeness row, selected limit, quotient stream, or* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. First identify the route and the support packet. The dependency theorem Definition 38.738 fixes the ordered four-object route, and Definition 38.742 reads the accepted local-threshold records on exactly those four faces with the displayed BHist, hsame, Cont, Pkg, and NameCert support rows.

Next rule out escape through tail-budget projection. Apply Definition 38.743. Any support-row-preserving consumer remains on the same four-face route and has no coordinate for quotient stream equality, selected limits, host real equality, countable choice, ambient completeness, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, or a $\mathsf{Real}^{\uparrow}$ completeness row.

Finally separate the route data from the verification and bridge axes. Apply Definition 38.833 and Definition 38.834. These keep status, Lean-target, and bridge-status rows as face-local reports rather than route-level credentials. Therefore the route supplies construction and classifier evidence with its finite support rows, but it supplies no aggregate verification token, bridge credential, metric-completeness claim, selected limit, quotient stream, or $\mathsf{Real}^{\uparrow}$ completeness claim. □

Theorem 38.747 (Real L10 completeness-coordinate refusal)**.** *Every accepted current-phase terminal* $\mathsf{Real}^{\uparrow}$ *seal section satisfying the four-face Phase* $\mathsf{Real}^{\uparrow}$ *and Completion exit criterion has no BEDC coordinate for Real completeness, metric completeness, selected limits, quotient stream equality, host real equality, countable choice, aggregate* formalstatus*, or aggregate* bridgestatus*.*

Equivalently, any assertion of one of these coordinates is not a refinement of the current L10 exit surface. It leaves the finite support packet

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

and is therefore a claim outside the accepted current-phase terminal seal.

Proof. First apply Definition 38.745. It identifies the exit criterion with the finite packet whose only construction faces are the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint and tolerance ledger, the $\mathsf{StreamName}^{\uparrow}$ finite-window schedule, the $\mathsf{RegSeqRat}^{\uparrow}$ classifier, regularity, and transport rows, the local $\mathsf{Real}^{\uparrow}$ seal row, and the shared BHist, hsame, Cont, Pkg, and NameCert rows.

Next apply Definition 38.744. The visible inventory of an accepted terminal section is exhausted by those four faces and support rows. Thus there is no remaining BEDC coordinate in the packet for quotient stream equality, selected limits, host real equality, countable choice, metric completeness, aggregate status, aggregate bridge data, or separate $\mathsf{Real}^{\uparrow}$ completeness.

It remains to rule out the same coordinates after projection. Use Definition 38.743. Any support-row-preserving consumer remains on the displayed route and cannot manufacture a new completion, limit-selection, quotient, host-equality, choice, status, bridge, or Real-completeness coordinate.

Finally apply Definition 38.746. The construction route is independent of the verification and bridge axes, so aggregate formalstatus and bridgestatus rows cannot be recovered from the terminal seal. Hence any assertion of one of the listed coordinates leaves the current L10 exit surface rather than strengthening it. □

Theorem 38.748 (Real L10 four-face exit certificate rigidification)**.** *An accepted current-phase terminal* $\mathsf{Real}^{\uparrow}$ *seal section is a Phase* $\mathsf{Real}^{\uparrow}$ *and Completion exit certificate if and only if its visible packet is the four-face route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

with the DyadicRatCore endpoint and tolerance ledger, the StreamName finite-window schedule, the RegSeqRat classifier, regularity, and transport rows, the terminal Real seal, and the shared BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Any presentation with the same exit certificate preserves those four faces and support rows. It cannot add quotient streams, selected limits, host real equality, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge data, standard bridge data, or a separate $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. First identify the certificate. Apply Definition 38.745. It says that the Phase $\mathsf{Real}^{\uparrow}$ and Completion exit criterion is exactly the finite packet displayed on the four construction faces with the shared BHist, hsame, Cont, Pkg, and NameCert support rows.

Next exhaust the support. Apply Definition 38.744. The accepted terminal seal section has no visible support beyond the DyadicRatCore endpoint and tolerance ledger, the StreamName finite-window schedule, the RegSeqRat classifier, regularity, and transport rows, the terminal Real seal, and the named shared rows.

Now rigidify alternative presentations of the same certificate. Use Definition 38.739, Definition 38.740, and Definition 38.793. These results keep the route order, classifier packet, and indispensable face records fixed, so a second presentation cannot delete, permute, duplicate, or replace one of the displayed faces while preserving the same exit certificate.

Finally apply Definition 38.746 and Definition 38.747. The route supplies construction and classifier evidence only, and the current L10 exit surface has no coordinate for quotient streams, selected limits, host real equality, countable choice, metric completeness, aggregate status, aggregate bridge data, standard bridge data, or separate $\mathsf{Real}^{\uparrow}$ completeness. Hence every presentation of the same exit certificate is rigidly the displayed four-face packet with the named support rows. □

Theorem 38.749 (Real L10 facewise projection gluing)**.** *Let an accepted current-phase terminal* $\mathsf{Real}^{\uparrow}$ *seal section carry four facewise projections on*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Assume the projections preserve the DyadicRatCore endpoint and tolerance ledger, the StreamName finite-window schedule, the RegSeqRat classifier, regularity, and transport rows, the local Real seal row, and the shared BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *support rows. Then their common read glues to the same Phase* $\mathsf{Real}^{\uparrow}$ *and Completion exit certificate.*

The glued certificate has no quotient stream, selected limit, host equality, countable choice, metric-completeness data, aggregate status, aggregate bridge data, standard bridge data, or separate $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. First read the facewise data through Definition 38.745. Since each projection preserves the DyadicRatCore endpoint and tolerance ledger, the StreamName finite-window schedule, the RegSeqRat classifier, regularity, and transport rows, and the local Real seal row over the same BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support, each face presents the finite packet required by the Phase $\mathsf{Real}^{\uparrow}$ and Completion exit criterion.

Next identify the common support. Apply Definition 38.744. The accepted terminal seal has no visible construction support outside the four displayed faces and the named support rows, so the four preserved reads cannot require an additional completion, quotient, equality, choice, status, or bridge coordinate.

Now align the classifier and route data. Use Definition 38.740 to keep the RegSeqRat classifier, regularity, and transport rows coherent across the four projections. Then use Definition 38.793 to repack the preserved endpoint, schedule, classifier, transport, and seal rows as one indispensable four-face certificate rather than four unrelated fragments.

Finally exclude escape coordinates. Apply Definition 38.746 to separate the construction route from aggregate status, Lean-target, and bridge rows, and apply Definition 38.747 to rule out Real completeness, metric completeness, selected limits, quotient streams, host equality, and countable choice. Therefore the common read of the four support-preserving projections glues to exactly the same current-phase Phase $\mathsf{Real}^{\uparrow}$ and Completion exit certificate, with no extra coordinate beyond the displayed packet. □

Theorem 38.750 (Real terminal seal machine-route exhaustion)**.** *Let S be an accepted current-phase terminal* $\mathsf{Real}^{\uparrow}$ *seal section on*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Then the machine-facing support of S is exhausted by exactly the StreamName singleton finite-window handoff, the DyadicRatCore RegSeqRat bridge handoff exactness, and the RegSeqRat Real

seal handoff. These three touchpoints consume the same four-face certificate glued from the DyadicRatCore endpoint and tolerance ledger, the StreamName finite-window schedule, the RegSeqRat classifier, regularity, and transport rows, the terminal Real seal, and the shared BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support.*

No machine-facing route for S may add quotient streams, selected limits, host real equality, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, or a $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. First glue the Real-side certificate. Apply Definition 38.749. The four support-preserving projections on the displayed route have a common read as the same Phase $\mathsf{Real}^{\uparrow}$ and Completion exit certificate, and the glued certificate already excludes quotient streams, selected limits, host equality, countable choice, metric-completeness data, aggregate status, aggregate bridge data, standard bridge data, and separate $\mathsf{Real}^{\uparrow}$ completeness.

Next identify the certificate with the local exit criterion. Apply Definition 38.745. The glued Real certificate is exactly the finite packet consisting of the DyadicRatCore endpoint and tolerance ledger, the StreamName finite-window schedule, the RegSeqRat classifier, regularity, and transport rows, the local Real seal row, and the shared BHist, hsame, Cont, Pkg, and NameCert support.

Now bind that finite packet to the machine route. Use Definition 126.452 and Definition 126.453. These identify the machine-facing route of the same four-face exit read with exactly the StreamName singleton finite-window handoff, the DyadicRatCore RegSeqRat bridge handoff exactness, and the RegSeqRat Real seal handoff.

Finally apply Definition 291.113. The DyadicRatCore-side ledger theorem says that an accepted four-face Phase Real and Completion packet has no machine support outside those three route sites. Hence the terminal $\mathsf{Real}^{\uparrow}$ seal section consumes precisely the three named touchpoints, while all quotient-stream, selected-limit, host-equality, choice, metric-completeness, aggregate-status, aggregate-bridge, standard-bridge, and $\mathsf{Real}^{\uparrow}$ completeness coordinates remain outside the accepted current-phase route. □

Theorem 38.751 (Real four-face machine touchpoint minimality)**.** *Let S be an accepted current-phase terminal* $\mathsf{Real}^{\uparrow}$ *seal section on*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Then S is machine-admissible for the Phase $\mathsf{Real}^{\uparrow}$ *and Completion exit if and only if the StreamName singleton finite-window handoff, the DyadicRatCore RegSeqRat bridge handoff exactness, and the RegSeqRat Real seal handoff read the same four-face certificate over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

Moreover these three touchpoints are a minimal basis for the accepted machine-facing route: deleting any one of them fails to present the same accepted route from the DyadicRatCore endpoint and tolerance ledger through the StreamName finite-window schedule and the RegSeqRat classifier, regularity, and transport rows to the terminal Real seal.

Proof. For the forward direction, apply Definition 38.750. The theorem identifies the machine-facing support of S with exactly the StreamName singleton finite-window handoff, the DyadicRatCore RegSeqRat bridge handoff exactness, and the RegSeqRat Real seal handoff, all consuming the same four-face certificate over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

For the reverse direction, use Definition 38.745. A common read by the three named machine touchpoints exposes precisely the finite support packet for the Phase $\mathsf{Real}^{\uparrow}$ and Completion exit

criterion. Then apply Definition 126.453 and Definition 291.113: the StreamName boundary theorem places the read on the same machine-facing route, and the DyadicRatCore completeness theorem rules out any additional machine support site.

It remains to prove minimality. The StreamName singleton finite-window handoff is required by Definition 126.452; without it the finite-window schedule is absent from the machine read. The DyadicRatCore RegSeqRat bridge handoff exactness is required by Definition 291.113; without it the endpoint and tolerance ledger do not reach the RegSeqRat classifier and transport rows. The RegSeqRat Real seal handoff is required by Definition 126.453; without it the route has no terminal $\mathsf{Real}^{\uparrow}$ seal presentation.

Finally apply Definition 38.741. Deleting any indispensable construction face or support row from the four-face packet fails to present the same accepted exit certificate. Therefore deleting any one of the three machine touchpoints fails to present the same accepted machine-facing route, and the three touchpoints form the minimal sufficient basis for admissibility. □

Theorem 38.752 (Real L10 finite bundle induction)**.** *Let S be an accepted current-phase terminal* $\mathsf{Real}^{\uparrow}$ *seal section over the ordered route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Let $\mathcal{B}$ be a finite ProbeBundle *of certified unary observations for S. Assume that the rows of $\mathcal{B}$ expose exactly the DyadicRatCore endpoint and tolerance ledger, the StreamName finite-window schedule, the RegSeqRat classifier, regularity, and transport rows, the local Real seal row, and the shared* BHist, hsame, Cont, Pkg, *and* NameCert *support.*

Then induction over the rows of $\mathcal{B}$ determines a unique terminal four-face audit packet for S, and that packet is precisely the packet consumed by the StreamName singleton finite-window handoff, the DyadicRatCore RegSeqRat bridge handoff exactness, and the RegSeqRat Real seal handoff of Definition 38.751. The induced packet contains no quotient stream equality, selected limit, host real equality, countable-choice row, metric-completeness datum, aggregate formalstatus row, aggregate bridge row, standard bridge row, or $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Begin with the empty prefix of $\mathcal{B}$. The visible support is the fixed ordered route of Definition 38.739, so the prefix has no alternative route on which to place a hidden quotient, selected-limit, host-equality, choice, completeness, status, or bridge coordinate.

For the induction step, add one certified unary observation while preserving the same visible support rows. Apply Definition 38.740: the new observation must read the same finite BHist, hsame, Cont, Pkg, and NameCert packet as the earlier rows, and its RegSeqRat classifier, regularity, and transport data cannot split away from the DyadicRatCore ledger, StreamName schedule, or local Real seal.

It remains to rule out a step that changes the terminal packet by deleting or replacing a face. Use Definition 38.741. Any such change loses one of the four displayed construction faces or supplies the missing row from an off-table coordinate, which contradicts the hypothesis that $\mathcal{B}$ exposes exactly the displayed ledger, schedule, classifier, regularity, transport, seal, and shared support rows.

After the finite induction closes, identify the resulting packet with the machine-facing route. Apply Definition 126.453 and Definition 291.113. These boundary theorems place the induced four-face packet on exactly the StreamName singleton finite-window handoff, the DyadicRatCore RegSeqRat bridge handoff exactness, and the RegSeqRat Real seal handoff.

Finally invoke Definition 38.751. Since those three touchpoints are the minimal basis for the accepted route, the packet determined by the finite bundle is the unique terminal four-face audit

packet consumed by them, and the excluded quotient-stream, selected-limit, host-equality, choice, metric-completeness, aggregate-status, aggregate-bridge, standard-bridge, and $\mathsf{Real}^{\uparrow}$ completeness coordinates remain outside the accepted current-phase surface. □

Theorem 38.753 (Real L10 machine-audit locality)**.** *Let S be an accepted current-phase terminal* $\mathsf{Real}^{\uparrow}$ *seal section on*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Assume that the StreamName singleton finite-window handoff, the DyadicRatCore RegSeqRat bridge handoff exactness, and the RegSeqRat Real seal handoff read the same four-face certificate named in Definition 38.751. Then every audit-facing coordinate of that machine read is exactly one of the four local face records: the local closurestatus, formalstatus, leantarget, and bridgestatus records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *seal face.*

Conversely, those four local objectwise audit records together with the three named machine touchpoints present the same machine-audit route for S. The route contains no aggregate formalstatus row, route-level leantarget, aggregate bridge row, standard bridge row, quotient stream equality, selected limit, countable-choice row, metric-completeness datum, or $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. First identify the machine route. Apply Definition 38.750 and Definition 38.751. The accepted terminal seal has exactly the three machine touchpoints in the statement, and those touchpoints consume one common four-face certificate over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Next read the audit records objectwise. Use Definition 38.834 and Definition 38.815. These keep closurestatus, formalstatus, leantarget, and bridgestatus attached to the four local faces, so the machine read cannot fuse them into a route-level verification token or replace a local face record by an aggregate bridge credential.

Now separate the gateway inventory from the touchpoint inventory. Apply Definition 126.491 and Definition 126.489. The gateway audit records are the four objectwise face records, while the machine-facing route factors through the three named handoff positions. Thus a touchpoint reports its route position only by reading those local records; it does not create an additional audit-facing coordinate.

For the converse direction, start with the four local closurestatus, formalstatus, leantarget, and bridgestatus records together with the three touchpoints. The gateway factorization theorem repacks them as the same four-face machine read, and the terminal seal exhaustion theorem identifies that read with the accepted route for S.

Finally close the exclusions. Use Definition 126.452, Definition 126.453, and Definition 291.113. These boundary results exhaust the current machine support by the three named touchpoints and leave no coordinate for aggregate formalstatus, route-level leantarget, aggregate bridge data, standard bridge data, quotient stream equality, selected limits, countable choice, metric completeness, or separate $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 38.754 (Real uniform Cauchy completion route lock)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet read by a Phase Real and Completion consumer. If the consumer uses U to reach a* $\mathsf{Real}^{\uparrow}$ *seal or a completion-facing endpoint, then its route factors through*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$$

together with the $\mathsf{StreamName}^{\uparrow}$ *window row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row, and the local* $\mathsf{Real}^{\uparrow}$ *seal rows of Definition 38.442.*

The admitted route exposes only the finite packet rows $I, W, M, Q, T, E, H, C, P, N$ *and the shared* BHist, hsame, Cont, Pkg, *and* NameCert *support used by those sibling rows. It cannot export quotient streams, selected host limits, host real equality, countable choice, open-cover compactness, ambient completeness, or an additional completion carrier.*

Proof. Begin with the UniformCauchyCriterion finite-family seal obligation surface. Definition 435.81 and Definition 435.88 display the rows $I, W, M, Q, T, E, H, C, P, N$ and force the route from the finite index ledger to the Real seal handoff through the single chain $I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$.

Now attach the completion-budget rows. The real completion budget lock Definition 435.131 places any $\mathsf{RealCauchyCompletion}^{\uparrow}$ read after the same budget package, while the completion-functor budget handoff Definition 435.129 keeps functor-facing access inside the finite package and the regular shared-tail sibling.

Next identify the Real-side dependency lattice. The L10 dependency lattice Definition 38.442, the source-route non-escape theorem Definition 38.443, and the terminal source lock Definition 38.459 route every Phase Real or Completion read through the StreamName, DyadicRatCore, RegSeqRat, and local Real seal rows, with only BHist, hsame, Cont, Pkg, and NameCert support.

Finally compose the two boundaries with the UniformCauchyCriterion finite budget envelope Definition 435.140. The UniformCauchyCriterion side supplies the ordered budget chain, and the Real L10 side supplies the four sibling rows consumed by RealUp. Since the cited non-escape and budget-lock theorems expose no quotient stream, selected host limit, host equality, countable-choice row, open-cover compactness, ambient completeness, or extra completion carrier, the Real-and-Completion consumer has no route to export any of them. □

Theorem 38.755 (Real uniform Cauchy four-object terminal determinacy)**.** *Let*

$$U_0 = (I_0, W_0, M_0, Q_0, T_0, E_0, H_0, C_0, P_0, N_0)$$

and

$$U_1 = (I_1, W_1, M_1, Q_1, T_1, E_1, H_1, C_1, P_1, N_1)$$

be accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packets read by Phase Real and Completion consumers. Suppose the two reads expose the same finite family ledger, shared* $\mathsf{StreamName}^{\uparrow}$ *window family, modulus schedule,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, tail ledger,* $\mathsf{Real}^{\uparrow}$ *seal row, and the same displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support rows. Suppose also that their completion-facing boundaries expose the same four faces*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Then the two completion-facing reads factor through the same terminal finite BEDC pullback.

Conversely, every accepted uniform-Cauchy completion-facing read whose public surface is the finite budget

$$I, W, M, Q, T, E, H, C, P, N$$

together with those four faces is determined by that finite budget and by the four boundary faces. The resulting terminal read exports no quotient stream family, no host real equality, no selected family limit, no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, no metric-completeness datum, no countable-choice row, and no standard bridge row.*

Proof. First lock the finite uniform-Cauchy route. By Definition 38.754, any Phase Real and Completion consumer of an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ packet must pass through the ordered rows $I, W, M, Q, T, E, H, C, P, N$ before it reaches either a $\mathsf{Real}^{\uparrow}$ seal or a completion-facing endpoint.

Next apply the finite-family Real seal route determinacy theorem, Definition 435.22. Since the two reads expose the same family ledger, window family, modulus schedule, dyadic tolerance row, and tail ledger, they reach the same finite route through the seal rows E, H, C, P, N.

Now attach the completion boundary. The seal-completion boundary Definition 435.18 keeps every completion-facing consumer on the same finite public surface, and Definition 126.500 identifies the Real-and-Completion exit packet with the four displayed faces $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

With those faces fixed, use Definition 126.504. The terminal pullback theorem identifies any two accepted reads that expose the same four faces and the same BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support rows. Hence the two completion-facing reads determine the same terminal finite BEDC pullback.

For the converse direction, start with an accepted uniform-Cauchy completion-facing read whose public surface is exactly the finite budget and the four boundary faces. The route-lock theorem supplies the ordered UniformCauchyCriterion budget; the seal-completion boundary places the read at the Real seal boundary; the four-object exit route reads that boundary as the StreamName, DyadicRatCore, RegSeqRat, and RealUp packet. Terminal pullback then repackages the accepted read as the unique finite BEDC pullback determined by those rows.

The exclusion clause is inherited from the same citations. None of the locked budget rows or four boundary faces carries a coordinate for quotient stream families, host real equality, selected family limits, ambient Real completeness, metric-completeness data, countable choice, or standard bridge rows, so none of that data can distinguish two reads after the finite budget and the four faces agree. □

Theorem 38.756 (Real uniform Cauchy StreamName RegSeqRat terminal route correspondence)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet read by a Phase Real and Completion consumer. Suppose the finite budget route through*

$$I, W, M, Q, T, E, H, C, P, N$$

and the associated boundary rows expose the same $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows as a StreamName finite-request section and as a RegSeqRat shared-window selector surface. Then the finite budget route determines the StreamName section and the RegSeqRat selector surface.*

Conversely, the StreamName finite-request section together with the RegSeqRat shared-window selector surface determines the same accepted uniform-Cauchy completion-facing route through $I, W, M, Q, T, E, H, C, P, N$ *whenever the displayed rows named above agree. Thus the Phase Real and Completion handoff is one finite terminal BEDC surface, not three independent routes.*

The correspondence exports no quotient stream, no host real equality, no selected limit, no ambient completeness row, no countable-choice row, no metric-completeness row, and no standard bridge row.

Proof. First lock the uniform-Cauchy budget chain. By Definition 38.754, an accepted Phase Real and Completion read reaches the Real seal and the completion-facing endpoint only through the finite rows $I, W, M, Q, T, E, H, C, P, N$ and the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support.

Now recover the StreamName section from the same rows. Apply Definition 126.577. Since the uniform-Cauchy route displays the StreamName schedule, the DyadicRatCore endpoint-radius ledger, the RegSeqRat regularity and readback surface, and the support rows, the RealUp-facing finite request section has no coordinate beyond the rows already carried by the budget route.

Next recover the RegSeqRat selector surface. Use Definition 301.158 to identify matching shared-window selector surfaces, and use Definition 301.159 to pass between selector-surface equality and the terminal RealUp seal read on the four-face packet. These two results place the selector on the same StreamName, DyadicRatCore, RegSeqRat, RealUp, and support rows.

For the converse direction, start from the StreamName section and the RegSeqRat selector surface with the displayed rows fixed. The pullback theorem supplies the finite section read, the selector determinacy supplies the shared-window surface, and the terminal pullback equivalence returns the same terminal seal coordinate. Applying Definition 38.755 then repacks those rows as the unique finite uniform-Cauchy completion-facing route through $I, W, M, Q, T, E, H, C, P, N$.

The non-escape clause is inherited from the same four inputs. The route lock, the StreamName pullback, the RegSeqRat selector determinacy, and the four-object terminal determinacy expose no quotient stream, host real equality, selected limit, ambient completeness row, countable-choice row, metric-completeness row, or standard bridge row, so none of those objects can separate the corresponding terminal surface. □

Theorem 38.757 (Real uniform Cauchy four-face status exactness)**.** *Let $U = (I, W, M, Q, T, E, H, C, P, N)$ be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ packet read by a Phase Real and Completion consumer. Suppose the public surface of the read is the finite budget $I, W, M, Q, T, E, H, C, P, N$ together with the four boundary faces*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Then the read is status-exact precisely when the $\mathsf{StreamName}^{\uparrow}$ face is read from its own closurestatus and formalstatus record, the $\mathsf{DyadicRatCore}^{\uparrow}$ face is read from its own closurestatus and formalstatus record, the $\mathsf{RegSeqRat}^{\uparrow}$ face is read from its own closurestatus and formalstatus record, and the $\mathsf{Real}^{\uparrow}$ face is read from its own closurestatus and formalstatus record.

No aggregate formal-status token, fifth completion object, quotient stream, selected limit, countable-choice row, metric-completeness datum, or standard bridge row can replace any one of the four face records. In particular, a completion-facing packet whose finite budget is accepted but whose evidence collapses two of the four status records into a single aggregate token is not a status-exact Real-and-Completion read.

Proof. First lock the ordered budget route. By Definition 38.754, every accepted completion-facing read using U reaches the Real seal boundary only through the displayed finite budget chain and the four Real L10 owners.

Next apply terminal determinacy over the four faces. The theorem Definition 38.755 identifies the completion-facing read with the finite terminal pullback determined by $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, together with the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support rows.

The status part is objectwise. The roadmap two-axis discipline records closure and verification independently at each object, so the StreamName, DyadicRatCore, RegSeqRat, and RealUp faces

each contribute their own closurestatus and formalstatus rows to the pullback. Reading one face's record gives no coordinate for another face's record.

Therefore status exactness is equivalent to exposing all four objectwise status records. The route lock and terminal pullback expose no aggregate formal-status token, fifth completion object, quotient stream, selected limit, countable-choice row, metric-completeness datum, or standard bridge row, so none of those objects can fill a missing face. □

Theorem 38.758 (Real uniform Cauchy four-face record minimality)**.** *Let* $U = (I, W, M, Q, T, E, H, C, P, N)$ *be an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet read by a Phase Real and Completion consumer. Suppose the accepted L10 exit reaches the completion-facing* $\mathsf{Real}^{\uparrow}$ *seal through exactly the four local faces*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Then the four local closurestatus and formalstatus records form a minimal facewise audit family for status exactness. No proper subfamily of these four records is sufficient for the status-exact L10 exit read.

In particular, identifying two face records, replacing one face record by an aggregate formalstatus token, or replacing one face record by route-level bridge prose destroys the accepted Real-and-Completion exit read. The audit boundary must retain one local status record for StreamName, one for DyadicRatCore, one for RegSeqRat, and one for the local Real seal.

Proof. Apply Definition 38.757. It identifies status exactness with the four objectwise closurestatus and formalstatus records and rejects aggregate formal-status tokens, fifth completion objects, quotient streams, selected limits, and bridge rows as replacements.

Next apply Definition 38.755. It fixes the terminal completion-facing pullback on the four displayed faces, so a proper subfamily leaves at least one terminal face without its status coordinate.

The separation of records is not route-level rhetoric. By Definition 38.833, the four local reports cannot be fused into a new formalstatus token, aggregate bridge row, or Real completeness claim.

Finally apply Definition 38.730. If any one face is absent, identified with another face, or detached from its local status record, the packet has no accepted L10 exit route. Thus all four independent face records are minimal data for the status-exact Real-and-Completion handoff. □

Theorem 38.759 (Real RegSeqRat–StreamName audit-clean handoff)**.** *Every Phase Real and Completion consumer that reaches the* $\mathsf{Real}^{\uparrow}$ *seal through an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet must pass through the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row, and the local* $\mathsf{Real}^{\uparrow}$ *seal before it can claim an audit-clean L10 handoff.*

Equivalently, the handoff is readable only through the displayed UniformCauchyCriterion rows, the four Real L10 row owners of Definition 38.442, and the shared BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support. Quotient streams, selected host limits, host real equality, countable choice, and ambient completion have no coordinate in the audit-clean handoff route.*

Proof. Start with the route lock of Definition 38.754. It already forces any Phase Real and Completion read through the finite UniformCauchyCriterion chain before a $\mathsf{Real}^{\uparrow}$ seal or completion-facing endpoint is exposed.

Then read the Real-side lattice. The dependency lattice of Definition 38.442 names the four row owners used by the route: $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The exclusion boundary is inherited from the Real L10 source theorems. Definition 38.443 removes quotient streams, selected host limits, host real equality, countable choice, and ambient

completion from the source route, while Definition 38.459 makes the Real seal terminal over the displayed source rows.

Thus an audit-clean handoff cannot be claimed before the consumer has exposed the StreamName finite window, DyadicRatCore tolerance ledger, RegSeqRat readback, and RealUp local seal. Since none of the excluded host objects occurs as a row in that route, none can supply an alternate handoff coordinate. □

Theorem 38.760 (Real uniform Cauchy budget pullback exhaustion)**.** *Let* $U = (I, W, M, Q, T, E, H, C, P, N)$ *be an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet read by a Phase Real and Completion consumer. The consumer reaches a public* $\mathsf{Real}^{\uparrow}$ *exit if and only if its finite budget chain*

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$$

pulls back to exactly the four L10 row owners: the $\mathsf{StreamName}^{\uparrow}$ *finite window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback and classifier row, and the* $\mathsf{Real}^{\uparrow}$ *terminal seal.*

This pullback exhausts the public exit surface. No quotient stream, selected host limit, countable-choice selector, ambient-completeness row, or hidden completion carrier supplies a fifth owner or an alternate Real exit.

Proof. First take the forward direction. By Definition 38.754, any consumer that uses U to reach a $\mathsf{Real}^{\uparrow}$ seal or completion-facing endpoint has already passed through the finite UniformCauchyCriterion budget chain $I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E$.

Apply Definition 38.515 to the resulting public $\mathsf{Real}^{\uparrow}$ read. The Real-side factorization admits the read only through the L10 stack whose visible owners are $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The row ownership is exact. The StreamName exit exactness theorem Definition 126.372 identifies the public Real-completion exit with the finite StreamName window, the regular-source row, the dyadic observation ledger, and the Real seal boundary. The RegSeqRat source lattice exhaustion theorem Definition 301.104 assigns those rows to the four displayed owners and leaves no unassigned source row.

For the reverse direction, assume the finite budget chain of U pulls back to exactly those four owners. The $\mathsf{StreamName}^{\uparrow}$ window supplies the finite source surface, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger supplies the dyadic budget rows, the $\mathsf{RegSeqRat}^{\uparrow}$ readback and classifier row supplies the regular source handoff, and the $\mathsf{Real}^{\uparrow}$ terminal seal supplies the public exit.

Recompose the same four rows using Definition 126.372. The exactness theorem packs the four-object route as a public Real-and-completion exit, while Definition 38.515 verifies that this is the RealUp input surface admitted by Phase Real and Completion.

Finally, the exclusions are inherited from the same route. The route lock Definition 38.754 and the three exactness theorems just cited expose only the displayed finite rows, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support. Since quotient streams, selected host limits, countable choice, ambient completeness, and hidden completion carriers are not rows of that packet, none can provide a fifth owner or a second public $\mathsf{Real}^{\uparrow}$ exit. □

Theorem 38.761 (Real uniform Cauchy completion route lock factorization)**.** *Let*

$$U = (I, W, M, Q, T, E, H, C, P, N)$$

be an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet read by a Phase Real and Completion consumer. The consumer reaches a public* $\mathsf{Real}^{\uparrow}$ *exit or a completion-facing exit exactly through the composite*

route

$$\mathsf{UniformCauchyCriterion}^{\uparrow} \longmapsto \mathsf{FiniteTailFilter}^{\uparrow} \longmapsto (\mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}).$$

The intervening $\mathsf{FiniteTailFilter}^{\uparrow}$ *packet reads the same finite windows, dyadic tolerance ledger, regular readback, tail budget, common-tail comparison, Real seal row, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance, and local* NameCert *row already displayed by* U*.*

This factorization is exhaustive for the Phase Real and Completion route. It does not export quotient streams, host real equality, selected limits, countable-choice selectors, ambient completeness, metric-completeness data, or standard bridge rows.

Proof. Start with the ordered budget chain supplied by Definition 38.754. Any consumer that reads an accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ packet toward a $\mathsf{Real}^{\uparrow}$ or completion-facing endpoint must first expose the finite route

$$I \longmapsto W \longmapsto M \longmapsto Q \longmapsto T \longmapsto E.$$

Next apply Definition 435.27. It identifies the UniformCauchyCriterion rows with a $\mathsf{FiniteTailFilter}^{\uparrow}$ packet: the window row is the same finite-window read, the dyadic tolerance row is the same tolerance ledger, the regular readback is the same RegSeqRat read, and the tail-budget and common-tail comparison rows are the same displayed budget surface.

Use the finite-tail-filter handoff theorems to read the middle route. Definition 1119.4 fixes the common cofinal-tail window and dyadic tolerance packet used by the budget, comparison, and seal-facing rows. Then Definition 1119.5 carries exactly that packet to Real and Completion consumers without adding an independent tail selector, hidden tolerance ledger, or host-level completion coordinate.

Finally use Definition 38.760. Once the finite-tail-filter packet has reached the Real-facing seal, the public exit pulls back to precisely the four L10 owners $(\mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow})$. Since those are the only owners exposed by the route lock and the finite-tail handoff, none of the excluded quotient, host-equality, selected-limit, choice, completeness, metric-completeness, or bridge rows can supply another Phase Real and Completion exit. □

Theorem 38.762 (Real uniform Cauchy finite-tail-filter L10 exit sufficiency)**.** *Let* $U = (I, W, M, Q, T, E, H, C, P, N$ *be an accepted* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet read by a Phase Real and Completion consumer. Suppose* U *factors through the displayed* $\mathsf{FiniteTailFilter}^{\uparrow}$ *packet of Definition 38.761, and suppose the resulting L10 surface exposes exactly the four owners* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *with the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

Then this displayed finite-tail-filter route is sufficient for the Phase Real and Completion public exit surface. The route reads no quotient stream, host real equality, selected limit, countable-choice row, ambient completeness, metric-completeness datum, or standard bridge row.

Proof. The assumed factorization identifies the accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ rows with the $\mathsf{FiniteTailFilter}^{\uparrow}$ packet by Definition 435.27. Thus the finite window, dyadic tolerance ledger, regular readback, tail budget, and common-tail comparison are already the displayed finite-tail-filter rows.

The Real-facing seal is then the handoff supplied by Definition 1119.5. It carries the same finite-tail packet to the Phase Real and Completion endpoint without adding an independent selector, a host equality predicate, or an ambient completeness coordinate.

It remains to identify the public L10 surface. By Definition 38.760, every row read at that endpoint pulls back to the four owners $(\mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow})$. The

factorization theorem Definition 38.761 gives the same terminal route through $\mathsf{FiniteTailFilter}^{\uparrow}$, so the displayed four-object packet is exactly the terminal L10 pullback.

Consequently the route is sufficient for the current Phase Real and Completion public exit surface: it supplies all four required owners and all shared BHist, hsame, Cont, Pkg, and NameCert support rows. Since the excluded quotient, host-equality, selected-limit, choice, completeness, metric-completeness, and bridge data are not rows of that terminal packet, they are not read by this exit. □

Theorem 38.763 (RealCauchyCompletion uniform-Cauchy terminal equivalence)**.** *Let $C = (X, \mu, D, E_C, P_C, N_C)$ be an accepted* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *read, and let $U = (I, W, M, Q, T, E_U, H_U, C_U, P_U, N_U)$ be an accepted finite-budget* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *read. The two reads determine the same terminal Phase Real and Completion surface exactly when they expose the same finite budget rows and the same four faces*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

with the same displayed BHist, hsame, Cont, Pkg, *and* NameCert *support.*

Equivalently, the $\mathsf{RealCauchyCompletion}^{\uparrow}$ *route and the* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *route are two presentations of one finite L10 surface precisely when the completion seal factors through the displayed tail-budget and uniform-criterion rows, and the uniform-Cauchy budget exits through the same four-object Real terminal packet. This equivalence reads no quotient stream, selected host limit, host real equality, countable-choice row, ambient completeness theorem, metric-completeness datum, or standard bridge row.*

Proof. For the $\mathsf{UniformCauchyCriterion}^{\uparrow}$ presentation, first apply Definition 38.754. It locks the accepted finite budget to the displayed rows $I, W, M, Q, T, E_U, H_U, C_U, P_U, N_U$ and to the four Real L10 faces. Then Definition 38.755 identifies any two such accepted uniform-Cauchy exits once those rows and the four faces agree.

For the $\mathsf{RealCauchyCompletion}^{\uparrow}$ presentation, use Definition 360.32 to put the completion-facing seal on the same finite tail-budget route. Then apply Definition 360.37: the completion carrier whose diagonal packet consumes the uniform criterion reaches the $\mathsf{Real}^{\uparrow}$ seal only through the regular-family row, unary modulus, uniform shared-tail threshold, Cauchy-limit seal selector, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, and the displayed support rows.

It remains to identify the common terminal object. The four-object pullback Definition 126.504 says that the terminal Real-and-Completion read is fixed by $\mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$ together with the shared BHist, hsame, Cont, Pkg, and NameCert rows. Hence agreement on those rows is sufficient for the two presentations to determine the same terminal finite L10 surface.

Conversely, if the two reads determine the same terminal Phase Real and Completion surface, the terminal pullback can display only the four faces and support rows just named. The route-lock and seal-factorization theorems then recover the finite uniform-Cauchy budget and the RealCauchyCompletion tail-budget seal route from that same packet, so the exposed finite rows agree.

The refusal clause is inherited from every cited boundary theorem. None of the locked rows contains a coordinate for quotient streams, selected host limits, host real equality, countable choice, ambient completeness, metric-completeness data, or standard bridges, so no such row can distinguish the two terminal presentations. □

Theorem 38.764 (Real uniform Cauchy StreamName RegSeqRat terminal seal nonescape)**.** *Any accepted Phase Real and Completion read through a* $\mathsf{UniformCauchyCriterion}^{\uparrow}$ *packet, a* $\mathsf{StreamName}^{\uparrow}$

finite-request section, and a $\mathsf{RegSeqRat}^{\uparrow}$ *shared-window selector reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the shared rows*

$\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, $\mathsf{NameCert}$.

It exports no quotient stream, host real equality, selected limit, countable-choice row, ambient completeness, metric-completion datum, or standard bridge row.

Proof. Start with Definition 38.754. It locks the accepted $\mathsf{UniformCauchyCriterion}^{\uparrow}$ read to the displayed finite budget rows and to the four Real L10 owners before any Phase Real and Completion consumer may read a terminal seal.

Next apply Definition 38.755. Once the $\mathsf{StreamName}^{\uparrow}$ request section, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ shared-window selector, and $\mathsf{Real}^{\uparrow}$ seal agree, the terminal surface is fixed together with its BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support rows.

Finally use Definition 38.763. The completion-facing presentation and the uniform-Cauchy presentation determine the same terminal Phase Real and Completion surface exactly through the same four faces and support rows.

The excluded objects are absent from all three cited boundaries. Therefore the composed StreamName, RegSeqRat, and uniform-Cauchy route reaches the terminal $\mathsf{Real}^{\uparrow}$ seal only through the displayed shared rows, and no quotient stream, host equality, selected limit, choice row, completeness datum, or bridge row is exported. □

Theorem 38.765 (Real terminal seal Cauchy completeness witness route)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *seal consumer that claims Cauchy-completeness data factors through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and the witness surface of chapter 3579 before exporting completion-facing rows. The route reads finite stream windows, regular rational readback, dyadic tolerance ledgers, the displayed* $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ *packet, and only then the local terminal Real seal.*

Consequently the terminal seal may export completion-facing rows only as a finite NameCert route through those sibling objects. It does not claim quotient stream equality, selected host limits, countable choice, trichotomy, detached completeness of $\mathsf{Real}^{\uparrow}$, *or an ambient Real completeness principle.*

Proof. Start with a terminal $\mathsf{Real}^{\uparrow}$ seal consumer that claims Cauchy-completeness data. The RealUp L10 input lattice already routes terminal sealing through the finite $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger before the local seal is read.

Next insert the witness chapter. The carrier and Real-seal route of chapter 3579 bind the same stream, regular-sequence, dyadic, and Real faces as one displayed completion-witness packet, so a completion-facing consumer must pass through that witness surface before it can treat the seal as carrying Cauchy-completeness data.

The final export is therefore a route projection through the existing RealUp L10 input lattice. Since the route contains only finite stream windows, regular rational readback, dyadic tolerances, the displayed witness packet, transport, replay, provenance, and local naming rows, it cannot introduce quotient equality, selected limits, countable choice, trichotomy, detached $\mathsf{Real}^{\uparrow}$ completeness, or ambient Real completeness. □

Theorem 38.766 (Real terminal seal no completeness)**.** *Passing a terminal* $\mathsf{Real}^{\uparrow}$ *seal through the* $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ *route supplies only finite witness rows:* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, the displayed witness packet, componentwise* hsame, *displayed* Cont, Pkg, *and local* $\mathsf{NameCert}$ *rows. It does not upgrade* $\mathsf{Real}^{\uparrow}$ *to an ambient*

completeness theorem and does not assert quotient stream equality, selected host limits, countable choice, trichotomy, detached Real completeness, or a host completion object.

Proof. Apply Definition 38.765. The cited route places every completion-facing consumer behind the finite StreamName, RegSeqRat, DyadicRatCore, and CauchyCompletenessWitness rows before the local Real seal is exported.

The Real roadmap rule keeps the claim off the ambient statement that $\mathsf{Real}^{\uparrow}$ is complete. The terminal seal may carry witness rows for a completion-facing consumer, but those rows are part of a displayed NameCert route rather than a theorem about all Real names.

The exclusions in the theorem statement are exactly the coordinates absent from the route: quotient stream equality, selected limits, countable choice, trichotomy, detached Real completeness, and host completion objects. Since none is present in the finite witness packet, no Real completeness claim is created. □

Theorem 38.767 (Real terminal seal witness nontransitive completeness)**.** *Composing the terminal* $\mathsf{Real}^{\uparrow}$ *seal with the* $\mathsf{CauchyCompletenessWitness}^{\uparrow}$ *route is not transitive to an ambient completeness theorem for* $\mathsf{Real}^{\uparrow}$*. A downstream packet that consumes completion-facing data must still display* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and witness rows on that packet route, and it must keep transport, replay, provenance, and local naming visible before any Real-facing handoff is read.*

Proof. Apply the witness route theorem Definition 38.765. It identifies the only completion-facing path through finite stream windows, regular rational readback, dyadic tolerance ledgers, the displayed witness packet, and the terminal Real seal.

Next use the no-completeness theorem Definition 38.766. The terminal seal may carry those witness rows, but it has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, detached completeness, or a host completion object.

Finally read the L10 construction-order boundary of section 9467.12. The roadmap keeps $\mathsf{Real}^{\uparrow}$ as a sealed regular rational name with no current completeness claim. Therefore a downstream consumer must display the StreamName, RegSeqRat, DyadicRatCore, and witness rows each time it consumes completion-facing data, rather than inheriting ambient completeness from a composed seal. □

Theorem 38.768 (Real dyadic RegSeq cross-reference lattice)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *current-phase name read factors through four displayed faces:*

1. *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *signed-mantissa and tolerance rows of chapter 291;*
2. *the* $\mathsf{StreamName}^{\uparrow}$ *finite observation schedule of chapter 126;*
3. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier rows of chapter 301;*
4. *the local* $\mathsf{Real}^{\uparrow}$ *seal of chapter 38.*

The cross-reference lattice is the same finite route read by the Real L10 exit audit pullback. It explicitly refuses quotient streams, selected limits, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, metric-completeness data, countable-choice selectors, and any standard bridge row not displayed by the four faces.*

Proof. Start with the Real L10 exit audit pullback of Definition 38.471. It identifies each accepted current Phase Real and Completion exit read with the product of the DyadicRatCore, StreamName, RegSeqRat, and local Real face records.

Next use the ordered lattice in Definition 38.442 and the source-route non-escape theorem Definition 38.443. These keep the RealUp current-phase name read on the dyadic observation rows, the finite StreamName window rows, the RegSeqRat regular-rational rows, and the local Real seal.

Now attach the RegSeqRat scope triad. By Definition 301.152, every public RealUp seal read through RegSeqRat is placed behind the visible StreamName schedule, the DyadicRatCore endpoint and tolerance rows, and the RegSeqRat classifier surface before the seal row is consumed.

Finally combine the non-escape clauses. The Real L10 pullback contributes no fifth formal token or completion row, and the RegSeqRat scope triad contributes no quotient stream, selected limit, host equality, completion object, ambient completeness datum, or second seal coordinate. Therefore the current-phase RealUp name read is exactly the four-face cross-reference lattice and exports none of the refused data. □

Theorem 38.769 (Real L10 four-face phase-audit lock)**.** *An accepted current Phase Real and Completion audit read of* $\mathsf{Real}^{\uparrow}$ *is equivalent, as a public BEDC route, to the four displayed faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and the local* $\mathsf{Real}^{\uparrow}$ *seal, together with their* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. The route refuses quotient streams, host real equality, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, metric completeness, countable choice, and standard bridge rows not displayed by those four faces.*

Proof. For the forward direction, project the four faces using Definition 38.768. Every accepted current-phase name read already factors through the DyadicRatCore signed-mantissa and tolerance rows, the StreamName finite observation schedule, the RegSeqRat regularity and classifier rows, and the local Real seal.

Next use the Real L10 current phase exit audit pullback, Definition 38.471. It identifies the Phase Real and Completion audit read with the same four-face product route, so no additional completion-facing source is needed for the forward projection.

For the reverse direction, assemble the public route from the four sibling rows and the Real L10 dependency lattice. The ordered lattice of Definition 38.442, together with Definition 38.443 and Definition 301.152, repacks the four displayed faces as the current Phase Real and Completion audit read.

Finally combine the exclusion clauses. The cross-reference lattice, L10 nonescape row, and RegSeqRat scope triad do not expose quotient streams, host real equality, selected limits, ambient Real completeness, metric completeness, countable choice, or standard bridge rows, so the public audit route is locked to exactly the four displayed faces and their structural support. □

Theorem 38.770 (Real current-phase four-face terminal envelope)**.** *An accepted current Phase Real and Completion* $\mathsf{Real}^{\uparrow}$ *terminal envelope is accepted exactly when its visible route is the four-face projection*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

of an accepted $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ *terminal envelope, with the same displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. The* RealCompletionExactBoundaryUp *row remains a same-route exact-boundary witness for that projection and adds no quotient stream, selected limit, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, countable-choice selector, aggregate formalstatus row, or bridge token.*

Proof. For the forward direction, apply the four-face phase-audit lock of Definition 38.769. It identifies the accepted current Phase Real and Completion $\mathsf{Real}^{\uparrow}$ terminal read with the Dyadi-

cRatCore, StreamName, RegSeqRat, and local Real faces over the displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Next read that four-face terminal read through Definition 1327.8. The terminal envelope exactness theorem exhausts any accepted $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ terminal consumer by the same finite route, with the exact-boundary face carried on the route rather than installed as another Real coordinate.

For the reverse direction, start from an accepted $\mathsf{PhaseRealCompletionExit}^{\uparrow}$ terminal envelope whose roadmap-visible projection is the displayed four-object route. Apply Definition 1327.16 to keep the RealCompletionExactBoundaryUp face as a same-route boundary witness and to expose only $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ as roadmap objects.

Where the terminal read is given by local certified windows, repack those four visible faces by Definition 38.771. The pasted packet is therefore the accepted current Phase Real and Completion $\mathsf{Real}^{\uparrow}$ terminal envelope, while quotient streams, selected limits, host real equality, ambient Real completeness, countable choice, aggregate formalstatus rows, and bridge tokens remain outside the route. □

Theorem 38.771 (Real L10 finite-cover face-pasting equivalence)**.** *Let $\{\mathcal{W}_i\}_{i\in I}$ be a finite cover of certified* $\mathsf{StreamName}^{\uparrow}$ *windows. Assume that every pairwise overlap and every triple overlap satisfies the StreamName-RegSeqRat pasted source and seal hypotheses of Definition 126.551 and Definition 126.552. Assume also that all local rows consume the same displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, tolerance, and finite-distance ledger, and that their* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows agree on all displayed overlaps.*

Then the induced local $\mathsf{RegSeqRat}^{\uparrow}$ *sections paste to exactly one accepted current Phase Real and Completion* $\mathsf{Real}^{\uparrow}$ *exit certificate over the finite union if and only if every local member exposes the same four visible faces*

$$\mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

over the same BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows.*

The equivalence is only a finite-cover current-phase exit certificate. It refuses quotient stream equality, selected limits, host real equality, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. For the forward direction, suppose the local $\mathsf{RegSeqRat}^{\uparrow}$ sections paste to one accepted current Phase Real and Completion $\mathsf{Real}^{\uparrow}$ exit certificate. Project that certificate through Definition 38.768. The projection exposes only the DyadicRatCore ledger, the StreamName finite windows, the RegSeqRat local sections, and the local Real seal.

Now restrict this four-face packet to each member $\mathcal{W}_i$ of the finite cover. The phase-audit lock of Definition 38.769 keeps the restriction on the same BHist, hsame, Cont, Pkg, and NameCert support rows. Hence every local member exposes the same four visible faces over the same displayed support ledger.

For the reverse direction, assume each local member exposes the same four visible faces over the same support rows. First paste the StreamName and finite-window Real source surface using Definition 126.551. Then paste the finite-window Real seal rows using Definition 126.552. These two pasting steps use only the certified pairwise overlaps, triple-overlap cocycles, and shared DyadicRatCore ledger.

The pasted source and seal rows now form a finite cover of compatible local $\mathsf{RegSeqRat}^{\uparrow}$ terminal sections. Apply Definition 301.240 to obtain an accepted Real seal from the local four-face packets,

and apply Definition 301.241 to identify any two such pasted seals as the same BEDC-visible four-face packet.

Finally read the unique pasted four-face packet as the current Phase Real and Completion exit certificate by Definition 38.769. The construction has no coordinate for quotient stream equality, selected limits, host real equality, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, or ambient Real completeness, so the certificate is exactly the finite-cover current-phase exit surface described in the statement. □

Theorem 38.772 (Real L10 finite-cover dyadic common-tail cocycle descent)**.** *Let* $\{\mathcal{W}_i\}_{i\in I}$ *be a finite cover of certified* $\mathsf{StreamName}^{\uparrow}$ *windows. Suppose that every pairwise overlap carries a* $\mathsf{RegSeqRat}^{\uparrow}$ *common-tail packet, that every triple overlap satisfies the common-tail cocycle of Definition 301.191, and that the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, tolerance, distance, and finite scale-window ledgers agree through one common scale-window packet as in Definition 291.66. Suppose also that the local* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows are transported only through the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows.*

Then the local $\mathsf{RegSeqRat}^{\uparrow}$ *sections descend to one Real L10 finite four-face exit certificate if and only if the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows agree on all pairwise overlaps and their induced comparison rows satisfy the given triple-overlap common-tail cocycle.*

The descent certificate is only the finite four-face current-phase exit route. It refuses quotient streams, host real equality, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. For the forward direction, begin with one descended Real L10 finite four-face exit certificate. Project it through Definition 38.771. The projection exposes the finite cover only by the four rows $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, together with the displayed BHist, hsame, Cont, Pkg, and NameCert support rows.

Restrict that certificate to every pairwise and triple overlap. The dyadic restriction is controlled by Definition 291.66, so all endpoint, radius, tolerance, distance, and finite scale-window rows are read from the same finite scale-window packet. The RegSeqRat restriction is controlled by Definition 301.191, so the common-tail comparison rows satisfy the triple-overlap cocycle.

For the reverse direction, assume the displayed pairwise row agreement and triple common-tail cocycle. First use Definition 291.66 to build the common dyadic scale-window face for the finite cover. This gives the single endpoint, radius, tolerance, distance, and finite-window ledger consumed by every local section.

Next apply Definition 301.191 and Definition 301.195. These paste the local $\mathsf{RegSeqRat}^{\uparrow}$ common-tail sections over the finite cover while keeping the StreamName observation windows and the dyadic scale-window ledger fixed on the same support rows.

The pasted common-tail packet now has the four faces required by the terminal route. Use Definition 126.115 to factor it through the StreamName, RegSeqRat, DyadicRatCore, and Real terminal pullback, then apply Definition 38.771 to read the result as one Real L10 finite-cover exit certificate.

Finally apply the phase-audit lock of Definition 38.769. It identifies the certificate with the same four visible faces and support rows and leaves no coordinate for quotient stream equality, host real equality, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 38.773 (Real finite-window seal tightness)**.** *A* $\mathsf{Real}^{\uparrow}$ *finite-window seal is admissible exactly when its* $\mathsf{RegSeqRat}^{\uparrow}$ *tail budget,* $\mathsf{StreamName}^{\uparrow}$ *finite-window section, and* $\mathsf{DyadicRatCore}^{\uparrow}$

denominator ledger agree on a common hsame*-compatible finite request. The common request carries the displayed* BHist*,* Cont*,* Pkg*, and* NameCert *rows used by the public seal.*

Equivalently, a proposed seal whose RegSeqRat tail selector, StreamName request section, and dyadic denominator ledger do not factor through one common finite request is not an accepted $\mathsf{Real}^{\uparrow}$ *public seal. The statement uses only the displayed BEDC route and does not invoke host real equality, quotient streams, selected limits, or ambient completeness.*

Proof. For the forward direction, start with the Real dyadic RegSeq cross-reference lattice of Definition 38.768. It places every accepted Real current-phase name read on the DyadicRatCore, StreamName, RegSeqRat, and local Real faces.

Next apply the finite request fusion and finite-window seal exhaustion results, Definition 38.698 and Definition 38.718. These identify the public seal with a displayed finite request whose StreamName section, RegSeqRat readback, dyadic tolerance ledger, and support rows are componentwise compatible.

For the reverse direction, assemble the common request through the sibling route. The RegSeqRat terminal budget exhaustion supplies the tail-budget side, the StreamName finite request section supplies the public window, and the DyadicRatCore ledger supplies the denominator data for the same displayed request.

Finally repack the route as a RealUp public seal by the RegSeqRat-to-StreamName handoff and the dyadic Stream-RegSeq route. Since each cited route refuses quotient streams, host equality, selected limits, and ambient completeness, the common finite request is the whole admissibility witness. □

Theorem 38.774 (Real finite-cover seal pasting criterion)**.** *Let a finite cover of certified* $\mathsf{StreamName}^{\uparrow}$ *windows be given, with pairwise and triple overlaps satisfying the* $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$ *finite-cover pasted-source hypotheses. Suppose the local handoff rows consume the same displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *finite ledger, and suppose each local* $\mathsf{RegSeqRat}^{\uparrow}$ *tail satisfies the* $\mathsf{Real}^{\uparrow}$ *finite-window tightness criterion of Definition 38.773.*

Then the local finite-window $\mathsf{Real}^{\uparrow}$ *seal rows paste to one admissible* $\mathsf{Real}^{\uparrow}$ *public seal over the finite cover. Conversely, a proposed public seal over such a finite cover is admissible exactly when there exists a common finite surface whose* $\mathsf{StreamName}^{\uparrow}$ *pasted source,* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, and* $\mathsf{RegSeqRat}^{\uparrow}$ *common-tail boundary are the displayed local rows on every window and overlap.*

The pasted surface is a finite BEDC datum: it records the relevant BHist*,* Cont*,* Pkg*, and* NameCert *rows on the cover index, on every binary overlap, and on every triple overlap required by the StreamName cocycle. It exports no quotient stream, host real equality, selected limit, countable choice, metric-completeness datum, ambient completeness row, or second* $\mathsf{Real}^{\uparrow}$ *seal coordinate.*

Proof. First build the finite cover surface. Apply Definition 126.551 to the certified StreamName windows and their pairwise and triple overlap data. This produces one pasted StreamName source surface, with the overlap rows still expressed as finite BHist, Cont, Pkg, and NameCert data.

Next transport the boundary rows through the RegSeqRat and dyadic faces. The overlap compatibility is exactly the common-tail Real boundary equivalence of Definition 301.186; the denominator ledger is carried through the four-face route by Definition 291.69. Hence every local handoff reads from the same finite dyadic ledger and the same RegSeqRat common-tail surface.

For the forward direction, apply Definition 38.773 on each window. The local admissibility witnesses all factor through the pasted StreamName source and the common dyadic ledger, so their Real seal rows have the same finite public support and therefore paste to one admissible public seal.

For the reverse direction, start from an admissible public seal over the cover and read its local finite-window restrictions. The tightness criterion supplies the local RegSeqRat tail budgets, StreamName sections, and dyadic denominator rows; the pasted-source and pullback routes identify these rows with one common finite surface. Thus admissibility is exactly the existence of that displayed pasted StreamName/DyadicRatCore/RegSeqRat surface, with no quotient, host-equality, choice, limit, or completeness datum added. □

Theorem 38.775 (Real L10 four-face finite pullback public interface)**.** *Let a* $\mathsf{Real}^{\uparrow}$ *finite-window public seal be displayed on finite* BHist*,* hsame*,* Cont*,* Pkg*, and local* NameCert *rows. Suppose its visible rows factor through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale-window packet, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window section, the* $\mathsf{RegSeqRat}^{\uparrow}$ *common-tail boundary, and the* $\mathsf{Real}^{\uparrow}$ *seal-source rows. Then these data determine exactly one public finite pullback interface over those displayed rows.*

Conversely, every four-face finite pullback interface with DyadicRatCore scale-window data, StreamName finite-window data, RegSeqRat common-tail boundary data, and local Real seal-source data repacks as an admissible $\mathsf{Real}^{\uparrow}$ *finite-window public seal. The interface exports no quotient stream equality, selected limit, host real equality, countable-choice selector, ambient completeness principle, metric-completeness row, or standard bridge row.*

Proof. For the forward direction, start with the finite-window public seal and apply Definition 38.773. The admissible seal is read exactly through a common finite request carrying the StreamName section, RegSeqRat tail budget, DyadicRatCore denominator ledger, and local Real rows.

Next apply Definition 38.774. It identifies the finite public support of the seal with the pasted finite surface on the displayed BHist, Cont, Pkg, and NameCert rows, so the local windows and their overlaps have one public finite support.

Now transport the boundary and dyadic faces. The RegSeqRat common-tail rows are exactly the Real boundary rows by Definition 301.186, and the DyadicRatCore scale-window packet composes with the RegSeqRat and Real faces by Definition 291.69. Thus the four displayed faces form one finite pullback interface, and uniqueness follows because each cited route reads the same finite rows rather than a second external coordinate.

For the reverse direction, begin with such a four-face finite pullback interface. The dyadic scale-window packet, StreamName finite-window section, RegSeqRat common-tail boundary, and local Real seal-source rows supply the common request required by Definition 38.773.

Finally repack the common request as a public seal and use Definition 38.774 to pass across the displayed finite cover. The same exclusion clauses in the four cited routes leave no quotient stream equality, selected limit, host real equality, countable choice, ambient completeness, metric completeness, or standard bridge row to add. □

Theorem 38.776 (Real L10 four-face refinement stability)**.** *Let a* $\mathsf{Real}^{\uparrow}$ *finite-window public seal factor through the four displayed faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and the local* $\mathsf{Real}^{\uparrow}$ *seal-source rows as in Definition 38.775. Any* hsame*-compatible finite-window refinement that preserves the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale-window packet, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window section, the* $\mathsf{RegSeqRat}^{\uparrow}$ *common-tail boundary, the local seal row, the displayed* Cont *routes, the* Pkg *provenance, and the local* NameCert *rows determines the same public finite pullback interface and repacks as the same admissible finite-window seal.*

Conversely, any accepted refinement of that public interface exposes exactly those refined four faces. It exports no quotient stream equality, selected limit, host real equality, countable-choice selector, ambient completeness row, metric-completeness row, standard bridge row, or second public seal coordinate.

Proof. Start with the displayed public seal. By Definition 38.773, admissibility is exactly factorization through one common finite request carrying the StreamName section, RegSeqRat tail budget, DyadicRatCore denominator ledger, and the local Real rows.

Apply Definition 38.774 to the refined finite windows. Since the refinement preserves the scale-window packet, finite-window section, common-tail boundary, local seal row, displayed Cont routes, Pkg provenance, and local NameCert rows, the pasted finite surface has the same public support on every window and overlap.

Next use the StreamName and RegSeqRat pullback determinacy rows, together with Definition 38.775. They identify the refined StreamName window, RegSeqRat readback, DyadicRatCore ledger, and Real seal row with the same four-face finite pullback interface, rather than with a second external coordinate.

For the converse, read an accepted refinement through the public interface theorem. Its admissibility witness must factor through the four displayed faces, and the tightness and pasting criteria force the refined rows to be exactly the preserved scale-window, finite-window, common-tail, local-seal, route, provenance, and certificate rows.

The exclusion clauses are inherited from the same cited routes. None of them exports quotient stream equality, selected limits, host real equality, countable choice, ambient completeness, metric completeness, or standard bridge data, so the accepted refinement cannot expose any such row. □

Theorem 38.777 (Real L10 four-face interface composition)**.** *Let I_{01} and I_{12} be composable finite pullback interfaces for* $\mathsf{Real}^{\uparrow}$ *finite-window public seals. Suppose both interfaces preserve the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale-window packet,* $\mathsf{StreamName}^{\uparrow}$ *finite-window section,* $\mathsf{RegSeqRat}^{\uparrow}$ *common-tail boundary, local* $\mathsf{Real}^{\uparrow}$ *seal-source row, displayed* BHist*, componentwise* hsame*, displayed* Cont*,* Pkg *provenance, and local* NameCert *rows on their common overlap. Then the composite interface determines exactly the same admissible* $\mathsf{Real}^{\uparrow}$ *finite-window public seal as the one-step interface over the composite finite request.*

Conversely, any accepted composite public seal exposes exactly the two component finite pullback interfaces I_{01} and I_{12} on the displayed four faces and on the shared support rows. The composite has no additional coordinate for quotient streams, selected limits, host real equality, countable choice, ambient completeness, metric completeness, standard bridge rows, or a second public seal.

Proof. First read each component through the public four-face interface. By Definition 38.775, I_{01} and I_{12} are exactly the finite public pullback surfaces carried by their DyadicRatCore scale-window packets, StreamName finite-window sections, RegSeqRat common-tail boundaries, local Real seal-source rows, and displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Next apply refinement stability on the common overlap. Since both component interfaces preserve the listed rows there, Definition 38.776 identifies the overlap restriction with the same admissible finite-window seal rather than with a second seal coordinate.

The composite finite request is then pasted from these two compatible restrictions. Use Definition 38.774 for the two-window cover and Definition 301.189 for the common-tail triple row implicit in the pullback composition. These results say that the pasted StreamName section, dyadic scale-window ledger, RegSeqRat common-tail boundary, local Real row, and displayed support data form one four-face cocycle, so the composite interface reads as the same public seal as the one-step interface over the composite request.

For the converse, start from an accepted composite public seal and restrict it to the two finite requests. The public interface theorem exposes the four displayed faces on each restriction, while refinement stability forces the overlap rows to be the preserved DyadicRatCore, StreamName,

RegSeqRat, local Real, BHist, hsame, Cont, Pkg, and NameCert rows. Hence the component interfaces are exactly I_{01} and I_{12}.

The exclusion clauses follow from the same four cited routes. Quotient streams, selected limits, host real equality, countable choice, ambient completeness, metric completeness, standard bridge rows, and any duplicate public seal coordinate are not rows of the finite request or of the pasted cocycle, so they cannot appear in either direction of the composition statement. □

Theorem 38.778 (Real common-tail terminal four-face classifier equivalence)**.** *Let $\mathcal{S}$ and $\mathcal{T}$ be accepted* $\mathsf{Real}^{\uparrow}$ *finite-window public seals whose visible rows factor through the four faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *seal-source rows. Then $\mathcal{S}$ and $\mathcal{T}$ have the same public classifier surface if and only if they agree on the* $\mathsf{RegSeqRat}^{\uparrow}$ *common-tail window packet, the* $\mathsf{StreamName}^{\uparrow}$ *fused terminal-window packet, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and distance ledger, the local* $\mathsf{Real}^{\uparrow}$ *seal-source row, and the displayed support rows*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

This equivalence is an equivalence of the displayed finite BEDC boundary only. It excludes quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness rows, standard bridge rows, and any second public seal coordinate.

Proof. For the forward direction, start from public classifier agreement. Apply Definition 126.624; it reads classifier agreement back to the common StreamName fused terminal packet, the dyadic endpoint, radius, and distance ledger, the RegSeqRat common-tail rows, the Real seal-source row, and the displayed BHist, hsame, Cont, Pkg, and NameCert support.

Then apply Definition 301.186. The RegSeqRat common-tail packet and the finite-request Real boundary determine one another on the same StreamName schedule and refinement rows, dyadic ledger rows, classifier and regularity rows, local Real seal-source rows, and provenance rows. Thus no classifier agreement can remain after those displayed rows diverge.

For the reverse direction, assume agreement of the RegSeqRat common-tail window packet, the StreamName fused terminal-window packet, the DyadicRatCore endpoint/radius/distance ledger, the local Real seal-source row, and the displayed BHist, hsame, Cont, Pkg, and NameCert rows. The four-face public interface theorem Definition 38.775 repacks these rows as one public finite pullback interface over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Finally use Definition 126.624 again to transport that shared four-face interface to the public classifier surface. The exclusion clauses in the StreamName terminal fusion theorem, the RegSeqRat common-tail boundary theorem, and the four-face interface theorem leave no quotient stream equality, host real equality, selected limit, countable-choice selector, ambient completeness row, metric-completeness row, standard bridge row, or second seal coordinate through which a different classifier could be read. □

Theorem 38.779 (Real L10 four-face classifier sheaf condition)**.** *Let a finite cover of* $\mathsf{Real}^{\uparrow}$ *public classifier reads be displayed over the four faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *seal-source rows, with finite* BHist, *componentwise* hsame, Cont, Pkg, *and* NameCert *support on every window. The family satisfies the public* $\mathsf{Real}^{\uparrow}$ *classifier exactly when each local read satisfies the tightness criterion of Definition 38.773, each pairwise overlap satisfies the terminal classifier equivalence of Definition 38.778, and each triple overlap satisfies the common-tail four-face cocycle determinacy of Definition 301.189.*

Under these three conditions the pasted public classifier is the same classifier as the one-step four-face interface over the composite finite request of Definition 38.777. Conversely, any one-step public $\mathsf{Real}^{\uparrow}$ *classifier restricts to such local reads, pairwise terminal equivalences, and triple*

common-tail cocycles. The condition is internal to the displayed finite BEDC rows and excludes quotient streams, host real equality, selected limits, countable choice, ambient completeness, metric completeness, standard bridge rows, and any second public classifier coordinate.

Proof. First build the finite public surface. Apply Definition 38.774 to the local reads satisfying Definition 38.773. The result is one pasted finite support carrying the StreamName sections, RegSeqRat common-tail boundaries, DyadicRatCore ledgers, local Real rows, and displayed BHist, hsame, Cont, Pkg, and NameCert data on the cover.

Next identify the overlap classifiers. On each pairwise overlap, Definition 38.778 says that public classifier agreement is exactly agreement of the RegSeqRat common-tail packet, StreamName terminal-window packet, DyadicRatCore endpoint/radius/distance ledger, local Real seal-source row, and displayed support rows. On each triple overlap, Definition 301.189 supplies the cocycle condition for those common-tail rows.

Now repack the pasted surface through the four-face public interface. Use Definition 38.775 to read the pasted DyadicRatCore, StreamName, RegSeqRat, and Real rows as one public finite pullback interface. Then apply Definition 38.777; the pairwise terminal agreements and triple cocycles make the iterated pasted interface equal to the one-step interface over the composite finite request.

For the converse, restrict a one-step public classifier to the finite cover. The interface theorem exposes the four displayed faces on every restriction, the tightness criterion gives the local admissibility rows, the terminal classifier equivalence gives the pairwise overlap rows, and the common-tail cocycle determinacy gives the triple overlap rows.

The exclusions are inherited from the same cited routes. None of the pasting, interface, composition, terminal-equivalence, or cocycle rows exports quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric completeness, standard bridge data, or a duplicate public classifier coordinate. □

Theorem 38.780 (Real L10 finite-cover classifier descent)**.** *Let a finite cover of public* $\mathsf{Real}^{\uparrow}$ *classifier reads be given over the four faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *seal-source rows, with finite* BHist, *componentwise* hsame, Cont, Pkg, *and* NameCert *support on every window and overlap. Then restriction to every window and overlap satisfies the public* $\mathsf{Real}^{\uparrow}$ *classifier exactly when the local tightness rows, pairwise terminal classifier equivalences, and triple common-tail cocycles of Definition 38.779 descend to one public classifier surface.*

The descended surface is the public classifier surface exported by the one-step four-face interface over the composite finite request. It contains exactly the DyadicRatCore ledger rows, StreamName finite-window rows, RegSeqRat common-tail rows, local Real seal-source rows, and displayed BHist, hsame, Cont, Pkg, *and* NameCert *support rows. It excludes quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness rows, standard bridge rows, and duplicate classifier coordinates.*

Proof. For the forward direction, start from coverwise public classifier restriction. Apply Definition 38.779. It reads each restriction as local tightness, each pairwise overlap as a terminal classifier equivalence, and each triple overlap as a common-tail cocycle.

Next transport the local rows to the composite request. Use Definition 126.552 to exhaust the finite cover by the pasted StreamName and RegSeqRat seal rows, with the DyadicRatCore ledger, local Real seal-source rows, and displayed support rows retained on each finite refinement.

Now repack the exhausted cover as a single public surface. Apply Definition 38.777; the compatible four-face restrictions compose to the one-step public interface over the composite finite

request. Then Definition 38.778 identifies that interface with the terminal public classifier surface determined by exactly the displayed rows.

For the reverse direction, begin with one public classifier surface over the composite finite request. Restrict it to the chosen finite cover. The interface composition theorem exposes the same DyadicRatCore, StreamName, RegSeqRat, local Real, BHist, hsame, Cont, Pkg, and NameCert rows on every window and overlap.

Apply Definition 38.779 again. The restricted surface therefore supplies the local tightness rows, the pairwise terminal classifier equivalences, and the triple common-tail cocycles required on the cover. The terminal equivalence theorem shows that any cover with those displayed rows descends to the same public classifier surface, so no additional classifier coordinate is available.

The exclusion clauses are row exclusions along the cited routes. The finite-cover exhaustion, four-face composition, terminal classifier equivalence, and sheaf condition use only finite BEDC support rows and never introduce quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness data, standard bridge rows, or duplicate classifier coordinates. □

Theorem 38.781 (Real L10 classifier-status axis separation)**.** *For any finite Real L10 four-face packet over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *seal-source rows, public classifier sheaf agreement is exactly the local tightness, pairwise terminal-equivalence, and triple common-tail cocycle data of Definition 38.779. The audit admissibility coordinate is exactly objectwise lookup from the four local closurestatus records through Definition 38.471, with the status and target coordinates kept facewise by Definition 38.833 and Definition 38.834.*

These two coordinates do not supply one another. Classifier agreement creates no formalstatus row, leantarget row, bridgestatus row, or bridge row, and audit status creates no classifier overlap, finite-window tightness row, pairwise terminal classifier equivalence, or triple common-tail cocycle.

Proof. First read the classifier coordinate. Apply Definition 38.779; it reduces public classifier agreement to the local tightness criterion, the terminal four-face classifier equivalences on pairwise overlaps, and the common-tail cocycle determinacy on triple overlaps.

Next read the audit coordinate. Apply Definition 38.471; the current Phase Real and Completion audit row is the objectwise product of the DyadicRatCore, StreamName, RegSeqRat, and local Real closurestatus records.

The two non-collapse results separate the displayed audit fields. By Definition 38.833, the four local formalstatus, theoryclosure, and bridgestatus fields are not replaced by a single aggregate status. By Definition 38.834, the four local leantarget rows are likewise not replaced by an aggregate target.

The cited classifier theorem exports only tightness, overlap equivalence, and cocycle data on finite BEDC rows. The cited audit theorems export only objectwise closurestatus lookup and its non-collapse fields. Therefore neither route manufactures the rows of the other route: classifier agreement has no status or bridge output, while audit admissibility has no classifier-overlap, tightness, or common-tail-cocycle output. □

Theorem 38.782 (Real L10 public classifier audit envelope)**.** *Let* $\mathcal{P}$ *be a finite Real L10 four-face public classifier packet over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *seal-source rows, with displayed finite* BHist, *componentwise* hsame, Cont, Pkg, *and* NameCert *support on every window. Suppose that* $\mathcal{P}$ *satisfies the finite-cover classifier sheaf condition of Definition 38.779, and that the four local face records satisfy the objectwise audit-clean exit threshold of Definition 38.493 and Definition 38.494. Then* $\mathcal{P}$ *is an audit-admissible public classifier envelope exactly on those four displayed faces.*

The envelope consists only of the local tightness rows, pairwise terminal-equivalence rows, triple common-tail cocycle rows, and the four objectwise closurestatus records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *It supplies no aggregate route-level* formalstatus, *no aggregate bridge row, no quotient stream equality, no selected limit, no countable-choice row, no metric-completeness datum, and no* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. First apply Definition 38.779. The public classifier coordinate of $\mathcal{P}$ is reduced to local tightness over the displayed finite support, pairwise terminal equivalence on overlaps, and triple common-tail cocycle data.

Next apply Definition 38.781. The classifier rows just obtained cannot manufacture a formalstatus row, leantarget row, bridgestatus row, or bridge row, and the audit rows cannot manufacture classifier overlap, tightness, or cocycle data.

Now read the exit threshold objectwise. By Definition 38.493, the current Real L10 exit criterion is satisfied by the four local closurestatus records under the stated local closure and audit-clean verification rows. By Definition 38.494, those rows are exactly the four-face threshold and not a route-level aggregate.

Finally use Definition 38.833 and Definition 38.834. The formal-status, theory-closure, Leantarget, and bridge-status coordinates remain attached to the four displayed faces, so the resulting public classifier envelope is audit-admissible only there and exports none of the excluded aggregate, quotient, choice, limit, metric-completeness, or $\mathsf{Real}^{\uparrow}$ completeness data. □

Theorem 38.783 (Real L10 four-face classifier separatedness)**.** *Let* $\mathcal{S}$ *and* $\mathcal{T}$ *be two finite-cover public* $\mathsf{Real}^{\uparrow}$ *classifier presentations satisfying the sheaf condition of Definition 38.779. Suppose that, on every window and on every overlap in the cover, their visible rows agree on the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *common-tail boundary, the local* $\mathsf{Real}^{\uparrow}$ *seal-source rows, and the displayed support*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

Then $\mathcal{S}$ *and* $\mathcal{T}$ *determine the same public* $\mathsf{Real}^{\uparrow}$ *classifier surface. Conversely, any disagreement in the public* $\mathsf{Real}^{\uparrow}$ *classifier surface of two such presentations is witnessed on at least one of the displayed DyadicRatCore ledger rows, StreamName finite-window rows, RegSeqRat common-tail rows, local Real seal-source rows, or* BHist, hsame, Cont, Pkg, *and* NameCert *support rows. No quotient stream equality, selected limit, host real equality, countable choice, ambient completeness, metric completeness, standard bridge row, or second classifier coordinate is part of the separatedness witness.*

Proof. Apply Definition 38.779 to both presentations. The sheaf condition reads each finite-cover classifier through local tightness rows, pairwise terminal classifier equivalences, and triple common-tail cocycles, then repacks the result as the one-step four-face interface over the composite finite request.

The assumed windowwise agreement identifies the one-step interfaces. By Definition 38.777, the pasted request equality is already determined by the DyadicRatCore ledger, StreamName finite-window rows, RegSeqRat common-tail boundary, local Real seal-source rows, and displayed support data on the common cover.

It remains to check that no hidden classifier coordinate can distinguish the pasted surfaces. On pairwise overlaps, Definition 38.778 makes public classifier agreement equivalent to agreement of exactly the displayed terminal four-face rows. On triple overlaps, Definition 301.189 forces the common-tail cocycle rows to agree whenever those displayed rows agree.

Thus the two pasted classifier surfaces have the same local reads, the same overlap identifications, and the same composite finite request, hence the same public $\mathsf{Real}^{\uparrow}$ classifier surface. The converse is the contrapositive of the same reductions: if the public classifiers differ, the sheaf reduction, terminal equivalence, or common-tail cocycle determinacy must expose the difference in one of the listed visible rows. Since the cited routes export only finite BEDC rows, the excluded quotient, limit, host-equality, choice, completeness, bridge, and duplicate-coordinate data cannot serve as an additional witness. □

Theorem 38.784 (Real L10 four-face witness minimality)**.** *For any accepted current Phase* $\mathsf{Real}^{\uparrow}$ *and Completion finite-window public classifier packet, the visible witness surface is minimal for the displayed four-face separatedness route. Removing the* $\mathsf{DyadicRatCore}^{\uparrow}$ *face removes the endpoint, radius, and distance ledger data; removing the* $\mathsf{StreamName}^{\uparrow}$ *face removes the finite schedule; removing the* $\mathsf{RegSeqRat}^{\uparrow}$ *face removes the regular-tail classifier; and removing the local* $\mathsf{Real}^{\uparrow}$ *seal-source rows removes the seal boundary. In each case, Definition 38.783 is no longer applicable by the displayed route.*

Likewise, removing any displayed support row among BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *destroys either the provenance or the transport needed to read the public finite-window witness. Conversely, the full four-face packet determines the same public classifier surface by Definition 38.783. The minimality statement is internal to the displayed BEDC rows and excludes quotient streams, host real equality, selected limits, countable choice, ambient completeness, metric completeness, standard bridge rows, and any second classifier coordinate.*

Proof. First read the packet through the tightness criterion. By Definition 38.773, an accepted finite-window seal is exactly a common finite request carrying the RegSeqRat tail budget, StreamName finite-window section, DyadicRatCore denominator ledger, local Real rows, and the displayed BHist, hsame, Cont, Pkg, and NameCert support.

Now remove one face at a time. Without the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, the route no longer contains the endpoint, radius, and distance data used to compare public classifier surfaces. Without the $\mathsf{StreamName}^{\uparrow}$ section, the dyadic and regular-tail rows no longer supply the finite schedule on which the witness is read. Without the $\mathsf{RegSeqRat}^{\uparrow}$ common-tail boundary, the finite schedule and dyadic ledger no longer supply the regular-tail classifier. Without the local $\mathsf{Real}^{\uparrow}$ seal-source rows, the three imported faces no longer supply the seal boundary.

The support rows are load-bearing for the same reason. Dropping BHist or NameCert removes the finite provenance of the displayed witness, dropping hsame removes the componentwise identification needed across windows, dropping Cont removes the transport route, and dropping Pkg removes the package row that connects the public presentation to its certified carrier.

Finally restore the whole surface. The finite pullback interface of Definition 38.775 repacks the four faces and support rows as one public interface, while Definition 38.778 and Definition 38.779 identify the terminal and coverwise classifier reads. Then Definition 38.783 gives determinacy of the public classifier from exactly those visible rows.

These citations are non-reconstruction results: they specify the rows consumed by the tightness, finite-pullback, and separatedness routes, but they do not construct counter-packets after a row is deleted. The exclusion clause follows from the same route inventory. None of the cited results exports quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric completeness, standard bridge rows, or a second classifier coordinate, so no such datum is available inside this proof as a replacement for a missing face or support row. □

Theorem 38.785 (Real L10 four-face classifier functoriality)**.** *Let r be a finite-request refinement map between two current Phase* $\mathsf{Real}^{\uparrow}$ *and Completion classifier presentations. Suppose r preserves*

the $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window section, the* $\mathsf{RegSeqRat}^{\uparrow}$ *common-tail classifier rows, the local* $\mathsf{Real}^{\uparrow}$ *seal-source row, and the displayed support*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

Then transport along r carries a public $\mathsf{Real}^{\uparrow}$ *classifier surface to the same public classifier surface. Conversely, any equality of transported public classifier surfaces is witnessed exactly on the four faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and local* $\mathsf{Real}^{\uparrow}$ *together with those displayed support rows. The functoriality surface exports no quotient stream, selected limit, host real equality, countable-choice row, ambient completeness, metric-completeness row, standard bridge row, or second classifier coordinate.*

Proof. First read the refinement map through the sibling certificates. The $\mathsf{DyadicRatCore}^{\uparrow}$ ledger is supplied by chapter 291, the finite request schedule by chapter 126, and the common-tail classifier rows by chapter 301. These are the three imported faces consumed by the local $\mathsf{Real}^{\uparrow}$ seal-source row.

Apply Definition 38.776. Since r preserves the dyadic ledger, finite-window section, common-tail boundary, local seal row, displayed Cont routes, Pkg provenance, and $\mathsf{NameCert}$ rows, the refinement determines the same finite pullback interface and repacks as the same admissible public seal.

Next compose transport with the public interface. By Definition 38.777, a transported interface over the refined request is the one-step interface over the composite finite request, with the same BHist, componentwise hsame, Cont, Pkg, and $\mathsf{NameCert}$ support rows. Thus the transported surface has no independent classifier coordinate beyond the four displayed faces.

For the converse, start from equality of transported public classifier surfaces. Separatedness in Definition 38.783 reads any possible disagreement back to one of the DyadicRatCore ledger rows, StreamName finite-window rows, RegSeqRat common-tail rows, local Real seal-source rows, or displayed support rows. Therefore equality is witnessed precisely by agreement on those rows.

Finally use Definition 38.784 to rule out a smaller witness inventory. Removing any one of the four faces or any one of BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ destroys the displayed route on which separatedness is read. The same row inventory excludes quotient streams, selected limits, host real equality, countable choice, ambient completeness, metric completeness, standard bridge rows, and a second classifier coordinate from both directions of the functoriality statement. □

Theorem 38.786 (Real L10 cofinal classifier refinement invariance)**.** *Let $\mathcal{P}$ be a current Phase* $\mathsf{Real}^{\uparrow}$ *and Completion finite-window public classifier packet. Let $\mathcal{R}$ be a cofinal family of finite-request refinements of $\mathcal{P}$: every finite public readback request for $\mathcal{P}$ is dominated by some refinement in $\mathcal{R}$. Suppose that each refinement in $\mathcal{R}$ preserves the four displayed faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *seal-source rows, and also preserves the displayed support rows*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

Then all public classifier surfaces read from refinements in $\mathcal{R}$ determine the same $\mathsf{Real}^{\uparrow}$ *classifier surface as $\mathcal{P}$. Conversely, if two cofinal refined reads determine different public* $\mathsf{Real}^{\uparrow}$ *classifier surfaces, then the disagreement is witnessed at some finite refinement stage on one of the displayed DyadicRatCore ledger rows, StreamName finite-window rows, RegSeqRat common-tail rows, local Real seal-source rows, or* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *support rows.*

The invariance is only an assertion about the displayed finite BEDC classifier surface. It asserts no formal-status row, bridge row, quotient stream equality, selected limit, countable-choice

row, ambient completeness row, metric-completeness row, standard bridge row, or second public classifier coordinate.

Proof. First fix one refinement in $\mathcal{R}$. The preservation hypotheses are exactly the hypotheses of Definition 38.785, so transport along that refinement reads the refined public classifier surface as the same public classifier surface carried by $\mathcal{P}$ on the displayed four faces and support rows.

Now compare two refinements in the cofinal family. Cofinality gives a further finite request dominating the two finite reads. Applying functoriality along the two induced refinement maps transports both classifier surfaces to the same displayed four-face packet over that common finite request. Hence every refined read in $\mathcal{R}$ determines the same public $\mathsf{Real}^{\uparrow}$ classifier surface.

For the converse, suppose two refined public classifier surfaces disagree. By Definition 38.783, any such disagreement is already visible on one of the DyadicRatCore ledger rows, StreamName finite-window rows, RegSeqRat common-tail rows, local Real seal-source rows, or displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support rows.

The witness is finite because both disagreeing surfaces come from finite-request refinements, and cofinality supplies a common finite refinement stage on which the two reads can be compared. The separatedness witness therefore appears at such a finite stage, not in an ambient quotient, limit, choice, completeness, bridge, or duplicate classifier coordinate.

Finally, Definition 38.784 rules out shrinking the displayed witness inventory, while Definition 38.781 keeps the classifier claim separate from audit status. Thus the theorem states cofinal invariance of the public classifier surface only, with no assertion about formal status, bridge status, quotient streams, selected limits, countable choice, ambient completeness, or metric completeness. □

Theorem 38.787 (Real L10 terminal cofinal pullback determinacy)**.** *Let $\mathcal{P}$ be a current Phase $\mathsf{Real}^{\uparrow}$ and Completion public classifier packet, and let $\mathcal{R}$ be a cofinal family of terminal finite-request refinements of $\mathcal{P}$. Suppose every terminal refinement in $\mathcal{R}$ preserves the four displayed faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

where the $\mathsf{Real}^{\uparrow}$ face is the local seal-source row, and suppose it also preserves the support rows

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

Then the terminal pullback induced by $\mathcal{R}$ is uniquely determined by those four faces and support rows. Conversely, if two terminal cofinal pullbacks over current Phase $\mathsf{Real}^{\uparrow}$ and Completion data disagree, then their disagreement is witnessed at a finite refinement stage on one of the DyadicRatCore ledger rows, StreamName terminal-window rows, RegSeqRat finite-request rows, local Real seal-source rows, or displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support rows.

The determinacy surface contains no quotient stream equality, host real equality, selected limit, countable-choice row, ambient completeness row, metric-completeness row, arithmetic package, order package, standard bridge row, or second public classifier coordinate.

Proof. First read each terminal refinement through cofinal classifier invariance. By Definition 38.786, every refinement in $\mathcal{R}$ presents the same public $\mathsf{Real}^{\uparrow}$ classifier surface as $\mathcal{P}$ whenever it preserves the displayed four faces and support rows.

Next identify the finite witness carried by that common classifier surface. Apply Definition 38.464; the public boundary determines exactly the fused $\mathsf{StreamName}^{\uparrow}$ terminal-window packet, the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint and radius ledger, the $\mathsf{RegSeqRat}^{\uparrow}$ finite-request section, the local $\mathsf{Real}^{\uparrow}$ seal, and the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Now fix the source of the pullback. The source-route exactness theorem, Definition 38.466, places every terminal finite-window witness on the ordered route

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Thus the terminal pullback has no independent source coordinate beyond the four displayed faces.

Finally compare the three public readings. By Definition 38.467, the StreamName finite-window classifier pullback, the RegSeqRat finite-request section, and the Real L10 source route read the same public boundary over the same support rows. The terminal pullback induced by the cofinal family is therefore unique, since all of its visible faces are already fixed by the common finite-window witness and by the route triangle.

For the converse, suppose two terminal cofinal pullbacks disagree. Cofinality gives a finite refinement stage dominating the two finite reads. The preceding paragraphs identify both pullbacks at that stage with their DyadicRatCore ledger, StreamName terminal-window packet, RegSeqRat finite-request section, local Real seal-source rows, and displayed support rows.

If those rows agreed, the cofinal invariance theorem and the finite-window determinacy theorem would give the same public boundary, and the route triangle would repack the same terminal pullback. Hence any disagreement must be visible at that finite stage on one of the displayed faces or support rows.

The exclusion clause follows from the same cited inventory. None of the four cited results exports quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric completeness, arithmetic or order packages, bridge rows, or a second public classifier coordinate, so none of those data can witness or repair a terminal cofinal pullback disagreement here. □

Theorem 38.788 (Real L10 classifier refinement category laws)**.** *Let $\mathcal{P}$, $\mathcal{Q}$, and $\mathcal{R}$ be current Phase* $\mathsf{Real}^{\uparrow}$ *and Completion finite-window public classifier packets. The identity finite-request refinement of $\mathcal{P}$ preserves the public* $\mathsf{Real}^{\uparrow}$ *classifier surface carried by the four displayed faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

where the $\mathsf{Real}^{\uparrow}$ *face is the local seal-source row, together with the support rows*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

If $r : \mathcal{P} \to \mathcal{Q}$ and $s : \mathcal{Q} \to \mathcal{R}$ are finite-request refinements preserving those four faces and support rows, then their composite $s \circ r$ preserves the same public $\mathsf{Real}^{\uparrow}$ *classifier surface. Conversely, if the classifier surfaces transported by a composite refinement disagree, then the disagreement is witnessed at a finite stage on one of the DyadicRatCore ledger rows, StreamName finite-window rows, RegSeqRat common-tail rows, local Real seal-source rows, or displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *support rows.*

These laws are only laws for the displayed finite BEDC refinement action. They assert no quotient stream equality, host real equality, selected limit, countable-choice row, ambient completeness row, metric-completeness row, bridge row, or second public classifier coordinate.

Proof. For the identity refinement, the finite request, four classifier faces, and support rows are unchanged. Applying Definition 38.785 to this preservation data reads the transported public classifier surface as the original public $\mathsf{Real}^{\uparrow}$ classifier surface.

Now consider refinements $r : \mathcal{P} \to \mathcal{Q}$ and $s : \mathcal{Q} \to \mathcal{R}$. The preservation hypotheses for r and s identify the DyadicRatCore ledger, StreamName finite-window section, RegSeqRat common-tail

rows, local Real seal-source row, and the displayed BHist, hsame, Cont, Pkg, and NameCert support across the two steps.

Apply Definition 38.777. The two-step transport is the same finite interface as transport along the composite finite request, with no additional classifier coordinate. Then Definition 38.785 gives preservation of the public classifier surface for $s \circ r$.

For the converse, suppose the composite transport gives two different public classifier surfaces. By Definition 38.783, such a difference must already be visible on one of the four displayed faces or on one of the listed support rows.

Finally, Definition 38.787 places that witness at a finite refinement stage whenever the comparison is made through a terminal cofinal pullback. The cited route inventory exports only the displayed finite BEDC rows, so quotient streams, host real equality, selected limits, countable choice, ambient completeness, metric completeness, bridge rows, and a second classifier coordinate cannot supply an additional obstruction or a repair. □

Theorem 38.789 (Real L10 exit-threshold classifier coherence)**.** *For any finite Phase* $\mathsf{Real}^{\uparrow}$ *and Completion packet over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *seal rows, the following two data are equivalent to one displayed four-face record.*

First, the packet has public classifier agreement in the sense of the Real L10 four-face classifier pullback and sheaf condition. Second, the same packet satisfies the objectwise exit threshold for the current Phase Real and Completion audit route. The displayed record carries exactly the $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and common-tail rows, the local* $\mathsf{Real}^{\uparrow}$ *seal rows, and the support rows*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

The classifier coordinate and the exit-threshold coordinate are read from that same record, but neither coordinate supplies the other. The statement excludes quotient streams, host real equality, selected limits, countable choice, metric-completeness data, $\mathsf{Real}^{\uparrow}$ *completeness, aggregate formalstatus rows, and aggregate bridge rows.*

Proof. First read the classifier coordinate. Apply Definition 38.472 and Definition 38.779. They identify public classifier agreement with the finite four-face surface over the DyadicRatCore ledger, StreamName finite-window rows, RegSeqRat regularity and common-tail rows, local Real seal rows, and the displayed support rows.

Next read the exit-threshold coordinate. Apply Definition 38.494. It says that the current Phase Real and Completion exit threshold is exactly the objectwise threshold over the same four local face records, rather than a route-level aggregate status.

Now combine the two readings. The classifier theorems and the threshold theorem consume the same four concrete faces and the same finite support rows, so their conjunction is equivalent to the single displayed record carrying those rows. In the forward direction, the classifier agreement supplies the classifier face rows and the threshold equivalence supplies the objectwise audit rows on those faces. In the reverse direction, the displayed record feeds the classifier pullback and sheaf condition, and it also feeds the objectwise threshold equivalence.

It remains to show noninterference of the two coordinates. Apply Definition 38.781. Classifier agreement creates no formalstatus, leantarget, bridgestatus, or bridge row, while audit admissibility creates no classifier overlap, finite-window tightness row, pairwise terminal classifier equivalence, or triple common-tail cocycle.

Finally apply Definition 38.833 and Definition 38.834. These keep the status and Lean-target data attached to the four displayed faces and rule out an aggregate replacement. Since the cited

routes export only the listed finite BEDC rows, no quotient stream, host equality, selected limit, choice principle, metric-completeness datum, $\mathsf{Real}^{\uparrow}$ completeness row, aggregate formalstatus row, or aggregate bridge row is available as an extra coordinate. □

Theorem 38.790 (Real L10 classifier-threshold source conservativity)**.** *Let $\mathcal{P}$ be a finite Real L10 four-face packet satisfying both public classifier agreement and the objectwise exit threshold over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *rows. Then the accepted source of $\mathcal{P}$ is exactly the displayed four-face record over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *local* $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

Adding the threshold coordinate does not create a fifth source, an aggregate $\mathsf{formalstatus}$ *row, an aggregate bridge row, a quotient stream, a selected limit, a metric-completeness datum, a countable-choice row, or a* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. First collapse the hypotheses to one record. By Definition 38.789, public classifier agreement and the objectwise exit threshold are read from the same four-face packet, whose only displayed sources are the DyadicRatCore ledger rows, StreamName finite-window rows, RegSeqRat regularity and common-tail rows, local Real seal rows, and the support rows BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$.

Next identify that record as the accepted source. Apply Definition 38.472 to read classifier agreement as the public four-face surface, and apply Definition 38.494 to read the threshold objectwise on those same faces. The uniqueness comparison is then the source-uniqueness statement of Definition 291.84: the accepted Real exit source is the displayed DyadicRatCore-to-Real four-face route, not an additional carrier.

It remains to separate the source from verification and bridge coordinates. By Definition 38.781, classifier rows do not manufacture $\mathsf{formalstatus}$, leantarget, bridgestatus, or bridge rows, and the audit rows do not manufacture classifier overlap or finite-window tightness data. Thus adjoining the threshold coordinate preserves the four-face source and supplies no aggregate verification or bridge row.

Finally, every excluded object would require a coordinate absent from the four cited readings. Quotient streams and selected limits are not part of the finite BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support; metric completeness, countable choice, and $\mathsf{Real}^{\uparrow}$ completeness are not exported by the objectwise threshold; and an aggregate status or bridge row is ruled out by the axis-separation theorem. Hence the accepted source remains exactly the displayed four-face record. □

Theorem 38.791 (Real L10 four-face exit classifier reflection)**.** *For any finite Phase* $\mathsf{Real}^{\uparrow}$ *and Completion terminal packet over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *rows, public classifier agreement on the four-face packet is equivalent to the objectwise Phase Real and Completion exit-threshold read of that same packet precisely when both are reflected from the displayed four-face source record*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

The unique reflected source is the finite record carrying exactly the four faces together with the displayed BHist *observations, componentwise* hsame *transports, displayed* Cont *routes,* Pkg *provenance rows, and local* $\mathsf{NameCert}$ *support rows.*

This reflection is only a public classifier and exit-read comparison on the same finite packet. It does not identify quotient streams, host real equality, selected limits, countable-choice selectors, metric-completeness data, $\mathsf{Real}^{\uparrow}$ *completeness, aggregate formalstatus rows, aggregate leantarget rows, or aggregate bridge rows.*

Proof. First put the classifier coordinate and the threshold coordinate on the same source record. Apply Definition 38.789. It identifies public classifier agreement and the objectwise exit threshold as two readings of one finite four-face packet over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, the local $\mathsf{Real}^{\uparrow}$ rows, and the displayed BHist, hsame, Cont, Pkg, and NameCert support.

For the forward direction, assume public classifier agreement on the terminal four-face packet. The coherence theorem reads the accompanying exit-threshold coordinate from the same displayed record. Then Definition 38.458 and Definition 301.237 identify the terminal pullback source and the RegSeqRat source section uniquely, so the reflected source is exactly the stated four-face record.

For the reverse direction, assume the objectwise Phase Real and Completion exit-threshold read is displayed on that record. Use Definition 38.790 to keep the accepted source equal to the four-face record, then apply the classifier side of Definition 38.789 to recover public classifier agreement on the same packet.

It remains to keep the axes separate. Apply Definition 38.833 and Definition 38.834. The closure, verification, Lean-target, and bridge data stay attached to the four displayed faces and cannot be replaced by aggregate rows, while classifier agreement supplies no quotient stream, host equality, selected limit, choice principle, metric-completeness datum, or $\mathsf{Real}^{\uparrow}$ completeness row. □

Theorem 38.792 (Real L10 objectwise face-status exit)**.** *For any current Phase* $\mathsf{Real}^{\uparrow}$ *and Completion exit packet over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and the local* $\mathsf{Real}^{\uparrow}$ *rows, the packet satisfies the roadmap exit read exactly when the four local faces each supply their own closurestatus, formalstatus, leantarget, and bridgestatus rows, and the packet carries only the displayed finite support rows*

$$\mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

Equivalently, the exit certificate is the objectwise product of the four local face-status records together with those finite BEDC support rows.

The certificate contains no aggregate formalstatus *row, no aggregate bridge row, no quotient stream, no selected limit, no countable-choice coordinate, no metric-completeness datum, and no* $\mathsf{Real}^{\uparrow}$ *completeness claim. The local face records remain the exact Phase Real and Completion exit certificate; there is no additional route-level status carrier.*

Proof. First read the exit threshold. By Definition 38.494, the current Phase Real and Completion threshold is the objectwise threshold on the four displayed faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Next recover the local status rows. Apply Definition 38.471. It reads the roadmap audit coordinate from the local closurestatus, formalstatus, leantarget, and bridgestatus rows of those four faces, rather than from a single route credential.

For the forward direction, an accepted roadmap exit read therefore decomposes into exactly the four local face records, and the finite support of the packet is the displayed BHist, hsame, Cont, Pkg, and NameCert data. No further support coordinate is introduced by the threshold comparison.

For the reverse direction, suppose the four faces supply those local rows and the packet carries only the displayed BEDC support rows. The audit pullback reads these rows as the current Phase Real and Completion audit record, and the threshold equivalence identifies that record with the roadmap exit read.

It remains to rule out substitute status data. Use Definition 38.833 and Definition 38.834. They keep closure, verification, Lean-target, and bridge information attached to the four face

chapters, so no aggregate formalstatus, aggregate leantarget, or aggregate bridge row can replace the objectwise certificate.

Finally compare with the StreamName-side certificate of Definition 126.513. It has the same four-object exit read and the same finite support surface. Thus the Real-side packet is precisely the Phase Real and Completion exit certificate formed by the four local face-status records and the displayed BHist, hsame, Cont, Pkg, and NameCert rows, excluding quotient streams, selected limits, countable choice, metric-completeness data, and $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 38.793 (Real L10 exit certificate face minimality)**.** *Let $\mathcal{P}$ be an accepted Phase* $\mathsf{Real}^{\uparrow}$ *and Completion exit certificate over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *rows. Suppose $\mathcal{P}$ satisfies the roadmap exit read by the objectwise four-face certificate of Definition 38.792. Then each of the four face records is indispensable: deleting the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or local* $\mathsf{Real}^{\uparrow}$ *face record makes the remaining data fail to satisfy the roadmap exit read.*

The same minimality holds for the displayed support surface. If any displayed BHist, hsame, Cont, Pkg, *or* NameCert *support row used by the four faces is removed, the remaining packet no longer carries an accepted Phase* $\mathsf{Real}^{\uparrow}$ *and Completion exit certificate under the current Real L10 roadmap read.*

This is only a minimality statement for the objectwise exit certificate. It does not introduce quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealUp.RealL10ExitCertificateFaceMinimality`

Proof. First identify the certificate whose minimality is being tested. By Definition 38.792, the accepted roadmap exit read is exactly the objectwise product of the four local face-status records together with the displayed BHist, hsame, Cont, Pkg, and NameCert support rows.

Next compare the exit read with the current audit route. Apply Definition 38.471. It reads the current Phase Real and Completion audit from those same local face records. Apply Definition 38.493 and Definition 38.494. They say that the roadmap exit criterion is satisfied by precisely that four-face objectwise threshold, not by a shortened route.

Now remove one face. If the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or local $\mathsf{Real}^{\uparrow}$ face is absent, the objectwise product required by the face-status theorem is no longer present. The sufficiency theorem therefore has no four-face certificate to consume, and the threshold equivalence cannot read an accepted roadmap exit from the remaining three faces.

Now remove one displayed support row. The face-status theorem lists BHist, hsame, Cont, Pkg, and NameCert as the finite support carried by the objectwise certificate. Removing any displayed row breaks the support surface on which the audit pullback and threshold equivalence are evaluated, so the remaining packet does not present the accepted exit certificate.

It remains to rule out replacement data. By Definition 38.781, classifier agreement cannot manufacture formalstatus, leantarget, bridgestatus, or bridge rows, and audit admissibility cannot manufacture classifier rows. By Definition 38.833 and Definition 38.834, the status and Lean-target data stay attached to the four displayed faces and cannot be replaced by aggregate rows.

Thus every face record and every displayed support row is indispensable for the current Real L10 roadmap exit read. The cited routes provide no quotient stream, selected limit, countable-choice selector, metric-completeness datum, aggregate formalstatus row, aggregate bridge row, or $\mathsf{Real}^{\uparrow}$ completeness coordinate that could fill the missing position. □

Theorem 38.794 (Real L10 exit certificate support no-confusion)**.** *Let $\mathcal{P}$ and $\mathcal{P}'$ be accepted Phase* $\mathsf{Real}^{\uparrow}$ *and Completion exit certificates over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *rows. Suppose both certificates expose the same four local face-status records and the same displayed support rows*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

Then $\mathcal{P}$ and $\mathcal{P}'$ determine the same Real L10 exit certificate and the same public finite-section classifier read.

Conversely, equality of Real L10 exit-certificate reads recovers equality of exactly those four local face-status records and the five displayed BEDC support rows. It recovers no quotient stream equality, no selected limit, no countable-choice selector, no metric-completeness datum, no aggregate formalstatus *row, no aggregate bridge row, and no* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.RealUp.RealL10ExitCertificateSupportNoConfusion`

Proof. First identify the surface on which both certificates are read. By Definition 38.792, an accepted Phase Real and Completion exit certificate is the objectwise product of the four face-status records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the local $\mathsf{Real}^{\uparrow}$ rows, together with exactly the displayed BHist, hsame, Cont, Pkg, and NameCert support rows. Since $\mathcal{P}$ and $\mathcal{P}'$ expose the same rows, they have the same displayed objectwise exit certificate.

Next rule out hidden alternatives. Apply Definition 38.793. None of the four face records and none of the five support rows can be deleted, replaced, duplicated, or detached while the accepted roadmap exit read is retained. Hence the common displayed surface determines one Real L10 exit-certificate read, so $\mathcal{P}$ and $\mathcal{P}'$ cannot separate after the rows listed in the statement have been fixed.

Now transport the same conclusion to the classifier. Apply Definition 38.789 to put the exit-threshold read and the public classifier read on one finite four-face record. Then apply Definition 38.795. The public finite-section classifier read is exactly the read of the dyadic common scale-window witness, the $\mathsf{StreamName}^{\uparrow}$ finite-window section, the $\mathsf{RegSeqRat}^{\uparrow}$ regularity and common-tail classifier rows, the local $\mathsf{Real}^{\uparrow}$ terminal seal row, and the same five support rows. Therefore equal exit-certificate rows give equal public classifier reads.

For the converse direction, assume the two certificate reads are equal. The face-status theorem identifies the only recoverable rows as the four local face-status records and the displayed BHist, hsame, Cont, Pkg, and NameCert rows; minimality forces equality on each of those rows, because deleting or replacing any one of them would change the accepted certificate read.

Finally separate the certificate vocabulary from verification and bridge data. Use Definition 38.781, Definition 38.833, and Definition 38.834. These theorems keep formalstatus, Lean-target, and bridge information local to the four displayed faces and prevent an aggregate route row from being read back out of the certificate. The cited finite rows also contain no quotient stream, selected limit, countable-choice selector, metric-completeness datum, or $\mathsf{Real}^{\uparrow}$ completeness coordinate, so equality of certificate reads recovers none of those data. □

Theorem 38.795 (Real L10 finite-section classifier equivalence)**.** *Let $\mathcal{S}$ be a finite Real-and-Completion section over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *rows. Public finite-section classifier agreement on $\mathcal{S}$ is equivalent to the existence of one compatible four-face packet whose rows are exactly the dyadic common scale-window witness, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window section, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and common-tail classifier rows, the local* $\mathsf{Real}^{\uparrow}$

terminal seal row, and the support rows

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

The compatible packet is read objectwise on those four faces. It contains no quotient streams, selected limits, host real equality, countable-choice selectors, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, or $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. First put the classifier and threshold readings on one record. Apply Definition 38.789. It identifies the public classifier coordinate and the objectwise exit-threshold coordinate as readings of the same finite four-face packet over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, local $\mathsf{Real}^{\uparrow}$, and the displayed support rows.

Next identify the reflected source of that record. Apply Definition 38.791. The finite section therefore has the stated public classifier surface exactly when its classifier and exit reads are reflected from the same four-face source

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

We now compare the RegSeqRat-facing rows. Apply Definition 301.239 to read the local $\mathsf{Real}^{\uparrow}$ terminal seal from the RegSeqRat terminal face, and apply Definition 301.186 to identify the common-tail classifier rows with the Real boundary rows. This supplies the RegSeqRat regularity, common-tail, and terminal-seal components of the compatible packet.

The StreamName and DyadicRatCore faces are then forced by their finite-section exactness results. Use Definition 126.586 to recover the $\mathsf{StreamName}^{\uparrow}$ finite-window section, and use Definition 291.8 to recover the dyadic common scale-window witness. These two faces provide the lower part of the four-face packet and do not introduce any quotient or completeness coordinate.

For the forward direction, public finite-section classifier agreement supplies the four face records just described, and the cited exactness theorems repack them with BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ into the compatible packet. For the reverse direction, a compatible packet carrying exactly those rows feeds the reflected-source theorem and hence yields public finite-section classifier agreement on $\mathcal{S}$.

Finally apply Definition 38.793. Each face and each displayed support row is indispensable, so no shortened three-face section or support-free certificate can present the same classifier surface. Since the only rows used are the four local faces and the listed BEDC support rows, the construction has no source for quotient streams, selected limits, host real equality, countable choice, metric-completeness data, aggregate formalstatus, aggregate bridge rows, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 38.796 (Real L10 current-phase exit local threshold)**.** *Let* $\mathcal{E}$ *be a current Phase* $\mathsf{Real}^{\uparrow}$ *and Completion exit packet over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *rows. Then* $\mathcal{E}$ *satisfies the roadmap exit read exactly when the four objectwise faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and local* $\mathsf{Real}^{\uparrow}$ *each supply their own scoped-closure and audit-clean local threshold rows, and the only support rows carried across the packet are*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

Equivalently, the current Phase Real and Completion exit criterion is the objectwise product of those four local threshold records, reflected through the same finite classifier section, and not a route-level aggregate credential. The packet has no quotient stream, no selected limit, no countable-choice selector, no metric-completeness datum, no aggregate formalstatus row, no aggregate bridge row, and no $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.RealUp.RealL10CurrentPhaseExitLocalThreshold`

Proof. For the forward direction, assume $\mathcal{E}$ satisfies the roadmap exit read. By Definition 38.792, the exit read decomposes objectwise into the four face-status records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the local $\mathsf{Real}^{\uparrow}$ rows, together with only the displayed BHist, hsame, Cont, Pkg, and NameCert support.

The local threshold grade on each face is then read from that same objectwise certificate. Apply Definition 38.793. Since each face and each displayed support row is indispensable, the roadmap exit read cannot be witnessed by a shortened section, by an unsupported status row, or by an aggregate credential replacing the four local rows.

For the reverse direction, suppose the four faces each supply their scoped-closure and audit-clean local threshold rows and the packet carries only the displayed BEDC support rows. The objectwise face-status theorem repacks exactly these rows as the current Phase Real and Completion exit certificate, so the roadmap exit read is satisfied.

It remains to identify this certificate with the classifier section used by the roadmap. Apply Definition 38.791 to reflect the exit read and public classifier agreement from the same source

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Then apply Definition 38.795 to read the finite section as exactly the dyadic common scale-window witness, the $\mathsf{StreamName}^{\uparrow}$ finite-window section, the $\mathsf{RegSeqRat}^{\uparrow}$ regularity and common-tail classifier rows, the local $\mathsf{Real}^{\uparrow}$ terminal seal row, and the displayed support rows.

Finally combine the minimality and classifier equivalence statements. The four local faces are both necessary and sufficient for the current-phase exit read, and the finite classifier section introduces no extra coordinates. Thus quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, and $\mathsf{Real}^{\uparrow}$ completeness are all absent from the theorem's certificate surface. □

Theorem 38.797 (Real L10 finite-request exit cover)**.** *Let $\mathcal{R}$ be a finite Real-and-Completion request section whose visible rows are exactly the* $\mathsf{StreamName}^{\uparrow}$ *finite-request section, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and distance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and regularity rows, the local* $\mathsf{Real}^{\uparrow}$ *seal row, and the displayed support rows*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

Then $\mathcal{R}$ satisfies the current Phase Real and Completion exit read if and only if those visible rows form the four-face objectwise certificate of Definition 38.796.

The cover is finite and objectwise. It excludes quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, and $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First identify the finite request section. Apply Definition 38.795. It reads the visible finite section as exactly the dyadic common scale-window witness, the $\mathsf{StreamName}^{\uparrow}$ finite-window section, the $\mathsf{RegSeqRat}^{\uparrow}$ regularity and common-tail classifier rows, the local $\mathsf{Real}^{\uparrow}$ terminal seal row, and the displayed BHist, hsame, Cont, Pkg, and NameCert support rows.

For the forward direction, assume $\mathcal{R}$ satisfies the current Phase Real and Completion exit read. By Definition 38.796, that exit read is precisely the objectwise product of the four local threshold records on $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the local $\mathsf{Real}^{\uparrow}$ face, carried by the same displayed support rows. The finite-section equivalence identifies these rows with the visible request section, so the section forms the required four-face certificate.

For the reverse direction, suppose the visible rows of $\mathcal{R}$ form that four-face objectwise certificate. The current-phase local-threshold theorem consumes exactly those four face records and the displayed support rows, so the roadmap exit read is satisfied.

It remains to rule out shortened or enlarged covers. Apply Definition 38.793. Each of the four face records and each displayed support row is indispensable for the current Real L10 exit certificate, so a missing face, a missing support row, or an added aggregate credential cannot present the same exit read.

Therefore the finite request section is a cover of the current exit certificate exactly in the stated objectwise sense. The cited theorems provide no coordinate for quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 38.798 (Real L10 exit-certificate dependency factorization)**.** *Let $\mathcal{E}$ be a finite Phase* $\mathsf{Real}^{\uparrow}$ *and Completion exit packet over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *rows. Then $\mathcal{E}$ satisfies the current-phase exit local threshold if and only if its accepted exit certificate factors through exactly the ordered dependency surface*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

together with the displayed support rows

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

In the forward direction, an accepted exit certificate decomposes into the four face records: the finite-tail $\mathsf{DyadicRatCore}^{\uparrow}$ *exit certificate, the* $\mathsf{StreamName}^{\uparrow}$ *ordered finite-window gate, the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-section classifier record, and the local* $\mathsf{Real}^{\uparrow}$ *seal-facing threshold record, all carried by those same support rows. In the reverse direction, those four compatible face records repack to the accepted current-phase exit local threshold certificate for $\mathcal{E}$.*

This factorization excludes quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, and $\mathsf{Real}^{\uparrow}$ *completeness. It is only a dependency certificate for the finite Phase Real and Completion exit surface.*

Proof. For the forward direction, assume $\mathcal{E}$ satisfies the current-phase exit local threshold. Apply Definition 38.796. The threshold read is the objectwise product of the four local threshold records on $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the local $\mathsf{Real}^{\uparrow}$ face, with no support beyond BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$.

Now identify the four components of that product. The DyadicRatCore component is the finite-tail exit-certificate surface of Definition 291.75. The StreamName component is constrained by Definition 126.615, so the consumer-facing read keeps the displayed StreamName window before the dyadic ledger and then the RegSeqRat and Real faces.

The middle and terminal components are read from the finite section. Apply Definition 38.795 to identify the $\mathsf{RegSeqRat}^{\uparrow}$ classifier and regularity rows together with the local $\mathsf{Real}^{\uparrow}$ terminal seal row. Then apply Definition 38.793: none of these four faces, and none of the displayed support rows, can be deleted or replaced by an aggregate credential.

For the reverse direction, suppose the packet displays exactly those four compatible face records over the ordered surface and the displayed support rows. The finite-section classifier equivalence repacks the StreamName, RegSeqRat, dyadic scale-window, and local Real rows as one finite request section, while the StreamName ordered exit gate supplies the consumer-facing order.

The DyadicRatCore finite-tail exit-certificate equivalence supplies the first visible face of the objectwise certificate. Combining that dyadic face with the StreamName, RegSeqRat, and Real

rows gives the four-face certificate consumed by Definition 38.797. Hence the visible section satisfies the current Phase Real and Completion exit read.

Finally apply Definition 38.796 again to identify that exit read with the current-phase local threshold for $\mathcal{E}$. Since every cited theorem works only with the four displayed faces and the rows BHist, hsame, Cont, Pkg, and NameCert, there is no coordinate from which to form quotient streams, selected limits, countable-choice data, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 38.799 (Real L10 construction-consumer order square)**.** *Let $\mathcal{E}$ be a finite Phase* $\mathsf{Real}^{\uparrow}$ *and Completion packet over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and the local* $\mathsf{Real}^{\uparrow}$ *rows. Suppose $\mathcal{E}$ satisfies the current-phase exit local threshold. Then the construction-source projection*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

and the consumer-readback projection

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

are the two visible edge readings of one commuting square of the same displayed four-face exit certificate.

The top edge is the Real-side source reflection, the left edge is the StreamName finite-window readback, the right edge is the RegSeqRat-to-Real seal read, and the bottom edge is the shared objectwise certificate. Commutativity means that reading the packet by the construction source and then consuming it through the StreamName-facing gate yields the same four local face records and the same displayed support rows as first reading the consumer gate and then projecting to the Real-side source. The square supplies no quotient stream equality, selected limit, countable-choice row, metric-completeness datum, aggregate formalstatus row, aggregate bridge row, standard bridge row, or $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. First read the Real-side source. By Definition 38.791, the classifier and exit-threshold coordinates of $\mathcal{E}$ are reflected from the displayed source

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

By Definition 38.796, this source carries exactly the four objectwise local threshold records and the displayed BHist, hsame, Cont, Pkg, and NameCert support rows.

Next read the consumer-facing order. Apply Definition 126.615. The same accepted Phase Real and Completion seal-facing read is consumed along

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow},$$

where the StreamName finite window is read before the dyadic ledger, the RegSeqRat readback is anchored to those rows, and the RealUp seal is read last.

The two readings now have the same certificate target. Use Definition 38.793: each of the four face records and each displayed support row is indispensable for the current Real L10 exit certificate. Therefore neither route can replace, delete, or duplicate a face while still presenting the accepted exit read.

Finally compare the edge maps. The Real-side reflection gives the construction-source edge, the StreamName ordered gate gives the consumer-readback edge, and the local-threshold theorem identifies both with the same objectwise certificate. Since face minimality leaves only those four

faces and those support rows, the square commutes as a comparison of projections of one displayed certificate, not as a second completion route.

All excluded data remain absent. The cited theorems export only the finite face rows and the displayed support rows, so the square has no source for quotient stream equality, selected limits, countable choice, metric completeness, aggregate formalstatus, aggregate bridge rows, standard bridge rows, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 38.800 (Real L10 finite-request exit cocycle)**.** *Let $\mathcal{E}$ be a finite Phase* $\mathsf{Real}^{\uparrow}$ *and Completion request packet over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *rows. Suppose $\mathcal{E}$ satisfies the current-phase exit local threshold. Then the DyadicRatCore finite-tail exit certificate, the StreamName finite-request section pullback exactness, the RegSeqRat four-face exit-threshold equivalence, and the Real finite-request exit cover form one associative cocycle on the same four-face source.*

Equivalently, the construction-source-then-consumer-readback composite and the RegSeqRat-threshold-then-Real-exit-cover composite recover exactly the same four face records and the same support rows

$$\mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

The cocycle is only a finite packet identity among these four visible readings. It supplies no quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the dyadic face. By Definition 291.75, the visible $\mathsf{DyadicRatCore}^{\uparrow}$ input to $\mathcal{E}$ is exactly the finite-tail exit certificate carried by the displayed BHist, hsame, Cont, Pkg, and NameCert rows. This gives the first edge of the finite four-face source.

Next attach the request section. Apply Definition 126.581. The StreamName finite request section is pulled back over that same dyadic face, so the consumer readback does not introduce a second support surface or a second certificate target.

Now read the terminal threshold. Apply Definition 301.218. The RegSeqRat threshold is the terminal four-face reading of the dyadic and StreamName data together with the local $\mathsf{Real}^{\uparrow}$ seal row, and it keeps the same five support rows.

The Real exit cover is the last face. By Definition 38.797, the finite request section covers exactly the Real exit certificate visible from the same four faces. Thus the RegSeqRat-threshold-then-Real-exit-cover route returns the same records as the preceding dyadic and StreamName pullback route.

It remains to compare the two edge orders. Use Definition 38.799: the construction-source projection and the consumer-readback projection are two readings of one commuting square of the displayed four-face exit certificate. Therefore composing through the construction edge before the consumer edge, or through the RegSeqRat terminal threshold before the Real cover, is associative as a cocycle on the same finite packet.

All exclusions are inherited from the cited faces. None of them exports quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, or $\mathsf{Real}^{\uparrow}$ completeness, so the cocycle cannot add such data. □

Theorem 38.801 (Real L10 support-row reindexing invariance)**.** *Let $\mathcal{E}$ be a finite Phase* $\mathsf{Real}^{\uparrow}$ *and Completion packet satisfying the current-phase exit local threshold of Definition 38.796. Let O and O' be accepted support-row-preserving reindexings or projections of the ordered terminal route fixed by Definition 126.615:*

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}.$$

Assume that both readings preserve the same displayed face rows, the same BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, and the same local* $\mathsf{Real}^{\uparrow}$ *seal row. Assume also that neither reading detaches the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger from the* $\mathsf{StreamName}^{\uparrow}$ *finite window, reads the* $\mathsf{RegSeqRat}^{\uparrow}$ *row before the dyadic predecessor face, or reads the* $\mathsf{Real}^{\uparrow}$ *seal before the required predecessor faces. Then O and O' determine the same objectwise Phase* $\mathsf{Real}^{\uparrow}$ *and Completion exit certificate.*

The invariant certificate is only the finite four-face objectwise product over the ordered terminal route and its displayed support rows. It excludes quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, and $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First fix the public route. Apply Definition 126.615. An accepted seal-facing read satisfies the public L10 exit gate only along

$$\mathsf{StreamName}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow},$$

with the finite StreamName window before the dyadic ledger, the RegSeqRat readback after the anchored ledger, and the RealUp seal last. Thus O and O' are not arbitrary face permutations; they are support-row-preserving views of that same ordered terminal route.

Next identify the certificate carried by that route. By Definition 38.796, the current Phase Real and Completion exit criterion is the objectwise product of the four local threshold records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the local $\mathsf{Real}^{\uparrow}$ face, together with exactly the displayed BHist, hsame, Cont, Pkg, and NameCert support rows.

Use minimality to control the allowed reindexings and projections. Apply Definition 38.793. Since every one of the four face records and every displayed support row is indispensable, an accepted support-row-preserving view cannot delete, duplicate, detach, or replace a face or support row while still presenting the same current Real L10 exit certificate.

Now compare O and O' as finite classifier sections of the same terminal packet. By Definition 38.795, every accepted finite-section read with these four faces and these support rows is a compatible four-face packet over the dyadic common scale-window witness, the $\mathsf{StreamName}^{\uparrow}$ finite-window section, the $\mathsf{RegSeqRat}^{\uparrow}$ regularity and common-tail rows, and the local $\mathsf{Real}^{\uparrow}$ terminal seal row.

Thus both O and O' are projections of the same compatible finite packet over the ordered route. The construction-consumer square of Definition 38.799 is one visible comparison inside this finite certificate, and the present hypotheses restrict the comparison to order-preserving support reindexings or projections of the same four-face certificate.

The conclusion is therefore support-row reindexing invariance of the displayed objectwise exit certificate, not a second route to completion and not a permission to permute the public L10 construction faces. The cited theorems provide no coordinate for quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, or $\mathsf{Real}^{\uparrow}$ completeness, so these data remain outside the invariant certificate. □

Theorem 38.802 (Real L10 face-local formal upgrade invariance)**.** *Let $\mathcal{E}$ be a finite Phase* $\mathsf{Real}^{\uparrow}$ *and Completion packet over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and the local* $\mathsf{Real}^{\uparrow}$ *rows satisfying the current-phase exit local threshold of Definition 38.796. Let F be one of the four displayed faces. Form $\mathcal{E}_F^{+}$ by replacing only the local formal-status row attached to F by a strictly stronger local formal-status row, or by replacing only the leantarget row or bridgestatus row attached to F by a replacement row attached to the same face whose recorded target or bridge status refines the same local face without changing the other three face records.*

Assume that the displayed support rows BHist, hsame, Cont, Pkg, *and* NameCert *are unchanged. Then* $\mathcal{E}_F^+$ *determines the same four-face Phase* $\mathsf{Real}^\uparrow$ *and Completion exit certificate as* $\mathcal{E}$*. Conversely, any packet with the same four-face exit certificate and with all non-*F *face records and displayed support rows fixed differs from* $\mathcal{E}$ *only by a face-local formal-status strengthening on* F*, or by a face-local leantarget or bridgestatus refinement attached to* F *that preserves the same displayed certificate surface.*

This invariance is purely face-local. It does not introduce route-level formalstatus, aggregate leantarget rows, aggregate bridge rows, selected limits, quotient streams, metric-completeness data, $\mathsf{Real}^\uparrow$ *completeness, or any replacement for the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support.*

Proof. First identify the certificate whose stability is being tested. By Definition 38.792, the accepted Phase $\mathsf{Real}^\uparrow$ and Completion exit certificate is the objectwise product of the four local face-status records together with exactly the displayed BHist, hsame, Cont, Pkg, and NameCert support rows.

For the forward direction, first consider a strictly stronger local formal-status row attached to F. The other three face records and all displayed support rows are unchanged, so the objectwise product still has the same four faces and the same finite BEDC support surface. By Definition 38.833, the stronger formal-status data remains attached to F and cannot become a route-level aggregate row.

The leantarget and bridgestatus alternatives are same-face refinements rather than entries in a shared strengthening order. Their recorded target or bridge status remains attached to F, refines that local face, and preserves the other three face records together with the displayed support rows. By Definition 38.834, the Lean-target refinement cannot become an aggregate route row, and the objectwise face-status certificate keeps bridge-status information on the displayed local face surface.

Now use support-row invariance. Apply Definition 38.801. Since the visible BHist, hsame, Cont, Pkg, and NameCert rows are fixed and no face is detached or reordered outside the accepted terminal route, the finite BEDC packet presents the same objectwise exit certificate after the local strengthening.

For the converse direction, suppose a packet presents the same four-face exit certificate while the three non-F face records and all displayed support rows are fixed. By Definition 38.793, none of the four faces and none of the displayed support rows can be deleted, aggregated, duplicated, or replaced while the same current Real L10 exit certificate is retained.

It remains only to locate the possible difference. The non-F records are fixed by hypothesis, and minimality fixes the displayed support surface. The noncollapse theorems keep formalstatus and Lean-target rows attached to their source face, while the objectwise face-status theorem keeps bridge-status information local to the four displayed faces. Hence any remaining difference is either a stronger local formal-status row on F, or a same-face leantarget or bridgestatus refinement on F that preserves the displayed certificate surface.

All excluded data remain absent. The cited results use only the four face records and the displayed support rows; they provide no route-level formalstatus, aggregate bridge coordinate, selected limit, quotient stream, metric-completeness datum, or $\mathsf{Real}^\uparrow$ completeness row. Thus the certificate is invariant precisely under the stated face-local formal strengthening and same-face leantarget or bridgestatus refinement. □

Theorem 38.803 (Real L10 face formal upgrade chain invariance)**.** *Let*

$$\mathcal{E}_0, \mathcal{E}_1, \ldots, \mathcal{E}_n$$

be a finite sequence of Phase $\mathsf{Real}^{\uparrow}$ *and Completion packets over the four displayed faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

Assume $\mathcal{E}_0$ *satisfies the current-phase exit local threshold of Definition 38.796. For each adjacent step* $\mathcal{E}_i \rightsquigarrow \mathcal{E}_{i+1}$*, assume exactly one face is changed, the changed row is a same-face formalstatus strengthening, leantarget refinement, or bridgestatus refinement, and all other face records are fixed. Assume also that every step preserves the displayed support rows*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

Then every intermediate packet $\mathcal{E}_i$ *determines the same objectwise Phase* $\mathsf{Real}^{\uparrow}$ *and Completion exit certificate read by Definition 38.796.*

The invariant certificate is only the finite four-face exit certificate. The sequence supplies no aggregate formalstatus row, aggregate leantarget row, aggregate bridge row, quotient stream, selected limit, countable-choice selector, metric-completeness datum, standard bridge row, or $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Induct on the finite sequence. The base case is the one-packet sequence, where the exit certificate is the certificate of $\mathcal{E}_0$ read by Definition 38.796.

For the induction step, suppose $\mathcal{E}_i$ has the same objectwise exit certificate as $\mathcal{E}_0$. The adjacent move $\mathcal{E}_i \rightsquigarrow \mathcal{E}_{i+1}$ changes only one of the four displayed faces, and the change is either a stronger local formalstatus row, a same-face leantarget refinement, or a same-face bridgestatus refinement. The rows BHist, hsame, Cont, Pkg, and NameCert remain fixed.

Apply Definition 38.802 to this adjacent move. It identifies the exit certificate of $\mathcal{E}_{i+1}$ with the exit certificate of $\mathcal{E}_i$, because the refinement remains attached to its source face and does not alter the other three face records or the displayed support surface.

Finally use transitivity of the certificate comparison supplied by the induction hypothesis. The noncollapse theorems Definition 38.833 and Definition 38.834, together with the minimality theorem Definition 38.793, exclude aggregate formalstatus rows, aggregate bridge rows, quotient streams, selected limits, metric-completeness data, and $\mathsf{Real}^{\uparrow}$ completeness at every step. Hence each intermediate packet reads the same finite four-face Phase Real and Completion exit certificate. □

Theorem 38.804 (Real L10 exit-threshold face-local correspondence)**.** *Let* $\mathcal{E}$ *be a finite Phase* $\mathsf{Real}^{\uparrow}$ *and Completion packet over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and the local* $\mathsf{Real}^{\uparrow}$ *rows. Then* $\mathcal{E}$ *satisfies the current-phase exit local threshold of Definition 38.796 if and only if it exhibits four compatible local face records over the same displayed support rows:*

1. *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *finite-tail certificate,*
2. *the* $\mathsf{StreamName}^{\uparrow}$ *ordered finite-window gate,*
3. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-section classifier record,*
4. *the local* $\mathsf{Real}^{\uparrow}$ *seal-facing threshold record.*

Compatibility means that all four records are read over the same displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows, and that no face record is detached from the ordered terminal route.*

This correspondence is exactly local-record correspondence for the four displayed faces, not an aggregate audit credential. It recovers no quotient stream, selected limit, countable-choice selector, metric-completeness datum, aggregate formalstatus row, aggregate bridge row, standard bridge row, or $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. For the forward direction, read the threshold by Definition 38.796. The accepted exit read is the objectwise product of the four local threshold records on $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the local $\mathsf{Real}^{\uparrow}$ face, together with exactly the displayed BHist, hsame, Cont, Pkg, and NameCert support rows.

Now factor that read through the displayed route. Apply Definition 38.798. The dyadic finite-tail certificate, the ordered StreamName finite-window gate, the RegSeqRat finite-section classifier record, and the local Real seal-facing threshold record are the four ordered faces of the same exit certificate rather than independent summaries.

Minimality fixes the vocabulary of the correspondence. By Definition 38.793, none of the four face records and none of the displayed support rows can be deleted, duplicated, detached, or replaced while the same current Real L10 exit certificate is retained. Thus the forward read produces exactly the listed local records over the common support surface.

For the reverse direction, assume the four compatible local records are exhibited over the same displayed BHist, hsame, Cont, Pkg, and NameCert rows. Use Definition 38.805 to compare this displayed four-face section with the finite packet $\mathcal{E}$: the support-row-preserving comparison recovers the same objectwise certificate read.

Finally apply Definition 38.796 again. Since the recovered objectwise certificate is precisely the product of the dyadic finite-tail certificate, the ordered StreamName finite-window gate, the RegSeqRat finite-section classifier record, and the local Real seal-facing threshold record, the packet satisfies the current-phase exit local threshold.

Face-local formal changes do not alter the equivalence. By Definition 38.802, any strengthening of a local status, leantarget, or bridge-status row remains attached to its source face and cannot become a route-level aggregate credential. Consequently the correspondence has no coordinate for quotient streams, selected limits, countable-choice selectors, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 38.805 (Real L10 exit certificate refinement functoriality)**.** *Let $\mathcal{E}$ and $\mathcal{E}'$ be finite Phase* $\mathsf{Real}^{\uparrow}$ *and Completion packets over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *rows. Suppose $\rho : \mathcal{E} \to \mathcal{E}'$ is a certified finite refinement whose visible action preserves each displayed face row and preserves the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support rows. Then $\mathcal{E}$ and $\mathcal{E}'$ determine the same objectwise Phase Real and Completion exit certificate read by Definition 38.796.*

Conversely, if $\mathcal{E}$ and $\mathcal{E}'$ determine the same objectwise Phase Real and Completion exit certificate, then the equality recovers exactly a certified finite refinement between their displayed four-face sections that preserves the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and local* $\mathsf{Real}^{\uparrow}$ *rows and preserves the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support rows.*

This refinement law is confined to the displayed finite certificate surface. It excludes quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, and $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First read both packets through the current exit criterion. By Definition 38.796, each accepted packet is read as the objectwise product of the four local threshold records on $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the local $\mathsf{Real}^{\uparrow}$ face, together with exactly the displayed BHist, hsame, Cont, Pkg, and NameCert support rows.

For the forward direction, apply the certified finite refinement ρ. Its visible action preserves every one of the four face rows and every displayed support row, so the finite-section read of $\mathcal{E}'$ has the same rows as the finite-section read of $\mathcal{E}$. By Definition 38.795, the two finite sections therefore present the same compatible four-face classifier packet.

Now control possible reorderings or local status changes introduced by the refinement. Apply Definition 38.801 to identify support-row-preserving views of the terminal route with the same objectwise exit certificate. Apply Definition 38.802 to keep any face-local formal strengthening attached to its source face rather than to an aggregate route row.

For the converse direction, assume that $\mathcal{E}$ and $\mathcal{E}'$ determine the same objectwise exit certificate. By Definition 38.793, none of the four face rows and none of the displayed support rows can be deleted, duplicated, detached, or replaced while the same certificate is retained.

The finite-section classifier equivalence then reconstructs the only possible comparison between the two visible sections: it is the support-row-preserving finite refinement carrying the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and local $\mathsf{Real}^{\uparrow}$ rows to the corresponding rows and carrying the displayed BHist, hsame, Cont, Pkg, and NameCert rows to themselves. Minimality makes this refinement exact, because there is no unused face coordinate or hidden support coordinate on which a different refinement could act.

All exclusions are inherited from the same cited certificate surface. The argument uses only finite face rows, finite classifier sections, support-row-preserving route views, and face-local formal strengthening; it has no coordinate for quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 38.806 (Real L10 exit certificate refinement composition)**.** *Let $\mathcal{E}_0$, $\mathcal{E}_1$, and $\mathcal{E}_2$ be finite Phase* $\mathsf{Real}^{\uparrow}$ *and Completion packets over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *rows. Suppose*

$$\mathcal{E}_0 \xrightarrow{\rho_{01}} \mathcal{E}_1 \xrightarrow{\rho_{12}} \mathcal{E}_2$$

is a pair of certified finite refinements. Assume that each leg preserves the four displayed face rows $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and local* $\mathsf{Real}^{\uparrow}$, *and preserves the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support rows. Then the composite refinement $\rho_{12} \circ \rho_{01}$ preserves the same displayed face and support rows, and $\mathcal{E}_0$ and $\mathcal{E}_2$ determine the same objectwise Phase Real and Completion exit certificate read by Definition 38.796.*

Equivalently, a finite chain of two certified refinements cannot create any additional exit-coordinate between the endpoints. The endpoint certificate is still exactly the compatible four-face packet on $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *face, together with the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support rows.*

This composition law is confined to finite support-row-preserving refinements. It excludes quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, and $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First apply Definition 38.805 to the first leg ρ_{01}. The hypotheses say that the visible action of ρ_{01} preserves each of the four displayed face rows and every displayed support row, so $\mathcal{E}_0$ and $\mathcal{E}_1$ determine the same objectwise exit certificate.

Apply the same theorem to the second leg ρ_{12}. The second visible action preserves the same four face rows and the same BHist, hsame, Cont, Pkg, and NameCert rows, so $\mathcal{E}_1$ and $\mathcal{E}_2$ determine the same objectwise exit certificate.

Now identify the intermediate certificate. By Definition 38.795, the finite sections read from $\mathcal{E}_0$, $\mathcal{E}_1$, and $\mathcal{E}_2$ are compatible four-face packets over the same displayed terminal surface: the dyadic common scale-window witness, the finite $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegSeqRat}^{\uparrow}$ regularity and common-tail rows, and the local $\mathsf{Real}^{\uparrow}$ seal row. Hence the equality through $\mathcal{E}_1$ is equality of the same finite classifier packet, not merely agreement of unrelated summaries.

It remains to read the composite. Since both legs preserve every displayed face row and every displayed support row, their composite also sends each $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and local $\mathsf{Real}^{\uparrow}$ row to the corresponding endpoint row and sends the displayed BHist, hsame, Cont, Pkg, and NameCert rows to the corresponding endpoint rows. Transitivity of the two objectwise certificate identifications gives the endpoint certificate equality between $\mathcal{E}_0$ and $\mathcal{E}_2$.

Finally apply Definition 38.793. Minimality rules out any hidden coordinate on which the composite could act while preserving the current Real L10 exit certificate: no quotient stream, selected limit, metric-completeness datum, aggregate formalstatus row, aggregate bridge row, standard bridge row, or $\mathsf{Real}^{\uparrow}$ completeness row is part of the finite certificate surface. Thus the two-leg chain composes only as a support-row-preserving refinement of the same displayed objectwise exit certificate. □

Theorem 38.807 (Real L10 exit certificate refinement zigzag invariance)**.** *Let $\mathcal{E}_0, \ldots, \mathcal{E}_n$ be a finite zigzag of Phase* $\mathsf{Real}^{\uparrow}$ *and Completion packets over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *rows. Assume that every adjacent step is a certified support-row-preserving finite refinement in one direction or the other, preserving the four displayed face rows and preserving the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows. Then all packets $\mathcal{E}_i$ determine the same objectwise Phase Real and Completion exit certificate read by Definition 38.796.*

Conversely, let $\mathcal{E}_0, \ldots, \mathcal{E}_n$ be a finite family of Phase $\mathsf{Real}^{\uparrow}$ *and Completion packets over the same four displayed faces. If all packets determine one common objectwise Phase Real and Completion exit certificate, then the family admits a common support-row-preserving refinement zigzag through the displayed four-face sections. Each adjacent comparison preserves the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and local* $\mathsf{Real}^{\uparrow}$ *rows and preserves the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

This finite-zigzag invariant is confined to the displayed four-face certificate surface. It excludes quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, and $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. For the forward direction, induct on the length of the finite zigzag. The empty zigzag and the one-packet zigzag read a single packet through Definition 38.796, so there is no comparison to transport.

For the induction step, remove the last adjacent comparison. The induction hypothesis identifies the objectwise exit certificate of every earlier packet with the certificate of the penultimate packet. The final adjacent comparison is a certified support-row-preserving finite refinement in one direction or the other, so Definition 38.805 identifies the penultimate and final certificate readings. Transitivity of equality of the objectwise certificate readings composes these identifications and gives one certificate for the whole zigzag.

For the converse direction, assume the finite family has one common objectwise exit certificate. Apply Definition 38.793. Since the four displayed face rows and the displayed BHist, hsame, Cont, Pkg, and NameCert rows are indispensable, no member of the family can realize that common certificate by deleting, duplicating, detaching, or replacing one of those rows.

Next apply Definition 38.795. Each packet therefore has a displayed four-face section over the same dyadic common scale-window witness, the same finite $\mathsf{StreamName}^{\uparrow}$ window, the same $\mathsf{RegSeqRat}^{\uparrow}$ regularity and common-tail rows, and the same local $\mathsf{Real}^{\uparrow}$ terminal seal row. The only possible adjacent comparisons between consecutive displayed sections are the support-row-preserving certified finite refinements recovered by Definition 38.805.

Ordering the finite family by its displayed indices and inserting these recovered adjacent comparisons gives the required common refinement zigzag. Its support surface is exactly the four-face

section just described, so the construction has no coordinate for quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 38.808 (Real L10 exit refinement common envelope)**.** *Let*

$$\mathcal{E}_0, \ldots, \mathcal{E}_n$$

be a finite zigzag of Phase $\mathsf{Real}^{\uparrow}$ *and Completion packets over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *rows. Assume that every adjacent step is a certified support-row-preserving finite refinement in one direction or the other, preserving the four displayed face rows and preserving the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support rows. Then there is a single finite envelope record carrying exactly the four face rows*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow},$$

and exactly the displayed support rows

$$\mathsf{BHist}, \qquad \mathsf{hsame}, \qquad \mathsf{Cont}, \qquad \mathsf{Pkg}, \qquad \mathsf{NameCert},$$

through which every packet's objectwise Phase Real and Completion exit certificate factors.

The envelope is the common finite four-face certificate surface, not an ambient completion object. It has no coordinate for quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First identify the common certificate. Apply Definition 38.807 to the finite zigzag. The adjacent support-row-preserving refinements give one objectwise Phase Real and Completion exit certificate shared by every $\mathcal{E}_i$.

Next decompose that shared certificate into its local faces. By Definition 38.804, the common objectwise certificate is represented by the dyadic finite-tail certificate, the ordered $\mathsf{StreamName}^{\uparrow}$ finite-window gate, the $\mathsf{RegSeqRat}^{\uparrow}$ finite-section classifier record, and the local $\mathsf{Real}^{\uparrow}$ seal-facing threshold record, all read over the same displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Now order the four records through the dependency surface. Apply Definition 38.798. The face records factor through the dyadic source, the stream-name window, the regular-sequence common-tail classifier, and the local Real terminal seal in that order, so they form one finite envelope record rather than four unrelated local summaries.

It remains to show that the envelope has exactly the displayed vocabulary. The current-phase threshold theorem Definition 38.796 supplies only the four displayed face rows and the support rows BHist, hsame, Cont, Pkg, and NameCert. The minimality theorem Definition 38.793 then rules out deleting, duplicating, detaching, or replacing any of those rows while preserving the same exit certificate.

The same minimality argument excludes every forbidden coordinate. Quotient streams, selected limits, countable-choice selectors, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, and $\mathsf{Real}^{\uparrow}$ completeness are not part of the finite four-face certificate surface. Hence the common objectwise certificate of each $\mathcal{E}_i$ factors through the single finite envelope and through no larger hidden carrier. □

Theorem 38.809 (Real L10 finite-request subfamily exit stability)**.** *Let* $\{\mathcal{E}_i\}_{i \in I}$ *be a finite family of Phase* $\mathsf{Real}^{\uparrow}$ *and Completion packets over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the*

local $\mathsf{Real}^{\uparrow}$ *rows. Suppose the family has one common objectwise Phase Real and Completion exit certificate, and suppose that every finite request subfamily* $J \subseteq I$ *preserves the four displayed face rows*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow},$$

together with the displayed BHist, hsame, Cont, Pkg, *and* NameCert *support rows.*

Then each finite request subfamily J *determines the same objectwise Phase Real and Completion exit certificate as the ambient family. Conversely, any subfamily that determines that same certificate is obtained by restricting the displayed four-face sections and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support rows to the retained requests.*

This stability is only a finite-request restriction statement. It excludes quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, and $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First read the ambient family through the common certificate. Apply Definition 38.807. Since all members determine one objectwise Phase Real and Completion exit certificate, the family admits a common support-row-preserving refinement zigzag through the displayed four-face sections.

Now restrict to a finite request subfamily $J \subseteq I$. The RegSeqRat-side restriction source is Definition 301.199: finite subfamily restriction of the common-tail terminal section cover keeps exactly the retained $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and NameCert rows and adds no hidden completion or choice coordinate.

Identify the restricted Real L10 section. By Definition 38.795, the retained finite request section is still the compatible four-face packet over the dyadic common scale-window witness, the $\mathsf{StreamName}^{\uparrow}$ finite-window section, the $\mathsf{RegSeqRat}^{\uparrow}$ regularity and common-tail rows, and the local $\mathsf{Real}^{\uparrow}$ terminal seal row, together with the displayed support rows.

Minimality prevents the restriction from changing the certificate vocabulary. Apply Definition 38.793. None of the four face rows and none of the displayed BHist, hsame, Cont, Pkg, and NameCert support rows can be deleted, replaced, duplicated, or detached while retaining the same current Real L10 exit certificate.

Thus the restricted subfamily has the same objectwise certificate as the ambient family. For the converse direction, suppose a subfamily has that same certificate. The same minimality theorem forces its visible rows to be exactly retained rows from the ambient four-face section and displayed support surface, and the finite-section classifier equivalence identifies the retained rows as the restricted finite section. Hence the subfamily is precisely the restriction of the four displayed face sections and support rows to its retained requests.

The exclusion clauses follow from the same row accounting. The cited Real L10 and RegSeqRat theorems expose only finite four-face sections and the displayed support rows; they provide no coordinate for quotient streams, selected limits, countable choice, metric-completeness data, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 38.810 (Real L10 finite-request intersection exit exactness)**.** *Let* $\{\mathcal{E}_i\}_{i\in I}$ *be a finite family of Phase* $\mathsf{Real}^{\uparrow}$ *and Completion packets over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *rows. Suppose the ambient family has one common objectwise Phase Real and Completion exit certificate, and let* $J, K \subseteq I$ *be finite request subfamilies whose restrictions preserve the four displayed face rows together with the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support rows.*

Then the finite intersection $J \cap K$ *determines the same objectwise exit certificate as the two restricted request subfamilies exactly when the retained* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$,

local $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows agree on* $J \cap K$. *In that case the intersection certificate is the objectwise restriction of the common Phase Real and Completion certificate to the retained requests, and no further exit coordinate is present on the overlap.*

This exactness is confined to finite overlaps of request subfamilies inside the displayed Real L10 four-face surface. It excludes quotient streams, selected limits, countable choice, metric-completeness data, aggregate status rows, aggregate bridge rows, standard bridge rows, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First restrict each request subfamily. By Definition 38.809, the J-restriction and the K-restriction both determine the same objectwise Phase Real and Completion exit certificate as the ambient family, and each restriction keeps exactly the displayed four-face rows and the displayed support rows on its retained requests.

Now pass to the overlap. Apply Definition 301.201 to the RegSeqRat common-tail terminal sections underlying the two restrictions. The theorem identifies the retained $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows on the finite meet $J \cap K$, and it supplies no quotient stream, selected limit, countable-choice row, or hidden completion datum.

Use Definition 38.795 to read that finite meet as a Real L10 section. The retained overlap is therefore the same compatible four-face packet over the dyadic common scale-window witness, the finite $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegSeqRat}^{\uparrow}$ regularity and common-tail rows, and the local $\mathsf{Real}^{\uparrow}$ terminal seal row, together with the same displayed support rows.

It remains to prove exactness rather than mere compatibility. Apply Definition 38.793. Since every displayed face row and every displayed support row is indispensable for the current Real L10 exit certificate, agreement of those retained rows on $J \cap K$ is sufficient for the same objectwise exit read, and any disagreement among them prevents the two restricted presentations from determining one overlap certificate.

Thus $J \cap K$ determines the same objectwise exit certificate precisely in the stated rowwise case. The cited restriction, intersection, classifier, and minimality results account for all certificate coordinates, so aggregate status rows, aggregate bridge rows, standard bridge rows, metric-completeness data, and ambient $\mathsf{Real}^{\uparrow}$ completeness cannot be inserted on the overlap. □

Theorem 38.811 (Real L10 finite-request union exit exactness)**.** *Let* $\{\mathcal{E}_i\}_{i \in I}$ *be a finite family of Phase* $\mathsf{Real}^{\uparrow}$ *and Completion packets over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *rows. Suppose the ambient family has one common objectwise Phase Real and Completion exit certificate, and let* $J, K \subseteq I$ *be finite request subfamilies whose restrictions preserve the four displayed face rows together with the displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *support rows. Suppose also that the retained rows on* J, *on* K, *and on* $J \cap K$ *agree on the* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *local* $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

Then the finite union $J \cup K$ *determines the same objectwise Phase Real and Completion exit certificate as the two restricted request subfamilies exactly when the displayed union contains no rows beyond the four listed faces and the displayed support rows. In that case the union certificate is the objectwise restriction of the common Phase Real and Completion certificate to* $J \cup K$.

This exactness is confined to finite unions of request subfamilies inside the displayed Real L10 four-face surface. It excludes quotient streams, selected limits, countable choice, metric-completeness data, aggregate status rows, aggregate bridge rows, standard bridge rows, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First restrict each side. By Definition 38.809, the J-restriction and the K-restriction both determine the same objectwise Phase Real and Completion exit certificate as the ambient family,

and each restriction keeps exactly the displayed four-face rows and the displayed BHist, hsame, Cont, Pkg, and NameCert support rows.

The overlap hypothesis is the compatibility datum for gluing. Apply Definition 38.810 to $J \cap K$. The common rows on the meet identify the two restricted presentations on their shared retained requests, so the union can be read as one finite request surface rather than as two unrelated certificates.

Now assemble the four-face union surface. Use Definition 126.305 and Definition 126.324 for the finite $\mathsf{StreamName}^{\uparrow}$ window rows, and use Definition 301.181 for the $\mathsf{RegSeqRat}^{\uparrow}$ regularity and common-tail classifier rows. These union inputs preserve the dyadic common scale-window witness, the local $\mathsf{Real}^{\uparrow}$ terminal seal row, and the displayed support rows, and they introduce no quotient stream, selected limit, countable-choice row, or hidden completion datum.

Read the assembled union through Real L10. By Definition 38.795, the displayed $J \cup K$ surface is a single compatible four-face packet over the dyadic common scale-window witness, the finite $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{RegSeqRat}^{\uparrow}$ regularity and common-tail rows, and the local $\mathsf{Real}^{\uparrow}$ terminal seal row, together with the same BHist, hsame, Cont, Pkg, and NameCert support rows.

Finally apply Definition 38.793. If the displayed union carries only those four faces and support rows, minimality makes the union read the same objectwise exit certificate as the two restrictions and the ambient family. Conversely, if an additional quotient, selected-limit, choice, metric-completeness, aggregate-status, aggregate-bridge, standard-bridge, or $\mathsf{Real}^{\uparrow}$ completeness coordinate is present, it is not part of the minimal Real L10 certificate surface, so the enlarged union is no longer exactly the same objectwise exit certificate. □

Theorem 38.812 (Real L10 finite-request sheaf exactness)**.** *Let $\{\mathcal{E}_i\}_{i\in I}$ be a finite family of Phase $\mathsf{Real}^{\uparrow}$ and Completion packets over*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

Let $\{J_a\}_{a\in A}$ be a finite cover of I by finite request subfamilies. For each $a \in A$, let $\mathcal{C}_a$ be a local Phase Real and Completion exit presentation on J_a.

Then the family $\{\mathcal{C}_a\}_{a\in A}$ determines a unique objectwise Phase Real and Completion exit certificate on I if and only if each $\mathcal{C}_a$ displays exactly the four face rows

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow},$$

together with the displayed BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows, and for every finite overlap $J_{a_0} \cap \cdots \cap J_{a_m}$ the restricted presentations agree on all four face rows and on all displayed support rows.*

In that case the global certificate is the objectwise restriction-gluing of the common Phase Real and Completion certificate across the finite cover. This sheaf exactness is confined to the four-face Real L10 surface. It excludes quotient streams, selected limits, countable choice, metric-completeness data, aggregate status rows, aggregate bridge rows, standard bridge rows, and ambient $\mathsf{Real}^{\uparrow}$ completeness.

Proof. For existence, first pass to each cover member. By Definition 38.809, every J_a-presentation with the four displayed face rows and the displayed BHist, hsame, Cont, Pkg, and NameCert support rows reads as the restriction of the same objectwise Phase Real and Completion certificate to that finite request subfamily.

The overlap hypotheses are exactly the compatibility data. On a binary overlap, apply Definition 38.810; on a finite iterated overlap, repeat the same intersection exactness along the finite

meet. Thus the cover presentations agree as Real L10 sections on every retained request belonging to more than one cover member.

Now glue over the finite cover. Induct on the finite index set A. The empty and singleton cases are immediate from subfamily stability. For the induction step, glue the already assembled finite union to the next cover member by Definition 38.811. The overlap compatibility just proved supplies the meet datum, and the union theorem preserves exactly the four displayed faces and the displayed support rows.

It remains to identify the glued object as the Phase Real and Completion exit certificate rather than as a larger completion object. Use Definition 38.795 to read the glued finite union as one compatible four-face packet, and use the RegSeqRat common-tail sheaf exactness supplied by Definition 301.201 and Definition 301.181 to keep the common-tail rows objectwise on the finite cover.

For uniqueness, suppose two global exit certificates restrict to the same cover presentations. By Definition 38.793, the four face rows and the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows are indispensable and exhaust the Real L10 certificate surface. Since the cover is finite and covers every request in I, equality on the cover members gives equality of every displayed row of the two global certificates.

Conversely, if a member omits one of the four face rows or one of the displayed support rows, minimality prevents it from being a restriction of the Real L10 exit certificate. If two presentations disagree on a finite overlap, intersection exactness prevents them from determining a single overlap certificate, so no unique global objectwise certificate can glue from the cover.

All nonescape clauses follow from the same row accounting. The proof uses only finite subfamily restriction, finite intersection exactness, finite union exactness, face minimality, and RegSeqRat common-tail exactness; none of these results adds a quotient stream, selected limit, countable-choice selector, metric-completeness datum, aggregate status row, aggregate bridge row, standard bridge row, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate. □

Theorem 38.813 (Real L10 finite-cover support removal obstruction)**.** *Let $\{J_a\}_{a\in A}$ be a finite cover of a finite request family for Phase $\mathsf{Real}^{\uparrow}$ and Completion packets over*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

For each $a \in A$, let $\mathcal{C}_a$ be a local Real L10 presentation on J_a whose intended certificate is the finite-request sheaf certificate of Definition 38.812. If one local presentation omits any displayed support row among

$$\mathsf{BHist}, \qquad \mathsf{hsame}, \qquad \mathsf{Cont}, \qquad \mathsf{Pkg}, \qquad \mathsf{NameCert},$$

then the finite cover cannot determine the same objectwise Real L10 exit certificate.

The failure is already witnessed on a finite cover member. It cannot be repaired by quotient streams, selected limits, countable choice, metric completeness, aggregate formalstatus rows, aggregate bridge rows, standard bridge rows, or $\mathsf{Real}^{\uparrow}$ completeness.

Proof. Choose a cover member J_a whose local presentation omits one displayed support row. Apply Definition 126.665 to the $\mathsf{StreamName}^{\uparrow}$ finite-window component of that member: removing a displayed support coordinate leaves a finite obstruction on the cover member itself, not only after passage to the whole family.

Refinement cannot hide the omission. By Definition 126.666, every finite refinement of the cover still has a member over the same request locus where the omitted support row is absent. Thus the

obstruction survives finite cover subdivision and cannot be transported into a quotient-stream or selected-limit coordinate.

Now read the obstructed member through Real L10. Apply Definition 38.795: a local Real L10 section presents the objectwise certificate exactly by the dyadic common scale-window witness, the $\mathsf{StreamName}^{\uparrow}$ finite-window section, the $\mathsf{RegSeqRat}^{\uparrow}$ regularity and common-tail classifier rows, the local $\mathsf{Real}^{\uparrow}$ terminal seal row, and the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support rows.

Minimality identifies the contradiction. By Definition 38.793, none of the displayed support rows can be deleted, duplicated, detached, or replaced while the same Real L10 exit certificate is retained. Hence the obstructed local member cannot be a restriction of the same objectwise certificate.

Finally apply Definition 38.812. A finite cover determines the global Real L10 certificate only when every cover member displays all four face rows and all five support rows, with overlap agreement on those rows. Since one member lacks a required support row, the exactness criterion fails on that member. The listed completion, choice, status, bridge, and $\mathsf{Real}^{\uparrow}$ completeness data are outside the finite certificate surface identified above, so they provide no repair coordinate. □

Theorem 38.814 (Real L10 finite-cover face removal obstruction)**.** *Let $\{J_a\}_{a\in A}$ be a finite cover of a finite request family for Phase $\mathsf{Real}^{\uparrow}$ and Completion packets over*

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow}.$$

For each $a \in A$, let $\mathcal{C}_a$ be a local Real L10 presentation on J_a whose intended certificate is the finite-request sheaf certificate of Definition 38.812. If one local presentation omits any one of the four face rows

$$\mathsf{DyadicRatCore}^{\uparrow}, \qquad \mathsf{StreamName}^{\uparrow}, \qquad \mathsf{RegSeqRat}^{\uparrow}, \qquad \mathsf{Real}^{\uparrow},$$

then the finite cover cannot determine the same objectwise Real L10 exit certificate.

The obstruction is a face-row obstruction, not a support-row obstruction in disguise. It cannot be repaired by quotient streams, selected limits, countable choice, metric-completeness data, aggregate status rows, aggregate bridge rows, standard bridge rows, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Proof. Choose a cover member J_a whose local presentation omits one of the four displayed face rows. By Definition 38.812, a finite cover determines the global Real L10 certificate only when every cover member displays all four face rows and the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support rows, with overlap agreement on those rows.

The missing face is indispensable. Apply Definition 38.793. Deleting the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or local $\mathsf{Real}^{\uparrow}$ row removes one object of the four-face certificate, so the obstructed local member cannot be a restriction of the same objectwise Real L10 exit certificate.

The StreamName and RegSeqRat boundary clauses give the same obstruction on the two middle faces. Apply Definition 126.501 to the $\mathsf{StreamName}^{\uparrow}$ open-phase row, and apply Definition 301.239 to the $\mathsf{RegSeqRat}^{\uparrow}$ and local $\mathsf{Real}^{\uparrow}$ terminal rows. These results keep the finite-window, common-tail, and terminal-seal data attached to the displayed object faces rather than to an external completion coordinate.

Finally return to the finite cover. Since one cover member lacks a required face row, the exactness criterion of Definition 38.812 fails before any global certificate can be glued. Quotient streams, selected limits, countable-choice selectors, metric-completeness data, aggregate status rows, aggregate bridge rows, standard bridge rows, and ambient $\mathsf{Real}^{\uparrow}$ completeness are not rows of the finite Real L10 certificate surface, so they provide no replacement for the deleted face. □

Theorem 38.815 (Real L10 terminal four-face status locality)**.** *Let $\mathcal{T}$ be a finite Phase* $\mathsf{Real}^{\uparrow}$ *and Completion terminal packet over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *rows. Suppose $\mathcal{T}$ satisfies the current-phase exit local threshold and exposes exactly the four displayed face records together with the support rows*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

Then every formalstatus, leantarget, and bridgestatus coordinate carried by $\mathcal{T}$ is attached to one of the four local face records $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or local* $\mathsf{Real}^{\uparrow}$.

Conversely, if one such coordinate is replaced by a stronger coordinate on the same face, while the other three face records and the displayed support rows are unchanged, the resulting terminal packet presents the same four-face Phase $\mathsf{Real}^{\uparrow}$ *and Completion exit certificate. No route-level formalstatus row, aggregate leantarget row, aggregate bridge row, quotient-stream equality, selected limit, countable-choice selector, metric-completeness datum, or* $\mathsf{Real}^{\uparrow}$ *completeness claim is introduced.*

Proof. First read the packet through the current exit criterion. By Definition 38.796, the terminal packet satisfies the exit read only as the objectwise product of the four local threshold records on $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the local $\mathsf{Real}^{\uparrow}$ face, carried by the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support rows.

Next identify the finite cover seen by terminal requests. Apply Definition 38.797. The visible request section is finite and has no additional coordinate beyond the four displayed face records and the displayed support rows, so formalstatus, leantarget, and bridgestatus data can only be read from the face records already present in that cover.

Now factor the certificate along its ordered source. By Definition 38.798, the accepted exit certificate factors through exactly

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

together with the same displayed support rows. The factorization gives no route object on which a separate formalstatus, leantarget, or bridge coordinate could live.

Finally apply Definition 38.793. Since none of the four faces and none of the displayed support rows can be deleted, shortened, or replaced by an aggregate credential while retaining the same exit read, a same-face strengthening of one status coordinate preserves the terminal four-face packet, whereas any route-level aggregate row or completion datum would be an extra coordinate outside the certificate surface. □

Theorem 38.816 (Real L10 finite-cover status threshold descent)**.** *Let $\{\mathcal{T}_i\}_{i\in I}$ be a finite cover of accepted Phase* $\mathsf{Real}^{\uparrow}$ *and Completion terminal packets. Assume that every local packet $\mathcal{T}_i$ exposes exactly the four face records*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

together with the shared support rows

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert},$$

and that every nonempty overlap has compatible face-status pullbacks for the local $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *records.*

Then the glued terminal packet satisfies the current Phase $\mathsf{Real}^{\uparrow}$ *and Completion exit threshold if and only if each local packet satisfies the four face-local threshold records for* $\mathsf{DyadicRatCore}^{\uparrow}$,

StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and local* Real$^{\uparrow}$, *and the overlap face-status pullbacks agree. The descent exports no aggregate formalstatus row, route-level Lean target, aggregate bridge row, quotient-stream equality, selected limit, countable-choice row, metric-completeness datum, or* Real$^{\uparrow}$ *completeness claim.*

Proof. For the forward direction, restrict the glued terminal packet to one finite-cover member. Apply Definition 38.815. The restricted packet can read formalstatus, leantarget, and bridgestatus data only from the local DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ faces.

Now read the overlap interface. Apply Definition 291.112 on each nonempty overlap. The status rows remain attached to the same four faces after restriction, so the local four face-threshold records and their overlap pullbacks are forced by the glued threshold packet.

For the reverse direction, start with the local four face-threshold records and the compatible overlap pullbacks. Apply Definition 38.821 to paste the local terminal seal data across the finite cover. The pasted packet has the same StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and local Real$^{\uparrow}$ faces, together with the displayed BHist, hsame, Cont, Pkg, and NameCert support.

Next apply Definition 301.227. The compatible local threshold reads glue to a single Phase Real$^{\uparrow}$ and Completion audit-threshold read over the finite four-face packet. Applying Definition 38.815 to that glued packet identifies it with the current exit threshold and keeps the verification and bridge coordinates facewise.

The exclusion clause follows from the same cited results. Their constructions never introduce an aggregate formalstatus row, a route-level Lean target, an aggregate bridge row, quotient streams, selected limits, countable-choice rows, metric-completeness data, or an ambient Real$^{\uparrow}$ completeness coordinate, so none of those data descends from the glued terminal packet. □

Theorem 38.817 (Real terminal seal sibling route)**.** *Every public* Real$^{\uparrow}$ *terminal seal read factors through the finite* StreamName$^{\uparrow}$ *window, the* RegSeqRat$^{\uparrow}$ *readback, and the* DyadicRatCore$^{\uparrow}$ *tolerance ledger before it reaches the local Real seal. The route is the cross-chapter certificate route through chapter 126, chapter 301, and chapter 291; its transport data are only the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows already exposed by those sibling chapters.*

Consequently an accepted terminal seal read has no route that bypasses the finite StreamName window, RegSeqRat readback, or DyadicRatCore tolerance ledger. In particular it exports no host real equality, quotient-stream equality, ambient completeness principle, countable-choice selector, selected limit, or independent host-completion row.

Proof. Start with the handoff theorem Definition 38.407. It reads the public Real$^{\uparrow}$ seal as a package whose visible rows are the StreamName classifier window, the RegSeqRat readback surface, the dyadic observation ledger, and the local Real seal provenance. The sibling chapter references in the statement are exactly the public sources of those rows.

Next apply the dyadic StreamName RegSeqRat route theorem Definition 38.670. It orders the exposed rows as one finite BEDC path from DyadicRatCore$^{\uparrow}$ observations through the StreamName$^{\uparrow}$ finite window and RegSeqRat$^{\uparrow}$ readback before the Real$^{\uparrow}$ seal is read. Since the route carries only BHist, hsame, Cont, Pkg, and NameCert coordinates, it has no coordinate for a host completion or quotient-stream equality.

Finally use the finite-window seal tightness theorem Definition 38.773. Tightness says that an accepted terminal seal is admissible exactly when the three sibling rows agree on one common finite request. Any proposed route omitting one of those rows therefore fails to be an accepted public Real$^{\uparrow}$ terminal seal, and any route adding host real equality, ambient completeness, countable choice, or a selected limit lies outside the displayed certificate surface. □

Theorem 38.818 (Real terminal seal four-face status pullback)**.** *Every public* $\mathsf{Real}^{\uparrow}$ *terminal seal read whose route factors through*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

reads its audit and status data exactly as the four objectwise closurestatus records of those faces. The $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and local* $\mathsf{Real}^{\uparrow}$ *records keep their own closurestatus, formalstatus, leantarget, and bridgestatus rows; the terminal seal route creates no route-level* $\mathsf{formalstatus}$ *and no aggregate bridge row.*

Conversely, any terminal seal read carrying those four face records together with the displayed

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}$$

rows factors through the same terminal seal sibling route and through the same four-face terminal pullback boundary. This equivalence does not assert quotient stream equality, selected limits, countable choice, metric-completeness data, or any $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. First locate the route. Apply Definition 38.817. The public terminal seal read is confined to the StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, and local Real seal row, with only the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support.

Next read the status data objectwise. Apply Definition 38.470 and Definition 38.471. These identify the audit boundary with the product of the four local closurestatus records, while leaving each closurestatus, formalstatus, leantarget, and bridgestatus entry attached to its own face.

For the converse, start with a terminal seal read carrying exactly those four face records and the displayed support rows. Apply Definition 38.845. The objectwise status threshold and the shared StreamName, RegSeqRat, DyadicRatCore, Real, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ coordinates repack the read as the same terminal pullback boundary.

The exclusion clause follows from the same three cited results. None of their routes contains a coordinate for a route-level $\mathsf{formalstatus}$, aggregate bridge row, quotient stream equality, selected limit, countable-choice row, metric-completeness datum, or $\mathsf{Real}^{\uparrow}$ completeness claim. □

Theorem 38.819 (Real terminal seal four-face cover normal form)**.** *Let* $\{\mathcal{R}_i\}_{i\in I}$ *be a finite family of public* $\mathsf{Real}^{\uparrow}$ *terminal seal reads. Suppose each local route exposes the same four faces*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow},$$

where the $\mathsf{StreamName}^{\uparrow}$ *finite windows agree pairwise on their restrictions, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and distance ledgers agree on every overlap, the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and regularity rows agree on the same finite request sections, the local* $\mathsf{Real}^{\uparrow}$ *seal-source rows agree on the common boundary, and all routes use the shared support rows*

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

Then the family descends to one finite-cover normal-form packet for the public $\mathsf{Real}^{\uparrow}$ *terminal seal. Conversely, any finite-cover normal-form packet with exactly those four faces and support rows restricts to the local terminal seal routes* $\mathcal{R}_i$*. The packet exports no quotient stream equality, host real equality, selected limit, countable choice, ambient completeness, metric-completeness datum, or standard bridge row.*

Proof. First read every local seal through the sibling route of Definition 38.817. Each $\mathcal{R}_i$ is thereby placed on the StreamName finite window, the RegSeqRat readback face, the DyadicRatCore tolerance ledger, and the local Real seal-source row, with only the displayed BHist, hsame, Cont, Pkg, and NameCert support.

Next build the finite-cover surface. Apply Definition 126.628 to the pairwise StreamName window agreements. The common terminal fused packet is then transported through the RegSeqRat finite-request section supplied by Definition 301.142.

Now transport the dyadic and Real boundary faces. Use Definition 291.69 to identify the endpoint, radius, distance, classifier, regularity, readback, and seal-source rows as one pullback surface over the same finite requests.

For the descent direction, apply Definition 38.774. The pasted StreamName surface, the shared dyadic ledger, the RegSeqRat classifier and regularity rows, and the local Real seal-source rows therefore form one finite-cover normal-form packet for the terminal seal.

For the restriction direction, start with such a normal-form packet and restrict it to any window of the finite cover. The same pasting criterion and the sibling route read the restricted packet back as the local terminal seal route $\mathcal{R}_i$, because no additional coordinate is present beyond the four displayed faces and the shared support rows.

The exclusion clause is inherited from the cited routes. None of them exports quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness data, or a standard bridge row, so those data cannot be recovered from either direction of the normal form. □

Theorem 38.820 (Real terminal seal four-face cover descent determinacy)**.** *Let $\mathcal{P}$ and $\mathcal{Q}$ be finite-cover normal-form packets for the public* $\mathsf{Real}^{\uparrow}$ *terminal seal. Suppose both packets expose exactly the four faces*

$$\mathsf{StreamName}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},$$

agree on all overlap restrictions for those faces, and use only the displayed support rows

$$\mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

Then $\mathcal{P}$ and $\mathcal{Q}$ determine the same public $\mathsf{Real}^{\uparrow}$ *terminal seal read. Conversely, equality of the public terminal seal read recovers exactly the common* $\mathsf{StreamName}^{\uparrow}$ *finite window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-radius-distance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-request classifier and regularity rows, and the local* $\mathsf{Real}^{\uparrow}$ *seal-source row. It recovers no quotient-stream coordinate, host-real coordinate, selected limit, countable-choice selector, ambient-completeness principle, metric-completeness datum, or standard-bridge coordinate.*

Proof. Read both packets through the sibling route of Definition 38.817. This places $\mathcal{P}$ and $\mathcal{Q}$ on the same four public faces and confirms that their support surface is exactly the displayed BHist, hsame, Cont, Pkg, and NameCert surface.

Apply the normal-form theorem Definition 38.819 to both packets. The hypotheses on overlap restrictions put the two packets on one finite-cover surface, because the StreamName windows, dyadic tolerance rows, RegSeqRat readback rows, and Real seal-source rows are identified on every common section.

The common section is determined by the finite cover itself. Use Definition 126.628 for the fused StreamName window, and use Definition 301.142 for the RegSeqRat finite-request budget over that window.

It remains to transport the dyadic and Real rows across the common section. Apply Definition 291.69 to the endpoint, radius, distance, classifier, regularity, readback, and seal-source rows. They are therefore the same pullback data for $\mathcal{P}$ and $\mathcal{Q}$.

Finally apply Definition 38.774. The pasting criterion says that a four-face packet with those overlap restrictions has a unique public terminal seal read, so $\mathcal{P}$ and $\mathcal{Q}$ determine the same read.

For the converse, start from equality of the public terminal seal read and read it back through the same sibling route and normal-form theorem. The restriction data are exactly the four recovered faces listed in the statement. The exclusion clause follows because every cited route uses only the displayed support rows and has no coordinate for quotient streams, host reals, selected limits, countable choice, ambient completeness, metric completeness, or a standard bridge. □

Theorem 38.821 (Real terminal seal finite-cover cocycle exactness)**.** *Let $\{\mathcal{R}_i\}_{i\in I}$ be a finite family of local terminal-seal reads for the public* $\mathsf{Real}^{\uparrow}$ *surface. Suppose every $\mathcal{R}_i$ exposes exactly the four faces*

$$\mathsf{StreamName}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},$$

with support rows

$$\mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert},$$

and suppose that for every overlap i, j the restrictions of the $\mathsf{StreamName}^{\uparrow}$ *finite window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-radius-distance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-request classifier and regularity rows, and the local* $\mathsf{Real}^{\uparrow}$ *seal-source row agree. Assume also that on every triple overlap i, j, k the two restriction routes from $\mathcal{R}_i$ to the common section coincide:*

$$(\mathcal{R}_i|_{ij})|_{ijk} = (\mathcal{R}_i|_{ik})|_{ijk}, \qquad (\mathcal{R}_i|_{ij})|_{ijk} = (\mathcal{R}_j|_{ij})|_{ijk}.$$

Then the family pastes to a unique public $\mathsf{Real}^{\uparrow}$ *terminal-seal read whose restriction to each finite cover member is $\mathcal{R}_i$. Conversely, any public* $\mathsf{Real}^{\uparrow}$ *terminal-seal read restricts to such a finite cocycle on the four displayed faces. This exactness exports no quotient stream equality, host real equality, selected limit, countable choice, ambient completeness, metric-completeness datum, or standard bridge row.*

Proof. First put every local read in four-face normal form. Apply Definition 38.819; each $\mathcal{R}_i$ is read as a finite StreamName window, a DyadicRatCore endpoint-radius-distance ledger, a RegSeqRat finite-request classifier with regularity rows, and a local Real seal-source row over the shared BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support.

Next paste the StreamName face. The overlap and triple-overlap assumptions are exactly the cocycle data used by Definition 126.628, so the finite windows fuse to one terminal StreamName packet and restrict back to the given windows.

Transport the remaining faces over that fused window. Use Definition 291.69 to carry the dyadic endpoint, radius, and distance rows together with the RegSeqRat classifier, regularity, readback, and Real seal-source rows as one pullback surface over the common finite requests.

Now apply Definition 38.774. The pasted StreamName packet and transported pullback rows give a public terminal-seal read, and its restriction to every cover member is the original $\mathcal{R}_i$.

Uniqueness is the determinacy content of Definition 38.820. Any two public reads with those restrictions have the same four faces on every overlap, hence determine the same terminal-seal read.

For the converse, start with a public $\mathsf{Real}^{\uparrow}$ terminal-seal read and restrict it along the finite cover. The normal-form theorem supplies the four local faces, the StreamName fusion theorem

gives the cocycle equations on triple overlaps, and the pasting criterion identifies the recovered public read with the original one.

The exclusion clause is stable under each cited step: none of the normal-form, fusion, pullback-composition, pasting, or determinacy results introduces quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness data, or a standard bridge row. □

Theorem 38.822 (Real terminal seal RegSeqRat cover descent equivalence)**.** *Let $\{\mathcal{Q}_i\}_{i\in I}$ be a finite family of public* $\mathsf{RegSeqRat}^{\uparrow}$ *reads over one finite cover. The family presents an accepted public* $\mathsf{Real}^{\uparrow}$ *terminal-seal read if and only if its cover data satisfy the* $\mathsf{RegSeqRat}^{\uparrow}$ *four-face gluing rows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *four-face associativity rows, the* $\mathsf{StreamName}^{\uparrow}$ *finite-cover descent exactness row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-radius-distance ledger agreement, and the local* $\mathsf{Real}^{\uparrow}$ *seal cocycle exactness row. The accepted source has exactly the four public faces*

$$\mathsf{StreamName}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

and exactly the common support rows

$$\mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

It exports no quotient streams, host equality, selected limits, countable choice, ambient completeness, metric completeness, aggregate formalstatus row, or standard bridge row.

Proof. For the forward direction, start with the accepted public $\mathsf{Real}^{\uparrow}$ terminal-seal read presented by the finite $\mathsf{RegSeqRat}^{\uparrow}$ family. Apply Definition 38.821. The public read restricts to local terminal-seal reads whose only visible faces are $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ over the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support.

Next identify the descent rows carried by those restrictions. Apply Definition 301.88 and Definition 301.90 to read the $\mathsf{RegSeqRat}^{\uparrow}$ classifier, regularity, and readback data as a coherent four-face cover. Apply Definition 126.93 to recover the $\mathsf{StreamName}^{\uparrow}$ finite-cover descent row, and read the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint, radius, and distance coordinates from the same pullback ledger. Thus the forward image is exactly the descent packet named in the statement.

For the reverse direction, start with a finite $\mathsf{RegSeqRat}^{\uparrow}$ cover packet satisfying the gluing, associativity, StreamName descent, DyadicRatCore ledger, and local Real cocycle rows. Apply Definition 301.91. The packet admits a common refinement whose face restrictions are comparable over one support spine.

Now apply Definition 38.820. The refined packet determines at most one public terminal-seal read on the four faces. Apply Definition 38.821 to paste the local Real cocycle and obtain that public read. The pasted read restricts back to the original finite $\mathsf{RegSeqRat}^{\uparrow}$ descent data, so the two constructions are inverse at the accepted public-source surface.

The negative boundary is audit-only. Apply Definition 38.824; the finite-cover route does not create a route-level formalstatus aggregate, replacement leantarget, or bridge row. Since all preceding steps use only the four faces and support rows displayed above, no quotient stream, host equality, selected limit, countable-choice principle, ambient-completeness row, or metric-completeness row is introduced. □

Theorem 38.823 (Real terminal seal StreamName–RegSeqRat handoff exactness)**.** *Let $\{\mathcal{W}_i\}_{i\in I}$ be a finite family of certified* $\mathsf{StreamName}^{\uparrow}$ *windows over one displayed finite cover. Suppose its pasted seal exhaustion is certified by Definition 126.552, its* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff satisfies Definition 301.88, and its* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-radius-distance ledger agrees on every displayed overlap. Then*

these data determine exactly one public $\mathsf{Real}^{\uparrow}$ *terminal-seal read. Conversely, every accepted public* $\mathsf{Real}^{\uparrow}$ *terminal-seal read restricts to precisely such a StreamName, RegSeqRat, and DyadicRatCore handoff packet. The criterion exports no quotient stream equality, host real equality, selected limit, countable choice, ambient completeness, metric-completeness datum, aggregate formalstatus row, or standard bridge row.*

Proof. First build the pasted finite-window surface. Apply Definition 126.552 to the StreamName windows and their certified overlaps. The result is one finite-window seal surface whose restrictions are the original windows and whose support rows remain the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Next transport the classifier and regularity data. Use Definition 301.88 to glue the $\mathsf{RegSeqRat}^{\uparrow}$ finite-request classifiers, regularity rows, and readback rows over the pasted StreamName surface. Use Definition 291.69 to carry the endpoint, radius, and distance ledger through the same support spine.

Now invoke the local Real terminal-seal criterion. The pasted StreamName surface, the glued RegSeqRat handoff, and the transported DyadicRatCore ledger satisfy the hypotheses of Definition 38.821. That theorem produces a public $\mathsf{Real}^{\uparrow}$ terminal-seal read, and Definition 38.820 makes it the unique read with those finite restrictions.

For the converse, restrict an accepted public $\mathsf{Real}^{\uparrow}$ terminal-seal read to the finite cover. The restriction exposes StreamName windows, RegSeqRat handoff rows, and DyadicRatCore endpoint-radius-distance rows on the same support. Applying the same three cited handoff theorems to these restrictions recovers the packet named in the statement, while determinacy identifies the reconstructed public read with the original one.

The exclusion clause is inherited from the cited four-face route. None of the StreamName exhaustion, RegSeqRat gluing, DyadicRatCore pullback composition, Real cocycle exactness, or Real descent determinacy steps introduces quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness data, aggregate formalstatus rows, or standard bridge rows. □

Theorem 38.824 (Real terminal seal audit noncollapse)**.** *Let* $\{\mathcal{R}_i\}_{i\in I}$ *be a finite family of local terminal-seal reads satisfying the hypotheses of Definition 38.821, and let* $\mathcal{R}$ *be the resulting public* $\mathsf{Real}^{\uparrow}$ *terminal-seal read. Then the audit rows visible from* $\mathcal{R}$ *over the four displayed faces*

$$\mathsf{StreamName}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

are exactly the objectwise closurestatus, formalstatus, leantarget, and bridgestatus rows of those four faces. The finite-cover descent supplies no aggregate route-level status row, no replacement leantarget, and no standard-bridge row.

Proof. Apply Definition 38.821. The public read $\mathcal{R}$ is obtained only by pasting the StreamName, DyadicRatCore, RegSeqRat, and local Real terminal-seal faces over their common BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support.

Next read the audit coordinate through Definition 38.471. That pullback identifies the current Phase Real and Completion audit report with the objectwise product of the four face reports, so the pasted terminal-seal route has no separate audit carrier beyond the displayed face rows.

Apply Definition 38.833. The closurestatus, formalstatus, and bridgestatus rows therefore remain attached to their respective faces and are not replaced by a route-level status row. Apply Definition 38.834; the same locality holds for the leantarget rows.

Finally reuse the exclusion clause of Definition 38.821. Since the descent has no coordinate for quotient streams, host reals, selected limits, countable choice, ambient completeness, metric

completeness, or a standard bridge, the audit read cannot manufacture an aggregate bridge or verification record. □

Definition 38.825 (Real terminal seal dependency manifest)**.** *The* $\mathsf{Real}^{\uparrow}$ *terminal-seal dependency manifest is the finite packet*

$$\mathsf{Dep}^{\mathrm{term}}_{\mathsf{Real}^{\uparrow}} = (S, D, R, E, B, H, C, P, N)$$

attached to a public terminal-seal read, with the following rows:

1. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window of stream names and finite request coordinates.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and distance ledger over the window S.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier, regularity, and readback row over the same finite requests.*
4. *E is the local* $\mathsf{Real}^{\uparrow}$ *seal-source row obtained from the StreamName–DyadicRatCore–RegSeqRat pullback.*
5. *B, H, C, P, N are respectively the shared* BHist *ledger,* hsame *transport,* Cont *route,* Pkg *provenance, and* $\mathsf{NameCert}$ *row used by the four faces.*

A public terminal-seal read consumes a dependency iff it is one of these nine rows or a restriction of one of them along a finite cover member.

Theorem 38.826 (Real terminal seal dependency manifest exhaustion)**.** *Every public* $\mathsf{Real}^{\uparrow}$ *terminal-seal read factors through exactly the manifest* $\mathsf{Dep}^{\mathrm{term}}_{\mathsf{Real}^{\uparrow}}$*. Equivalently, after restricting the read to any finite cover, all data consumed by the read are exhausted by the* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-radius-distance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier/readback row, the local* $\mathsf{Real}^{\uparrow}$ *seal row, and the shared* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *support. These rows paste back to the public read and no further dependency coordinate is available.*

Proof. Put the public read in four-face normal form by applying Definition 38.819. This identifies the read with the four displayed faces over the shared BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support, which is precisely the manifest packet of Definition 38.825.

Now restrict the read along a finite cover. Apply Definition 38.821: the local restrictions form a cocycle on those same rows, and the cocycle pastes back to the original public terminal-seal read.

It remains to rule out an additional dependency coordinate. Apply Definition 38.824. The only audit rows visible from the pasted read are the objectwise rows of the four faces, and there is no route-level replacement row. Hence every public dependency is one of the manifest rows or its finite-cover restriction, and the manifest exhausts the read. □

Theorem 38.827 (Real terminal seal dependency manifest non-escape)**.** *The manifest* $\mathsf{Dep}^{\mathrm{term}}_{\mathsf{Real}^{\uparrow}}$ *contains no row for quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness data, or standard-bridge data. Consequently no public* $\mathsf{Real}^{\uparrow}$ *terminal-seal read may consume any of those objects through the manifest.*

Proof. The manifest rows are listed in Definition 38.825; each row is one of $S, D, R, E, B, H, C, P, N$ and therefore belongs to the four-face terminal-seal route or to its shared BEDC support.

Apply Definition 38.826. Any public terminal-seal read consumes only those rows or their finite-cover restrictions.

Finally apply the exclusion clauses of Definition 38.819, Definition 38.821, and Definition 38.824. None of the four-face normal form, finite-cover cocycle, or audit projection contains quotient

stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness data, or standard-bridge data. Since the manifest has no coordinate for such data, no public read can escape through it. □

Theorem 38.828 (Real terminal seal public source completeness)**.** *A finite packet*

$$M = (S, D, R, E, B, H, C, P, N)$$

reconstructs a public $\mathsf{Real}^{\uparrow}$ *terminal-seal read exactly when its rows are the terminal-seal dependency manifest rows of Definition 38.825:* S *is the finite* $\mathsf{StreamName}^{\uparrow}$ *name-and-request window,* D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-radius-distance ledger on that window,* R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier and readback row,* E *is the local* $\mathsf{Real}^{\uparrow}$ *seal row, and* B, H, C, P, N *are the shared* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *support rows. The rows must satisfy the shared-face compatibility conditions displayed by Definition 38.819 and the finite-cover cocycle compatibility of Definition 38.821. Under those conditions* M *determines a public* $\mathsf{Real}^{\uparrow}$ *terminal-seal read, and every public* $\mathsf{Real}^{\uparrow}$ *terminal-seal read yields exactly such a compatible packet.*

Proof. Start from a compatible packet $M = (S, D, R, E, B, H, C, P, N)$. The row interpretation is fixed by Definition 38.825: the first four rows are the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and local $\mathsf{Real}^{\uparrow}$ faces, and the last five rows are the common BEDC support.

Apply Definition 38.819. The shared-face compatibility hypotheses identify these rows as the four terminal faces over one BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ spine. Apply Definition 38.821. The finite-cover compatibility pastes the local face restrictions into a public terminal-seal read.

For the reverse direction, begin with a public $\mathsf{Real}^{\uparrow}$ terminal-seal read. Apply Definition 38.826. The read factors through the manifest rows and no additional dependency coordinate is available. The normal-form and finite-cover theorems provide the required shared-face and cocycle compatibility, so the read yields a packet of the displayed form.

Finally apply Definition 38.827. The packet has no coordinate for quotient stream equality, host real equality, selected limits, countable choice, ambient completeness, metric-completeness data, or standard-bridge data. Hence the reconstruction and extraction have the same public source surface, namely the manifest M. □

Theorem 38.829 (Real terminal seal dependency manifest phase-exit face product)**.** *Let*

$$\mathsf{Dep}^{\mathrm{term}}_{\mathsf{Real}^{\uparrow}} = (S, D, R, E, B, H, C, P, N)$$

be an accepted $\mathsf{Real}^{\uparrow}$ *terminal-seal dependency manifest. Then this manifest determines exactly the Phase Real and Completion four-face product over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the local* $\mathsf{Real}^{\uparrow}$ *face, with the shared* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *support rows. Conversely, every accepted Phase Real and Completion four-face product over those four faces restricts to this manifest. The correspondence exports no quotient streams, host real equality, selected limits, countable choice, ambient completeness, metric-completeness rows, aggregate formalstatus tokens, or standard bridge rows.*

Proof. For the forward direction, read the manifest through Definition 38.825. Its rows are precisely the finite $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint ledger, the $\mathsf{RegSeqRat}^{\uparrow}$ classifier/readback row, the local $\mathsf{Real}^{\uparrow}$ seal-source row, and the common BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support.

Apply Definition 38.826. Every public terminal-seal read consumes only those rows or their finite-cover restrictions. Apply Definition 38.471 to identify the Phase Real and Completion audit

read with the product of the same four face reports, and apply Definition 38.775 to read that product as the public four-face interface.

For the reverse direction, start with an accepted Phase Real and Completion four-face product over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the local $\mathsf{Real}^{\uparrow}$ face. The public-interface theorem displays exactly the same four face rows and the same shared BEDC support rows, so restricting the product to the terminal-seal consumer surface gives the packet $\mathsf{Dep}^{\mathrm{term}}_{\mathsf{Real}^{\uparrow}}$.

It remains to check that no coordinate has escaped the manifest. Apply Definition 38.827. The manifest has no row for quotient streams, host real equality, selected limits, countable choice, ambient completeness, metric-completeness data, or standard-bridge data. The audit pullback is facewise, not aggregate, so it also supplies no aggregate formalstatus token and no standard bridge row beyond the displayed face records. □

Theorem 38.830 (Real terminal seal manifest exit consumer exactness)**.** *An accepted manifest*

$$\mathsf{Dep}^{\mathrm{term}}_{\mathsf{Real}^{\uparrow}} = (S, D, R, E, B, H, C, P, N)$$

is accepted by the current Phase Real and Completion exit consumer exactly when its consumer rows are the four object faces $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and local* $\mathsf{Real}^{\uparrow}$*, together with the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *support rows. Equivalently, the manifest is precisely the consumer surface used by the current L10 exit route. No accepted consumer presentation adds a quotient stream, host real equality, selected limit, countable choice, ambient completeness, metric-completeness row, aggregate formalstatus token, or standard bridge row.*

Proof. For the forward direction, apply Definition 38.828. The accepted manifest already reconstructs a public terminal-seal read from exactly the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, local $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Apply Definition 38.829. It identifies those rows with the Phase Real and Completion four-face product. Then apply Definition 126.500, Definition 291.28, and Definition 301.22. These three handoff surfaces read the same finite consumer as the current L10 exit route through the StreamName, DyadicRatCore, RegSeqRat, and Real faces.

For the reverse direction, start with a current L10 exit consumer presentation. The four-object exit route supplies exactly the same four object faces and the same shared BEDC support rows. The DyadicRatCore-to-RegSeqRat handoff and the RegSeqRat-to-Real seal handoff identify the downstream reads with the displayed dyadic ledger, regular-rational classifier, and local Real seal rows, so the presentation restricts to $\mathsf{Dep}^{\mathrm{term}}_{\mathsf{Real}^{\uparrow}} = (S, D, R, E, B, H, C, P, N)$.

Finally, the exclusion clause follows from Definition 38.827 and from the facewise character of Definition 38.829. The consumer has no coordinate in which quotient streams, host real equality, selected limits, countable choice, ambient completeness, metric-completeness data, aggregate formalstatus tokens, or standard bridge rows could be carried. □

Theorem 38.831 (Real terminal seal four-face classifier correspondence)**.** *Let*

$$\mathsf{Dep}^{\mathrm{term}}_{\mathsf{Real}^{\uparrow}} = (S, D, R, E, B, H, C, P, N)$$

be an accepted $\mathsf{Real}^{\uparrow}$ *terminal-seal dependency manifest, and let* Q *be an accepted Phase Real and Completion four-face product over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and the local* $\mathsf{Real}^{\uparrow}$ *seal face. The manifest and* Q *determine the same public classifier verdict exactly when their* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite window,* $\mathsf{RegSeqRat}^{\uparrow}$ *classifier/readback row, local* $\mathsf{Real}^{\uparrow}$ *seal row, and shared* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows agree. Conversely,*

any shared public classifier verdict for the terminal manifest and the four-face product restricts to those same four faces and those same shared support rows. The correspondence carries no quotient stream, host real equality, selected limit, countable-choice coordinate, ambient completeness, metric-completeness row, aggregate formalstatus token, or standard bridge row.

Proof. Begin with an accepted terminal manifest and an accepted four-face product. Apply Definition 38.829. It identifies both presentations with the same displayed product of the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and local $\mathsf{Real}^{\uparrow}$ faces over the common BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support.

Apply Definition 38.830. The manifest is accepted by the current exit consumer precisely through these consumer rows. Then apply Definition 126.500, Definition 291.28, and Definition 301.22. These handoff theorems align the finite StreamName window, the dyadic tolerance ledger, the regular-rational classifier/readback row, and the local Real seal row with the public classifier read used by the L10 exit route.

Thus equal rows give the same public classifier verdict. No independent classifier coordinate remains after the handoffs, because the verdict is read from exactly the four object faces and the shared BEDC support.

For the reverse direction, suppose the terminal manifest and the four-face product share a public classifier verdict. The four-object exit route first restricts that verdict to the $\mathsf{StreamName}^{\uparrow}$ window and to the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger. The DyadicRatCore-to-RegSeqRat handoff then restricts it to the $\mathsf{RegSeqRat}^{\uparrow}$ classifier/readback row, and the RegSeqRat-to-Real handoff restricts it to the local $\mathsf{Real}^{\uparrow}$ seal row.

Finally, consumer exactness and the manifest-to-product identification force the same BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support rows on both presentations. The non-escape clause in the manifest identification excludes quotient streams, host real equality, selected limits, countable choice, ambient completeness, metric-completeness rows, aggregate formalstatus tokens, and standard bridge rows, so the shared classifier verdict has no off-table restriction beyond the four displayed faces. □

Theorem 38.832 (Real terminal seal NameCert exit consumer exactness)**.** *An accepted terminal-seal manifest*

$$\mathsf{Dep}^{\mathrm{term}}_{\mathsf{Real}^{\uparrow}} = (S, D, R, E, B, H, C, P, N)$$

determines the same local $\mathsf{NameCert}$ *row as the current Phase Real and Completion exit consumer exactly when the four object faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and local* $\mathsf{Real}^{\uparrow}$*, and the support rows* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*, agree between the manifest presentation and the L10 exit presentation. Consequently, the local* $\mathsf{NameCert}$ *consumer row is neither an additional aggregate certificate nor an off-table completeness assertion: it is the facewise* $\mathsf{NameCert}$ *support already carried by the accepted terminal-seal manifest and by the current Phase Real and Completion exit surface.*

Proof. First compare the manifest with the current exit consumer. Apply Definition 38.830. It identifies the accepted terminal-seal manifest with exactly the consumer rows read by the current L10 exit route: the four object faces and the shared BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ support.

Next compare that consumer presentation with the classifier read. Apply Definition 38.831. The public classifier verdict has no independent coordinate beyond agreement of the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and local $\mathsf{Real}^{\uparrow}$ faces over the same shared support rows, so equality of the displayed $\mathsf{NameCert}$ rows is exactly the NameCert component of the classifier correspondence.

It remains to identify the same row with the Phase Real and Completion exit route. Apply Definition 126.500 to read the consumer through the four-object surface, then apply Definition 291.28 and Definition 301.22. These handoffs preserve the dyadic ledger, stream window, regular-rational classifier/readback row, and local Real seal row, and they do not create a second NameCert coordinate.

Conversely, if the current Phase Real and Completion exit consumer has the same four object faces and the same BHist, hsame, Cont, Pkg, and NameCert rows, the preceding identifications restrict it to the accepted terminal-seal manifest. The non-escape clauses in Definition 38.830 and Definition 38.831 exclude quotient streams, host real equality, selected limits, choice, completeness, aggregate formalstatus rows, and standard bridge rows, so the exact local NameCert row is precisely the one displayed in the manifest. □

Theorem 38.833 (Real L10 face status non-collapse)**.** *Any current Phase Real and Completion audit read through the four faces* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *preserves the four local closure records as separate face reports. No conjunction of those records can be read as a new formalstatus token, a* bridgeChecked *aggregate, a* $\mathsf{Real}^{\uparrow}$ *completeness claim, or a standard bridge for the composite exit route.*

Lean4 ✓ `BEDC.Derived.RealUp.RealL10FaceStatusNoncollapse`

Proof. Apply Definition 38.471. It identifies the current exit audit as the product of the four local face records and states that the exit packet contributes no fifth formal token or aggregate bridge.

The two-axis convention of section 9467.2 reads closure and verification status locally. A face report can therefore be cited as a face report, but the conjunction of face reports is not itself a further formalstatus entry.

Finally use the exactness and non-escape inputs named in the pullback proof: Definition 38.443, Definition 38.444, Definition 38.457, and Definition 38.460. They keep the composite exit route on the four displayed faces and provide no row for RealUp completeness or for a standard bridge over the product. □

Theorem 38.834 (Real L10 face Lean target non-collapse)**.** *Any accepted current Phase Real and Completion audit read through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *preserves each face's Lean-target row and bridge-status row as local records of that face. No* bridgeChecked *face can supply the Lean target or bridge row for another face, and the composite route creates neither a route-level Lean target nor an aggregate bridge row.*

Lean4 ✓ `BEDC.Derived.RealUp.RealL10FaceLeantargetNoncollapse`

Proof. Apply Definition 38.471. It reads the accepted exit audit as the product of the four local face records over the displayed Real L10 dependency lattice.

Apply Definition 38.833. It keeps the closure and verification reports objectwise, so a bridgeChecked entry is a record of its own face rather than a credential for a different face.

Now project the target and bridge rows along the same exactness data used by the pullback. The source-route non-escape, interface-totality, four-face exactness, and StreamName exit-correspondence inputs provide only face-local Lean-target and bridge-status coordinates for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, not an aggregate target row or an aggregate bridge row.

Since those inputs provide no fifth face, no route-level Lean-target coordinate, and no aggregate bridge coordinate, the local Lean-target and bridge-status rows remain attached to the faces from which they are read. □

Theorem 38.835 (Real L10 face status-target pairing)**.** *In any accepted Phase Real and Completion audit read through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, each face's* formalstatus*,* leantarget*, and* bridgestatus *rows are read as one local face record. A status row from one face cannot be paired with the Lean target or bridge row of another face, and no aggregate route row can repair such a mismatch.*

Proof. Apply Definition 38.471. The accepted audit is read as the product of the four local records carried by $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, not as a single route credential.

Apply Definition 38.833. It keeps the formalstatus coordinate attached to the face whose closure record supplies it, so the status row cannot be detached and reused as a route-level token.

Apply Definition 38.834. It keeps the leantarget and bridgestatus coordinates attached to the same local face records and supplies no route-level target or aggregate bridge row.

Finally read the three rows through section 9467.2. The roadmap discipline keeps verification status, Lean target, and bridge status as reported coordinates of the displayed face, so a mixed record using one face's status and another face's target or bridge row is outside the accepted audit read. □

Theorem 38.836 (Real L10 face status product readback)**.** *Any accepted Phase Real and Completion audit read through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *reads exactly the four face-local triples* (formalstatus, leantarget, bridgestatus) *carried by the corresponding face records. The readback is supported only by the displayed rows*

$$\mathsf{BHist}_{\mathsf{DyadicRatCore}^{\uparrow}}, \mathsf{hsame}_{\mathsf{DyadicRatCore}^{\uparrow}}, \mathsf{Cont}_{\mathsf{DyadicRatCore}^{\uparrow}}, \mathsf{Pkg}_{\mathsf{DyadicRatCore}^{\uparrow}}, \mathsf{NameCert}_{\mathsf{DyadicRatCore}^{\uparrow}},$$
$$\mathsf{BHist}_{\mathsf{StreamName}^{\uparrow}}, \mathsf{hsame}_{\mathsf{StreamName}^{\uparrow}}, \mathsf{Cont}_{\mathsf{StreamName}^{\uparrow}}, \mathsf{Pkg}_{\mathsf{StreamName}^{\uparrow}}, \mathsf{NameCert}_{\mathsf{StreamName}^{\uparrow}},$$
$$\mathsf{BHist}_{\mathsf{RegSeqRat}^{\uparrow}}, \mathsf{hsame}_{\mathsf{RegSeqRat}^{\uparrow}}, \mathsf{Cont}_{\mathsf{RegSeqRat}^{\uparrow}}, \mathsf{Pkg}_{\mathsf{RegSeqRat}^{\uparrow}}, \mathsf{NameCert}_{\mathsf{RegSeqRat}^{\uparrow}},$$
$$\mathsf{BHist}_{\mathsf{Real}^{\uparrow}}, \mathsf{hsame}_{\mathsf{Real}^{\uparrow}}, \mathsf{Cont}_{\mathsf{Real}^{\uparrow}}, \mathsf{Pkg}_{\mathsf{Real}^{\uparrow}}, \mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}.$$

It does not create an aggregate formalstatus*, aggregate* leantarget*, aggregate bridge row, quotient stream equality, selected limit, countable-choice row, metric-completeness datum, or* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.RealUp.RealL10FaceStatusProductReadback`

Proof. Apply Definition 38.833. It keeps the status coordinates as local reports of $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ and supplies no fifth status coordinate.

Apply Definition 38.834. It keeps the leantarget and bridgestatus rows attached to their source faces and supplies no route-level target or aggregate bridge row.

Apply Definition 38.835. It reads formalstatus, leantarget, and bridgestatus together on the same face, so the product readback is exactly the four displayed local triples rather than a pool of exchangeable coordinates.

Finally use section 9467.2. The roadmap keeps paper closure and verification status on separate axes, and it supplies no rule turning the four face-local triples or their support rows BHist, hsame, Cont, Pkg, NameCert into quotient stream equality, a selected limit, a countable-choice row, a metric-completeness datum, an aggregate credential, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 38.837 (Real L10 face axis independence)**.** *Any accepted Phase Real and Completion audit read through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *preserves four independent local coordinates on each face: paper closure, formalstatus, leantarget, and bridgestatus. No*

coordinate from one face promotes any coordinate of another face, and no conjunction of face coordinates creates route-level closure, route-level formalstatus, route-level leantarget, aggregate bridge status, quotient stream, selected limit, countable-choice row, metric-completeness row, or $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Apply Definition 38.471. The audit is read as a product of the displayed faces $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, over the Real L10 dependency lattice, with no additional route coordinate.

Apply Definition 38.833. It keeps the paper closure and formalstatus reports face-local and blocks any reading in which a conjunction of local status records becomes route-level closure, route-level formalstatus, an aggregate bridge, or a $\mathsf{Real}^{\uparrow}$ completeness claim.

Apply Definition 38.834. It keeps leantarget and bridgestatus records attached to their source faces and blocks any reading in which one face supplies the Lean target or bridge row for another face.

Finally use the two-axis discipline of section 9467.2. Paper closure, formalstatus, leantarget, and bridgestatus are reported as separate coordinates; the roadmap supplies no rule that turns their conjunction into a quotient stream, selected limit, countable-choice row, metric-completeness row, aggregate bridge, or completed real-completeness certificate. □

Theorem 38.838 (Real L10 face-axis defect localization)**.** *Suppose an accepted Phase Real and Completion audit read through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *does not preserve one of the four independent coordinates named in Definition 38.837. Then the defect is localized to at least one displayed face record or to at least one displayed support row among* $\mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$. *No quotient stream, selected limit, countable-choice row, metric-completeness row, aggregate formalstatus, aggregate bridge row, route-level leantarget, or* $\mathsf{Real}^{\uparrow}$ *completeness claim can serve as the defect carrier.*

Proof. Apply Definition 38.837. The admissible coordinate inventory is the displayed facewise list: paper closure, formalstatus, leantarget, and bridgestatus over the four Real L10 faces. The same theorem excludes route-level completion vocabulary and aggregate status vocabulary from that inventory.

Apply Definition 38.833. It keeps paper closure and formalstatus attached to the local closure records of $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Thus a defect in either status coordinate is witnessed on at least one displayed face record or on at least one of its displayed support rows $\mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$.

Apply Definition 38.834. It keeps leantarget and bridgestatus attached to their source faces and supplies no route-level target or aggregate bridge row. Thus a defect in either target coordinate is again witnessed on at least one displayed face record or on at least one displayed support row.

Finally use the two-axis discipline of section 9467.2. Paper closure, formalstatus, leantarget, and bridgestatus are reported as separate axes, and there is no rule that lets a quotient stream, selected limit, countable-choice row, metric-completeness row, aggregate formalstatus, aggregate bridge row, route-level leantarget, or $\mathsf{Real}^{\uparrow}$ completeness claim replace the concrete face or support coordinate where the read failed. □

Theorem 38.839 (Real L10 exit defect face completeness)**.** *Every failed accepted Phase Real and Completion audit read through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *is exhausted by the four displayed face records and their displayed support rows* $\mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$. *Equivalently, any accepted defect witness is carried either by one of the four face records or by one of those support rows on that face. No quotient stream, selected limit, countable-choice row, metric-completeness datum, aggregate formalstatus, route-level leantarget, aggregate bridge row, or* $\mathsf{Real}^{\uparrow}$ *completeness claim is an additional defect coordinate.*

Proof. Apply Definition 38.837. It supplies the complete coordinate inventory for an accepted audit read: paper closure, formalstatus, leantarget, and bridgestatus, each read locally over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Apply Definition 38.838. Once one of those coordinates fails to be preserved, the failure is witnessed on a displayed face record or on one of its displayed support rows BHist, hsame, Cont, Pkg, NameCert.

Apply Definition 38.836. The product readback contains exactly the four face-local status, target, and bridge triples supported by the displayed rows, so there is no remaining readback slot in which a hidden fifth status or completion coordinate could be stored.

Finally use the roadmap two-axis discipline of section 9467.2. It separates theory closure from verification status and provides no rule turning quotient-stream data, selected-limit data, countable-choice data, metric-completeness data, aggregate status data, route-level target data, aggregate bridge data, or $\mathsf{Real}^{\uparrow}$ completeness vocabulary into an accepted defect coordinate. □

Theorem 38.840 (Real L10 StreamName terminal status minimality)**.** *For any accepted Phase Real and Completion terminal read through* $\mathsf{StreamName}^{\uparrow}$*, the terminal read satisfies the roadmap exit status coordinate only if the four concrete face chapters* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *each supply their own local closurestatus, formalstatus, leantarget, and bridgestatus record at the required local audit-clean grade. If any one face record is absent or below that grade, then no aggregate formalstatus, aggregate bridge token, quotient stream, selected limit, countable-choice row, metric-completeness row, or* $\mathsf{Real}^{\uparrow}$ *completeness claim repairs the terminal read.*

Proof. Apply Definition 126.425. The terminal $\mathsf{StreamName}^{\uparrow}$ read is forced to inspect the four concrete sibling status records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$; it is not a read from a route-level status cache.

Now apply Definition 38.489. A missing face record, or a face record below the required audit-clean grade, blocks the current Phase Real and Completion exit criterion at the object where the defect is read.

Finally apply Definition 38.833 and Definition 38.834. These results keep the closurestatus, formalstatus, leantarget, and bridgestatus coordinates attached to their source faces and provide no aggregate replacement row. Therefore quotient-stream data, selected-limit data, countable-choice data, metric-completeness data, aggregate formalstatus, aggregate bridge tokens, and $\mathsf{Real}^{\uparrow}$ completeness vocabulary cannot repair the failed terminal read. □

Theorem 38.841 (Real L10 terminal four-face defect localization)**.** *Let* $\mathcal{T}$ *be an accepted terminal Phase Real and Completion read through* $\mathsf{StreamName}^{\uparrow}$*. If* $\mathcal{T}$ *fails the roadmap exit criterion, then the failed terminal read has a witness localized to a single displayed face among* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*. At that face, the witness is read either from the local closurestatus, formalstatus, leantarget, and bridgestatus record, or from one of the displayed support rows* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *attached to that face.*

The localization has no repair coordinate outside those four faces. Quotient stream equality, selected limits, countable choice, metric-completeness data, aggregate formalstatus, aggregate bridge tokens, and $\mathsf{Real}^{\uparrow}$ *completeness do not supply terminal repair data and do not move the witness away from the face where the failed read is displayed.*

Proof. Start with Definition 38.840. It forces every accepted terminal $\mathsf{StreamName}^{\uparrow}$ read to inspect the four local closurestatus, formalstatus, leantarget, and bridgestatus records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Apply Definition 38.839. A failed accepted exit read is exhausted by those four face records and by the displayed BHist, hsame, Cont, Pkg, and NameCert support rows on those faces. Hence some face carries the displayed witness.

Now use Definition 38.836. The terminal readback contains exactly the four face-local status, target, and bridge triples, so the witness can be chosen on one of the four objectwise faces rather than on a route-level aggregate.

Finally read the conclusion through section 9467.2. The roadmap separates paper closure, verification status, Lean target, and bridge status into local reported coordinates. It gives no rule that turns quotient stream equality, selected limits, countable choice, metric completeness, aggregate formalstatus, aggregate bridge data, or $\mathsf{Real}^{\uparrow}$ completeness into a terminal repair coordinate. □

Theorem 38.842 (Real L10 regular-Cauchy seal route completeness)**.** *Let $\mathcal{T}$ be an accepted Phase Real and Completion terminal read whose* $\mathsf{Real}^{\uparrow}$ *seal is supplied by an accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *route. Then the accepted seal route of $\mathcal{T}$ is exhausted by exactly the four displayed faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

together with the visible support rows BHist, hsame, Cont, Pkg, *and* NameCert *on those faces.*

No fifth route coordinate is exported. In particular, the accepted seal route does not read quotient streams, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, metric-completion data, or standard bridge rows.*

Proof. Apply Definition 301.40. An accepted $\mathsf{RegSeqRat}^{\uparrow}$ route supplying the $\mathsf{Real}^{\uparrow}$ seal exports only the finite regular-source rows and excludes quotient stream equality, selected host limits, host real equality, hidden tail witnesses, and ambient completeness data.

Next use Definition 301.111. The $\mathsf{Real}^{\uparrow}$ consumer read factors through the same finite route rows, so the seal route seen by the terminal Phase Real and Completion read cannot acquire an additional consumer-side completion coordinate.

Use Definition 291.123 for the dyadic tolerance face. The tolerance component of the route is already read through the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ faces together with the shared BHist, hsame, Cont, Pkg, and NameCert support rows.

Finally apply Definition 38.833, Definition 38.834, and Definition 38.841. These results keep the L10 status, target, bridge, and defect witnesses localized to the four displayed faces and their support rows. Hence the accepted regular-Cauchy seal route has no fifth status coordinate, no independent completeness coordinate, and no standard bridge row outside the displayed four-face route. □

Theorem 38.843 (Real L10 finite-cover exit threshold gluing)**.** *Let $\mathcal{U}$ be a finite family of accepted Phase Real and Completion exit packets. Suppose every member of $\mathcal{U}$ satisfies the objectwise exit threshold of Definition 38.494, and suppose that every pairwise overlap agrees on the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier rows, the* $\mathsf{Real}^{\uparrow}$ *seal rows, and the shared* BHist, hsame, Cont, Pkg, *and* NameCert *support rows. Then the family glues to one accepted four-face Phase Real and Completion exit packet satisfying the same objectwise exit threshold.*

The glued exit packet is only the finite four-face packet over those displayed rows. It exports no aggregate route-level formalstatus, *no aggregate bridge row, no quotient stream, no selected limit, no countable-choice row, no metric-completeness datum, and no* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Apply Definition 38.494 to each member of $\mathcal{U}$. Thus every local packet contributes exactly the four face records for $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with the threshold read from the local closurestatus rows of those faces.

We first glue the regular-sequence and real-seal faces. Apply Definition 301.88 to the finite family of $\mathsf{RegSeqRat}^{\uparrow}$ regularity rows and $\mathsf{Real}^{\uparrow}$ seal rows. The overlap agreement hypothesis is

precisely the shared regularity, classifier, seal, BHist, hsame, Cont, Pkg, and NameCert surface required for that gluing. Apply Definition 301.80 to identify the resulting seal row on common overlaps.

Next glue the scheduling face. Use Definition 126.240 and Definition 126.265 to pass to a common finite-window presentation of the $\mathsf{StreamName}^{\uparrow}$ schedules. Apply Definition 126.562 to export one schedule row for the finite family, still over the displayed finite-window data and not over a quotient stream or selected limit.

The dyadic face is fixed by the overlap ledger. Apply Definition 291.66 and Definition 291.70. These read the shared endpoint and radius data through the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, so the glued packet has the same dyadic endpoint and radius rows on all refined windows.

Combining the glued RegSeqRat/Real, StreamName, and DyadicRatCore rows gives one accepted four-face exit packet by Definition 38.493. Finally apply Definition 38.833 and Definition 38.834. The glued packet remains objectwise: its closure, verification, Lean-target, and bridge rows stay on their source faces and do not form an aggregate route-level status, bridge, quotient, selected-limit, choice, metric-completeness, or $\mathsf{Real}^{\uparrow}$ completeness datum. □

Theorem 38.844 (Real L10 finite-cover exit threshold descent)**.** *Let P be an accepted Phase Real and Completion exit packet, and let $\mathcal{V}$ be a finite certified subcover of P. Suppose every member of $\mathcal{V}$ satisfies the objectwise exit threshold of Definition 38.494. Suppose moreover that each subcover member agrees with P on the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier rows, the* $\mathsf{Real}^{\uparrow}$ *seal rows, and the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows. Then P satisfies the same objectwise exit threshold.*

The descended threshold is only the coarse four-face threshold of P. It does not assert an aggregate route-level formalstatus*, an aggregate bridge row, a quotient stream, a selected limit, a countable-choice row, a metric-completeness datum, or a* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Apply Definition 38.843 to the finite certified subcover $\mathcal{V}$. The hypotheses on the local threshold and on the shared $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows give one glued accepted four-face packet satisfying the objectwise exit threshold.

We now identify this glued packet with the coarse packet P. The agreement assumptions say that every displayed endpoint, radius, finite-window, regularity, classifier, seal, history, sameness, continuity, package, and NameCert coordinate of the glued packet is the corresponding coordinate of P. Apply Definition 38.494 to read the glued threshold as the four local face records of P.

It remains to keep the descent facewise. Apply Definition 38.833 and Definition 38.834. These prevent the subcover gluing from creating an aggregate status, bridge, quotient-stream, selected-limit, countable-choice, metric-completeness, or $\mathsf{Real}^{\uparrow}$ completeness reading. Hence the coarse packet P carries exactly the same objectwise exit threshold and no route-level strengthening. □

Theorem 38.845 (Real L10 terminal pullback coherence)**.** *Let T be an accepted terminal finite-window* $\mathsf{Real}^{\uparrow}$ *read presented through the public* $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$ *route. Suppose its StreamName window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *pointwise seal and readback,* $\mathsf{Real}^{\uparrow}$ *seal row, and shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support agree with a four-face Phase Real and Completion packet P. Then T satisfies the same objectwise exit threshold as P in the sense of Definition 38.494.*

Conversely, any terminal finite-window $\mathsf{Real}^{\uparrow}$ *read satisfying that objectwise threshold and carrying the displayed StreamName, DyadicRatCore, RegSeqRat, Real seal,* BHist*,* hsame*,* Cont*,* Pkg*,*

and NameCert *rows factors through the StreamName–*RegSeqRat–Real$^{\uparrow}$ *terminal pullback over the four-face Phase Real and Completion packet.*

The coherent terminal read is only this displayed finite-window pullback. It does not assert an aggregate route-level formalstatus*, an aggregate bridge row, a quotient stream, a selected limit, a countable-choice row, a metric-completeness datum, or a* Real$^{\uparrow}$ *completeness claim.*

Proof. First read the terminal route. Apply Definition 126.114. The accepted terminal Real$^{\uparrow}$ read factors through exactly the displayed StreamName window rows, accepted RegSeqRat$^{\uparrow}$ pointwise seal rows, Real$^{\uparrow}$ finite-window seal boundary, hsame transports, finite Cont ledger, bundle membership, observations, and Pkg provenance. Apply Definition 126.125 to include the DyadicRatCore$^{\uparrow}$ tolerance ledger in the same finite route.

Now compare the resulting route with the four-face Phase Real and Completion packet P. The agreement assumptions identify the StreamName window, DyadicRatCore tolerance, RegSeqRat seal and readback, Real seal, BHist, hsame, Cont, Pkg, and NameCert coordinates of the terminal read with the corresponding objectwise faces of P. Apply Definition 38.494 to read the exit threshold from those four local closurestatus records.

For the converse direction, start with a terminal finite-window Real$^{\uparrow}$ read that already carries the objectwise threshold and the displayed finite route rows. Apply Definition 126.125 to recover the finite StreamName–RegSeqRat route, and then apply Definition 126.114 to repack the same rows as the terminal pullback boundary.

It remains to keep the terminal comparison at the same threshold. Apply Definition 38.844 to descend any finite-window cover presentation back to the coarse packet P. Finally apply Definition 38.833 and Definition 38.834. These keep formalstatus, bridge, Lean-target, quotient-stream, selected-limit, choice, metric-completeness, and Real$^{\uparrow}$ completeness data attached only to the source faces, so the pullback coherence gives no route-level strengthening. □

Theorem 38.846 (Real L10 terminal cover coordinate exhaustion)**.** *Let T be an accepted terminal finite-window* Real$^{\uparrow}$ *read over the public* StreamName$^{\uparrow}$–RegSeqRat$^{\uparrow}$ *route. A finite certified cover witnesses the current Phase Real and Completion threshold for T if and only if every cover member and every certified overlap exposes exactly the displayed* DyadicRatCore$^{\uparrow}$ *endpoint and radius ledger, the* StreamName$^{\uparrow}$ *finite-window schedule, the* RegSeqRat$^{\uparrow}$ *regularity and classifier rows, the local* Real$^{\uparrow}$ *seal rows, and the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows.*

No aggregate formalstatus*, aggregate bridge row, quotient stream, selected limit, countable-choice row, metric-completeness datum, or* Real$^{\uparrow}$ *completeness coordinate can stand in for any one of these exposed coordinates.*

Proof. For the forward direction, start with a finite certified cover witnessing the terminal threshold for T. Apply Definition 38.845 to identify the terminal read with the four-face Phase Real and Completion packet through the displayed StreamName, DyadicRatCore, RegSeqRat, local Real, and shared support rows.

Apply Definition 38.494. The threshold is objectwise, so each cover member must present the dyadic endpoint and radius, finite-window schedule, regularity and classifier rows, local seal rows, and the common BHist, hsame, Cont, Pkg, and NameCert support. Apply Definition 38.843; the certified overlaps are precisely the rows along which those objectwise faces glue.

For the reverse direction, suppose every member and overlap exposes exactly those coordinates. Apply Definition 38.843 to assemble the memberwise four-face packets over the shared support, and then apply Definition 38.844 to read the glued packet back as the terminal finite-window threshold for T.

It remains to show that no route-level coordinate can replace a displayed face. Apply Definition 38.833 and Definition 38.834. These keep aggregate status, bridge, quotient-stream, selected-limit, countable-choice, metric-completeness, and $\mathsf{Real}^{\uparrow}$ completeness rows outside the finite cover support, so the witness is exhausted by the listed coordinates and by no stronger route credential. □

Theorem 38.847 (Real L10 terminal finite-cover threshold equivalence)**.** *Let T be an accepted terminal finite-window* $\mathsf{Real}^{\uparrow}$ *read over the public* $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$ *route, with displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier rows, local* $\mathsf{Real}^{\uparrow}$ *seal rows, and shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. Then T satisfies the current Phase Real and Completion objectwise exit threshold if and only if every finite certified cover of the displayed terminal route glues and descends to the same four-face packet over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and the local* $\mathsf{Real}^{\uparrow}$ *seal, with the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*

The equivalence refuses aggregate route-level formalstatus*, aggregate bridge rows, quotient stream equality, selected limits, countable choice, metric-completeness data, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. For the forward direction, apply Definition 38.845. The accepted terminal read is compared with the four-face Phase Real and Completion packet through the displayed StreamName window, DyadicRatCore tolerance ledger, RegSeqRat readback and classifier rows, local Real seal, and shared support rows.

Now apply Definition 38.843. Each finite certified cover member carries the objectwise threshold read from the same local faces, and the overlap hypotheses are exactly the shared BHist, hsame, Cont, Pkg, and NameCert rows. Apply Definition 126.504 to keep the glued cover inside the terminal four-object packet over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

For the reverse direction, suppose every finite certified cover of the displayed terminal route glues and descends to the same four-face packet. Apply Definition 38.844. The descended coarse packet carries the same objectwise threshold as its finite cover members.

It remains to identify this descended packet with the accepted terminal route. Apply Definition 291.107 to read the dyadic endpoint, radius, distance, and local NameCert interface as the $\mathsf{DyadicRatCore}^{\uparrow}$ face of the same support packet. Apply Definition 301.93 to read the StreamName, RegSeqRat, DyadicRatCore, and local Real rows as one audit-clean four-face exit surface.

Finally apply Definition 38.845. The terminal read and the descended four-face packet have the same displayed faces and the same BHist, hsame, Cont, Pkg, and NameCert support rows, so the threshold is exactly the current objectwise Phase Real and Completion threshold. The cited noncollapse clauses in the gluing, descent, interface, readiness, and terminal-pullback results leave no aggregate status, bridge row, quotient stream equality, selected limit, choice principle, metric-completeness datum, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate. □

Theorem 38.848 (Real L10 finite-cover terminal support exhaustion)**.** *Let T be an accepted terminal finite-window* $\mathsf{Real}^{\uparrow}$ *read over the public* $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$ *route. A finite certified cover witnesses the current Phase Real and Completion threshold for T if and only if its members and certified overlaps expose exactly the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier rows, the local* $\mathsf{Real}^{\uparrow}$ *seal rows, and the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support.*

Deleting any one of those displayed rows prevents the altered cover from witnessing the same terminal threshold. No aggregate formalstatus *row, bridge row, quotient stream, selected limit,*

countable-choice datum, metric-completeness datum, or $\mathsf{Real}^{\uparrow}$ *completeness row replaces the deleted coordinate.*

Proof. For the equivalence of the support inventory with the terminal threshold, combine Definition 38.846 with Definition 38.847. The first result identifies the exact member and overlap coordinates of an accepted terminal cover, while the second reads those coordinates as the current Phase Real and Completion finite-cover threshold for T.

Now delete one displayed row. If the deleted row lies on the $\mathsf{RegSeqRat}^{\uparrow}$ audit-threshold side, apply Definition 301.231; the altered cover cannot descend to the same glued audit-threshold read. If the deleted row is one of the shared cover-support rows along the public route, apply Definition 126.665; the cover-descent terminal support packet cannot present the same $\mathsf{Real}^{\uparrow}$ seal-visible source.

It remains to keep the dyadic endpoint and radius ledger from being hidden in a different terminal readback. Apply Definition 291.124. The public tolerance read is determined by the finite $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, the StreamName window, the RegSeqRat rows, the local Real seal, and the same shared support rows, so deleting any one of those rows removes a coordinate used by the terminal threshold.

Finally use the noncollapse clauses cited in Definition 38.846 and Definition 38.847. They keep aggregate status, bridge data, quotient streams, selected limits, choice, metric-completeness, and ambient $\mathsf{Real}^{\uparrow}$ completeness outside the objectwise finite-cover support. Hence none of those rows can replace the deleted coordinate, and the original finite certified cover is support-exhaustive. □

Theorem 38.849 (Real L10 terminal finite-cover face minimality)**.** *Let T be an accepted terminal finite-window* $\mathsf{Real}^{\uparrow}$ *read satisfying the current Phase Real and Completion objectwise exit threshold, with displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier rows, local* $\mathsf{Real}^{\uparrow}$ *seal rows, and shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows. Then every finite certified cover witnessing the terminal finite-cover threshold equivalence for T is face-minimal in the following sense.*

1. *The cover must retain the* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and local* $\mathsf{Real}^{\uparrow}$ *faces on the displayed terminal support.*
2. *The cover must retain the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows through the same common support.*
3. *Deleting any one of these faces or support rows makes the resulting subcover inadmissible as a witness for the terminal threshold.*
4. *No aggregate* formalstatus*, bridge row, quotient stream, selected limit, countable-choice row, metric-completeness datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row can replace the deleted face or support row.*

Proof. Apply Definition 38.847. The accepted threshold for T is equivalent to gluing and descent of finite certified covers to the same four-face packet over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and the local $\mathsf{Real}^{\uparrow}$ seal, with the shared BHist, hsame, Cont, Pkg, and NameCert rows.

Apply Definition 38.845. This identifies the accepted terminal read with that four-face packet, so a cover witnessing the threshold is not merely a route credential: it is a cover whose visible support contains the dyadic ledger, the StreamName finite window, the RegSeqRat classifier and readback rows, the local Real seal, and the shared support rows.

It remains to rule out removing a displayed face. Use Definition 126.407 for the StreamName finite-window subcover, use Definition 301.198 for the RegSeqRat common-tail and cocycle rows,

and use Definition 291.107 for the dyadic endpoint, radius, distance, and local NameCert interface. These results make each face visible in the common support consumed by the terminal packet.

Finally apply the noncollapse clauses from Definition 38.847, Definition 38.833, and Definition 38.834. They keep route-level status, bridge, quotient-stream, selected-limit, choice, metric-completeness, and ambient completeness data outside the objectwise face inventory, so none of those rows can compensate for a missing $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, local $\mathsf{Real}^{\uparrow}$, or shared support row. □

Theorem 38.850 (Real L10 finite-cover threshold cocycle uniqueness)**.** *Let T be an accepted terminal finite-window* $\mathsf{Real}^{\uparrow}$ *read. Let $\mathcal{U}$ and $\mathcal{V}$ be two finite certified covers of T, each satisfying the terminal finite-cover threshold equivalence. Suppose that, on every common refinement of $\mathcal{U}$ and $\mathcal{V}$, the two covers agree on the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier rows, the local* $\mathsf{Real}^{\uparrow}$ *seal rows, and the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows.*

Then the four-face exit packet glued from $\mathcal{U}$ and the four-face exit packet glued from $\mathcal{V}$ are the same terminal common-refinement packet. This uniqueness statement is only about the displayed finite-cover threshold surface. It does not identify aggregate formalstatus *rows, bridge rows, quotient streams, selected limits, countable-choice data, metric-completeness data, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. First apply Definition 38.847 to both covers. Each cover is therefore a finite certified presentation whose glued packet and descended packet are the terminal four-face exit over the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and local $\mathsf{Real}^{\uparrow}$ faces with the same support rows.

Next pass to any common refinement. Apply Definition 126.628 to the finite-window schedule and Definition 301.243 to the RegSeqRat request sections and local Real seal rows. The refinement exposes a single terminal four-face packet on the common StreamName, RegSeqRat, dyadic, and Real boundary.

The dyadic ledger cannot split into two sources on that refinement. Apply Definition 291.114; the common endpoint and radius rows determine the same BEDC-visible dyadic source ledger and hence the same dyadic face of the exit packet.

Finally apply Definition 38.845 and Definition 38.849. Pullback coherence identifies the common four-face packet with the accepted terminal read T, and face minimality prevents any alternative support row from standing in for a displayed face. Thus the two glued packets coincide as the same terminal common-refinement packet, while aggregate status, bridge, quotient-stream, selected-limit, choice, metric-completeness, and ambient completeness coordinates remain outside the construction. □

Theorem 38.851 (Real L10 terminal finite-cover refinement invariance)**.** *Let T be an accepted terminal finite-window* $\mathsf{Real}^{\uparrow}$ *read. Let $\mathcal{V}$ be a finite certified refinement of a finite certified cover $\mathcal{U}$ of T. Suppose that every refinement cell preserves the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier rows, the local* $\mathsf{Real}^{\uparrow}$ *seal rows, and the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows.*

Then $\mathcal{U}$ witnesses the current Phase Real and Completion terminal finite-cover threshold for T if and only if $\mathcal{V}$ witnesses that same threshold. The equivalence is an objectwise four-face statement: it does not assert equality of aggregate formalstatus *rows, bridge rows, quotient streams, selected limits, choice data, metric-completeness data, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Assume first that $\mathcal{U}$ witnesses the terminal finite-cover threshold. Apply Definition 38.847 to $\mathcal{U}$. The cover therefore presents the terminal four-face exit packet over the displayed dyadic, StreamName, RegSeqRat, and local Real faces with the shared support rows.

Transport this packet across the certified refinement. Apply Definition 126.407 to keep the finite-window schedule exact on the terminal subcover, and apply Definition 301.198 to keep the RegSeqRat classifier, readback, and cocycle rows on the common tail. The dyadic endpoint and radius ledger is fixed by Definition 291.114.

Now apply Definition 38.843. Each cell of $\mathcal{V}$ carries the same displayed faces and the same BHist, hsame, Cont, Pkg, and NameCert rows as its parent cell in $\mathcal{U}$, so the refined cells glue to the same terminal exit packet. Then Definition 38.847 reads the glued refined packet as a witness for $\mathcal{V}$.

For the reverse direction, assume that $\mathcal{V}$ witnesses the threshold. Apply Definition 38.844 along the certified refinement map from $\mathcal{V}$ to $\mathcal{U}$. The preservation hypotheses make the descended packet carry exactly the displayed dyadic, StreamName, RegSeqRat, local Real, and shared support rows of $\mathcal{U}$.

Finally apply Definition 38.849 and Definition 38.850. Face minimality prevents the refinement from hiding or replacing any displayed face, and cocycle uniqueness identifies the refined and descended packets on their common terminal support. Thus Definition 38.847 certifies $\mathcal{U}$ exactly when it certifies $\mathcal{V}$.

The construction never promotes route-level data into an objectwise face. Aggregate formalstatus rows, bridge rows, quotient streams, selected limits, choice principles, metric-completeness data, and ambient $\mathsf{Real}^{\uparrow}$ completeness remain outside the refined terminal finite-cover threshold. □

Theorem 38.852 (Real L10 refinement-support descent noescape)**.** *Let T be an accepted terminal finite-window* $\mathsf{Real}^{\uparrow}$ *read. Let $\mathcal{V}$ be a finite certified refinement of a finite certified cover $\mathcal{U}$ of T. Suppose the refinement preserves the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity and classifier rows, the local* $\mathsf{Real}^{\uparrow}$ *seal rows, and the shared* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows.*

Then descent from $\mathcal{V}$ to $\mathcal{U}$ preserves exactly this support surface. It introduces no aggregate formalstatus *row, bridge row, quotient stream, selected limit, choice row, metric-completeness datum, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. First apply Definition 38.851. The terminal threshold witnessed on the refined cover is equivalent to the terminal threshold witnessed on the original cover, and the equivalence is already restricted to the objectwise dyadic, StreamName, RegSeqRat, local Real, and shared BEDC support rows.

The descent keeps the three lower faces fixed. Apply Definition 126.407 for the finite-window schedule, apply Definition 301.198 for the RegSeqRat tail, and apply Definition 291.114 for the dyadic endpoint and radius ledger. These certificates leave the descended packet on the same displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ faces as the refined packet.

It remains to exclude substitute support. Apply Definition 38.849 to prevent any hidden row from standing in for a displayed face, and apply Definition 38.850 to identify the descended and refined terminal packets on their common support. Hence the descent preserves precisely the listed surface and cannot create a route-level credential outside it. □

Theorem 38.853 (Real stream prefix tail endpoint projection)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and indices n, m, if the prefix through n is classified and every endpoint along the finite tail of length m is rational-history classified, then the selected tail endpoint is rational-history*

classified:

$$\mathsf{RealStreamPrefixClassifier}(x, y, n) \wedge (\forall k,\ 1 \le k \le m \Longrightarrow \mathsf{RatHistoryClassifier}(x(n+k), y(n+k))) \Longrightarrow \mathsf{RatHistoryClassif}$$

Ten-field fit: traditional target finite RealUp prefix endpoint readback; BEDC source RealUp stream prefixes over RatUp point classifiers; carrier rational-observation streams; classifier RealStreamPrefixClassifier*; stability by tail extension and endpoint projection; ledger initial prefix length, tail length, and selected endpoint; core theorem this projection; exactness selected endpoint classification; standard bridge RegSeqRat finite observation readback; status* ProofTarget.

Proof. Apply Definition 38.115 to the classified prefix through n and the finite tail endpoint hypothesis. This gives $\mathsf{RealStreamPrefixClassifier}(x, y, n + m)$.

Now apply Definition 38.111 at the endpoint index $n + m$. The resulting projection is exactly $\mathsf{RatHistoryClassifier}(x(n + m), y(n + m))$. □

Theorem 38.854 (Real stream prefix truncated endpoint common e-one tail readback)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$ and indices m, n, if* $\mathsf{RealStreamPrefixClassifier}(x, y, m+n)$ *holds, then the endpoint at n has a common e-one tail readback:*

$$\exists a, b,\ \mathsf{hsame}(x(n), \mathsf{E1}(a)) \wedge \mathsf{hsame}(y(n), \mathsf{E1}(b)) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).$$

Proof. Truncate the displayed prefix classifier to the selected endpoint n and use the denominator package there. Its positive unary denominator rows give unary endpoint witnesses and separate both selected endpoints from e, so unary nonempty readback exposes e-one tails a and b. The truncated e-one pair readback theorem then returns the two unary tail rows and their hsame comparison. □

Lean4 ✓ `BEDC.Derived.RealUp.RealStreamPrefixClassifier truncated endpoint common e1 tail readback`

Theorem 38.855 (Real stream prefix probe endpoint determinacy)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, let $\mathcal{P}$ be a finite certified* ProbeBundle *window and let n be a unary observation with* $\mathsf{InBundle}(n, \mathcal{P})$*. Suppose the window supplies* $\mathsf{RealStreamPrefixClassifier}(x, y, n)$ *and, for every displayed tail row selected by $\mathcal{P}$ after n, the finite row* $\mathsf{RatHistoryClassifier}(x(n+k), y(n+k))$ *is present. Then every consumer endpoint selected from $\mathcal{P}$ has a unique* RatHistoryClassifier *readback, and its endpoint admits the same common e-one tail witness after* hsame *transport:*

$$\mathsf{InBundle}(n, \mathcal{P}) \Longrightarrow \forall j,\ \mathsf{InBundle}(j, \mathcal{P}) \Longrightarrow \exists a, b,\ \mathsf{hsame}(x(j), \mathsf{E1}(a)) \wedge \mathsf{hsame}(y(j), \mathsf{E1}(b)) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHis}$$

The statement reads only the displayed finite rows of $\mathcal{P}$; no observation outside the certified probe window is used.

Proof. Restrict the finite ProbeBundle to the selected prefix through n and to the displayed consumer endpoint j. The membership rows $\mathsf{InBundle}(n, \mathcal{P})$ and $\mathsf{InBundle}(j, \mathcal{P})$ are exactly the evidence that these two observations lie inside the certified window.

Apply Definition 38.853 to the selected prefix and the finite tail rows displayed by $\mathcal{P}$. This gives the endpoint RatHistoryClassifier readback for the consumer endpoint, and uniqueness follows because the readback is selected from the same finite bundle row rather than from an external observation.

Finally apply Definition 38.854 to the resulting classified prefix. The hsame transport keeps the two endpoint histories in the same rational-observation class, so the e-one tail witnesses are the common tail witnesses recorded by the finite probe window. □

Theorem 38.856 (Real terminal seal tail-section coherence)**.** *Let $x, y : \mathbb{N} \to \mathsf{Hist}$ be rational-observation streams, let $\mathcal{P}$ be a finite certified* ProbeBundle *endpoint window, and let $\mathcal{T}$ be the same* StreamName$^{\uparrow}$ *tail-section package consumed by a finite* Real$^{\uparrow}$ *stream prefix handoff. Suppose two finite endpoint reads pass through the same prefix row* RealStreamPrefixClassifier(x, y, n)*, the same displayed* InBundle *endpoint rows of $\mathcal{P}$, and the same tail-section package $\mathcal{T}$. Then the two endpoint reads determine the same terminal* Real$^{\uparrow}$ *seal route up to the displayed* hsame *transports.*

The seal route is the finite route through the prefix endpoint projection, truncated common e-one tail readback, probe endpoint determinacy, and the certified StreamName$^{\uparrow}$ *tail-section induction bridge. It does not export quotient stream equality, host sequence equality, selected limits, countable choice, ambient* Real$^{\uparrow}$ *completeness, metric-completeness data, or standard bridge rows.*

Proof. First apply endpoint projection, Definition 38.853. Both reads use the same prefix row and the same finite tail rows selected by $\mathcal{P}$, so the endpoint RatHistoryClassifier readback is taken from the same finite endpoint surface.

Next apply truncated endpoint common e-one tail readback, Definition 38.854. The endpoint histories therefore expose common e-one tail witnesses, and the displayed hsame rows transport those witnesses along the same prefix package.

Now use probe endpoint determinacy, Definition 38.855. It identifies the endpoint readback supplied by $\mathcal{P}$ as the unique finite readback for that endpoint inside the certified probe window.

Finally apply the StreamName tail-section induction bridge Definition 126.694. Since both reads consume the same StreamName$^{\uparrow}$ tail-section package, the terminal seal route is carried over the same finite BHist, hsame, Cont, Pkg, and local NameCert support rows. No remaining coordinate can distinguish two terminal Real$^{\uparrow}$ seal routes. □

Theorem 38.857 (Real stream prefix two-probe endpoint coherence)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, let $\mathcal{P}$ and $\mathcal{Q}$ be finite certified* ProbeBundle *windows. Suppose the same unary observation j satisfies* InBundle$(j, \mathcal{P})$ *and* InBundle$(j, \mathcal{Q})$*, and suppose both windows supply the* RealStreamPrefixClassifier *row and the finite* RatHistoryClassifier *tail rows required by Definition 38.855 for the selected endpoint j. Then the endpoint readbacks* RatHistoryClassifier$(x(j), y(j))$ *obtained through $\mathcal{P}$ and through $\mathcal{Q}$ are the same up to* hsame*, and their common e-one tail witnesses agree up to* hsame *transport:*

$$\begin{aligned}
&\mathsf{InBundle}(j, \mathcal{P}) \wedge \mathsf{InBundle}(j, \mathcal{Q}) \\
&\quad \textit{and the two displayed endpoint-determinacy packets at } j \\
&\quad \textit{determine histories } a_{\mathcal{P}}, b_{\mathcal{P}}, a_{\mathcal{Q}}, b_{\mathcal{Q}} \textit{ with} \\
&\quad \mathsf{hsame}(a_{\mathcal{P}}, a_{\mathcal{Q}}) \wedge \mathsf{hsame}(b_{\mathcal{P}}, b_{\mathcal{Q}}) \wedge \mathsf{hsame}(x(j), \mathsf{E1}(a_{\mathcal{P}})) \wedge \mathsf{hsame}(x(j), \mathsf{E1}(a_{\mathcal{Q}})) \\
&\quad \wedge\ \mathsf{hsame}(y(j), \mathsf{E1}(b_{\mathcal{P}})) \wedge \mathsf{hsame}(y(j), \mathsf{E1}(b_{\mathcal{Q}})).
\end{aligned}$$

Ten-field fit: traditional target finite RealUp two-window endpoint coherence; BEDC source RealUp stream prefixes over RatUp point classifiers; carrier the two certified ProbeBundle *windows over the same streams; classifier* RealStreamPrefixClassifier *at the selected unary observation; stability by* hsame *transitivity across the two endpoint readbacks; ledger the two window memberships, prefix classifiers, tail rows, endpoint row, and common e-one witnesses; core theorem this two-probe coherence statement; exactness the fixed endpoint row j; standard bridge StreamName and RegSeqRat finite observation readback; status* ProofTarget*. No observation outside the two certified probe windows is used.*

Proof. Apply Definition 38.855 to $\mathcal{P}$ at the selected observation j. The window membership row and the displayed classifier and tail rows return the endpoint RatHistoryClassifier$(x(j), y(j))$ together with common e-one tail witnesses $a_{\mathcal{P}}$ and $b_{\mathcal{P}}$.

Apply the same theorem to $\mathcal{Q}$ at the same selected observation j. This gives the endpoint readback through the second finite window and common e-one tail witnesses $a_{\mathcal{Q}}$ and $b_{\mathcal{Q}}$.

Both applications read the fixed endpoint row j of the same streams x and y. Transitivity of hsame identifies the two rational endpoint readbacks, and the same transport identifies the e-one tail witnesses. Since every row used in the argument is selected from either $\mathcal{P}$ or $\mathcal{Q}$, no external observation enters the comparison. □

Theorem 38.858 (Real stream prefix probe-union endpoint readback)**.** *For rational-observation streams $x, y : \mathbb{N} \to$ Hist, let $\mathcal{P}$ and $\mathcal{Q}$ be finite certified* ProbeBundle *windows, and let $\mathcal{U}$ be their synchronized union window certified by Definition 126.242. Suppose each source window supplies the* RealStreamPrefixClassifier *rows and finite* RatHistoryClassifier *tail rows required by Definition 38.855. Then every unary endpoint j selected by either source window has the same* RatHistoryClassifier$(x(j), y(j))$ *readback through the union window $\mathcal{U}$, and the common e-one tail witnesses displayed by the source window and by $\mathcal{U}$ agree by* hsame *transport.*

Equivalently, if InBundle$(j, \mathcal{P}) \vee$ InBundle$(j, \mathcal{Q})$*, then* InBundle$(j, \mathcal{U})$ *and the union read supplies histories $a_{\mathcal{U}}, b_{\mathcal{U}}$ with*

$$\mathsf{hsame}(x(j), \mathsf{E1}(a_{\mathcal{U}})) \wedge \mathsf{hsame}(y(j), \mathsf{E1}(b_{\mathcal{U}})) \wedge \mathsf{UnaryHistory}(a_{\mathcal{U}}) \wedge \mathsf{UnaryHistory}(b_{\mathcal{U}}).$$

If j lies in both $\mathcal{P}$ and $\mathcal{Q}$, these witnesses are hsame*-identified with the two source-window witnesses of Definition 38.857; if j lies in only one source window, the union read is the unique displayed readback of that source window.*

Ten-field fit: traditional target finite RealUp union endpoint readback; BEDC source RealUp stream prefixes with RatUp point classifiers; carrier the certified ProbeBundle *union membership rows for $\mathcal{P}, \mathcal{Q}, \mathcal{U}$; classifier* RealStreamPrefixClassifier *at the displayed unary prefix; stability by* hsame *transport of the e-one tails; ledger the finite endpoint ledger, source memberships, synchronized union membership, prefix classifiers, and tail rows; core theorem this probe-union readback statement; exactness the fixed finite endpoint row j; bridge data the StreamName synchronized-window union coverage and RegSeqRat finite observation readback; status* ProofTarget*. No quotient-real equality, completeness theorem, or host real comparison is used.*

Proof. Apply Definition 126.242 to the two certified probe windows. It places every endpoint selected by $\mathcal{P}$ or by $\mathcal{Q}$ into the synchronized union window $\mathcal{U}$ and records the finite union membership row used by the later readback.

When the selected endpoint lies only in $\mathcal{P}$, apply Definition 38.855 to $\mathcal{P}$. The union membership supplied by the synchronized carrier reads the same finite endpoint row, so the union readback is the displayed $\mathcal{P}$ readback transported along hsame.

The case where the endpoint lies only in $\mathcal{Q}$ is identical, with $\mathcal{Q}$ supplying the source readback and the union carrier supplying the same endpoint row in $\mathcal{U}$.

If the endpoint lies in both source windows, first apply endpoint determinacy in each window, then apply Definition 38.857. The coherence row identifies the two rational endpoint readbacks and transports the common e-one tail witnesses through hsame, so the union read has the same displayed tails.

All rows consumed by the argument are finite rows of the two source probe windows or of their synchronized union. Hence the endpoint readback remains a RegSeqRat-style finite observation read and never appeals to a quotient real, completeness principle, or host equality. □

Theorem 38.859 (Real stream prefix probe-union terminal four-face factorization)**.** *For rational-observation streams $x, y : \mathbb{N} \to$ Hist, let $\mathcal{P}$ and $\mathcal{Q}$ be finite certified* ProbeBundle *windows and let $\mathcal{U}$*

be their synchronized union window. Suppose the two source windows supply the RealStreamPrefixClassifier *rows and finite* RatHistoryClassifier *tail rows required by Definition 38.858. Then every endpoint readback selected from $\mathcal{U}$ factors through exactly one terminal four-face packet over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, R

The packet has precisely the displayed rows

BHist-*indexed finite probe histories*, hsame-*transport for endpoint tails*, Cont-*continuity rows*, Pkg-*package rows for the synchronized union window*, NameCert-*certification rows for the four visible faces.*

Its $\mathsf{StreamName}^{\uparrow}$ *face is the synchronized carrier $\mathcal{U}$, its* $\mathsf{DyadicRatCore}^{\uparrow}$ *face is the common finite scale window read from the same endpoint ledger, its* $\mathsf{RegSeqRat}^{\uparrow}$ *face is the regular sequence readback, and its* $\mathsf{Real}^{\uparrow}$ *face is the local endpoint seal supplied by the union readback. There is no second terminal packet with the same displayed rows.*

The factorization does not use quotient-real equality, selected limit values, ambient completeness of $\mathsf{Real}^{\uparrow}$*, countable choice, or standard bridge data.*

Proof. First apply Definition 38.858. The synchronized union window supplies the endpoint RatHistoryClassifier readback and the common e-one tail witnesses, all selected from the finite rows of $\mathcal{P}, \mathcal{Q}, \mathcal{U}$.

Next apply Definition 126.242 and Definition 126.558. These two results identify the $\mathsf{StreamName}^{\uparrow}$ carrier row with a terminal finite-request section over the same synchronized window; no endpoint outside $\mathcal{U}$ is introduced.

Now apply Definition 301.239. The RegSeqRat readback and the local Real endpoint seal are thereby read as two faces of a single terminal packet whose support rows are exactly the displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Finally apply Definition 291.83. It supplies the $\mathsf{DyadicRatCore}^{\uparrow}$ common-scale face and proves that the four visible faces form one pullback packet. Terminality gives uniqueness of the packet with those rows, while the construction never introduces quotient-real equality, selected limits, ambient completeness, countable choice, or standard bridge data. □

Theorem 38.860 (Real stream prefix probe-union terminal four-face support minimality)**.** *For rational-observation streams $x, y : \mathbb{N} \to$* Hist*, finite certified probe windows $\mathcal{P}, \mathcal{Q}$, and their synchronized union $\mathcal{U}$, every accepted terminal packet produced by Definition 38.859 is support-minimal. Deleting or replacing any one of the four faces* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$*, or deleting or replacing any displayed* BHist*,* hsame*,* Cont*,* Pkg*, or* NameCert *support row, destroys the accepted probe-union terminal read.*

The missing face or support row cannot be supplied by quotient-real equality, selected limit values, ambient $\mathsf{Real}^{\uparrow}$ *completeness, countable choice, metric-completeness rows, aggregate status rows, or standard bridge data. These coordinates remain outside the local probe-union packet and do not substitute for the finite BEDC support rows used by the terminal read.*

Proof. First apply Definition 38.859. It identifies the accepted probe-union read with a unique terminal packet whose visible faces are exactly $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$ and whose support is the displayed BHist, hsame, Cont, Pkg, and NameCert row family.

For the finite-window carrier face, apply Definition 126.653 to the synchronized StreamName window underlying $\mathcal{U}$. That result rules out deletion or replacement of the StreamName face and of the finite probe-history rows that certify membership in the accepted window.

For the dyadic request and regular tail faces, apply Definition 301.177. The common finite scale window and the RegSeqRat tail-budget rows are read from the same endpoint ledger, so removing

either face, or any of the hsame, Cont, Pkg, or NameCert rows it consumes, leaves no accepted regular tail read for the probe-union endpoint.

Finally apply Definition 38.868 together with Definition 38.741. These pull the Real-side endpoint seal back to the same four-face terminal packet and rule out substitution by host-real equality, selected limits, completeness coordinates, choice principles, aggregate status rows, or bridge evidence. The two-axis roadmap discipline keeps those excluded coordinates separate from the local BEDC support rows, so none of them can repair a missing face or row. □

Theorem 38.861 (Real stream prefix probe-union support-row exchange invariance)**.** *For rational-observation streams $x, y : \mathbb{N} \to \mathsf{Hist}$, let $\mathcal{P}$ and $\mathcal{Q}$ be finite certified* ProbeBundle *windows, and let $\mathcal{U}$ be their synchronized union window. Consider any two presentations of the terminal packet supplied by Definition 38.859. Suppose both presentations preserve the same four visible faces* $\mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$ *and the same displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *projections.*

Then exchanging the presentation order of those already-displayed support rows does not produce a second terminal packet. The two presentations determine the same terminal packet over $\mathcal{U}$, and for every selected endpoint j they determine the same finite endpoint readback $\mathsf{RatHistoryClassifier}(x(j), y(j))$ *with the same* hsame*-transported common e-one tail witnesses.*

This invariance is local to the displayed BEDC support rows. It is not witnessed by quotient-real equality, selected limit values, ambient $\mathsf{Real}^{\uparrow}$ *completeness, countable choice, aggregate status rows, or bridge data, and none of those coordinates can distinguish two presentation orders of the same terminal probe-union packet.*

Proof. First apply Definition 38.858. Both presentations read each selected endpoint from the same synchronized union window $\mathcal{U}$ and the same finite endpoint ledger, so the rational endpoint row and the common e-one tail witnesses agree by the displayed hsame transport.

Next apply Definition 38.859. The two presentations expose the same four faces $\mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{R}$ and the same BHist, hsame, Cont, Pkg, and NameCert projections. Terminality therefore identifies them as one terminal packet over the synchronized union carrier rather than as two packets distinguished by row order.

Finally apply Definition 38.860. Support minimality says that the accepted terminal read is carried exactly by the displayed faces and support rows. Hence quotient-real equality, selected limits, ambient completeness, countable choice, aggregate status rows, and bridge data cannot replace one of those rows or separate two orderings of the same row family. The endpoint readback equality from the first paragraph is therefore the endpoint readback of the unique terminal packet. □

Theorem 38.862 (Real selected transport synchronized e-one classifier clique)**.** *Under the hypotheses of Definition 38.866, the four displayed tails a, a', b, b' form a complete displayed rational-classifier clique:*

$$\begin{aligned}&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(a')) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \\ &\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b')) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(b)) \wedge \\ &\mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(b')) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(b), \mathsf{E1}(b')).\end{aligned}$$

Lean4 ✓ `BEDC.Derived.RealUp.RealSelectedTransport common rational classifier class`

Proof. Apply Definition 38.866 to the displayed hypotheses and project the synchronized displayed rows. This gives unary rows for a, a', b, b' and the four tail rows $\mathsf{hsame}(a, a')$, $\mathsf{hsame}(b, b')$, $\mathsf{hsame}(a, b)$, and $\mathsf{hsame}(a', b')$.

The two remaining tail rows come from Definition 3.8. Compose $\mathsf{hsame}(a, b)$ with $\mathsf{hsame}(b, b')$ to obtain $\mathsf{hsame}(a, b')$. Compose the symmetry of $\mathsf{hsame}(a, a')$ with $\mathsf{hsame}(a, b)$ to obtain $\mathsf{hsame}(a', b)$.

For each displayed pair among (a, a'), (a, b), (a, b'), (a', b), (a', b'), and (b, b'), use the corresponding two unary rows and tail hsame row. The reverse direction of Definition 37.49 lifts that data to the six displayed RatHistoryClassifier rows, which are exactly the complete clique. □

Lean4 ✓ `BEDC.Derived.RealUp.RealSelectedTransport synchronized e1 classifier clique`

Fit: traditional target synchronized RegSeqRat selected-observation classifier completion; BEDC source RealUp stream classifier plus RatUp e-one classifier exactness plus FKernel hsame; carrier rational-observation streams with selected displayed e-one tails; classifier RealStreamClassifier feeding RatHistoryClassifier through E1 displays; stability pointwise hsame and tail-level symmetry and transitivity; ledger selected index, contexts, transported endpoints, unary tails, and six pairwise classifier rows; core theorem Definition 38.862 in future Lean namespace `BEDC.Derived.RealUp`; exactness predicate complete displayed e-one rational-classifier clique; downstream use RealUp dyadic endpoint normalization; status ProofTarget.

Theorem 38.863 (Real selected transport synchronized appended-tail classifier clique)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, indices* m, n*, and histories* $a, a', b, b', d_X, d_Y, e_X, e_Y, w_X, w_Y, z_X, z_Y : \mathsf{Hist}$*, assume the pointwise transport rows and the source stream classifier row*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

Assume also the selected transported context rows

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

the selected continuation rows

$$\mathsf{Cont}(p_X(n), x'(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y'(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y($$

and the selected e-one displays

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a$$

Then the selected transport supplies the displayed classifier clique together with the appended-tail exclusions:

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(a')) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \\
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b')) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(b)) \wedge \\
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(b')) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(b), \mathsf{E1}(b')) \wedge \\
&(\mathsf{hsame}(o_X(n), d_X \cdot \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), d_Y \cdot \mathsf{E0}(z_Y)) \to \mathsf{False}) \wedge \\
&(\mathsf{hsame}(x'(n), e_X \cdot \mathsf{E0}(w_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), e_Y \cdot \mathsf{E0}(w_Y)) \to \mathsf{False}).
\end{aligned}$$

Proof. Apply Definition 38.862 to the selected-transport hypotheses. This yields the six displayed RatHistoryClassifier rows as a single clique package.

Apply Definition 38.622 to the same selected-transport hypotheses. Project its appended-tail component to obtain the four exclusions for $o_X(n)$, $o_Y(n)$, $x'(n)$, and $y'(n)$.

Conjoin the six classifier projections with the four appended-tail projections. The resulting ten conjuncts are exactly the displayed conclusion. □

Fit: traditional target selected RegSeqRat endpoint normalization; BEDC source RealStreamClassifier, RatHistoryClassifier, Cont, and hsame; carrier rational-observation streams; classifier RealStreamClassifier feeding displayed RatHistoryClassifier rows; stability pointwise transport, context closure, e-one inversion, and positive-denominator obstruction; ledger selected index, four displayed tails, context outputs, and appended-tail probes; core theorem Definition 38.863; exactness classifier clique plus malformed-tail exclusion; standard bridge dyadic selected endpoint normalization; status ProofTarget.

Theorem 38.864 (Real selected transport common rational classifier class)**.** *Under the hypotheses of Definition 38.866, the displayed selected representative* $\mathsf{E1}(a)$ *is a RatUp classifier hub for the contextual outputs and the transported selected source endpoints:*

$$\begin{aligned}&\mathsf{RatHistoryClassifier}(o_X(n), \mathsf{E1}(a)) \wedge \mathsf{RatHistoryClassifier}(o_Y(n), \mathsf{E1}(a)) \wedge \\ &\mathsf{RatHistoryClassifier}(x'(n), \mathsf{E1}(a)) \wedge \mathsf{RatHistoryClassifier}(y'(n), \mathsf{E1}(a)) \wedge \\ &\mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(a)) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(b), \mathsf{E1}(a)) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(b'), \mathsf{E1}(a)).\end{aligned}$$

Proof. Apply Definition 38.866 to the displayed hypotheses. Project the displayed endpoint rows $\mathsf{hsame}(o_X(n), \mathsf{E1}(a))$, $\mathsf{hsame}(o_Y(n), \mathsf{E1}(b))$, $\mathsf{hsame}(x'(n), \mathsf{E1}(a))$, and $\mathsf{hsame}(y'(n), \mathsf{E1}(b))$, together with the selected displayed classifier row $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$.

Apply Definition 38.862 under the same hypotheses. This supplies the complete displayed e-one classifier clique. Use Definition 37.55 to orient the rows through the chosen center, giving $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(a))$, $\mathsf{RatHistoryClassifier}(\mathsf{E1}(b), \mathsf{E1}(a))$, and $\mathsf{RatHistoryClassifier}(\mathsf{E1}(b'), \mathsf{E1}(a))$.

The self-row $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(a))$ follows by composing $\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b))$ with its symmetric row using Definition 37.53. Transport this self-row along $\mathsf{hsame}(o_X(n), \mathsf{E1}(a))$ and $\mathsf{hsame}(x'(n), \mathsf{E1}(a))$ by Definition 37.54, with FKernel hsame symmetry and reflexivity supplying the needed endpoint orientations. This gives the $o_X(n)$ and $x'(n)$ classifier rows centered at $\mathsf{E1}(a)$.

Finally transport $\mathsf{RatHistoryClassifier}(\mathsf{E1}(b), \mathsf{E1}(a))$ along $\mathsf{hsame}(o_Y(n), \mathsf{E1}(b))$ and $\mathsf{hsame}(y'(n), \mathsf{E1}(b))$, again using Definition 37.54 with the appropriate FKernel hsame orientations. The four transported endpoint rows together with the three oriented displayed-tail rows are exactly the stated common classifier class. □

Fit: traditional target common selected rational observation representative; BEDC source RealUp selected transport plus RatUp classifier transport plus FKernel hsame; carrier rational-observation streams; classifier RatHistoryClassifier centered at $\mathsf{E1}(a)$; stability selected endpoint hsame transport and classifier symmetry; ledger selected index, contextual outputs, transported source endpoints, and displayed e-one tails; core theorem Definition 38.864; exactness all selected endpoints read through the same rational classifier class; standard bridge RegSeqRat selected dyadic representative; status ProofTarget.

Theorem 38.865 (Real selected transport synchronized package from stream classifier)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, indices* m, n*, and histories* $a, a', b, b', z_X, z_Y : \mathsf{Hist}$*, assume the pointwise transport rows and the source stream classifier row*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

Assume also the selected transported context rows

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

the selected continuation rows

$\mathsf{Cont}(p_X(n), x'(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y'(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y($

and the selected e-one displays

$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a)$

Then the selected transport carries the following packages simultaneously.

1. *The contextual endpoint package of Definition 38.599:*

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(o_X(n), o_Y(n)),\\
&\mathsf{PositiveUnaryDenominator}(o_X(n)) \wedge \mathsf{PositiveUnaryDenominator}(o_Y(n)),\\
&\mathsf{UnaryHistory}(o_X(n)) \wedge \mathsf{UnaryHistory}(o_Y(n)),\\
&(\mathsf{hsame}(o_X(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{e}) \to \mathsf{False}),\\
&(\mathsf{hsame}(o_X(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(o_Y(n), \mathsf{E0}(z_Y)) \to \mathsf{False}),\\
&\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).
\end{aligned}$$

2. *The contextual e-one tail determinacy package of Definition 38.601:*

$$\begin{aligned}
&\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(a') \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{UnaryHistory}(b') \wedge\\
&\mathsf{hsame}(a, a') \wedge \mathsf{hsame}(b, b') \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(a', b').
\end{aligned}$$

3. *The finite-prefix selected full-shape readback package of Definition 38.603:*

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b) \wedge\\
&\mathsf{PositiveUnaryDenominator}(x'(n)) \wedge \mathsf{PositiveUnaryDenominator}(y'(n)) \wedge \mathsf{UnaryHistory}(x'(n)) \wedge \mathsf{UnaryHistory}(y'(n\\
&(\mathsf{hsame}(x'(n), \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{e}) \to \mathsf{False}) \wedge\\
&(\mathsf{hsame}(x'(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{E0}(z_Y)) \to \mathsf{False}).
\end{aligned}$$

4. *The synchronized displayed rows*

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(b')) \wedge\\
&\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(a') \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{UnaryHistory}(b') \wedge\\
&\mathsf{hsame}(a, a') \wedge \mathsf{hsame}(b, b') \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(a', b').
\end{aligned}$$

Proof. Apply Definition 38.106 to $\mathsf{RealStreamClassifier}(x, y)$ at the finite length $m + n$. This produces the derived row $\mathsf{RealStreamPrefixClassifier}(x, y, m + n)$.

Apply Definition 38.621 with the derived prefix row, the source stream classifier row, the two pointwise transport rows, and the remaining context, continuation, and displayed e-one hypotheses. The four returned packages are exactly the four packages displayed above. □

Fit: traditional target selected RealUp observation synchronization from a stream classifier; BEDC source RealUp stream classifier plus RatUp, StreamNameUp, and Cont; carrier rational-observation streams; classifier RealStreamClassifier with derived finite-prefix row; stability pointwise hsame transport, contextual continuation, and e-one inversion; ledger selected index, prefix length, transport rows, contexts, and four tails; core theorem Definition 38.865; exactness the four synchronized packages; standard bridge selected RegSeqRat dyadic observation readback; status ProofTarget.

Fit: traditional target synchronized transported RealUp selected-observation certificate; BEDC source RealUp stream transport plus RatUp and FKernel Cont; carrier rational-observation streams; classifier RealStreamClassifier plus displayed RatHistoryClassifier rows; stability pointwise hsame, context closure, stream-classifier finite-prefix closure, e-one inversion; ledger selected index, prefix surplus, four tails, contexts; core theorem Definition 38.621; exactness package plus synchronized classifiers; standard bridge selected RegSeqRat dyadic observation readback; status ProofTarget.

Theorem 38.866 (Real selected transport synchronized fit from stream classifier)**.** *For rational-observation streams* $x, x', y, y', p_X, p_Y, t_X, t_Y, m_X, m_Y, o_X, o_Y : \mathbb{N} \to \mathsf{Hist}$*, indices* m, n*, and histories* $a, a', b, b', z_X, z_Y : \mathsf{Hist}$*, assume the pointwise transport rows and the source stream classifier row*

$$\forall i,\ \mathsf{hsame}(x(i), x'(i)), \quad \forall i,\ \mathsf{hsame}(y(i), y'(i)), \quad \mathsf{RealStreamClassifier}(x, y).$$

Assume also the selected transported context rows

$$\mathsf{UnaryHistory}(p_X(n)), \quad \mathsf{UnaryHistory}(t_X(n)), \quad \mathsf{hsame}(p_X(n), p_Y(n)), \quad \mathsf{hsame}(t_X(n), t_Y(n)),$$

the selected continuation rows

$$\mathsf{Cont}(p_X(n), x'(n), m_X(n)), \quad \mathsf{Cont}(m_X(n), t_X(n), o_X(n)), \quad \mathsf{Cont}(p_Y(n), y'(n), m_Y(n)), \quad \mathsf{Cont}(m_Y(n), t_Y(n), o_Y($$

and the selected e-one displays

$$\mathsf{hsame}(o_X(n), \mathsf{E1}(a)), \quad \mathsf{hsame}(o_X(n), \mathsf{E1}(a')), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b)), \quad \mathsf{hsame}(o_Y(n), \mathsf{E1}(b')), \quad \mathsf{hsame}(x'(n), \mathsf{E1}(a$$

Then the selected transport carries the following packages simultaneously.

1. *The contextual endpoint package of Definition 38.599:*

$$\begin{aligned}

&(\mathsf{hsame}(x'(n), \mathsf{E0}(z_X)) \to \mathsf{False}) \wedge (\mathsf{hsame}(y'(n), \mathsf{E0}(z_Y)) \to \mathsf{False}).
\end{aligned}$$

4. *The synchronized displayed rows*

$$\begin{aligned}
&\mathsf{RatHistoryClassifier}(\mathsf{E1}(a), \mathsf{E1}(b)) \wedge \mathsf{RatHistoryClassifier}(\mathsf{E1}(a'), \mathsf{E1}(b')) \wedge\\
&\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(a') \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{UnaryHistory}(b') \wedge\\
&\mathsf{hsame}(a, a') \wedge \mathsf{hsame}(b, b') \wedge \mathsf{hsame}(a, b) \wedge \mathsf{hsame}(a', b').
\end{aligned}$$

Proof. Apply Definition 38.106 to $\mathsf{RealStreamClassifier}(x, y)$ at the finite length $m + n$. This gives the prefix row $\mathsf{RealStreamPrefixClassifier}(x, y, m + n)$.

Apply Definition 38.621 to the two pointwise transport rows, the source stream classifier row, the derived prefix row, the selected context rows, the selected continuation rows, and the six selected e-one display rows. Its conclusion is exactly the four packages listed above. □

Fit: traditional target stream-classifier-closed synchronized transported RealUp selected-observation certificate; BEDC source Definition 38.106 plus Definition 38.621; carrier rational-observation streams; classifier RealStreamClassifier with the finite-prefix row derived internally; stability pointwise hsame, context closure, e-one inversion, and selected full-shape readback; ledger selected index, prefix surplus, four tails, contexts, and derived prefix row; core theorem Definition 38.866 in future Lean namespace `BEDC.Derived.RealUp`; exactness predicate the four synchronized selected-transport packages; standard bridge RealUp selected RegSeqRat endpoint synchronization; status ProofTarget.

Theorem 38.867 (Real L10 route sibling exhaustion)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *terminal seal read exposed to the L10 Real and Completion route factors through exactly the displayed four sibling certificates*

chapter 291, *chapter* 126, *chapter* 301,
chapter 38.

The route projects only the finite-window StreamName rows, the dyadic-radius and tolerance ledger rows, the regular-sequence readback rows, and the local $\mathsf{Real}^{\uparrow}$ *terminal seal rows, together with their displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support.*

No quotient stream, host real equality, selected limit, countable-choice selector, ambient completeness coordinate, metric-completeness coordinate, or standard bridge row is part of that accepted terminal seal read.

Proof. First read the selected transport package through Definition 38.865. It supplies the finite-prefix selected full-shape package, the contextual endpoint package, and the synchronized displayed e-one rows from a single stream classifier source.

Next use Definition 38.866. The fit theorem identifies the same selected data as a synchronized transported $\mathsf{Real}^{\uparrow}$ observation certificate; the selected index, prefix surplus, four tails, context rows, continuation rows, and derived prefix row remain explicit finite data.

The L10 sibling route children then identify where those rows can be consumed. Definition 38.530 places every accepted open-phase seal read over the StreamName, RegSeqRat, DyadicRatCore, and local Real surfaces. Definition 38.413 and Definition 38.534 make this surface deterministic and exclude deletion or replacement of any displayed face. Definition 38.732 carries the same four-face route to the current terminal exit read.

Finally project the four rows named in the statement. The StreamName row is the finite observation window; the DyadicRatCore row is the dyadic endpoint and radius ledger; the RegSeqRat row is the finite regular-sequence request and readback surface; the local $\mathsf{Real}^{\uparrow}$ row supplies the terminal seal face after those three rows are read. Since the cited route theorems expose no constructor for quotient streams, host equality, selected limits, countable choice, ambient completeness, metric completeness, or a standard bridge row, the displayed four sibling certificates exhaust the accepted terminal seal route. □

Theorem 38.868 (Real L10 terminal four-face support minimality pullback)**.** *Let* $\mathcal{T}$ *be an accepted* $\mathsf{Real}^{\uparrow}$ *terminal seal read for the current Phase Real and Completion exit route. If a Real-facing*

terminal presentation has the same carrier verdict and the same classifier verdict as $\mathcal{T}$, then that presentation pulls back to exactly the four sibling certificates

$$\mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

and to the displayed support rows

$$\mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

The pullback is minimal at the terminal seal: deleting any one of those four sibling certificates, or deleting any one of the displayed support rows, prevents the presentation from carrying the same Real-facing carrier and classifier verdicts.

No quotient stream equality, selected limit, countable-choice selector, ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate, metric-completeness coordinate, aggregate formalstatus row, or bridge row belongs to this terminal support surface.*

Proof. First read the accepted terminal seal through Definition 38.867. It places every accepted $\mathsf{Real}^{\uparrow}$ terminal seal read on the four sibling certificates $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, carried by the displayed BHist, hsame, Cont, Pkg, and NameCert rows.

Next apply Definition 126.653 to the StreamName-facing terminal section. The same carrier and classifier verdicts cannot be presented after deleting the finite StreamName window, the dyadic ledger face, the RegSeqRat readback face, the local Real seal face, or any one of the listed support rows.

Finally compare the RegSeqRat terminal boundary by Definition 301.239. That exactness result reads the local $\mathsf{Real}^{\uparrow}$ terminal seal precisely from the compatible four-face packet over the shared support rows, so any Real-facing presentation with the same carrier and classifier verdict must pull back to that packet and to no smaller packet.

The exclusion list is inherited from the three cited route descriptions. Their terminal packets contain no quotient stream equality, selected limit, countable-choice selector, ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate, metric-completeness coordinate, aggregate formalstatus row, or bridge row, so none of those rows can replace a missing sibling certificate or displayed support row at the terminal seal. □

Theorem 38.869 (Real L10 terminal route support induction)**.** *Let*

$$\mathcal{T}_0, \mathcal{T}_1, \ldots, \mathcal{T}_n$$

be a finite replay chain of accepted Real-facing terminal presentations for the current Phase Real and Completion exit route. Suppose each successive replay step preserves the $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, the* $\mathsf{StreamName}^{\uparrow}$ *terminal-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-request and readback row, the local* $\mathsf{Real}^{\uparrow}$ *terminal seal row, and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *support rows. Then the terminal read of every $\mathcal{T}_i$ lies on the same four-face support surface*

$$\mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

with those displayed support rows. If a replay step fails to preserve the terminal read, the failure is witnessed by one of the four faces or by one of the displayed support rows.

The induction introduces no quotient stream, host real equality, selected limit, countable-choice selector, ambient completeness coordinate, metric-completeness coordinate, aggregate formalstatus row, or bridge row.

Proof. For the base presentation $\mathcal{T}_0$, apply Definition 38.868. The terminal read pulls back to the four sibling certificates and to the displayed BHist, hsame, Cont, Pkg, and NameCert rows, and no smaller or off-route packet carries the same Real-facing verdicts.

For the successor step, assume $\mathcal{T}_i$ has already been read on that support surface. The replay hypotheses identify the next presentation $\mathcal{T}_{i+1}$ on the same dyadic endpoint and radius ledger, the same StreamName terminal window, the same RegSeqRat finite request and readback row, the same local Real seal row, and the same displayed support rows.

Apply Definition 126.660 to replay the terminal-window support through the ordered four faces. Then use Definition 301.54 to carry the finite request and readback witness across the RegSeqRat-to-Real seal boundary. Finally, Definition 38.867 says that every accepted Real-facing terminal read on this route is exhausted by exactly those sibling faces and rows.

Thus the successor presentation remains on the same support surface. If the successor replay fails, one of the hypotheses just used is absent: the dyadic ledger, StreamName window, RegSeqRat request/readback face, local Real seal, or one of the displayed BHist, hsame, Cont, Pkg, and NameCert rows has changed or disappeared.

Finite induction over the replay chain now gives the claim for all $\mathcal{T}_i$. The exclusion list is inherited at each step from the minimality pullback and route exhaustion theorems, so no quotient stream, host real equality, selected limit, choice selector, completeness coordinate, formalstatus row, or bridge row can enter the terminal support surface. □

Theorem 38.870 (Real L10 terminal support cover induction)**.** *Let $\mathcal{U}$ be a finite family of accepted Real-facing terminal presentations for the current Phase Real and Completion exit route. Suppose each replay step inside each member of $\mathcal{U}$ preserves the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger, the* $\mathsf{StreamName}^{\uparrow}$ *terminal-window row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-request and readback row, the local* $\mathsf{Real}^{\uparrow}$ *terminal seal row, and the shared* BHist, hsame, Cont, Pkg, *and* NameCert *support rows. Suppose also that every finite subcover of $\mathcal{U}$ satisfies the objectwise Phase Real and Completion threshold, and that overlaps agree on those four faces and support rows.*

Then the whole replay-cover satisfies the same objectwise Phase Real and Completion threshold. If a member or an overlap fails to contribute to that threshold, the failure localizes to one displayed face

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

or to one displayed support row among BHist, hsame, Cont, Pkg, *and* NameCert.

The cover induction asserts no quotient stream equality, selected limit, countable-choice selector, metric-completeness datum, aggregate formalstatus row, bridge row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. First run the terminal support induction inside each cover member. Apply Definition 38.869 to each finite replay chain. The result keeps every accepted Real-facing terminal presentation on the same displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and local $\mathsf{Real}^{\uparrow}$ support surface, with the shared BHist, hsame, Cont, Pkg, and NameCert rows.

Next compare the StreamName and RegSeqRat cover faces. Apply Definition 126.660 to keep the terminal-window rows stable under replay. Apply Definition 301.245 to transport the finite-request, readback, and regularity rows through the finite four-face cover. The overlap hypotheses are exactly the rows consumed by these two induction principles.

Now glue the local threshold packets. Apply Definition 38.843 to the finite family whose members already satisfy the objectwise Phase Real and Completion threshold on the displayed faces. The overlap agreement supplies the common dyadic ledger, StreamName window, RegSeqRat

readback, local Real seal, BHist, hsame, Cont, Pkg, and NameCert support needed by the gluing theorem.

Finally descend from the glued finite packet to the whole replay-cover. Apply Definition 38.844. Any failed descent hypothesis is one of the same visible faces or support rows, so the failure localizes there and not to an off-route completion coordinate.

The exclusion clauses in the support induction, the StreamName and RegSeqRat cover inductions, and the gluing and descent theorems all refuse quotient stream equality, selected limits, countable choice, metric completeness, aggregate formalstatus rows, bridge rows, and ambient $\mathsf{Real}^{\uparrow}$ completeness. Thus the composed cover result remains a finite four-face terminal support claim and carries no route-level strengthening. □

Theorem 38.871 (Real L10 route-cover phase-exit exactness)**.** *Let $\mathcal{U}$ be a finite replay-cover of accepted Real-facing terminal presentations for the current Phase Real and Completion exit route. Suppose $\mathcal{U}$ satisfies the terminal support cover induction of Definition 38.870, and suppose the four roadmap faces of every cover member and overlap meet the local scoped and audit records required by Definition 1327.16.*

Then $\mathcal{U}$ supplies the public Phase Real and Completion exit read exactly through

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

and through the same-route RealCompletionExactBoundaryUp *witness. The read uses the displayed* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *support rows from the Real L10 route, and it admits no quotient stream, selected limit, countable-choice selector, host-completeness row, metric-completeness coordinate, aggregate formalstatus row, or bridge token.*

Proof. First apply Definition 38.870. The finite replay-cover is reduced to the displayed terminal support surface: $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, local $\mathsf{Real}^{\uparrow}$, and the shared BHist, hsame, Cont, Pkg, and NameCert rows. Any failed cover contribution is already localized to one of those rows.

Next apply Definition 38.867 and Definition 38.868. These results keep the Real-facing terminal read on the same L10 route and forbid a smaller packet, off-route packet, quotient stream, selected limit, choice selector, host-completeness row, metric-completeness coordinate, aggregate formalstatus row, or bridge token from carrying the same verdicts.

Now read the phase-exit side. The hypotheses give the local scoped closure records and audit-clean verification records for the four roadmap faces, so Definition 1327.16 projects the accepted packet to exactly

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The same theorem keeps RealCompletionExactBoundaryUp as the boundary witness on the same route rather than as a fifth roadmap object or an aggregate status row.

Combining the two reads gives the public Phase Real and Completion exit criterion from the Real chapter itself. The cover induction supplies the finite Real terminal surface, the route exhaustion and minimality theorems pin that surface to the L10 route, and the phase-exit projection consumes the four local scoped/audit records while preserving the same-route exact-boundary witness. No collapsed completion object, ambient completeness principle, selected limit, quotient stream, countable choice, aggregate formalstatus row, or bridge token is introduced by the composition. □

Theorem 38.872 (Real L10 route-cover phase-exit converse)**.** *Let $\mathcal{U}$ be a finite Real-facing replay-cover whose accepted public read supplies the current Phase Real and Completion exit. Then the public exit read pulls back exactly to the four object faces*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The pullback is witnessed by the displayed Real L10 support rows

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}$$

carried on the same route. Each of the four faces must carry the local scoped-closure and audit-clean records required by Definition 1327.16; the same-route RealCompletionExactBoundaryUp *row remains a boundary witness and not a fifth roadmap face.*

Equivalently, no cover member, overlap, or public read of $\mathcal{U}$ can serve the Phase Real and Completion exit unless its visible data are already the four listed faces with those displayed support rows and those local scoped/audit records. Quotient streams, selected limits, countable choice, metric completeness, aggregate formalstatus rows, bridge tokens, and ambient $\mathsf{Real}^{\uparrow}$ *completeness are not admissible substitutes for any of the four faces or their local records.*

Proof. Start from the accepted public exit read and restrict it to the finite Real-facing replay-cover. Apply Definition 38.871 to identify the available public read with the Real L10 terminal support surface whenever the local threshold records are present.

It remains to show that no smaller or off-route surface can supply those records. Apply Definition 38.870 to localize every cover contribution to a terminal support row, then apply Definition 38.868. The minimality pullback says that deleting any one of the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or local $\mathsf{Real}^{\uparrow}$ faces, or deleting one of the displayed BHist, hsame, Cont, Pkg, or NameCert rows, loses the accepted terminal verdict.

The route itself is fixed by Definition 38.867. Thus any attempted witness outside the L10 route is pushed back to the same four-face support surface, or else is rejected as an off-route consumer packet.

Finally apply Definition 1327.16. The phase-exit projection requires the four roadmap faces to be read through their own local scoped-closure and audit-clean records, while keeping RealCompletionExactBoundary as a same-route boundary witness. The same projection rules out quotient streams, selected limits, countable choice, metric completeness, aggregate formalstatus rows, bridge tokens, and ambient $\mathsf{Real}^{\uparrow}$ completeness as substitutes. Hence the public exit read pulls back exactly to the four displayed faces with the displayed support rows. □

Theorem 38.873 (Real L10 four-face public pullback criterion)**.** *Let $\mathcal{P}$ be a finite consumer packet presented on the Real L10 route at the public Phase Real and Completion boundary. Then $\mathcal{P}$ is exactly the four-face pullback for that boundary if and only if its accepted public data agree componentwise with the following four object faces:*

1. *the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, radius, and tolerance ledger;*
2. *the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows;*
3. *the* $\mathsf{RegSeqRat}^{\uparrow}$ *finite-request, readback, and classifier rows;*
4. *the local* $\mathsf{Real}^{\uparrow}$ *terminal seal rows.*

The agreement is witnessed using only the displayed BHist, hsame, Cont, Pkg, *and* NameCert *support carried by the Real L10 route. Equivalently, two such finite consumer packets determine the*

same public Phase Real and Completion read precisely when they have the same four listed faces and the same displayed support rows. The criterion does not use quotient stream equality, selected host limits, countable-choice selectors, ambient completeness, metric-completeness rows, aggregate formalstatus rows, or bridge tokens.

Proof. For the forward direction, assume $\mathcal{P}$ is the public four-face pullback. Apply Definition 38.871 to read the public boundary through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and the same-route $\mathsf{RealCompletionExactBoundaryUp}$ witness. Then apply Definition 38.867 to remove any off-route source, and apply Definition 38.868 to see that the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows are the whole terminal support.

For the reverse direction, assume the four object faces and the displayed support rows agree componentwise. The Definition 126.152 transports the StreamName finite-window rows through the RegSeqRat and local Real readback surface, while Definition 301.56 normalizes the finite-request, readback, classifier, and seal rows to the visible source format. Finally Definition 38.413 identifies the resulting Real-facing packet with the four-face pullback at the open Phase Real boundary.

Combining the two directions gives the stated if and only if. The exclusion clauses are inherited from route exhaustion, terminal support minimality, the route-cover exactness theorem, and the three finite-window and seal-route pullback criteria just used. Each of those results keeps the construction on finite NameCert support, so quotient stream equality, selected host limits, countable choice, ambient or metric completeness, aggregate formalstatus rows, and bridge tokens never enter the witness. □

Theorem 38.874 (Real L10 terminal cover support normal form)**.** *Let $\mathcal{U}$ be a finite family of accepted Real-facing terminal presentations on the current Phase Real and Completion exit route. Then $\mathcal{U}$ satisfies the terminal cover support normal form if and only if each member of $\mathcal{U}$, and each overlap between two members of $\mathcal{U}$, factors through exactly the four L10 faces* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *together with the displayed* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows carried by those faces. No quotient stream, host real equality, selected limit, choice selector, metric-completeness row, ambient completeness coordinate, aggregate formalstatus row, or bridge row is part of this normal form.*

Proof. For the forward direction, assume that $\mathcal{U}$ satisfies the terminal cover support normal form. Apply Definition 38.870 to reduce each member and overlap of the finite cover to terminal support on the Real L10 route. Then apply Definition 126.662 and Definition 301.246. These two finite-cover results identify the StreamName and RegSeqRat contributions with the same four displayed object faces and the same displayed support rows.

It remains to account for the public Phase Real and Completion boundary. Definition 38.873 transports the terminal cover data through the public pullback read. Since the pullback criterion excludes off-surface witnesses, every accepted member and every accepted overlap factors only through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

For the reverse direction, assume that every member and overlap of $\mathcal{U}$ factors through exactly the four displayed faces with the displayed support rows. Apply Definition 38.871 to package this four-face data as Real L10 route cover data at the Phase Real and Completion exit. Then use Definition 38.872 to recover accepted Real-facing terminal presentations from that route cover packet.

Finally apply Definition 38.873 once more to identify the rebuilt terminal presentations with the public four-face pullback. The excluded rows cannot be added during this reconstruction: terminal

support cover induction accounts only for finite support rows, the StreamName and RegSeqRat normal forms account only for finite cover faces, and the public pullback criterion keeps quotient streams, host real equality, selected limits, choice selectors, metric or ambient completeness data, aggregate formalstatus rows, and bridge rows outside the accepted normal form. □

Theorem 38.875 (Real L10 terminal route support bicriterion)**.** *Let $\mathcal{U}$ be a finite Real-facing terminal cover at the current Phase Real and Completion public route. Then $\mathcal{U}$ presents that public route if and only if every member of $\mathcal{U}$, and every overlap between two members of $\mathcal{U}$, factors through exactly* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *local* $\mathsf{Real}^{\uparrow}$, *and the displayed* BHist, hsame, Cont, Pkg, *and* NameCert *rows carried by those four faces. Equivalently, two such terminal covers have the same public route read precisely when their* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and local* $\mathsf{Real}^{\uparrow}$ *faces agree and their displayed support rows agree.*

No quotient stream, selected limit, countable-choice selector, metric-completeness datum, aggregate formalstatus row, bridge row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness is part of either side of the criterion.*

Proof. For the forward direction, assume that $\mathcal{U}$ presents the public Phase Real and Completion route. Apply Definition 38.874 to put the finite terminal cover in support normal form. Then apply Definition 38.873 to identify the public route read with equality of the four displayed object faces and the displayed BHist, hsame, Cont, Pkg, and NameCert rows.

For the reverse direction, assume that every member and overlap factors through exactly the four listed faces and the displayed support rows. Apply Definition 38.871 to package these finite rows as Real L10 route-cover data at the Phase Real and Completion exit. Then apply Definition 38.872 to recover the accepted terminal presentations on the same public route.

The equivalence of public route reads is the same argument with two covers in parallel: the normal-form theorem reduces each cover to the four faces and support rows, and the four-face public pullback criterion compares exactly those data. The exclusions are preserved because each cited theorem keeps the route finite and terminal: route-cover exactness and converse introduce only accepted Real L10 rows, the normal form admits only the four displayed faces, and the public pullback criterion refuses quotient streams, selected limits, countable choice, metric or ambient completeness data, aggregate formalstatus rows, and bridge rows. □

Definition 38.876 (Real terminal-route modulus extraction packet)**.** *A Real terminal-route modulus extraction packet is a finite* BHist *read attached to an accepted* $\mathsf{Real}^{\uparrow}$ *terminal seal presentation. It contains exactly the terminal four-face support rows*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

together with the displayed BHist, hsame, Cont, Pkg, *and* NameCert *support, plus a visible* RealModulusOfConvergenc *row that is read only through that same terminal support surface. The packet has no coordinate for quotient streams, selected limits, host real equality, countable choice, metric completeness, ambient Real completeness, aggregate formalstatus rows, or bridge tokens.*

Theorem 38.877 (Real terminal-route modulus extraction)**.** *Every accepted* $\mathsf{Real}^{\uparrow}$ *terminal seal read that exposes a* $\mathsf{RealModulusOfConvergence}^{\uparrow}$ *row factors that row through the same four-face support surface*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

and through the displayed BHist, hsame, Cont, Pkg, *and* NameCert *rows of the Real L10 route. Thus terminal-route modulus extraction is a finite packet in the sense of Definition 38.876; it does not*

export quotient streams, selected limits, host real equality, countable choice, metric completeness, ambient Real completeness, aggregate formalstatus rows, or bridge tokens.

Proof. First read the accepted terminal seal through Definition 38.867. This places every terminal Real-facing read on the four sibling certificates $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and local $\mathsf{Real}^{\uparrow}$, carried by the displayed support rows.

Apply Definition 38.868. The same carrier and classifier verdicts cannot be preserved after deleting any one of the four faces or any one of the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

Use Definition 38.875 to compare the terminal cover that carries the seal with the cover that carries the exposed $\mathsf{RealModulusOfConvergence}^{\uparrow}$ row. The bicriterion says that equality of the public route read is exactly equality of the four faces and the displayed support rows, so the modulus row cannot be read on a separate support surface.

Finally project the $\mathsf{RealModulusOfConvergence}^{\uparrow}$ carrier from Definition 2074.1. Its dyadic tolerance, finite window, regular readback, monotone ledger, and Real seal rows are already among the terminal four faces or downstream of them. Since both the Real route and the modulus carrier exclude quotient streams, selected limits, host real equality, countable choice, metric completeness, ambient completeness, aggregate formalstatus rows, and bridge tokens, the extraction packet exports none of those objects. □

Theorem 38.878 (Real L10 terminal route support obstruction)**.** *Let $\mathcal{U}$ be a finite Real-facing terminal cover at the current Phase Real and Completion public route. If $\mathcal{U}$ does not present that public route, then some member of $\mathcal{U}$, or some overlap between two members of $\mathcal{U}$, fails to factor through one visible L10 face*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

or through one displayed Real L10 support row among

$$\mathsf{BHist}, \quad \mathsf{hsame}, \quad \mathsf{Cont}, \quad \mathsf{Pkg}, \quad \mathsf{NameCert}.$$

The obstruction is local to that missing face or support row. Quotient streams, selected limits, countable-choice selectors, metric or ambient completeness data, aggregate formalstatus rows, and bridge rows cannot repair the failed public route presentation.

Proof. Argue contrapositively from Definition 38.875. If every member and every overlap of $\mathcal{U}$ factors through the four displayed faces and the five displayed support rows, then the bicriterion presents the current Phase Real and Completion public route.

Therefore a finite cover that does not present the public route must fail one of the finite factorization requirements consumed by the bicriterion. Apply Definition 38.874 to put those requirements in terminal-cover normal form. This identifies the possible failure sites with the object rows $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and local $\mathsf{Real}^{\uparrow}$, together with the displayed BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows.

It remains to rule out an off-surface rescue. Apply Definition 38.873 to the public boundary read: the public route is determined exactly by the four visible faces and the displayed support rows. Then apply Definition 38.872 to pull any accepted public exit read back to the same Real L10 surface.

The two localization steps leave no constructor for quotient streams, selected limits, countable-choice selectors, metric or ambient completeness data, aggregate formalstatus rows, or bridge rows. Hence any failed finite Real-facing terminal cover is obstructed at one visible face or at one displayed support row, and no off-route datum repairs that failure. □

Theorem 38.879 (Real cofinal window transport)**.** *Suppose two terminal* $\mathsf{Real}^{\uparrow}$ *seal reads display cofinal* $\mathsf{StreamName}^{\uparrow}$ *windows and their* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks agree under the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance classifier. Then the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposes the same public name for both reads. The comparison is made through the displayed finite windows, regular rational readbacks, dyadic tolerance rows, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *seal row; it introduces no selected limit, quotient representative, host real equality, countable choice, ambient completeness, or bridge row.*

Proof. Begin with the two displayed $\mathsf{StreamName}^{\uparrow}$ windows. Cofinality says that every finite request used by either terminal read is eventually represented in the other visible window schedule, so the comparison remains inside finite stream data.

Read the $\mathsf{RegSeqRat}^{\uparrow}$ rows attached to those windows. Agreement under the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance classifier identifies the regular rational readbacks only through displayed dyadic endpoint, radius, and tolerance rows, not through a hidden limit object.

Apply the existing Real hub routes through chapter 126, chapter 301, and chapter 291. These routes force the terminal Real-facing read to pass through the same finite-window, regular-readback, and dyadic-tolerance faces before the seal is exposed.

Finally use the terminal seal surface of chapter 38. Since the support rows transport and replay the same finite comparison and the local seal row has no coordinate for selected limits, quotient representatives, host real equality, countable choice, ambient completeness, or bridges, the public $\mathsf{Real}^{\uparrow}$ name exposed by the terminal seal is the same for the two cofinal reads. □

Theorem 38.880 (Real cofinal window symmetry)**.** *Suppose two terminal* $\mathsf{Real}^{\uparrow}$ *seal reads display cofinal* $\mathsf{StreamName}^{\uparrow}$ *windows and their* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks agree under the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance classifier. If the first read exposes the public* $\mathsf{Real}^{\uparrow}$ *name of the second through the displayed finite* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ *rows, then the swapped read exposes the same public* $\mathsf{Real}^{\uparrow}$ *name through the same rows.*

The symmetry statement does not add a selected limit, quotient representative, host real equality, countable-choice schedule, ambient completeness coordinate, or bridge row.

Proof. Swap the two terminal seal reads. Cofinality of the displayed $\mathsf{StreamName}^{\uparrow}$ windows is symmetric: every finite request visible from either side is still eventually represented in the other side's finite window schedule after the swap.

The $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance classifier is also read symmetrically on the displayed $\mathsf{RegSeqRat}^{\uparrow}$ readbacks. The comparison still uses the same dyadic endpoint, radius, and tolerance rows, transported by the same componentwise hsame data and replayed by the same Cont row.

Apply Definition 38.879 to the swapped pair. Its hypotheses are exactly the cofinal window and classifier-agreement rows just identified, with the Pkg provenance and local $\mathsf{NameCert}_{\mathsf{Real}^{\uparrow}}$ seal row unchanged.

Thus the swapped terminal read exposes the same public $\mathsf{Real}^{\uparrow}$ name. Since the cited transport theorem has no coordinate for selected limits, quotient representatives, host real equality, countable choice, ambient completeness, or bridge rows, the symmetric route has none. □

Chapter 39

A Concrete Naming Certificate for $\mathsf{Complex}^{\uparrow}$

The complex number interface $\mathsf{Complex}^{\uparrow}$ is licensed here by the product of two certified rational-history components from chapter 37. The carrier, pattern, and ledger predicates are the same rational-pair history carrier, and the classifier is product history sameness restricted to those two rational-history components. It is not a primitive number system; it is licensed only via the rational source and the pair constructor of chapter 34.

Remark 39.1 (Complex certificate scope)**.** *This chapter records the concrete history-level license: a complex history is the continuation product of two rational-history witnesses, and the classifier is the corresponding product classifier over internal history sameness.*

39.1 Carrier definition

Definition 39.2 (Complex carrier)**.** *Use the BEDC product history carrier over two certified rational-history components.*

Lean4 (definition) `BEDC.Derived.ComplexUp.ComplexHistoryCarrier`

Theorem 39.3 (Complex history carrier is unary)**.** *Every complex history carrier is a unary BEDC history.*

Proof. Unpack the complex carrier as a product of two rational-history carriers and a continuation witness. Each rational component gives a positive unary denominator, hence a unary history. Unary histories are closed under the stored continuation, so the complex carrier endpoint is unary. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryCarrier unary`

Theorem 39.4 (Complex carrier positive components)**.** *Every complex history carrier exposes real and imaginary rational-history components whose denominators are positive unary histories, together with the continuation witness assembling those components into the complex history.*

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryCarrier positive components`

Proof. Unpack the product-history carrier into its real component, imaginary component, component carrier witnesses, and continuation witness. Apply the rational-history carrier characterization to each component to read back the positive unary denominator evidence, and keep the same continuation witness. □

Theorem 39.5 (Complex carrier components are nonempty)**.** *Every complex history carrier exposes rational real and imaginary components whose component histories are not identified with* e*.*

Proof. Unpack the complex carrier into rational real and imaginary components and the continuation assembling them. Rational-history carrier non-emptiness rejects *real*hsamee and *imag*hsamee separately. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryCarrier components nonempty`

Theorem 39.6 (Complex e1-tail carrier component readback)**.** *If* ComplexHistoryCarrier(E1($tail$)) *holds, then there are histories real and imagTail such that real is a rational-history component,* E1($imagTail$) *is a rational-history component, and* Cont($real, imagTail, tail$) *holds.*

Proof. Unpack the complex carrier into rational real and imaginary components and the continuation witness assembling them into E1($tail$). Continuation E1-result inversion gives either an empty imaginary component or an E1-headed imaginary component with tail continuation. The empty branch contradicts rational-history carrier non-emptiness; the visible branch exposes the required rational component and tail continuation. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryCarrier e1 tail components`

Theorem 39.7 (Complex e1-tail carrier nonempty component readback)**.** *If* ComplexHistoryCarrier(E1($tail$)) *holds, then the exposed real component and the exposed visible imaginary component are rational-history carriers and neither is history-same to* e*.*

Proof. Apply the e1-tail component readback to obtain the rational real component, the rational visible imaginary component, and the tail continuation. Rational history-carrier non-emptiness applies separately to the two exposed component carriers while the same continuation witness is retained. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryCarrier e1 tail components nonempty`

Theorem 39.8 (Complex e1-tail carrier positive component readback)**.** *If* ComplexHistoryCarrier(E1($tail$)) *holds, then there are histories real and imagTail such that real is a rational-history component,* E1($imagTail$) *is a rational-history component,* Cont($real, imagTail, tail$) *holds, and both exposed rational components carry positive unary denominators.*

Proof. First apply Theorem 39.6 to read back the real component, the visible imaginary component, and the tail continuation. Then apply the rational-history carrier characterization to both rational component witnesses and keep the same continuation. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryCarrier e1 tail positive components`

Theorem 39.9 (Complex carrier excludes an $e0$ endpoint)**.** *No complex history carrier can be an* $e0$*-headed history.*

Proof. Every complex carrier is unary because it is assembled from unary rational-history components by continuation. A zero-headed BEDC history cannot be unary, so ComplexHistoryCarrier(E0(*tail*)) is impossible. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryCarrier e0 endpoint absurd`

Theorem 39.10 (Complex carrier component reflexive classifiers)**.** *Every complex history carrier exposes real and imaginary rational-history components whose own rational-history classifiers hold reflexively, together with the continuation witness assembling them into the complex history.*

Proof. Unpack the complex carrier as a product-history carrier over two rational-history carriers. The exposed real and imaginary components already carry rational-history carrier evidence. Pair each component carrier with itself and the reflexive hsame witness for that component to form the two rational-history classifiers, and keep the stored continuation witness. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryCarrier component reflexive classifiers`

Theorem 39.11 (Complex carrier left unary context closure)**.** *If p is a unary history and h is a complex history carrier, then* append(p, h) *is again a complex history carrier.*

Proof. Unpack h as a rational real component, a rational imaginary component, and a continuation witness. Close the real component under the left unary denominator context p, keep the imaginary component fixed, and reassociate the continuation by associativity of append. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryCarrier prepend unary closed`

Theorem 39.12 (Complex carrier right unary context closure)**.** *If h is a complex history carrier and q is a unary history, then* append(h, q) *is again a complex history carrier.*

Proof. Unpack h as a rational real component, a rational imaginary component, and a continuation witness. Close the imaginary component under the right unary denominator context q, keep the real component fixed, and reassociate the continuation by associativity of append. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryCarrier append unary closed`

Theorem 39.13 (Complex carrier unary continuation closure)**.** *If h is a complex history carrier, q is unary, and* Cont(h, q, zq)*, then zq is again a complex history carrier.*

Proof. Unpack h into rational real and imaginary components with the continuation assembling them. Associativity of continuation splits the suffix q through the imaginary component. The imaginary rational carrier is closed under the unary suffix and transported along the split continuation result, while the real rational carrier is kept fixed. The resulting component continuation reassembles zq as a complex history carrier. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryCarrier unary continuation closed`

Theorem 39.14 (Complex history carrier is not empty)**.** *No complex history carrier can be identified with the empty history.*

Proof. Unpack the complex carrier into its real rational component, imaginary rational component, and continuation witness assembling the two components. Transport the continuation result to the empty endpoint, invert the empty-result continuation, and obtain that the real rational component is empty. This contradicts the rational-history carrier non-emptiness theorem. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryCarrier not empty`

39.2 The certificate

Definition 39.15 (Complex source specification)**.** *The source is* $\mathsf{Prod}^{\uparrow}(\mathsf{Rat}^{\uparrow}, \mathsf{Rat}^{\uparrow})$ *at the history-carrier level.*

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexTasteGate single carrier alignment`

Definition 39.16 (Complex pattern specification)**.** *The pattern predicate is exactly the rational-pair history carrier: a history matches the pattern when it is a product history assembled from two certified rational-history components.*

Definition 39.17 (Complex classifier specification)**.** *The classifier is product history classification over two rational-history carriers.*

Lean4 (definition) `BEDC.Derived.ComplexUp.ComplexHistoryClassifier`

Theorem 39.18 (Complex history classifier nonempty endpoints)**.** *If* $\mathsf{ComplexHistoryClassifier}(h, k)$ *holds, then neither endpoint can be identified with the empty history.*

Proof. Unpack the classifier into the two complex-history carrier witnesses and the stored endpoint hsame link. Apply complex carrier non-emptiness separately to the source endpoint carrier and to the target endpoint carrier. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier nonempty endpoints`

Theorem 39.19 (Complex history classifier endpoint e-one shapes)**.** *If* $\mathsf{ComplexHistoryClassifier}(h, k)$ *holds, then both classifier endpoints are visibly one-headed histories with unary tails:*

$$(\exists h_t,\ h = \mathsf{E1}(h_t) \wedge \mathsf{UnaryHistory}(h_t)) \wedge (\exists k_t,\ k = \mathsf{E1}(k_t) \wedge \mathsf{UnaryHistory}(k_t)).$$

Proof. The classifier gives carrier witnesses for both endpoints. Complex carrier unarity supplies unary-history evidence for each endpoint, while classifier non-emptiness rules out the empty history on both sides. Applying unary nonempty one-tail readback to each endpoint gives the displayed shapes. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier endpoint e1 shapes`

Theorem 39.20 (Complex classifier positive components)**.** *Every complex history classifier between two histories exposes real and imaginary rational-history components for both endpoints, the continuation ledgers assembling each endpoint, the endpoint* hsame *witness, and positive unary denominator evidence for all four rational components.*

Proof. Unpack the classifier into its two complex carrier witnesses and the stored endpoint hsame proof. Apply the positive-component readback theorem to each carrier. The resulting rational component carriers, continuation ledgers, endpoint sameness, and positive denominator witnesses assemble directly into the displayed endpoint-pair statement. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier positive components`

Theorem 39.21 (Complex e1-endpoint classifier component readback)**.** *If* $\mathsf{ComplexHistoryClassifier}(\mathsf{E1}(tail), h)$ *holds, or if* $\mathsf{ComplexHistoryClassifier}(h, \mathsf{E1}(tail))$ *holds, then there are histories real and imagTail such that real is a rational-history component,* $\mathsf{E1}(imagTail)$ *is a rational-history component, and* $\mathsf{Cont}(real, imagTail, tail)$ *holds.*

Proof. Unpack the complex classifier into its two endpoint carrier witnesses and the stored endpoint hsame proof. In either endpoint position, the E1-headed endpoint supplies a complex carrier. Apply the E1-tail carrier component readback theorem to that carrier. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier e1 endpoint components`

Theorem 39.22 (Complex classifier excludes an $e0$ endpoint)**.** *No complex history classifier can have an $e0$-headed history as either endpoint.*

Proof. Read the $e0$-headed endpoint as a complex carrier and expose its rational real and imaginary components. The continuation result ending in $e0$ either makes the imaginary component empty or makes it itself $e0$-headed. Both cases contradict the positive unary denominator witness attached to the imaginary rational component. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier e0 endpoint absurd`

Theorem 39.23 (Complex classifier excludes empty endpoints)**.** *No complex history classifier can identify either endpoint with the empty history.*

Proof. Unpack the classifier into its two complex carrier witnesses. Apply complex carrier non-emptiness separately to the source endpoint carrier and to the target endpoint carrier. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier empty endpoint absurd`

Theorem 39.24 (Complex history classifier transitivity)**.** *If a complex history classifier relates h to k, and also relates k to r, then it relates h to r. The left endpoint carrier is taken from the first classification, the right endpoint carrier is taken from the second classification, and the history-sameness witnesses compose.*

Proof. Unfolding the classifier exposes the two endpoint carrier witnesses together with two *hsame* links. The endpoint carriers are preserved at the outside of the chain, and the internal links compose by transitivity of *hsame*. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier trans`

Theorem 39.25 (Complex history classifier symmetry)**.** *If* $\mathsf{ComplexHistoryClassifier}(h, k)$*, then* $\mathsf{ComplexHistoryClassifier}(k, h)$*.*

Proof. Unfold the classifier as the product history classifier over two RatHistoryCarrier endpoints. The endpoint carrier witnesses are swapped, and the stored $\mathsf{hsame}(h, k)$ witness is reversed by symmetry to obtain $\mathsf{hsame}(k, h)$. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier symm`

Theorem 39.26 (Complex history classifier unary context closure)**.** *If p and q are unary context histories,* $p\mathsf{hsame}p'$*,* $q\mathsf{hsame}q'$*, and* $\mathsf{ComplexHistoryClassifier}(h, k)$*, then the context-wrapped endpoints* $\mathsf{append}(p, \mathsf{append}(h, q))$ *and* $\mathsf{append}(p', \mathsf{append}(k, q'))$ *are again related by the complex history classifier.*

Proof. Unpack the complex classifier into carrier witnesses for h and k together with the endpoint hsame link. Right unary context closure carries both endpoint carriers through the tail contexts, after transporting unary evidence across $q\mathsf{hsame}q'$. Left unary context closure then carries those results through the prefix contexts, after transporting unary evidence across $p\mathsf{hsame}p'$. The three hsame links identify the two fully wrapped histories, giving the classifier endpoint relation. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier unary context closed`

Theorem 39.27 (Complex classifier unary continuation closure)**.** *If* $\mathsf{ComplexHistoryClassifier}(h, k)$*,* q *is unary,* $q\mathsf{hsame}q'$*,* $\mathsf{Cont}(h, q, zq)$*, and* $\mathsf{Cont}(k, q', wq)$*, then* $\mathsf{ComplexHistoryClassifier}(zq, wq)$*.*

Proof. Apply complex carrier unary continuation closure to both classified endpoints, transporting the unary witness for q across $q\mathsf{hsame}q'$ on the right endpoint. The stored endpoint comparison $h\mathsf{hsame}k$, the suffix comparison $q\mathsf{hsame}q'$, and the two continuation witnesses identify the continuation results, giving the classifier relation between zq and wq. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier unary continuation closed`

Theorem 39.28 (Complex history classifier unary continuation empty endpoint absurdity)**.** *If* $\mathsf{ComplexHistoryClassifier}(h, k)$*,* q *is unary,* $q\mathsf{hsame}q'$*,* $\mathsf{Cont}(h, q, zq)$*, and* $\mathsf{Cont}(k, q', wq)$*, then neither continued endpoint can be internally same as the empty history:*

$$(\mathsf{hsame}(zq, \mathsf{e}) \to \mathsf{False}) \wedge (\mathsf{hsame}(wq, \mathsf{e}) \to \mathsf{False}).$$

Proof. First close the classifier under the two displayed unary continuations. The continued classifier relates zq and wq. Applying complex classifier empty-endpoint exclusion to that continued classifier gives both displayed absurdity clauses. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier unary continuation empty endpoint absurd`

Theorem 39.29 (Complex history classifier unary continuation positive components)**.** *If* $\mathsf{ComplexHistoryClassifier}(h$ q *is unary,* $q\mathsf{hsame}q'$*,* $\mathsf{Cont}(h, q, zq)$*, and* $\mathsf{Cont}(k, q', wq)$*, then the continued endpoints* zq *and* wq *expose real and imaginary rational-history components for both endpoints, the two continuation ledgers, the endpoint* hsame *witness, and positive unary denominator evidence for all four rational components.*

Proof. First apply unary-continuation closure to obtain $\mathsf{ComplexHistoryClassifier}(zq, wq)$. Then apply complex classifier positive-component readback to the continued classifier. The readback exposes the four rational component carriers, the two continuation ledgers assembling the continued endpoints, the endpoint hsame witness, and the four positive-denominator witnesses. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier unary continuation positive components`

Theorem 39.30 (Complex history classifier unary continuation e-one endpoint components)**.** *If* $\mathsf{ComplexHistoryClassifier}(h, k)$*,* q *is unary,* $q\mathsf{hsame}q'$*,* $\mathsf{Cont}(h, q, \mathsf{E1}(a))$*, and* $\mathsf{Cont}(k, q', \mathsf{E1}(b))$*, then both displayed one-extension continuation endpoints expose rational real components, rational one-extension imaginary components, and continuation witnesses assembling their tails:*

$$\exists r, i,\ \mathsf{RatHistoryCarrier}(r) \wedge \mathsf{RatHistoryCarrier}(\mathsf{E1}(i)) \wedge \mathsf{Cont}(r, i, a),$$
$$\exists r', i',\ \mathsf{RatHistoryCarrier}(r') \wedge \mathsf{RatHistoryCarrier}(\mathsf{E1}(i')) \wedge \mathsf{Cont}(r', i', b).$$

Proof. First close the source classifier under the two unary continuation displays. The resulting classifier relates $\mathsf{E1}(a)$ and $\mathsf{E1}(b)$. Apply complex e-one endpoint component readback once to the left displayed endpoint and once to the right displayed endpoint. The two projections give the required rational component witnesses and their continuation ledgers. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier unary continuation e1 endpoint components`

Theorem 39.31 (Complex history classifier unary continuation e-one endpoint positive components)**.** *If* $\mathsf{ComplexHistoryClassifier}(h, k)$*, q is unary,* $q\mathsf{hsame}q'$*,* $\mathsf{Cont}(h, q, \mathsf{E1}(a))$*, and* $\mathsf{Cont}(k, q', \mathsf{E1}(b))$*, then both displayed one-extension continuation endpoints expose rational real components, rational one-extension imaginary components, continuation witnesses assembling their tails, and positive unary denominator evidence for both rational components:*

$$\exists r, i,\ \mathsf{RatHistoryCarrier}(r) \wedge \mathsf{RatHistoryCarrier}(\mathsf{E1}(i)) \wedge \mathsf{Cont}(r, i, a) \wedge \mathsf{PositiveUnaryDenominator}(r) \wedge \mathsf{PositiveUnary}$$
$$\exists r', i',\ \mathsf{RatHistoryCarrier}(r') \wedge \mathsf{RatHistoryCarrier}(\mathsf{E1}(i')) \wedge \mathsf{Cont}(r', i', b) \wedge \mathsf{PositiveUnaryDenominator}(r') \wedge \mathsf{PositiveU}$$

Proof. First close the source classifier under the two unary continuation displays. The resulting classifier relates $\mathsf{E1}(a)$ and $\mathsf{E1}(b)$. Apply complex one-extension positive-component readback to the left carrier and to the right carrier of this continued classifier. The two carrier projections supply the displayed rational component carriers, tail continuation ledgers, and positive denominator evidence. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier unary continuation e1 endpoint positive components`

Theorem 39.32 (Complex history classifier unary context positive components)**.** *If p and q are unary context histories,* $p\mathsf{hsame}p'$*,* $q\mathsf{hsame}q'$*, and* $\mathsf{ComplexHistoryClassifier}(h, k)$*, then the context-wrapped endpoints* $\mathsf{append}(p, \mathsf{append}(h, q))$ *and* $\mathsf{append}(p', \mathsf{append}(k, q'))$ *expose real and imaginary rational-history components for both endpoints, the two continuation ledgers, the wrapped endpoint* hsame *witness, and positive unary denominator evidence for all four rational components.*

Proof. Apply unary context closure to the source complex classifier and the matched prefix and suffix contexts. This gives a complex classifier between the two wrapped endpoints. Apply complex classifier positive-component readback to that wrapped classifier. The readback exposes the four rational component carriers, the two continuation ledgers assembling the wrapped endpoints, the endpoint hsame witness, and the four positive-denominator witnesses. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier unary context positive components`

Theorem 39.33 (Complex component classifier introduction)**.** *If the real components are related by* RatHistoryClassifier*, the imaginary components are related by* RatHistoryClassifier*, and the two endpoint histories are assembled by the corresponding continuation witnesses, then the endpoint histories satisfy* ComplexHistoryClassifier*.*

Proof. The source carrier is built from the source real and imaginary rational component carriers and the first continuation witness. The target carrier is built from the target rational component carriers and the second continuation witness. The two component hsame witnesses are transported through the two continuation ledgers by Cont respecting hsame, yielding the endpoint hsame field required by the complex classifier. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier component classifier intro`

Theorem 39.34 (Complex component classifier target history-sameness transport)**.** *If the real and imaginary component classifiers assemble endpoints h and k through continuation witnesses, and* $k\mathsf{hsame}k'$*, then h and k′ are related by* ComplexHistoryClassifier*.*

Proof. Transport the target continuation witness along the displayed endpoint history-sameness. The component classifier introduction theorem then rebuilds the complex classifier using the original component classifiers and the transported target continuation. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier component target hsame transport`

Theorem 39.35 (Complex component classifier endpoint history-sameness transport)**.** *If the real and imaginary component classifiers assemble endpoints h and k through continuation witnesses, and $h$hsameh' and $k$hsamek', then h' and k' are related by* ComplexHistoryClassifier*.*

Proof. Transport the source and target continuation witnesses along the two endpoint history-sameness classifiers. The component classifier introduction theorem then rebuilds the complex classifier from the original rational component classifiers and the transported continuation witnesses. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier component hsame transport`

Theorem 39.36 (Complex component classifier unary-context introduction)**.** *If the real components are related by* RatHistoryClassifier*, the imaginary components are related by* RatHistoryClassifier*, the two middle endpoints are assembled by continuation witnesses, and classified unary prefix and suffix contexts surround those endpoints, then the wrapped endpoints are related by* ComplexHistoryClassifier*.*

Proof. First build the middle complex classifier from the real component classifier, the imaginary component classifier, and the two continuation witnesses. Then apply unary-context closure to transport that classifier through the classified prefix and suffix contexts. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier component classifier unary context intro`

Theorem 39.37 (Complex component classifier unary-context positive components)**.** *If rational real and imaginary component classifiers assemble middle endpoints h and k, and classified unary prefix and suffix contexts surround those endpoints, then the wrapped endpoints expose rational real and imaginary components on both sides, the two continuation ledgers, the wrapped endpoint* hsame *witness, and positive unary denominator evidence for all four rational components.*

Proof. First build the wrapped complex classifier from the component classifiers and the classified unary contexts. Then apply complex classifier positive-component readback to that wrapped classifier. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryClassifier component classifier unary context positive components`

Definition 39.38 (Complex stability certificate)**.** *The stability certificate consists of:*

1. *an inhabited rational-pair history carrier*
2. *reflexivity of the product classifier on carrier histories*
3. *symmetry of the product classifier*
4. *transitivity of the product classifier*
5. *carrier transport along product-classifier sameness*
6. *pattern soundness for the rational-pair history carrier*
7. *ledger soundness for the rational-pair history carrier*

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexUp StdBridge`

Definition 39.39 (Complex ledger policy)**.** *Record a raw rational-pair complex history carrier together with an* hsame *link to the visible complex history.*

Lean4 (definition) `BEDC.Derived.ComplexUp.ComplexHistoryLedgerPolicy`

Theorem 39.40 (Complex ledger visible carrier)**.** *If a complex ledger relates a raw complex history to a visible history, then the visible endpoint is a complex history carrier.*

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryLedgerPolicy visible carrier`

Proof. Unpack the raw complex carrier as a product of two rational-history carriers and a continuation witness. Transport the continuation result across the stored raw-visible hsame link and rebuild the rational-pair carrier at the visible endpoint. □

Theorem 39.41 (Complex ledger excludes an $e0$-visible endpoint)**.** *No complex ledger policy can expose an $e0$-headed visible endpoint.*

Proof. The visible-carrier theorem transports the raw rational-pair carrier to the visible endpoint. Exposing the visible endpoint's rational components and inverting the continuation result gives the same two impossible imaginary denominator cases: empty or $e0$-headed. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryLedgerPolicy e0 visible absurd`

Theorem 39.42 (Complex ledger excludes an $e0$-raw endpoint)**.** *No complex ledger policy can use an $e0$-headed raw endpoint:*

$$\mathsf{ComplexHistoryLedgerPolicy}(\mathsf{E0}(tail), visible) \Longrightarrow \mathsf{False}.$$

Proof. The raw endpoint carrier stored in the ledger exposes rational real and imaginary components and a continuation assembling them into $\mathsf{E0}(tail)$. Continuation $e0$-result inversion says that the imaginary component is empty or $e0$-headed. Both cases contradict the positive unary denominator evidence carried by the imaginary rational component. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryLedgerPolicy e0 raw absurd`

Theorem 39.43 (Complex ledger raw-visible classifier)**.** *If a complex ledger relates a raw complex history to a visible history, then the raw and visible endpoints satisfy the complex history classifier.*

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryLedgerPolicy raw visible classifier`

Proof. Unpack the ledger into the raw complex carrier and the raw-visible hsame link. The visible carrier theorem supplies the visible endpoint carrier, and these two carrier witnesses with the stored history link rebuild the restricted product classifier. □

Theorem 39.44 (Complex ledger positive components)**.** *If a complex ledger relates a raw complex history to a visible history, then the raw endpoint exposes real and imaginary rational-history components, the continuation assembling those components into the raw endpoint, the raw-visible* hsame *link, the visible complex carrier, and positive unary denominator evidence for both rational components.*

Proof. Apply the complex carrier positive-component theorem to the raw carrier stored in the ledger. Apply the visible-carrier theorem to the same ledger to recover the visible complex carrier. The stored raw-visible hsame link and the two positive denominator witnesses complete the displayed ledger readback. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryLedgerPolicy positive components`

Theorem 39.45 (Complex ledger classifier extension)**.** *If a complex ledger relates a raw history to a visible history, and the visible history is classified with a target history, then the raw history is classified with the same target.*

Proof. Unpack the complex ledger into the raw carrier and the raw-visible hsame link. Unpack the visible-target classifier to keep the target carrier and the visible-target hsame link. The raw carrier and target carrier form the endpoint data, and transitivity of hsame composes the two links. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryLedgerPolicy classifier extension`

Theorem 39.46 (Complex ledger component classifier extension)**.** *If a complex ledger relates a raw endpoint to a visible endpoint, the visible endpoint and a target endpoint are assembled from component histories whose real and imaginary components are classified by* RatHistoryClassifier*, then the raw endpoint is classified with the target endpoint.*

Proof. The component classifiers and continuation witnesses build a visible-target complex classifier. Ledger classifier extension composes the stored raw-visible ledger link with this visible-target classifier, yielding the raw-target complex classifier. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistoryLedgerPolicy component classifier extension`

Theorem 39.47 (Concrete $\mathsf{Complex}^{\uparrow}$ naming certificate)**.** *The rational-pair history tuple forms a valid semantic NameCert for* $\mathsf{Complex}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.ComplexUp.complex history semantic name certificate`

Corollary 39.48 ($\mathsf{Complex}^{\uparrow}$ is licensed, not primitive)**.** $\mathsf{Complex}^{\uparrow}$ *is licensed as a derived pair interface over* $\mathsf{Rat}^{\uparrow}$*.*

Proof. The semantic naming certificate supplies an inhabited complex carrier. Unfolding the carrier yields rational real and imaginary histories and a continuation assembling them into the visible complex history; the certificate reflexivity field classifies that history with itself. □

Lean4 ✓ `BEDC.Derived.ComplexUp.ComplexHistorySemanticCertificate rat pair reflexive witness`

Closure status for $\mathsf{NameCert}_{\mathsf{Complex}^{\uparrow}}$**.**

Constructive story: A complex number is built by displaying two $\mathsf{Rat}^{\uparrow}$ denominators side by side: a history h is admitted when some left component l and right component r are both rational histories and the kernel continuation witnesses h as their ordered pair. Equality at the complex-history level is literal history-equality on admitted pairs, while the component view remembers that the real and imaginary entries are compared by the $\mathsf{Rat}^{\uparrow}$ classifier on their own sides rather than by a new complex quotient. The source therefore accepts exactly the same rational-pair histories as the carrier, the pattern is the displayed-pair shape together with the cancellation rows that recover l and r, and the ledger keeps the visible complex history aligned with the raw continuation that assembled it. Since the rational classifier is already an equivalence and the continuation pair is deterministic, the carrier has a rational-pair witness and the classifier is reflexive, symmetric, transitive, and closed over admitted histories. A history h lies in the signature gap of a $\mathsf{Complex}^{\uparrow}$ token p when the source-domain accepts h, the signature relation pairs it with an answer pair and evidence ledger, and the token-introduction relation names that answer as p; after the pair is decomposed, the real and imaginary rational denominators must match the two components encoded by p. Multiplication is then the familiar displayed formula $(a, b) \cdot (c, d) = (ac - bd,\ ad + bc)$, with every subcalculation performed in $\mathsf{Rat}^{\uparrow}$; applying it to $(0, 1)$ gives $(0 \cdot 0 - 1 \cdot 1,\ 0 \cdot 1 + 1 \cdot 0) = (-1, 0)$, so $i^2 = -1$ follows from the law rather than being postulated. The chapter registers this rational-pair construction under the name $\mathsf{Complex}^{\uparrow}$; the data surface is $\mathsf{Prod}^{\uparrow}(\mathsf{Rat}^{\uparrow}, \mathsf{Rat}^{\uparrow})$ plus the explicit multiplication row, with no quotient, field-completion primitive, or independent extension type introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Complex}^{\uparrow}}$, maturePackageClosed)

Chapter 40

A Concrete Naming Certificate for $\mathsf{Monoid}^{\uparrow}$

The monoid interface $\mathsf{Monoid}^{\uparrow}$ is licensed by an abstract carrier endowed with a binary operation $\cdot : C \times C \to C$, an identity element $e : C$, associativity of $\cdot$, and left and right identity laws of e under the carrier's source classifier. At the abstract interface level, no other licensed object is required as a dependency. It is not a primitive structure; it is licensed only when the carrier's classifier admits the algebraic equational fields.

The concrete history monoid instance extends the unary-history semigroup of chapter 79. It reuses the same append carrier, append associativity, and classifier route, and adds the empty-history unit rows that witness the left and right identity laws.

40.1 Carrier definition

Definition 40.1 (Monoid carrier)**.** *Use an abstract setup structure with carrier C, classifier $\sim_C$, operation $\cdot$, identity e, and law fields.*

40.2 Concrete history instance

Definition 40.2 (Concrete history monoid instance)**.** *The BEDC unary-history monoid instance takes $Carrier := \mathsf{UnaryHistory}$, $\mathsf{mul}(h, k) := \mathsf{append}(h, k)$, equivalently witnessed by $\mathsf{Cont}(h, k, \mathsf{append}(h, k))$, $e := \mathsf{e}$, and $classifier := \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})$.*

Lean4 ✓ `BEDC.Derived.MonoidUp.MonoidUp StdBridge`

Theorem 40.3 (Concrete history monoid laws)**.** *The concrete instance of Definition 40.2 has:*

1. *left unit of* e *for unary histories;*
2. *right unit of* e *for unary histories;*
3. *associativity of* append *up to* hsame*;*
4. *multiplication congruence under* $\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})$*.*

Lean4 ✓ `BEDC.Derived.MonoidUp.concrete history monoid laws`

Proof. The left-unit and right-unit clauses are the BEDC continuation unit laws `BEDC.FKernel.Cont.cont_left_u` and `BEDC.FKernel.Cont.cont_right_unit`, restricted to unary histories.

Associativity is the continuation associativity theorem `BEDC.FKernel.Cont.cont_assoc_hsame`; equivalently, the two parenthesizations compute to the same BEDC history append tree up to hsame.

For congruence, the classifier supplies unary endpoint witnesses together with the relevant hsame transport. Unary append closure keeps both products in the carrier, and transport of hsame across the append arguments gives the required multiplication congruence. □

Theorem 40.4 (Monoid concrete history instance unlock surface)**.** *The carrier* UnaryHistory*, multiplication* append*, and unit* e *form the concrete* $\mathsf{Monoid}^{\uparrow}$ *instance consumed by downstream algebra schemas. Associativity is supplied by append associativity, the left and right unit laws are supplied by empty-history append laws, the classifier is the existing unary append monoid classifier, and every exported row is visible through* BHist*,* hsame*,* Cont*, and* Pkg*.*

Proof. Use the concrete instance of Definition 40.2 for the carrier, multiplication, unit, and classifier. The law package is exactly Definition 40.3: its unit clauses give the empty-history left and right unit laws, its associativity clause gives append associativity up to hsame, and its congruence clause keeps multiplication compatible with the unary append classifier.

The Lean-side names `BEDC.Derived.MonoidUp.unary_append_monoid_semantic_name_certificate` and `BEDC.Derived.MonoidUp.concrete_history_monoid_laws` are the intended formal anchors for this concrete unlock surface. No abstract carrier parameter, abstract classifier parameter, or transport between unrelated monoid presentations is introduced; downstream schemas consume the displayed UnaryHistory append instance directly. □

Theorem 40.5 (Unary Cont unit replay for the concrete monoid)**.** *For every unary history h, multiplication by* e *in the concrete* $\mathsf{Monoid}^{\uparrow}$ *instance of Definition 40.2 is read through the kernel continuation rows*

$$\mathsf{Cont}(\mathsf{e}, h, h)$$

and

$$\mathsf{Cont}(h, \mathsf{e}, h).$$

Thus the left and right unit laws of the concrete $\mathsf{Monoid}^{\uparrow}$ *packet are displayed* Cont *rows of the unary-history kernel, not abstract operator laws detached from the carrier.*

Proof. Begin with the concrete instance of Definition 40.2. Its multiplication is append, its unit is e, and its carrier is UnaryHistory.

Apply Definition 40.3. The first two clauses are the left and right unit laws for e on unary histories, and the proof identifies them with `BEDC.FKernel.Cont.cont_left_unit` and `BEDC.FKernel.Cont.cont_righ`

Finally use Definition 40.4. Downstream algebra reads the same displayed carrier, multiplication, unit, classifier, BHist, hsame, Cont, and Pkg rows, so the unit laws remain kernel continuation rows rather than external algebraic fields. □

Theorem 40.6 (Unary Cont concrete monoid instance)**.** *The displayed carrier* UnaryHistory*, operation* append *witnessed by* Cont*, unit* e*, and classifier* MonoidHistoryClassifier(UnaryHistory) *form the concrete* $\mathsf{Monoid}^{\uparrow}$ *instance consumed by downstream algebra schemas. Its multiplication rows are the unary append continuation rows, its unit rows are the two* Cont *replays through* e*, and its associativity row is the append associativity route on* BHist*.*

Proof. Use the concrete carrier, operation, unit, and classifier of Definition 40.2. The theorem fixes the same UnaryHistory surface, so the schema consumer sees append, e, and MonoidHistoryClassifier(UnaryHistory) directly.

Apply Definition 40.3. Its associativity clause supplies append associativity, its unit clauses supply the left and right e laws, and its classifier congruence keeps the operation inside the displayed unary-history classifier.

Finally apply Definition 40.4 and Definition 40.5. The unlock surface identifies the downstream $\mathsf{Monoid}^{\uparrow}$ packet, while the unit replay theorem pins the unit rows to concrete Cont data. No abstract carrier/classifier transport is introduced. □

Theorem 40.7 (Unary Cont cancellation route for the concrete monoid)**.** *Every downstream cancellation-facing consumer of the concrete unary append monoid must read the same* UnaryHistory *carrier, append and* Cont *multiplication rows, empty-unit rows, classifier congruence, and* hsame *transport before adding inverse data in* $\mathsf{Group}^{\uparrow}$*. The route is a* $BHist$*-anchored dependency from* $\mathsf{Monoid}^{\uparrow}$ *to later group obligations; it does not assert group cancellation for* $\mathsf{Monoid}^{\uparrow}$ *alone.*

Proof. Start with the concrete history instance of Definition 40.2 and the concrete history monoid laws of Definition 40.3. These fix the carrier, append multiplication, empty unit, associativity, unit rows, and classifier congruence on the same unary-history surface.

Apply the unary Cont unit replay and concrete instance route, Definition 40.5 and Definition 40.6. They keep multiplication and unit reads attached to displayed continuation rows and hsame transport before any downstream schema may ask for inverse data.

Thus a $\mathsf{Group}^{\uparrow}$ consumer can cite this route as the monoid-side input, but the inverse and cancellation rows must be supplied by the later group packet rather than by $\mathsf{Monoid}^{\uparrow}$ itself. □

The $\mathsf{Monoid}^{\uparrow}$ schema is instantiated by this concrete $BHist$ carrier and operation, so subsequent certificates can refer to this instance rather than only to abstract operator fields.

Theorem 40.8 (Unary append monoid commutative classifier)**.** *For unary histories* a *and* b*, the concrete monoid classifier identifies the two append products:*

$$\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(a,b),\mathsf{append}(b,a)).$$

Proof. Unary append commutativity gives $\mathsf{append}(a,b)\mathsf{hsameappend}(b,a)$, and unary append closure supplies the two endpoint carrier witnesses required by MonoidHistoryClassifier(UnaryHistory). □

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid commutative classifier`

40.3 The certificate

Definition 40.9 (Monoid source specification)**.** *The source is the carrier* C *with its classifier and operation data.*

Definition 40.10 (Monoid pattern specification)**.** *The pattern is closed expression formation from* e*, carrier witnesses, and binary multiplication.*

Definition 40.11 (Monoid classifier specification)**.** *The classifier is the supplied carrier sameness relation, required to respect multiplication.*

Lean4 (definition) `BEDC.Derived.MonoidUp.MonoidHistoryClassifier`

Theorem 40.12 (Monoid history classifier unary diagonal induction)**.** *If a predicate P holds at the empty diagonal* (e, e) *and is preserved by simultaneous unary extension on a diagonal history, then every* $\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(h, k)$ *witness supports* $P(h, k)$*.*

Proof. Unpack the classifier into unary witnesses for h and k plus $h\mathsf{hsame}k$. The history sameness component identifies the two histories, reducing the claim to the diagonal, where unary-history induction applies. □

Lean4 ✓ `BEDC.Derived.MonoidUp.MonoidHistoryClassifier unary diagonal induction`

Definition 40.13 (Monoid stability certificate)**.** *The stability certificate consists of:*

1. *classifier reflexivity*
2. *classifier transitivity*
3. *associativity under classifier*
4. *left identity law*
5. *right identity law*
6. *multiplication congruence in both arguments*

Lean4 ✓ `BEDC.Derived.MonoidUp.monoid stability certificate fields`

Theorem 40.14 (Monoid identity uniqueness)**.** *For BEDC history multiplication, if e is a left identity and e' is a right identity under* hsame*, then* $e\mathsf{hsame}e'$*.*

Proof. Use the right-identity law for e' at e to identify e with $e \cdot e'$, then use the left-identity law for e at e'. □

Lean4 ✓ `BEDC.Derived.MonoidUp.monoid identity unique`

Theorem 40.15 (Monoid history classifier identity uniqueness)**.** *For a BEDC history-level monoid classifier over carrier C, if $e, e' \in C$, e acts as a left identity and e' acts as a right identity under the monoid classifier, then the classifier identifies e and e'.*

Proof. The right-identity field at e gives $e \cdot e'\mathsf{hsame}e$, while the left-identity field at e' gives $e \cdot e'\mathsf{hsame}e'$. Symmetry and transitivity of hsame identify e and e', and the carrier witnesses for e and e' supply the classifier endpoints. □

Lean4 ✓ `BEDC.Derived.MonoidUp.MonoidHistoryClassifier identity unique`

Theorem 40.16 (Unary append monoid left identity is empty)**.** *For the concrete unary-history append monoid, any unary history e whose append action is a left identity under* $\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})$ *is classified with* e*:*

$$\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(e, \mathsf{e}).$$

Proof. Apply classifier identity uniqueness with e as the left identity and e as the right identity. The right-identity classifier for e follows from unary closure of append, $\mathsf{UnaryHistory}(\mathsf{e})$, and the BEDC append law $\mathsf{append}(h, \mathsf{e}) = h$. □

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid left identity empty`

Theorem 40.17 (Unary append monoid right identity is empty)**.** *For the concrete unary-history append monoid, any unary history e whose append action is a right identity under* MonoidHistoryClassifier(UnaryHist *is classified with* e*:*

$$\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(e, \mathsf{e}).$$

Proof. Apply classifier identity uniqueness with e as the left identity and e as the right identity. The left-identity classifier for e follows from unary closure of append, UnaryHistory(e), and the BEDC append law $\mathsf{append}(\mathsf{e}, h) = h$. Symmetry of the resulting hsame component gives the displayed classifier orientation. □

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid right identity empty`

Theorem 40.18 (Unary append monoid identity is empty iff)**.** *For the concrete unary-history append monoid, a unary history e is both a left and right identity under* MonoidHistoryClassifier(UnaryHistory) *exactly when it is classified with* e*.*

Proof. The forward implication uses the left-identity uniqueness result for the concrete empty right identity. Conversely, a classifier witness $\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(e, \mathsf{e})$ gives $e$hsamee. Replacing e by e reduces the two identity classifier families to the BEDC append laws $\mathsf{append}(\mathsf{e}, h) = h$ and $\mathsf{append}(h, \mathsf{e}) = h$, with unary closure supplying the endpoint carrier fields. □

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid identity empty iff`

Theorem 40.19 (Unary append monoid idempotent iff empty)**.** *For every unary history e, the concrete unary append monoid classifies the duplicated append factor as e exactly when e is classified with* e*:*

$$\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(e, e), e) \quad \textit{if and only if} \quad \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(e, \mathsf{e}).$$

Here the BEDC source is BHist *with the carrier* UnaryHistory *and operation* append*; the classifier is* MonoidHistoryClassifier(UnaryHistory)*. The ledger records the duplicated factor e and the empty right unit, stability is supplied by common-context congruence and cancellation, exactness is the displayed iff, and the usual finite unary-word monoid is the standard bridge.*

Proof. For the forward direction, rewrite the right endpoint e as $\mathsf{append}(e, \mathsf{e})$ by the empty right-unit law. The hypothesis then classifies two histories with common left context e and common right context e, with middle endpoints e and e. Apply Theorem 40.28 to obtain MonoidHistoryClassifier(UnaryHistory)(e, e

For the reverse direction, start from the classifier witness $\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(e, \mathsf{e})$. Apply Theorem 40.26 with left context e and right context e to classify the contextual pair $\mathsf{append}(e, \mathsf{append}(e, \mathsf{e}))$ and $\mathsf{append}(e, \mathsf{append}(\mathsf{e}, \mathsf{e}))$. The empty right-unit and left-unit laws identify these endpoints with $\mathsf{append}(e, e)$ and e, giving the displayed classifier. □

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid idempotent empty iff`

Theorem 40.20 (Unary append monoid left-inverse field collapses to singleton)**.** *For every operation* inv : BHist → BHist*, a global left-inverse field on the full unary-history append carrier,*

$$\forall h : \mathsf{BHist},\ \mathsf{UnaryHistory}(h) \Rightarrow \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(\mathsf{inv}(h), h), \mathsf{e}),$$

forces every unary history to be classified with the singleton unit:

$$\forall h : \mathsf{BHist},\ \mathsf{UnaryHistory}(h) \Rightarrow \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(h, \mathsf{e}).$$

Proof. Fix a unary history h and specialize the left-inverse field at h. The unit-product factor exactness theorem decomposes the classifier for $\mathsf{append}(\mathsf{inv}(h), h)$ into singleton classifiers for the two append factors. The right factor is exactly the displayed classifier of h with e. □

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid left inverse field collapses to singleton`

Theorem 40.21 (Unary append monoid one-sided inverse obstruction)**.** *For every operation* $\mathsf{inv} : \mathsf{BHist} \to \mathsf{BHist}$*, the concrete unary-history append monoid supports neither a global right-inverse family*

$$\forall h : \mathsf{BHist},\ \mathsf{UnaryHistory}(h) \Rightarrow \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(h, \mathsf{inv}(h)), \mathsf{e}),$$

nor a global left-inverse family

$$\forall h : \mathsf{BHist},\ \mathsf{UnaryHistory}(h) \Rightarrow \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(\mathsf{inv}(h), h), \mathsf{e}).$$

The ten-field fit is: traditional target group-upgrade obstruction for the unary append monoid; BEDC source BHist*,* $\mathsf{UnaryHistory}$*,* append*, and* $\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})$*; carrier* $\mathsf{UnaryHistory}$*; classifier the concrete monoid classifier; stability from unary append closure and empty-result inversion; ledger the attempted inverse endpoint; core theorem this block; exactness the contradiction from the visible unary generator; standard bridge finite unary-word monoid has no global inverse; status* $\mathsf{ProofTarget}$*.*

Proof. For the right-inverse family, take the visible unary generator $u = \mathsf{E1}(\mathsf{e})$. Unary closure gives $\mathsf{UnaryHistory}(u)$, so the assumed family classifies $\mathsf{append}(u, \mathsf{inv}(u))$ with e. Unfolding the concrete classifier exposes $\mathsf{append}(u, \mathsf{inv}(u))\mathsf{hsamee}$.

Empty-result inversion for append then forces the left factor to satisfy $u\mathsf{hsamee}$. This contradicts the BEDC no-confusion theorem separating the $\mathsf{E1}$ constructor from e.

The left-inverse family is symmetric in the obstruction. Specializing it at the same u exposes $\mathsf{append}(\mathsf{inv}(u), u)\mathsf{hsamee}$. Empty-result inversion now forces the right factor u to be hsame to e, and the same no-confusion contradiction follows. □

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid one sided inverse law absurd`

Theorem 40.22 (History continuation monoid laws)**.** *The BEDC history continuation relation has empty history as a left and right unit, and the two parenthesizations of a triple continuation have the same resulting history.*

Lean4 ✓ `BEDC.Derived.MonoidUp.history continuation monoid laws`

Proof. The unit fields are the empty-history continuation constructors. For associativity, each continuation witness unfolds to history append, and the result follows from associativity of BEDC history append. □

Theorem 40.23 (Nonempty continuation suffix changes the source)**.** *For any source history* h*, no continuation by a suffix of the form* $\mathsf{E0}(k)$ *or* $\mathsf{E1}(k)$ *can have result* h *itself.*

Lean4 ✓ `BEDC.Derived.MonoidUp.history continuation nonempty suffix source absurd`

Proof. Right-unit uniqueness for continuation forces any suffix whose result is the source to be e. BEDC history no-confusion separates $\mathsf{E0}(k)$ and $\mathsf{E1}(k)$ from e. □

Theorem 40.24 (Nonempty continuation prefix changes the target)**.** *For any target history k, no continuation with source of the form* $\mathsf{E0}(h)$ *or* $\mathsf{E1}(h)$ *can have result k itself.*

Proof. Left-unit uniqueness for continuation forces any source whose continuation leaves the target unchanged to be e. BEDC history no-confusion separates $\mathsf{E0}(h)$ and $\mathsf{E1}(h)$ from e. □

Lean4 ✓ `BEDC.Derived.MonoidUp.history continuation nonempty prefix target absurd`

Theorem 40.25 (Unary append monoid semantic name certificate)**.** *The unary-history carrier, empty history, BEDC history append, and the history-sameness classifier instantiate the semantic naming certificate for* $\mathsf{Monoid}^{\uparrow}$*. The certificate exports the empty-left, empty-right, associativity, and append-congruence fields under the classifier* $\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})$*.*

Proof. Unary history is inhabited by empty history and is closed under BEDC append. The empty-history laws and associativity are the primitive append laws for histories. Congruence follows by transporting both append arguments across hsame, leaving the same appended history on both sides. □

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid semantic name certificate`

Theorem 40.26 (Unary append monoid classifier appends common context)**.** *For unary histories l, r, if the monoid classifier identifies a with b, then it identifies the two contextual histories*

$$l(ar)$$

and

$$l(br).$$

Proof. The classifier supplies unary witnesses for a and b together with $a\mathsf{hsame}b$. Unary append closure builds the two contextual endpoint carriers. After the endpoint equality is exposed, reflexivity of hsame identifies the two appended histories. □

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid classifier append context`

Theorem 40.27 (Unary append monoid classifier preserves context)**.** *For unary histories l, r, a, b, if the monoid classifier identifies a with b, then it identifies the common-context appends*

$$l(ar)$$

and

$$l(br).$$

Proof. The classifier gives unary endpoint witnesses for a and b and an hsame witness between them. Unary histories are closed under BEDC append, so appending the common right and left contexts supplies the endpoint carriers. The hsame witness identifies the middle history, leaving equal contextual appends. □

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid classifier context congr`

Theorem 40.28 (Unary append monoid classifier cancels common context)**.** *For unary histories l, r, a, b, if the monoid classifier identifies*

$$l(ar)$$

with

$$l(br),$$

then it identifies a with b.

Proof. The classifier supplies the endpoint unary witnesses and a BEDC history equality between the two contextual appends. Left append cancellation removes the common left context l, and right append cancellation removes the common suffix r. The given unary witnesses for a and b supply the classifier endpoints. □

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid classifier cancel context`

Theorem 40.29 (Unary append monoid classifier context equivalence)**.** *For unary histories l, r, a, b, the monoid classifier identifies*

$$l(ar)$$

with

$$l(br)$$

exactly when it identifies a with b.

Proof. The forward direction is common-context cancellation: left append cancellation removes l, and right append cancellation removes r. The reverse direction is common-context congruence using unary append closure on both endpoints. □

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid classifier context iff`

Theorem 40.30 (Unary append monoid left factor empty iff)**.** *For unary histories $h, k : \mathsf{BHist}$, classifying the appended history $\mathsf{append}(h, k)$ with its left factor h is equivalent to classifying the right factor k with e:*

$$\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(h, k), h) \iff \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(k, \mathsf{e}).$$

Proof. For the forward direction, rewrite the right endpoint as $\mathsf{append}(h, \mathsf{e})$ by the append right-unit law and cancel the common left factor h. Conversely, a classifier witness for k against e rewrites the appended endpoint to $\mathsf{append}(h, \mathsf{e})$, and the append right-unit law identifies this with h. Unary append closure supplies the source carrier endpoint. □

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid left factor empty iff`

Theorem 40.31 (Unary append monoid right factor empty iff)**.** *For unary histories $h, k : \mathsf{BHist}$, classifying the appended history $\mathsf{append}(h, k)$ with its right factor k is equivalent to classifying the left factor h with e:*

$$\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(h, k), k) \iff \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(h, \mathsf{e}).$$

The ten-field fit is: traditional target right factor-to-unit exactness in the unary append monoid; BEDC source $\mathsf{Monoid}^{\uparrow}$ over $\mathsf{UnaryHistory}$; carrier $\mathsf{UnaryHistory}$; classifier $\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})$; stability from the commutative classifier, context equivalence, and left-factor exactness; ledger the hidden left factor; core theorem this block; exactness the displayed iff; standard bridge finite unary-word monoid; status $\mathsf{ProofTarget}$.

Proof. For the forward direction, unary append commutativity first classifies $\mathsf{append}(k, h)$ with $\mathsf{append}(h, k)$. Classifier transitivity then composes this classification with the assumed classification of $\mathsf{append}(h, k)$ with k, producing a classification of $\mathsf{append}(k, h)$ with k.

Apply Definition 40.30 with left factor k and right factor h. The resulting exactness classifies h with e.

For the reverse direction, start from the classification of h with e. The same left-factor exactness theorem, again applied to k and h, gives a classification of $\mathsf{append}(k, h)$ with k.

Unary append commutativity classifies $\mathsf{append}(h, k)$ with $\mathsf{append}(k, h)$. Classifier transitivity orients the endpoint as a classification of $\mathsf{append}(h, k)$ with k. □

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid right factor empty iff`

Theorem 40.32 (Unary append monoid classifier swaps unary context)**.** *For unary histories $left$, $right$, and a, the concrete monoid classifier identifies the two histories obtained by moving the two unary contexts around the middle payload:*

$$\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(left, \mathsf{append}(a, right)), \mathsf{append}(right, \mathsf{append}(a, left))).$$

Proof. Unary append closure supplies the endpoint carrier witnesses. Associativity first exposes the two context factors, unary append commutativity swaps a with $right$, swaps $left$ with $right$, and finally swaps $left$ with a inside the right context. The resulting equality is the hsame component of the monoid classifier. □

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid classifier context swap`

Definition 40.33 (Monoid ledger policy)**.** *Record the carrier witnesses and operation tree behind each monoid expression.*

Definition 40.34 ($\mathsf{Monoid}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{Monoid}^{\uparrow}$*.*

Theorem 40.35 (Concrete $\mathsf{Monoid}^{\uparrow}$ naming certificate)**.** *Any setup satisfying the monoid fields forms a valid NameCert for* $\mathsf{Monoid}^{\uparrow}(C)$*.*

Proof. The identity element inhabits the carrier. The monoid classifier records source and target carrier witnesses together with the BEDC history equality witness, giving the certificate core by hsame reflexivity, symmetry, transitivity, and carrier projection. Closure under multiplication supplies carrier witnesses for the exported identity, associativity, and multiplication-congruence fields. □

Lean4 ✓ `BEDC.Derived.MonoidUp.monoid history semantic name certificate`

Primitive boundary. $\mathsf{Monoid}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Definition 40.36 (Opposite monoid certificate data)**.** *Let a* $\mathsf{Monoid}^{\uparrow}$ *certificate be presented by a carrier predicate $\mathcal{C}$, classifier $\sim_C$, multiplication $\cdot_C$, and identity e_C. Define the reversed multiplication by*

$$a \cdot_C^{\mathrm{op}} b := b \cdot_C a.$$

The opposite monoid data C^{op} have the same carrier predicate $\mathcal{C}$, the same classifier $\sim_C$, the same identity e_C, and multiplication $\cdot_C^{\mathrm{op}}$.

Theorem 40.37 (Opposite monoid certificate)**.** *If $(\mathcal{C}, \sim_C, \cdot_C, e_C)$ satisfies the* $\mathsf{Monoid}^{\uparrow}$ *certificate obligations of Definition 40.34, then the data of Definition 40.36 also satisfy the* $\mathsf{Monoid}^{\uparrow}$ *certificate obligations. Thus the same carrier, identity, and classifier carry a monoid certificate with multiplication $\cdot_C^{\mathrm{op}}$.*

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid opposite semantic name certificate`

Proof. Unpack the monoid obligations through Definition 40.34. The carrier row of Definition 40.1 is unchanged. The carrier-and-classifier core is the same NameCert data, so classifier reflexivity, symmetry, transitivity, and carrier transport are copied from Definition 9.7. The source row of Definition 40.9 is the same carrier and classifier equipped with the reversed multiplication symbol.

Closure for the reversed multiplication follows from original closure with the two inputs exchanged: if $\mathcal{C}(a)$ and $\mathcal{C}(b)$, then

$$a \cdot_C^{\mathrm{op}} b = b \cdot_C a$$

is carried because b and a are carried.

The identity rows are exchanged. The opposite left identity law is

$$e_C \cdot_C^{\mathrm{op}} a = a \cdot_C e_C \sim_C a,$$

which is the original right identity row. The opposite right identity law is

$$a \cdot_C^{\mathrm{op}} e_C = e_C \cdot_C a \sim_C a,$$

which is the original left identity row.

For associativity, the two opposite bracketings unfold to

$$(a \cdot_C^{\mathrm{op}} b) \cdot_C^{\mathrm{op}} c = c \cdot_C (b \cdot_C a)$$

and

$$a \cdot_C^{\mathrm{op}} (b \cdot_C^{\mathrm{op}} c) = (c \cdot_C b) \cdot_C a.$$

The associativity row in Definition 40.13, applied to the original multiplication at the triple (c, b, a), supplies

$$(c \cdot_C b) \cdot_C a \sim_C c \cdot_C (b \cdot_C a).$$

Classifier symmetry gives the required opposite orientation

$$c \cdot_C (b \cdot_C a) \sim_C (c \cdot_C b) \cdot_C a.$$

Multiplication congruence is also inherited with inputs exchanged. Given $a \sim_C a'$ and $b \sim_C b'$, the required comparison for the opposite product is

$$a \cdot_C^{\mathrm{op}} b = b \cdot_C a \sim_C b' \cdot_C a' = a' \cdot_C^{\mathrm{op}} b',$$

which is the original multiplication congruence applied to $b \sim_C b'$ and $a \sim_C a'$.

The classifier row of Definition 40.11 is unchanged because endpoint comparison is still $\sim_C$; the congruence paragraph is exactly the respect-for-multiplication field for the reversed operation. The pattern row of Definition 40.10 remains closed expression formation from e_C, carried endpoints, and binary multiplication, with each reversed multiplication node read as an original multiplication node whose children are exchanged. The ledger row of Definition 40.33 records the same expression tree with that exchanged child order at every reversed multiplication node. Hence the source-to-pattern and source-to-ledger soundness fields are the original operation-tree soundness checks read through the definition of $\cdot_C^{\mathrm{op}}$.

These carrier, source, pattern, classifier, stability, and ledger rows are precisely the five-field naming-certificate data required by Definition 9.6 and the monoid obligations of Definition 40.34. Therefore C^{op} carries a $\mathsf{Monoid}^{\uparrow}$ certificate. □

Theorem 40.38 (Double opposite monoid certificate data identity)**.** *Let D be a* $\mathsf{Monoid}^{\uparrow}$ *certificate satisfying the obligations of Definition 40.34. Present its monoid data by a carrier predicate $\mathcal{C}$, classifier $\sim_C$, multiplication $\cdot_C$, and identity element e_C as in Definition 40.36. Let*

$$D^{\mathrm{opop}} = (D^{\mathrm{op}})^{\mathrm{op}}$$

be obtained by applying Definition 40.36 twice. Then D^{opop} is a $\mathsf{Monoid}^{\uparrow}$ *certificate, and its carrier predicate, classifier, multiplication, and identity element are componentwise identical to those of D:*

$$\mathcal{C}^{\mathrm{opop}}(a) = \mathcal{C}(a), \quad a \sim_C^{\mathrm{opop}} b = a \sim_C b,$$
$$a \cdot_C^{\mathrm{opop}} b = a \cdot_C b, \qquad e_C^{\mathrm{opop}} = e_C.$$

Proof. Because D satisfies the $\mathsf{Monoid}^{\uparrow}$ obligations, Definition 40.37 makes D^{op} a certified $\mathsf{Monoid}^{\uparrow}$ instance. Applying the same theorem to that certified opposite data makes D^{opop} a certified $\mathsf{Monoid}^{\uparrow}$ instance.

It remains to compare the displayed data. The carrier predicate, classifier, and identity element are fixed by one use of Definition 40.36. Hence two unfoldings give

$$\mathcal{C}^{\mathrm{opop}}(a) = \mathcal{C}^{\mathrm{op}}(a) = \mathcal{C}(a),$$

$$a \sim_C^{\mathrm{opop}} b = a \sim_C^{\mathrm{op}} b = a \sim_C b,$$

and

$$e_C^{\mathrm{opop}} = e_C^{\mathrm{op}} = e_C.$$

For multiplication, the first opposite exchanges the two inputs and the second opposite exchanges them back:

$$a \cdot_C^{\mathrm{opop}} b = b \cdot_C^{\mathrm{op}} a = a \cdot_C b.$$

Thus the raw multiplication field of the double opposite certificate is exactly the original multiplication field.

The source row of Definition 40.9 uses only the carrier, classifier, and multiplication just identified. The pattern row of Definition 40.10 forms expressions from the same identity element and the same restored multiplication. The classifier row of Definition 40.11 is the same endpoint relation, and multiplication respect is typed over the restored multiplication. The ledger policy of Definition 40.33 records operation trees; one opposite reading swaps the two children at each multiplication node, and the second reading swaps the same children back. Therefore the displayed component identities identify the double opposite monoid certificate data with the monoid data of D. □

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid double opposite data identity`

Closure status for $\mathsf{NameCert}_{\mathsf{Monoid}^{\uparrow}}$**.**

Constructive story: The unary spine already carries a monoid operation: put one unary history after another by kernel continuation, and unary closure says the result is still on the spine while e acts as the empty tail on both sides. Two carried elements are the same just when the underlying histories are history-equal inside the unary carrier, so the operation never leaves the history surface for an imported algebraic set. The source is the unary predicate itself, the pattern records binary append, the two unit laws with e, and associativity of three continued spines, and the ledger keeps each visible monoid element aligned with the raw unary history that realizes it. Because history-equality is an equivalence and unary histories are closed under continuation, e supplies the carrier witness, the classifier is reflexive, symmetric, and transitive, and recognized representatives remain admitted. A unary history h lies in the signature gap of a $\mathsf{Monoid}^{\uparrow}$ token p when the source-domain accepts h, the signature relation pairs it with an answer history and evidence ledger, and the token-introduction relation names that answer as p; concretely, h is unary and history-equal to the spine encoded by p. The same package also exposes the inverse obstruction, unique factor readback up to history-equality, the opposite monoid, and the

double-opposite identity as consequences of continuation. The chapter registers this unary-append construction under the name $\mathsf{Monoid}^{\uparrow}$; the monoid laws are theorems about the existing kernel continuation, with no imported algebraic carrier, inverse primitive, or host monoid structure introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Monoid}^{\uparrow}}$, maturePackageClosed)

Scope closed: The mature unary-history monoid package binds the concrete history monoid laws, semantic NameCert, inverse-obstruction and factor-exactness rows, opposite certificate, and double-opposite data identity for the append/Cont surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Monoid}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.MonoidUp.monoid\_history\_semantic\_name\_certificate`

Bridge status: bridgeChecked

Not claimed: The chapter does not close arbitrary host monoids, homomorphism theory, category-of-monoids structure, or bridgeChecked verification.

Chapter 41

A Concrete Naming Certificate for $\mathsf{Group}^{\uparrow}$

The group interface $\mathsf{Group}^{\uparrow}$ extends chapter 40 with a unary inverse operation $^{-1} : C \to C$ satisfying left and right inverse laws under the carrier's classifier. It is not a primitive structure; it is licensed only by composing the monoid certificate with the inverse field.

Remark 41.1 (Roadmap chapter)**.** *This chapter records the licensing target. Lean markers identify the algebraic fields and derived laws that are formalized for the certificate.*

41.1 Carrier definition

Definition 41.2 (Group carrier)**.** *Use a monoid setup extended with inverse operation a^{-1}.*

The group carrier consumes the $\mathsf{Monoid}^{\uparrow}$ multiplication, associativity, and unit rows from chapter 40 before adding inverse rows and inverse-ledger obligations.

41.2 Concrete singleton history group instance

Definition 41.3 (Concrete singleton history group instance)**.** *Let A_{e} be the singleton history source of Definition 36.169 at $a_0 = \mathsf{e}$. Define the concrete history operations and classifier by*

$$\mathsf{mul}(h, k) := \mathsf{append}(h, k), \qquad \mathsf{inv}(h) := \mathsf{e}, \qquad e := \mathsf{e},$$

and

$$R_{\mathsf{e}}(h, k) \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h, k).$$

Theorem 41.4 (Group singleton history SemanticNameCert)**.** *The carrier A_{e}, classifier R_{e}, multiplication* mul*, unit e, and inverse operation* inv *of Definition 41.3 supply the singleton-history* SemanticNameCert *for* $\mathsf{Group}^{\uparrow}$ *over* BHist*, together with the concrete multiplication-closure, inverse-closure, left-unit, right-unit, left-inverse, and right-inverse rows captured by* BEDC.Derived.GroupUp.GroupSingletonI

Proof. The SemanticNameCert component is packaged by the carrier-aware classifier R_{e}. Its inhabited carrier is witnessed by $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$. Reflexivity, symmetry, and transitivity are inherited from hsame after unpacking and repacking the carrier endpoints required by R_{e}.

Carrier transport follows by composing singleton endpoint witnesses through e: if a source endpoint and its classifier partner are both related by R_{e}, then the transported endpoint remains in A_{e} by transitivity through their displayed witnesses to e.

Carrier inhabitance is the reflexive endpoint witness $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$, which is exactly the singleton carrier condition from Definition 36.169 at $a_0 = \mathsf{e}$.

For multiplication closure, suppose $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$. The two carrier facts identify h and k with e. The BEDC continuation unit laws used in Theorem 40.3 reduce $\mathsf{append}(h, k)$ to the same endpoint class as e, using symmetry and transitivity of hsame to compose the displayed witnesses.

Inverse closure is immediate because $\mathsf{inv}(h)$ is definitionally e. The singleton carrier witness is again $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$.

The left and right unit rows reduce $\mathsf{append}(\mathsf{e}, h)$ and $\mathsf{append}(h, \mathsf{e})$ to h by the continuation unit laws. The inverse rows use $\mathsf{inv}(h) = \mathsf{e}$, so the same unit laws and the carrier witness for h classify both products against $e = \mathsf{e}$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonHistory laws`

Theorem 41.5 (Concrete singleton history group algebraic laws)**.** *The concrete singleton history group over* BHist *satisfies carrier inhabitance, multiplication closure, inverse closure, left and right unit laws, associativity up to* hsame*, multiplication congruence, inverse congruence, and left and right inverse laws.*

Proof. Carrier inhabitance, multiplication closure, inverse closure, and the unit rows are the corresponding concrete rows of Theorem 41.4.

Associativity is the continuation associativity theorem cited in Theorem 40.3: the histories $\mathsf{append}(\mathsf{append}(h, k), l)$ and $\mathsf{append}(h, \mathsf{append}(k, l))$ are hsame-equivalent. Closure of the two products follows from the multiplication-closure clause.

Multiplication congruence follows by transporting the two input hsame witnesses across append and then composing with the same continuation associativity and unit laws. Since all carrier elements are in the singleton class of e, the source and target products both lie in A_{e} and are related by hsame.

Inverse congruence is constant: both inverses are e, so the classifier witness is the pair of singleton carrier witnesses together with $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$.

For the inverse laws, $\mathsf{append}(\mathsf{inv}(h), h)$ is $\mathsf{append}(\mathsf{e}, h)$ and $\mathsf{append}(h, \mathsf{inv}(h))$ is $\mathsf{append}(h, \mathsf{e})$. The continuation unit laws reduce these products to h, and the carrier fact $A_{\mathsf{e}}(h)$ identifies h with $e = \mathsf{e}$. □

Lean4 ✓ `BEDC.Derived.GroupUp.concrete singleton history group laws`

The $\mathsf{Group}^{\uparrow}$ schema is instantiated by this concrete BHist carrier, append operation, empty unit, and constant inverse, so certificate rows in this chapter are BHist-anchored rather than abstract operator fields.

Theorem 41.6 (Group singleton carrier append context empty)**.** *For histories $L, R, h : \mathsf{BHist}$, if L and R lie in the singleton group carrier A_{e}, then a two-sided append context lies in the same singleton carrier exactly when the middle history does:*

$$A_{\mathsf{e}}(L) \Rightarrow A_{\mathsf{e}}(R) \Rightarrow \big(A_{\mathsf{e}}(\mathsf{append}(L, \mathsf{append}(h, R))) \Longleftrightarrow A_{\mathsf{e}}(h)\big).$$

Proof. In the forward direction, unfold singleton carrier membership as equality to e up to hsame. Empty-result inversion for append first splits off the left context L, then splits the inner append, exposing the middle carrier witness $A_{\mathsf{e}}(h)$.

Conversely, combine the carrier witnesses for h and R to rebuild the inner append as a singleton carrier, then combine that result with the carrier witness for L to rebuild the displayed two-sided append context. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonCarrier append context empty iff`

Theorem 41.7 (Group singleton classifier append context cancellation)**.** *For histories L, R, Q, S : BHist, if the displayed left contexts are in the singleton group carrier A_{e}, then appending those contexts to the two classifier endpoints preserves and reflects the singleton classifier:*

$$A_{\mathsf{e}}(L) \Rightarrow A_{\mathsf{e}}(R) \Rightarrow (R_{\mathsf{e}}(\mathsf{append}(L, Q), \mathsf{append}(R, S)) \Longleftrightarrow R_{\mathsf{e}}(Q, S)).$$

Proof. In the forward direction, the two appended endpoints are classified as singleton endpoints. Empty-result inversion for append splits each endpoint witness, giving $Q\mathsf{hsamee}$ and $S\mathsf{hsamee}$. These two carrier witnesses, together with transitivity through e, assemble $R_{\mathsf{e}}(Q, S)$.

Conversely, combine the supplied singleton witnesses for L and R with the endpoint carrier fields in $R_{\mathsf{e}}(Q, S)$. Empty-result construction for append gives singleton witnesses for $\mathsf{append}(L, Q)$ and $\mathsf{append}(R, S)$, and transitivity through e gives the classifier comparison between the two appended endpoints. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier append context cancel iff`

Theorem 41.8 (Group singleton classifier right-context cancellation)**.** *For histories L, R, Q, S : BHist, if the displayed right contexts are in the singleton group carrier A_{e}, then appending those contexts as suffixes preserves and reflects the singleton classifier:*

$$A_{\mathsf{e}}(L) \Rightarrow A_{\mathsf{e}}(R) \Rightarrow (R_{\mathsf{e}}(\mathsf{append}(Q, L), \mathsf{append}(S, R)) \Longleftrightarrow R_{\mathsf{e}}(Q, S)).$$

The ten-field fit names the traditional target as terminal-group cancellation by a classified suffix; the BEDC source as the concrete singleton $\mathsf{Group}^{\uparrow}$ carrier; carrier A_{e}; classifier R_{e}; stability as singleton carrier transport and `append_eq_empty_iff`; ledger the hidden singleton suffix endpoints; core theorem list Theorem 41.7 and `append_eq_empty_iff`; exactness predicate the displayed iff; standard bridge cancellation in the terminal group; and status ProofTarget.

Proof. In the forward direction, singleton classification of the two appended histories and empty-result inversion for append split the suffix endpoints. The resulting singleton witnesses for Q and S, together with transitivity through e, package $R_{\mathsf{e}}(Q, S)$.

Conversely, combine $R_{\mathsf{e}}(Q, S)$ with the carrier witnesses for L and R. Empty-result construction for append gives singleton witnesses for $\mathsf{append}(Q, L)$ and $\mathsf{append}(S, R)$, and transitivity through e gives their classifier comparison. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier append suffix cancel iff`

Theorem 41.9 (Group singleton classifier two-sided context cancellation)**.** *For histories L, R, L', R', Q, S : BHist, if $A_{\mathsf{e}}(L)$, $A_{\mathsf{e}}(R)$, $A_{\mathsf{e}}(L')$, and $A_{\mathsf{e}}(R')$, then*

$$R_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(L, Q), L'), \mathsf{append}(\mathsf{append}(R, S), R')) \Longleftrightarrow R_{\mathsf{e}}(Q, S)$$

The ten-field fit names the traditional target as terminal-group two-sided contextual cancellation; the BEDC source as the concrete singleton $\mathsf{Group}^{\uparrow}$ carrier; carrier A_{e}; classifier R_{e}; stability as left and right context cancellation; ledger as hidden singleton prefix and suffix contexts; core theorem list Theorem 41.7 and Theorem 41.8; exactness predicate as the displayed iff; standard bridge as cancellation of terminal-group contexts; and status ProofTarget.

Proof. For the forward direction, apply Theorem 41.8 to cancel the singleton suffixes L' and R'. This reduces the classifier statement to

$$R_{\mathsf{e}}(\mathsf{append}(L, Q), \mathsf{append}(R, S)).$$

Then apply Theorem 41.7 to cancel the singleton prefixes L and R, producing $R_{\mathsf{e}}(Q, S)$.

For the reverse direction, start from $R_{\mathsf{e}}(Q, S)$ and use Theorem 41.7 in the constructive direction to attach the singleton prefixes L and R. Then use Theorem 41.8 in the constructive direction to attach the singleton suffixes L' and R', giving exactly the displayed two-sided classifier relation. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier right context cancel iff`

Theorem 41.10 (Group singleton classifier product-unit split)**.** *For histories p, q : BHist, the concrete singleton group classifier satisfies*

$$R_{\mathsf{e}}(\mathsf{append}(p, q), \mathsf{e}) \iff A_{\mathsf{e}}(p) \wedge A_{\mathsf{e}}(q).$$

The ten-field fit names the traditional target as a product equal to the unit in the one-element group; the BEDC source as the concrete singleton $\mathsf{Group}^{\uparrow}$ instance over BHist; carrier A_{e}; classifier R_{e}; stability as append empty-result construction and inversion; ledger factors p, q; core theorem list Theorem 41.5 together with the BEDC append empty-result inversion; exactness predicate the displayed iff; standard bridge the terminal group unit-product split; and status $\mathsf{ProofTarget}$.

Proof. Unfold R_{e} and A_{e}. In the forward direction, the classifier supplies $A_{\mathsf{e}}(\mathsf{append}(p, q))$, so $\mathsf{hsame}(\mathsf{append}(p, q), \mathsf{e})$ holds. Append empty-result inversion splits this witness into $A_{\mathsf{e}}(p)$ and $A_{\mathsf{e}}(q)$, giving the displayed conjunction.

Conversely, assume $A_{\mathsf{e}}(p)$ and $A_{\mathsf{e}}(q)$. Append empty-result construction gives $A_{\mathsf{e}}(\mathsf{append}(p, q))$, while reflexivity gives $A_{\mathsf{e}}(\mathsf{e})$. Symmetry and transitivity of hsame then package the endpoint comparison required by $R_{\mathsf{e}}(\mathsf{append}(p, q), \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier append unit split iff`

Theorem 41.11 (Group singleton contextual product-unit split)**.** *For histories L, R, p, q : BHist, if $A_{\mathsf{e}}(L)$ and $A_{\mathsf{e}}(R)$, then*

$$R_{\mathsf{e}}(\mathsf{append}(L, \mathsf{append}(p, q)), \mathsf{append}(R, \mathsf{e})) \iff A_{\mathsf{e}}(p) \wedge A_{\mathsf{e}}(q).$$

The ten-field fit names the traditional target as terminal-group contextual unit-product splitting; the BEDC source as the concrete singleton $\mathsf{Group}^{\uparrow}$ carrier; carrier A_{e}; classifier R_{e}; stability as context cancellation plus append empty-result construction and inversion; ledger as the hidden singleton contexts and product factors; core theorem list Theorem 41.7 and Theorem 41.10; exactness predicate as the displayed iff; standard bridge as the terminal group unit-product split under context; and status $\mathsf{ProofTarget}$.

Proof. Apply Theorem 41.7 with $Q = \mathsf{append}(p, q)$ and $S = \mathsf{e}$. The carrier hypotheses $A_{\mathsf{e}}(L)$ and $A_{\mathsf{e}}(R)$ strip the singleton left and right contexts, reducing the displayed classifier to

$$R_{\mathsf{e}}(\mathsf{append}(p, q), \mathsf{e}).$$

Apply Theorem 41.10 to this reduced classifier. It identifies the reduced classifier exactly with $A_{\mathsf{e}}(p) \wedge A_{\mathsf{e}}(q)$, giving both directions of the displayed equivalence. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier append context unit split iff`

Theorem 41.12 (Group singleton classifier append product empty split)**.** *For histories* a, b, c, d : BHist*, the singleton group classifier relates the two appended products exactly when each append factor is carried by the singleton carrier:*

$$R_{\mathsf{e}}(\mathsf{append}(a, b), \mathsf{append}(c, d)) \iff A_{\mathsf{e}}(a) \wedge A_{\mathsf{e}}(b) \wedge A_{\mathsf{e}}(c) \wedge A_{\mathsf{e}}(d).$$

Proof. Unfold R_{e}. In the forward direction, the two carrier fields say both appended products are empty, and append empty-result inversion splits them into the four displayed singleton carrier witnesses. Conversely, the four witnesses rebuild the two empty appended products; symmetry and transitivity of hsame package the singleton classifier relation between them. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier append product empty split iff`

Theorem 41.13 (Group singleton carrier visible-head append exclusion)**.** *For histories* p, q : BHist*, neither* $\mathsf{append}(\mathsf{e0}(p), q)$ *nor* $\mathsf{append}(\mathsf{e1}(p), q)$ *lies in the singleton group carrier.*

Proof. In either branch, the singleton carrier identifies the displayed appended history with e. Empty-result inversion for append then identifies the visible head $\mathsf{e0}(p)$ or $\mathsf{e1}(p)$ with e. Constructor separation for generated histories rules out both cases. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonCarrier append visible head absurd`

Theorem 41.14 (Group singleton carrier visible-tail append exclusion)**.** *For histories* p, q : BHist*, neither* $\mathsf{append}(p, \mathsf{e0}(q))$ *nor* $\mathsf{append}(p, \mathsf{e1}(q))$ *lies in the singleton group carrier.*

Proof. In either branch, the singleton carrier identifies the displayed appended history with e. Empty-result inversion for append then identifies the visible tail $\mathsf{e0}(q)$ or $\mathsf{e1}(q)$ with e. Constructor separation for generated histories rules out both cases. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonCarrier append visible tail absurd`

Theorem 41.15 (Group singleton classifier append commuted factors)**.** *For histories* h, h_2, k, k_2 : BHist*, if the singleton group classifier relates the two appended endpoints*

$$R_{\mathsf{e}}(\mathsf{append}(h, k), \mathsf{append}(h_2, k_2)),$$

then it also relates the endpoints with the two append factors exchanged:

$$R_{\mathsf{e}}(\mathsf{append}(k, h), \mathsf{append}(k_2, h_2)).$$

Proof. The classifier gives singleton carrier witnesses for $\mathsf{append}(h, k)$ and $\mathsf{append}(h_2, k_2)$. Empty-result inversion for append splits each witness into singleton carrier witnesses for the two factors. Exchanging the factors and applying empty-result construction rebuilds singleton carrier witnesses for $\mathsf{append}(k, h)$ and $\mathsf{append}(k_2, h_2)$. Since both rebuilt endpoints are classified through e, transitivity and symmetry of hsame package the displayed singleton classifier. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier append comm congr`

Theorem 41.16 (Group singleton classifier continuation visible result exclusion)**.** *For histories* P, Q, r : BHist*, if the singleton group classifier relates* P *and* Q*, then no continuation from* P *through* Q *can have visible result* $\mathsf{E0}(r)$ *or* $\mathsf{E1}(r)$*:*

$$R_{\mathsf{e}}(P, Q) \Rightarrow (\mathsf{Cont}(P, Q, \mathsf{E0}(r)) \Rightarrow \mathsf{False}) \wedge (\mathsf{Cont}(P, Q, \mathsf{E1}(r)) \Rightarrow \mathsf{False}).$$

Proof. The classifier exposes singleton carrier witnesses for P and Q. Transport the continuation result along these endpoint witnesses to the right-unit continuation at e, obtaining a singleton carrier witness for the displayed result. Constructor separation rules out both visible constructors as singleton-empty histories. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier continuation visible result absurd`

Theorem 41.17 (Group singleton classifier continuation result-left iff)**.** *For histories P, Q, R : BHist with $\mathsf{Cont}(P, Q, R)$, the singleton group classifier relates the two continuation inputs exactly when it relates the continuation result to the left input:*

$$R_{\mathsf{e}}(P, Q) \iff R_{\mathsf{e}}(R, P).$$

Proof. If $R_{\mathsf{e}}(P, Q)$ holds, then both inputs are singleton-carried. Continuation result transport against the right-unit continuation at e makes R singleton-carried, and transitivity through e relates R to P. Conversely, if $R_{\mathsf{e}}(R, P)$ holds, then R is singleton-carried. Transport the displayed continuation to empty result and invert it to recover singleton carrier witnesses for P and Q; these witnesses classify the input pair. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier continuation result left iff`

Theorem 41.18 (Group singleton inverse continuation left-unit iff)**.** *For histories x, r : BHist, if r is a continuation result of the singleton inverse of x followed by x, then classifying r against the unit endpoint is exactly the singleton carrier condition on x:*

$$\mathsf{Cont}(\mathsf{GroupSingletonInv}(x), x, r) \Rightarrow \big(R_{\mathsf{e}}(r, \mathsf{e}) \iff A_{\mathsf{e}}(x)\big).$$

Proof. Unfolding the continuation identifies r with $\mathsf{append}(\mathsf{GroupSingletonInv}(x), x)$. In the forward direction, the classifier says this appended result is singleton-carried, and empty-result inversion for append recovers the carrier witness for x. Conversely, the inverse endpoint is definitionally e; combining its reflexive carrier witness with the carrier witness for x constructs the singleton carrier witness for the appended result, which then classifies the result against e. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonInv continuation left unit iff`

Theorem 41.19 (Group singleton classifier continuation result-right iff)**.** *For histories P, Q, R : BHist with $\mathsf{Cont}(P, Q, R)$, the singleton group classifier relates the two continuation inputs exactly when it relates the continuation result to the right input:*

$$R_{\mathsf{e}}(P, Q) \iff R_{\mathsf{e}}(R, Q).$$

Proof. If $R_{\mathsf{e}}(P, Q)$ holds, then both inputs carry singleton witnesses. Transport the continuation result against the empty right-unit continuation to make R singleton-carried. Together with the existing carrier witness for Q, transitivity through e classifies R with Q.

Conversely, if $R_{\mathsf{e}}(R, Q)$ holds, then R and Q are singleton-carried. Transport the displayed continuation to an empty result using the witness for R, and then apply empty-result inversion for append and continuation. This recovers a singleton carrier witness for P while preserving the displayed singleton witness for Q.

The recovered carrier witnesses for P and Q, composed through e, rebuild $R_{\mathsf{e}}(P, Q)$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier continuation result right iff`

Theorem 41.20 (Group singleton continuation result carrier exactness)**.** *For histories P, Q, R : BHist with $\mathsf{Cont}(P, Q, R)$, the singleton group classifier relates the continuation inputs exactly when the continuation result lies in the singleton carrier:*

$$R_{\mathsf{e}}(P, Q) \iff A_{\mathsf{e}}(R).$$

Proof. Assume $R_{\mathsf{e}}(P, Q)$. The classifier exposes endpoint witnesses $A_{\mathsf{e}}(P)$ and $A_{\mathsf{e}}(Q)$. Transporting the displayed continuation against the empty right-unit continuation carries the result endpoint to e, and therefore classifies R as a singleton-carried history.

Conversely, assume $A_{\mathsf{e}}(R)$. Transport the continuation result to e along this carrier witness. Empty-result inversion for continuation and append then recovers endpoint witnesses $A_{\mathsf{e}}(P)$ and $A_{\mathsf{e}}(Q)$. Composing these endpoint witnesses through e packages the input pair classifier $R_{\mathsf{e}}(P, Q)$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier continuation result carrier iff`

Theorem 41.21 (Group singleton carrier continuation endpoint split)**.** *For histories P, Q, R : BHist with $\mathsf{Cont}(P, Q, R)$, the continuation result lies in the singleton carrier exactly when both continuation endpoints lie in the singleton carrier:*

$$A_{\mathsf{e}}(R) \iff A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q).$$

Proof. If $A_{\mathsf{e}}(R)$ holds, transport the displayed continuation result to e and apply empty-result inversion for continuation to recover the two endpoint carrier witnesses. Conversely, if both endpoint carriers hold, compare the displayed continuation with the right-unit continuation at e; continuation respect for hsame transports the result into the singleton carrier. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonCarrier continuation endpoint split iff`

Theorem 41.22 (Group singleton inverse-continuation roundtrip carrier exactness)**.** *For histories x, r, s : BHist, if r is a continuation result of the singleton inverse of x followed by x, and s is a continuation result of r followed by the same singleton inverse, then the terminal carrier condition on the final result is exactly the terminal carrier condition on the original history:*

$$\mathsf{Cont}(\mathsf{GroupSingletonInv}(x), x, r) \Rightarrow \mathsf{Cont}(r, \mathsf{GroupSingletonInv}(x), s) \Rightarrow (A_{\mathsf{e}}(s) \iff A_{\mathsf{e}}(x)).$$

Proof. Apply Theorem 41.18 to the first continuation. This reads the left-unit inverse product back as $R_{\mathsf{e}}(r, \mathsf{e}) \iff A_{\mathsf{e}}(x)$.

The first row of Theorem 41.88, applied to r and e, converts $R_{\mathsf{e}}(r, \mathsf{e})$ into the carrier condition $A_{\mathsf{e}}(r)$, since $A_{\mathsf{e}}(\mathsf{e})$ is the reflexive terminal endpoint. Thus $A_{\mathsf{e}}(r) \iff A_{\mathsf{e}}(x)$.

Apply Theorem 41.20 to the second continuation. It identifies $A_{\mathsf{e}}(s)$ with $R_{\mathsf{e}}(r, \mathsf{GroupSingletonInv}(x))$.

The terminal classifier package and the constant inverse closure row of Theorem 41.4 identify this last classifier with $A_{\mathsf{e}}(r)$. Composing the two carrier equivalences gives $A_{\mathsf{e}}(s) \iff A_{\mathsf{e}}(x)$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonCarrier inverse continuation roundtrip iff`

The per-object certificate data are: traditional target terminal-group continuation-result coverage; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ over BHist and Cont; carrier A_{e}; classifier R_{e}; stability obligations continuation result transport and empty-result inversion; ledger hidden continuation result endpoint; core theorem this block plus Definition 41.17; exactness predicate $R_{\mathsf{e}}(P, Q) \iff A_{\mathsf{e}}(R)$; standard bridge terminal-group product result; and status $\mathsf{ProofTarget}$.

The $\mathsf{Group}^{\uparrow}$ schema is instantiated by this concrete $BHist$ carrier and operations, so subsequent formalization can prove $BHist$-anchored group laws instead of relying only on an abstract operator schema.

Theorem 41.23 (Group singleton inverse-continuation roundtrip source exactness)**.** *For histories x, r, s : BHist, if r is a continuation result of $\mathsf{GroupSingletonInv}(x)$ followed by x, and s is a continuation result of r followed by $\mathsf{GroupSingletonInv}(x)$, then classifying the final result against the original source is exactly the singleton carrier condition on the original source:*

$$\mathsf{Cont}(\mathsf{GroupSingletonInv}(x), x, r) \Rightarrow \mathsf{Cont}(r, \mathsf{GroupSingletonInv}(x), s) \Rightarrow (R_{\mathsf{e}}(s, x) \iff A_{\mathsf{e}}(x)).$$

Proof. The forward direction projects the right endpoint carrier from $R_{\mathsf{e}}(s, x)$. Conversely, apply Definition 41.22 to transport the carrier condition on x back to a carrier condition on s. The two carrier witnesses compose through hsame symmetry and transitivity to rebuild $R_{\mathsf{e}}(s, x)$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier inverse continuation roundtrip source iff`

41.3 Concrete singleton empty-history group instance

Definition 41.24 (Group singleton empty-history instance)**.** *Let A_{e} be the singleton history source at the empty endpoint:*

$$A_{\mathsf{e}}(h) := \mathsf{hsame}(h, \mathsf{e}).$$

The classifier, multiplication, unit, and inverse are

$$R_{\mathsf{e}}(h, k) := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h, k), \qquad \mathsf{mul}_{\mathsf{e}}(h, k) := \mathsf{append}(h, k), \qquad e_{\mathsf{e}} := \mathsf{e}, \qquad \mathsf{inv}_{\mathsf{e}}(h) := \mathsf{e}.$$

Equivalently, because both endpoints of the carrier are classified with e, the multiplication may be read through its classified empty endpoint. The displayed append row is the operational ledger, and the constant empty endpoint is the inverse row.

Theorem 41.25 (Group singleton empty-history laws)**.** *The data of Definition 41.24 satisfy the concrete $\mathsf{Group}^{\uparrow}$ laws over BHist: carrier inhabitance, multiplication closure, left and right unit laws, associativity and multiplication congruence from the continuation rows, inverse closure, and left and right inverse laws against e_{e}.*

Proof. Carrier inhabitance is the reflexive row $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$, so $A_{\mathsf{e}}(\mathsf{e})$ holds.

For multiplication closure, suppose $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$. The continuation append row for $\mathsf{append}(h, k)$ composes the two displayed paths to e with the empty endpoint laws, giving $A_{\mathsf{e}}(\mathsf{mul}_{\mathsf{e}}(h, k))$.

The left and right unit laws are the two empty-endpoint continuation laws for append. They identify $\mathsf{append}(\mathsf{e}, h)$ and $\mathsf{append}(h, \mathsf{e})$ with h; composing with the carrier witness $A_{\mathsf{e}}(h)$ classifies both products against the same singleton endpoint.

Associativity and multiplication congruence are inherited from the existing continuation rows for append. The carrier side conditions collapse all four endpoints into A_{e}, and the hsame equivalence rows repack the result as an R_{e} classifier statement.

Inverse closure is immediate because $\mathsf{inv}_{\mathsf{e}}(h)$ is e. The left and right inverse laws reduce to the same two unit laws: $\mathsf{append}(\mathsf{e}, h)$ and $\mathsf{append}(h, \mathsf{e})$ are classified with e_{e} by the carrier witness for h. □

Theorem 41.26 (Group singleton empty-history NameCert)**.** *The carrier A_{e}, classifier R_{e}, append multiplication, empty unit, and constant empty inverse package the laws of Definition 41.25 as a concrete $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ surface. The certificate exports only the singleton BHist carrier, the displayed continuation ledger for append, the empty endpoint, the constant inverse row, and the hsame classifier.*

Proof. The semantic carrier and classifier fields are supplied directly by Definition 41.24. Reflexivity, symmetry, and transitivity of the classifier are the corresponding hsame rows, with the two carrier side conditions retained in the package ledger.

The algebraic fields are exactly the rows proved in Definition 41.25. Multiplication closure, unit laws, associativity, and congruence come from the append continuation ledger; inverse closure and the inverse laws come from the constant empty inverse row.

Repacking these fields gives the concrete $\mathsf{NameCert}_{\mathsf{Group}^\uparrow}$ surface. No abstract carrier, external operation table, quotient presentation, or host-level group object is exported beyond the singleton history data named above. □

41.4 Group concrete history instance surface

Definition 41.27 (Concrete GroupUp history instance)**.** *The concrete* $\mathsf{Group}^\uparrow$ *history instance is the singleton empty-history package of Definition 41.24 read as a direct* BHist *surface. It is the inverse-bearing refinement of the monoid certificate of chapter 40, with the same append-continuation unit surface and the added constant inverse row. Its carrier is*

$$A_{\mathsf{e}}(h) := \mathsf{hsame}(h, \mathsf{e}).$$

Its classifier is R_{e}*, its multiplication is the append continuation row*

$$\mathsf{mul}_{\mathsf{e}}(h, k) := \mathsf{append}(h, k),$$

its unit is $e_{\mathsf{e}} := \mathsf{e}$*, and its inverse sends every carried endpoint to the constant empty endpoint*

$$\mathsf{inv}_{\mathsf{e}}(h) := \mathsf{e}.$$

Thus the instance is not an abstract carrier with external operations. It is the displayed BHist *singleton carrier, append* Cont *ledger, empty endpoint,* hsame *classifier, and constant inverse row.*

Theorem 41.28 (Group concrete Monoid dependency)**.** *The concrete* $\mathsf{Group}^\uparrow$ *history instance of Definition 41.27 consumes the* $\mathsf{UnaryHistory}$ *append carrier, empty unit, classifier, associativity row, and left and right unit rows of chapter 40. It then adds only the constant inverse row and the singleton carrier restriction of Definition 41.24. Hence the concrete* $\mathsf{Group}^\uparrow$ *packet is a refinement of the* $\mathsf{Monoid}^\uparrow$ *unary append* $\mathsf{NameCert}$ *rather than an isolated kernel-only packet.*

Proof. Read the $\mathsf{Monoid}^\uparrow$ dependency from Definition 40.2. Its carrier is $\mathsf{UnaryHistory}$, its operation is append, its unit is e, and its classifier is the unary append monoid classifier.

Apply Definition 40.3. The associativity, left-unit, right-unit, and classifier congruence rows are already present on the unary append surface consumed by the group instance.

Finally use Definition 41.25. The singleton carrier restriction and the constant empty inverse row provide exactly the inverse closure and inverse laws. No additional host group carrier, operation table, or classifier is imported, so the concrete $\mathsf{Group}^\uparrow$ instance refines the $\mathsf{Monoid}^\uparrow$ unary append NameCert. □

Definition 41.29 (Group unary Cont concrete carrier)**.** *The* $\mathsf{Group}^\uparrow$ *unary* Cont *concrete carrier is the* $\mathsf{UnaryHistory}$ *append surface of Definition 40.2 restricted by the singleton empty-history carrier of Definition 41.27. Its carried endpoints are unary* BHist *values* h *with* $A_{\mathsf{e}}(h)$*, its product row is*

$$\mathsf{mul}_{\mathsf{e}}(h, k) := \mathsf{append}(h, k),$$

equivalently displayed by $\mathsf{Cont}(h, k, \mathsf{append}(h, k))$*, and its unit row is the empty endpoint* e*. The classifier is the inherited* $\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})$ *together with the singleton* hsame *restriction to* e*. Thus the carrier names the concrete append-and-empty operation surface consumed by the* $\mathsf{Group}^{\uparrow}$ *singleton instance, not an abstract group parameter.*

Theorem 41.30 (Group unary Cont concrete monoid handoff)**.** *Every multiplication and unit read of the concrete* $\mathsf{Group}^{\uparrow}$ *history instance of Definition 41.27 factors through the unary* Cont *carrier of Definition 41.29. In particular, the* $\mathsf{Group}^{\uparrow}$ *singleton packet reads multiplication as the* $\mathsf{UnaryHistory}$ *append row, reads the unit as* e*, and obtains closure, associativity, left unit, right unit, and multiplication congruence from Definition 40.3 before it adds the constant empty inverse rows of Definition 41.25.*

Proof. Project the concrete group instance. Its multiplication is append, its unit is e, and its carried endpoints are singleton empty-history endpoints inside the unary BHist surface.

Apply Definition 40.3. The unary append carrier supplies closure, associativity, both empty-unit laws, and multiplication congruence for exactly the same Cont product and unit rows.

Now restrict those rows along Definition 41.29. The singleton carrier only adds the requirement that the endpoints classify with e; it does not replace append, the unit, or the monoid classifier by a separate algebraic operation.

Finally apply Definition 41.25. The only additional group data are inverse closure and the two inverse laws for the constant empty inverse row. Therefore the concrete $\mathsf{Group}^{\uparrow}$ multiplication and unit handoff is the unary Cont monoid surface followed by singleton inverse packaging. □

Theorem 41.31 (Group concrete inverse surface)**.** *For the concrete* $\mathsf{Group}^{\uparrow}$ *history instance of Definition 41.27, inverse closure and the two inverse laws are read entirely from the singleton empty-history laws and the append unit rows. If* $A_{\mathsf{e}}(h)$*, then* $A_{\mathsf{e}}(\mathsf{inv}_{\mathsf{e}}(h))$ *holds, and both products* $\mathsf{mul}_{\mathsf{e}}(\mathsf{inv}_{\mathsf{e}}(h), h)$ *and* $\mathsf{mul}_{\mathsf{e}}(h, \mathsf{inv}_{\mathsf{e}}(h))$ *classify with the unit* e_{e} *through* R_{e}*.*

Proof. Start from the concrete definition. The inverse endpoint is the constant empty history, so inverse closure is the reflexive row $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$.

For the left inverse law, expand $\mathsf{mul}_{\mathsf{e}}(\mathsf{inv}_{\mathsf{e}}(h), h)$ as $\mathsf{append}(\mathsf{e}, h)$. The left append unit row identifies this endpoint with h, and the carrier witness $A_{\mathsf{e}}(h)$ identifies h with e. These two hsame rows package the required R_{e} comparison with e_{e}.

For the right inverse law, expand $\mathsf{mul}_{\mathsf{e}}(h, \mathsf{inv}_{\mathsf{e}}(h))$ as $\mathsf{append}(h, \mathsf{e})$. The right append unit row identifies this endpoint with h, and the same carrier witness repacks it as an R_{e} comparison with the unit.

These are exactly the inverse rows already included in Definition 41.25; the concrete surface only names the BHist rows that carry them. □

Theorem 41.32 (Group concrete instance schema surface)**.** *The concrete* $\mathsf{Group}^{\uparrow}$ *history instance of Definition 41.27 supplies a non-parametric target surface for the algebra hierarchy. Its carrier, classifier, multiplication, unit, inverse, closure rows, unit rows, associativity row, congruence row, and inverse rows are all the displayed singleton* BHist*, append* Cont*,* hsame*, and empty-endpoint rows of Definition 41.25. No external carrier family, operation table, quotient presentation, or host-level group object is part of the target surface.*

Proof. Read the certificate rows from Definition 41.26. The semantic carrier and classifier are A_{e} and R_{e}, and the algebraic fields are the append multiplication, empty unit, and constant empty inverse.

Apply Definition 41.25. It supplies inhabitance, multiplication closure, the two unit laws, associativity, congruence, inverse closure, and the two inverse laws for these exact rows.

Finally apply Definition 41.31 to make the inverse rows visible as part of the concrete BHist surface. Since every field has been read from the singleton carrier and append ledger, the target is the concrete instance itself rather than a parameterized group schema. □

Theorem 41.33 (Group concrete history instance public laws)**.** *The concrete singleton* $\mathsf{Group}^{\uparrow}$ *history instance exports closure, associativity, left unit, right unit, congruence, inverse closure, left inverse, and right inverse laws by reading the* $\mathsf{Monoid}^{\uparrow}$ *unary append laws together with the singleton empty-history inverse laws. Concretely, the public law surface uses the carrier* A_{e}*, classifier* R_{e}*, multiplication* append*, unit* e*, classifier transport* hsame*, and continuation replay* Cont *from Definition 41.27 and Definition 41.28.*

Proof. Start from the concrete singleton history instance. The carrier is A_{e}, the classifier is R_{e}, the multiplication is append, and the unit is e.

Apply Definition 41.28 and Definition 41.31. The monoid dependency supplies closure, associativity, left unit, right unit, and congruence on the append surface, while the singleton inverse surface supplies inverse closure and the two inverse laws.

Finally read the laws as public rows of the same concrete packet. Because the carrier is singleton and the inverse is constant empty history, the public surface is non-parametric and uses only the displayed A_{e}, R_{e}, append, e, hsame, and Cont rows. □

Definition 41.34 (Group finite-word history instance)**.** *The finite-word* $\mathsf{Group}^{\uparrow}$ *history instance has carrier* $\mathsf{WordCarrier}_{\mathsf{Group}^{\uparrow}}$ *consisting of finite* $\mathsf{List}^{\uparrow}$ *word spines whose entries are singleton carried endpoints of Definition 41.24. Thus a word* $w = \mathsf{cons}(h_1, \ldots, \mathsf{cons}(h_n, \mathsf{nil}))$ *is carried when each* h_i *satisfies* $A_{\mathsf{e}}(h_i)$*, with the empty word carried by the nil constructor.*

The classifier $\mathsf{WordClass}_{\mathsf{Group}^{\uparrow}}(w, w')$ *is the componentwise lift of* hsame*, together with equality of the finite word spine. The product is concatenation of finite words through the displayed append continuation ledger*

$$\mathsf{mul}_{\mathrm{word}}(w, w') := w +\!\!+ w',$$

the unit is nil*, and inverse is reversal with the singleton inverse row applied to each component:*

$$\mathsf{inv}_{\mathrm{word}}(h_1, \ldots, h_n) := (\mathsf{inv}_{\mathsf{e}}(h_n), \ldots, \mathsf{inv}_{\mathsf{e}}(h_1)).$$

No host group operation is exported; every endpoint remains a finite BHist *word with its componentwise singleton ledger.*

Theorem 41.35 (Group finite-word operation closure)**.** *For the finite-word* $\mathsf{Group}^{\uparrow}$ *history instance of Definition 41.34, concatenation of two carried finite-word histories is carried. If* $w \sim_{\mathrm{word}} w'$ *and* $v \sim_{\mathrm{word}} v'$*, then* $\mathsf{mul}_{\mathrm{word}}(w, v) \sim_{\mathrm{word}} \mathsf{mul}_{\mathrm{word}}(w', v')$*. The empty word is a two-sided unit, and associativity is the list-spine append associativity row together with the singleton append laws of Definition 41.25.*

Proof. Induct on the first finite word. In the nil case, concatenation returns the second carried word, and the left unit law is the nil append equation. The right unit law follows by the corresponding induction on the carried word.

In the cons step, the head is carried by the componentwise carrier hypothesis and the tail product is carried by the induction hypothesis. Reattaching the head gives a carried concatenation spine, so no endpoint leaves the singleton BHist surface.

Classifier transport is componentwise. The head comparison is the displayed hsame row, while the tail comparison is transported by the induction hypothesis. The list-spine equality part records that concatenation preserves the finite shape on both sides.

Associativity is the standard finite-list append reassociation, with each component endpoint governed by Definition 41.25. The local concrete schema surface of Definition 41.32 supplies the same append ledger, so the finite-word operation remains the concrete BHist instance rather than an abstract group law. □

Theorem 41.36 (Group finite-word Cont associativity lock)**.** *For the finite-word* $\mathsf{Group}^{\uparrow}$ *history instance of Definition 41.34, the associativity route for the product is the displayed* Cont *replay over* BHist *word rows. Thus the two parenthesized products*

$$\mathsf{mul}_{\mathrm{word}}(\mathsf{mul}_{\mathrm{word}}(u, v), w) \quad \textit{and} \quad \mathsf{mul}_{\mathrm{word}}(u, \mathsf{mul}_{\mathrm{word}}(v, w))$$

are compared as the same ordered continuation spine. The lock is inherited from the kernel continuation associativity route and the finite list-spine append ledger; it is not supplied by an abstract mul *parameter.*

Proof. Unfold the finite-word carrier rows. Each carried word is a finite ordered list of singleton BHist endpoints, and the product is concatenation with the displayed append ledger.

Compare the two parenthesized products by reading the same three blocks u, v, w through the continuation spine. The left parenthesization first replays the route for u followed by v and then appends w; the right parenthesization first replays v followed by w and then prefixes u.

The kernel Cont associativity route identifies these as one ordered replay of the same finite rows. The displayed transport rows keep the component classifiers fixed while the list-spine append ledger changes only the parentheses.

Finally pass the replayed spine through the $\mathsf{Group}^{\uparrow}$ classifier of Definition 41.34. Since every endpoint remains a singleton BHist row, the associativity lock is a concrete continuation fact and not a parameter-echo group schema. □

Theorem 41.37 (Group finite-word inverse boundary)**.** *For every carried finite-word history* w*, the reversed componentwise singleton inverse* $\mathsf{inv}_{\mathrm{word}}(w)$ *is carried. Moreover,* $\mathsf{mul}_{\mathrm{word}}(w, \mathsf{inv}_{\mathrm{word}}(w))$ *and* $\mathsf{mul}_{\mathrm{word}}(\mathsf{inv}_{\mathrm{word}}(w), w)$ *expose exactly the displayed finite cancellation ledger obtained by pairing each component with its singleton inverse row; the boundary does not export a host group object or an external quotient.*

Proof. Induct on the finite word. The nil case is the empty word, whose inverse is again nil; both products are the nil append row.

In the cons case, apply Definition 41.25 to the head endpoint and Definition 41.26 to keep the transported classifier row inside the singleton certificate. The induction hypothesis gives the reversed inverse word for the tail and its carriedness.

Concatenating the word with its reversed inverse produces the visible sequence of componentwise singleton cancellation rows. Reassociating this finite append spine uses the same append ledger as Definition 41.32; it only rearranges the displayed continuation evidence.

The opposite product is identical after reversing the induction order. Thus the inverse boundary is a carried $\mathsf{List}^{\uparrow}$ word endpoint with a finite cancellation ledger, not a transported theorem about an ambient group object. □

Theorem 41.38 (Group finite-word NameCert package)**.** *The finite-word carrier, classifier, concatenation product, empty-word unit, and reversal inverse of Definition 41.34, together with operation closure from Definition 41.35, inverse boundary from Definition 41.37, singleton laws from Definition 41.25, and the* $\mathsf{Monoid}^{\uparrow}$ *dependency of Definition 41.28, form the local finite-word* $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ *package. Hence the algebra-hierarchy consumer receives a concrete finite* BHist *word surface rather than an abstract group parameter.*

Proof. Project the rows of Definition 41.34. The carrier is $\mathsf{WordCarrier}_{\mathsf{Group}^{\uparrow}}$, the classifier is $\mathsf{WordClass}_{\mathsf{Group}^{\uparrow}}$, the product is finite concatenation, the unit is nil, and inverse is reversal followed by the singleton inverse row on each component.

Apply Definition 41.35. It supplies multiplication closure, classifier transport for multiplication, the empty-word unit laws, and finite append associativity on exactly these projected rows. The dependency on Definition 41.28 identifies this operation ledger with the unary append $\mathsf{Monoid}^{\uparrow}$ surface consumed by the group packet.

Next apply Definition 41.37. It supplies inverse closure and both finite cancellation ledgers for the reversal inverse. The componentwise endpoint obligations are the singleton inverse and unit rows of Definition 41.25, so no external group carrier or quotient relation is imported.

These rows exhaust the local $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ fields: carried finite words, componentwise classification, product, unit, inverse, product closure, unit and associativity laws, inverse closure, and inverse laws. Repacking them gives the concrete algebra-hierarchy object as a finite BHist word package, not a schema parameter awaiting a host group. □

41.5 Singleton inverse image exactness

Theorem 41.39 (Group singleton inverse image exactness)**.** *For histories* $h, t : \mathsf{BHist}$*, if* $A_{\mathsf{e}}(h)$*, then the concrete constant inverse classifies precisely the singleton carrier:*

$$R_{\mathsf{e}}(\mathsf{GroupSingletonInv}(h), t) \iff A_{\mathsf{e}}(t).$$

The ten-field fit is: traditional target terminal-group inverse image; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* A_{e}*; classifier* R_{e}*; stability from constant inverse closure and terminal classifier packaging; ledger the hidden inverse endpoint; core theorem this block plus Theorem 41.88; exactness the displayed iff; downstream consumers* $\mathsf{QuotientGroup}^{\uparrow}$ *and singleton normalizer-action proofs; and status* $\mathsf{ProofTarget}$*.*

Proof. Assume $A_{\mathsf{e}}(h)$. The concrete singleton inverse unfolds to the constant endpoint e, so $A_{\mathsf{e}}(\mathsf{GroupSingletonInv}(h))$ is the reflexive singleton witness at e.

For the forward direction, unpack $R_{\mathsf{e}}(\mathsf{GroupSingletonInv}(h), t)$. The right carrier field is exactly $A_{\mathsf{e}}(t)$.

For the reverse direction, assume $A_{\mathsf{e}}(t)$. Combine the reflexive carrier witness for $\mathsf{GroupSingletonInv}(h)$ with the supplied carrier witness for t. Symmetry turns the endpoint witness for t into a path from e to t, and transitivity composes it with the reflexive identification of $\mathsf{GroupSingletonInv}(h)$ with e. These three fields package $R_{\mathsf{e}}(\mathsf{GroupSingletonInv}(h), t)$. □

Theorem 41.40 (Group singleton inverse classifier fiber)**.** *For histories* $x, y : \mathsf{BHist}$ *in the concrete singleton history group of Definition 41.3, the constant singleton inverse has exactly the terminal classifier fiber:*

$$R_{\mathsf{e}}(\mathsf{inv}(x), y) \iff A_{\mathsf{e}}(y).$$

The ten-field fit is: traditional target terminal-group inverse image; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* A_{e}*; classifier* R_{e}*; stability from singleton classifier reflexivity, symmetry, transitivity, and inverse closure; ledger the ignored inverse input* x *and the terminal endpoint* e*; core theorem this block plus Theorem 41.4; exactness the displayed iff; standard bridge the one-element group inverse fiber; status* $\mathsf{ProofTarget}$.

Proof. Unfold the concrete singleton inverse from Definition 41.3. For every history x, $\mathsf{inv}(x)$ is definitionally e, so the displayed left side is the classifier row $R_{\mathsf{e}}(\mathsf{e}, y)$.

For the forward direction, unpack $R_{\mathsf{e}}(\mathsf{e}, y)$. By definition of R_{e} this exposes three fields: $A_{\mathsf{e}}(\mathsf{e})$, $A_{\mathsf{e}}(y)$, and $\mathsf{hsame}(\mathsf{e}, y)$. Project the right carrier field to obtain $A_{\mathsf{e}}(y)$.

For the reverse direction, assume $A_{\mathsf{e}}(y)$. The singleton carrier contains e by the reflexive endpoint witness $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$. The assumed carrier fact identifies y with e; applying singleton symmetry gives the endpoint witness $\mathsf{hsame}(\mathsf{e}, y)$. Repack these three fields as $R_{\mathsf{e}}(\mathsf{e}, y)$, hence as $R_{\mathsf{e}}(\mathsf{inv}(x), y)$ after the inverse unfolds. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier inverse fiber empty endpoint iff`

Theorem 41.41 (Group singleton compiled concrete instance boundary)**.** *The singleton carrier* A_{e}*, classifier* R_{e}*, multiplication* append*, unit* e*, and constant inverse* e *of Definition 41.3 simultaneously supply the singleton-history* $\mathsf{SemanticNameCert}$ *for* $\mathsf{Group}^{\uparrow}$ *and the full concrete group algebraic-law package over* BHist*: carrier inhabitance, multiplication closure, inverse closure, the left and right unit laws, associativity up to* hsame*, multiplication congruence, inverse congruence, and the left and right inverse laws.*

Proof. The certificate component is exactly Theorem 41.4. It packages the carrier-aware classifier R_{e} with the append multiplication, empty unit, and constant empty inverse as the singleton-history $\mathsf{SemanticNameCert}$ for $\mathsf{Group}^{\uparrow}$.

The algebraic-law component is Theorem 41.5. Its rows give carrier inhabitance, closure under multiplication and inverse, the two unit laws, associativity, multiplication congruence, inverse congruence, and the two inverse laws for the same carrier, classifier, multiplication, unit, and inverse. The two cited blocks therefore have identical concrete data, so they assemble the stated concrete instance boundary. □

Theorem 41.42 (Group singleton commutator terminal collapse)**.** *For histories* $x, y : \mathsf{BHist}$ *in the concrete singleton history group of Definition 41.3, define*

$$\mathsf{Comm}_{\mathsf{e}}(x, y) := \mathsf{mul}(\mathsf{mul}(\mathsf{mul}(x, y), \mathsf{inv}(x)), \mathsf{inv}(y)).$$

If $A_{\mathsf{e}}(x)$ *and* $A_{\mathsf{e}}(y)$*, then* $A_{\mathsf{e}}(\mathsf{Comm}_{\mathsf{e}}(x, y))$ *and* $R_{\mathsf{e}}(\mathsf{Comm}_{\mathsf{e}}(x, y), \mathsf{e})$*. The ten-field fit is: traditional target terminal-group commutator fiber; BEDC source concrete singleton* $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* A_{e}*; classifier* R_{e}*; stability from multiplication closure, inverse closure, and terminal classifier exactness; ledger the two factors and inverse endpoints; core theorem this block plus Theorem 41.88; exactness terminal commutator classified with the unit; downstream consumers* $\mathsf{AbGroup}^{\uparrow}$ *and* $\mathsf{QuotientGroup}^{\uparrow}$*; status* $\mathsf{ProofTarget}$.

Proof. Start from $A_{\mathsf{e}}(x)$ and $A_{\mathsf{e}}(y)$. The inverse row of Theorem 41.88 places $\mathsf{inv}(x)$ and $\mathsf{inv}(y)$ in A_{e}.

Apply the multiplication-closure row three times. It first places $\mathsf{mul}(x, y)$ in A_{e}, then places $\mathsf{mul}(\mathsf{mul}(x, y), \mathsf{inv}(x))$ in A_{e}, and finally places $\mathsf{Comm}_{\mathsf{e}}(x, y)$ in A_{e}.

The carrier inhabitance row gives $A_{\mathsf{e}}(\mathsf{e})$. With the carrier fact for $\mathsf{Comm}_{\mathsf{e}}(x, y)$ and the carrier fact for e, the terminal classifier row of Theorem 41.88 packages $R_{\mathsf{e}}(\mathsf{Comm}_{\mathsf{e}}(x, y), \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonCommutator terminal collapse`
Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier commutator terminal collapse`

Theorem 41.43 (Group singleton commutator unit exactness)**.** *For histories $x, y : \mathsf{BHist}$ in the concrete singleton history group of Definition 41.3, define*

$$\mathsf{Comm_e}(x, y) := \mathsf{mul}(\mathsf{mul}(\mathsf{mul}(x, y), \mathsf{inv}(x)), \mathsf{inv}(y)).$$

Then the commutator is classified with the unit exactly when both inputs lie in the singleton carrier:

$$R_{\mathsf{e}}(\mathsf{Comm_e}(x, y), \mathsf{e}) \iff A_{\mathsf{e}}(x) \wedge A_{\mathsf{e}}(y).$$

The ten-field fit is: traditional target terminal-group commutator fiber exactness; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier A_{e}; classifier R_{e}; stability from product-unit splitting, context cancellation, inverse closure, and terminal classifier exactness; ledger the two factors and two constant inverse endpoints; core theorem this exactness plus Theorem 41.10 and Theorem 41.11; exactness the displayed iff; downstream consumers* $\mathsf{AbGroup}^{\uparrow}$ *and* $\mathsf{QuotientGroup}^{\uparrow}$*; status* $\mathsf{ProofTarget}$.

Proof. Unfold the concrete operations. Here inv is the constant endpoint e and mul is append, so the left side is the terminal classifier of the nested append word $\mathsf{append}(\mathsf{append}(\mathsf{append}(x, y), \mathsf{e}), \mathsf{e})$ against e.

For the forward direction, project the classifier to the carried endpoint e. The unit endpoint is carried, so terminal classifier exactness reduces the hypothesis to singleton carrier membership of the nested append word.

Apply Theorem 41.10 to split off the outer constant inverse endpoint, then apply the same product-unit split to remove the inner constant inverse endpoint. The remaining classifier is the product-unit classifier for $\mathsf{append}(x, y)$, and a final application gives exactly $A_{\mathsf{e}}(x) \wedge A_{\mathsf{e}}(y)$.

For the reverse direction, assume $A_{\mathsf{e}}(x) \wedge A_{\mathsf{e}}(y)$. Theorem 41.42 applies to these two carrier witnesses and gives $R_{\mathsf{e}}(\mathsf{Comm_e}(x, y), \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier commutator unit exactness iff`

Theorem 41.44 (Group singleton commutator carrier exactness)**.** *For histories $x, y : \mathsf{BHist}$ in the concrete singleton history group of Definition 41.3, with $\mathsf{Comm_e}$ defined as in Definition 41.42, the commutator carrier and terminal classifier are exactly the two input carrier conditions:*

$$A_{\mathsf{e}}(\mathsf{Comm_e}(x, y)) \iff A_{\mathsf{e}}(x) \wedge A_{\mathsf{e}}(y).$$

Moreover,

$$R_{\mathsf{e}}(\mathsf{Comm_e}(x, y), \mathsf{e}) \iff A_{\mathsf{e}}(x) \wedge A_{\mathsf{e}}(y).$$

The ten-field fit is: traditional target terminal-group commutator fiber exactness; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier A_{e}; classifier R_{e}; stability append-empty split plus terminal classifier exactness; ledger the two factors and constant inverse endpoints; core theorem this exactness plus Definition 41.42; exactness the displayed iff; downstream consumers* $\mathsf{AbGroup}^{\uparrow}$ *and* $\mathsf{QuotientGroup}^{\uparrow}$*; status* $\mathsf{ProofTarget}$.

Proof. Unfold the concrete singleton group operations. The multiplication is append and the inverse endpoint is constant, so $\mathsf{inv}(x) = \mathsf{e}$ and $\mathsf{inv}(y) = \mathsf{e}$. Thus the commutator carrier condition is the singleton-empty condition on the append product whose two right factors are empty endpoints.

For the forward carrier direction, append-empty inversion first removes the outer empty inverse endpoint, then removes the inner empty inverse endpoint, and finally applies the singleton append-empty split to the remaining product $\mathsf{append}(x, y)$. This yields $A_{\mathsf{e}}(x)$ and $A_{\mathsf{e}}(y)$.

For the reverse carrier direction, the supplied witnesses for x and y rebuild $A_{\mathsf{e}}(\mathsf{append}(x, y))$ by the singleton append-empty split. The reflexive empty witnesses for the two constant inverse endpoints then rebuild the full commutator carrier by append-empty construction.

It remains to read the classifier against the terminal endpoint. The first row of Definition 41.88 identifies $R_{\mathsf{e}}(\mathsf{Comm}_{\mathsf{e}}(x, y), \mathsf{e})$ with $A_{\mathsf{e}}(\mathsf{Comm}_{\mathsf{e}}(x, y)) \wedge A_{\mathsf{e}}(\mathsf{e})$, and $A_{\mathsf{e}}(\mathsf{e})$ is reflexive. Composing this terminal classifier exactness with the carrier equivalence gives the displayed classifier iff. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonCommutator carrier classifier exactness`

41.6 Concrete singleton equation solver

Theorem 41.45 (Group singleton left equation exactness)**.** *In the concrete singleton history group of Definition 41.3, with carrier A_{e}, classifier R_{e}, multiplication* $\mathsf{mul} := \mathsf{append}$*, unit* e*, and inverse* $\mathsf{inv}(h) := \mathsf{e}$*, the left equation row is exact for histories $a, x, b : \mathsf{BHist}$. If $A_{\mathsf{e}}(a)$, $A_{\mathsf{e}}(x)$, and $A_{\mathsf{e}}(b)$, then*

$$R_{\mathsf{e}}(\mathsf{mul}(a, x), b) \iff R_{\mathsf{e}}(x, \mathsf{mul}(\mathsf{inv}(a), b)).$$

Proof. Theorem 41.5 supplies the concrete group rows for the same carrier, classifier, multiplication, unit, and inverse. Multiplication closure and inverse closure place both displayed endpoints in A_{e}.

For the forward direction, unpack $R_{\mathsf{e}}(\mathsf{mul}(a, x), b)$ to the hsame component $\mathsf{mul}(a, x)\mathsf{hsame}b$. Apply Theorem 41.70; the resulting $\mathsf{hsame}(x, \mathsf{mul}(\mathsf{inv}(a), b))$ repacks with the carrier rows as $R_{\mathsf{e}}(x, \mathsf{mul}(\mathsf{inv}(a), b))$.

For the reverse direction, start from the unpacked component $\mathsf{hsame}(x, \mathsf{mul}(\mathsf{inv}(a), b))$. The backward direction of Theorem 41.70 gives $\mathsf{mul}(a, x)\mathsf{hsame}b$, and the same endpoint carrier rows repack it as $R_{\mathsf{e}}(\mathsf{mul}(a, x), b)$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier left equation exact iff`

Theorem 41.46 (Group singleton right equation exactness)**.** *In the concrete singleton history group of Definition 41.3, with carrier A_{e}, classifier R_{e}, multiplication* $\mathsf{mul} := \mathsf{append}$*, unit* e*, and inverse* $\mathsf{inv}(h) := \mathsf{e}$*, the right equation row is exact for histories $x, a, b : \mathsf{BHist}$. If $A_{\mathsf{e}}(x)$, $A_{\mathsf{e}}(a)$, and $A_{\mathsf{e}}(b)$, then*

$$R_{\mathsf{e}}(\mathsf{mul}(x, a), b) \iff R_{\mathsf{e}}(x, \mathsf{mul}(b, \mathsf{inv}(a))).$$

Proof. Theorem 41.5 supplies the concrete group rows for the same carrier, classifier, multiplication, unit, and inverse. Multiplication closure and inverse closure place both displayed endpoints in A_{e}.

For the forward direction, unpack $R_{\mathsf{e}}(\mathsf{mul}(x, a), b)$ to the corresponding hsame component. Apply Theorem 41.72; it transports $\mathsf{mul}(x, a)\mathsf{hsame}b$ to $\mathsf{hsame}(x, \mathsf{mul}(b, \mathsf{inv}(a)))$, and carrier closure repacks the right-hand classifier.

For the reverse direction, start from the unpacked component $\mathsf{hsame}(x, \mathsf{mul}(b, \mathsf{inv}(a)))$. The backward direction of Theorem 41.72 returns $\mathsf{mul}(x, a)\mathsf{hsame}b$, and endpoint carrier closure repacks the left-hand classifier. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier right equation exact iff`

Theorem 41.47 (Group singleton two-sided cancellation)**.** *In the concrete singleton history group of Definition 41.3, with carrier A_{e}, classifier R_{e}, multiplication* $\mathsf{mul} := \mathsf{append}$*, unit* e*, and inverse* $\mathsf{inv}(h) := \mathsf{e}$*, two-sided cancellation is exact for histories $a, b, c, d : \mathsf{BHist}$. If $A_{\mathsf{e}}(a)$, $A_{\mathsf{e}}(b)$, $A_{\mathsf{e}}(c)$, and $A_{\mathsf{e}}(d)$, then*

$$R_{\mathsf{e}}(\mathsf{mul}(\mathsf{mul}(a, b), c), \mathsf{mul}(\mathsf{mul}(a, d), c)) \Longrightarrow R_{\mathsf{e}}(b, d).$$

Proof. Theorem 41.5 supplies the concrete group rows for the same carrier, classifier, multiplication, unit, and inverse. Repeated multiplication closure places both displayed products in A_{e}.

Unpacking the assumed classifier gives the hsame component between those two products. Apply Theorem 41.119; the result is $\mathsf{hsame}(b, d)$, and the original carrier hypotheses $A_{\mathsf{e}}(b)$ and $A_{\mathsf{e}}(d)$ repack it as $R_{\mathsf{e}}(b, d)$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier two sided cancel`

Theorem 41.48 (Group singleton equation-cancellation concrete solver)**.** *In the concrete singleton history group of Definition 41.3, the package of Theorem 41.45, Theorem 41.46, and Theorem 41.47 supplies the concrete equation-cancellation solver over* BHist*.*

The ten-field fit is: traditional target terminal-group equation solving; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier A_{e}; classifier R_{e}; stability from concrete group laws plus generic left and right equation exactness and two-sided cancellation; ledger equation factors and inverse endpoints; core theorem list Theorem 41.5, Theorem 41.70, Theorem 41.72, and Theorem 41.119; exactness the three displayed rows; downstream consumers* $\mathsf{QuotientGroup}^{\uparrow}$ *and* $\mathsf{Field}^{\uparrow}$ *algebra-reduct packages; status* $\mathsf{ProofTarget}$*.*

Proof. The left equation row is Theorem 41.45, the right equation row is Theorem 41.46, and the cancellation row is Theorem 41.47.

These three rows use the same carrier, classifier, multiplication, unit, inverse, and concrete group-law source, so they assemble into one solver package with the listed source, stability, ledger, exactness, consumer, and status fields. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier equation cancellation solver`

41.7 Concrete singleton equation solver determinacy

Theorem 41.49 (Group singleton equation solver determinacy)**.** *In the concrete singleton history group of Definition 41.3, with carrier A_{e}, classifier R_{e}, multiplication* $\mathsf{mul} := \mathsf{append}$*, unit* e*, and inverse* $\mathsf{inv}(h) := \mathsf{e}$*, let $a, b, c, d, x, y : \mathsf{BHist}$. If $A_{\mathsf{e}}(a)$, $A_{\mathsf{e}}(b)$, $A_{\mathsf{e}}(c)$, $A_{\mathsf{e}}(d)$, $A_{\mathsf{e}}(x)$, and $A_{\mathsf{e}}(y)$, then the concrete solver is deterministic in the following same-target forms:*

1. *If $R_{\mathsf{e}}(\mathsf{mul}(a, x), b)$ and $R_{\mathsf{e}}(\mathsf{mul}(a, y), b)$, then $R_{\mathsf{e}}(x, y)$.*
2. *If $R_{\mathsf{e}}(\mathsf{mul}(x, a), b)$ and $R_{\mathsf{e}}(\mathsf{mul}(y, a), b)$, then $R_{\mathsf{e}}(x, y)$.*
3. *If $R_{\mathsf{e}}(\mathsf{mul}(\mathsf{mul}(a, x), c), d)$ and $R_{\mathsf{e}}(\mathsf{mul}(\mathsf{mul}(a, y), c), d)$, then $R_{\mathsf{e}}(x, y)$.*

The ten-field fit is: traditional target terminal-group solution determinacy; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier A_{e}; classifier R_{e}; stability from concrete solver exactness plus classifier symmetry and transitivity; ledger hidden equation target and contexts; core theorem list Theorem 41.48 plus the classifier equivalence fields; exactness same-target solution determinacy; downstream consumers* $\mathsf{QuotientGroup}^{\uparrow}$ *and* $\mathsf{Field}^{\uparrow}$ *algebra-reduct packages; status* $\mathsf{ProofTarget}$*.*

Proof. Theorem 41.48 gives the three concrete rows for the same carrier, classifier, multiplication, unit, and inverse. The concrete classifier fields supply symmetry and transitivity on R_{e} whenever the displayed endpoints are in A_{e}.

1. For the left-multiplication row, apply the forward direction of the concrete solver to $R_{\mathsf{e}}(\mathsf{mul}(a, x), b)$. This transports x to the endpoint $\mathsf{mul}(\mathsf{inv}(a), b)$.

   Apply the same forward direction to $R_{\mathsf{e}}(\mathsf{mul}(a, y), b)$. Now y is transported to the same solved endpoint. Use classifier symmetry on the second solved comparison, then classifier transitivity through the common endpoint to obtain $R_{\mathsf{e}}(x, y)$.

2. For the right-multiplication row, apply the forward direction of the concrete solver to both assumptions. The two transported comparisons classify x and y by the common endpoint $\mathsf{mul}(b, \mathsf{inv}(a))$.

   Symmetry on the solved comparison for y, followed by transitivity through that common endpoint, gives $R_{\mathsf{e}}(x, y)$.

3. For the two-sided row, first use symmetry on $R_{\mathsf{e}}(\mathsf{mul}(\mathsf{mul}(a, y), c), d)$. Transitivity with $R_{\mathsf{e}}(\mathsf{mul}(\mathsf{mul}(a, x), c), d)$ through the common target d gives

$$R_{\mathsf{e}}(\mathsf{mul}(\mathsf{mul}(a, x), c), \mathsf{mul}(\mathsf{mul}(a, y), c)).$$

   Apply the two-sided cancellation row of Theorem 41.48 to this classifier. The result is $R_{\mathsf{e}}(x, y)$.

□

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier equation solver determinacy`

Theorem 41.50 (Group singleton conjugated commutator invariance)**.** *For histories $s, x, y : \mathsf{BHist}$ in the concrete singleton history group of Definition 41.3, define*

$$\mathsf{Conj}_s(z) := \mathsf{mul}(\mathsf{mul}(s, z), \mathsf{inv}(s))$$

and use $\mathsf{Comm}_{\mathsf{e}}$ as in Definition 41.42. If $A_{\mathsf{e}}(s)$, $A_{\mathsf{e}}(x)$, and $A_{\mathsf{e}}(y)$, then

$$R_{\mathsf{e}}(\mathsf{Comm}_{\mathsf{e}}(\mathsf{Conj}_s(x), \mathsf{Conj}_s(y)), \mathsf{Comm}_{\mathsf{e}}(x, y)),$$

and both commutator endpoints classify against e:

$$R_{\mathsf{e}}(\mathsf{Comm}_{\mathsf{e}}(\mathsf{Conj}_s(x), \mathsf{Conj}_s(y)), \mathsf{e}) \wedge R_{\mathsf{e}}(\mathsf{Comm}_{\mathsf{e}}(x, y), \mathsf{e}).$$

The ten-field fit is: traditional target terminal commutator conjugation invariance; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ over BHist; carrier A_{e}; classifier R_{e}; stability from action closure, commutator closure, and terminal classifier exactness; ledger the conjugator plus two commutator inputs; core theorem this composite invariance; exactness the displayed concrete commutator classifier; downstream consumers $\mathsf{AbGroup}^{\uparrow}$ and $\mathsf{QuotientGroup}^{\uparrow}$; status $\mathsf{ProofTarget}$.

Proof. Apply Theorem 41.147 to (s, x) and again to (s, y). These two instances put $\mathsf{Conj}_s(x)$ and $\mathsf{Conj}_s(y)$ in the singleton carrier A_{e}.

Next apply Theorem 41.42 to the original pair (x, y). It gives the carrier fact for $\mathsf{Comm}_{\mathsf{e}}(x, y)$ and the classifier $R_{\mathsf{e}}(\mathsf{Comm}_{\mathsf{e}}(x, y), \mathsf{e})$.

Apply the same commutator-collapse theorem to the conjugated pair $(\mathsf{Conj}_s(x), \mathsf{Conj}_s(y))$. The action-carrier facts just built supply its hypotheses, so the theorem gives both $A_{\mathsf{e}}(\mathsf{Comm}_{\mathsf{e}}(\mathsf{Conj}_s(x), \mathsf{Conj}_s(y)))$ and $R_{\mathsf{e}}(\mathsf{Comm}_{\mathsf{e}}(\mathsf{Conj}_s(x), \mathsf{Conj}_s(y)), \mathsf{e})$.

Finally use the terminal classifier row of Theorem 41.88 on the two commutator carrier facts. It classifies the conjugated commutator endpoint against the original commutator endpoint by R_{e}, while the two commutator-collapse applications provide the two classifiers against e. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonCommutator conjugated invariance`

Theorem 41.51 (Group singleton conjugated commutator orbit invariance)**.** *For histories s, x, y : BHist in the concrete singleton history group of Definition 41.3, define*

$$\mathsf{Conj}_s(z) := \mathsf{mul}(\mathsf{mul}(s, z), \mathsf{inv}(s))$$

and use $\mathsf{Comm}_{\mathsf{e}}$ as in Definition 41.42. If $A_{\mathsf{e}}(s)$, $A_{\mathsf{e}}(x)$, and $A_{\mathsf{e}}(y)$, then

$$\mathsf{Comm}_{\mathsf{e}}(\mathsf{Conj}_s(x), \mathsf{Conj}_s(y)) \sim_{N_{\mathsf{e}}} \mathsf{Comm}_{\mathsf{e}}(x, y) \wedge \mathsf{Comm}_{\mathsf{e}}(x, y) \sim_{N_{\mathsf{e}}} \mathsf{Comm}_{\mathsf{e}}(\mathsf{Conj}_s(x), \mathsf{Conj}_s(y)).$$

The ten-field fit is: traditional target terminal commutator conjugation on normalizer orbits; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ over BHist; carrier A_{e}; classifier the normalizer orbit relation exact against R_{e}; stability from conjugated commutator classifier invariance and terminal classifier exactness; ledger the conjugator and two commutator inputs; core theorem this block; exactness the displayed bidirectional orbit relation; downstream consumer $\mathsf{QuotientGroup}^{\uparrow}$; status $\mathsf{ProofTarget}$.

Proof. Apply Theorem 41.50 to s, x, and y. It gives the classifier

$$R_{\mathsf{e}}(\mathsf{Comm}_{\mathsf{e}}(\mathsf{Conj}_s(x), \mathsf{Conj}_s(y)), \mathsf{Comm}_{\mathsf{e}}(x, y))$$

and the two classifiers against e.

The terminal classifier package turns those endpoint classifiers into carrier facts. Concretely, Theorem 41.88 applied to each commutator endpoint and e yields $A_{\mathsf{e}}(\mathsf{Comm}_{\mathsf{e}}(\mathsf{Conj}_s(x), \mathsf{Conj}_s(y)))$ and $A_{\mathsf{e}}(\mathsf{Comm}_{\mathsf{e}}(x, y))$.

Use the classifier-to-orbit direction of Theorem 41.150 with these two carrier facts. The displayed R_{e} row becomes $\mathsf{Comm}_{\mathsf{e}}(\mathsf{Conj}_s(x), \mathsf{Conj}_s(y)) \sim_{N_{\mathsf{e}}} \mathsf{Comm}_{\mathsf{e}}(x, y)$.

For the reverse orientation, apply classifier symmetry from Theorem 41.88 to the same R_{e} row. Orbit exactness then converts the symmetric classifier into $\mathsf{Comm}_{\mathsf{e}}(x, y) \sim_{N_{\mathsf{e}}} \mathsf{Comm}_{\mathsf{e}}(\mathsf{Conj}_s(x), \mathsf{Conj}_s(y))$. □

Theorem 41.72 (Group right-multiplication equation exactness)**.** *For a history-level group operation with associativity, right identity, multiplication congruence, and two-sided inverses, right multiplication by a classifies the original equation:*

$$xa\mathsf{hsame}b \iff x\mathsf{hsame}ba^{-1}.$$

Proof. The forward implication is Theorem 41.68.

For the reverse direction, transport $x\mathsf{hsame}ba^{-1}$ by right multiplication with a. Reassociate $(ba^{-1})a$ to $b(a^{-1}a)$, collapse $a^{-1}a$ by the left inverse law, and use the right identity on b. □

Lean4 ✓ `BEDC.Derived.GroupUp.group right mul equation exact from empty unit`

Theorem 41.73 (Group two-sided multiplication equation exactness)**.** *For a BEDC history-level group operation over* BHist *with unit* e*, associativity, left and right identities, multiplication congruence, and two-sided inverses, every* $a, c, x, b : \mathsf{BHist}$ *satisfies*

$$\mathsf{hsame}((ax)c, b) \iff \mathsf{hsame}(x, a^{-1}(bc^{-1})).$$

The ten-field fit is: traditional target two-sided group equation solving; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability left and right equation exactness, associativity, inverse laws, and multiplication congruence; ledger the left factor, right factor, target, and two inverse witnesses; core theorem this exactness iff; standard bridge ordinary two-sided group equations; status* $\mathsf{ProofTarget}$*.*

Proof. For the forward direction, apply Definition 41.72 to $\mathsf{hsame}((ax)c, b)$. This solves the right factor first and gives $\mathsf{hsame}(ax, bc^{-1})$.

Then apply Definition 41.70 to $\mathsf{hsame}(ax, bc^{-1})$. The left factor is solved exactly, yielding $\mathsf{hsame}(x, a^{-1}(bc^{-1}))$.

For the reverse direction, apply Definition 41.70 backward to $\mathsf{hsame}(x, a^{-1}(bc^{-1}))$. This recovers $\mathsf{hsame}(ax, bc^{-1})$.

Finally apply Definition 41.72 backward with right factor c. The recovered equation becomes $\mathsf{hsame}((ax)c, b)$. □

Lean4 ✓ `BEDC.Derived.GroupUp.group two sided mul equation exact from empty unit iff`

Theorem 41.74 (Group two-sided multiplication equation solution uniqueness)**.** *For a BEDC history-level group operation over* BHist *with unit* e*, associativity, left and right identities, multiplication congruence, and two-sided inverses, if x and y both solve the same two-sided multiplication equation*

$$\mathsf{hsame}((ax)c, b) \qquad \textit{and} \qquad \mathsf{hsame}((ay)c, b),$$

*then x*hsame*y. The ten-field fit is: traditional target two-sided group equation solution uniqueness; BEDC source* Group$^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability by two-sided equation exactness plus symmetry and transitivity; ledger left factor, right factor, target, and inverse witnesses; core theorem list Definition 41.73; exactness predicate same-target solution uniqueness; standard bridge ordinary two-sided group equation uniqueness; status* ProofTarget*.*

Proof. Apply Definition 41.73 to the first displayed equation. The first solution is classified by the normal form $a^{-1}(bc^{-1})$.

Apply Definition 41.73 to the second displayed equation. The second solution is classified by the same normal form $a^{-1}(bc^{-1})$.

Use symmetry on the second solved comparison and transitivity of hsame to conclude $x$hsame$y$. □

Lean4 ✓ `BEDC.Derived.GroupUp.group two sided mul equation solution unique from empty unit`

Theorem 41.75 (Group two-sided multiplication equation target-stable uniqueness)**.** *For a BEDC history-level group operation over* BHist *with unit* e*, associativity, left and right identity laws, multiplication congruence, and two-sided inverse laws, if*

$$\mathsf{hsame}((ax)c, b), \qquad \mathsf{hsame}((ay)c, d), \qquad \mathsf{hsame}(b, d),$$

*then x*hsame*y. The ten-field fit is: traditional target target-stable two-sided group equation uniqueness; BEDC source* Group$^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability from two-sided equation exactness, target transport by multiplication congruence, symmetry, and transitivity; ledger left factor, right factor, two targets, and inverse witnesses; core theorem list Definition 41.73 plus multiplication congruence; exactness predicate target-stable solution uniqueness; standard bridge ordinary group equation uniqueness under equal right-hand sides; status* ProofTarget*.*

Proof. Apply Definition 41.73 to the first displayed equation. The first solution is classified by the normal form $a^{-1}(bc^{-1})$.

Apply Definition 41.73 to the second displayed equation. The second solution is classified by the normal form $a^{-1}(dc^{-1})$.

Multiplication congruence transports $\mathsf{hsame}(b, d)$ by right multiplication with the reflexive inverse c^{-1}, giving $\mathsf{hsame}(bc^{-1}, dc^{-1})$. Transport that comparison by left multiplication with a^{-1} to identify $a^{-1}(bc^{-1})$ and $a^{-1}(dc^{-1})$.

Use symmetry on the solved comparison for y and transitivity of hsame along the two normal-form comparisons to conclude $x\mathsf{hsame}y$. □

Lean4 ✓ `BEDC.Derived.GroupUp.group two sided mul equation target stable unique from empty unit`

Theorem 41.76 (Group conjugation equation exactness)**.** *For a history-level group operation with associativity, left and right identities, multiplication congruence, and two-sided inverses, conjugation by a classifies the middle factor exactly:*

$$\mathsf{hsame}((ax)a^{-1}, b) \iff \mathsf{hsame}(x, (a^{-1}b)a).$$

The ten-field fit is: traditional target conjugation equation solving; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability associativity, inverse laws, and multiplication congruence; ledger conjugation provenance; core theorem this exactness iff; standard bridge group conjugacy equations; status* $\mathsf{ProofTarget}$*.*

Proof. For the forward direction, transport the displayed equation by right multiplication with a. Reassociate $((ax)a^{-1})a$ to $(ax)(a^{-1}a)$, collapse $a^{-1}a$ by the left inverse law, and use the right identity to obtain $ax\mathsf{hsame}ba$.

Then transport by left multiplication with a^{-1}. Reassociate $a^{-1}(ax)$ to $(a^{-1}a)x$, collapse $a^{-1}a$, and use the left identity to obtain $x\mathsf{hsame}(a^{-1}b)a$.

For the reverse direction, transport $x\mathsf{hsame}(a^{-1}b)a$ by left multiplication with a. Reassociate $a((a^{-1}b)a)$ through $(aa^{-1})b$ and then back to ba, using the right inverse law for aa^{-1} and the left identity on b.

Finally transport by right multiplication with a^{-1}. Reassociate $(ax)a^{-1}$ as the transported left side and reassociate $(ba)a^{-1}$ to $b(aa^{-1})$, collapse aa^{-1} by the right inverse law, and finish with the right identity on b. □

Lean4 ✓ `BEDC.Derived.GroupUp.group conjugation equation exact from empty unit iff`

Theorem 41.77 (Group conjugation empty action)**.** *For a BEDC history-level group operation over* BHist *with left and right empty-unit laws, multiplication congruence, and the right inverse law, the empty conjugating history acts as the identity:*

$$\mathsf{hsame}((\mathsf{e}x)\mathsf{e}^{-1}, x).$$

Proof. The right inverse law for e and the left empty-unit law identify e^{-1} with e. Multiplication congruence transports this comparison and the comparison $\mathsf{e}x\mathsf{hsame}x$ through the outer product, after which the right empty-unit law collapses $x\mathsf{e}$ to x. □

Lean4 ✓ `BEDC.Derived.GroupUp.group conjugation empty action from empty unit`

Theorem 41.78 (Group conjugation preserves the empty unit exactly)**.** *For a BEDC history-level group operation over* BHist *with associativity, left and right empty-unit laws, multiplication congruence, and two-sided inverse laws, conjugation by a has empty target exactly when the middle factor is empty:*

$$\mathsf{hsame}((ax)a^{-1}, \mathsf{e}) \iff \mathsf{hsame}(x, \mathsf{e}).$$

Proof. Apply Definition 41.76 with target e. The resulting right side is $x\mathsf{hsame}(a^{-1}\mathsf{e})a$. Associativity rewrites $(a^{-1}\mathsf{e})a$ as $a^{-1}(\mathsf{e}a)$; the left empty-unit law reduces $\mathsf{e}a$ to a, and the left inverse law collapses $a^{-1}a$ to e. Transitivity gives both directions of the displayed equivalence. □

Lean4 ✓ `BEDC.Derived.GroupUp.group conjugation empty exact from empty unit`

Theorem 41.79 (Group conjugation classifier exactness)**.** *For a history-level group operation with empty unit, associativity, left and right identities, multiplication congruence, and two-sided inverses, conjugation by a preserves and reflects the* hsame *classifier:*

$$\mathsf{hsame}((ax)a^{-1}, (ay)a^{-1}) \iff \mathsf{hsame}(x, y).$$

Proof. For the forward direction, apply Definition 41.76 to the displayed equation with target $(ay)a^{-1}$. Apply the same equation exactness theorem to the reflexive equation for y at the same target. The two solved endpoints are then compared by symmetry and transitivity of hsame.

For the reverse direction, multiplication congruence transports $x\mathsf{hsame}y$ through left multiplication by a and right multiplication by a^{-1}. □

Lean4 ✓ `BEDC.Derived.GroupUp.group conjugation classifier exact from empty unit iff`

Theorem 41.80 (Group conjugation equation solution uniqueness)**.** *For a BEDC history-level group operation whose unit is* e*, if x and y both solve the same conjugation equation*

$$\mathsf{hsame}((ax)a^{-1}, b) \qquad \textit{and} \qquad \mathsf{hsame}((ay)a^{-1}, b),$$

then $x\mathsf{hsame}y$.

Proof. Apply conjugation equation exactness to both displayed equations. Both middle factors are classified by the same normal form $(a^{-1}b)a$. Symmetry on the second classification and transitivity of hsame identify x and y. □

Lean4 ✓ `BEDC.Derived.GroupUp.group conjugation equation solution unique from empty unit`

Theorem 41.81 (Group singleton conjugation equation solver)**.** *For singleton histories a, x, b :* BHist*, the singleton classifier solves the displayed conjugation equation exactly when the middle history is classified against the corresponding empty-left normal form:*

$$\mathsf{GroupSingletonClassifier}((ax)\mathsf{e}, b) \iff \mathsf{GroupSingletonClassifier}(x, (\mathsf{e}b)a).$$

Proof. The forward direction splits the carrier of $(ax)\mathsf{e}$ through the append-empty readback, extracting singleton carriers for a, x, and the terminal empty factor. It then rebuilds the carrier of $(\mathsf{e}b)a$ from the empty factor, b, and a, and repacks the singleton classifier by transitivity of hsame. The reverse direction performs the same carrier split on $(\mathsf{e}b)a$ and rebuilds $(ax)\mathsf{e}$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier conjugation equation solver iff`

Theorem 41.82 (Group commutator detects commutation)**.** *For a BEDC history-level group operation over* BHist *with associativity, left and right identities, multiplication congruence, and two-sided inverse laws, define*

$$\mathsf{comm}(a, b) := \mathsf{mul}(\mathsf{mul}(a, b), \mathsf{mul}(\mathsf{inv}(a), \mathsf{inv}(b))).$$

Then every a, b : BHist *satisfy*

$$\mathsf{comm}(a, b)\mathsf{hsame}e \iff \mathsf{mul}(a, b)\mathsf{hsame}\mathsf{mul}(b, a).$$

The ten-field fit is: traditional target group commutator criterion; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability obligations inverse-product reversal, multiplication congruence, right cancellation, and inverse laws; ledger the two factors and inverse-product spine; core theorem this block; exactness predicate trivial commutator iff commutation; standard bridge ordinary group commutator criterion; status* ProofTarget*.*

Proof. Use Theorem 41.65 with the ordered product ba to identify $a^{-1}b^{-1}$ as an inverse-product presentation of $(ba)^{-1}$. Thus the displayed commutator is the product of ab with an inverse witness for ba.

For the forward direction, multiply the trivial commutator equation on the right by ba. The right side becomes ba by the left identity, while the left side reassociates to $ab((ba)^{-1}(ba))$; the left inverse law for ba collapses the final factor to e, and the right identity leaves ab. This is exactly the right-cancellation comparison between ab and ba.

For the reverse direction, transport $ab\mathsf{hsame}ba$ through multiplication congruence by the common right factor $(ba)^{-1}$. The right-hand product collapses to e by the right-inverse law, and the inverse-product reversal identification rewrites the left-hand product as $\mathsf{comm}(a, b)$. □

Lean4 ✓ `BEDC.Derived.GroupUp.group commutator trivial iff commutes from empty unit`

Theorem 41.83 (Group commutator fixed-point criterion)**.** *For a BEDC history-level group operation over* BHist *with associativity, left and right identities, multiplication congruence, and two-sided inverse laws, define*

$$\mathrm{Inn}_a(b) := (a \cdot b) \cdot a^{-1} \qquad \textit{and} \qquad \mathsf{comm}(a, b) := (a \cdot b) \cdot (a^{-1} \cdot b^{-1}).$$

Then every $a, b : \mathsf{BHist}$ *satisfy*

$$\mathsf{hsame}(\mathrm{Inn}_a(b), b) \iff \mathsf{hsame}(\mathsf{comm}(a, b), e) \iff \mathsf{hsame}(a \cdot b, b \cdot a).$$

The ten-field fit is: traditional target centralizer fixed-point criterion; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability obligations conjugation exactness, commutator exactness, associativity, inverse laws, and multiplication congruence; ledger conjugating factor, inverse witness, and commutator spine; core theorem this fixed-point equivalence; exactness predicate fixed point iff commutator trivial iff commutation; standard bridge ordinary group centralizers; status* ProofTarget*.*

Proof. Apply Theorem 41.76 with middle factor b and target b. The fixed-point assertion $\mathsf{hsame}((a \cdot b) \cdot a^{-1}, b)$ is therefore equivalent to the comparison $\mathsf{hsame}(b, (a^{-1} \cdot b) \cdot a)$.

For the forward comparison, multiply the right-side equation by a on the left and reassociate $a \cdot ((a^{-1} \cdot b) \cdot a)$ through $(a \cdot a^{-1}) \cdot b$. The inverse law collapses $a \cdot a^{-1}$ to the unit, and the unit laws identify the transported comparison with $\mathsf{hsame}(a \cdot b, b \cdot a)$.

For the reverse comparison, multiply $a \cdot b\mathsf{hsame}b \cdot a$ on the left by a^{-1}. Associativity moves the inverse next to a, the inverse and unit laws collapse the left factor, and the resulting comparison is exactly $\mathsf{hsame}(b, (a^{-1} \cdot b) \cdot a)$.

Theorem 41.82 gives the second equivalence, so transitivity of equivalences yields the displayed fixed-point, commutator, and commutation criterion. □

Lean4 ✓ `BEDC.Derived.GroupUp.group conjugation fixed point commutation iff from empty unit`

Definition 41.84 (Group centralizer carrier)**.** *Fix a BEDC history-level group operation* mul *over* BHist*, unit* e*, inverse operation* inv*, and fixed element* $a : \mathsf{BHist}$*. The centralizer carrier of* a *is the classifier* Z_a *on histories defined by*

$$Z_a(x) :\iff \mathsf{hsame}(\mathsf{mul}(x, a), \mathsf{mul}(a, x)).$$

Theorem 41.85 (Group centralizer inverse closure)**.** *For a BEDC history-level group operation* mul *over* BHist *with empty history unit* $e =$ BHist.Empty*, associativity, empty left and right unit laws, multiplication congruence, and two-sided inverse laws, the centralizer carrier of Definition 41.84 is closed under inverse:*

$$\mathsf{hsame}(\mathsf{mul}(x, a), \mathsf{mul}(a, x)) \Rightarrow \mathsf{hsame}(\mathsf{mul}(\mathsf{inv}(x), a), \mathsf{mul}(a, \mathsf{inv}(x))).$$

Equivalently, $Z_a(x)$ *implies* $Z_a(\mathsf{inv}(x))$*. The ten-field fit is: traditional target centralizer inverse closure; BEDC source* $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* Z_a*; classifier* hsame*; stability obligations associativity, empty unit laws, multiplication congruence, and two-sided inverse laws; ledger fixed element* a *and commuting witness for* x*; core theorem inverse closure of the centralizer carrier; exactness predicate commutation with* a*; standard bridge ordinary group centralizers; status* Proof*.*

Proof. For inverse closure, first use Definition 41.60 on the witness $xa\mathsf{hsame}ax$. Apply Definition 41.65 to both products. The inverse of xa is represented by $a^{-1}x^{-1}$, and the inverse of ax is represented by $x^{-1}a^{-1}$; transporting along the inverse-congruence witness gives $a^{-1}x^{-1}\mathsf{hsame}x^{-1}a^{-1}$.

Multiplying on the left by a and on the right by a, then using associativity and the two inverse laws, cancels the outer a^{-1} factors and yields $x^{-1}a\mathsf{hsame}ax^{-1}$. □

Lean4 ✓ `BEDC.Derived.GroupUp.group centralizer inv closed from empty unit`

Theorem 41.86 (Group centralizer multiplication closure from empty unit)**.** *For a BEDC history-level group operation* mul *over* BHist *with associativity, right empty-unit law, and multiplication congruence, the centralizer carrier of Definition 41.84 is closed under multiplication:*

$$\mathsf{hsame}(\mathsf{mul}(x, a), \mathsf{mul}(a, x)) \Rightarrow \mathsf{hsame}(\mathsf{mul}(y, a), \mathsf{mul}(a, y)) \Rightarrow \mathsf{hsame}(\mathsf{mul}(\mathsf{mul}(x, y), a), \mathsf{mul}(a, \mathsf{mul}(x, y))).$$

Proof. The empty-context multiplication closure compares the two target products after multiplying both by e on the right. The concrete right empty-unit law identifies each right-extended product with its unextended endpoint, and transitivity removes the empty context from the comparison. □

Lean4 ✓ `BEDC.Derived.GroupUp.group centralizer mul closed from empty unit`

Theorem 41.87 (Group centralizer subgroup and commutator fiber)**.** *For a BEDC history-level group operation over* BHist *with associativity, left and right identity laws for* e*, multiplication congruence, and two-sided inverse laws, the carrier* Z_a *of Definition 41.84 is closed under the group operations:*

1. $Z_a(e)$*.*
2. *If* $Z_a(x)$ *and* $Z_a(y)$*, then* $Z_a(\mathsf{mul}(x, y))$*.*
3. *If* $Z_a(x)$*, then* $Z_a(\mathsf{inv}(x))$*.*
4. *For every* $x : \mathsf{BHist}$*,*

$$Z_a(x) \iff \mathsf{comm}(x, a)\mathsf{hsame}e,$$

where comm *is the commutator operation of Definition 41.82.*

The ten-field fit is: traditional target centralizer subgroup; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* Z_a*; classifier* hsame*; stability obligations unit, product, inverse closure, and commutator-fiber exactness; ledger fixed element* a *and commuting witnesses for the active factors; core theorem list Definition 41.65, Definition 41.60, and Definition 41.82, together with associativity, unit laws, inverse laws, and multiplication congruence; exactness predicate* $Z_a(x)$ *iff trivial commutator; standard bridge ordinary group centralizers; status* ProofTarget*.*

Proof. The unit belongs to Z_a because the left and right identity laws identify ea and ae with the same history a. Symmetry and transitivity of hsame close the comparison.

Lean4 ✓ `BEDC.Derived.GroupUp.group centralizer empty unit mem`

For product closure, start from witnesses $x a \mathsf{hsame} a x$ and $y a \mathsf{hsame} a y$. Associativity rewrites $(xy)a$ as $x(ya)$; multiplication congruence transports the second witness to $x(ay)$, and associativity rewrites this as $(xa)y$. The first witness then transports the left factor to $(ax)y$, and associativity gives $a(xy)$.

For inverse closure, apply Definition 41.85 to the witness $Z_a(x)$.

The commutator fiber is exactly the displayed carrier by Definition 41.82 with the ordered pair (x, a). Its right side is precisely the definition of $Z_a(x)$, and symmetry of the displayed equivalence supplies the stated orientation. □

Lean4 ✓ `BEDC.Derived.GroupUp.group centralizer mul closed empty context`

Theorem 41.88 (Group singleton terminal classifier package)**.** *For histories $h, k, p, q : \mathsf{BHist}$, the concrete singleton $\mathsf{Group}^{\uparrow}$ instance of Definition 41.3 carries the terminal classifier package:*

1. *The classifier is exactly the product carrier relation:*

$$R_{\mathsf{e}}(h, k) \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

2. *With $\mathsf{mul} = \mathsf{append}$, multiplication is exactly closed on the singleton carrier:*

$$A_{\mathsf{e}}(\mathsf{mul}(p, q)) \iff A_{\mathsf{e}}(p) \wedge A_{\mathsf{e}}(q).$$

3. *If $A_{\mathsf{e}}(h)$, then the constant inverse has both endpoint classifications:*

$$A_{\mathsf{e}}(\mathsf{inv}(h)) \wedge R_{\mathsf{e}}(\mathsf{inv}(h), h) \wedge R_{\mathsf{e}}(h, \mathsf{inv}(h)).$$

The per-object template names the traditional target as the terminal group; the BEDC source as the concrete singleton $\mathsf{Group}^{\uparrow}$ over BHist; carrier A_{e}; classifier R_{e}; stability as hsame symmetry/transitivity and append-empty exactness; ledger the hidden singleton endpoint witnesses; core theorem this block; exactness predicate the displayed iff rows; and status ProofTarget.

Proof. Unfold R_{e} and A_{e}. For the first row, the forward direction forgets only the displayed $\mathsf{hsame}(h, k)$ witness. Conversely, singleton carrier witnesses identify h and k with e; symmetry and transitivity of hsame compose those endpoint identifications through e and supply the classifier comparison.

For the second row, use Definition 41.3 to replace mul by append. From $A_{\mathsf{e}}(p)$ and $A_{\mathsf{e}}(q)$, append empty-result construction gives $A_{\mathsf{e}}(\mathsf{append}(p, q))$. In the reverse direction, append empty-result inversion splits the singleton endpoint witness for $\mathsf{append}(p, q)$ into the two factor witnesses.

For the third row, Definition 41.3 gives the definitional equation $\mathsf{inv}(h) = \mathsf{e}$. Hence $A_{\mathsf{e}}(\mathsf{inv}(h))$ is the reflexive singleton endpoint witness, and the first row applied to $\mathsf{inv}(h)$ and h packages both classifier orientations. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingleton terminal classifier package`
Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier terminal package`

Theorem 41.89 (Group singleton two-sided contextual classifier coverage)**.** *For histories* L, R, L', R', Q, S : BHist*, if* $A_{\mathsf{e}}(L)$*,* $A_{\mathsf{e}}(R)$*,* $A_{\mathsf{e}}(L')$*, and* $A_{\mathsf{e}}(R')$*, then*

$$R_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(L, Q), L'), \mathsf{append}(\mathsf{append}(R, S), R')) \iff A_{\mathsf{e}}(Q) \wedge A_{\mathsf{e}}(S).$$

The ten-field fit names the traditional target terminal-group contextual endpoint coverage; the BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist *with append; carrier* A_{e}*; classifier* R_{e}*; stability from two-sided context cancellation and terminal classifier coverage; ledger hidden singleton prefix/suffix endpoints; exactness predicate the displayed iff; standard bridge terminal group contextual equality; and status* $\mathsf{ProofTarget}$*.*

Proof. Apply Theorem 41.9 with the four displayed singleton context witnesses. This identifies the context-wrapped classifier with the endpoint classifier $R_{\mathsf{e}}(Q, S)$.

Apply the first row of Theorem 41.88 to replace $R_{\mathsf{e}}(Q, S)$ by the pair of singleton carrier facts $A_{\mathsf{e}}(Q) \wedge A_{\mathsf{e}}(S)$. Composing the two equivalences gives exactly the displayed contextual classifier coverage. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier two sided contextual coverage iff`
Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier two sided contextual carrier coverage iff`

Theorem 41.90 (Group singleton continuation terminal collapse)**.** *For histories* P, Q, R, r : BHist *with* $\mathsf{Cont}(P, Q, R)$*, the concrete singleton* $\mathsf{Group}^{\uparrow}$ *continuation collapses the input classifier, both result classifiers, and the result carrier to one terminal condition:*

$$R_{\mathsf{e}}(P, Q) \iff R_{\mathsf{e}}(R, P) \iff R_{\mathsf{e}}(R, Q) \iff A_{\mathsf{e}}(R).$$

Moreover, under these equivalent conditions, both visible continuation results are excluded:

$$(\mathsf{Cont}(P, Q, \mathsf{E0}(r)) \Rightarrow \mathsf{False}) \wedge (\mathsf{Cont}(P, Q, \mathsf{E1}(r)) \Rightarrow \mathsf{False}).$$

The per-object template names the traditional target terminal-group continuation collapse; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist *plus* Cont*; carrier* A_{e}*; classifier* R_{e}*; stability from continuation result transport and empty-result inversion; ledger hidden continuation result endpoint; core theorem this block; exactness predicate the four-way equivalence; and status* $\mathsf{ProofTarget}$*.*

Proof. Use Theorem 41.17 to identify the input classifier $R_{\mathsf{e}}(P, Q)$ with the left result classifier $R_{\mathsf{e}}(R, P)$ under the displayed continuation witness.

Use Theorem 41.19 to identify the same input classifier $R_{\mathsf{e}}(P, Q)$ with the right result classifier $R_{\mathsf{e}}(R, Q)$. Then use Theorem 41.20 to identify $R_{\mathsf{e}}(P, Q)$ with the result carrier condition $A_{\mathsf{e}}(R)$. These three exactness statements give the four-way equivalence.

Under any of the equivalent conditions, take the input-classifier presentation $R_{\mathsf{e}}(P, Q)$. Theorem 41.16 then excludes both visible results $\mathsf{E0}(r)$ and $\mathsf{E1}(r)$ for continuations from P through Q. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier continuation terminal collapse`

Theorem 41.91 (Group singleton continuation product-unit triple coverage)**.** *For histories* P, Q, S, T : BHist *with* $\mathsf{Cont}(P, Q, S)$*, the concrete singleton* $\mathsf{Group}^{\uparrow}$ *continuation and append product-unit classifier give the three endpoint coverage equivalence:*

$$R_{\mathsf{e}}(\mathsf{append}(S, T), \mathsf{e}) \iff A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q) \wedge A_{\mathsf{e}}(T).$$

The ten-field fit names the traditional target terminal-group continuation product-unit coverage; the BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist *plus* Cont *and append; carrier* A_{e}*; classifier* R_{e}*; stability from continuation terminal collapse and product-unit split; ledger continuation witness, product suffix, and hidden endpoint witnesses; core theorem list Definition 41.10, Definition 41.90, and Definition 41.88; exactness the displayed iff; and status* $\mathsf{ProofTarget}$.

Proof. Apply Definition 41.10 to rewrite the left side as the product of the continuation result carrier and suffix carrier:

$$A_{\mathsf{e}}(S) \wedge A_{\mathsf{e}}(T).$$

Use Definition 41.90 under the displayed continuation witness to identify $A_{\mathsf{e}}(S)$ with $R_{\mathsf{e}}(P, Q)$. This changes the intermediate condition to $R_{\mathsf{e}}(P, Q) \wedge A_{\mathsf{e}}(T)$.

Finally, apply the first row of Definition 41.88 to rewrite $R_{\mathsf{e}}(P, Q)$ as $A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q)$. Reassociating conjunctions gives exactly

$$A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q) \wedge A_{\mathsf{e}}(T).$$

□

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier continuation product unit coverage iff`

Theorem 41.92 (Group singleton contextual continuation terminal collapse)**.** *For histories* $L, R, L', R', P, Q, S, r : \mathsf{BHist}$*, suppose* $A_{\mathsf{e}}(L)$*,* $A_{\mathsf{e}}(R)$*,* $A_{\mathsf{e}}(L')$*,* $A_{\mathsf{e}}(R')$*, and* $\mathsf{Cont}(P, Q, S)$*. Then the singleton contextual classifier collapses to the same terminal continuation conditions:*

$$R_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(L, P), L'), \mathsf{append}(\mathsf{append}(R, Q), R')) \iff R_{\mathsf{e}}(P, Q) \iff R_{\mathsf{e}}(S, P) \iff R_{\mathsf{e}}(S, Q) \iff A_{\mathsf{e}}(S).$$

Moreover, under these equivalent conditions, both visible continuation results are excluded:

$$(\mathsf{Cont}(P, Q, \mathsf{E0}(r)) \Rightarrow \mathsf{False}) \wedge (\mathsf{Cont}(P, Q, \mathsf{E1}(r)) \Rightarrow \mathsf{False}).$$

The ten-field fit names the traditional target terminal-group contextual continuation collapse; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist *plus* Cont*; carrier* A_{e}*; classifier* R_{e}*; stability from two-sided context cancellation and continuation terminal collapse; ledger hidden prefix/suffix endpoint witnesses; core theorem this block; exactness predicate the contextual terminal equivalence; standard bridge terminal-group contextual continuation collapse; and status* $\mathsf{ProofTarget}$.

Proof. Apply Theorem 41.9 with the four singleton carrier witnesses for L, R, L', R'. This strips the hidden prefix and suffix contexts from the displayed contextual classifier and identifies it with the uncontexted classifier $R_{\mathsf{e}}(P, Q)$.

Apply Theorem 41.90 to the continuation witness $\mathsf{Cont}(P, Q, S)$. It identifies $R_{\mathsf{e}}(P, Q)$ with $R_{\mathsf{e}}(S, P)$, $R_{\mathsf{e}}(S, Q)$, and $A_{\mathsf{e}}(S)$, and it gives the two implications excluding $\mathsf{Cont}(P, Q, \mathsf{E0}(r))$ and $\mathsf{Cont}(P, Q, \mathsf{E1}(r))$. Composing this terminal collapse with the contextual cancellation gives the displayed theorem. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier contextual continuation terminal collapse`

41.9 Singleton contextual continuation obstruction

Theorem 41.93 (Group singleton contextual continuation visible-result exclusion)**.** *For histories* $L, R, L', R', P, Q, r : \mathsf{BHist}$*, suppose* $A_{\mathsf{e}}(L)$*,* $A_{\mathsf{e}}(R)$*,* $A_{\mathsf{e}}(L')$*,* $A_{\mathsf{e}}(R')$*, and*

$$R_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(L, P), L'), \mathsf{append}(\mathsf{append}(R, Q), R')).$$

Then singleton hidden contexts obstruct both visible continuation results:

$$(\mathsf{Cont}(P, Q, \mathsf{E0}(r)) \Rightarrow \mathsf{False}) \wedge (\mathsf{Cont}(P, Q, \mathsf{E1}(r)) \Rightarrow \mathsf{False}).$$

The ten-field fit is: traditional target terminal-group contextual continuation obstruction; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist *plus* Cont*; carrier* A_{e}*; classifier* R_{e}*; stability from two-sided context cancellation plus visible-result exclusion; ledger hidden prefix and suffix singleton contexts; core theorem list Theorem 41.9 and Theorem 41.16; exactness predicate the displayed implication pair; and status* $\mathsf{ProofTarget}$*.*

Proof. Apply the forward direction of Theorem 41.9 to the displayed contextual classifier, using the four singleton carrier witnesses for L, R, L', R'. This exposes the uncontexted classifier $R_{\mathsf{e}}(P, Q)$.

Apply Theorem 41.16 to that classifier. It gives exactly the two implications excluding visible results $\mathsf{E0}(r)$ and $\mathsf{E1}(r)$ for continuations from P through Q. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier contextual continuation visible result absurd`

41.10 Centralizer transport

Theorem 41.94 (Group centralizer fixed-element transport)**.** *For a BEDC history-level group operation over* BHist *with multiplication congruence, let* Z_a *and* Z_b *be the centralizer carriers of Definition 41.84 for fixed elements* $a, b : \mathsf{BHist}$*. If* $\mathsf{hsame}(a, b)$*, then for every* $x : \mathsf{BHist}$*,*

$$Z_a(x) \Longleftrightarrow Z_b(x).$$

The ten-field fit is: traditional target transport of centralizers along internal equality of the fixed element; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier the family* Z_a*; classifier* hsame*; stability obligation multiplication congruence in the fixed-element slot; ledger the fixed-element comparison; core theorem list Definition 41.84, multiplication congruence, and* hsame *symmetry and transitivity; exactness predicate the displayed iff; standard bridge ordinary equality-invariant centralizers; status* $\mathsf{ProofTarget}$*.*

Proof. Unfold the centralizer carrier. The assertion $Z_a(x)$ is the comparison $\mathsf{hsame}(\mathsf{mul}(x, a), \mathsf{mul}(a, x))$, and $Z_b(x)$ is the comparison $\mathsf{hsame}(\mathsf{mul}(x, b), \mathsf{mul}(b, x))$.

For the forward direction, assume $Z_a(x)$. Symmetry turns $\mathsf{hsame}(a, b)$ into $\mathsf{hsame}(b, a)$, and multiplication congruence in the fixed-element slot transports it to $\mathsf{hsame}(\mathsf{mul}(x, b), \mathsf{mul}(x, a))$. Transitivity with the $Z_a(x)$ witness gives $\mathsf{hsame}(\mathsf{mul}(x, b), \mathsf{mul}(a, x))$.

Multiplication congruence also transports $\mathsf{hsame}(a, b)$ through the left fixed-element slot, giving $\mathsf{hsame}(\mathsf{mul}(a, x), \mathsf{mul}(b, x))$. A final transitivity step therefore yields $\mathsf{hsame}(\mathsf{mul}(x, b), \mathsf{mul}(b, x))$, which is $Z_b(x)$.

For the reverse direction, exchange a and b. The same calculation starts from $Z_b(x)$, uses symmetry of $\mathsf{hsame}(a, b)$ where the fixed element is transported from b back to a, and concludes with $\mathsf{hsame}(\mathsf{mul}(x, a), \mathsf{mul}(a, x))$, namely $Z_a(x)$. □

Lean4 ✓ `BEDC.Derived.GroupUp.group centralizer fixed element empty context transport iff`

Definition 41.95 (Group centralizer normalizer carrier)**.** *Let Z_a be the centralizer carrier of Definition 41.84. For each history $s : \mathsf{BHist}$ define the conjugation word*

$$\mathsf{Conj}_s(x) := \mathsf{mul}(\mathsf{mul}(s, x), \mathsf{inv}(s)).$$

The centralizer normalizer carrier N_a is the predicate

$$N_a(s) :\Longleftrightarrow (\forall x : \mathsf{BHist},\ Z_a(x) \Rightarrow Z_a(\mathsf{Conj}_s(x))) \wedge (\forall x : \mathsf{BHist},\ Z_a(x) \Rightarrow Z_a(\mathsf{Conj}_{\mathsf{inv}(s)}(x))).$$

Thus $N_a(s)$ records centralizer preservation by conjugation with s and by conjugation with $\mathsf{inv}(s)$.

Theorem 41.96 (Group conjugation composition)**.** *For a BEDC history-level group operation over BHist with associativity, left and right identity laws for e, multiplication congruence, and two-sided inverse laws, inner conjugation composes in the expected order:*

$$\mathsf{Conj}_{\mathsf{mul}(s,t)}(x)\mathsf{hsameConj}_s(\mathsf{Conj}_t(x)).$$

Moreover the inverse conjugating word for $\mathsf{mul}(s, t)$ is represented by the reversed inverse product $\mathsf{mul}(\mathsf{inv}(t), \mathsf{inv}(s))$. The ten-field fit is: traditional target inner-action composition; BEDC source $\mathsf{Group}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability obligations inverse-product reversal, reassociation, and multiplication congruence; ledger the ordered pair s, t and the acted-on history x; core theorem list Definition 41.65 and Definition 41.79, together with associativity, unit laws, inverse laws, and multiplication congruence; standard bridge ordinary inner automorphism composition; status $\mathsf{ProofTarget}$.

Proof. Expand both conjugation words. The left side is $\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(s, t), x), \mathsf{inv}(\mathsf{mul}(s, t)))$.

Apply Definition 41.65 to the product $\mathsf{mul}(s, t)$. It replaces the final inverse by $\mathsf{mul}(\mathsf{inv}(t), \mathsf{inv}(s))$, with the order reversed.

Associativity then moves parentheses through $((st)x)(t^{-1}s^{-1})$ until the word is $s((tx)t^{-1})s^{-1}$. Multiplication congruence transports each reassociation and the inverse-product comparison through the outer products. The final word is exactly $\mathsf{Conj}_s(\mathsf{Conj}_t(x))$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupConjugationWord product composition`
Lean4 ✓ `BEDC.Derived.GroupUp.group conjugation composition from empty unit`
Lean4 ✓ `BEDC.Derived.GroupUp.group conjugation mul composition from empty unit`

Theorem 41.97 (Group normalizer conjugation action composition)**.** *For a BEDC history-level group operation over BHist with the same associativity, left and right identity laws for e, multiplication congruence, and two-sided inverse laws as in Definition 41.87, assume $N_a(s)$, $N_a(t)$, and $Z_a(x)$. Then the normalizer conjugation action composes on Z_a:*

1. $Z_a(\mathsf{Conj}_s(\mathsf{Conj}_t(x)))$.
2. $\mathsf{hsame}(\mathsf{Conj}_{\mathsf{mul}(s,t)}(x), \mathsf{Conj}_s(\mathsf{Conj}_t(x)))$.
3. $Z_a(\mathsf{Conj}_{\mathsf{inv}(t)}(\mathsf{Conj}_{\mathsf{inv}(s)}(x)))$.
4. $\mathsf{hsame}(\mathsf{Conj}_{\mathsf{inv}(\mathsf{mul}(s,t))}(x), \mathsf{Conj}_{\mathsf{inv}(t)}(\mathsf{Conj}_{\mathsf{inv}(s)}(x)))$.

The ten-field fit is: traditional target normalizer conjugation action; BEDC source $\mathsf{Group}^{\uparrow}$ over BHist; carrier Z_a; classifier hsame; stability action composition and inverse-action composition; ledger conjugating pair and inverse-product witness; core theorem list Definition 41.65, Definition 41.79, and associativity, unit, inverse, and congruence laws; exactness predicate preservation of Z_a; standard bridge ordinary normalizer action; status $\mathsf{ProofTarget}$.

Proof. Unfold Conj. Associativity reassociates the product word $\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(s,t),x),\mathsf{inv}(\mathsf{mul}(s,t)))$ to the nested conjugation word $\mathsf{Conj}_s(\mathsf{Conj}_t(x))$, after Definition 41.65 identifies the inverse factor with $\mathsf{mul}(\mathsf{inv}(t),\mathsf{inv}(s))$.

The classifier comparison is transported through the surrounding multiplications by multiplication congruence. Then Definition 41.79 reads the reassociated word as the same Z_a-classifier witness, giving the displayed hsame statement for $\mathsf{Conj}_{\mathsf{mul}(s,t)}(x)$.

For preservation, apply the forward clause of $N_a(t)$ to $Z_a(x)$, obtaining $Z_a(\mathsf{Conj}_t(x))$. Apply the forward clause of $N_a(s)$ to that result, giving $Z_a(\mathsf{Conj}_s(\mathsf{Conj}_t(x)))$.

For the inverse-action word, use the inverse clause of $N_a(s)$ first and the inverse clause of $N_a(t)$ second. This gives $Z_a(\mathsf{Conj}_{\mathsf{inv}(t)}(\mathsf{Conj}_{\mathsf{inv}(s)}(x)))$.

Finally apply the same reassociation and congruence calculation to the inverse-product word. Theorem 41.65 identifies $\mathsf{inv}(\mathsf{mul}(s,t))$ with $\mathsf{mul}(\mathsf{inv}(t),\mathsf{inv}(s))$, so the classifier exactness theorem supplies the displayed hsame comparison for the inverse-action composition. □

Lean4 ✓ `BEDC.Derived.GroupUp.group normalizer conjugation action composition from empty unit`
Lean4 ✓ `BEDC.Derived.GroupUp.group centralizer normalizer forward action composition from empty unit`

Theorem 41.98 (Group centralizer normalizer subgroup)**.** *For a BEDC history-level group operation over* BHist *with the same associativity, left and right identity laws for e, multiplication congruence, and two-sided inverse laws as in Definition 41.87, the carrier N_a of Definition 41.95 is the two-sided normalizer subgroup of Z_a:*

1. $N_a(e)$.
2. *If* $N_a(s)$ *and* $N_a(t)$*, then* $N_a(\mathsf{mul}(s,t))$.
3. *If* $N_a(s)$*, then* $N_a(\mathsf{inv}(s))$.
4. *If* $N_a(s)$ *and* $\mathsf{hsame}(s,t)$*, then* $N_a(t)$.
5. *If* $Z_a(s)$*, then* $N_a(s)$.

The ten-field fit is: traditional target normalizer of a subgroup; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier N_a; classifier* hsame*; stability conjugation closure in both directions; ledger conjugating element and inverse witness; exactness normalizer action on the centralizer; core theorem list Definition 41.87, Definition 41.79, and Definition 41.65, together with associativity, unit laws, inverse laws, and multiplication congruence; standard bridge ordinary subgroup normalizer; status* $\mathsf{ProofTarget}$.

Proof. For the unit row, the unit laws identify $\mathsf{Conj}_e(x)$ with x for every x. The inverse laws identify $\mathsf{inv}(e)$ with e, so the second half of the carrier is the same calculation. Hence any $Z_a(x)$ is returned to Z_a by both unit conjugation clauses.

For product closure, assume $N_a(s)$ and $N_a(t)$. Associativity rewrites $\mathsf{Conj}_{\mathsf{mul}(s,t)}(x)$ as $\mathsf{Conj}_s(\mathsf{Conj}_t(x))$ by Definition 41.96. If $Z_a(x)$, first apply the forward normalizer clause for t and then the forward clause for s.

For the inverse-conjugation half of the product, use the same conjugation composition reading with the reversed inverse word $\mathsf{mul}(\mathsf{inv}(t),\mathsf{inv}(s))$. Starting from $Z_a(x)$, the inverse clause for s gives preservation by $\mathsf{inv}(s)$, and the inverse clause for t then gives preservation by $\mathsf{inv}(t)$. The classifier comparison with $\mathsf{Conj}_{\mathsf{inv}(\mathsf{mul}(s,t))}(x)$ is supplied by Definition 41.65, Definition 41.96, and multiplication congruence.

For inverse closure, the first clause of $N_a(\mathsf{inv}(s))$ is exactly the second clause of $N_a(s)$. The second clause of $N_a(\mathsf{inv}(s))$ conjugates by $\mathsf{inv}(\mathsf{inv}(s))$, which the inverse laws identify with s under

hsame; multiplication congruence and Definition 41.79 transport the existing first clause of $N_a(s)$ across that classifier equality.

For classifier transport, assume $N_a(s)$ and $\mathsf{hsame}(s,t)$. Multiplication congruence transports each word $\mathsf{mul}(\mathsf{mul}(s,x),\mathsf{inv}(s))$ to the corresponding word with t, using the inverse-congruence consequence of the group laws for the last factor. The classifier exactness theorem then shows that the transported conjugation has the same Z_a membership, so the two clauses defining $N_a(s)$ give the two clauses defining $N_a(t)$.

Finally assume $Z_a(s)$. By the inverse row of Definition 41.87, $Z_a(\mathsf{inv}(s))$ also holds. For any $Z_a(x)$, the product row first gives $Z_a(\mathsf{mul}(s,x))$ and then $Z_a(\mathsf{mul}(\mathsf{mul}(s,x),\mathsf{inv}(s)))$.

The same argument with $\mathsf{inv}(s)$ as the first centralizer element and s as the final one proves the conjugation clause for $\mathsf{inv}(s)$. These two preservation clauses are exactly $N_a(s)$. □

Lean4 ✓ `BEDC.Derived.GroupUp.group centralizer normalizer subgroup from empty unit`

Theorem 41.99 (Centralizer normal in its normalizer)**.** *For a BEDC history-level group operation over* BHist *with the same associativity, left and right identity laws for e, multiplication congruence, and two-sided inverse laws as in Definition 41.87, the centralizer carrier Z_a of Definition 41.84 forms a normal subgroup package inside the normalizer carrier N_a of Definition 41.95. Namely:*

1. *The identity, product, inverse, and* hsame*-transport subgroup rows for Z_a are those of Definition 41.87.*
2. *If $Z_a(s)$, then $N_a(s)$.*
3. *If $N_a(s)$ and $Z_a(x)$, then $Z_a(\mathsf{Conj}_s(x))$.*
4. *If $N_a(s)$ and $Z_a(x)$, then $Z_a(\mathsf{Conj}_{\mathsf{inv}(s)}(x))$.*
5. *If $\mathsf{hsame}(s,t)$, then the two displayed conjugation-closure rows transport from s to t by the classifier comparison for the corresponding conjugation words.*

Proof. The subgroup data are exactly the first four rows of Definition 41.87. The inclusion $Z_a(s) \Rightarrow N_a(s)$ is the final row of Definition 41.98, so the carrier inclusion needed for a normal-subgroup package is already part of the normalizer subgroup theorem.

It remains to identify the conjugation action of N_a on Z_a. Unpack Definition 41.95. Its first clause says that every $Z_a(x)$ is sent to $Z_a(\mathsf{Conj}_s(x))$, and its second clause says that every $Z_a(x)$ is sent to $Z_a(\mathsf{Conj}_{\mathsf{inv}(s)}(x))$. These are precisely the two normality closure rows.

For classifier transport, assume $\mathsf{hsame}(s,t)$. Multiplication congruence transports the word $\mathsf{mul}(\mathsf{mul}(s,x),\mathsf{inv}(s))$ to $\mathsf{mul}(\mathsf{mul}(t,x),\mathsf{inv}(t))$, using inverse congruence for the last factor. Applying Definition 41.79 identifies the corresponding conjugation classifiers, and the hsame-transport row of Definition 41.87 carries Z_a membership across the comparison.

The same multiplication-congruence and inverse-congruence calculation with $\mathsf{inv}(s)$ and $\mathsf{inv}(t)$ gives transport for the inverse conjugation row. Thus centralizer membership is closed under conjugation by normalizer elements and by their inverse conjugation words, with the closure stable under the ambient history classifier. □

Lean4 ✓ `BEDC.Derived.GroupUp.group centralizer normal in normalizer from empty unit`

Theorem 41.100 (Group centralizer normalizer action automorphism and kernel exactness)**.** *For a BEDC history-level group operation over* BHist *with associativity, left and right identity laws for e, multiplication congruence, inverse congruence, and two-sided inverse laws as in Definition 41.98,*

fix $a : \mathsf{BHist}$. *Let* Z_a *be the centralizer carrier of Definition 41.84, let* N_a *be the normalizer carrier of Definition 41.95, and write*

$$\mathrm{Act}_s(x) := \mathsf{Conj}_s(x).$$

If $N_a(s)$ *and* $Z_a(x)$*, then conjugation by* s *restricts to a classifier-exact automorphism of* Z_a *with inverse action by* $\mathsf{inv}(s)$*:*

1. $Z_a(\mathrm{Act}_s(x))$ *and* $Z_a(\mathrm{Act}_{\mathsf{inv}(s)}(x))$.
2. $\mathsf{hsame}(\mathrm{Act}_{\mathsf{inv}(s)}(\mathrm{Act}_s(x)), x)$.
3. $\mathsf{hsame}(\mathrm{Act}_s(\mathrm{Act}_{\mathsf{inv}(s)}(x)), x)$.

For every s *with* $N_a(s)$*, the action kernel is exact:*

$$(\forall x : \mathsf{BHist},\ Z_a(x) \Rightarrow \mathsf{hsame}(\mathrm{Act}_s(x), x)) \Longleftrightarrow (\forall x : \mathsf{BHist},\ Z_a(x) \Rightarrow \mathsf{hsame}(\mathsf{mul}(s, x), \mathsf{mul}(x, s))).$$

The ten-field fit is: traditional target normalizer action by automorphisms and action kernel; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* Z_a*; classifier* hsame*; stability normalizer preservation, inverse action, and fixed-point exactness; ledger fixed element, normalizer witness, acted element, inverse parameter, and centralizing witness; core theorem list Definition 41.98, Definition 41.79, Definition 41.65, and Definition 41.83, together with the group associativity, unit, inverse, multiplication-congruence, and inverse-congruence laws; exactness predicate pointwise fixed action iff pointwise centralizing; standard bridge ordinary normalizer action on a subgroup; status* $\mathsf{ProofTarget}$.

Proof. The two preservation rows come directly from the defining clauses of N_a. The first clause sends $Z_a(x)$ to $Z_a(\mathrm{Act}_s(x))$, and the second clause sends $Z_a(x)$ to $Z_a(\mathrm{Act}_{\mathsf{inv}(s)}(x))$. The inverse-closure row of Definition 41.98 records the same preservation with the inverse parameter as a normalizer witness.

For the first inverse-action identity, expand $\mathrm{Act}_{\mathsf{inv}(s)}(\mathrm{Act}_s(x))$ as the conjugation word with parameter $\mathsf{inv}(s)$ applied to the conjugation word with parameter s. Associativity regroups the product into the adjacent inverse factors; the two-sided inverse laws reduce those factors to e, and the left and right unit laws reduce the remaining word to x. Multiplication congruence and Definition 41.79 carry this calculation through hsame.

The second inverse-action identity is symmetric. Expand $\mathrm{Act}_s(\mathrm{Act}_{\mathsf{inv}(s)}(x))$, regroup by associativity, reduce the adjacent factors $\mathsf{mul}(s, \mathsf{inv}(s))$ and $\mathsf{mul}(\mathsf{inv}(s), s)$ by the inverse laws, and use the unit laws to obtain x under hsame. The inverse-product reversal theorem supplies the same ordered-word comparison when the composite is read through the normalizer-action product row.

For kernel exactness, fix x with $Z_a(x)$. The fixed-point criterion Definition 41.83 identifies the statement $\mathsf{hsame}(\mathrm{Act}_s(x), x)$ with the pointwise centralizing statement $\mathsf{hsame}(\mathsf{mul}(s, x), \mathsf{mul}(x, s))$.

Quantifying that equivalence over all elements of Z_a gives the displayed kernel clause. No additional carrier is introduced: the kernel predicate is the pointwise fixed-action predicate for the restricted normalizer action. □

Lean4 ✓ `BEDC.Derived.GroupUp.group centralizer normalizer action automorphism kernel exactness from empty unit`

Theorem 41.101 (Group centralizer normalizer conjugation action)**.** *For a BEDC history-level group operation over* BHist *with the same associativity, left and right identity laws for* e*, multiplication congruence, inverse congruence, and two-sided inverse laws as in Definition 41.98, let*

$$\mathsf{Conj}_s(x) := \mathsf{mul}(\mathsf{mul}(s, x), \mathsf{inv}(s)).$$

If $N_a(s)$*,* $N_a(t)$*, and* $Z_a(x)$*, then the induced conjugation action on the centralizer carrier has the following rows:*

1. $Z_a(\mathsf{Conj}_s(x))$.
2. $\mathsf{hsame}(\mathsf{Conj}_e(x), x)$.
3. $Z_a(\mathsf{Conj}_s(\mathsf{Conj}_t(x)))$ *and* $\mathsf{hsame}(\mathsf{Conj}_{\mathsf{mul}(s,t)}(x), \mathsf{Conj}_s(\mathsf{Conj}_t(x)))$.
4. *If* $\mathsf{hsame}(s,t)$, *then* $\mathsf{hsame}(\mathsf{Conj}_s(x), \mathsf{Conj}_t(x))$.

Proof. The carrier preservation row is the first clause in the definition of $N_a(s)$: starting from $Z_a(x)$, conjugation by s returns $Z_a(\mathsf{Conj}_s(x))$.

For the identity action, expand $\mathsf{Conj}_e(x)$ as $\mathsf{mul}(\mathsf{mul}(e,x), \mathsf{inv}(e))$. The inverse laws identify $\mathsf{inv}(e)$ with e, and the left and right unit laws then identify the whole word with x under hsame.

For composition, first apply the forward clause of $N_a(t)$ to $Z_a(x)$, giving $Z_a(\mathsf{Conj}_t(x))$. Applying the forward clause of $N_a(s)$ to that result gives $Z_a(\mathsf{Conj}_s(\mathsf{Conj}_t(x)))$.

The classifier comparison is the product-closure calculation from Definition 41.98. Associativity moves the parentheses in the fourfold word, while Definition 41.65 identifies the inverse of $\mathsf{mul}(s,t)$ with $\mathsf{mul}(\mathsf{inv}(t), \mathsf{inv}(s))$; multiplication congruence then yields $\mathsf{hsame}(\mathsf{Conj}_{\mathsf{mul}(s,t)}(x), \mathsf{Conj}_s(\mathsf{Conj}_t(x)))$.

Finally assume $\mathsf{hsame}(s,t)$. Inverse congruence gives $\mathsf{hsame}(\mathsf{inv}(s), \mathsf{inv}(t))$, and two uses of multiplication congruence carry the classifier equality through $\mathsf{mul}(\mathsf{mul}(_, x), \mathsf{inv}(_))$. Hence $\mathsf{Conj}_s(x)$ and $\mathsf{Conj}_t(x)$ are hsame-equal. □

Lean4 ✓ `BEDC.Derived.GroupUp.group conjugation parameter hsame congr from empty unit`

Theorem 41.102 (Group centralizer normalizer action inverse)**.** *For a BEDC history-level group operation over* BHist *with the same associativity, left and right identity laws for e, multiplication congruence, inverse congruence, and two-sided inverse laws as in Definition 41.98, let*

$$\mathsf{Conj}_s(x) := \mathsf{mul}(\mathsf{mul}(s,x), \mathsf{inv}(s)).$$

If $N_a(s)$ and $Z_a(x)$, then the normalizer action restricts to a classifier equivalence on the centralizer:

1. $Z_a(\mathsf{Conj}_s(x))$.
2. $Z_a(\mathsf{Conj}_{\mathsf{inv}(s)}(\mathsf{Conj}_s(x)))$.
3. $\mathsf{hsame}(\mathsf{Conj}_{\mathsf{inv}(s)}(\mathsf{Conj}_s(x)), x)$.
4. $Z_a(\mathsf{Conj}_{\mathsf{inv}(s)}(x))$.
5. $Z_a(\mathsf{Conj}_s(\mathsf{Conj}_{\mathsf{inv}(s)}(x)))$.
6. $\mathsf{hsame}(\mathsf{Conj}_s(\mathsf{Conj}_{\mathsf{inv}(s)}(x)), x)$.

The ten-field per-object fit is: traditional target normalizer action by equivalences; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier Z_a; classifier* hsame*; stability inverse action, identity action, and composition; ledger normalizer witness, inverse witness, and acted-on centralizer element; core theorem list Definition 41.98, Definition 41.97, and Definition 41.101, together with the inverse and unit laws; exactness predicate restricted action invertibility on Z_a; standard bridge ordinary normalizer action by automorphisms; status* ProofTarget.

Proof. The first and fourth rows are the two carrier clauses in the definition of $N_a(s)$: the normalizer witness sends a centralizer element forward by Conj_s and backward by $\mathsf{Conj}_{\mathsf{inv}(s)}$. The inverse-closure row of Definition 41.98 also records $N_a(\mathsf{inv}(s))$.

Using $N_a(\mathsf{inv}(s))$ with $Z_a(\mathsf{Conj}_s(x))$, the forward preservation row of Definition 41.101 gives $Z_a(\mathsf{Conj}_{\mathsf{inv}(s)}(\mathsf{Conj}_s(x)))$. Using $N_a(s)$ with $Z_a(\mathsf{Conj}_{\mathsf{inv}(s)}(x))$ gives $Z_a(\mathsf{Conj}_s(\mathsf{Conj}_{\mathsf{inv}(s)}(x)))$.

For the left inverse identity, the composition row of Definition 41.97 identifies $\mathsf{Conj}_{\mathsf{mul}(\mathsf{inv}(s),s)}(x)$ with $\mathsf{Conj}_{\mathsf{inv}(s)}(\mathsf{Conj}_s(x))$. The two-sided inverse law identifies $\mathsf{mul}(\mathsf{inv}(s), s)$ with e, and the identity row of Definition 41.101 identifies $\mathsf{Conj}_e(x)$ with x under hsame.

For the right inverse identity, the same composition row identifies $\mathsf{Conj}_{\mathsf{mul}(s,\mathsf{inv}(s))}(x)$ with $\mathsf{Conj}_s(\mathsf{Conj}_{\mathsf{inv}(s)}(x))$. The other two-sided inverse law reduces $\mathsf{mul}(s, \mathsf{inv}(s))$ to e, and the identity row again gives the comparison with x. Multiplication congruence and inverse congruence supply the classifier transport at each product replacement. □

Lean4 ✓ `BEDC.Derived.GroupUp.group centralizer normalizer action inverse from empty unit`

41.11 Centralizer normalizer orbit relation

Definition 41.103 (Group centralizer normalizer orbit relation)**.** *Let Z_a be the centralizer carrier of Definition 41.84, let N_a be the normalizer carrier of Definition 41.95, and let*

$$\mathsf{Conj}_s(x) := \mathsf{mul}(\mathsf{mul}(s, x), \mathsf{inv}(s)).$$

For carried centralizer histories $x, y : \mathsf{BHist}$, define the normalizer-orbit relation by

$$x \sim_{N_a} y :\Longleftrightarrow \exists s : \mathsf{BHist},\ N_a(s) \wedge Z_a(x) \wedge Z_a(y) \wedge \mathsf{hsame}(\mathsf{Conj}_s(x), y).$$

This is a quotient-free classifier of reachability inside Z_a by conjugation with histories carried by N_a.

Theorem 41.104 (Group centralizer normalizer orbit equivalence)**.** *For a BEDC history-level group operation over* BHist *with the same associativity, left and right identity laws for e, multiplication congruence, inverse congruence, and two-sided inverse laws as in Definition 41.98, let Z_a, N_a, and Conj_s be as in Definition 41.103. For $x, y, z : \mathsf{BHist}$ with $Z_a(x)$, $Z_a(y)$, and $Z_a(z)$, the relation $\sim_{N_a}$ is reflexive, symmetric, and transitive on the centralizer carrier:*

1. *$x \sim_{N_a} x$.*
2. *If $x \sim_{N_a} y$, then $y \sim_{N_a} x$.*
3. *If $x \sim_{N_a} y$ and $y \sim_{N_a} z$, then $x \sim_{N_a} z$.*

The ten-field fit is: traditional target group-action orbit relation on a centralizer; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier Z_a; classifier $\sim_{N_a}$; stability reflexive, symmetric, and transitive; ledger source endpoint x; target endpoint y; intermediate endpoint z; conjugator s; inverse conjugator* $\mathsf{inv}(s)$*; product conjugator* $\mathsf{mul}(t, s)$*; core theorem list Definition 41.98, Definition 41.101, and Definition 41.96; exactness orbit reachability on centralizer elements; standard bridge ordinary orbit relation for normalizer action; status* $\mathsf{ProofTarget}$.

Proof. For reflexivity, use the identity row of Definition 41.98 to obtain $N_a(e)$. The identity action row of Definition 41.101 gives $\mathsf{hsame}(\mathsf{Conj}_e(x), x)$, so e is the orbit witness for $x \sim_{N_a} x$ together with the carried endpoint $Z_a(x)$.

For symmetry, unpack a witness s for $x \sim_{N_a} y$. Inverse closure in Definition 41.98 gives $N_a(\mathsf{inv}(s))$, and the inverse-conjugation clause in the definition of N_a keeps the conjugated history inside Z_a.

The composition row of Definition 41.101, the inverse laws, and transitivity of hsame identify conjugating back by $\mathsf{inv}(s)$ with the original source endpoint. Classifier transport across the displayed witness $\mathsf{hsame}(\mathsf{Conj}_s(x), y)$ then replaces the acted-on endpoint by y, producing a witness for $y \sim_{N_a} x$.

For transitivity, unpack witnesses s for $x \sim_{N_a} y$ and t for $y \sim_{N_a} z$. Product closure in Definition 41.98 gives $N_a(\mathsf{mul}(t, s))$.

The composition row of Definition 41.101 compares $\mathsf{Conj}_{\mathsf{mul}(t,s)}(x)$ with $\mathsf{Conj}_t(\mathsf{Conj}_s(x))$. The first witness transports $\mathsf{Conj}_s(x)$ to y, and the second witness transports $\mathsf{Conj}_t(y)$ to z. Transitivity of hsame combines these comparisons, while $Z_a(x)$ and $Z_a(z)$ supply the carried endpoints, so $\mathsf{mul}(t, s)$ witnesses $x \sim_{N_a} z$. □

Lean4 ✓ `BEDC.Derived.GroupUp.group centralizer normalizer orbit equivalence from empty unit`

Theorem 41.105 (Group centralizer normalizer orbit hsame lift)**.** *For a BEDC history-level group operation over* BHist *with the same associativity, left and right identity laws for* e*, multiplication congruence, and two-sided inverse laws as in Definition 41.104, fix* $a : \mathsf{BHist}$*. Let* Z_a*,* N_a*,* Conj_s*, and* $\sim_{N_a}$ *be as in Definition 41.103. For carried centralizer histories* $x, y : \mathsf{BHist}$*,*

$$Z_a(x) \wedge Z_a(y) \wedge \mathsf{hsame}(x, y) \Longrightarrow x \sim_{N_a} y.$$

The ten-field fit is: traditional target identity-conjugator orbit lift; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* Z_a*; classifier* $\sim_{N_a}$*; stability by endpoint transport from the identity orbit witness; ledger identity conjugator* e *and the two centralizer endpoints; core theorem list Definition 41.104 and normalizer-orbit endpoint transport; exactness predicate* hsame *implies normalizer-orbit reachability on carried endpoints; standard bridge ordinary orbit relation contains classifier equality; status* $\mathsf{ProofTarget}$*.*

Proof. The equivalence theorem supplies the reflexive orbit witness $x \sim_{N_a} x$ on the centralizer carrier. Endpoint transport for the same orbit relation keeps the source endpoint fixed and moves the target endpoint from x to y along the given $\mathsf{hsame}(x, y)$ comparison. The carried endpoint witnesses $Z_a(x)$ and $Z_a(y)$ provide the transport hypotheses, so the transported witness is exactly $x \sim_{N_a} y$. □

Lean4 ✓ `BEDC.Derived.GroupUp.group centralizer normalizer orbit hsame lift from empty unit`

Definition 41.106 (Group center carrier)**.** *Fix a BEDC history-level group operation* mul *over* BHist*. The center carrier* $\mathsf{Z}(G)$ *is the predicate*

$$\mathsf{Z}(G)(x) :\Longleftrightarrow \forall a : \mathsf{BHist}, \mathsf{hsame}(\mathsf{mul}(x, a), \mathsf{mul}(a, x)).$$

Theorem 41.107 (Group center normal subgroup)**.** *For a BEDC history-level group operation over* BHist *with associativity, left and right identity laws for* e*, multiplication congruence, and two-sided inverse laws, the center carrier* $\mathsf{Z}(G)$ *of Definition 41.106 is a normal subgroup:*

1. $\mathsf{Z}(G)(e)$*.*
2. *If* $\mathsf{Z}(G)(x)$ *and* $\mathsf{Z}(G)(y)$*, then* $\mathsf{Z}(G)(\mathsf{mul}(x, y))$*.*
3. *If* $\mathsf{Z}(G)(x)$*, then* $\mathsf{Z}(G)(\mathsf{inv}(x))$*.*
4. *If* $\mathsf{Z}(G)(x)$ *and* $\mathsf{hsame}(x, y)$*, then* $\mathsf{Z}(G)(y)$*.*
5. *If* $\mathsf{Z}(G)(x)$*, then for every* $s : \mathsf{BHist}$*,* $\mathsf{Z}(G)(\mathsf{Conj}_s(x))$*.*
6. *Every center element lies in every centralizer* Z_a *and therefore in every centralizer normalizer* N_a*.*

The ten-field fit is: traditional target center normal subgroup; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* $\mathsf{Z}(G)$*; classifier* hsame*; stability obligations unit, product, inverse, classifier transport, and arbitrary conjugation; ledger the central history and the acting history; core theorem list Definition 41.87, Definition 41.98, Definition 41.96, Definition 41.79, and Definition 41.65, together with associativity, unit laws, inverse laws, and multiplication congruence; standard bridge ordinary group centers; status* $\mathsf{ProofTarget}$*.*

Proof. The unit row follows pointwise. For any a, the left and right identity laws identify $\mathsf{mul}(e, a)$ and $\mathsf{mul}(a, e)$ with the same history a.

For product closure, fix a and assume that both x and y commute with every history. Reassociate $(xy)a$ to $x(ya)$, commute y past a, reassociate to $(xa)y$, commute x past a, and reassociate to $a(xy)$. Multiplication congruence transports the two pointwise centrality witnesses through the surrounding products.

For inverse closure, apply the inverse row of Definition 41.87 at each centralizer Z_a. Since a center element lies in every Z_a, its inverse also lies in every Z_a, which is exactly the defining universal condition for $\mathsf{Z}(G)$.

Classifier transport is pointwise. If $\mathsf{hsame}(x, y)$, multiplication congruence transports $\mathsf{mul}(x, a)\mathsf{hsamemul}(a, x)$ to $\mathsf{mul}(y, a)\mathsf{hsamemul}(a, y)$ for each a, using symmetry and transitivity of hsame for the two transported endpoints.

For conjugation stability, fix s and a center element x. Centrality gives $\mathsf{hsame}(\mathsf{mul}(s, x), \mathsf{mul}(x, s))$ and $\mathsf{hsame}(\mathsf{mul}(x, \mathsf{inv}(s)), \mathsf{mul}(\mathsf{inv}(s), x))$. Associativity, the inverse laws, and multiplication congruence identify $\mathsf{Conj}_s(x)$ with x.

The classifier exactness theorem transports this identification across every test product with a, so $\mathsf{Conj}_s(x)$ commutes with every history. Equivalently, Definition 41.96 records the same inner-action calculation and Definition 41.65 supplies the inverse word used in the conjugating product.

Finally, the definition of $\mathsf{Z}(G)$ says that a center element commutes with the particular history a, hence it is in Z_a. The last row of Definition 41.98 then places it in N_a for the same a. □

Lean4 ✓ `BEDC.Derived.GroupUp.group center normal subgroup from empty unit`

Theorem 41.108 (Group normalizer quotient conjugation well-defined)**.** *For a BEDC history-level* $\mathsf{Group}^{\uparrow}$ *operation over* BHist *with the same associativity, left and right identity laws for* e*, multiplication congruence, inverse congruence, and two-sided inverse laws as in Definition 41.100, let* $S : \mathsf{BHist} \to \mathsf{Prop}$ *be a carried subgroup predicate. Define*

$$\mathsf{Conj}_u(s) := \mathsf{mul}(\mathsf{mul}(u, s), \mathsf{inv}(u)),$$

$$C_G(S)(c) :\Longleftrightarrow \forall s : \mathsf{BHist},\ S(s) \Rightarrow \mathsf{hsame}(\mathsf{mul}(c, s), \mathsf{mul}(s, c)),$$

and

$$N_G(S)(u) :\Longleftrightarrow (\forall s : \mathsf{BHist},\ S(s) \Rightarrow S(\mathsf{Conj}_u(s))) \wedge (\forall s : \mathsf{BHist},\ S(s) \Rightarrow S(\mathsf{Conj}_{\mathsf{inv}(u)}(s))).$$

If $N_G(S)(n)$ *and* $N_G(S)(n')$*, then the quotient-kernel clause for* $N_G(S)/C_G(S)$ *is exactly equality of the restricted conjugation actions:*

$$C_G(S)(\mathsf{mul}(\mathsf{inv}(n), n')) \Longleftrightarrow \forall s : \mathsf{BHist},\ S(s) \Rightarrow \mathsf{hsame}(\mathsf{Conj}_n(s), \mathsf{Conj}_{n'}(s)).$$

The ten-field fit is: traditional target normalizer quotient conjugation well-definedness; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist *with a carried* $\mathsf{Subgroup}^{\uparrow}$ *predicate* S*; carrier* $N_G(S)$*; classifier the*

quotient-kernel clause by $C_G(S)$; stability from conjugation composition and conjugation classifier exactness; ledger the two normalizer representatives, the relative kernel word, and the acted subgroup element; core theorem list Definition 41.96, Definition 41.79, and Definition 41.65; exactness predicate representatives act equally on S if and only if their relative displacement centralizes S; downstream consumer $\mathsf{QuotientGroup}^{\uparrow}$*; status* $\mathsf{ProofTarget}$.

Proof. The endpoint hypotheses $N_G(S)(n)$ and $N_G(S)(n')$ make both conjugation maps restrict to the carrier S. Thus, for any s with $S(s)$, the displayed pointwise comparison is a classifier comparison between two carried endpoints of the same subgroup predicate.

Set

$$c := \mathsf{mul}(\mathsf{inv}(n), n').$$

The group laws give $\mathsf{hsame}(\mathsf{mul}(n, c), n')$: reassociate $\mathsf{mul}(n, \mathsf{mul}(\mathsf{inv}(n), n'))$ to $\mathsf{mul}(\mathsf{mul}(n, \mathsf{inv}(n)), n')$, reduce the adjacent inverse product to e, and then use the left unit law. Multiplication congruence and inverse congruence therefore transport the parameter of the conjugation word from n' to $\mathsf{mul}(n, c)$.

Assume first $C_G(S)(c)$ and fix s with $S(s)$. The centralizer clause gives $\mathsf{hsame}(\mathsf{mul}(c, s), \mathsf{mul}(s, c))$. Multiplying this comparison on the right by $\mathsf{inv}(c)$ and reducing the product $\mathsf{mul}(c, \mathsf{inv}(c))$ by the inverse and unit laws gives

$$\mathsf{hsame}(\mathsf{Conj}_c(s), s).$$

By Definition 41.96, conjugation by $\mathsf{mul}(n, c)$ is the composite of conjugation by c followed by conjugation by n. Hence $\mathsf{Conj}_{n'}(s)$ is hsame-equal to $\mathsf{Conj}_n(\mathsf{Conj}_c(s))$. Transporting $\mathsf{hsame}(\mathsf{Conj}_c(s), s)$ through the outer conjugation word by multiplication congruence gives $\mathsf{hsame}(\mathsf{Conj}_{n'}(s), \mathsf{Conj}_n(s))$, and symmetry gives the displayed pointwise action equality.

Conversely assume the pointwise action equality and fix s with $S(s)$. The same parameter calculation and Definition 41.96 identify $\mathsf{Conj}_{n'}(s)$ with $\mathsf{Conj}_n(\mathsf{Conj}_c(s))$. Combining this with the pointwise hypothesis gives

$$\mathsf{hsame}(\mathsf{Conj}_n(s), \mathsf{Conj}_n(\mathsf{Conj}_c(s))).$$

The reflection direction of Definition 41.79, applied to the conjugating parameter n, yields $\mathsf{hsame}(s, \mathsf{Conj}_c(s))$. After symmetry, multiply this comparison on the right by c. Associativity reduces $\mathsf{mul}(\mathsf{Conj}_c(s), c)$ to $\mathsf{mul}(c, s)$, because the middle product $\mathsf{mul}(\mathsf{inv}(c), c)$ collapses to e and the unit laws remove e. The transported comparison is exactly

$$\mathsf{hsame}(\mathsf{mul}(c, s), \mathsf{mul}(s, c)).$$

Since s was arbitrary under $S(s)$, this proves $C_G(S)(c)$, namely $C_G(S)(\mathsf{mul}(\mathsf{inv}(n), n'))$. □

41.12 Normalizer orbit classifier stability

Theorem 41.109 (Group centralizer normalizer orbit classifier certificate)**.** *For a BEDC history-level group operation over* BHist *with the same associativity, left and right identity laws for e, multiplication congruence, inverse congruence, and two-sided inverse laws as in Definition 41.104, let Z_a, N_a,* Conj_s*, and $\sim_{N_a}$ be as in Definition 41.103. For $x, y, x', y' : \mathsf{BHist}$, assume $Z_a(x)$, $Z_a(y)$, $Z_a(x')$, $Z_a(y')$,* $\mathsf{hsame}(x, x')$*, and* $\mathsf{hsame}(y, y')$*. Then endpoint transport preserves and reflects orbit reachability:*

$$x \sim_{N_a} y \iff x' \sim_{N_a} y'.$$

Together with Definition 41.104, this endpoint-transport row supplies the quotient-free classifier fields on the centralizer carrier: carrier reflexivity, symmetry, transitivity, and stability under replacement of both exposed endpoints by hsame*-equal histories.*

Proof. For the forward direction, unpack an orbit witness s for $x \sim_{N_a} y$. Keep the same normalizer witness $N_a(s)$ and replace only the source and target endpoints.

Multiplication congruence transports the conjugation word $\mathsf{Conj}_s(x)$ across $\mathsf{hsame}(x, x')$, giving a comparison between $\mathsf{Conj}_s(x')$ and $\mathsf{Conj}_s(x)$. Compose this comparison with the original endpoint witness $\mathsf{hsame}(\mathsf{Conj}_s(x), y)$ and then with $\mathsf{hsame}(y, y')$. The carried assumptions $Z_a(x')$ and $Z_a(y')$ repack the same s as a witness for $x' \sim_{N_a} y'$.

For the reverse direction, apply the same argument after exchanging (x, y) with (x', y'). Symmetry of hsame turns the displayed endpoint comparisons into $\mathsf{hsame}(x', x)$ and $\mathsf{hsame}(y', y)$, so the witness for $x' \sim_{N_a} y'$ transports back to a witness for $x \sim_{N_a} y$.

The classifier certificate now has its structural rows from Definition 41.104: reflexivity, symmetry, and transitivity on the carrier Z_a. The two endpoint-transport directions above add stability under hsame-replacement of the visible source and target endpoints, without passing to a quotient object. □

41.13 Normalizer action on the centralizer

Theorem 41.110 (Group normalizer conjugation inverse roundtrip)**.** *For a BEDC history-level group operation over* BHist *with the same associativity, left and right identity laws for e, multiplication congruence, inverse congruence, and two-sided inverse laws as in Definition 41.98, let Z_a be the centralizer carrier of Definition 41.84, let N_a be the normalizer carrier of Definition 41.95, and write*

$$\mathsf{Conj}_s(x) := \mathsf{mul}(\mathsf{mul}(s, x), \mathsf{inv}(s)).$$

If $N_a(s)$ and $Z_a(x)$ hold, then:

1. $Z_a(\mathsf{Conj}_s(x))$.
2. $Z_a(\mathsf{Conj}_{\mathsf{inv}(s)}(x))$.
3. $\mathsf{hsame}(\mathsf{Conj}_{\mathsf{inv}(s)}(\mathsf{Conj}_s(x)), x)$.
4. $\mathsf{hsame}(\mathsf{Conj}_s(\mathsf{Conj}_{\mathsf{inv}(s)}(x)), x)$.

The ten-field fit is: traditional target inverse-action certificate for the normalizer action; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier Z_a; classifier* hsame*; stability obligations the two normalizer clauses and the two classifier return equations; ledger conjugating element, inverse conjugating word, and centralizer witness; core theorem list Definition 41.96, Definition 41.65, Definition 41.57, and Definition 41.58; exactness predicate conjugation by s and by* $\mathsf{inv}(s)$ *are mutual classifier inverses on Z_a; standard bridge ordinary inverse inner action on the centralizer; status* ProofTarget.

Proof. The carrier rows are exactly the two clauses of $N_a(s)$. Applying the forward clause to $Z_a(x)$ gives $Z_a(\mathsf{Conj}_s(x))$, and applying the inverse clause to the same $Z_a(x)$ gives $Z_a(\mathsf{Conj}_{\mathsf{inv}(s)}(x))$.

For the first classifier return equation, expand $\mathsf{Conj}_{\mathsf{inv}(s)}(\mathsf{Conj}_s(x))$. By Definition 41.96, this is the same conjugation word as $\mathsf{Conj}_{\mathsf{mul}(\mathsf{inv}(s),s)}(x)$. The left inverse law reduces $\mathsf{mul}(\mathsf{inv}(s), s)$ to e, and the unit laws reduce $\mathsf{Conj}_e(x)$ to x.

For the second return equation, expand $\mathsf{Conj}_s(\mathsf{Conj}_{\mathsf{inv}(s)}(x))$. The same composition theorem reads it as $\mathsf{Conj}_{\mathsf{mul}(s,\mathsf{inv}(s))}(x)$; the right inverse law reduces the conjugating product to e, and the unit laws again reduce $\mathsf{Conj}_e(x)$ to x.

Equivalently, the expanded words contain the adjacent inverse products exposed by associativity. Theorem 41.65 controls the inverse word, while Definition 41.57 and Definition 41.58 identify the double inverse $\mathsf{inv}(\mathsf{inv}(s))$ with s before the inverse and unit laws close the two classifier comparisons. □

Lean4 ✓ `BEDC.Derived.GroupUp.group normalizer conjugation inverse roundtrip from empty unit`

Theorem 41.111 (Group normalizer inverse closure)**.** *For a BEDC history-level group operation over* BHist *with the same associativity, unit, multiplication-congruence, and two-sided inverse laws as in Definition 41.110, let Z_a be the centralizer carrier and let N_a be the two-sided centralizer normalizer carrier. If $N_a(s)$ holds, then $N_a(\mathsf{inv}(s))$ holds.*

Proof. Unfold N_a. Its first row for $\mathsf{inv}(s)$ is exactly the inverse-action row already present in $N_a(s)$. For the second row, the target conjugating parameter is $\mathsf{inv}(\mathsf{inv}(s))$. The group inverse-involutive calculation identifies this parameter with s, multiplication congruence carries the conjugation word across that hsame comparison, and centralizer membership transports along the resulting conjugation-word equality. □

Lean4 ✓ `BEDC.Derived.GroupUp.group normalizer inv closed from empty unit`

Theorem 41.112 (Group normalizer inverse hsame transport)**.** *For the same history-level group data and centralizer normalizer carrier N_a, if $N_a(s)$ holds and $\mathsf{hsame}(\mathsf{inv}(s), t)$, then $N_a(t)$ holds.*

Proof. First apply Definition 41.111 to obtain $N_a(\mathsf{inv}(s))$. The comparison $\mathsf{hsame}(\mathsf{inv}(s), t)$ transports the forward conjugation row by multiplication congruence and inverse congruence. Applying inverse congruence to the same comparison gives $\mathsf{hsame}(\mathsf{inv}(\mathsf{inv}(s)), \mathsf{inv}(t))$, which transports the inverse-conjugation row. These two transported rows are precisely $N_a(t)$. □

Lean4 ✓ `BEDC.Derived.GroupUp.group normalizer inverse hsame transport from empty unit`

Theorem 41.113 (Group centralizer normalizer conjugation automorphism)**.** *For a BEDC history-level group operation over* BHist *with the same associativity, left and right identity laws for e, multiplication congruence, inverse congruence, and two-sided inverse laws as in Definition 41.98, let Z_a be the centralizer carrier of Definition 41.84, let N_a be the normalizer carrier of Definition 41.95, and write*

$$\mathsf{Conj}_s(x) := \mathsf{mul}(\mathsf{mul}(s, x), \mathsf{inv}(s)).$$

If $N_a(s)$ holds, then conjugation by s restricts to Z_a and is classifier-bijective on that carrier:

1. *If $Z_a(x)$, then $Z_a(\mathsf{Conj}_s(x))$.*
2. *For every $y : \mathsf{BHist}$ with $Z_a(y)$, the witness $x := \mathsf{Conj}_{\mathsf{inv}(s)}(y)$ satisfies $Z_a(x)$ and $\mathsf{hsame}(\mathsf{Conj}_s(x), y)$.*
3. *For all $x, y : \mathsf{BHist}$ with $Z_a(x)$ and $Z_a(y)$,*

$$\mathsf{hsame}(\mathsf{Conj}_s(x), \mathsf{Conj}_s(y)) \iff \mathsf{hsame}(x, y).$$

The ten-field fit is: traditional target centralizer normalizer action; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier Z_a; classifier* hsame*; stability obligations normalizer preservation, inverse-conjugation witness, and conjugation classifier exactness; ledger conjugating element, inverse word, and centralizer membership witnesses; core theorem list Definition 41.98, Definition 41.110, Definition 41.79, and Definition 41.65; exactness predicate conjugation is a classifier automorphism of Z_a; standard bridge ordinary normalizer action on a subgroup; status* ProofTarget*.*

Proof. The restriction row is the first clause of $N_a(s)$. Starting from $Z_a(x)$, that clause returns $Z_a(\mathsf{Conj}_s(x))$ directly.

For the classifier-surjectivity row, let y satisfy $Z_a(y)$ and set $x := \mathsf{Conj}_{\mathsf{inv}(s)}(y)$. The second clause of $N_a(s)$ gives $Z_a(x)$ from $Z_a(y)$. The second return equation of Definition 41.110, applied to $Z_a(y)$, gives $\mathsf{hsame}(\mathsf{Conj}_s(x), y)$.

For classifier exactness, apply Definition 41.79 to the conjugating word s. Its preservation direction gives $\mathsf{hsame}(x, y) \Rightarrow \mathsf{hsame}(\mathsf{Conj}_s(x), \mathsf{Conj}_s(y))$, and its reflection direction gives the converse implication. Restricting the inputs to $Z_a(x)$ and $Z_a(y)$ therefore makes conjugation by s a classifier automorphism of the centralizer carrier. □

Theorem 41.119 (Group two-sided cancellation)**.** *For a history-level group operation with associativity, left and right identities, multiplication congruence, and two-sided inverses, equality of* $(ab)c$ *and* $(ad)c$ *under* hsame *implies equality of* b *and* d *under* hsame*.*

Proof. First apply right cancellation to the common final factor c, reducing the displayed equality to $\mathsf{hsame}(ab, ad)$. Then apply left cancellation to the common initial factor a, yielding $\mathsf{hsame}(b, d)$. □

Lean4 ✓ `BEDC.Derived.GroupUp.group two sided cancel`

Definition 41.120 (Group ledger policy)**.** *Record the monoid ledger plus every inverse operation applied.*

Definition 41.121 ($\mathsf{Group}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{Group}^{\uparrow}$*.*

Primitive boundary. $\mathsf{Group}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Proposition 41.122 (Group forgets to Monoid certificate)**.** *Let* C *carry a* $\mathsf{Group}^{\uparrow}(C)$ *certificate with multiplication* $\cdot$*, identity* e*, inverse operation* $^{-1}$*, and classifier* $\sim_C$*. If the inverse operation, inverse closure, inverse congruence, left and right inverse rows, and ledger entries whose expression provenance uses inverse formation are omitted, then the retained carrier, source, monoid pattern, classifier, monoid stability fields, and monoid ledger form a* $\mathsf{Monoid}^{\uparrow}(C)$ *certificate. The carrier* C*, multiplication* $\cdot$*, identity* e*, and classifier* $\sim_C$ *are unchanged.*

Proof. By Definition 41.121, the given certificate supplies carrier, source, pattern, classifier, stability, and ledger data for $\mathsf{Group}^{\uparrow}(C)$. The construction keeps exactly the coordinates whose operations and endpoint claims use only the monoid part of the group structure.

By Definition 41.2, a group carrier is a monoid setup extended with an inverse operation. Omitting the inverse operation leaves the same carrier C, the same classifier $\sim_C$, the same multiplication $\cdot$, and the same identity e. These are precisely the carrier data listed in Definition 40.1.

By Definition 41.52, the source is a certified monoid carrier plus inverse data. Removing the inverse component leaves the certified monoid carrier required by Definition 40.9. No source endpoint, carrier witness, multiplication operation, identity element, or classifier is replaced.

By Definition 41.53, the group pattern is monoid expression formation extended by inverse formation. Restricting to expressions with no inverse node leaves expression formation from e, carrier witnesses, and binary multiplication, which is exactly the monoid pattern of Definition 40.10.

By Definition 41.54, the group classifier is the monoid carrier classifier together with inverse congruence. The retained relation is therefore the same carrier classifier required by Definition 40.11; the omitted inverse congruence row is not a $\mathsf{Monoid}^{\uparrow}$ obligation.

By Definition 41.55, the group stability certificate consists of all monoid stability fields together with inverse congruence, left inverse law, right inverse law, and closure under inverse. The

first component is exactly the list in Definition 40.13: classifier reflexivity, classifier transitivity, associativity under classifier, left identity, right identity, and multiplication congruence. The inverse-specific rows mention $^{-1}$ and are not required for $\mathsf{Monoid}^{\uparrow}$.

Finally, Definition 41.120 records the monoid ledger plus every inverse operation applied. Omitting entries justified by inverse formation leaves the carrier witnesses and multiplication-expression provenance described by Definition 40.33. Hence the retained carrier, source, pattern, classifier, stability, and ledger data satisfy the obligations named in Definition 40.34, with C, $\cdot$, e, and $\sim_C$ copied from the original $\mathsf{Group}^{\uparrow}(C)$ certificate. □

Definition 41.123 (Opposite group certificate data)**.** *Let a $\mathsf{Group}^{\uparrow}(C)$ certificate be presented by a carrier predicate $\mathcal{C}$, a classifier $\sim_C$, multiplication $\cdot_C$, identity e_C, and inverse operation i_C. Define the opposite multiplication by*

$$a \star_C b := b \cdot_C a.$$

The opposite group data C^{op} have the same carrier predicate $\mathcal{C}$, the same classifier $\sim_C$, the same identity e_C, the same inverse operation i_C, and multiplication $\star_C$.

Theorem 41.124 (Opposite group certificate)**.** *If $(\mathcal{C}, \sim_C, \cdot_C, e_C, i_C)$ satisfies the $\mathsf{Group}^{\uparrow}$ certificate obligations of Definition 41.121, then the data of Definition 41.123 also satisfy the $\mathsf{Group}^{\uparrow}$ certificate obligations. Thus the same carrier, classifier, identity, and inverse operation carry a group certificate with multiplication $\star_C$.*

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonHistory opposite laws`

Proof. Unpack the group obligations through Definition 41.121. The monoid reduct supplied by Definition 41.122 has carrier $\mathcal{C}$, classifier $\sim_C$, multiplication $\cdot_C$, and identity e_C. Applying Definition 40.37 to that reduct gives the carrier, source, monoid pattern, classifier, monoid stability rows, and monoid ledger for the multiplication $\star_C$ with the same identity e_C.

These rows supply exactly the monoid part demanded by Definition 41.52, Definition 41.53, and the first component of Definition 41.55. The carrier data of Definition 41.2 are also present: the carrier, classifier, and identity are unchanged, the multiplication is $\star_C$, and the inverse operation is still i_C.

It remains to check the inverse-specific group rows. Inverse closure is copied from the original group certificate because the inverse operation and carrier predicate are unchanged: from $\mathcal{C}(a)$ the original row gives $\mathcal{C}(i_C(a))$. Inverse congruence is copied for the same reason: from $a \sim_C b$ the original row gives $i_C(a) \sim_C i_C(b)$, and the classifier is still $\sim_C$.

The two inverse laws exchange their handedness under the reversed multiplication. The opposite left-inverse row at a carried element a unfolds to

$$i_C(a) \star_C a = a \cdot_C i_C(a) \sim_C e_C,$$

which is the original right-inverse row. The opposite right-inverse row unfolds to

$$a \star_C i_C(a) = i_C(a) \cdot_C a \sim_C e_C,$$

which is the original left-inverse row.

The classifier row of Definition 41.54 is the same carrier classifier equipped with the inverse congruence just copied. For the pattern and ledger, a $\star_C$ group-expression tree is interpreted as a $\cdot_C$ group-expression tree by exchanging the two children at each binary multiplication node

while leaving carrier leaves, the identity leaf, and inverse nodes unchanged. The opposite monoid certificate supplies the binary-node source and ledger reading; the inverse nodes use the original inverse source and ledger entries of Definition 41.120. Thus the source, pattern, classifier, stability, and ledger rows form the $\mathsf{Group}^{\uparrow}$ certificate data required by Definition 9.6 and Definition 41.121. □

Theorem 41.125 (Group product-unit inverse correspondence)**.** *For a BEDC history-level group operation over* BHist *with associativity, left and right identity laws for* e*, multiplication congruence, and two-sided inverse laws, write* xy *for* $\mathsf{mul}(x, y)$ *and* x^{-1} *for* $\mathsf{inv}(x)$*. Then every* $a, b : \mathsf{BHist}$ *satisfies*

$$\mathsf{hsame}(ab, \mathsf{e}) \iff \mathsf{hsame}(a, b^{-1}) \iff \mathsf{hsame}(b, a^{-1}).$$

The ten-field fit is: traditional target product-equals-empty inverse extraction; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability obligations left and right equation exactness, unit laws, inverse laws, inverse uniqueness, inverse involutivity, and multiplication congruence; ledger the two factors and the two extracted inverse witnesses; core theorem this block; exactness predicate the displayed chain of equivalences; standard bridge ordinary group inverse extraction from* $ab = \mathsf{e}$*; status* $\mathsf{ProofTarget}$*.*

Proof. Apply Theorem 41.72 to the equation $\mathsf{hsame}(ab, \mathsf{e})$ with right factor b. It classifies the same equation by $\mathsf{hsame}(a, \mathsf{e}b^{-1})$. The left identity law reduces $\mathsf{e}b^{-1}$ to b^{-1}, so the product-empty equation is equivalent to $\mathsf{hsame}(a, b^{-1})$.

Apply Theorem 41.70 to the same equation with left factor a. It classifies the equation by $\mathsf{hsame}(b, a^{-1}\mathsf{e})$. The right identity law reduces $a^{-1}\mathsf{e}$ to a^{-1}, giving the equivalence with $\mathsf{hsame}(b, a^{-1})$.

The two extracted descriptions are compatible because a witness $\mathsf{hsame}(a, b^{-1})$ makes a a right-inverse presentation for b, while $\mathsf{hsame}(b, a^{-1})$ makes b a left-inverse presentation for a. The inverse uniqueness theorem identifies the two presentations, and inverse involutivity returns either double-inverse comparison to the original factor. □

Lean4 ✓ `BEDC.Derived.GroupUp.group product unit inverse correspondence iff`

Theorem 41.126 (Group product-empty unit inverse correspondence)**.** *For a BEDC history-level group operation over* BHist *with associativity, left and right identity laws for* e*, multiplication congruence, and two-sided inverse laws, write* xy *for* $\mathsf{mul}(x, y)$ *and* x^{-1} *for* $\mathsf{inv}(x)$*. Then every* $a, b : \mathsf{BHist}$ *satisfies*

$$\mathsf{hsame}(ab, \mathsf{e}) \iff \big(\mathsf{hsame}(a, b^{-1}) \wedge \mathsf{hsame}(b, a^{-1})\big).$$

The ten-field fit is: traditional target product-equals-empty paired inverse witnesses; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability obligations the same left and right equation exactness, unit laws, inverse laws, and multiplication congruence as in Definition 41.125; ledger the product equation and the two extracted inverse witnesses; core theorem this block; exactness predicate the displayed equivalence; standard bridge ordinary group inverse extraction from an empty-history product; status* $\mathsf{ProofTarget}$*.*

Proof. For the forward direction, apply Definition 41.125 to the product equation $\mathsf{hsame}(ab, \mathsf{e})$. The two equivalences give $\mathsf{hsame}(a, b^{-1})$ and $\mathsf{hsame}(b, a^{-1})$, which pair into the displayed conjunction.

For the reverse direction, start from the conjunction and use its first witness $\mathsf{hsame}(a, b^{-1})$. The right-multiplication exactness argument from Definition 41.125 transports that witness back to the product equation $\mathsf{hsame}(ab, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.GroupUp.group product unit inverse correspondence from empty unit iff`

41.14 Center orbit collapse

Theorem 41.127 (Group center normalizer orbit collapse)**.** *For a BEDC history-level group operation over* BHist *with the same associativity, left and right identity laws for* e*, multiplication congruence, inverse congruence, and two-sided inverse laws as in Definition 41.98, let* $\mathsf{Z}(G)$ *be the center carrier of Definition 41.106, and let* Z_a*,* N_a*,* Conj_s*, and* $\sim_{N_a}$ *be as in Definition 41.95 and Definition 41.103. For histories* $x, y : \mathsf{BHist}$*, if* $\mathsf{Z}(G)(x)$ *and* $Z_a(y)$*, then*

$$x \sim_{N_a} y \iff \mathsf{hsame}(x, y).$$

The per-object template names the traditional target center orbit collapse; the BEDC source as $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* $\mathsf{Z}(G)$ *inside* Z_a*; classifier* $\sim_{N_a}$ *versus* hsame*; stability from conjugation fixedness of center elements; ledger the normalizer witness; core theorem list Definition 41.98, Definition 41.101, Definition 41.104, and Definition 41.107; exactness predicate the displayed iff; standard bridge ordinary center elements have singleton conjugation orbits; and status* $\mathsf{ProofTarget}$*.*

Proof. The last row of Definition 41.107 places the center element x in the centralizer carrier Z_a. Thus the orbit relation has both endpoint carrier facts available once $Z_a(y)$ is supplied.

For the forward direction, unpack a witness s for $x \sim_{N_a} y$. Centrality of x commutes x past s and past $\mathsf{inv}(s)$. Associativity, the two-sided inverse laws, unit laws, multiplication congruence, and inverse congruence then identify $\mathsf{Conj}_s(x) = \mathsf{mul}(\mathsf{mul}(s, x), \mathsf{inv}(s))$ with x under hsame.

Composing this fixedness comparison with the orbit endpoint witness $\mathsf{hsame}(\mathsf{Conj}_s(x), y)$ gives $\mathsf{hsame}(x, y)$ by symmetry and transitivity of hsame.

For the reverse direction, use the identity element as the normalizer witness. The identity row of Definition 41.98 gives $N_a(e)$, and the identity-action row of Definition 41.101 gives $\mathsf{hsame}(\mathsf{Conj}_e(x), x)$.

Together with the center-to-centralizer carrier fact for x, the supplied $Z_a(y)$, and the assumed $\mathsf{hsame}(x, y)$, these data package the orbit witness for $x \sim_{N_a} y$. □

Lean4 ✓ `BEDC.Derived.GroupUp.group center normalizer orbit collapse from empty unit iff`

Theorem 41.128 (Group center normalizer orbit fiber determinacy)**.** *For a BEDC history-level group operation over* BHist *with the same hypotheses and notation* $\mathsf{Z}(G)$*,* Z_a*,* N_a*,* Conj_s*, and* $\sim_{N_a}$ *as in Definition 41.127, every* $x, y, z : \mathsf{BHist}$ *satisfies*

$$\mathsf{Z}(G)(x) \wedge Z_a(y) \wedge Z_a(z) \wedge x \sim_{N_a} y \wedge x \sim_{N_a} z \Longrightarrow \mathsf{hsame}(y, z).$$

The per-object template names the traditional target central-orbit fiber determinacy; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist *plus the normalizer orbit relation; carrier* Z_a *with central anchor* $\mathsf{Z}(G)$*; classifier* hsame*; stability from orbit collapse and the symmetry and transitivity laws for* hsame*; ledger the two normalizer witnesses over the same central anchor; core theorem list Definition 41.127 and the* hsame *equivalence laws; exactness predicate the displayed implication; and status* $\mathsf{ProofTarget}$*.*

Proof. Start from the five displayed assumptions. Apply Definition 41.127 to the first orbit witness $x \sim_{N_a} y$, using the centrality of x and the carrier fact $Z_a(y)$, to obtain $\mathsf{hsame}(x, y)$. Apply the same collapse theorem to the second orbit witness $x \sim_{N_a} z$, using the same centrality of x and the carrier fact $Z_a(z)$, to obtain $\mathsf{hsame}(x, z)$.

The first comparison reverses by symmetry of hsame, giving $\mathsf{hsame}(y, x)$. Transitivity of hsame then composes $\mathsf{hsame}(y, x)$ with $\mathsf{hsame}(x, z)$ and produces the required classifier equality $\mathsf{hsame}(y, z)$. □

Lean4 ✓ `BEDC.Derived.GroupUp.group center normalizer orbit fiber determinacy from empty unit`

41.15 Singleton continuation endpoint equivalence

Theorem 41.129 (Group singleton continuation endpoint equivalence)**.** *For histories* P, Q, R : BHist *with* $\mathsf{Cont}(P, Q, R)$*, the concrete singleton group classifier compares the continuation result with either input endpoint equivalently:*

$$R_{\mathsf{e}}(R, P) \iff R_{\mathsf{e}}(R, Q).$$

The ten-field fit is: traditional target terminal-group endpoint agreement under continuation; BEDC source the concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist *and* Cont*; carrier* A_{e}*; classifier* R_{e}*; stability from result-left and result-right classifier exactness; ledger the continuation witness; core theorem list Theorem 41.17 and Theorem 41.19; exactness predicate the displayed iff; standard bridge the one-element group; and status* $\mathsf{ProofTarget}$*.*

Proof. Use Theorem 41.17 to identify $R_{\mathsf{e}}(R, P)$ with the input classifier $R_{\mathsf{e}}(P, Q)$ under the given continuation witness.

Use Theorem 41.19 to identify the same input classifier $R_{\mathsf{e}}(P, Q)$ with $R_{\mathsf{e}}(R, Q)$. Composing these two equivalences gives the displayed endpoint-to-endpoint equivalence. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier continuation endpoint equivalence iff`

Theorem 41.130 (Group singleton contextual continuation endpoint equivalence)**.** *For histories* L, R, L', R', P, Q, S : BHist*, if* $A_{\mathsf{e}}(L)$*,* $A_{\mathsf{e}}(R)$*,* $A_{\mathsf{e}}(L')$*,* $A_{\mathsf{e}}(R')$*, and* $\mathsf{Cont}(P, Q, S)$*, then the concrete singleton group classifier compares the hidden-context continuation result with either endpoint equivalently:*

$$R_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(L, S), L'), \mathsf{append}(\mathsf{append}(R, P), R')) \iff R_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(L, S), L'), \mathsf{append}(\mathsf{append}(R, Q), R$$

The ten-field fit is: traditional target terminal-group contextual endpoint agreement under continuation; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist *plus* Cont*; carrier* A_{e}*; classifier* R_{e}*; stability from two-sided context cancellation and continuation endpoint equivalence; ledger hidden prefix/suffix singleton contexts plus the continuation witness; core theorem this block; exactness predicate the displayed iff; standard bridge terminal group contextual endpoint agreement; and status* $\mathsf{ProofTarget}$*.*

Proof. For the forward direction, apply Theorem 41.9 with the four singleton carrier witnesses for L, R, L', R'. This cancels the hidden contexts around the left displayed classifier and exposes $R_{\mathsf{e}}(S, P)$.

Apply Theorem 41.129 to the continuation witness $\mathsf{Cont}(P, Q, S)$. It transports the exposed endpoint classifier from $R_{\mathsf{e}}(S, P)$ to $R_{\mathsf{e}}(S, Q)$.

Apply the reverse direction of Theorem 41.9 with the same four singleton carrier witnesses. This reinstates the hidden contexts around S and Q, producing the right displayed classifier.

For the reverse direction, apply Theorem 41.9 to cancel the hidden contexts around the right displayed classifier and expose $R_{\mathsf{e}}(S, Q)$.

Use the reverse direction of Theorem 41.129 under the same continuation witness to obtain $R_{\mathsf{e}}(S, P)$.

Reattach the hidden contexts by the reverse direction of the two-sided cancellation theorem, producing the left displayed classifier. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier contextual continuation endpoint equivalence iff`

Theorem 41.131 (Group singleton suffix-context product-unit split)**.** *For histories L, R, p, q : BHist, if $A_{\mathsf{e}}(L)$ and $A_{\mathsf{e}}(R)$, then*

$$R_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(p, q), L), \mathsf{append}(\mathsf{e}, R)) \iff A_{\mathsf{e}}(p) \wedge A_{\mathsf{e}}(q).$$

The ten-field fit names the traditional target as terminal-group unit-product split under suffix contexts; the BEDC source as the concrete singleton $\mathsf{Group}^{\uparrow}$ over BHist; carrier A_{e}; classifier R_{e}; stability as right-context cancellation plus append empty-result split; ledger the hidden suffix endpoints and factors p, q; core theorem list Definition 41.8 and Definition 41.10; exactness predicate the displayed iff; standard bridge terminal group suffix-context unit-product split; and status $\mathsf{ProofTarget}$.

Proof. Apply Definition 41.8 with $Q = \mathsf{append}(p, q)$ and $S = \mathsf{e}$. The carrier hypotheses $A_{\mathsf{e}}(L)$ and $A_{\mathsf{e}}(R)$ strip the singleton suffix contexts, reducing the displayed classifier to

$$R_{\mathsf{e}}(\mathsf{append}(p, q), \mathsf{e}).$$

Apply Definition 41.10 to this reduced classifier. It identifies the reduced classifier exactly with $A_{\mathsf{e}}(p) \wedge A_{\mathsf{e}}(q)$, giving both directions of the displayed equivalence. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier suffix context product unit split iff`
Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier append suffix unit split iff`
Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier suffix product unit split iff`

Theorem 41.132 (Group singleton classifier append context visible middle exclusion)**.** *For histories L, R, p, q, S : BHist, if $A_{\mathsf{e}}(L)$ and $A_{\mathsf{e}}(R)$, then a visible endpoint exposed after appending hidden singleton contexts cannot support the concrete singleton group classifier:*

$$\begin{aligned}
&(R_{\mathsf{e}}(\mathsf{append}(L, \mathsf{E0}(p)), \mathsf{append}(R, S)) \to \mathsf{False}) \wedge \\
&(R_{\mathsf{e}}(\mathsf{append}(L, \mathsf{E1}(p)), \mathsf{append}(R, S)) \to \mathsf{False}) \wedge \\
&(R_{\mathsf{e}}(\mathsf{append}(L, S), \mathsf{append}(R, \mathsf{E0}(q))) \to \mathsf{False}) \wedge \\
&(R_{\mathsf{e}}(\mathsf{append}(L, S), \mathsf{append}(R, \mathsf{E1}(q))) \to \mathsf{False}).
\end{aligned}$$

The ten-field fit is: traditional target terminal-group visible-endpoint exclusion under hidden singleton contexts; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ over BHist; carrier A_{e}; classifier R_{e}; stability by context cancellation and constructor no-confusion; ledger hidden singleton contexts and visible endpoint witness; core theorem list Definition 41.7, Definition 41.13, and Definition 41.14; exactness predicate the four displayed contradictions; standard bridge the terminal group has no visible non-unit endpoint; and status $\mathsf{ProofTarget}$.

Proof. Apply Definition 41.7 with the supplied carrier hypotheses $A_{\mathsf{e}}(L)$ and $A_{\mathsf{e}}(R)$. In each of the four displayed cases, context cancellation exposes the corresponding uncontexted classifier with either an $\mathsf{E0}$ or an $\mathsf{E1}$ endpoint.

Unfolding R_{e} gives the two endpoint carrier witnesses for that uncontexted classifier. In the first two cases the left carrier contains a visible head created by $\mathsf{append}(L, \mathsf{E0}(p))$ or $\mathsf{append}(L, \mathsf{E1}(p))$, so Definition 41.13 contradicts the singleton carrier.

In the last two cases the right carrier contains a visible tail created by $\mathsf{append}(R, \mathsf{E0}(q))$ or $\mathsf{append}(R, \mathsf{E1}(q))$, so Definition 41.14 gives the contradiction. Constructor separation distinguishes the $\mathsf{E0}$ and $\mathsf{E1}$ branches without any additional classifier data. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier append context visible middle absurd`

Theorem 41.133 (Group singleton two-sided contextual visible middle exclusion)**.** *For histories L, R, L', R', p, q, M : BHist, if $A_{\mathsf{e}}(L)$, $A_{\mathsf{e}}(R)$, $A_{\mathsf{e}}(L')$, and $A_{\mathsf{e}}(R')$, then visible middle endpoints remain impossible after hidden prefix and suffix contexts:*

$$\begin{aligned}
&(R_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(L, \mathsf{E0}(p)), L'), \mathsf{append}(\mathsf{append}(R, M), R')) \to \mathsf{False}) \wedge \\
&(R_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(L, \mathsf{E1}(p)), L'), \mathsf{append}(\mathsf{append}(R, M), R')) \to \mathsf{False}) \wedge \\
&(R_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(L, M), L'), \mathsf{append}(\mathsf{append}(R, \mathsf{E0}(q)), R')) \to \mathsf{False}) \wedge \\
&(R_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(L, M), L'), \mathsf{append}(\mathsf{append}(R, \mathsf{E1}(q)), R')) \to \mathsf{False}).
\end{aligned}$$

The ten-field fit is: traditional target terminal-group visible-endpoint exclusion under hidden two-sided singleton contexts; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ over BHist; carrier A_{e}; classifier R_{e}; stability by right-context cancellation followed by prefix-context visible-middle exclusion; ledger prefix contexts L, R, suffix contexts L', R', neutral middle witness M, and visible endpoint witnesses p, q; core theorem list Definition 41.8 and Definition 41.132; exactness predicate the four displayed contradictions; standard bridge the terminal group has no visible middle endpoint under hidden contexts; and status $\mathsf{ProofTarget}$.

Proof. Start with any one of the four displayed classifier antecedents. Apply Definition 41.8 with the suffix carrier witnesses $A_{\mathsf{e}}(L')$ and $A_{\mathsf{e}}(R')$. This removes the right contexts and reduces the antecedent to the corresponding classifier without the outer suffixes.

For the first two reduced classifiers, use the left-middle clauses of Definition 41.132 with the prefix carrier witnesses $A_{\mathsf{e}}(L)$ and $A_{\mathsf{e}}(R)$. They rule out the exposed $\mathsf{E0}(p)$ and $\mathsf{E1}(p)$ endpoints.

For the last two reduced classifiers, use the right-middle clauses of the same theorem with the same prefix carrier witnesses. They rule out the exposed $\mathsf{E0}(q)$ and $\mathsf{E1}(q)$ endpoints, completing the four contradictions. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier two sided contextual visible middle absurd`

41.16 Singleton two-sided product-unit exactness

Theorem 41.134 (Group singleton two-sided contextual product-unit split)**.** *For L, R, L', R', p, q : BHist, if $A_{\mathsf{e}}(L)$, $A_{\mathsf{e}}(R)$, $A_{\mathsf{e}}(L')$, and $A_{\mathsf{e}}(R')$, then*

$$\begin{aligned}
&R_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(L, \mathsf{append}(p, q)), L'), \mathsf{append}(\mathsf{append}(R, \mathsf{e}), R')) \\
&\qquad \iff A_{\mathsf{e}}(p) \wedge A_{\mathsf{e}}(q).
\end{aligned}$$

The ten-field fit is: traditional target terminal-group product-unit exactness under two-sided contexts; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ over BHist and append; carrier A_{e}; classifier R_{e}; stability from two-sided context cancellation and append empty-result split; ledger prefix and suffix contexts and factors p, q; core theorem list Definition 41.9 and Definition 41.10; exactness predicate the displayed iff; standard bridge terminal group; and status $\mathsf{ProofTarget}$.

Proof. Apply Definition 41.9 with $Q = \mathsf{append}(p, q)$ and $S = \mathsf{e}$. The four singleton carrier hypotheses strip the prefix and suffix context pairs, reducing the displayed classifier to

$$R_{\mathsf{e}}(\mathsf{append}(p, q), \mathsf{e}).$$

Apply Definition 41.10 to the reduced classifier. It identifies the reduced classifier with $A_{\mathsf{e}}(p) \wedge A_{\mathsf{e}}(q)$, giving the desired equivalence. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier two sided contextual product unit split iff`

Theorem 41.135 (Group singleton two-sided contextual continuation product-unit coverage)**.** *For histories* $L_0, R_0, L_1, R_1, P, Q, S, T : \mathsf{BHist}$*, if* $A_\mathsf{e}(L_0)$*,* $A_\mathsf{e}(R_0)$*,* $A_\mathsf{e}(L_1)$*,* $A_\mathsf{e}(R_1)$*, and* $\mathsf{Cont}(P, Q, S)$*, then*

$$R_\mathsf{e}(\mathsf{append}(\mathsf{append}(L_0, \mathsf{append}(S, T)), L_1), \mathsf{append}(\mathsf{append}(R_0, \mathsf{e}), R_1)) \iff A_\mathsf{e}(P) \wedge A_\mathsf{e}(Q) \wedge A_\mathsf{e}(T).$$

The ten-field fit is: traditional target terminal-group continuation product-unit exactness under two-sided contexts; BEDC source concrete singleton $\mathsf{Group}^\uparrow$ *over* BHist *plus* Cont *and* append*; carrier* A_e*; classifier* R_e*; stability from two-sided context cancellation, continuation terminal collapse, and product-unit split; ledger the prefix and suffix contexts, continuation witness, suffix factor* T*, and hidden endpoint witnesses; core theorem list Definition 41.134, Definition 41.90, and Definition 41.88; exactness the displayed iff; standard bridge terminal group contextual product-unit coverage; and status* $\mathsf{ProofTarget}$*.*

Proof. Apply Definition 41.134 with $p = S$ and $q = T$. The four context carrier hypotheses strip the two prefix and suffix pairs, reducing the displayed classifier to $A_\mathsf{e}(S) \wedge A_\mathsf{e}(T)$.

Use Definition 41.90 under the continuation witness $\mathsf{Cont}(P, Q, S)$ to identify $A_\mathsf{e}(S)$ with $R_\mathsf{e}(P, Q)$. The intermediate condition is therefore $R_\mathsf{e}(P, Q) \wedge A_\mathsf{e}(T)$.

Apply the first row of Definition 41.88 to replace $R_\mathsf{e}(P, Q)$ by $A_\mathsf{e}(P) \wedge A_\mathsf{e}(Q)$. Reassociating conjunctions gives the stated three-factor coverage. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier two sided contextual continuation product unit coverage iff`

Theorem 41.136 (Group singleton two-sided contextual continuation product-unit visible exclusion)**.** *For histories* $L_0, R_0, L_1, R_1, P, Q, S, T, r : \mathsf{BHist}$*, if* $A_\mathsf{e}(L_0)$*,* $A_\mathsf{e}(R_0)$*,* $A_\mathsf{e}(L_1)$*,* $A_\mathsf{e}(R_1)$*, and* $\mathsf{Cont}(P, Q, S)$*, and if*

$$R_\mathsf{e}(\mathsf{append}(\mathsf{append}(L_0, \mathsf{append}(S, T)), L_1), \mathsf{append}(\mathsf{append}(R_0, \mathsf{e}), R_1))$$

holds, then

$$(\mathsf{Cont}(P, Q, \mathsf{E0}(r)) \Rightarrow \mathsf{False}) \wedge (\mathsf{Cont}(P, Q, \mathsf{E1}(r)) \Rightarrow \mathsf{False}).$$

The ten-field template names the traditional target terminal-group contextual continuation product-unit visibility exclusion; BEDC source concrete singleton $\mathsf{Group}^\uparrow$ *over* BHist *plus* Cont*; carrier* A_e*; classifier* R_e*; stability from contextual product-unit coverage and terminal collapse; ledger the two contexts, continuation witness, suffix factor, and visible result endpoint; core theorem list Definition 41.135, Definition 41.88, and Definition 41.90; exactness the displayed implication package; downstream consumer* $\mathsf{Group}^\uparrow$ *and* $\mathsf{Subgroup}^\uparrow$ *quotient visibility guards; and status* $\mathsf{ProofTarget}$*.*

Proof. Apply Definition 41.135 to the four context carrier witnesses and the continuation witness $\mathsf{Cont}(P, Q, S)$. The forward direction sends the displayed contextual classifier to $A_\mathsf{e}(P) \wedge A_\mathsf{e}(Q) \wedge A_\mathsf{e}(T)$.

Keep the first two carrier components. Use the reverse direction of the first row of Definition 41.88 to repack $A_\mathsf{e}(P) \wedge A_\mathsf{e}(Q)$ as $R_\mathsf{e}(P, Q)$.

Apply the visible-result part of Definition 41.90 under $\mathsf{Cont}(P, Q, S)$. The repacked input classifier is one of the terminal conditions, so the two continuation endpoints $\mathsf{E0}(r)$ and $\mathsf{E1}(r)$ are excluded as displayed. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier two sided contextual continuation product unit visible absurd`

Theorem 41.137 (Group singleton double continuation product-unit chain coverage)**.** *For histories* $P, Q, S, T, U, V : \mathsf{BHist}$ *with* $\mathsf{Cont}(P, Q, S)$ *and* $\mathsf{Cont}(S, T, U)$*, the concrete singleton* $\mathsf{Group}^{\uparrow}$ *instance satisfies*

$$R_{\mathsf{e}}(\mathsf{append}(U, V), \mathsf{e}) \iff A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q) \wedge A_{\mathsf{e}}(T) \wedge A_{\mathsf{e}}(V).$$

The ten-field fit names the traditional target terminal-group two-step continuation product-unit coverage; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist *plus two* Cont *witnesses and append; carrier* A_{e}*; classifier* R_{e}*; stability from continuation product-unit coverage, continuation terminal collapse, and terminal classifier packaging; ledger the two continuation witnesses and suffix endpoint; exactness the displayed iff; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$ *path compression; and status* $\mathsf{ProofTarget}$*.*

Proof. Apply Definition 41.91 to the continuation witness $\mathsf{Cont}(S, T, U)$. This rewrites the left side as

$$A_{\mathsf{e}}(S) \wedge A_{\mathsf{e}}(T) \wedge A_{\mathsf{e}}(V).$$

Use Definition 41.90 under the continuation witness $\mathsf{Cont}(P, Q, S)$ to identify $A_{\mathsf{e}}(S)$ with $R_{\mathsf{e}}(P, Q)$. The intermediate condition becomes

$$R_{\mathsf{e}}(P, Q) \wedge A_{\mathsf{e}}(T) \wedge A_{\mathsf{e}}(V).$$

Finally, apply the first row of Definition 41.88 to rewrite $R_{\mathsf{e}}(P, Q)$ as $A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q)$. Reassociating conjunctions gives exactly

$$A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q) \wedge A_{\mathsf{e}}(T) \wedge A_{\mathsf{e}}(V).$$

□

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier double continuation product unit chain coverage iff`

Theorem 41.138 (Group singleton double continuation product-unit visible exclusion)**.** *For histories* $P, Q, S, T, U, V, r : \mathsf{BHist}$ *with* $\mathsf{Cont}(P, Q, S)$ *and* $\mathsf{Cont}(S, T, U)$*, if*

$$R_{\mathsf{e}}(\mathsf{append}(U, V), \mathsf{e})$$

holds, then the concrete singleton $\mathsf{Group}^{\uparrow}$ *instance excludes visible results for both continuation witnesses:*

$$(\mathsf{Cont}(P, Q, \mathsf{E0}(r)) \Rightarrow \mathsf{False}) \wedge (\mathsf{Cont}(P, Q, \mathsf{E1}(r)) \Rightarrow \mathsf{False}) \wedge (\mathsf{Cont}(S, T, \mathsf{E0}(r)) \Rightarrow \mathsf{False}) \wedge (\mathsf{Cont}(S, T, \mathsf{E1}(r)) \Rightarrow \mathsf{False})$$

The ten-field template names the traditional target terminal-group two-step continuation visibility guard; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist *with two* Cont *witnesses and append; carrier* A_{e}*; classifier* R_{e}*; stability from double continuation product-unit coverage, terminal classifier packaging, and continuation terminal collapse; ledger the two continuation witnesses, suffix endpoint, and visible result endpoint; core theorem this block; exactness the four displayed contradictions; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$ *path compression and subgroup visibility guards; and status* $\mathsf{ProofTarget}$*.*

Proof. Apply Definition 41.137 to the two continuation witnesses and the product-unit classifier. The forward direction gives

$$A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q) \wedge A_{\mathsf{e}}(T) \wedge A_{\mathsf{e}}(V).$$

Keep the first two carrier components. Use the reverse direction of the first row of Definition 41.88 to repack $A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q)$ as $R_{\mathsf{e}}(P, Q)$.

Apply the visible-result part of Definition 41.90 under $\mathsf{Cont}(P, Q, S)$. The repacked input classifier excludes $\mathsf{Cont}(P, Q, \mathsf{E0}(r))$ and $\mathsf{Cont}(P, Q, \mathsf{E1}(r))$, and the same collapse identifies the terminal condition $A_{\mathsf{e}}(S)$.

Combine this $A_{\mathsf{e}}(S)$ with the retained factor $A_{\mathsf{e}}(T)$. The reverse direction of the first row of Definition 41.88 repacks $A_{\mathsf{e}}(S) \wedge A_{\mathsf{e}}(T)$ as $R_{\mathsf{e}}(S, T)$.

Apply the visible-result part of Definition 41.90 under $\mathsf{Cont}(S, T, U)$. The repacked second input classifier excludes $\mathsf{Cont}(S, T, \mathsf{E0}(r))$ and $\mathsf{Cont}(S, T, \mathsf{E1}(r))$, giving the four displayed contradictions. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier double continuation product unit visible exclusion`

Theorem 41.139 (Group singleton triple continuation product-unit chain coverage)**.** *For histories* $P, Q, S, T, U, V, W, X : \mathsf{BHist}$ *with* $\mathsf{Cont}(P, Q, S)$*,* $\mathsf{Cont}(S, T, U)$*, and* $\mathsf{Cont}(U, V, W)$*, the concrete singleton* $\mathsf{Group}^{\uparrow}$ *instance satisfies*

$$R_{\mathsf{e}}(\mathsf{append}(W, X), \mathsf{e}) \iff A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q) \wedge A_{\mathsf{e}}(T) \wedge A_{\mathsf{e}}(V) \wedge A_{\mathsf{e}}(X).$$

The ten-field fit names terminal-group three-step continuation product-unit coverage; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist *plus three* Cont *witnesses and append; carrier* A_{e}*; classifier* R_{e}*; stability from continuation product-unit triple coverage, continuation terminal collapse, and terminal classifier packaging; ledger the three continuation witnesses and suffix endpoint; exactness the displayed iff; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$ *path compression and group orbit compression; status* $\mathsf{ProofTarget}$*.*

Proof. The displayed equivalence is obtained by chaining reversible classifier identifications. Apply Definition 41.91 to $\mathsf{Cont}(U, V, W)$, which identifies the left side with

$$A_{\mathsf{e}}(U) \wedge A_{\mathsf{e}}(V) \wedge A_{\mathsf{e}}(X).$$

Use Definition 41.90 under $\mathsf{Cont}(S, T, U)$ to identify $A_{\mathsf{e}}(U)$ with $R_{\mathsf{e}}(S, T)$. Then apply the first row of Definition 41.88 to replace $R_{\mathsf{e}}(S, T)$ by

$$A_{\mathsf{e}}(S) \wedge A_{\mathsf{e}}(T).$$

It remains to expand the new terminal factor $A_{\mathsf{e}}(S)$. Use Definition 41.90 under $\mathsf{Cont}(P, Q, S)$ to identify $A_{\mathsf{e}}(S)$ with $R_{\mathsf{e}}(P, Q)$, and apply the same terminal classifier package to replace it by

$$A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q).$$

Reassociating the conjunctions gives exactly

$$A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q) \wedge A_{\mathsf{e}}(T) \wedge A_{\mathsf{e}}(V) \wedge A_{\mathsf{e}}(X).$$

□

41.17 Concrete singleton continuation group instance

Definition 41.140 (Group singleton continuation group instance)**.** *The singleton continuation group instance over* BHist *uses the carrier*

$$A_{\mathsf{Cont,e}}(h) := \mathsf{hsame}(h, \mathsf{e}).$$

The product is read by Cont *on the singleton endpoint: for carried* h *and* k*, the product row is the unique endpoint* p *whose continuation ledger* $\mathsf{Cont}(h, k, p)$ *is classified with* e*. The identity is* e*, and the inverse operation is the same singleton endpoint,*

$$e_{\mathsf{Cont,e}} := \mathsf{e}, \qquad \mathsf{inv}_{\mathsf{Cont,e}}(h) := \mathsf{e}.$$

The classifier is the restricted singleton classifier

$$R_{\mathsf{Cont,e}}(h, k) := A_{\mathsf{Cont,e}}(h) \wedge A_{\mathsf{Cont,e}}(k) \wedge \mathsf{hsame}(h, k).$$

Theorem 41.141 (Group singleton continuation laws)**.** *The data of Definition 41.140 satisfy the concrete* $\mathsf{Group}^{\uparrow}$ *laws over* BHist*. Multiplication closure, the left and right identity laws, associativity, multiplication congruence, inverse closure, and the left and right inverse laws are all witnessed by the continuation unit and associativity rows already used by the singleton* $\mathsf{Group}^{\uparrow}$ *chapter.*

Proof. Carrier inhabitance is $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$. Hence the displayed identity endpoint is carried, and the constant inverse endpoint is carried for every admitted input.

For multiplication closure, suppose $A_{\mathsf{Cont,e}}(h)$ and $A_{\mathsf{Cont,e}}(k)$. The continuation product row is read at the singleton endpoint; composing the two carrier witnesses with the continuation unit rows classifies the product endpoint with e.

The left and right unit laws are the continuation unit rows specialized to the empty endpoint. Since every admitted endpoint is already classified with e, both products are classified with the original input through $R_{\mathsf{Cont,e}}$.

Associativity and multiplication congruence follow from the same continuation associativity and transport rows used by the surrounding singleton product-unit theorems. All intermediate endpoints collapse to the singleton carrier, so the two parenthesized products repack into the same restricted classifier.

For inverses, $\mathsf{inv}_{\mathsf{Cont,e}}(h)$ is e. The two inverse products therefore reduce to the left and right unit rows, and the resulting endpoint is classified with $e_{\mathsf{Cont,e}}$. □

Theorem 41.142 (Group singleton inverse boundary)**.** *In the concrete singleton continuation group instance, the inverse field is visible at the public boundary: every admitted endpoint* h *satisfies* $\mathsf{hsame}(h, \mathsf{e})$*, and the inverse row is the displayed endpoint* e *with the same singleton classifier and continuation provenance.*

Proof. Project the carrier in Definition 41.140. Admission of h is exactly the row $\mathsf{hsame}(h, \mathsf{e})$, so the public packet already contains the comparison that identifies h with the singleton endpoint.

The inverse field is not computed by an external operation table. It is the displayed endpoint e, accompanied by the same carrier proof $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$ and the same continuation provenance used for the identity rows.

Thus every inverse read is visible as a projection of the singleton carrier and continuation ledger. There is no hidden inverse selector or ambient group object outside the BHist boundary. □

Theorem 41.143 (Group singleton triple continuation product-unit coverage and visibility)**.** *For histories* $P, Q, S, T, U, V, W, X, r : \mathsf{BHist}$ *with* $\mathsf{Cont}(P, Q, S)$*,* $\mathsf{Cont}(S, T, U)$*, and* $\mathsf{Cont}(U, V, W)$*, the concrete singleton* $\mathsf{Group}^{\uparrow}$ *instance satisfies*

$$R_{\mathsf{e}}(\mathsf{append}(W, X), \mathsf{e}) \iff A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q) \wedge A_{\mathsf{e}}(T) \wedge A_{\mathsf{e}}(V) \wedge A_{\mathsf{e}}(X).$$

Under the left-hand classifier, all three continuation witnesses exclude visible results:

$$(\mathsf{Cont}(P, Q, \mathsf{E0}(r)) \Rightarrow \mathsf{False}) \wedge (\mathsf{Cont}(P, Q, \mathsf{E1}(r)) \Rightarrow \mathsf{False}) \wedge (\mathsf{Cont}(S, T, \mathsf{E0}(r)) \Rightarrow \mathsf{False}) \wedge (\mathsf{Cont}(S, T, \mathsf{E1}(r)) \Rightarrow \mathsf{False})$$

The ten-field fit names the traditional target terminal-group three-step continuation product-unit coverage with visibility guard; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist *plus three* Cont *witnesses and append; carrier* A_{e}*; classifier* R_{e}*; stability from product-unit continuation coverage, terminal collapse, and terminal classifier packaging; ledger the three continuation witnesses, suffix endpoint, and visible result endpoint; exactness the displayed iff and six contradictions; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$ *path compression; and status* $\mathsf{ProofTarget}$*.*

Proof. Apply Definition 41.91 to the third continuation witness $\mathsf{Cont}(U, V, W)$. This rewrites the left-hand classifier as

$$A_{\mathsf{e}}(U) \wedge A_{\mathsf{e}}(V) \wedge A_{\mathsf{e}}(X).$$

Use Definition 41.90 under $\mathsf{Cont}(S, T, U)$ to identify $A_{\mathsf{e}}(U)$ with $R_{\mathsf{e}}(S, T)$. Then apply the first row of Definition 41.88 to rewrite that classifier as $A_{\mathsf{e}}(S) \wedge A_{\mathsf{e}}(T)$. The condition is now

$$A_{\mathsf{e}}(S) \wedge A_{\mathsf{e}}(T) \wedge A_{\mathsf{e}}(V) \wedge A_{\mathsf{e}}(X).$$

Apply Definition 41.90 again, this time under $\mathsf{Cont}(P, Q, S)$, to identify $A_{\mathsf{e}}(S)$ with $R_{\mathsf{e}}(P, Q)$. The first row of Definition 41.88 replaces $R_{\mathsf{e}}(P, Q)$ by $A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q)$, yielding the displayed five-factor classifier.

For visibility, assume the left-hand classifier. The forward direction just constructed supplies the carrier factors for P, Q, T, V, X, and the two terminal collapse steps also supply the hidden endpoint carriers $A_{\mathsf{e}}(S)$ and $A_{\mathsf{e}}(U)$.

Repack $A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q)$, $A_{\mathsf{e}}(S) \wedge A_{\mathsf{e}}(T)$, and $A_{\mathsf{e}}(U) \wedge A_{\mathsf{e}}(V)$ into the adjacent endpoint classifiers $R_{\mathsf{e}}(P, Q)$, $R_{\mathsf{e}}(S, T)$, and $R_{\mathsf{e}}(U, V)$ by the reverse direction of the terminal classifier package.

Apply the visible-result clause of Definition 41.90 at each boundary. The three repacked classifiers respectively rule out visible results for $\mathsf{Cont}(P, Q, -)$, $\mathsf{Cont}(S, T, -)$, and $\mathsf{Cont}(U, V, -)$, which gives the six displayed implications. □

Theorem 41.144 (Group singleton contextual triple continuation product-unit exact visibility)**.** *For histories* $L_0, R_0, L_1, R_1, P, Q, S, T, U, V, W, X, r : \mathsf{BHist}$*, if* $A_{\mathsf{e}}(L_0)$*,* $A_{\mathsf{e}}(R_0)$*,* $A_{\mathsf{e}}(L_1)$*,* $A_{\mathsf{e}}(R_1)$*,* $\mathsf{Cont}(P, Q, S)$*,* $\mathsf{Cont}(S, T, U)$*, and* $\mathsf{Cont}(U, V, W)$*, then*

$$R_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(L_0, \mathsf{append}(W, X \iff$$

$$(A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q) \wedge A_{\mathsf{e}}(T) \wedge A_{\mathsf{e}}(V) \wedge A_{\mathsf{e}}(X)) \wedge (\mathsf{Cont}(P, Q, \mathsf{E0}(r)) \Rightarrow \mathsf{False}) \wedge (\mathsf{Cont}(P, Q, \mathsf{E1}(r)) \Rightarrow \mathsf{False}) \wedge (\mathsf{Cont}($$

The ten-field fit is: traditional target terminal-group contextual three-step continuation product-unit exact visibility; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist *plus two context pairs, three* Cont *witnesses, visible continuation endpoints, and append; carrier* A_{e}*; classifier* R_{e}*; stability from two-sided context cancellation, triple continuation product-unit coverage, terminal collapse, and terminal classifier packaging; ledger the two hidden context pairs, three continuation witnesses, suffix endpoint, and visible result seed* r*; core theorem list Definition 41.9 and Definition 41.143; exactness the displayed iff package; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$ *path compression; and status* $\mathsf{ProofTarget}$*.*

Proof. For the forward direction, assume the displayed contextual classifier. Apply Definition 41.9 with $Q = \mathsf{append}(W, X)$ and $S = \mathsf{e}$ to the four context carrier witnesses. This strips the hidden contexts and reduces the classifier to $R_{\mathsf{e}}(\mathsf{append}(W, X), \mathsf{e})$.

Apply Definition 41.143 to the three continuation witnesses. Its classifier direction supplies the five carrier factors $A_{\mathsf{e}}(P)$, $A_{\mathsf{e}}(Q)$, $A_{\mathsf{e}}(T)$, $A_{\mathsf{e}}(V)$, and $A_{\mathsf{e}}(X)$; its visibility clause supplies the six visible-result exclusions for the same endpoint seed r.

Conjoining these facts gives the full right-hand visible-classification package. No extra hidden context data remains, because all four context carriers were consumed by the cancellation step.

For the reverse direction, assume the right-hand package. Its carrier component contains $A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q) \wedge A_{\mathsf{e}}(T) \wedge A_{\mathsf{e}}(V) \wedge A_{\mathsf{e}}(X)$, which is exactly the carrier side of the triple continuation product-unit coverage theorem.

Use the reverse classifier direction of Definition 41.143 with $\mathsf{Cont}(P, Q, S)$, $\mathsf{Cont}(S, T, U)$, and $\mathsf{Cont}(U, V, W)$ to reconstruct $R_{\mathsf{e}}(\mathsf{append}(W, X), \mathsf{e})$. The six exclusion clauses remain part of the package but are not needed to rebuild this unwrapped classifier.

Finally apply the reverse direction of Definition 41.9 with the four context carrier witnesses. This wraps the unwrapped classifier by the left and right context pairs and gives the displayed contextual classifier. □

41.18 Singleton conjugation terminal collapse

Theorem 41.145 (Group singleton conjugation terminal collapse)**.** *For histories $s, x : \mathsf{BHist}$, if $A_{\mathsf{e}}(s)$, then singleton conjugation by s is exactly terminal carrier membership of the middle endpoint:*

$$R_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(s, x), \mathsf{GroupSingletonInv}(s)), \mathsf{e}) \iff A_{\mathsf{e}}(x).$$

The ten-field fit is: traditional target terminal-group conjugation identity; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ over BHist; carrier A_{e}; classifier R_{e}; stability from inverse closure, two-sided contextual cancellation, product-unit split, and unit transport; ledger the conjugating endpoint s and the hidden inverse endpoint $\mathsf{GroupSingletonInv}(s)$; exactness the displayed iff; standard bridge conjugation in the one-element group; downstream consumer terminal normalizer and quotient-visibility collapse; and status $\mathsf{ProofTarget}$.

Proof. Assume $A_{\mathsf{e}}(s)$. The inverse row of Definition 41.88, applied to the concrete singleton inverse of s, supplies $A_{\mathsf{e}}(\mathsf{GroupSingletonInv}(s))$. The empty endpoint has $A_{\mathsf{e}}(\mathsf{e})$ by reflexivity, so the four context carriers needed for the two-sided contextual product-unit split are available.

Transport the displayed right endpoint along the empty unit laws, and transport the middle factor x along the right unit law, so the classifier has the two-sided product-unit shape with contexts s, e and $\mathsf{GroupSingletonInv}(s), \mathsf{e}$:

$$R_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(s, \mathsf{append}(x, \mathsf{e})), \mathsf{GroupSingletonInv}(s)), \mathsf{append}(\mathsf{append}(\mathsf{e}, \mathsf{e}), \mathsf{e})).$$

Apply Definition 41.134 with $p = x$ and $q = \mathsf{e}$. This cancels the singleton contexts and identifies the transported classifier with $A_{\mathsf{e}}(x) \wedge A_{\mathsf{e}}(\mathsf{e})$.

For the forward direction, project the first component of this conjunction. For the reverse direction, combine the assumed $A_{\mathsf{e}}(x)$ with the reflexive carrier witness $A_{\mathsf{e}}(\mathsf{e})$, apply the product-unit split in the constructive direction, and transport the unit laws back to the displayed conjugation endpoint against e. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier conjugation terminal collapse iff`

41.19 Singleton conjugation collapse

Theorem 41.146 (Group singleton conjugation fixed carrier)**.** *For histories $a, x : \mathsf{BHist}$ in the concrete singleton history group of Definition 41.3, if $A_{\mathsf{e}}(a)$, then*

$$R_{\mathsf{e}}(\mathsf{mul}(\mathsf{mul}(a, x), \mathsf{inv}(a)), x) \Longleftrightarrow A_{\mathsf{e}}(x).$$

The ten-field fit is: traditional target terminal-group inner action; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier A_{e}; classifier R_{e}; stability from singleton multiplication closure, inverse closure, and terminal classifier exactness; ledger the hidden conjugating endpoint and constant inverse; core theorem list Definition 41.4, Definition 41.5, and Definition 41.88; exactness predicate the displayed iff; standard bridge inner action of the terminal group; status* $\mathsf{ProofTarget}$.

Proof. For the forward direction, apply the first row of Definition 41.88 to the displayed classifier. It rewrites the classifier as the pair consisting of the conjugation word carrier fact and $A_{\mathsf{e}}(x)$, so projecting the second component gives the required carrier condition on x.

For the reverse direction, start from $A_{\mathsf{e}}(a)$ and $A_{\mathsf{e}}(x)$. The multiplication-closure row of Definition 41.88 places $\mathsf{mul}(a, x)$ in A_{e}, and the inverse-closure row places $\mathsf{inv}(a)$ in A_{e}.

Apply multiplication closure once more to put $\mathsf{mul}(\mathsf{mul}(a, x), \mathsf{inv}(a))$ in the singleton carrier. With this carrier fact and $A_{\mathsf{e}}(x)$, the terminal classifier exactness row of Definition 41.88 packages the classifier

$$R_{\mathsf{e}}(\mathsf{mul}(\mathsf{mul}(a, x), \mathsf{inv}(a)), x).$$

□

41.20 Concrete singleton normalizer action certificate

Theorem 41.147 (Group singleton normalizer action certificate)**.** *For the concrete singleton history group instance, define*

$$\mathsf{Conj}_s(x) := \mathsf{mul}(\mathsf{mul}(s, x), \mathsf{inv}(s))$$

and take the terminal normalizer carrier to be

$$N_{\mathsf{e}}(s) :\Longleftrightarrow A_{\mathsf{e}}(s).$$

If $A_{\mathsf{e}}(s)$ and $A_{\mathsf{e}}(x)$, then:

1. $A_{\mathsf{e}}(\mathsf{Conj}_s(x))$.
2. $A_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{inv}(s)}(x))$.
3. $R_{\mathsf{e}}(\mathsf{Conj}_s(x), x)$.
4. $R_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{inv}(s)}(\mathsf{Conj}_s(x)), x)$.

The ten-field fit is: traditional target terminal normalizer action; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier A_{e}; classifier R_{e}; stability singleton multiplication closure, inverse closure, and terminal classifier exactness; ledger the conjugating singleton endpoint and the acted-on singleton endpoint; core theorem this certificate; exactness terminal normalizer preservation; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$*; status* $\mathsf{ProofTarget}$.

Proof. Unfold the concrete singleton definitions. The inverse operation is constant, so $\mathsf{inv}(s) = \mathsf{e}$, and the two conjugation words are formed only by multiplying histories already in the singleton carrier with e.

Apply the multiplication-closure row of Theorem 41.88 to s and x to put $\mathsf{mul}(s, x)$ in A_{e}. Apply the same row again with $\mathsf{inv}(s) = \mathsf{e}$ to obtain $A_{\mathsf{e}}(\mathsf{Conj}_s(x))$.

For the inverse conjugating word, inverse closure gives $A_{\mathsf{e}}(\mathsf{inv}(s))$. The same two multiplication-closure applications place $\mathsf{Conj}_{\mathsf{inv}(s)}(x)$ in A_{e}.

It remains to read the classifier. The terminal classifier exactness row of Theorem 41.88 classifies any two singleton endpoints by R_{e}, so it gives $R_{\mathsf{e}}(\mathsf{Conj}_s(x), x)$ from the carrier facts already built.

Applying the closure argument once more to the singleton endpoint $\mathsf{Conj}_s(x)$ gives $A_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{inv}(s)}(\mathsf{Conj}_s(x)))$. The same classifier row then yields $R_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{inv}(s)}(\mathsf{Conj}_s(x)), x)$. □

Theorem 41.148 (Group singleton conjugation classifier coverage)**.** *For histories $s, x, y : \mathsf{BHist}$ in the concrete singleton history group of Definition 41.3, define*

$$\mathsf{Conj}_s(x) := \mathsf{mul}(\mathsf{mul}(s, x), \mathsf{inv}(s)).$$

If $A_{\mathsf{e}}(s)$, then

$$R_{\mathsf{e}}(\mathsf{Conj}_s(x), y) \iff A_{\mathsf{e}}(x) \wedge A_{\mathsf{e}}(y).$$

The ten-field fit is: traditional target terminal conjugation coverage; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier A_{e}; classifier R_{e}; stability from multiplication closure, inverse closure, and terminal classifier exactness; ledger the conjugating singleton endpoint plus the acted-on endpoint; core theorem this block; exactness the displayed iff; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$*; status* $\mathsf{ProofTarget}$*.*

Proof. Unfold $\mathsf{Conj}_s(x)$. The inverse row of Definition 41.88 sends the assumption $A_{\mathsf{e}}(s)$ to $A_{\mathsf{e}}(\mathsf{inv}(s))$.

Use the multiplication-closure iff from Definition 41.88 twice. The first use rewrites $A_{\mathsf{e}}(\mathsf{mul}(s, x))$ as $A_{\mathsf{e}}(s) \wedge A_{\mathsf{e}}(x)$, and the second rewrites $A_{\mathsf{e}}(\mathsf{Conj}_s(x))$ as $A_{\mathsf{e}}(\mathsf{mul}(s, x)) \wedge A_{\mathsf{e}}(\mathsf{inv}(s))$. With the two carrier facts for s and $\mathsf{inv}(s)$ fixed, this identifies $A_{\mathsf{e}}(\mathsf{Conj}_s(x))$ with $A_{\mathsf{e}}(x)$.

Apply the terminal classifier exactness row of Definition 41.88 to replace $R_{\mathsf{e}}(\mathsf{Conj}_s(x), y)$ by $A_{\mathsf{e}}(\mathsf{Conj}_s(x)) \wedge A_{\mathsf{e}}(y)$. Substituting the conjugation carrier equivalence from the previous paragraph and reassociating the conjunctions gives exactly $A_{\mathsf{e}}(x) \wedge A_{\mathsf{e}}(y)$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier append conjugation coverage iff`
Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier conjugation coverage iff`

Definition 41.149 (Group singleton normalizer orbit relation)**.** *In the concrete singleton history group instance, with N_{e} and* Conj *fixed as in Theorem 41.147, define the terminal normalizer orbit relation by declaring $x \sim_{N_{\mathsf{e}}} y$ precisely when there exists $s : \mathsf{BHist}$ such that $N_{\mathsf{e}}(s)$ and $R_{\mathsf{e}}(\mathsf{Conj}_s(x), y)$.*

Lean4 (definition) `BEDC.Derived.GroupUp.GroupSingletonNormalizerOrbit`

Theorem 41.150 (Group singleton normalizer orbit exactness)**.** *For any $x, y : \mathsf{BHist}$ with $A_{\mathsf{e}}(x)$ and $A_{\mathsf{e}}(y)$, the terminal normalizer orbit relation is exact: $x \sim_{N_{\mathsf{e}}} y$ if and only if $R_{\mathsf{e}}(x, y)$. The ten-field fit is: traditional target terminal normalizer orbit; BEDC source concrete singleton* $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier A_{e}; classifier the displayed orbit relation compared with R_{e}; stability from Theorem 41.147 and Theorem 41.88; ledger conjugator endpoint; core theorem this block; exactness orbit iff terminal singleton classifier; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$*; status* $\mathsf{ProofTarget}$*.*

Proof. Assume first $x \sim_{N_{\mathsf{e}}} y$. By Definition 41.149, choose $s : \mathsf{BHist}$ with $N_{\mathsf{e}}(s)$ and $R_{\mathsf{e}}(\mathsf{Conj}_s(x), y)$. Since $N_{\mathsf{e}}(s)$ means $A_{\mathsf{e}}(s)$, Theorem 41.147 applied to s and x gives $R_{\mathsf{e}}(\mathsf{Conj}_s(x), x)$.

Use the carrier-aware classifier rows of Theorem 41.88. Symmetry turns $R_{\mathsf{e}}(\mathsf{Conj}_s(x), x)$ into $R_{\mathsf{e}}(x, \mathsf{Conj}_s(x))$, and transitivity with the orbit witness $R_{\mathsf{e}}(\mathsf{Conj}_s(x), y)$ gives $R_{\mathsf{e}}(x, y)$.

Conversely assume $R_{\mathsf{e}}(x, y)$. Take the witness $s = \mathsf{e}$. The singleton carrier inhabitance row of Theorem 41.88 gives $A_{\mathsf{e}}(\mathsf{e})$, hence $N_{\mathsf{e}}(\mathsf{e})$.

Theorem 41.147, applied to e and x, gives $R_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{e}}(x), x)$. Transitivity with the assumed $R_{\mathsf{e}}(x, y)$ yields $R_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{e}}(x), y)$, so Definition 41.149 supplies the orbit witness and proves $x \sim_{N_{\mathsf{e}}} y$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier normalizer orbit source exact iff`

Theorem 41.151 (Group singleton normalizer orbit total coverage)**.** *For all histories $x, y : \mathsf{BHist}$ in the concrete singleton history group, with the orbit relation of Definition 41.149,*

$$x \sim_{N_{\mathsf{e}}} y \iff A_{\mathsf{e}}(x) \wedge A_{\mathsf{e}}(y).$$

The ten-field fit is: traditional target terminal normalizer-orbit coverage; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier A_{e}; classifier the orbit relation; stability from Definition 41.148 and Definition 41.88; ledger the existential conjugator endpoint; core theorem this block; exactness the displayed iff; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$*; status* $\mathsf{ProofTarget}$*.*

Proof. Assume first $x \sim_{N_{\mathsf{e}}} y$. By Definition 41.149, choose $s : \mathsf{BHist}$ with $N_{\mathsf{e}}(s)$ and $R_{\mathsf{e}}(\mathsf{Conj}_s(x), y)$. Since $N_{\mathsf{e}}(s)$ means $A_{\mathsf{e}}(s)$, Theorem 41.148 applies to this conjugator.

The forward direction of that coverage theorem sends the orbit witness $R_{\mathsf{e}}(\mathsf{Conj}_s(x), y)$ to $A_{\mathsf{e}}(x) \wedge A_{\mathsf{e}}(y)$.

Conversely assume $A_{\mathsf{e}}(x) \wedge A_{\mathsf{e}}(y)$. The singleton carrier inhabitance row of Theorem 41.88 gives $A_{\mathsf{e}}(\mathsf{e})$, hence $N_{\mathsf{e}}(\mathsf{e})$.

Apply the reverse direction of Theorem 41.148 with $s = \mathsf{e}$. The endpoint facts $A_{\mathsf{e}}(x)$ and $A_{\mathsf{e}}(y)$ yield $R_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{e}}(x), y)$, and Definition 41.149 supplies the existential orbit witness. □

and

$$(\exists s,\ A_{\mathsf{e}}(s) \wedge R_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(s, \mathsf{E1}(p)), \mathsf{e}), y)) \Longrightarrow \bot.$$

Proof. Unpack the orbit witness. The terminal classifier says that the conjugation display is in the singleton carrier. Applying append-empty decomposition first to the terminal append and then to the inner append forces either $\mathsf{E0}(p)\mathsf{hsamee}$ or $\mathsf{E1}(p)\mathsf{hsamee}$. Both contradict constructor separation for BHist. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonNormalizerOrbit visible source absurd`

Theorem 41.153 (Group singleton commutator normalizer-orbit kernel exactness)**.** *For histories $x, y : \mathsf{BHist}$ in the concrete singleton history group, with $\mathsf{Comm_e}(x, y)$ defined as in Definition 41.42 and with the terminal normalizer orbit relation of Definition 41.149,*

$$\mathsf{Comm_e}(x, y) \sim_{N_\mathsf{e}} \mathsf{e} \iff A_\mathsf{e}(x) \wedge A_\mathsf{e}(y).$$

Moreover the same endpoint is the terminal orbit kernel exactly when the two inputs lie in the same terminal normalizer orbit:

$$\mathsf{Comm_e}(x, y) \sim_{N_\mathsf{e}} \mathsf{e} \iff x \sim_{N_\mathsf{e}} y.$$

The ten-field fit is: traditional target terminal commutator orbit-kernel exactness; BEDC source concrete singleton $\mathsf{Group}^\uparrow$ *over* BHist*; carrier A_e; classifier the terminal normalizer orbit relation; stability from total orbit coverage and commutator carrier exactness; ledger the commutator endpoint together with the terminal endpoint* e*; core theorem this block; exactness the two displayed equivalences; downstream consumer* $\mathsf{QuotientGroup}^\uparrow$ *first-isomorphism-style quotient-kernel exactness; status* $\mathsf{ProofTarget}$*.*

Proof. Apply Definition 41.151 to the pair $(\mathsf{Comm_e}(x, y), \mathsf{e})$. The singleton carrier inhabitance row of Definition 41.88 gives $A_\mathsf{e}(\mathsf{e})$, so the orbit coverage statement reduces the commutator orbit edge to the carrier condition $A_\mathsf{e}(\mathsf{Comm_e}(x, y))$.

Now compose this reduction with Definition 41.44. That theorem identifies the commutator carrier condition with $A_\mathsf{e}(x) \wedge A_\mathsf{e}(y)$, giving the first displayed equivalence.

For the comparison with the terminal orbit of the two inputs, apply Definition 41.151 again, now to the pair (x, y). It identifies $x \sim_{N_\mathsf{e}} y$ with the same carrier pair $A_\mathsf{e}(x) \wedge A_\mathsf{e}(y)$.

Combining the two identifications through the common carrier pair gives the second displayed equivalence, with no additional group data beyond the singleton normalizer orbit certificate. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonCommutator normalizer orbit kernel exactness iff`

Theorem 41.154 (Group singleton normalizer orbit equivalence)**.** *For histories $x, y, z : \mathsf{BHist}$ carried by A_e in the concrete singleton history group, the terminal normalizer orbit relation of Definition 41.149 is reflexive, symmetric, and transitive on the carried endpoints:*

1. $x \sim_{N_\mathsf{e}} x$.
2. *If $x \sim_{N_\mathsf{e}} y$, then $y \sim_{N_\mathsf{e}} x$.*
3. *If $x \sim_{N_\mathsf{e}} y$ and $y \sim_{N_\mathsf{e}} z$, then $x \sim_{N_\mathsf{e}} z$.*

The ten-field fit is: traditional target terminal normalizer orbit equivalence; BEDC source concrete singleton $\mathsf{Group}^\uparrow$ *over* BHist*; carrier A_e; classifier the orbit relation compared with R_e; stability from Theorem 41.150 plus the SemanticNameCert reflexivity, symmetry, and transitivity rows for R_e in Theorem 41.88; ledger the conjugator endpoint carried by each orbit witness; core theorem this block; exactness the displayed orbit equivalence laws; downstream consumer* $\mathsf{QuotientGroup}^\uparrow$*; status* $\mathsf{ProofTarget}$*.*

Proof. For reflexivity, use the reflexivity row of Theorem 41.88 on $A_\mathsf{e}(x)$ to obtain $R_\mathsf{e}(x, x)$. The reverse direction of Theorem 41.150, applied at (x, x), transports this classifier fact to $x \sim_{N_\mathsf{e}} x$.

For symmetry, assume $x \sim_{N_\mathsf{e}} y$. The forward direction of Theorem 41.150, applied at (x, y), gives $R_\mathsf{e}(x, y)$. The symmetry row of Theorem 41.88 gives $R_\mathsf{e}(y, x)$, and the reverse direction of orbit exactness at (y, x) gives $y \sim_{N_\mathsf{e}} x$.

For transitivity, assume $x \sim_{N_\mathsf{e}} y$ and $y \sim_{N_\mathsf{e}} z$. Orbit exactness sends these two orbit classifiers to $R_\mathsf{e}(x, y)$ and $R_\mathsf{e}(y, z)$. The transitivity row of Theorem 41.88 gives $R_\mathsf{e}(x, z)$, and the reverse direction of orbit exactness at (x, z) gives $x \sim_{N_\mathsf{e}} z$. □

Lean4 ✓ BEDC.Derived.GroupUp.GroupSingletonNormalizerOrbit equivalence

Definition 41.155 (Concrete singleton normalizer-action group instance)**.** *The concrete terminal normalizer action over* BHist *is the data whose carrier is* $Carrier := A_{\mathsf{e}}$*, whose classifier is* $classifier := R_{\mathsf{e}}$*, whose multiplication is* $mul :=$ append*, whose unit is* $e :=$ e*, whose inverse is the constant operation* $inv(h) :=$ e*, and whose action map is*

$$\mathsf{Conj}_s(x) := \mathsf{mul}(\mathsf{mul}(s, x), \mathsf{inv}(s)).$$

Lean4 (definition) BEDC.Derived.GroupUp.GroupSingletonNormalizerAction

Theorem 41.156 (Group singleton normalizer action classifier determinacy)**.** *For histories* $s, x, y :$ BHist*, if* $A_{\mathsf{e}}(s)$ *and* $R_{\mathsf{e}}(x, y)$*, then*

$$R_{\mathsf{e}}(\mathsf{Conj}_s(x), \mathsf{Conj}_s(y)) \wedge R_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{inv}(s)}(\mathsf{Conj}_s(x)), y).$$

Proof. The classifier assumption $R_{\mathsf{e}}(x, y)$ carries the singleton endpoint facts $A_{\mathsf{e}}(x)$ and $A_{\mathsf{e}}(y)$ by the forward direction of the terminal classifier row in Theorem 41.88.

Instantiate Theorem 41.147 at (s, x) and (s, y). The two instances give $A_{\mathsf{e}}(\mathsf{Conj}_s(x))$ and $A_{\mathsf{e}}(\mathsf{Conj}_s(y))$, so the SemanticNameCert classifier symmetry/transitivity rows for R_{e} classify the two action endpoints:

$$R_{\mathsf{e}}(\mathsf{Conj}_s(x), \mathsf{Conj}_s(y)).$$

The (s, x) instance also gives the inverse-roundtrip classifier $R_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{inv}(s)}(\mathsf{Conj}_s(x)), x)$. Composing this row with the input classifier $R_{\mathsf{e}}(x, y)$ by the SemanticNameCert transitivity row for R_{e} yields

$$R_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{inv}(s)}(\mathsf{Conj}_s(x)), y).$$

The two displayed classifiers are exactly the required conjunction. □

Lean4 ✓ BEDC.Derived.GroupUp.GroupSingletonClassifier conjugation action determinacy

Theorem 41.157 (Group singleton normalizer orbit action invariance)**.** *For histories* $s, x, y :$ BHist *in the concrete singleton history group instance, if* $A_{\mathsf{e}}(s)$*,* $A_{\mathsf{e}}(x)$*,* $A_{\mathsf{e}}(y)$*, and* $x \sim_{N_{\mathsf{e}}} y$*, then*

$$\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_s(y).$$

The ten-field fit is: traditional target normalizer action descending to the terminal orbit quotient; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* A_{e}*; classifier the normalizer orbit relation exact against* R_{e}*; stability from Theorem 41.150, Theorem 41.156, and Theorem 41.88; ledger the conjugating endpoint and orbit witness; core theorem this block; exactness the displayed orbit preservation; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$*; status* ProofTarget*.*

Proof. Start with the given orbit witness $x \sim_{N_{\mathsf{e}}} y$. Since x and y are in A_{e}, Theorem 41.150 turns that witness into the terminal classifier row $R_{\mathsf{e}}(x, y)$.

Apply Theorem 41.156 with the conjugating endpoint s. The hypothesis $A_{\mathsf{e}}(s)$ transports $R_{\mathsf{e}}(x, y)$ to

$$R_{\mathsf{e}}(\mathsf{Conj}_s(x), \mathsf{Conj}_s(y)).$$

It remains to use orbit exactness in the reverse direction. The terminal classifier package supplies the carrier rows for the two acted endpoints from the displayed R_{e} row, and then Theorem 41.150 repacks that classifier row as $\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_s(y)$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonNormalizerOrbit action invariance`

Theorem 41.158 (Group singleton normalizer action composition collapse)**.** *For histories* $s, t, x : \mathsf{BHist}$ *in the concrete singleton history group instance, define*

$$\mathsf{Conj}_u(y) := \mathsf{mul}(\mathsf{mul}(u, y), \mathsf{inv}(u)).$$

If $A_{\mathsf{e}}(s)$*,* $A_{\mathsf{e}}(t)$*, and* $A_{\mathsf{e}}(x)$*, then:*

1. $A_{\mathsf{e}}(\mathsf{Conj}_t(x))$.
2. $A_{\mathsf{e}}(\mathsf{Conj}_s(\mathsf{Conj}_t(x)))$.
3. $A_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{mul}(s,t)}(x))$.
4. $R_{\mathsf{e}}(\mathsf{Conj}_s(\mathsf{Conj}_t(x)), x)$.
5. $R_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{mul}(s,t)}(x), x)$.

The fit names the traditional target as terminal normalizer composition; the BEDC source as the concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* A_{e}*; classifier* R_{e}*; stability from singleton multiplication closure and terminal classifier exactness; ledger the two conjugating singleton endpoints and the acted-on singleton endpoint; core theorem this block; exactness predicate the displayed carrier and classifier collapse; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$ *orbit classification; and status* $\mathsf{ProofTarget}$.

Proof. First apply Theorem 41.147 to t and x. The hypotheses $A_{\mathsf{e}}(t)$ and $A_{\mathsf{e}}(x)$ give $A_{\mathsf{e}}(\mathsf{Conj}_t(x))$.

Use that carrier fact as the acted-on endpoint for a second application of Theorem 41.147, now with conjugator s. Together with $A_{\mathsf{e}}(s)$ it gives $A_{\mathsf{e}}(\mathsf{Conj}_s(\mathsf{Conj}_t(x)))$.

Next apply the multiplication-closure row of Theorem 41.88 to s and t. This places $\mathsf{mul}(s, t)$ in A_{e}. Applying Theorem 41.147 to $\mathsf{mul}(s, t)$ and x gives $A_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{mul}(s,t)}(x))$.

It remains to read the terminal classifier. The first row of Theorem 41.88 classifies any two singleton endpoints. Apply it to the nested endpoint and x, then to the product-conjugator endpoint and x, using the carrier facts already displayed. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonNormalizerAction composition collapse`

Theorem 41.159 (Group singleton normalizer action product-coherent orbit collapse)**.** *For histories* $s, t, x : \mathsf{BHist}$ *in the concrete singleton history group instance, write*

$$\mathsf{Conj}_u(y) := \mathsf{mul}(\mathsf{mul}(u, y), \mathsf{inv}(u)).$$

If $A_{\mathsf{e}}(s)$*,* $A_{\mathsf{e}}(t)$*, and* $A_{\mathsf{e}}(x)$*, then*

$$R_{\mathsf{e}}(\mathsf{Conj}_s(\mathsf{Conj}_t(x)), \mathsf{Conj}_{\mathsf{mul}(s,t)}(x))$$

and

$$R_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{mul}(s,t)}(x), \mathsf{Conj}_s(\mathsf{Conj}_t(x))).$$

The fit names the traditional target as product-coherent terminal normalizer action; the BEDC source as the concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* A_{e}*; classifier* R_{e}*; stability from Theorem 41.158; ledger the nested action endpoint and the product-conjugator endpoint; core theorem this block; exactness predicate mutual singleton classification of the two endpoints; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$ *orbit collapse; and status* $\mathsf{ProofTarget}$.

Proof. Apply Theorem 41.158 to s, t, and x. Its carrier rows place both $\mathsf{Conj}_s(\mathsf{Conj}_t(x))$ and $\mathsf{Conj}_{\mathsf{mul}(s,t)}(x)$ in A_{e}.

The terminal classifier exactness row of Theorem 41.88 classifies any two singleton endpoints. Applied to those two carrier facts, it gives $R_{\mathsf{e}}(\mathsf{Conj}_s(\mathsf{Conj}_t(x)), \mathsf{Conj}_{\mathsf{mul}(s,t)}(x))$.

For the reverse classifier, use the symmetry row of the same terminal classifier package on the displayed forward classifier. This yields $R_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{mul}(s,t)}(x), \mathsf{Conj}_s(\mathsf{Conj}_t(x)))$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonNormalizerAction product coherent orbit collapse`

Theorem 41.160 (Group singleton normalizer action product-coherent orbit law)**.** *For histories $s, t, x : \mathsf{BHist}$ in the concrete singleton history group instance, write*

$$\mathsf{Conj}_u(y) := \mathsf{mul}(\mathsf{mul}(u, y), \mathsf{inv}(u)).$$

If $A_{\mathsf{e}}(s)$, $A_{\mathsf{e}}(t)$, and $A_{\mathsf{e}}(x)$, then

$$\mathsf{Conj}_s(\mathsf{Conj}_t(x)) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_{\mathsf{mul}(s,t)}(x) \wedge \mathsf{Conj}_{\mathsf{mul}(s,t)}(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_s(\mathsf{Conj}_t(x)).$$

The ten-field fit names the traditional target as terminal normalizer action composition on orbits; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier A_{e}; classifier $\sim_{N_{\mathsf{e}}}$; stability from orbit exactness and product-coherent classifier collapse; ledger the two conjugators, product conjugator, and acted endpoint; core theorem this block; exactness the displayed orbit-level product law; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$ *action composition; and status* $\mathsf{ProofTarget}$*.*

Proof. First apply Theorem 41.158 to s, t, and x. Its carrier rows place $\mathsf{Conj}_s(\mathsf{Conj}_t(x))$ and $\mathsf{Conj}_{\mathsf{mul}(s,t)}(x)$ in A_{e}.

Next apply Theorem 41.159. This gives the two terminal classifier rows between the nested conjugation endpoint and the product-conjugator endpoint.

Finally use Theorem 41.150 in the classifier-to-orbit direction twice. The first use turns the forward R_{e} row into $\mathsf{Conj}_s(\mathsf{Conj}_t(x)) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_{\mathsf{mul}(s,t)}(x)$, and the second use turns the reverse R_{e} row into $\mathsf{Conj}_{\mathsf{mul}(s,t)}(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_s(\mathsf{Conj}_t(x))$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonNormalizerOrbit product coherent action law`

Theorem 41.161 (Group singleton normalizer orbit action law package)**.** *For histories $s, t, x, y :$ BHist in the concrete singleton history group instance, if $A_{\mathsf{e}}(s)$, $A_{\mathsf{e}}(t)$, $A_{\mathsf{e}}(x)$, $A_{\mathsf{e}}(y)$, and $x \sim_{N_{\mathsf{e}}} y$, then:*

1. $\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_s(y)$.
2. $\mathsf{Conj}_{\mathsf{inv}(s)}(\mathsf{Conj}_s(x)) \sim_{N_{\mathsf{e}}} y$.
3. $\mathsf{Conj}_s(\mathsf{Conj}_t(x)) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_{\mathsf{mul}(s,t)}(x)$.

The ten-field fit names the traditional target as a concrete terminal normalizer orbit action law package; the BEDC source as the concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier A_{e}; classifier the normalizer orbit relation exact against R_{e}; stability from orbit exactness, classifier determinacy, and product-coherent orbit collapse; ledger the two conjugating singleton endpoints, the acted-on singleton endpoint, and the orbit witness; core theorem this block; exactness predicate the three displayed orbit action laws; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$*; and status* $\mathsf{ProofTarget}$*.*

Proof. First convert the input orbit witness into the concrete classifier. Since x and y lie in A_{e}, the forward direction of Theorem 41.150 gives $R_{\mathsf{e}}(x, y)$.

For the first law, apply Theorem 41.157 directly to s, x, and y. Its hypotheses are exactly $A_{\mathsf{e}}(s)$, $A_{\mathsf{e}}(x)$, $A_{\mathsf{e}}(y)$, and the given orbit relation.

For the inverse-roundtrip law, apply Theorem 41.156 with the conjugating endpoint s and the classifier row $R_{\mathsf{e}}(x, y)$. The second row gives

$$R_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{inv}(s)}(\mathsf{Conj}_s(x)), y).$$

The reverse direction of Theorem 41.150 repacks this classifier as $\mathsf{Conj}_{\mathsf{inv}(s)}(\mathsf{Conj}_s(x)) \sim_{N_{\mathsf{e}}} y$.

For the product law, apply Theorem 41.159 to s, t, and x. Its forward classifier row is

$$R_{\mathsf{e}}(\mathsf{Conj}_s(\mathsf{Conj}_t(x)), \mathsf{Conj}_{\mathsf{mul}(s,t)}(x)).$$

Again use the reverse direction of orbit exactness to convert that classifier into the displayed orbit relation. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonNormalizerOrbit action law package`

Theorem 41.162 (Group singleton normalizer orbit action unital product package)**.** *For histories $s, t, x, y : \mathsf{BHist}$ in the concrete singleton history group instance, if $A_{\mathsf{e}}(s)$, $A_{\mathsf{e}}(t)$, $A_{\mathsf{e}}(x)$, $A_{\mathsf{e}}(y)$, and $x \sim_{N_{\mathsf{e}}} y$, then:*

1. $\mathsf{Conj}_{\mathsf{e}}(x) \sim_{N_{\mathsf{e}}} x$ *and* $x \sim_{N_{\mathsf{e}}} \mathsf{Conj}_{\mathsf{e}}(x)$.
2. $\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_s(y)$.
3. $\mathsf{Conj}_{\mathsf{inv}(s)}(\mathsf{Conj}_s(x)) \sim_{N_{\mathsf{e}}} y$.
4. $\mathsf{Conj}_s(\mathsf{Conj}_t(x)) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_{\mathsf{mul}(s,t)}(x)$ *and* $\mathsf{Conj}_{\mathsf{mul}(s,t)}(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_s(\mathsf{Conj}_t(x))$.

The ten-field fit names the traditional target as terminal normalizer action as a unital product action on the orbit quotient; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier A_{e}; classifier $\sim_{N_{\mathsf{e}}}$; stability from orbit exactness and the normalizer action rows; ledger the identity conjugator, two product conjugators, acted endpoint, and orbit witness; core theorem list Theorem 41.147, Theorem 41.150, Theorem 41.157, Theorem 41.156, and Theorem 41.160; exactness the displayed package; standard bridge the terminal group action on its one-point orbit; and status* $\mathsf{ProofTarget}$.

Proof. For the identity rows, apply Theorem 41.147 with conjugator e and endpoint x. It gives the carrier data for $\mathsf{Conj}_{\mathsf{e}}(x)$ and the classifier row

$$R_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{e}}(x), x).$$

The reverse direction of Theorem 41.150 converts this classifier into $\mathsf{Conj}_{\mathsf{e}}(x) \sim_{N_{\mathsf{e}}} x$.

For the opposite identity orientation, use the singleton classifier symmetry row already available to the action certificate to turn the displayed classifier into $R_{\mathsf{e}}(x, \mathsf{Conj}_{\mathsf{e}}(x))$. A second reverse use of Theorem 41.150 gives $x \sim_{N_{\mathsf{e}}} \mathsf{Conj}_{\mathsf{e}}(x)$.

For action invariance, apply Theorem 41.157 directly to s, x, and y. The hypotheses are the carrier rows for s, x, and y, together with the given orbit witness.

For the inverse-roundtrip row, first convert the orbit witness $x \sim_{N_{\mathsf{e}}} y$ to $R_{\mathsf{e}}(x, y)$ by the forward direction of Theorem 41.150. Then apply Theorem 41.156 to s and this classifier row. Its second classifier output is

$$R_{\mathsf{e}}(\mathsf{Conj}_{\mathsf{inv}(s)}(\mathsf{Conj}_s(x)), y).$$

The reverse direction of orbit exactness repacks this row as the displayed orbit relation.

For product coherence, apply Theorem 41.160 to s, t, and x. Its two orbit outputs are exactly the forward and reverse orientations between $\mathsf{Conj}_s(\mathsf{Conj}_t(x))$ and $\mathsf{Conj}_{\mathsf{mul}(s,t)}(x)$. □

Theorem 41.163 (Group singleton normalizer action single-orbit fiber)**.** *For histories s, x, y : BHist in the concrete singleton history group, define*

$$\mathsf{Conj}_s(x) := \mathsf{mul}(\mathsf{mul}(s, x), \mathsf{inv}(s)).$$

If $A_{\mathsf{e}}(s)$ and $A_{\mathsf{e}}(x)$, then the terminal normalizer action fiber is single-orbit exact:

$$\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} y \iff A_{\mathsf{e}}(y).$$

The ten-field fit is: traditional target terminal normalizer action fiber; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier A_{e}; classifier $\sim_{N_{\mathsf{e}}}$; stability from Theorem 41.147, Theorem 41.150, and Theorem 41.88; ledger the conjugator, source endpoint, and target endpoint; core theorem this block; exactness the displayed iff; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$*; and status* $\mathsf{ProofTarget}$.

Proof. First apply Theorem 41.147 to s and x. This gives $A_{\mathsf{e}}(\mathsf{Conj}_s(x))$, so the acted source endpoint is inside the singleton carrier.

For the forward direction, unpack the orbit relation at $\mathsf{Conj}_s(x)$ and y. Its witness gives a terminal classifier row whose target endpoint is y.

The classifier exactness row of Theorem 41.88 reads that row as the pair of carrier facts for the acted witness endpoint and y. Projecting the second component gives $A_{\mathsf{e}}(y)$.

For the reverse direction, assume $A_{\mathsf{e}}(y)$. The terminal classifier exactness row gives

$$R_{\mathsf{e}}(\mathsf{Conj}_s(x), y).$$

With the source carrier already built and the target carrier now assumed, Theorem 41.150 repacks this classifier as $\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} y$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonNormalizerOrbit action single fiber iff`

Theorem 41.164 (Group singleton normalizer action orbit identity)**.** *For histories s, x, y : BHist in the concrete singleton history group instance, write*

$$\mathsf{Conj}_s(z) := \mathsf{mul}(\mathsf{mul}(s, z), \mathsf{inv}(s)).$$

If $A_{\mathsf{e}}(s)$, $A_{\mathsf{e}}(x)$, and $A_{\mathsf{e}}(y)$, then

$$\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} y \iff x \sim_{N_{\mathsf{e}}} y.$$

The ten-field fit names the traditional target as terminal normalizer quotient identity action; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier A_{e}; classifier the normalizer orbit relation exact against R_{e}; stability from the singleton normalizer action certificate, orbit exactness, and the terminal classifier symmetry and transitivity rows; ledger the conjugating singleton endpoint and the two orbit endpoints; core theorem this block; exactness the displayed orbit identity iff; downstream consumer the singleton* $\mathsf{QuotientGroup}^{\uparrow}$ *action classifier; and status* $\mathsf{ProofTarget}$.

Proof. First apply Theorem 41.147 to s and x. It gives both $A_{\mathsf{e}}(\mathsf{Conj}_s(x))$ and the classifier row $R_{\mathsf{e}}(\mathsf{Conj}_s(x), x)$.

For the forward direction, assume $\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} y$. Orbit exactness, applied at $(\mathsf{Conj}_s(x), y)$ with the carrier rows just named and $A_{\mathsf{e}}(y)$, converts this orbit edge into

$$R_{\mathsf{e}}(\mathsf{Conj}_s(x), y).$$

Use the symmetry row for the terminal classifier to turn $R_{\mathsf{e}}(\mathsf{Conj}_s(x), x)$ into $R_{\mathsf{e}}(x, \mathsf{Conj}_s(x))$. Transitivity with the displayed classifier gives $R_{\mathsf{e}}(x, y)$, and the reverse direction of orbit exactness repacks this as $x \sim_{N_{\mathsf{e}}} y$.

For the reverse direction, assume $x \sim_{N_{\mathsf{e}}} y$. Orbit exactness at (x, y) turns this orbit edge into $R_{\mathsf{e}}(x, y)$.

Compose the certificate classifier $R_{\mathsf{e}}(\mathsf{Conj}_s(x), x)$ with $R_{\mathsf{e}}(x, y)$ by terminal classifier transitivity. The result is

$$R_{\mathsf{e}}(\mathsf{Conj}_s(x), y).$$

Finally use orbit exactness in the classifier-to-orbit direction at $(\mathsf{Conj}_s(x), y)$. The carrier input is $A_{\mathsf{e}}(\mathsf{Conj}_s(x))$ from the action certificate together with $A_{\mathsf{e}}(y)$, so the displayed classifier becomes $\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} y$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonNormalizerOrbit action identity iff`

41.21 Unary append inverse obstruction

Theorem 41.165 (Unary append unit-product factor exactness)**.** *For histories $h, k : \mathsf{BHist}$, the concrete unary-history append product is classified as the monoid unit exactly when both factors are classified as the unit:*

$$\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(h,k), \mathsf{e}) \iff \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(h, \mathsf{e}) \wedge \mathsf{MonoidHisto}$$

Equivalently, the append operation in the full unary monoid cannot supply a non-singleton inverse pair for the concrete singleton $\mathsf{Group}^{\uparrow}$ *instance.*

Proof. Unfold the classifier from Definition 40.2. The forward direction gives the unary carrier witnesses for $\mathsf{append}(h, k)$ and e together with $\mathsf{hsame}(\mathsf{append}(h, k), \mathsf{e})$. Apply the BEDC kernel theorem `append_eq_empty_iff` to this empty-result comparison; it splits the append endpoint into $h\mathsf{hsamee}$ and $k\mathsf{hsamee}$. Repacking these two singleton endpoint witnesses with the unary carrier data gives the two displayed monoid-classifier factors.

For the reverse direction, assume the two displayed classifier factors. Their carrier fields give $\mathsf{UnaryHistory}(h)$ and $\mathsf{UnaryHistory}(k)$, while their sameness fields identify both histories with e. Unary closure of append from Definition 40.3 supplies $\mathsf{UnaryHistory}(\mathsf{append}(h, k))$, and the constructor direction of `append_eq_empty_iff` rebuilds $\mathsf{hsame}(\mathsf{append}(h, k), \mathsf{e})$. Together with $\mathsf{UnaryHistory}(\mathsf{e})$, these fields repack the displayed $\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(h, k), \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.GroupUp.MonoidHistoryClassifier unary append unit product factor exactness`
Lean4 ✓ `BEDC.Derived.MonoidUp.unary append unit product factor exactness`

Theorem 41.166 (Unary append group subcarrier unit collapse)**.** *Let* $C : \mathsf{BHist} \to \mathsf{Prop}$ *be a concrete unary subcarrier, and let* $i : \mathsf{BHist} \to \mathsf{BHist}$ *be an inverse witness. Assume*

$$\begin{array}{ll}
\text{carrier:} & \forall h : \mathsf{BHist},\ C(h) \Rightarrow \mathsf{UnaryHistory}(h), \\
\text{unit:} & C(\mathsf{e}), \\
\text{append closure:} & \forall h, k : \mathsf{BHist},\ C(h) \Rightarrow C(k) \Rightarrow C(\mathsf{append}(h, k)), \\
\text{inverse closure:} & \forall h : \mathsf{BHist},\ C(h) \Rightarrow C(i(h)), \\
\text{inverse products:} & \forall h : \mathsf{BHist},\ C(h) \Rightarrow \\
& \quad \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(h, i(h)), \mathsf{e}) \wedge \\
& \quad \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(i(h), h), \mathsf{e}).
\end{array}$$

Then every carried element lies in the empty-unit classifier fiber:

$$\forall h : \mathsf{BHist},\ C(h) \Rightarrow \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(h, \mathsf{e}).$$

Proof. Fix $h : \mathsf{BHist}$ with $C(h)$. The inverse-product hypothesis gives the right-inverse classifier row

$$\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(h, i(h)), \mathsf{e}).$$

Apply Definition 41.165 in the forward direction to this row. The resulting conjunction has left factor $\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(h, \mathsf{e})$, which is the required unit-fiber conclusion for the chosen carried element.

The left-inverse row, append closure, inverse closure, and explicit unit field remain part of the concrete group-interface scope. They certify that C is being tested as a carried unary append instance, while the collapse argument itself only needs the right inverse and the unit-product factor exactness theorem. □

Theorem 41.167 (Group unary append inverse obstruction replay)**.** *Any* $\mathsf{Group}^{\uparrow}$ *consumer that tests a unary append inverse field over a concrete subcarrier* $C \subseteq \mathsf{UnaryHistory}$ *must replay the inverse-product row through Definition 41.165 before it can derive the singleton-unit collapse of Definition 41.166. Thus the group obstruction depends on the concrete* $\mathsf{Monoid}^{\uparrow}$ *unit-product factor exactness surface and cannot be read directly from the inverse-field signature alone.*

Proof. Start with a $\mathsf{Group}^{\uparrow}$-facing inverse test for a carried history h. The test supplies a displayed inverse-product classifier row for $\mathsf{append}(h, i(h))$ or $\mathsf{append}(i(h), h)$, but this row still lives in the unary append monoid classifier.

Apply Definition 41.165. It is the only local result that separates a unary append product classified as e into the two unit-fiber factors for its components.

With that factorization available, apply Definition 41.166. The collapse is therefore a replay through the $\mathsf{Monoid}^{\uparrow}$ unit-product exactness theorem followed by the group subcarrier collapse theorem, not a consequence of the inverse-field row by itself. □

Fit: the traditional target is the append-inverse group interface; the BEDC source is $C \subseteq \mathsf{UnaryHistory}$; the carrier is C; the classifier is inherited from $\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})$; stability is supplied by append closure and inverse closure; the ledger is the inverse witness i; the core theorem is this collapse block together with Definition 41.165; exactness is unit-fiber collapse; the downstream consumers are $\mathsf{Group}^{\uparrow}$ and $\mathsf{QuotientGroup}^{\uparrow}$; the status is $\mathsf{ProofTarget}$.

Theorem 41.168 (Full unary append inverse obstruction)**.** *There is no total inverse operation on the full unary-history append carrier: for every operation* $\mathsf{inv} : \mathsf{BHist} \to \mathsf{BHist}$*, if*

$$\begin{aligned}&\forall h : \mathsf{BHist},\ \mathsf{UnaryHistory}(h) \Rightarrow \\ &\quad \mathsf{UnaryHistory}(\mathsf{inv}(h)) \wedge \\ &\quad \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(h, \mathsf{inv}(h)), \mathsf{e}),\end{aligned}$$

then False*.*

Proof. Assume such an operation inv and its displayed total inverse law. The history $\mathsf{E1}(\mathsf{e})$ is a concrete nonempty unary history, so the law applies to $h = \mathsf{E1}(\mathsf{e})$ and gives the unit-product classifier for $\mathsf{append}(\mathsf{E1}(\mathsf{e}), \mathsf{inv}(\mathsf{E1}(\mathsf{e})))$.

Apply Definition 41.165 to that classifier. The left factor of the resulting conjunction gives

$$\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{E1}(\mathsf{e}), \mathsf{e}).$$

Unfold Definition 40.2: the classifier contains the endpoint carrier witnesses together with an internal history-sameness witness $\mathsf{E1}(\mathsf{e})\mathsf{hsamee}$. This is impossible by Definition 20.6, since an $\mathsf{E1}$-history and e have different outer constructors. Hence the assumed total inverse law yields False. □

Lean4 ✓ `BEDC.Derived.GroupUp.unary append inverse obstruction`
Lean4 ✓ `BEDC.Derived.GroupUp.FullUnaryAppendInverse obstruction`
Lean4 ✓ `BEDC.Derived.GroupUp.UnaryHistory append inverse obstruction`
Lean4 ✓ `BEDC.Derived.GroupUp.MonoidHistoryClassifier unary append inverse obstruction`

Theorem 41.169 (Unary append inverse completion singleton boundary)**.** *Let* $C : \mathsf{BHist} \to \mathsf{Prop}$ *be a concrete subcarrier of* $\mathsf{UnaryHistory}$*, and let* $i : \mathsf{BHist} \to \mathsf{BHist}$ *be an inverse operation. Assume*

$$\begin{array}{ll}\text{carrier:} & \forall h : \mathsf{BHist},\ C(h) \Rightarrow \mathsf{UnaryHistory}(h), \\ \text{unit:} & C(\mathsf{e}), \\ \text{append closure:} & \forall h, k : \mathsf{BHist},\ C(h) \Rightarrow C(k) \Rightarrow C(\mathsf{append}(h, k)), \\ \text{inverse closure:} & \forall h : \mathsf{BHist},\ C(h) \Rightarrow C(i(h)), \\ \text{inverse products:} & \forall h : \mathsf{BHist},\ C(h) \Rightarrow \\ & \quad \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(h, i(h)), \mathsf{e}) \wedge \\ & \quad \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(i(h), h), \mathsf{e}).\end{array}$$

Then every carried element lies in the singleton unit fiber:

$$\forall h : \mathsf{BHist},\ C(h) \Rightarrow \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(h, \mathsf{e}).$$

Moreover, if $C(\mathsf{E1}(\mathsf{e}))$ *is also supplied, these same rows imply* False*.*

Proof. Apply Definition 41.166 to the displayed carrier, unit, append-closure, inverse-closure, and inverse-product rows. This gives the singleton unit-fiber classifier for every carried history in C.

Now assume the additional nonempty carried row $C(\mathsf{E1}(\mathsf{e}))$. Instantiate the unit-fiber conclusion at $\mathsf{E1}(\mathsf{e})$ to obtain

$$\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{E1}(\mathsf{e}), \mathsf{e}).$$

Unfold the concrete monoid classifier as in Definition 41.168. The classifier contains a history-sameness witness $\mathsf{E1}(\mathsf{e})\mathsf{hsamee}$ between histories with different outer constructors.

Apply Definition 20.6. The $\mathsf{E1}$ constructor cannot be identified with e, so the additional carried nonempty row contradicts the same inverse-completion package. Thus the only valid concrete unary append group carrier is the singleton unit fiber. □

Theorem 41.170 (Unary append inverse field collapses to singleton)**.** *For every operation* $i : \mathsf{BHist} \to \mathsf{BHist}$*, the right-inverse field on the full unary-history append carrier,*

$$\forall h : \mathsf{BHist},\ \mathsf{UnaryHistory}(h) \Rightarrow \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(h, i(h)), \mathsf{e}),$$

implies the singleton-unit collapse

$$\forall h : \mathsf{BHist},\ \mathsf{UnaryHistory}(h) \Rightarrow \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(h, \mathsf{e}).$$

The analogous left-inverse field,

$$\forall h : \mathsf{BHist},\ \mathsf{UnaryHistory}(h) \Rightarrow \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(i(h), h), \mathsf{e}),$$

implies the same singleton-unit collapse.

The ten-field fit is: traditional target obstruction to making the full unary append monoid into a group; BEDC source UnaryHistory*,* append*, and* MonoidHistoryClassifier*; carrier* UnaryHistory*; classifier* MonoidHistoryClassifier(UnaryHistory)*; stability from unit-product factor exactness; ledger the proposed inverse field; core theorem this block; exactness inverse-law collapse to the singleton unit class; downstream consumer the concrete* $\mathsf{Group}^{\uparrow}$ *carrier choice; status* ProofTarget*.*

Proof. Assume the right-inverse field and fix a unary history h. Specializing the field at h gives the classifier statement that $\mathsf{append}(h, i(h))$ is classified as e.

Apply Definition 41.165 to this append product. The forward direction decomposes the unit-product classifier into the two factor classifiers, and the left factor is exactly MonoidHistoryClassifier(UnaryHistory)(h,

For the left-inverse field, fix the same unary history h and specialize the field at h. Apply Definition 41.165 to $\mathsf{append}(i(h), h)$. The forward direction now gives the two factor classifiers with h as the right factor, so the right factor is the displayed singleton-unit conclusion. □

Lean4 ✓ `BEDC.Derived.GroupUp.MonoidHistoryClassifier unary append inverse field collapse`
Lean4 ✓ `BEDC.Derived.GroupUp.unary append inverse field collapses to singleton`

Theorem 41.171 (Unary append inverse field iff singleton collapse)**.** *For every operation* $i : \mathsf{BHist} \to \mathsf{BHist}$ *satisfying unary preservation*

$$\forall h : \mathsf{BHist},\ \mathsf{UnaryHistory}(h) \Rightarrow \mathsf{UnaryHistory}(i(h)),$$

the two-sided inverse-field laws under MonoidHistoryClassifier(UnaryHistory) *are equivalent to singleton-unit collapse:*

$$\begin{gathered}(\forall h : \mathsf{BHist},\ \mathsf{UnaryHistory}(h) \Rightarrow \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(h, i(h)), \mathsf{e})) \\ \wedge \\ (\forall h : \mathsf{BHist},\ \mathsf{UnaryHistory}(h) \Rightarrow \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(i(h), h), \mathsf{e}))\end{gathered} \iff \forall h : \mathsf{BHist},\ \mathsf{Unary}$$

The ten-field fit is: traditional target exact obstruction to a full unary append group; BEDC source UnaryHistory*,* append*, and* MonoidHistoryClassifier*; carrier* UnaryHistory*; classifier* MonoidHistoryClassifier(UnaryHist *stability from unit-product factor exactness and unary preservation; ledger the inverse candidate; core theorem this block; exactness the displayed iff; downstream consumer* $\mathsf{Group}^{\uparrow}$ *and* $\mathsf{QuotientGroup}^{\uparrow}$*; status* ProofTarget*.*

Proof. For the forward direction, assume the displayed conjunction of inverse-field laws and fix a unary history h. The right-inverse conjunct gives $\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(h, i(h)), \mathsf{e})$.

Apply Definition 41.165 to this classifier. The forward direction decomposes it into the two factor classifiers, and the left factor is exactly the displayed singleton-unit conclusion for h.

For the reverse direction, assume singleton-unit collapse and fix a unary history h. The collapse hypothesis gives $\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(h, \mathsf{e})$. Unary preservation gives $\mathsf{UnaryHistory}(i(h))$, and applying the same collapse hypothesis to $i(h)$ gives $\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(i(h), \mathsf{e})$.

Apply the reverse direction of Definition 41.165 to these two factor classifiers. This produces the right inverse-field classifier for $\mathsf{append}(h, i(h))$.

The left inverse-field classifier is obtained from the same two factor classifiers in the opposite order. Applying the reverse direction of Definition 41.165 to the pair $i(h)$, h classifies $\mathsf{append}(i(h), h)$ as e, completing the two-sided inverse-field laws. □

Lean4 ✓ `BEDC.Derived.MonoidUp.MonoidHistoryClassifier unary append inverse field singleton collapse iff`
Lean4 ✓ `BEDC.Derived.GroupUp.unary append inverse field singleton collapse iff`
Lean4 ✓ `BEDC.Derived.GroupUp.unary append inverse field iff singleton collapse`

Theorem 41.172 (Unary append singleton collapse obstruction)**.** *The full unary-history append classifier cannot classify every unary history as the singleton unit:*

$$(\forall h : \mathsf{BHist},\ \mathsf{UnaryHistory}(h) \Rightarrow \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(h, \mathsf{e})) \Rightarrow \mathsf{False}.$$

The ten-field fit is: traditional target obstruction to collapsing the full unary append carrier to the unit; BEDC source UnaryHistory*; carrier* UnaryHistory*; classifier* MonoidHistoryClassifier(UnaryHistory)*; stability from the concrete classifier fields; ledger the visible unary endpoint* E1(e)*; exactness the contradiction; downstream consumer the inverse-field obstruction; status* ProofTarget*.*

Proof. Assume the displayed singleton-unit collapse. The concrete history $\mathsf{E1}(\mathsf{e})$ is unary, so the collapse hypothesis classifies

$$\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{E1}(\mathsf{e}), \mathsf{e}).$$

Unfolding the classifier exposes the internal witness $\mathsf{E1}(\mathsf{e})\mathsf{hsamee}$, contradicting the BEDC history no-confusion theorem. □

Lean4 ✓ `BEDC.Derived.MonoidUp.MonoidHistoryClassifier unary append singleton collapse obstruction`

Theorem 41.173 (Full unary append right-inverse obstruction)**.** *For every operation* $\mathsf{inv} : \mathsf{BHist} \to \mathsf{BHist}$*, if the full unary-history append carrier carries the right-inverse law*

$$\forall h : \mathsf{BHist},\ \mathsf{UnaryHistory}(h) \Rightarrow \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(h, \mathsf{inv}(h)), \mathsf{e}),$$

then False*.*

The ten-field fit is: traditional target obstruction to a right-inverse field on the full unary append monoid; BEDC source UnaryHistory*,* append*, and* MonoidHistoryClassifier(UnaryHistory)*; carrier full unary histories; classifier* MonoidHistoryClassifier(UnaryHistory)*; stability from unit-product factor exactness; ledger the proposed inverse operation and the visible unary endpoint* E1(e)*; core theorem this block; exactness impossibility of the displayed right-inverse law; downstream consumer the concrete* $\mathsf{Group}^{\uparrow}$ *carrier boundary; status* ProofTarget*.*

Proof. Instantiate the displayed right-inverse law at the concrete unary history $\mathsf{E1}(\mathsf{e})$. Unit-product factor exactness reads the resulting classifier for $\mathsf{append}(\mathsf{E1}(\mathsf{e}), \mathsf{inv}(\mathsf{E1}(\mathsf{e})))$ back to a classifier of the visible left factor with e. Unfolding the monoid classifier exposes an internal sameness witness $\mathsf{E1}(\mathsf{e})\mathsf{hsamee}$, contradicting BEDC history no-confusion. □

Lean4 ✓ `BEDC.Derived.MonoidUp.unary append monoid right inverse law absurd`

Theorem 41.174 (Full unary append left-inverse obstruction)**.** *For every operation* $\mathsf{inv} : \mathsf{BHist} \to \mathsf{BHist}$*, if the full unary-history append carrier carries the left-inverse field*

$$\begin{aligned}\forall h : \mathsf{BHist},\ \mathsf{UnaryHistory}(h) \Rightarrow\\ \mathsf{UnaryHistory}(\mathsf{inv}(h)) \wedge\\ \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{append}(\mathsf{inv}(h), h), \mathsf{e}),\end{aligned}$$

then False*.*

The ten-field fit is: traditional target obstruction to the full unary append group; BEDC source $\mathsf{UnaryHistory}$*,* append*, and* $\mathsf{MonoidHistoryClassifier}$*; carrier full unary histories; classifier* $\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})$*; stability from unit-product factor exactness and singleton collapse; ledger the proposed left inverse operation; core theorem this block; exactness impossibility of the left-inverse field; downstream consumer the concrete* $\mathsf{Group}^{\uparrow}$ *carrier choice and* $\mathsf{QuotientGroup}^{\uparrow}$*; status* $\mathsf{ProofTarget}$*.*

Proof. Assume such an operation inv and its displayed left-inverse field. The left-inverse half of Definition 41.171 applies to the classifier component of that field and gives singleton-unit collapse:

$$\forall h : \mathsf{BHist},\ \mathsf{UnaryHistory}(h) \Rightarrow \mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(h, \mathsf{e}).$$

Instantiate the collapse at $h = \mathsf{E1}(\mathsf{e})$, using that $\mathsf{E1}(\mathsf{e})$ is a concrete unary history. This gives

$$\mathsf{MonoidHistoryClassifier}(\mathsf{UnaryHistory})(\mathsf{E1}(\mathsf{e}), \mathsf{e}).$$

The extra $\mathsf{UnaryHistory}(\mathsf{inv}(h))$ component supplied by the displayed field is retained by the ledger but is not needed for the contradiction.

Unfold the classifier from Definition 40.2. The displayed classifier contains the internal history-sameness witness $\mathsf{E1}(\mathsf{e})\mathsf{hsamee}$. This contradicts Definition 20.6, because an $\mathsf{E1}$-history and e have different outer constructors. Hence the left-inverse field yields False. □

Lean4 ✓ `BEDC.Derived.GroupUp.unary append left inverse field obstruction`

41.22 Terminal continuation boundary

Definition 41.175 (Group terminal continuation boundary)**.** *The terminal continuation boundary for the concrete singleton* $\mathsf{Group}^{\uparrow}$ *instance is the* BHist *surface with carrier* A_{e}*, classifier* R_{e}*, multiplication* $\mathsf{mul}(h, k) = \mathsf{append}(h, k)$*, unit* $e = \mathsf{e}$*, and inverse* $\mathsf{inv}(h) = \mathsf{e}$*. Its continuation row is read only through* $\mathsf{Cont}(P, Q, S)$ *together with the terminal collapse* $R_{\mathsf{e}}(P, Q) \iff A_{\mathsf{e}}(S)$ *supplied by Definition 41.90.*

Theorem 41.176 (Group terminal continuation boundary laws)**.** *On the boundary of Definition 41.175, the following laws are available to* $\mathsf{Group}^{\uparrow}$ *consumers:*

1. *A_{e} is inhabited and closed under* append.
2. *$e = \mathsf{e}$ is a left and right unit for* append *on A_{e}.*
3. *$\mathsf{inv}(h) = \mathsf{e}$ is closed on A_{e} and supplies both inverse classifier rows against e.*
4. *R_{e} is stable under* hsame *transport and under continuation readback through* Cont.

The ledger rows are exactly the singleton carrier, terminal classifier, continuation witness, append multiplication, empty unit, and constant inverse rows already present in the concrete singleton $\mathsf{Group}^{\uparrow}$ *instance.*

Proof. The carrier, unit, inverse, associativity, multiplication-congruence, and classifier-stability rows are the concrete rows of Definition 41.5.

Continuation readback is supplied by Definition 41.90: under a witness $\mathsf{Cont}(P, Q, S)$, the input classifier $R_{\mathsf{e}}(P, Q)$, the result classifiers, and the result carrier $A_{\mathsf{e}}(S)$ are the same terminal condition.

For append products against the unit, apply the product-unit rows such as Definition 41.91 and Definition 41.137. They reduce each displayed continuation product-unit classifier to the carrier facts on the visible endpoints, so no operation outside the boundary is needed. □

Theorem 41.177 (Group terminal continuation consumer surface)**.** *Every downstream use of this concrete* $\mathsf{Group}^{\uparrow}$ *boundary may read only the following public surface:* BHist*, the carrier A_{e}, the classifier R_{e},* Cont *and* append *as the multiplication boundary, $e = \mathsf{e}$, the constant inverse* $\mathsf{inv}(h) = \mathsf{e}$, hsame *transport, and the ledger rows cited in Definition 41.176. It does not expose non-singleton group carriers, subgroup lattices, quotient groups, or host inverse objects.*

Proof. The definition of the boundary lists exactly the exported objects. The algebraic rows of Definition 41.176 are all derived from the singleton carrier, terminal classifier, append, continuation, empty unit, constant inverse, and hsame transport.

Any consumer statement that asks for a product, unit, inverse, or continuation row can therefore be discharged by one of those ledger rows. A non-singleton carrier, subgroup lattice, quotient group, or host inverse object is not among the exported objects and is not used by the cited rows, so it has no readable role on this boundary. □

Theorem 41.178 (Group terminal continuation inverse obstruction)**.** *On the boundary of Definition 41.175, every accepted inverse read of a carried history h is classified by R_{e} against* e*. Thus a consumer row requiring an inverse endpoint outside the singleton carrier A_{e} is outside the exported* $\mathsf{Group}^{\uparrow}$ *boundary.*

Proof. The boundary definition fixes the inverse operation to the constant row $\mathsf{inv}(h) = \mathsf{e}$. By Definition 41.176, this row is closed on A_{e} and supplies both inverse classifier rows against the unit $e = \mathsf{e}$.

Continuation readback does not add another inverse endpoint. The terminal collapse theorem Definition 41.90 identifies the readback classifier with the singleton carrier condition, so every accepted continuation read remains a read against e.

Finally apply Definition 41.177. The exported surface lists the constant inverse and explicitly excludes host inverse objects. Therefore any consumer row whose inverse endpoint is not the singleton row e asks for data that the boundary does not export. □

41.23 Finite-history group-law witness

Definition 41.179 (Group finite-history law witness)**.** *The concrete finite-history law witness for* $\mathsf{Group}^{\uparrow}$ *is the singleton terminal continuation packet*

$$G_{\mathsf{e}} = (A_{\mathsf{e}}, R_{\mathsf{e}}, O_{\mathsf{e}}, e_{\mathsf{e}}, I_{\mathsf{e}}, T_{\mathsf{e}}, P_{\mathsf{e}}, N_{\mathsf{e}})$$

with the following displayed rows:

1. $A_{\mathsf{e}}(h) := \mathsf{hsame}(h, \mathsf{e})$ *is the carried finite-history endpoint.*
2. $R_{\mathsf{e}}(h, k) := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h, k)$ *is the restricted classifier.*
3. O_{e} *is the operation row*

$$O_{\mathsf{e}}(h, k, s) := \mathsf{Cont}(h, k, s) \wedge A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge A_{\mathsf{e}}(s).$$

4. $e_{\mathsf{e}} := \mathsf{e}$ *is the identity row.*
5. $I_{\mathsf{e}}(h) := \mathsf{e}$ *is the available inverse boundary inside the singleton carrier, and any requested inverse endpoint outside* A_{e} *is an obstruction row rather than exported inverse data.*
6. T_{e} *records componentwise* hsame *transport and displayed* Cont *replay for* $A_{\mathsf{e}}, R_{\mathsf{e}}, O_{\mathsf{e}}, e_{\mathsf{e}}, I_{\mathsf{e}}$.
7. P_{e} *records provenance from the singleton empty-history instance and terminal continuation boundary.*
8. N_{e} *is the local* $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ *row.*

Theorem 41.180 (Group finite-history continuation law witness)**.** *Every law read from the packet* G_{e} *is witnessed by the displayed* Cont *route rather than by an abstract multiplication symbol. In particular, if* $A_{\mathsf{e}}(h)$*,* $A_{\mathsf{e}}(k)$*, and* $\mathsf{Cont}(h, k, s)$*, then the operation row exposes* $A_{\mathsf{e}}(s)$*; the identity reads are the two continuation unit rows at* e*; and the inverse reads are the constant boundary* $I_{\mathsf{e}}(h) = \mathsf{e}$ *together with the obstruction against non-singleton inverse endpoints.*

Proof. Project the witness of Definition 41.179. Its carrier, classifier, identity, and inverse rows are exactly the singleton endpoint rows of Definition 41.24 and Definition 41.175.

For the operation row, use the terminal continuation collapse of Definition 41.90. Under the displayed route $\mathsf{Cont}(h, k, s)$, the input classifier and the result carrier are the same terminal condition, so an operation read exposes $A_{\mathsf{e}}(s)$ only through the continuation ledger.

For the identity rows, use Definition 41.176. The left and right unit laws are the continuation unit rows specialized to $e_{\mathsf{e}} = \mathsf{e}$; they do not require an external operation table.

For the inverse boundary, apply Definition 41.178. The available inverse is the displayed constant endpoint e, while any inverse endpoint outside the singleton carrier is outside the exported $\mathsf{Group}^{\uparrow}$ surface. Thus the packet supplies a concrete finite-history group-law witness over the terminal continuation route. □

Theorem 41.181 (Group finite-history NameCert surface)**.** *The rows* $A_{\mathsf{e}}, R_{\mathsf{e}}, O_{\mathsf{e}}, e_{\mathsf{e}}, I_{\mathsf{e}}, T_{\mathsf{e}}, P_{\mathsf{e}}, N_{\mathsf{e}}$ *form a concrete* $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ *surface for the singleton finite-history law witness. A consumer may inspect carrier membership, classifier transport, continuation operation, identity, available inverse boundary, provenance, and local naming; it receives no non-singleton carrier, subgroup lattice, quotient group, arbitrary homomorphism, or host inverse object.*

Proof. Use Definition 41.180 for the operation, identity, and inverse rows. It routes each law through the displayed Cont ledger and the terminal singleton carrier.

Use Definition 41.177 for the public boundary. That theorem lists exactly the exported finite-history objects: BHist, A_{e}, R_{e}, Cont, append, e, the constant inverse row, hsame transport, and the local ledger rows.

The provenance and naming coordinates $P_{\mathsf{e}}, N_{\mathsf{e}}$ therefore source and name only the displayed singleton packet. Since the excluded algebraic objects are absent from the carrier and from the continuation boundary, the listed rows exhaust this concrete $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ surface. □

41.24 Singleton contextual exact visibility

Theorem 41.182 (Group singleton two-sided contextual continuation product-unit exact visibility)**.** *For histories $L_0, R_0, L_1, R_1, P, Q, S, T, r : \mathsf{BHist}$, if $A_{\mathsf{e}}(L_0)$, $A_{\mathsf{e}}(R_0)$, $A_{\mathsf{e}}(L_1)$, $A_{\mathsf{e}}(R_1)$, and $\mathsf{Cont}(P, Q, S)$, then*

$$R_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(L_0, \mathsf{append}(S, T)), L_1), \mathsf{append}(\mathsf{append}(R_0, \mathsf{e}), R_1))$$
$$\Longleftrightarrow$$
$$(A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q) \wedge A_{\mathsf{e}}(T)) \wedge (\mathsf{Cont}(P, Q, \mathsf{E0}(r)) \Rightarrow \mathsf{False}) \wedge (\mathsf{Cont}(P, Q, \mathsf{E1}(r)) \Rightarrow \mathsf{False}).$$

The ten-field fit is: traditional target terminal-group contextual product-unit exact visibility; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ over BHist plus Cont and visible continuation endpoints; carrier A_{e}; classifier R_{e}; stability from contextual product-unit coverage and visible continuation exclusion; ledger the two context pairs, continuation witness, suffix factor, and endpoint seed r; core theorem list Definition 41.135 and Definition 41.136; exactness the displayed iff package; downstream consumer concrete $\mathsf{Group}^{\uparrow}$ visibility classification; and status $\mathsf{ProofTarget}$.

Proof. For the forward direction, assume the displayed contextual classifier. Apply Definition 41.135 to the four context carrier witnesses and $\mathsf{Cont}(P, Q, S)$. Its forward direction gives the carrier triple $A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q) \wedge A_{\mathsf{e}}(T)$.

Apply Definition 41.136 to the same context data, the same continuation witness, and the displayed classifier. This supplies the two visible endpoint exclusions for $\mathsf{E0}(r)$ and $\mathsf{E1}(r)$. Conjoining the carrier triple with these two exclusions gives the right-hand package.

For the reverse direction, assume the right-hand package. Its first component is the carrier triple $A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q) \wedge A_{\mathsf{e}}(T)$. Apply the reverse direction of Definition 41.135 with the four context carrier witnesses and $\mathsf{Cont}(P, Q, S)$ to reconstruct the displayed contextual classifier.

The two exclusion clauses remain part of the assumed package. They are not needed for the classifier reconstruction, but their presence is exactly what makes the right-hand side an exact visible-classification package rather than only the carrier coverage statement. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonClassifier two sided contextual continuation product unit exact visibility iff`

41.25 Singleton two-conjugator orbit coverage

Theorem 41.183 (Group singleton two-conjugator orbit coverage)**.** *For histories $s, t, x, y : \mathsf{BHist}$ in the concrete singleton history group, define*

$$\mathsf{Conj}_u(z) := \mathsf{mul}(\mathsf{mul}(u, z), \mathsf{inv}(u)).$$

If $A_{\mathsf{e}}(s)$ and $A_{\mathsf{e}}(t)$, then

$$\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_t(y) \iff A_{\mathsf{e}}(x) \wedge A_{\mathsf{e}}(y).$$

The ten-field fit is: traditional target terminal two-conjugator orbit coverage; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* A_{e}*; classifier the terminal normalizer orbit relation; stability from action carrier coverage plus total orbit coverage; ledger the two conjugating endpoints and two acted endpoints; core theorem list Definition 41.147 and Definition 41.151; exactness the displayed iff; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$*; status* $\mathsf{ProofTarget}$.

Proof. Use Definition 41.147 with s and x, and again with t and y. In the singleton carrier, the action carrier coverage identifies $A_{\mathsf{e}}(\mathsf{Conj}_s(x))$ with $A_{\mathsf{e}}(x)$ and $A_{\mathsf{e}}(\mathsf{Conj}_t(y))$ with $A_{\mathsf{e}}(y)$.

Apply Definition 41.151 to the pair $(\mathsf{Conj}_s(x), \mathsf{Conj}_t(y))$. It converts the orbit statement into the endpoint carrier conjunction

$$A_{\mathsf{e}}(\mathsf{Conj}_s(x)) \wedge A_{\mathsf{e}}(\mathsf{Conj}_t(y)).$$

Substitute the two carrier identifications from the action coverage step. After reassociating the conjunction, the right-hand side is exactly $A_{\mathsf{e}}(x) \wedge A_{\mathsf{e}}(y)$. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonNormalizerOrbit two conjugator coverage iff`

Theorem 41.184 (Group singleton two-conjugator orbit classifier)**.** *For histories $s, t, x, y : \mathsf{BHist}$ in the concrete singleton history group, write*

$$\mathsf{Conj}_u(z) := \mathsf{mul}(\mathsf{mul}(u, z), \mathsf{inv}(u)).$$

If $A_{\mathsf{e}}(s)$ and $A_{\mathsf{e}}(t)$, then

$$\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_t(y) \iff R_{\mathsf{e}}(x, y).$$

The ten-field fit is: traditional target terminal two-conjugator orbit classifier; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$*; carrier* A_{e}*; classifier* R_{e}*; stability from normalizer action coverage and terminal classifier packaging; ledger the two conjugators and endpoint witnesses; exactness the displayed iff; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$*; status* $\mathsf{ProofTarget}$.

Proof. Apply Definition 41.183 under the two displayed conjugator carrier witnesses. This rewrites the normalizer orbit relation between the acted endpoints as the endpoint carrier condition

$$A_{\mathsf{e}}(x) \wedge A_{\mathsf{e}}(y).$$

Apply the first row of Definition 41.88 to the same endpoint pair. It identifies $R_{\mathsf{e}}(x, y)$ with $A_{\mathsf{e}}(x) \wedge A_{\mathsf{e}}(y)$.

Composing the first equivalence with the reverse direction of the second gives exactly

$$\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_t(y) \iff R_{\mathsf{e}}(x, y).$$

□

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonNormalizerOrbit conjugator pair classifier iff`
Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonNormalizerOrbit two conjugator classifier iff`

Theorem 41.185 (Group singleton normalizer orbit action chain)**.** *For histories $s, x, y, z : \mathsf{BHist}$ carried by A_{e} in the concrete singleton history group, write*

$$\mathsf{Conj}_s(w) := \mathsf{mul}(\mathsf{mul}(s, w), \mathsf{inv}(s)).$$

If $A_{\mathsf{e}}(s)$, $A_{\mathsf{e}}(x)$, $A_{\mathsf{e}}(y)$, $A_{\mathsf{e}}(z)$, $x \sim_{N_{\mathsf{e}}} y$, and $y \sim_{N_{\mathsf{e}}} z$, then

$$\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_s(y) \wedge \mathsf{Conj}_s(y) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_s(z) \wedge \mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_s(z).$$

The ten-field fit is: traditional target action congruence on an orbit relation; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$*; carrier A_{e}; classifier the normalizer orbit relation exact against R_{e}; stability from the normalizer action certificate, orbit action invariance, and orbit equivalence; ledger the conjugator and two orbit witnesses; core theorem this block; exactness the displayed chain preservation; standard bridge terminal group action on its one orbit; status* ProofTarget*.*

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonNormalizerOrbit action chain`

Proof. First apply Definition 41.147 to the three pairs (s, x), (s, y), and (s, z). These instances carry $\mathsf{Conj}_s(x)$, $\mathsf{Conj}_s(y)$, and $\mathsf{Conj}_s(z)$ inside A_{e}.

Next apply Definition 41.157 to the input edge $x \sim_{N_{\mathsf{e}}} y$. Apply the same theorem to the input edge $y \sim_{N_{\mathsf{e}}} z$. This gives the two acted orbit edges

$$\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_s(y) \quad \text{and} \quad \mathsf{Conj}_s(y) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_s(z).$$

Finally use the transitivity row of Definition 41.154 on the three acted endpoints. The carrier rows supplied by the action certificate and the two acted orbit edges compose to $\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_s(z)$, and the three orbit relations form the displayed conjunction. □

Theorem 41.186 (Group singleton normalizer orbit action path iff)**.** *For histories $s, x, y, z : \mathsf{BHist}$ carried by A_{e} in the concrete singleton history group, write*

$$\mathsf{Conj}_s(w) := \mathsf{mul}(\mathsf{mul}(s, w), \mathsf{inv}(s)).$$

If $A_{\mathsf{e}}(s)$, $A_{\mathsf{e}}(x)$, $A_{\mathsf{e}}(y)$, and $A_{\mathsf{e}}(z)$, then the two-edge normalizer orbit path is reflected exactly by the terminal action:

$$(\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_s(y) \wedge \mathsf{Conj}_s(y) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_s(z)) \Longleftrightarrow (x \sim_{N_{\mathsf{e}}} y \wedge y \sim_{N_{\mathsf{e}}} z).$$

The transitive edge is reflected exactly as well:

$$\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_s(z) \Longleftrightarrow x \sim_{N_{\mathsf{e}}} z.$$

The ten-field fit is: traditional target terminal action path exactness; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$*; carrier A_{e}; classifier $\sim_{N_{\mathsf{e}}}$; stability from action identity iff, action invariance, and orbit equivalence; ledger the conjugator plus the two source orbit witnesses; core theorem this block; exactness the two displayed iff clauses; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$ *action-path classifier; status* ProofTarget*.*

Proof. First apply Definition 41.147 to the three pairs (s, x), (s, y), and (s, z). This supplies the carrier rows for $\mathsf{Conj}_s(x)$, $\mathsf{Conj}_s(y)$, and $\mathsf{Conj}_s(z)$.

For the forward direction of the two-edge path equivalence, assume the two acted orbit edges. Apply Definition 41.164 to $\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_s(y)$, with the carrier row for $\mathsf{Conj}_s(y)$ supplied by the action certificate, to replace the acted left endpoint by x.

Use the symmetry row of Definition 41.154 to turn this edge around. The same identity iff, now with source endpoint y and target endpoint x, replaces $\mathsf{Conj}_s(y)$ by y; symmetry turns the result back to $x \sim_{N_\mathsf{e}} y$.

The second acted edge is handled in the same way. First replace the acted left endpoint $\mathsf{Conj}_s(y)$ by y, then use orbit symmetry, the identity iff for z, and symmetry again. This gives $y \sim_{N_\mathsf{e}} z$.

For the reverse direction of the two-edge path equivalence, assume $x \sim_{N_\mathsf{e}} y$ and $y \sim_{N_\mathsf{e}} z$. Apply Definition 41.157 to each source edge. The two outputs are exactly

$$\mathsf{Conj}_s(x) \sim_{N_\mathsf{e}} \mathsf{Conj}_s(y) \quad \text{and} \quad \mathsf{Conj}_s(y) \sim_{N_\mathsf{e}} \mathsf{Conj}_s(z).$$

The transitivity row of Definition 41.154 also composes these acted edges to the acted transitive edge.

For the forward direction of the transitive-edge equivalence, assume $\mathsf{Conj}_s(x) \sim_{N_\mathsf{e}} \mathsf{Conj}_s(z)$. The action identity iff replaces the acted left endpoint by x, again using the carrier row for $\mathsf{Conj}_s(z)$, and gives $x \sim_{N_\mathsf{e}} \mathsf{Conj}_s(z)$.

Apply the symmetry row, the identity-iff row for z with target x, and symmetry once more to replace the remaining acted endpoint by z. The result is $x \sim_{N_\mathsf{e}} z$.

For the reverse direction of the transitive-edge equivalence, assume $x \sim_{N_\mathsf{e}} z$. Apply Definition 41.157 directly to this source edge. It gives $\mathsf{Conj}_s(x) \sim_{N_\mathsf{e}} \mathsf{Conj}_s(z)$, which is the acted transitive edge. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonNormalizerOrbit action path iff`

Theorem 41.187 (Group singleton normalizer orbit action conjugator independence)**.** *For histories $s, t, x, y, z : \mathsf{BHist}$ carried by A_e in the concrete singleton history group, write*

$$\mathsf{Conj}_u(w) := \mathsf{mul}(\mathsf{mul}(u, w), \mathsf{inv}(u)).$$

If $A_\mathsf{e}(s)$, $A_\mathsf{e}(t)$, $A_\mathsf{e}(x)$, $A_\mathsf{e}(y)$, and $A_\mathsf{e}(z)$, then the terminal two-edge normalizer action path is independent of the carried conjugator:

$$(\mathsf{Conj}_s(x) \sim_{N_\mathsf{e}} \mathsf{Conj}_s(y) \wedge \mathsf{Conj}_s(y) \sim_{N_\mathsf{e}} \mathsf{Conj}_s(z)) \iff (\mathsf{Conj}_t(x) \sim_{N_\mathsf{e}} \mathsf{Conj}_t(y) \wedge \mathsf{Conj}_t(y) \sim_{N_\mathsf{e}} \mathsf{Conj}_t(z)).$$

The induced transitive edge is independent of the carried conjugator as well:

$$\mathsf{Conj}_s(x) \sim_{N_\mathsf{e}} \mathsf{Conj}_s(z) \iff \mathsf{Conj}_t(x) \sim_{N_\mathsf{e}} \mathsf{Conj}_t(z).$$

The ten-field fit is: traditional target conjugator-independent terminal action paths; BEDC source concrete singleton $\mathsf{Group}^\uparrow$*; carrier A_e; classifier $\sim_{N_\mathsf{e}}$; stability from Definition 41.186; ledger the two conjugators and the two-edge source path; core theorem this block; exactness the displayed iff clauses; downstream consumer* $\mathsf{QuotientGroup}^\uparrow$ *action-path classifier; status* $\mathsf{ProofTarget}$.

Proof. Apply Definition 41.186 with conjugator s. Its first iff identifies the s-acted two-edge path with the source path $x \sim_{N_\mathsf{e}} y \wedge y \sim_{N_\mathsf{e}} z$, and its second iff identifies the s-acted transitive edge with the source edge $x \sim_{N_\mathsf{e}} z$.

Apply the same theorem with conjugator t. Its two iff clauses identify the t-acted two-edge path and the t-acted transitive edge with the same source path and source edge.

Compose the two iff chains through those shared source classifiers. The two-edge chain gives the displayed path equivalence, and the transitive-edge chain gives the displayed endpoint equivalence. □

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingletonNormalizerOrbit action conjugator independence`

Theorem 41.188 (Group singleton two-conjugator orbit path classifier)**.** *For histories* s, t, u, x, y, z : BHist *in the concrete singleton history group, write*

$$\mathsf{Conj}_q(r) := \mathsf{mul}(\mathsf{mul}(q, r), \mathsf{inv}(q)).$$

If $A_{\mathsf{e}}(s)$*,* $A_{\mathsf{e}}(t)$*, and* $A_{\mathsf{e}}(u)$*, then the two-edge acted normalizer path with independent conjugators is classified exactly by the two terminal classifier edges:*

$$(\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_t(y) \wedge \mathsf{Conj}_t(y) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_u(z)) \iff (R_{\mathsf{e}}(x, y) \wedge R_{\mathsf{e}}(y, z)).$$

When either side of this equivalence is available, the transitive acted edge also holds:

$$\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_u(z).$$

The ten-field fit is: traditional target terminal mixed-conjugator orbit-path exactness; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$*; carrier* A_{e}*; classifier the normalizer orbit relation exact against* R_{e}*; stability from two-conjugator orbit classification and orbit transitivity; ledger the three conjugators and two endpoint classifier witnesses; core theorem this block; exactness the displayed iff plus transitive edge; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$*; status* $\mathsf{ProofTarget}$*.*

Proof. For the forward direction of the path equivalence, assume the two acted orbit edges. Apply Definition 41.184 to the (s, t, x, y) edge, using the carrier witnesses for s and t, to obtain $R_{\mathsf{e}}(x, y)$.

Apply the same classifier to the (t, u, y, z) edge, using the carrier witnesses for t and u, to obtain $R_{\mathsf{e}}(y, z)$. These two outputs are exactly the right-hand side of the displayed equivalence.

For the reverse direction, assume $R_{\mathsf{e}}(x, y)$ and $R_{\mathsf{e}}(y, z)$. Apply Definition 41.184 in the reverse direction to (s, t, x, y), and then to (t, u, y, z). The two results are precisely the acted path edges.

It remains to produce the transitive acted edge. If the acted path side is available, use the transitivity row of Definition 41.154 on the three acted endpoints. The two input edges compose to $\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_u(z)$.

If the terminal classifier side is available instead, first use the reverse direction of the two equivalence steps above to obtain the two acted path edges. The same transitivity row of Definition 41.154 then composes them to the displayed transitive acted edge. □

Theorem 41.189 (Group singleton three-conjugator orbit path compression)**.** *For histories* s, t, u, v, x, y, z, w : BHist *in the concrete singleton history group, write*

$$\mathsf{Conj}_a(b) := \mathsf{mul}(\mathsf{mul}(a, b), \mathsf{inv}(a)).$$

If $A_{\mathsf{e}}(s)$*,* $A_{\mathsf{e}}(t)$*,* $A_{\mathsf{e}}(u)$*, and* $A_{\mathsf{e}}(v)$*, then the three acted normalizer edges with independent conjugators are classified exactly by the three terminal classifier edges:*

$$(\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_t(y) \wedge \mathsf{Conj}_t(y) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_u(z) \wedge \mathsf{Conj}_u(z) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_v(w)) \iff (R_{\mathsf{e}}(x, y) \wedge R_{\mathsf{e}}(y, z) \wedge R_{\mathsf{e}}(z, w)).$$

Moreover, any such path compresses to the endpoint acted edge and the terminal classifier edge:

$$(\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_t(y) \wedge \mathsf{Conj}_t(y) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_u(z) \wedge \mathsf{Conj}_u(z) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_v(w)) \implies (\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_v(w) \wedge R_{\mathsf{e}}(x, w)).$$

The ten-field fit is: traditional target terminal three-step conjugation orbit path; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* A_{e}*; classifier* R_{e} *and the normalizer orbit relation; stability from adjacent two-conjugator orbit classification plus terminal classifier transitivity; ledger the four conjugators and three path edges; core theorem this block; exactness the displayed iff plus compressed endpoint edge; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$ *path compression; status* $\mathsf{ProofTarget}$*.*

Proof. For the forward direction of the path equivalence, assume the three acted orbit edges. Apply Definition 41.184 to the (s, t, x, y) edge, then to the (t, u, y, z) edge, and then to the (u, v, z, w) edge. The carrier witnesses for the corresponding conjugator pairs supply $R_{\mathsf{e}}(x, y)$, $R_{\mathsf{e}}(y, z)$, and $R_{\mathsf{e}}(z, w)$.

For the reverse direction, assume $R_{\mathsf{e}}(x, y)$, $R_{\mathsf{e}}(y, z)$, and $R_{\mathsf{e}}(z, w)$. Apply the same two-conjugator orbit classifier in the reverse direction to (s, t, x, y), (t, u, y, z), and (u, v, z, w). These are precisely the three acted normalizer edges.

It remains to compress a given acted path. Use Definition 41.188 on the first two acted edges to obtain $R_{\mathsf{e}}(x, z)$, and use the adjacent classifier on the third edge to obtain $R_{\mathsf{e}}(z, w)$.

Apply the terminal transitivity supplied by Definition 41.88. The classifier row reads the two terminal edges as singleton carrier rows for x, z, and w, and repacks them as $R_{\mathsf{e}}(x, w)$.

Finally apply Definition 41.184 in the reverse direction to (s, v, x, w) with the carrier witnesses for s and v. This gives $\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_v(w)$, and together with $R_{\mathsf{e}}(x, w)$ it is the displayed compressed conclusion. □

Theorem 41.190 (Group singleton four-conjugator orbit path compression)**.** *For histories $s, t, u, v, r, x, y, z, w, q :$ BHist in the concrete singleton history group, write*

$$\mathsf{Conj}_a(b) := \mathsf{mul}(\mathsf{mul}(a, b), \mathsf{inv}(a)).$$

If $A_{\mathsf{e}}(s)$, $A_{\mathsf{e}}(t)$, $A_{\mathsf{e}}(u)$, $A_{\mathsf{e}}(v)$, and $A_{\mathsf{e}}(r)$, then the four acted normalizer edges with independent conjugators are classified exactly by the four terminal classifier edges:

$$(\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_t(y) \wedge \mathsf{Conj}_t(y) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_u(z) \wedge \mathsf{Conj}_u(z) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_v(w) \wedge \mathsf{Conj}_v(w) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_r(q)) \iff (R_{\mathsf{e}}(x, y) \wedge R$$

Moreover, any such path compresses to the endpoint acted edge and the terminal classifier edge:

$$(\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_t(y) \wedge \mathsf{Conj}_t(y) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_u(z) \wedge \mathsf{Conj}_u(z) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_v(w) \wedge \mathsf{Conj}_v(w) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_r(q)) \implies (\mathsf{Conj}_s(x) \sim$$

The ten-field fit is: traditional target terminal four-step conjugation orbit path; BEDC source concrete singleton $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier A_{e}; classifiers R_{e} and the normalizer orbit relation; stability from the existing two- and three-conjugator classifiers plus terminal classifier transitivity; ledger the five conjugators and four path edges; core theorem this block; exactness the displayed iff plus compressed endpoint edge; downstream consumer* $\mathsf{QuotientGroup}^{\uparrow}$ *path compression; status* $\mathsf{ProofTarget}$*.*

Proof. For the forward direction of the path equivalence, assume the four acted orbit edges. Apply Definition 41.189 to the first three acted edges, using the carrier witnesses for s, t, u, and v. This gives $R_{\mathsf{e}}(x, y)$, $R_{\mathsf{e}}(y, z)$, $R_{\mathsf{e}}(z, w)$, and the compressed terminal edge $R_{\mathsf{e}}(x, w)$.

Apply Definition 41.184 to the fourth acted edge (v, r, w, q), using the carrier witnesses for v and r, to obtain $R_{\mathsf{e}}(w, q)$. Together with the three terminal edges already obtained, this is the right-hand side of the displayed equivalence.

For the reverse direction, assume $R_{\mathsf{e}}(x, y)$, $R_{\mathsf{e}}(y, z)$, $R_{\mathsf{e}}(z, w)$, and $R_{\mathsf{e}}(w, q)$. Apply Definition 41.184 in the reverse direction to (s, t, x, y), (t, u, y, z), (u, v, z, w), and (v, r, w, q). These are precisely the four acted normalizer edges.

It remains to compress a given acted path. The first paragraph supplies $R_{\mathsf{e}}(x, w)$ from the first three acted edges, and the fourth acted edge supplies $R_{\mathsf{e}}(w, q)$ by the two-conjugator classifier.

Apply the terminal transitivity supplied by Definition 41.88. The two terminal edges $R_{\mathsf{e}}(x, w)$ and $R_{\mathsf{e}}(w, q)$ compose to $R_{\mathsf{e}}(x, q)$.

Finally apply Definition 41.184 in the reverse direction to (s, r, x, q) with the carrier witnesses for s and r. This gives $\mathsf{Conj}_s(x) \sim_{N_{\mathsf{e}}} \mathsf{Conj}_r(q)$, and together with $R_{\mathsf{e}}(x, q)$ it is the displayed compressed conclusion. □

41.26 Center abelian normal package

This package consumes the subgroup carrier and normal-subgroup rows of chapter 80 and the commutative operation surface of chapter 42. The center package is not a free-standing $\mathsf{Group}^{\uparrow}$ row: its normality component is a $\mathsf{Subgroup}^{\uparrow}$-style carrier obligation, and its abelian component is the $\mathsf{AbGroup}^{\uparrow}$ commutativity row restricted to the center carrier.

Theorem 41.191 (Group center abelian normal subgroup package)**.** *For a BEDC history-level group operation* mul *over* BHist *with associativity, left and right identity laws for e, multiplication congruence, and two-sided inverse laws, the center carrier* $\mathsf{Z}(G)$ *of Definition 41.106 has all normal-subgroup rows of Definition 41.107 and also the abelian row*

$$\forall x, y : \mathsf{BHist}, \quad \mathsf{Z}(G)(x) \Rightarrow \mathsf{Z}(G)(y) \Rightarrow \mathsf{hsame}(\mathsf{mul}(x, y), \mathsf{mul}(y, x)).$$

The ten-field fit is: traditional target center as an abelian normal subgroup; BEDC source $\mathsf{Group}^{\uparrow}$ *over* BHist*; carrier* $\mathsf{Z}(G)$*; classifier* hsame*; stability from the checked normal-subgroup theorem plus center commutativity at each test history; ledger central endpoints* x, y *and the two product orders* $\mathsf{mul}(x, y)$ *and* $\mathsf{mul}(y, x)$*; core theorem list Definition 41.107 and Definition 41.106; exactness the displayed commutativity row together with the normal-subgroup rows; standard bridge ordinary group center; status* ProofTarget*.*

Proof. The normal-subgroup part is exactly Definition 41.107. It supplies the unit, product, inverse, classifier transport, conjugation, and centralizer-normalizer inclusion rows for the carrier $\mathsf{Z}(G)$.

For the abelian row, fix $x, y : \mathsf{BHist}$ and assume $\mathsf{Z}(G)(x)$ and $\mathsf{Z}(G)(y)$. Unfold Definition 41.106. The witness $\mathsf{Z}(G)(x)$ is a universal commutativity certificate against every test history, so applying it to the test history y gives

$$\mathsf{hsame}(\mathsf{mul}(x, y), \mathsf{mul}(y, x)).$$

The carrier witness for y is part of the abelian normal-subgroup package interface, and it is used by the product and inverse rows inherited from Definition 41.107. The displayed pointwise commutativity itself only needs the center witness for x at the chosen test history y. □

Theorem 41.192 (Group singleton public operation surface)**.** *For the concrete singleton history group instance of Definition 41.3, the public carrier is* A_{e}*, multiplication is* append*, unit is* e*, inverse is the constant operation* $h \mapsto \mathsf{e}$*, and the public classifier is* R_{e}*. This surface is packaged by the following four clauses.*

1. *Multiplication, unit, and inverse endpoints remain in the carrier* A_{e} *and are classified by* R_{e} *whenever their inputs are carried.*
2. *Every public expression generated from carried endpoints by multiplication, unit, and inverse has readback classified with* e*.*
3. *Left and right singleton append contexts preserve and reflect the public classifier by the existing append-context cancellation rows.*
4. *The source, pattern, and ledger predicates expose only singleton carrier witnesses and append or inverse expression provenance. Hence the public surface admits no endpoint outside* A_{e}*.*

↪ variant BEDC.Derived.GroupUp.GroupUp StdBridge

Proof. The carrier, classifier, multiplication, unit, and inverse are exactly the objects named in Definition 41.3. Theorem 41.4 packages them as the singleton-history SemanticNameCert for $\mathsf{Group}^{\uparrow}$, so the source and classifier fields of the public surface are not additional data.

For the endpoint clauses, use Theorem 41.5 together with the singleton endpoint readback row recorded by BEDC.Derived.GroupUp.GroupSingletonHistory_laws. Multiplication closure carries $\mathsf{append}(h, k)$ from carried inputs; the unit row carries e; inverse closure carries the constant inverse endpoint e; and the readback row classifies each generated endpoint against e by R_{e}.

Public expressions are built by induction on the expression tree. The base case is a carried endpoint, whose singleton witness reads back to e. The unit and inverse cases use the constant endpoint e. The multiplication case applies multiplication closure to the two inducted carrier witnesses and then composes their readback classifiers through the append law supplied by the same checked singleton group rows.

For contextual visibility, apply Theorem 41.7 to the left append contexts. The right-context row in the same singleton block gives the corresponding suffix form, and the two-sided row combines the two orientations. Thus wrapping a public endpoint by singleton append contexts neither creates nor hides a classifier witness.

Finally, the no-hidden-leakage clause is just the exactness content of the singleton certificate. Source predicates expose carrier witnesses $A_{\mathsf{e}}(h)$, pattern predicates expose only the empty endpoint and append shape used by the generated expression, and ledger rows record the concrete append or constant-inverse provenance. Any admitted public endpoint therefore carries a witness to A_{e}, so no endpoint outside the singleton carrier is admitted by this operation surface. □

Definition 41.193 (Group singleton terminal standard reference)**.** *Let T_G^* denote the host-facing terminal group reference with one element $\star_G$. Its equality relation is terminal equality, so every pair of host-facing elements is identified. Its multiplication row is $\star_G \cdot \star_G = \star_G$, its unit row names $\star_G$ as the unit, and its inverse row sends $\star_G$ to $\star_G$.*

The finite theorem-preservation list for T_G^* contains exactly the terminal rows matched to the public singleton surface: multiplication closure, left and right unit, associativity, two-sided inverse, and append-context cancellation. The BEDC counterparts are the clauses of Definition 41.192 backed by BEDC.Derived.GroupUp.GroupSingletonHistory_laws.

Theorem 41.194 (Group singleton terminal standard bridge)**.** *The public singleton $\mathsf{Group}^{\uparrow}$ surface of Definition 41.192 supplies a paper-level $\mathsf{StandardBridge}(\mathsf{Group}^{\uparrow}, T_G^*)$. The encode field sends the unique point $\star_G$ of T_G^* to the BEDC endpoint e. The decode field sends every endpoint carried by A_{e} to $\star_G$. The decode-encode round trip is terminal equality in T_G^*, and the encode-decode round trip is the classifier witness $R_{\mathsf{e}}(h, \mathsf{e})$ for each carried endpoint $h : A_{\mathsf{e}}$. The operation translation is the same carrier A_{e}, classifier R_{e}, multiplication* append*, unit* e*, and constant inverse from the public surface. The theorem-preservation and no-host-leak fields are the finite list and public-object restriction of Definition 41.193.*

Lean4 ✓ `BEDC.Derived.GroupUp.GroupSingleton terminal standard bridge`

Proof. We check the six fields of section 9204.1. The encode field is the constant map from T_G^* to the empty BEDC endpoint e. The endpoint e is public by Definition 41.192, so the map lands in the carrier A_{e} and respects the classifier R_{e}.

The decode field sends every carried BEDC endpoint to the unique element of T_G^*. Since the host carrier has one element, classifier-respect is terminal equality: any two decoded carried endpoints are the same host point $\star_G$.

For the decode-encode round trip, start with the unique host element, encode it as e, and decode back to $\star_G$. This is exactly terminal equality in T^*_G.

For the encode-decode round trip, start with a carried endpoint $h : A_{\mathsf{e}}$. Decoding gives $\star_G$, and encoding returns e. The singleton carrier readback clause of Definition 41.192 supplies $R_{\mathsf{e}}(h, \mathsf{e})$, which is exactly the BEDC classifier witness required for this round trip.

The operation translation keeps the BEDC public data fixed: carrier A_{e}, classifier R_{e}, multiplication append, unit e, and constant inverse. The finite theorem-preservation field is the list in Definition 41.193. Each row is read through Definition 41.192 and the checked law package BEDC.Derived.GroupUp.GroupSingletonHistory_laws. No other host group theorem is claimed by this list.

Finally, the no-host-leak field follows from the public-object inventory in Definition 41.192. The bridge uses the host terminal reference only to name the unique decode value and terminal equality. The BEDC-facing surface remains BHist, A_{e}, R_{e}, append, e, and the constant inverse, so no host primitive enters the exported $\mathsf{Group}^{\uparrow}$ object. □

Theorem 41.195 (GroupUp checked standard bridge)**.** *The singleton terminal bridge of Definition 41.194, the public singleton operation surface of Definition 41.192, and the center package of Definition 41.191 are the paper-side bridge surface whose checked Lean target is* BEDC.Derived.GroupUp.GroupUp_S *In particular, the* $\mathsf{Group}^{\uparrow}$ *bridge status is grounded by the checked standard bridge theorem, not merely by the lower-level singleton law package.*

Proof. Definition 41.194 identifies the public singleton history carrier with the terminal standard group reference. Its encode, decode, round-trip, operation-translation, theorem-preservation, and no-host-leak clauses are exactly the paper bridge fields.

Definition 41.192 supplies the public BEDC operation surface: the carrier A_{e}, classifier R_{e}, append product, empty unit, constant inverse, product closure and classification, inverse closure and classification, and append-context cancellation iff. The center package records the abelian normal center rows over the same history-level operation surface.

The checked Lean theorem BEDC.Derived.GroupUp.GroupUp_StdBridge packages these clauses as a single standard bridge. Its payload includes the $\mathsf{SemanticNameCert}$ for $\mathsf{Group}^{\uparrow}$, the empty-carrier endpoint, the product and inverse closure with their classifiers, and the append-context cancellation iff. Therefore the closure block may use the standard bridge theorem itself as the formal grounding target. □

Theorem 41.196 (Group monoid semigroup sibling route)**.** *Every public* $\mathsf{Group}^{\uparrow}$ *operation read consumes the* $\mathsf{Semigroup}^{\uparrow}$ *associativity surface of chapter 79 and the* $\mathsf{Monoid}^{\uparrow}$ *unit surface of chapter 40 before inverse rows are meaningful. The* $\mathsf{Group}^{\uparrow}$ *packet adds inverse rows to those sibling obligations; it does not replace associativity, left unit, right unit, carrier transport, continuation, provenance, or local naming rows supplied by the semigroup and monoid certificates.*

Proof. First read the binary operation as a semigroup operation. The associativity surface supplied by chapter 79 is the row that makes iterated products stable under the public carrier classifier.

Next read the same operation through chapter 40. The left and right unit rows make the empty-history unit available before inverse equations can be interpreted as group equations.

Finally attach the $\mathsf{Group}^{\uparrow}$ inverse rows. They certify left and right inverse behavior inside the already associated and unital operation surface, while the structural transport, continuation, provenance, and local naming rows remain the sibling rows already consumed by the route. □

Theorem 41.197 (Group algebra hierarchy public exit package)**.** *The public* $\mathsf{Group}^{\uparrow}$ *package exported by this chapter is exactly the union of two concrete* BHist *surfaces: the singleton empty-history carrier of Definition 41.27 and the finite-word carrier of Definition 41.34. Its multiplication, unit, inverse, product closure, inverse boundary, and* NameCert *packaging are the rows supplied by Definition 41.32, Definition 41.35, Definition 41.37, and Definition 41.38, with the monoid dependency read through Definition 41.28. No host group carrier, quotient group object, external operation table, or ambient equality is exported by the public package.*

Lean4 ✓ `BEDC.Derived.GroupUp.GroupUp StdBridge`

Proof. Project the singleton rows first. The carrier is A_{e}, the classifier is R_{e}, multiplication is append, the unit is e, and inverse is the constant empty endpoint of Definition 41.27. Definition 41.32 supplies the corresponding operation, unit, associativity, congruence, inverse, and classifier rows, while Definition 41.28 records that the append ledger is the consumed $\mathsf{Monoid}^{\uparrow}$ dependency.

Next project the finite-word rows. The carrier and classifier are the finite word spine and componentwise singleton classifier of Definition 41.34. Product closure is Definition 41.35, the reversal inverse boundary is Definition 41.37, and the resulting finite $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ packet is Definition 41.38.

These two projections exhaust the public exit: singleton endpoints and finite singleton words, both with displayed BHist ledgers. Since every operation row is read from those carriers and their classifiers, the exported package contains no additional host group carrier, quotient object, operation table, or ambient equality relation. □

Closure status for $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$**.**

Constructive story: The group surface is anchored by the singleton history group, where every carried endpoint is classified with e, multiplication is continuation append, the unit is e, and inverse is the constant return to e; on top of the general history-level laws, the center package then carves out those endpoints that commute with every test history. The singleton carrier accepts exactly histories in the empty endpoint class, and the center carrier accepts exactly displayed central endpoints for an ambient history-level group operation; endpoints lacking the singleton witness or the universal commutativity row are outside the corresponding surface. Classification is always the displayed hsame relation restricted to the admitted carrier, with multiplication congruence, inverse congruence, and centralizer transport moving representatives, rather than an imported group equality. The source specification is the monoid-plus-inverse history surface together with the singleton and center witnesses, the pattern specification records append multiplication, empty unit, constant inverse, inverse laws, commutator collapse, conjugation invariance, normalizer action, center normality, and the abelian center row, and the ledger keeps generated expressions, central endpoints, conjugation paths, and the two product orders visible. The five name-certificate obligations are witnessed by e and the inherited hsame equivalence: carrier nonemptiness comes from the empty endpoint or a displayed central endpoint, classifier reflexivity, symmetry, and transitivity are componentwise, and multiplication, inverse, conjugation, and centralizer transport keep classified representatives inside the carrier. A history h lies in the signature gap of a $\mathsf{Group}^{\uparrow}$ token p when the source-domain accepts the singleton or center package row, the signature relation pairs it with an answer group endpoint and evidence ledger, and the token-introduction relation names that answer as p; unfolded, h is the encoded singleton endpoint or central endpoint together with its operation and commutativity ledger. The checked bridge reads the singleton surface as the terminal group and the center package as the ordinary abelian normal center rows, while the chapter registers the construction under $\mathsf{Group}^{\uparrow}$ without introducing non-singleton group carriers, subgroup lattices, quotient groups, arbitrary homomorphisms, or primitive inverse objects.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$, maturePackageClosed)

Scope closed: Definition 41.197, Definition 41.191, Definition 41.192, Definition 41.194, and Definition 41.195 form the mature singleton package: public carrier A_{e}, classifier R_{e}, append multiplication, empty unit, constant inverse, finite-word closure, generated-expression readback, no-hidden-leakage, the center abelian normal package, and the terminal paper bridge to T_G^*.

Chapter 42

A Concrete Naming Certificate for $\mathsf{AbGroup}^{\uparrow}$

The abelian group interface $\mathsf{AbGroup}^{\uparrow}$ extends chapter 41 with the commutativity field $a \cdot b = b \cdot a$ under the carrier's classifier. It is the abelian specialization of the group certificate. The concrete $\mathsf{AbGroup}^{\uparrow}$ instances in this chapter are the singleton BHist instances below, while the signed-unary $\mathsf{Int}^{\uparrow}$ carrier contributes the fixed-sign commutativity boundary recorded in Definition 42.4.

42.1 Carrier definition

Definition 42.1 (AbGroup carrier)**.** *Use a group setup extended with commutativity of the binary operation.*

Lean4 ✓ `BEDC.Derived.AbGroupUp.AbGroupTasteGate single carrier alignment`

42.2 Concrete singleton history abelian group instance

Definition 42.2 (Concrete singleton history abelian group instance)**.** *Let A_{e} and R_{e} be the singleton carrier and classifier from Definition 41.3. Define the operations by*

$$\mathsf{mul}(h, k) := \mathsf{append}(h, k), \qquad \mathsf{inv}(h) := \mathsf{e}, \qquad e := \mathsf{e}.$$

The resulting tuple $(A_{\mathsf{e}}, R_{\mathsf{e}}, \mathsf{mul}, e, \mathsf{inv})$ is the singleton history abelian group instance.

Theorem 42.3 (Concrete singleton history abelian group laws)**.** *The tuple $(A_{\mathsf{e}}, R_{\mathsf{e}}, \mathsf{mul}, e, \mathsf{inv})$ satisfies the concrete group laws of Theorem 41.5 and the abelian commutativity law $R_{\mathsf{e}}(\mathsf{mul}(h, k), \mathsf{mul}(k, h))$ for all histories h, k with $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$.*

Proof. The group fields are exactly the concrete singleton history group laws supplied by Theorem 41.5.

For commutativity, suppose $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$. These singleton carrier witnesses identify both h and k with e under hsame.

The continuation unit laws reduce $\mathsf{append}(h, k)$ and $\mathsf{append}(k, h)$ to the singleton class of e. Symmetry and transitivity of hsame then assemble the endpoint relation $\mathsf{hsame}(\mathsf{mul}(h, k), \mathsf{mul}(k, h))$.

The multiplication-closure clauses from the concrete group laws supply $A_{\mathsf{e}}(\mathsf{mul}(h, k))$ and $A_{\mathsf{e}}(\mathsf{mul}(k, h))$. Together with the endpoint relation, these are exactly the classifier witness $R_{\mathsf{e}}(\mathsf{mul}(h, k), \mathsf{mul}(k, h))$. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.concrete singleton history abgroup laws`

Definition 42.4 (Integer additive AbGroup obligation boundary)**.** *The signed-unary integer carrier supplies the carrier and classifier*

$$\mathsf{IntCarrier}(s,h), \qquad \mathsf{IntClassifierSpec}((s,h),(t,k)).$$

For a fixed sign s, the same-sign append operation row is

$$\mu_s((s,h),(s,k)) = (s, \mathsf{append}(h,k)).$$

The checked commutativity boundary for this row is supplied by Definition 31.27. An AbGroup instance over the signed carrier still requires the remaining certificate rows: zero representative, inverse or negation representative, cross-sign addition, associativity, unit, inverse, and congruence rows over IntClassifierSpec*.*

The ten-field template is: traditional target the integer additive abelian group; BEDC source $\mathsf{Int}^{\uparrow}$ *over signed unary histories; carrier* IntCarrier*; classifier* IntClassifierSpec*; stability obligations the rows just listed; ledger sign and magnitude witnesses plus continuation rows; core theorem list including Definition 31.27; exactness predicate the classifier laws over the signed carrier; standard bridge the integer additive group; and status* ProofTarget*.*

Thus the $\mathsf{AbGroup}^{\uparrow}$ schema is instantiated by this concrete BHist carrier and operation, so later Lean work can formalize BHist-anchored abelian group laws in BEDC.Derived.AbGroupUp rather than another abstract operator schema.

42.3 The certificate

Definition 42.5 (AbGroup source specification)**.** *The source is a certified group carrier plus a commutativity field.*

Definition 42.6 (AbGroup pattern specification)**.** *The pattern is group expression formation under an operation whose operands may be exchanged by certificate law.*

Definition 42.7 (AbGroup classifier specification)**.** *The classifier is the group carrier classifier.*

Definition 42.8 (AbGroup stability certificate)**.** *The stability certificate consists of:*

1. *all group stability fields*
2. *commutativity under classifier*
3. *compatibility of commutativity with inverse and multiplication congruence*

42.4 Concrete singleton empty-history abelian group instance

Definition 42.9 (Concrete singleton empty-history abelian group instance)**.** *The singleton empty-history abelian group instance is the tuple* $(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \mu_{\mathsf{e}}, e_{\mathsf{e}}, \iota_{\mathsf{e}})$ *where*

$$A_{\mathsf{e}}(x) \iff \mathsf{hsame}(x,\mathsf{e}), \qquad \mu_{\mathsf{e}}(x,y) := \mathsf{e}, \qquad e_{\mathsf{e}} := \mathsf{e}, \qquad \iota_{\mathsf{e}}(x) := \mathsf{e}.$$

The classifier $\rho_{\mathsf{e}}(x,y)$ *holds exactly when* $A_{\mathsf{e}}(x)$*,* $A_{\mathsf{e}}(y)$*, and* $\mathsf{hsame}(x,y)$ *all hold. Equip this tuple with the AbGroup commutativity field* $\rho_{\mathsf{e}}(\mu_{\mathsf{e}}(x,y),\mu_{\mathsf{e}}(y,x))$ *and the associated compatibility fields*

for multiplication and inverse transport on the singleton carrier. Its certificate is the ten-field fit with traditional target the one-element abelian group; BEDC source BHist*; carrier* A_{e}*; classifier* ρ_{e} *with the three carrier-aware components above; stability obligations for this classifier together with commutativity; ledger constant-operation provenance; core theorem Theorem 42.10; exactness the singleton endpoint classification* $A_{\mathsf{e}}(x)$*; standard bridge the one-object abelian group; certificate site Definition 42.11; and status* CheckedCert*.*

Theorem 42.10 (Singleton empty-history abelian group laws)**.** *The tuple* $(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \mu_{\mathsf{e}}, e_{\mathsf{e}}, \iota_{\mathsf{e}})$ *satisfies the AbGroup carrier, closure, unit, inverse, associativity, inverse, commutativity, and congruence laws for the singleton carrier* A_{e} *and the carrier-aware classifier* ρ_{e}*.*

Proof. Carrier inhabitance is $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$, hence $A_{\mathsf{e}}(\mathsf{e})$. Every operation in the tuple returns e, so the carrier endpoint required for closure, unit, inverse, associativity, inverse laws, commutativity, and constant-operation congruence is always witnessed by $A_{\mathsf{e}}(\mathsf{e})$.

For equality conclusions whose right endpoint is an original variable, the corresponding carrier witness is supplied by the input hypothesis $A_{\mathsf{e}}(x)$. Together with the defining clause $A_{\mathsf{e}}(x) \iff \mathsf{hsame}(x, \mathsf{e})$, this gives the required hsame component.

It remains to check the classifier components. Since $\mu_{\mathsf{e}}(x, y)$ and $\mu_{\mathsf{e}}(y, x)$ are both definitionally e, commutativity reduces to $\rho_{\mathsf{e}}(\mathsf{e}, \mathsf{e})$. Its three components are $A_{\mathsf{e}}(\mathsf{e})$, $A_{\mathsf{e}}(\mathsf{e})$, and $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$.

The same reduction handles closure, associativity, inverse compatibility, and multiplication congruence: every source product, target product, and inverse is definitionally e. Whenever a law compares e with an original endpoint, the classifier is assembled from $A_{\mathsf{e}}(\mathsf{e})$, the endpoint carrier hypothesis, and the corresponding hsame witness obtained from the singleton carrier definition. □

Theorem 42.11 (Concrete singleton empty-history $\mathsf{AbGroup}^{\uparrow}$ naming certificate)**.** *The tuple* $(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \mu_{\mathsf{e}}, e_{\mathsf{e}}, \iota_{\mathsf{e}})$ *of Definition 42.9 supplies a checked package whose* SemanticNameCert *row is carried by* A_{e} *and* ρ_{e} *and whose singleton operation rows are* $(\mu_{\mathsf{e}}, e_{\mathsf{e}}, \iota_{\mathsf{e}})$*, with source, stability, commutativity, ledger, and exactness rows forming a concrete* NameCert *licensing* $\mathsf{AbGroup}^{\uparrow}$ *over the singleton empty-history carrier* A_{e}*.*

Proof. The source row is BHist restricted by A_{e}, and the pattern row is the constant operation package $(\mu_{\mathsf{e}}, e_{\mathsf{e}}, \iota_{\mathsf{e}})$. The classifier row is the carrier-aware relation ρ_{e} from Definition 42.9.

The carrier, closure, unit, inverse, congruence, and commutativity rows are exactly the singleton empty-history AbGroup law package of Definition 42.10. That theorem also supplies the stability needed for the classifier under the displayed operations, since each operation returns e and all comparisons are repacked through A_{e} and ρ_{e}.

The ledger row is the constant-operation provenance required by Definition 42.31. Exactness is the endpoint classification already exposed by the carrier-aware classifier: a classified endpoint is precisely an endpoint in the singleton empty-history carrier, so the public $\mathsf{AbGroup}^{\uparrow}$ name has no additional hidden carrier cases. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.singleton empty history abgroup laws`

Thus the AbGroup schema is instantiated by this concrete BHist carrier and operations, so Lean formalization can target this BHist-anchored instance rather than only abstract operator fields.

Theorem 42.12 (AbGroup left-right multiplication swap)**.** *For BEDC histories equipped with an associative multiplication, commutativity, and multiplication congruence under* hsame*, the expression* $a \cdot (b \cdot c)$ *is internally the same as* $b \cdot (a \cdot c)$*.*

Proof. Reassociate $a \cdot (b \cdot c)$ to $(a \cdot b) \cdot c$, transport the left factor across commutativity, and reassociate $(b \cdot a) \cdot c$ back to $b \cdot (a \cdot c)$. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup mul left right swap`

Theorem 42.13 (AbGroup middle-four interchange)**.** *For BEDC histories equipped with an associative multiplication, commutativity, and multiplication congruence under* hsame*,*

$$\mathsf{hsame}((a \cdot b) \cdot (c \cdot d), (a \cdot c) \cdot (b \cdot d)).$$

Proof. Reassociate $(a \cdot b) \cdot (c \cdot d)$ to $a \cdot (b \cdot (c \cdot d))$. Apply the abelian left-right swap to the right factor, obtaining $a \cdot (c \cdot (b \cdot d))$, and reassociate back to $(a \cdot c) \cdot (b \cdot d)$. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup mul middle four`

Theorem 42.14 (AbGroup inverse pair multiplication collapse)**.** *For BEDC histories equipped with associative and commutative multiplication, a right identity, multiplication congruence, and right inverses,*

$$\mathsf{hsame}((a \cdot b) \cdot (a^{-1} \cdot b^{-1}), e).$$

Proof. Use middle-four interchange to regroup the expression as

$$(a \cdot a^{-1}) \cdot (b \cdot b^{-1}).$$

The two right-inverse laws collapse the factors to $e \cdot e$, and the right-identity law for e collapses the remaining product to e. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup mul inverse pair collapse`

Theorem 42.15 (AbGroup conjugation collapse)**.** *For BEDC histories equipped with associative and commutative multiplication, a right identity, multiplication congruence, and right inverses, every expression $a \cdot (b \cdot a^{-1})$ is internally the same as b.*

Proof. Use the abelian left-right swap to rewrite $a \cdot (b \cdot a^{-1})$ as $b \cdot (a \cdot a^{-1})$. Collapse $a \cdot a^{-1}$ to the identity by the right-inverse law, then use the right-identity law for b. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup conjugation collapse`

Theorem 42.16 (AbGroup inverse conjugation collapse)**.** *For BEDC histories equipped with associative and commutative multiplication, a right identity, multiplication congruence, and left inverses, every expression $a^{-1} \cdot (b \cdot a)$ is internally the same as b.*

Proof. Use the abelian left-right swap to rewrite $a^{-1} \cdot (b \cdot a)$ as $b \cdot (a^{-1} \cdot a)$. Collapse $a^{-1} \cdot a$ to the identity by the left-inverse law, then use the right-identity law for b. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup inverse conjugation collapse`

Theorem 42.17 (AbGroup centralizer and commutator collapse)**.** *For BEDC histories equipped with the* $\mathsf{Group}^{\uparrow}$ *associativity, unit, multiplication-congruence, and two-sided inverse laws, plus* $\mathsf{AbGroup}^{\uparrow}$ *commutativity under* hsame*, fix a :* BHist*. Let Z_a be the centralizer carrier of Definition 41.84, and let* $\mathsf{comm}(x, a)$ *be the commutator expression from Definition 41.82. Then every x :* BHist *satisfies:*

1. $Z_a(x)$.

2. $\mathsf{comm}(x, a)\mathsf{hsame}e$.

3. $\mathsf{hsame}((a \cdot x) \cdot a^{-1}, x)$.

The ten-field fit is: traditional target abelian groups have total centralizers; BEDC source $\mathsf{AbGroup}^{\uparrow}$ *over* BHist *plus the* $\mathsf{Group}^{\uparrow}$ *centralizer carrier; carrier* Z_a*; classifier* hsame*; stability from commutativity, commutator exactness, and conjugation collapse; ledger fixed element, commuting witness, commutator spine, and inverse witness; core theorem the three displayed clauses backed by Definition 41.84, Definition 41.82, and Definition 42.15; exactness predicate total centralizer iff trivial commutator; standard bridge ordinary abelian centralizer collapse; status* $\mathsf{ProofTarget}$.

Proof. Commutativity supplies the comparison $x \cdot a\mathsf{hsame}a \cdot x$. By the definition of Z_a in Definition 41.84, this is exactly the centralizer clause for the chosen x.

Apply Definition 41.82 to the same ordered pair (x, a). The commuting witness obtained above is transported to the trivial commutator fiber, giving $\mathsf{comm}(x, a)\mathsf{hsame}e$.

Finally apply Definition 42.15 with middle element x. The abelian conjugation spine collapses $(a \cdot x) \cdot a^{-1}$ to x, which gives the inner-conjugation fixed-point clause. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup centralizer commutator collapse`

Theorem 42.18 (AbGroup centralizer normalizer collapse)**.** *For BEDC histories equipped with the* $\mathsf{Group}^{\uparrow}$ *associativity, unit, multiplication-congruence, inverse-congruence, and two-sided inverse laws, plus* $\mathsf{AbGroup}^{\uparrow}$ *commutativity under* hsame*, fix* $a : \mathsf{BHist}$*. Let* Z_a*,* N_a*, and* $\mathsf{Conj}_s(x)$ *be the carriers/action from Definition 41.84 and Definition 41.95. Then every* $s : \mathsf{BHist}$ *satisfies:*

1. $N_a(s)$.

2. For every $x : \mathsf{BHist}$ *with* $Z_a(x)$*,* $Z_a(\mathsf{Conj}_s(x))$.

3. For every $x : \mathsf{BHist}$ *with* $Z_a(x)$*,* $\mathsf{hsame}(\mathsf{Conj}_s(x), x)$.

The ten-field fit is: traditional target abelian groups have total centralizer normalizers acting trivially; BEDC source $\mathsf{AbGroup}^{\uparrow}$ *plus* $\mathsf{Group}^{\uparrow}$ *normalizer carrier; carrier* N_a*; classifier* hsame*; stability from total centralizer, normalizer subgroup inclusion, and abelian conjugation collapse; ledger conjugating element and inverse witness; core theorem list Definition 42.17, Definition 41.98, and Definition 41.101; exactness trivial normalizer action; standard bridge ordinary abelian centralizer normalizer; status* $\mathsf{ProofTarget}$.

Proof. The first row of Definition 42.17 gives totality of Z_a: every history is a centralizer element for the fixed a. Applying this to the conjugating element gives $Z_a(s)$.

The final inclusion row of Definition 41.98 sends this centralizer witness to $N_a(s)$. Equivalently, unfolding Definition 41.95, totality applied to $\mathsf{Conj}_s(x)$ and to $\mathsf{Conj}_{\mathsf{inv}(s)}(x)$ supplies the two preservation clauses.

Now fix $x : \mathsf{BHist}$ with $Z_a(x)$. The carrier row of Definition 41.101, read with the just-built $N_a(s)$, gives $Z_a(\mathsf{Conj}_s(x))$.

Finally apply Definition 42.15 with conjugating element s and middle element x. The abelian conjugation word $\mathsf{Conj}_s(x)$ collapses to x under hsame, so the normalizer action is pointwise trivial on the centralizer carrier. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup centralizer normalizer collapse`

Theorem 42.19 (AbGroup centralizer normalizer orbit collapse)**.** *For a BEDC history-level group operation over* BHist *with the* $\mathsf{Group}^{\uparrow}$ *associativity, unit, multiplication-congruence, inverse-congruence, and two-sided inverse laws, plus* $\mathsf{AbGroup}^{\uparrow}$ *commutativity under* hsame*, fix* $a : \mathsf{BHist}$*.*

Let Z_a, N_a, Conj_s, and $\sim_{N_a}$ be the centralizer, normalizer, action, and orbit relation from Definition 41.84, Definition 41.95, and Definition 41.103. For carried centralizer histories $x, y : \mathsf{BHist}$ with $Z_a(x)$ and $Z_a(y)$,

$$x \sim_{N_a} y \iff \mathsf{hsame}(x, y).$$

The ten-field fit is: traditional target abelian normalizer orbits are singleton classifier fibers; BEDC source $\mathsf{AbGroup}^{\uparrow}$ *plus the* $\mathsf{Group}^{\uparrow}$ *normalizer orbit relation; carrier Z_a; classifier $\sim_{N_a}$; stability from trivial conjugation action and orbit equivalence; ledger conjugator and centralizer endpoint witnesses; core theorem list Definition 42.18, Definition 41.101, and Definition 41.104; exactness predicate orbit iff* hsame*; standard bridge ordinary abelian group normalizer-orbit collapse; status* ProofTarget*.*

Proof. For the forward direction, unpack an orbit witness s for $x \sim_{N_a} y$. The witness provides $N_a(s)$, the endpoint carriers $Z_a(x)$ and $Z_a(y)$, and the comparison $\mathsf{hsame}(\mathsf{Conj}_s(x), y)$.

Apply Definition 42.18 to the same conjugator s and centralizer endpoint x. Its trivial-action row gives $\mathsf{hsame}(\mathsf{Conj}_s(x), x)$. Symmetry and transitivity of hsame combine this with the orbit endpoint comparison, yielding $\mathsf{hsame}(x, y)$.

For the reverse direction, assume $\mathsf{hsame}(x, y)$. The collapse theorem gives $N_a(e)$ for the identity conjugator. The identity-action row of Definition 41.101 gives $\mathsf{hsame}(\mathsf{Conj}_e(x), x)$ on the carried endpoint $Z_a(x)$.

Transitivity of hsame composes the identity-action comparison with the assumed $\mathsf{hsame}(x, y)$. Together with $N_a(e)$ and the endpoint witnesses $Z_a(x)$ and $Z_a(y)$, this packages the orbit witness required by Definition 41.103. The equivalence context of Definition 41.104 records that the resulting classifier is stable on the centralizer carrier. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup centralizer normalizer orbit collapse from empty unit`

Theorem 42.20 (AbGroup total centralizer-normalizer orbit collapse)**.** *For a BEDC history-level group operation over* BHist *with the* $\mathsf{Group}^{\uparrow}$ *associativity, unit, multiplication-congruence, inverse-congruence, and two-sided inverse laws, plus* $\mathsf{AbGroup}^{\uparrow}$ *commutativity under* hsame*, fix $a : \mathsf{BHist}$. Let Z_a, N_a, Conj_s, and $\sim_{N_a}$ be the centralizer, normalizer, action, and orbit relation from Definition 41.84, Definition 41.95, and Definition 41.103. Then for all histories $x, y : \mathsf{BHist}$,*

$$x \sim_{N_a} y \iff \mathsf{hsame}(x, y).$$

The ten-field fit is: traditional target abelian normalizer orbits over the whole carrier; BEDC source $\mathsf{AbGroup}^{\uparrow}$ *plus the* $\mathsf{Group}^{\uparrow}$ *centralizer-normalizer orbit relation; carrier* BHist*; classifier $\sim_{N_a}$ exact against* hsame*; stability from total centralizer and the carried orbit collapse; ledger the two automatically supplied centralizer endpoint witnesses; core theorem list Definition 42.17 and Definition 42.19; exactness total-carrier orbit iff* hsame*; standard bridge ordinary abelian normalizer-orbit collapse; status* ProofTarget*.*

Proof. First obtain centralizer carriedness for the chosen endpoints. The totality row of Definition 42.17, read at the fixed element a, gives $Z_a(x)$ and $Z_a(y)$ for arbitrary $x, y : \mathsf{BHist}$.

For the forward direction, combine the orbit witness $x \sim_{N_a} y$ with these two centralizer endpoint witnesses. Apply Definition 42.19 in its forward direction to conclude $\mathsf{hsame}(x, y)$.

For the reverse direction, combine the assumed $\mathsf{hsame}(x, y)$ with the same two endpoint witnesses. Apply Definition 42.19 in its reverse direction to package the required orbit witness $x \sim_{N_a} y$. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup centralizer normalizer orbit total collapse from empty unit`

Theorem 42.21 (AbGroup total centralizer normalizer orbit fiber determinacy)**.** *For a BEDC history-level group operation over* BHist *with the* $\mathsf{Group}^{\uparrow}$ *associativity, unit, multiplication-congruence, inverse-congruence, and two-sided inverse laws, plus* $\mathsf{AbGroup}^{\uparrow}$ *commutativity under* hsame*, fix* $a : \mathsf{BHist}$*. Let* Z_a*,* N_a*,* Conj_s*, and* $\sim_{N_a}$ *be the centralizer, normalizer, action, and orbit relation from the existing centralizer-normalizer definitions. For all histories* $x, y, z : \mathsf{BHist}$*,*

$$x \sim_{N_a} y \wedge x \sim_{N_a} z \Longrightarrow \mathsf{hsame}(y, z).$$

The ten-field fit is: traditional target abelian normalizer-orbit fiber determinacy over the whole carrier; BEDC source $\mathsf{AbGroup}^{\uparrow}$ *plus the* $\mathsf{Group}^{\uparrow}$ *normalizer orbit relation; carrier* BHist*; classifier* hsame*; stability from total orbit collapse plus symmetry and transitivity of* hsame*; ledger the two normalizer witnesses over one anchor; core theorem list Definition 42.20 and the* hsame *equivalence laws; exactness predicate same-anchor orbit fibers collapse to one classifier class; status* ProofTarget*.*

Proof. Apply Definition 42.20 to the first orbit witness $x \sim_{N_a} y$ to obtain $\mathsf{hsame}(x, y)$. Apply the same collapse theorem to the second orbit witness $x \sim_{N_a} z$ to obtain $\mathsf{hsame}(x, z)$.

The first comparison reverses by symmetry of hsame, giving $\mathsf{hsame}(y, x)$. Transitivity of hsame composes $\mathsf{hsame}(y, x)$ with $\mathsf{hsame}(x, z)$ and yields the required classifier equality $\mathsf{hsame}(y, z)$. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup centralizer normalizer orbit total fiber determinacy from empty unit`

Theorem 42.22 (AbGroup centralizer normalizer orbit fiber determinacy)**.** *For a BEDC history-level group operation over* BHist *with the same* $\mathsf{Group}^{\uparrow}$ *associativity, unit, multiplication-congruence, inverse-congruence, and two-sided inverse laws, plus* $\mathsf{AbGroup}^{\uparrow}$ *commutativity under* hsame*, as in Definition 42.19, fix* $a : \mathsf{BHist}$*. Let* Z_a*,* N_a*,* Conj_s*, and* $\sim_{N_a}$ *be the centralizer, normalizer, action, and orbit relation from the existing centralizer-normalizer definitions. For histories* $x, y, z : \mathsf{BHist}$*,*

$$Z_a(x) \wedge Z_a(y) \wedge Z_a(z) \wedge x \sim_{N_a} y \wedge x \sim_{N_a} z \Longrightarrow \mathsf{hsame}(y, z).$$

The ten-field fit is: traditional target abelian normalizer-orbit fiber determinacy; BEDC source $\mathsf{AbGroup}^{\uparrow}$ *plus the* $\mathsf{Group}^{\uparrow}$ *normalizer orbit relation; carrier* Z_a*; classifier* hsame*; stability from orbit collapse plus symmetry and transitivity of* hsame*; ledger the two normalizer witnesses over one anchor; core theorem list Definition 42.19 and the* hsame *equivalence laws; exactness predicate same-anchor orbit fibers collapse to one classifier class; status* ProofTarget*.*

Proof. Start from the five displayed assumptions. Apply Definition 42.19 to the first orbit witness $x \sim_{N_a} y$, using the carrier facts $Z_a(x)$ and $Z_a(y)$, to obtain $\mathsf{hsame}(x, y)$. Apply the same collapse theorem to the second orbit witness $x \sim_{N_a} z$, using the carrier facts $Z_a(x)$ and $Z_a(z)$, to obtain $\mathsf{hsame}(x, z)$.

The first comparison reverses by symmetry of hsame, giving $\mathsf{hsame}(y, x)$. Transitivity of hsame composes $\mathsf{hsame}(y, x)$ with $\mathsf{hsame}(x, z)$ and yields the required classifier equality $\mathsf{hsame}(y, z)$. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup centralizer normalizer orbit fiber determinacy from empty unit`

Theorem 42.23 (AbGroup inverse preserves multiplication order)**.** *For BEDC histories equipped with group laws, commutative multiplication, and multiplication congruence under* hsame*, the inverse of a product is internally the product of the two inverses in the same order:*

$$\mathsf{hsame}((x \cdot y)^{-1}, x^{-1} \cdot y^{-1}).$$

Proof. The group inverse multiplication theorem identifies $(x \cdot y)^{-1}$ with $y^{-1} \cdot x^{-1}$. Commutativity then exchanges the two inverse factors, yielding $x^{-1} \cdot y^{-1}$. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup inverse mul`

Theorem 42.24 (AbGroup right factor swap)**.** *For BEDC histories equipped with an associative multiplication, commutativity, and multiplication congruence under* hsame*,*

$$\mathsf{hsame}((a \cdot b) \cdot c, (a \cdot c) \cdot b).$$

Proof. Reassociate $(a \cdot b) \cdot c$ to $a \cdot (b \cdot c)$, commute the inner factor $b \cdot c$ to $c \cdot b$ under multiplication congruence, and reassociate back to $(a \cdot c) \cdot b$. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup mul right factor swap`

Theorem 42.25 (AbGroup common left factor collection)**.** *For BEDC histories equipped with an associative multiplication, commutativity, and multiplication congruence under* hsame*,*

$$\mathsf{hsame}((a \cdot b) \cdot (a \cdot c), a \cdot (a \cdot (b \cdot c))).$$

Proof. Reassociate the left side to $a \cdot (b \cdot (a \cdot c))$. Apply the abelian left-right multiplication swap inside the tail to turn $b \cdot (a \cdot c)$ into $a \cdot (b \cdot c)$, and transport that tail equality through left multiplication by a. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup mul common left factor collect`

Theorem 42.26 (AbGroup common right factor collection)**.** *For BEDC histories equipped with an associative multiplication, commutativity, and multiplication congruence under* hsame*,*

$$\mathsf{hsame}((b \cdot a) \cdot (c \cdot a), a \cdot (a \cdot (b \cdot c))).$$

Proof. Commute the exposed right factors to rewrite the left side as $(a \cdot b) \cdot (a \cdot c)$. The common left factor collection theorem then collects the two occurrences of a and leaves the residual factor $b \cdot c$. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup mul common right factor collect`

Theorem 42.27 (AbGroup balanced multiplication cancellation)**.** *For BEDC histories equipped with group laws, commutativity, and multiplication congruence under* hsame*, if* $a \cdot b\mathsf{hsame}c \cdot a$*, then* $b\mathsf{hsame}c$*.*

Proof. Commute the right endpoint $c \cdot a$ to $a \cdot c$. The hypothesis then has the common left factor a on both sides, so group left cancellation removes that factor and yields $b\mathsf{hsame}c$. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup mul balanced cancel`

Theorem 42.28 (AbGroup middle-four double cancellation)**.** *For BEDC histories equipped with group laws, commutativity, and multiplication congruence under* hsame*, if*

$$\mathsf{hsame}((a \cdot b) \cdot (c \cdot d), (a \cdot c) \cdot (u \cdot d)),$$

then $\mathsf{hsame}(b, u)$*.*

Proof. The rule depends on the AbGroup middle-four theorem and on the Group left and right cancellation theorems; it is not merely a renamed form of any one theorem. Apply Theorem 42.13 to the left endpoint of the hypothesis and compose by symmetry and transitivity of hsame. This turns the supplied comparison into

$$\mathsf{hsame}((a \cdot c) \cdot (b \cdot d), (a \cdot c) \cdot (u \cdot d)).$$

Now apply group left cancellation, Theorem 41.66, to the common left factor $a{\cdot}c$. The remaining comparison is

$$\mathsf{hsame}(b \cdot d, u \cdot d).$$

Finally apply group right cancellation, Theorem 41.116, to the common right factor d, yielding $\mathsf{hsame}(b, u)$. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup mul middle four double cancel from empty unit`

Theorem 42.29 (AbGroup transported middle-four double cancellation)**.** *For BEDC histories equipped with group laws, commutativity, and multiplication congruence under* hsame*, if*

$$\mathsf{hsame}((a \cdot b) \cdot (c \cdot d), (a \cdot u) \cdot (c \cdot v))$$

and $\mathsf{hsame}(d, v)$*, then* $\mathsf{hsame}(b, u)$*.*

Proof. Apply Theorem 42.13 to the left endpoint of the supplied comparison, and apply the same theorem to the right endpoint. After symmetry and transitivity of hsame, the comparison has common leading factor $a \cdot c$:

$$\mathsf{hsame}((a \cdot c) \cdot (b \cdot d), (a \cdot c) \cdot (u \cdot v)).$$

Use multiplication congruence with the displayed witness $\mathsf{hsame}(d, v)$, and symmetry when orienting the witness, to transport the trailing factor in the right tail from v to d. This gives

$$\mathsf{hsame}((a \cdot c) \cdot (b \cdot d), (a \cdot c) \cdot (u \cdot d)).$$

Apply Theorem 41.66 to remove the common left factor $a \cdot c$. The remaining comparison is

$$\mathsf{hsame}(b \cdot d, u \cdot d).$$

Finally apply Theorem 41.116 to remove the common right factor d, yielding $\mathsf{hsame}(b, u)$. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup mul middle four transported double cancel from empty unit`

The ten-field fit is: traditional target transported abelian double cancellation; BEDC source $\mathsf{AbGroup}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability obligations middle-four interchange, trailing-factor transport, and group cancellation; ledger the two paired products and the transported trailing witness; core theorem list Theorems 42.13, 41.66, and 41.116; exactness predicate the displayed implication; standard bridge ordinary abelian group cancellation; status ProofTarget.

Theorem 42.30 (Nonempty history append cannot be right-absorbed)**.** *For every BEDC history h and right tail k, neither* $\mathsf{append}(\mathsf{e0}(h), k) = k$ *nor* $\mathsf{append}(\mathsf{e1}(h), k) = k$ *holds.*

Proof. Induct on the right tail k. The empty case is constructor disjointness against e. In the nonempty cases, append exposes the same outer constructor as the tail, so constructor injectivity reduces the claim to the induction hypothesis on the inner tail. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.history append nonempty left ne right`

Definition 42.31 (AbGroup ledger policy)**.** *Record group expression provenance and the commutativity law when used.*

Definition 42.32 ($\mathsf{AbGroup}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{AbGroup}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.AbGroupUp.AbGroupUp StdBridge`

Primitive boundary. $\mathsf{AbGroup}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Proposition 42.33 (AbGroup forgets to Group certificate)**.** *Let M carry an* $\mathsf{AbGroup}^{\uparrow}(M)$ *certificate. If the commutativity field and its compatibility data are omitted, the retained carrier, source, pattern, classifier, stability, and ledger fields form a* $\mathsf{Group}^{\uparrow}(M)$ *certificate. The carrier, multiplication $\cdot$, identity e, inverse operation $^{-1}$, and classifier are unchanged.*

This reduct is a concrete dependency on chapter 41: the AbGroup packet first consumes the GroupUp carrier, classifier, inverse, unit, stability, and ledger rows, then adds the commutativity row.

Proof. By Definition 42.32, the given certificate supplies carrier, source, pattern, classifier, stability, and ledger data for $\mathsf{AbGroup}^{\uparrow}$. The argument keeps the group-shaped fields among these data.

By Definition 42.1, an $\mathsf{AbGroup}^{\uparrow}$ carrier is a group setup together with commutativity of the binary operation. The underlying carrier, classifier, multiplication, identity, and inverse are therefore already the data listed in Definition 41.2.

By Definition 42.5, the source is a certified group carrier plus a commutativity field. Removing the commutativity component leaves the certified group carrier. By Definition 41.52, this is the certified monoid carrier plus inverse data required for the group source. By Definition 42.7, the classifier is the group carrier classifier, so it is exactly the classifier of Definition 41.54.

By Definition 42.6, the abelian group pattern is group expression formation with the added permission to exchange operands by the commutativity law. Omitting only that exchange permission leaves the group expression formation of Definition 41.53.

By Definition 42.8, the stability certificate contains all group stability fields, commutativity under classifier, and compatibility of commutativity with inverse and multiplication congruence. The first component is precisely the list of group stability fields in Definition 41.55; the latter components are not obligations for $\mathsf{Group}^{\uparrow}$. The remaining ledger is the group expression provenance of Definition 41.120, matching the group part of Definition 42.31.

The retained carrier, source, pattern, classifier, stability, and ledger data are exactly the obligations named in Definition 41.121. Since each retained operation and the classifier are copied from the original $\mathsf{AbGroup}^{\uparrow}(M)$ certificate, the resulting $\mathsf{Group}^{\uparrow}(M)$ source package has the same carrier operation, identity, inverse, and classifier. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.AbgroupForgetsGroupCertificate`

Theorem 42.34 (AbGroup additive negation involutivity)**.** *Let M carry an $\mathsf{AbGroup}^{\uparrow}(M)$ certificate. Write its carrier predicate as A, its classifier as $\sim_M$, its addition as $+$, its zero as 0, and its additive inverse operation as $-$. For every carried element x with $A(x)$,*

$$-(-x) \sim_M x.$$

The ten-field fit is: traditional target additive abelian groups have involutive negation; BEDC source $\mathsf{AbGroup}^{\uparrow}(M)$; carrier A; classifier $\sim_M$; stability obligations inverse closure, additive associativity, left and right zero laws, addition congruence, and the left inverse row inherited from the group reduct; ledger the two applications of the additive inverse operation; core theorem list Definition 42.33 and Definition 41.57; exactness predicate double negation returns to the input classifier fiber; standard bridge ordinary abelian-group negation; status ProofTarget.

Proof. Apply Definition 42.33 to the given $\mathsf{AbGroup}^{\uparrow}(M)$ certificate. The retained $\mathsf{Group}^{\uparrow}(M)$ package has the same carrier A, classifier $\sim_M$, additive operation $+$, zero 0, and inverse operation $-$.

Read Definition 41.57 in this retained group package, with multiplication written as $+$, identity written as 0, and inverse written as $-$. The inherited associativity, left and right zero laws, addition congruence, and left inverse row give the internal comparison

$$-(-x)\mathsf{hsame}x.$$

The inverse-closure row of the retained group package sends $A(x)$ first to $A(-x)$ and then to $A(-(-x))$. Repack these endpoint carrier witnesses with the displayed internal comparison through the unchanged carrier classifier $\sim_M$. The result is exactly $-(-x) \sim_M x$. □

Theorem 42.35 (AbGroup Group reduct commutativity centralizes commutators)**.** *Let M carry an $\mathsf{AbGroup}^{\uparrow}(M)$ certificate. In the retained $\mathsf{Group}^{\uparrow}(M)$ reduct of Definition 42.33, every displayed commutator route built from carried elements x and y is classified with the identity fiber. The route is read by first using the abelian commutativity row to identify $x + y$ with $y + x$, and then using the retained unit, inverse, associativity, and congruence rows of the group reduct to reduce the commutator word to the identity classifier. This conclusion introduces no quotient group, subgroup primitive, centralizer carrier, normalizer carrier, or host equality outside the omitted commutativity field and the retained $\mathsf{Group}^{\uparrow}(M)$ rows.*

Proof. Apply Definition 42.33. The reduct keeps the carrier, classifier, addition, zero, inverse operation, unit laws, inverse rows, associativity, and congruence data of the original $\mathsf{AbGroup}^{\uparrow}(M)$ packet.

Now read the commutativity field before the inverse rows are used. The abelian row identifies the two displayed products $x + y$ and $y + x$ in the carrier classifier, so the middle comparison in a displayed commutator word is already available on the BEDC surface.

Use the retained group rows to cancel the resulting adjacent inverse and unit terms. Associativity and congruence only reassociate and transport the displayed word; the inverse and unit rows collapse it to the identity classifier fiber.

All data used in the argument are rows of the original certificate or rows kept by the forgetful reduct. Hence the conclusion records a commutator collapse inside the retained group surface without adding a quotient construction, subgroup object, centralizer primitive, normalizer primitive, or host equality. □

Theorem 42.36 (AbGroup singleton terminal standard bridge)**.** *The public singleton empty-history* $\mathsf{AbGroup}^{\uparrow}$ *surface supplies a paper-level* $\mathsf{StandardBridge}(\mathsf{AbGroup}^{\uparrow}, T_A^*)$ *to the ordinary one-element abelian group. The encode field sends the unique host point of* T_A^* *to* e*. The decode field sends every carried endpoint in* A_{e} *to the host point. The decode-encode round trip is terminal equality, and the encode-decode round trip is the classifier witness* $\rho_{\mathsf{e}}(h, \mathsf{e})$ *for each carried endpoint* $h : A_{\mathsf{e}}$*. Operation translation reads the abelian operation as both addition and multiplication notation, sends zero and unit to* e*, and reads inverse and additive negation as the constant operation. The theorem-preservation field covers the carrier, closure, unit, inverse, associativity, commutativity, and double-negation rows. The no-host-leak field states that the exported BEDC surface remains* BHist*,* A_{e}*,* ρ_{e}*,* e*, and the displayed operations.*

Proof. We check the six fields of section 9204.1. The encode field is the constant map from the unique point of T_A^* to the empty BEDC endpoint e. The carrier and classifier laws of Definition 42.11 make this endpoint a public carried point of A_{e} and place it in the classifier fiber ρ_{e}.

The decode field sends every carried endpoint of A_{e} to the unique host point. Hence classifier-respect on decoded values and the decode-encode round trip are both terminal equality in the ordinary one-element abelian group.

For encode-decode, begin with a carried endpoint $h : A_{\mathsf{e}}$. Decoding gives the unique host point, and encoding returns e. The singleton classifier row of Definition 42.11 supplies exactly the witness $\rho_{\mathsf{e}}(h, \mathsf{e})$ required by the BEDC side of the round trip.

The operation translation keeps the BEDC public data fixed. The same singleton operation is read as addition and as multiplication notation, the zero and unit are both e, and inverse and additive negation are the constant operation. The group-shaped rows are inherited through Definition 42.33; the abelian commutativity row comes from Definition 42.11; and the double-negation row is Definition 42.34 read on the singleton surface.

Finally, no host primitive is exported. The host model supplies only the unique decode value and terminal equality used by the bridge argument. The BEDC-facing surface remains BHist, A_{e}, ρ_{e}, e, and the displayed constant operations. □

Lean4 ✓ `BEDC.Derived.AbGroupUp.abgroup singleton terminal standard bridge`

42.5 Public closure record

Theorem 42.37 (AbGroup public operation surface)**.** *The public* $\mathsf{AbGroup}^{\uparrow}$ *surface consists of the singleton empty-history carrier, classifier, and operation tuple from Definition 42.9; the checked singleton laws from Definition 42.10; the forgetful group reduct from Definition 42.33; the abelian normalizer-orbit collapse package from Definition 42.20; and the middle-four and double-cancellation normal-form rows represented by Definition 42.13, Definition 42.28, and Definition 42.29. No host equality, quotient carrier, subgroup primitive, or module equivalence is part of this surface.*

Proof. The carrier, classifier, multiplication, identity, inverse, and commutativity data are the singleton empty-history data of Definition 42.9. The checked laws in Definition 42.10 make those operations the displayed $\mathsf{AbGroup}^{\uparrow}$ singleton package.

The group-facing part is obtained by applying Definition 42.33; it keeps the same carrier, classifier, multiplication, identity, and inverse while only dropping the commutativity field as an extra obligation. The abelian operation consequences then remain visible through Definition 42.20 and the normal-form rows Definition 42.13, Definition 42.28, and Definition 42.29.

These cited rows exhaust the public operation surface asserted here: they expose the singleton carrier and laws, the group reduct, the centralizer and normalizer collapse, and the middle-four

cancellation forms. Since none of the cited rows constructs host equality, a quotient carrier, a subgroup primitive, or a module equivalence, the public surface adds none of those structures. □

Lemma 42.38 (AbGroup forgetful bridge determinacy)**.** *For the public singleton empty-history* $\mathsf{AbGroup}^{\uparrow}$ *surface, the bridge-facing* $\mathsf{Group}^{\uparrow}$ *consumer obtained by applying Definition 42.33 to Definition 42.36 is determined by the following finite local rows: the retained carrier, source, pattern, classifier, stability, and ledger fields of the forgetful reduct; the unchanged multiplication, unit, inverse, and classifier; the constant encode row to* e*; the terminal decode row; the terminal decode-encode row; the encode-decode readback row* $\rho_{\mathsf{e}}(h, \mathsf{e})$ *for each carried endpoint* $h : A_{\mathsf{e}}$*; the operation-translation row reading the same displayed operation as the group multiplication,* e *as the unit, and the constant operation as inverse; the theorem-preservation rows for carrier, closure, unit, inverse, and associativity; and the no-host-leak surface* BHist*,* A_{e}*,* ρ_{e}*,* e*, and the displayed operations. Hence every displayed route, transport, readback, or handoff available to such a consumer factors through these rows, and no unlisted bridge coordinate, host equality, quotient carrier, subgroup primitive, module equivalence, or commutativity obligation is available as part of the* $\mathsf{Group}^{\uparrow}$ *handoff.*

Proof. Apply Definition 42.33. It says exactly that the $\mathsf{Group}^{\uparrow}$ certificate retained from an $\mathsf{AbGroup}^{\uparrow}$ certificate consists of the carrier, source, pattern, classifier, stability, and ledger fields, with the carrier, multiplication, identity, inverse operation, and classifier copied unchanged. Thus any consumer-facing route or transport that asks only for a group certificate must enter through one of these retained rows.

Now read Definition 42.36 through this reduct. Its encode row is the constant map from the unique terminal host point to e, and its decode row sends every carried endpoint of A_{e} to the unique host point. The two round-trip rows are therefore fixed: decode-encode is terminal equality, while encode-decode is precisely the displayed classifier witness $\rho_{\mathsf{e}}(h, \mathsf{e})$. Consequently every readback available to the consumer factors through this single carrier-and-classifier surface.

The same theorem fixes the operation handoff. After forgetting commutativity, the group-facing operation translation is the unchanged displayed operation, with e as unit and the constant operation as inverse. The theorem- preservation rows needed by a $\mathsf{Group}^{\uparrow}$ consumer are exactly the carrier, closure, unit, inverse, and associativity rows, all of which are retained by the forgetful certificate. The abelian commutativity and double-negation rows remain rows of the abelian bridge, but they are not additional coordinates of the $\mathsf{Group}^{\uparrow}$ handoff.

Finally, the no-host-leak clause of Definition 42.36 restricts the exported BEDC-facing surface to BHist, A_{e}, ρ_{e}, e, and the displayed operations. Since Definition 42.33 adds no field while forming the reduct, a consumer has no route to any bridge coordinate outside the listed rows. The omitted commutativity obligation, commutativity-compatibility data, host equality, quotient carrier, subgroup primitive, and module equivalence are therefore unavailable as $\mathsf{Group}^{\uparrow}$ bridge handoff data. □

Definition 42.39 (AbGroup unary scalar multiple and torsion)**.** *Fix an* $\mathsf{AbGroup}^{\uparrow}$ *source package with carrier predicate* A*, classifier* ρ*, binary operation* $+$*, identity* 0*, and inverse operation* $-$*. Write* $x \sim_A y$ *for* $\rho(x, y)$*. The unary scalar-action relation* $\mathsf{AbNatAct}_A(n, a, x)$ *is the closed relation generated by:*

1. *for every carried* a*,* $\mathsf{AbNatAct}_A(\mathsf{e}, a, 0)$*;*
2. *if* $\mathsf{AbNatAct}_A(n, a, x)$ *and* $A(a)$*, then* $\mathsf{AbNatAct}_A(\mathsf{E1}(n), a, x + a)$*.*

Endpoint replacement in this relation is read through the classifier $\sim_A$ *using the congruence fields of the carrier.*

A unary history n is positive, written $\mathsf{PosUnary}(n)$*, when*

$$\mathsf{PosUnary}(n) \iff \exists t\,(\mathsf{Unary}(t) \wedge n = \mathsf{E1}(t)).$$

A multiplier n annihilates a carried element a, written $\mathsf{Ann}_A(n, a)$*, when $A(a)$ and there is an endpoint x such that* $\mathsf{AbNatAct}_A(n, a, x)$ *and $x \sim_A 0$. The torsion predicate is*

$$\mathsf{Tor}_A(a) \iff \exists n\,(\mathsf{PosUnary}(n) \wedge \mathsf{Ann}_A(n, a)).$$

Lemma 42.40 (Positive unary common product)**.** *If m and n are positive unary histories, then there is a positive unary history p and unary quotient witnesses q_m, q_n such that*

$$\mathsf{NatMul}(m, q_m, p) \qquad \textit{and} \qquad \mathsf{NatMul}(n, q_n, p).$$

Proof. Use totality of unary multiplication from Definition 64.17 to form a row product p_{mn} with $\mathsf{NatMul}(m, n, p_{mn})$ and a column product p_{nm} with $\mathsf{NatMul}(n, m, p_{nm})$.

A rectangular induction over the unary generators for m and n identifies these two products. The empty row and empty column are the zero constructor of Definition 64.1. In the one-step cases, unary continuation associativity and unary continuation commutativity from Definition 29.6 and Definition 9200.14 move the last row past the last column. Functionality of NatMul from Definition 64.12 then classifies the two resulting endpoints, giving $p_{mn}\mathsf{hsame}p_{nm}$.

Transport the column multiplication witness along this endpoint sameness by Definition 64.186, and take $p = p_{mn}$, $q_m = n$, and $q_n = m$. The result p is unary by Definition 64.18. Since m and n are positive, neither is history-same to e; if $p\mathsf{hsamee}$, then Definition 64.38 applied to $\mathsf{NatMul}(m, n, p)$ would force $n\mathsf{hsamee}$, a contradiction. Closed unary generation in Definition 28.1 therefore makes p a one-headed unary history, hence positive. □

Lemma 42.41 (AbGroup annihilator transport laws)**.** *For the torsion data of Definition 42.39:*

1. *if* $\mathsf{Ann}_A(m, a)$ *and* $\mathsf{NatMul}(m, q, p)$*, then* $\mathsf{Ann}_A(p, a)$*;*
2. *if* $\mathsf{Ann}_A(p, a)$ *and* $\mathsf{Ann}_A(p, b)$*, then* $\mathsf{Ann}_A(p, a + b)$*;*
3. *if* $\mathsf{Ann}_A(p, a)$*, then* $\mathsf{Ann}_A(p, -a)$*.*

Proof. For the first row, induct on the $\mathsf{NatMul}(m, q, p)$ witness. The empty quotient gives the zero scalar, which annihilates every carried element by the zero row of $\mathsf{AbNatAct}_A$. In the successor case, the scalar action over the appended unary multiplier decomposes into the previous block plus one m-block. The induction hypothesis classifies the previous block with 0, and the hypothesis $\mathsf{Ann}_A(m, a)$ classifies the new block with 0. The unit, associativity, and congruence fields inherited from Definition 42.1 collapse the sum of the two zero-classified blocks to 0.

For the second row, induct on the scalar-action witness for p. At the zero multiplier, both sides are the identity. In the successor case, the induction hypothesis gives the distributive comparison

$$p \cdot (a + b) \sim_A (p \cdot a) + (p \cdot b),$$

where $p \cdot a$ denotes the endpoint generated by $\mathsf{AbNatAct}_A(p, a, -)$. The next step adds one copy of $a + b$. Associativity, commutativity, and congruence regroup the endpoint as

$$(p \cdot a + a) + (p \cdot b + b),$$

which is the pair of successor scalar endpoints for a and b. The two annihilator hypotheses classify those endpoints with 0, and the unit law classifies their sum with 0.

For the third row, induct on the scalar-action witness for p. The zero multiplier gives 0. In the successor case, Definition 42.23 and commutativity identify the scalar endpoint for $-a$ with the inverse of the scalar endpoint for a. If the latter is classified with 0, inverse congruence classifies its inverse with -0. The inverse of 0 is classified with 0 by the group inverse uniqueness theorem Definition 41.59, using the group package retained by Definition 42.33. Thus the scalar endpoint for $-a$ is classified with 0. □

Theorem 42.42 (AbGroup torsion subgroup closure)**.** *Let an* $\mathsf{AbGroup}^{\uparrow}$ *carrier be written additively as in Definition 42.39. Then its torsion predicate contains* 0 *and is closed under addition and inverse: if* $\mathsf{Tor}_A(a)$ *and* $\mathsf{Tor}_A(b)$*, then* $\mathsf{Tor}_A(a+b)$ *and* $\mathsf{Tor}_A(-a)$*.*

Lean4 ✓ `BEDC.Derived.AbGroupUp.AbGroupTorsionSubgroup singleton closure`

Proof. The zero element is torsion: choose the positive unit multiplier $\mathsf{E1}(\mathsf{e})$. The one-step scalar action sends 0 to $0+0$, and the unit law classifies this endpoint with 0.

Now assume $\mathsf{Tor}_A(a)$ and $\mathsf{Tor}_A(b)$. Unpack Definition 42.39. Choose positive unary annihilators m and n with $\mathsf{Ann}_A(m,a)$ and $\mathsf{Ann}_A(n,b)$. By Definition 42.40, choose a positive common product p with multiplication witnesses $\mathsf{NatMul}(m,q_m,p)$ and $\mathsf{NatMul}(n,q_n,p)$.

Apply the first row of Definition 42.41 to transport the annihilator of a from m to p, and again to transport the annihilator of b from n to p. The second row of the same lemma then gives $\mathsf{Ann}_A(p,a+b)$. Since p is positive, the definition of torsion gives $\mathsf{Tor}_A(a+b)$.

For inverses, apply the third row of Definition 42.41 directly to $\mathsf{Ann}_A(m,a)$. The original multiplier m is positive, so the resulting annihilator witness gives $\mathsf{Tor}_A(-a)$. □

Theorem 42.43 (AbGroup singleton torsion unit exhaustion)**.** *On the singleton empty-history* $\mathsf{AbGroup}^{\uparrow}$ *public surface, every torsion witness* $\mathsf{Tor}_A(a)$ *forces* $a \sim_A 0$*. Moreover, every annihilator row* $\mathsf{Ann}_A(n,a)$ *factors through the same empty endpoint ledger: the scalar-action endpoint, the carried element, and the public zero row all classify to the singleton endpoint exposed by the public operation surface.*

Proof. Unpack torsion through Definition 42.39. A witness supplies a positive unary multiplier, an annihilator row, and a scalar-action endpoint classified with 0.

Project the carrier through the singleton public operation surface of Definition 42.37. On this surface the only carried endpoint is the empty-history endpoint, and all operation rows, including repeated addition and inverse, return to the same classifier class.

Use the closure theorem Definition 42.42 to keep the torsion row inside the public subgroup surface. Since the scalar-action endpoint has no non-empty carrier row available, the annihilator cannot distinguish a from the unit endpoint.

Finally compare the same surface with the singleton terminal standard bridge of Definition 42.36. The bridge reads the public $\mathsf{AbGroup}^{\uparrow}$ packet as the terminal trivial abelian group, so the annihilator ledger, scalar endpoint, and zero row all factor through the empty endpoint. Hence $a \sim_A 0$. □

Theorem 42.44 (AbGroup torsion local consumer coverage)**.** *For the unary scalar-action and torsion data of Definition 42.39, every accepted local consumer of the singleton torsion surface is exhausted by the displayed finite routes in this chapter. Namely, the consumer may read only the zero scalar-action row, the positive common-product route, the annihilator transport rows for scalar multiplication, addition, and inverse, the torsion subgroup closure row, and the singleton empty-endpoint ledger of Definition 42.43. It obtains no additional order-minimality coordinate, nontrivial cyclic-subgroup coordinate, quotient-torsion coordinate, or external scalar-action coordinate outside the displayed* $\mathsf{AbGroup}^{\uparrow}$ *packet.*

Proof. Unpack a local consumer through Definition 42.39. Its scalar-facing input is an $\mathsf{AbNatAct}_A$ witness, an annihilator row $\mathsf{Ann}_A(n, a)$, or a torsion row $\mathsf{Tor}_A(a)$. The definition supplies only two scalar-action constructors: the empty multiplier row

$$\mathsf{AbNatAct}_A(\mathsf{e}, a, 0)$$

and the one-step unary continuation row sending an endpoint x to $x + a$. Thus every scalar endpoint consumed from the packet is generated by repeated use of those two rows and classifier transport; there is no separate scalar-action table to project.

If the consumer reads an annihilator after changing the multiplier, the first row of Definition 42.41 is the only displayed transport route: an existing row $\mathsf{Ann}_A(m, a)$ is carried along a recorded multiplication witness $\mathsf{NatMul}(m, q, p)$ to $\mathsf{Ann}_A(p, a)$. If the consumer combines two torsion inputs, Definition 42.40 supplies the positive common product p, and the same transport row moves both annihilator witnesses to p. The second row of Definition 42.41 is then the displayed addition route, producing $\mathsf{Ann}_A(p, a + b)$. If the consumer reads an inverse, the third row of Definition 42.41 is the displayed route from $\mathsf{Ann}_A(p, a)$ to $\mathsf{Ann}_A(p, -a)$. These are exactly the alternatives used in Definition 42.42; the proof of that theorem introduces no further consumer coordinate.

It remains to check the singleton surface. By Definition 42.43, every torsion witness on the singleton empty-history public surface forces $a \sim_A 0$, and every annihilator row factors through the same empty endpoint ledger: the scalar-action endpoint, the carried element, and the public zero row all classify to the singleton endpoint exposed by the public operation surface. Therefore a consumer-facing singleton read has already passed through the finite scalar-action constructors, the annihilator transport rows, the torsion subgroup closure row when addition or inverse is requested, and the empty endpoint ledger.

The excluded alternatives named in the statement are not among these rows. Order-minimality would require comparing one positive annihilator against all smaller positive multipliers; no such comparison coordinate is present in Definition 42.39. A nontrivial cyclic-subgroup coordinate would require a stored orbit or generator subpacket beyond the endpoint relation $\mathsf{AbNatAct}_A$; none is present. A quotient-torsion coordinate would require a quotient carrier and quotient classifier; the singleton exhaustion row instead collapses the consumer read to $a \sim_A 0$. An external scalar-action coordinate would require a scalar operation not generated by e and $\mathsf{E1}(-)$; the definition supplies none. Hence every accepted local consumer is covered by the displayed finite routes, ledgers, and rows, and every unlisted coordinate remains outside the BEDC packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{AbGroup}^{\uparrow}}$.

Constructive story: An abelian group at this level uses the same empty-history singleton as the group marker, but now the endpoint is read through additive language. A history enters only by being history-equal to e, and two carried histories are classified by that same singleton equality, so the additive operation, zero, and negation all return to the one endpoint. The source is the singleton predicate, the pattern records continuation as addition, e as the unit, negation landing back at e, and the commutativity row in which continuing a then b and b then a both pull back to the endpoint; the ledger keeps visible and raw singleton histories aligned. Because the carrier has one inhabited class and history-equality is an equivalence, e gives nonemptiness and the classifier is reflexive, symmetric, transitive, and closed under the carrier. A history h lies in the signature gap of an $\mathsf{AbGroup}^{\uparrow}$ token p when the source-domain accepts h, the signature relation pairs it with an answer history and evidence ledger, and the token-introduction relation names that answer as p; unfolded, h is history-equal to e and p is the singleton abelian element. The terminal singleton bridge and torsion-subgroup row are then read off the same endpoint calculation. The chapter registers this singleton abelian construction under the name $\mathsf{AbGroup}^{\uparrow}$; commutativity is endpoint collapse on the singleton carrier, with no non-singleton abelian-group surface, quotient group, or homomorphism theory introduced.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbGroup}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The singleton empty-history carrier, classifier, and abelian group laws, the Group reduct rows, the additive negation rows, the public operation surface, the singleton terminal standard bridge of Definition 42.36, and the torsion subgroup closure of Definition 42.42 form the closed paper scope.

Formal verification: FormalStatus(NameCert$_{\mathsf{AbGroup}\uparrow}$, bridgeChecked)

Lean target: `BEDC.Derived.AbGroupUp.singleton\_empty\_history\_abgroup\_laws`

Bridge status: bridgeChecked

Not claimed: Arbitrary abelian groups, homomorphisms, quotients, non-singleton bridges, and Lean-side bridge verification remain outside this mature paper closure.

Upgrade path: No further upgrade – chapter at top of formal axis.

Chapter 43

A Concrete Naming Certificate for $\mathsf{Ring}^{\uparrow}$

The ring interface $\mathsf{Ring}^{\uparrow}$ is licensed by a carrier with two binary operations $+$ and $\cdot$ such that $(C, +)$ satisfies chapter 42 and $(C, \cdot)$ satisfies chapter 40, together with left and right distributivity of $\cdot$ over $+$. It is not a primitive structure; it is licensed only by composing the additive abelian group and multiplicative monoid certificates with the distributive law.

Remark 43.1 (Concrete stability fields)**.** *This chapter records the shared additive, multiplicative, congruence, and distributivity fields for the* $\mathsf{Ring}^{\uparrow}$ *naming certificate over BEDC histories.*

43.1 Carrier definition

Definition 43.2 (Ring carrier)**.** *Use a setup with carrier C, classifier, addition, zero, additive inverse, multiplication, one, and ring law fields.*

43.2 Concrete singleton history ring instance

Definition 43.3 (Concrete singleton history ring instance)**.** *Let A_{e} and R_{e} be the singleton carrier and classifier from Definition 41.3. Define the operations by*

$$\mathsf{add}(h, k) := \mathsf{append}(h, k), \qquad \mathsf{neg}(h) := \mathsf{e}, \qquad 0 := \mathsf{e},$$

and

$$\mathsf{mul}(h, k) := \mathsf{append}(h, k), \qquad 1 := \mathsf{e}.$$

The resulting tuple $(A_{\mathsf{e}}, R_{\mathsf{e}}, \mathsf{add}, 0, \mathsf{neg}, \mathsf{mul}, 1)$ is the concrete singleton history ring instance.

Theorem 43.4 (Concrete singleton history ring laws)**.** *The tuple $(A_{\mathsf{e}}, R_{\mathsf{e}}, \mathsf{add}, 0, \mathsf{neg}, \mathsf{mul}, 1)$ satisfies the additive abelian-group laws, multiplicative monoid laws, addition and multiplication congruence, left distributivity, and right distributivity under R_{e}.*

Proof. The additive component is the singleton history abelian group of Theorem 42.3, read with its binary operation as add. Thus additive closure, zero, inverse, associativity, commutativity, and additive congruence are already supplied over A_{e} and R_{e}.

The multiplicative component is the monoid part contained in Theorem 41.5, read with $\mathsf{mul}(h,k) := \mathsf{append}(h,k)$ and $1 := \mathsf{e}$. This gives multiplication closure, left and right unit laws, associativity, and multiplication congruence under the same classifier.

For left distributivity, assume $A_{\mathsf{e}}(h)$, $A_{\mathsf{e}}(k)$, and $A_{\mathsf{e}}(l)$. Closure for add and mul puts both $\mathsf{mul}(h, \mathsf{add}(k,l))$ and $\mathsf{add}(\mathsf{mul}(h,k), \mathsf{mul}(h,l))$ back in A_{e}. The singleton witnesses identify each side with e, and transitivity of hsame composes the two endpoint witnesses into the required R_{e} relation.

For right distributivity, the same argument applies to $\mathsf{mul}(\mathsf{add}(h,k),l)$ and $\mathsf{add}(\mathsf{mul}(h,l), \mathsf{mul}(k,l))$. Closure gives the two carrier witnesses, and the singleton endpoint e supplies the composed hsame witness required by R_{e}. □

Lean4 ✓ `BEDC.Derived.RingUp.concrete singleton history ring laws`

The RingUp schema is instantiated by this concrete BHist carrier and operations, so later formalization can target BHist-anchored ring laws rather than abstract operator fields.

43.3 Concrete singleton empty-history ring instance

Definition 43.5 (Singleton empty-history ring instance)**.** *Let A_{e} be the singleton history source of Definition 36.169 at $a_0 = \mathsf{e}$. Define the classifier*

$$\rho_{\mathsf{e}}(h,k) \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h,k).$$

Define the concrete ring operations by

$$\mathsf{add}(h,k) := \mathsf{e}, \qquad \mathsf{neg}(h) := \mathsf{e}, \qquad 0 := \mathsf{e}, \qquad \mathsf{mul}(h,k) := \mathsf{e}, \qquad 1 := \mathsf{e}.$$

This is the one-element BEDC history ring over the concrete carrier $A_{\mathsf{e}} : \mathsf{BHist} \to \mathsf{Prop}$ and classifier ρ_{e}.

Theorem 43.6 (Singleton empty-history ring laws)**.** *The tuple $(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \mathsf{add}, 0, \mathsf{neg}, \mathsf{mul}, 1)$ satisfies carrier inhabitance, additive abelian-group laws, multiplicative monoid laws, addition and multiplication congruence, left and right distributivity, and zero multiplication laws under ρ_{e}.*

Proof. Carrier inhabitance is the reflexive endpoint witness $\mathsf{hsame}(\mathsf{e},\mathsf{e})$. By Definition 36.169 at $a_0 = \mathsf{e}$, this is exactly the witness that e lies in A_{e}.

Every operation result in the displayed tuple is definitionally e. Hence addition closure, additive inverse closure, multiplication closure, and the closedness of 0 and 1 all use the same singleton carrier witness $\mathsf{hsame}(\mathsf{e},\mathsf{e})$.

The additive unit, inverse, associativity, and commutativity laws reduce both sides to e. The required endpoint facts for ρ_{e} are the singleton carrier witnesses; the relation component is reflexivity of hsame, with symmetry and transitivity used only to package classifier endpoints already identified with e.

The multiplicative left and right unit laws, associativity, and operation congruence are handled in the same way. Both source and target products are definitionally e, so the classifier relation is $\mathsf{hsame}(\mathsf{e},\mathsf{e})$.

For left and right distributivity, both the product over a sum and the sum of products reduce to e. The zero multiplication laws also reduce both sides to e, so each law is supplied by reflexivity of hsame together with the two singleton endpoint witnesses. □

Lean4 ✓ `BEDC.Derived.RingUp.RingSingletonEmptyHistory laws`

Theorem 43.7 (Ring singleton negation empty endpoint)**.** *For histories* $h, t : \mathsf{BHist}$ *with* $A_{\mathsf{e}}(h)$*,*

$$\rho_{\mathsf{e}}(\mathsf{RingSingletonNeg}(h), t) \iff A_{\mathsf{e}}(t) \wedge \mathsf{hsame}(\mathsf{RingSingletonNeg}(h), \mathsf{e}).$$

Proof. The singleton ring negation endpoint is definitionally e. In the forward direction, unfold ρ_{e} and read off the right carrier witness for t together with the left endpoint witness for $\mathsf{RingSingletonNeg}(h)$.

Conversely, the displayed pair supplies the two carrier endpoints. Symmetry of hsame turns the right carrier endpoint into an endpoint comparison back from e to t, and transitivity with the left endpoint witness packages the classifier relation required by ρ_{e}. □

Lean4 ✓ `BEDC.Derived.RingUp.RingSingletonClassifier neg empty endpoint iff`

Theorem 43.8 (Ring singleton classifier multiplication empty endpoint)**.** *For histories* h, k, out : BHist*,*

$$\rho_{\mathsf{e}}(\mathsf{RingSingletonMul}(h, k), out) \iff \mathsf{hsame}(out, \mathsf{e}).$$

Proof. The multiplication endpoint is definitionally e. Forward projection reads the right carrier field of ρ_{e}. Conversely, the displayed endpoint witness, the reflexive left carrier at e, and symmetry rebuild the classifier. □

Lean4 ✓ `BEDC.Derived.RingUp.RingSingletonClassifier mul empty endpoint iff`

Theorem 43.9 (Ring singleton classifier visible-right exclusion)**.** *For histories* h, p, q : BHist*, neither* $\rho_{\mathsf{e}}(h, \mathsf{append}(p, \mathsf{e0}(q)))$ *nor* $\rho_{\mathsf{e}}(h, \mathsf{append}(p, \mathsf{e1}(q)))$ *can hold.*

Proof. Unfold the singleton ring classifier. In either case, the right carrier field identifies the displayed append endpoint with e. Empty-result inversion for append then forces the visible right component, either $\mathsf{e0}(q)$ or $\mathsf{e1}(q)$, to be e. The closed constructors of BHist are disjoint, so both classifier assumptions are contradictory. □

Lean4 ✓ `BEDC.Derived.RingUp.RingSingletonClassifier append visible right absurd`

Theorem 43.10 (Ring singleton classifier visible-left exclusion)**.** *For histories* p, q, h : BHist*, neither* $\rho_{\mathsf{e}}(\mathsf{append}(p, \mathsf{e0}(q)), h)$ *nor* $\rho_{\mathsf{e}}(\mathsf{append}(p, \mathsf{e1}(q)), h)$ *can hold.*

Proof. Unfold the singleton ring classifier. In either case, the left carrier field identifies the displayed append endpoint with e. Empty-result inversion for append then forces the visible right component, either $\mathsf{e0}(q)$ or $\mathsf{e1}(q)$, to be e. Constructor separation for BHist rules out both alternatives. □

Lean4 ✓ `BEDC.Derived.RingUp.RingSingletonClassifier append visible left absurd`

Theorem 43.11 (Ring singleton classifier append split empty)**.** *For histories* p, q, h : BHist*,*

$$\rho_{\mathsf{e}}(\mathsf{append}(p, q), h) \iff A_{\mathsf{e}}(p) \wedge A_{\mathsf{e}}(q) \wedge A_{\mathsf{e}}(h).$$

This certificate has the following ten-field fit: the traditional target is singleton ring endpoint exactness; the BEDC source is the concrete singleton $\mathsf{Ring}^{\uparrow}$ *over* BHist*; the carrier is* A_{e}*; the classifier is* ρ_{e}*; stability comes from empty-result inversion and* hsame *transport; the ledger records append-factor endpoints; the core theorem is the displayed split; exactness is the displayed equivalence; the standard bridge is terminal ring endpoint equality; and the status is* $\mathsf{ProofTarget}$*.*

Proof. Unfold the singleton ring classifier. For the forward direction, the left carrier field identifies $\mathsf{append}(p, q)$ with e. Empty-result inversion for append splits this endpoint into the two factor witnesses $A_{\mathsf{e}}(p)$ and $A_{\mathsf{e}}(q)$, while the right carrier field gives $A_{\mathsf{e}}(h)$.

For the reverse direction, the two factor witnesses rebuild the empty appended endpoint. Together with the witness $A_{\mathsf{e}}(h)$, transitivity through e supplies the required classifier comparison between $\mathsf{append}(p, q)$ and h. □

Lean4 ✓ `BEDC.Derived.RingUp.RingSingletonClassifier append split empty`

Theorem 43.12 (Ring singleton classifier append commutation)**.** *For singleton ring carrier histories $h, k : \mathsf{BHist}$, the classifier relates the two appended endpoints with the factors exchanged:*

$$\rho_{\mathsf{e}}(\mathsf{append}(h, k), \mathsf{append}(k, h)).$$

Proof. The two carrier witnesses identify both h and k with e. Empty-result construction for append gives singleton carrier witnesses for $\mathsf{append}(h, k)$ and $\mathsf{append}(k, h)$. Since both endpoints are classified through e, transitivity and symmetry of hsame package the classifier relation. □

Lean4 ✓ `BEDC.Derived.RingUp.RingSingletonClassifier append comm`

Theorem 43.13 (Ring singleton classifier append associativity carrier exactness)**.** *For histories $a, b, c : \mathsf{BHist}$, the singleton ring classifier relates the two append bracketings exactly when all three factors are singleton carriers:*

$$\rho_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(a, b), c), \mathsf{append}(a, \mathsf{append}(b, c))) \iff A_{\mathsf{e}}(a) \wedge A_{\mathsf{e}}(b) \wedge A_{\mathsf{e}}(c).$$

Proof. The forward direction projects the left carrier field from the classifier. Nested empty-result inversion for append first splits $\mathsf{append}(\mathsf{append}(a, b), c)$ into the left bracketing and c, then splits the left bracketing into a and b.

Conversely, the three carrier witnesses rebuild singleton carrier witnesses for both append bracketings. Since both endpoints are classified through e, transitivity and symmetry of hsame give the classifier relation. □

Lean4 ✓ `BEDC.Derived.RingUp.RingSingletonClassifier append assoc carrier iff`

Theorem 43.14 (Ring singleton continuation empty result exactness)**.** *If $C_{\mathsf{e}}(h, k)$ and $\mathsf{Cont}(h, p, r)$, then $r\mathsf{hsamee}$ holds exactly when p is in the singleton carrier.*

Proof. Transporting an empty result into the continuation and inverting empty concatenation gives $p\mathsf{hsamee}$. Conversely, the classifier makes $h\mathsf{hsamee}$; with $p\mathsf{hsamee}$, determinacy of continuation compares $\mathsf{Cont}(h, p, r)$ with the right-unit continuation at e. □

Lean4 ✓ `BEDC.Derived.RingUp.RingSingletonClassifier cont result empty iff`

Theorem 43.15 (Ring singleton multiplication continuation classifier)**.** *If $\mathsf{Cont}(\mathsf{RingSingletonMul}(x, y), z, r)$, then*

$$C_{\mathsf{e}}(r, h) \iff A_{\mathsf{e}}(z) \wedge A_{\mathsf{e}}(h).$$

Proof. The singleton multiplication endpoint is e. In the forward direction, transport the classified empty result into the continuation and invert the empty continuation to obtain $z\mathsf{hsamee}$; the right classifier carrier gives $h\mathsf{hsamee}$. Conversely, $z\mathsf{hsamee}$ compares the continuation result with the right-unit continuation at $\mathsf{RingSingletonMul}(x, y)$, so r is empty and classifies against h. □

Lean4 ✓ `BEDC.Derived.RingUp.RingSingletonClassifier mul continuation classifier iff`

Theorem 43.16 (Ring singleton continuation visible result exclusion)**.** *If $C_{\mathsf{e}}(h,k)$, $A_{\mathsf{e}}(p)$, and $\mathsf{Cont}(h,p,-)$ is formed, then no visible endpoint can be the continuation result:*

$$\mathsf{Cont}(h,p,\mathsf{E0}(r)) \Longrightarrow \bot, \qquad \mathsf{Cont}(h,p,\mathsf{E1}(r)) \Longrightarrow \bot.$$

Proof. The classifier supplies $h\mathsf{hsamee}$, while the carrier hypothesis supplies $p\mathsf{hsamee}$. Continuation respects these two history-same witnesses, so a displayed continuation result would be history-same to the right-unit result at e. Constructor disjointness excludes both $\mathsf{E0}(r)$ and $\mathsf{E1}(r)$ from being history-same to e. □

Lean4 ✓ `BEDC.Derived.RingUp.RingSingletonClassifier continuation visible result absurd`

43.4 Singleton Empty-History Ring Instance

Definition 43.17 (Singleton empty-history RingUp instance)**.** *Let A_{e} be the singleton history source of Definition 36.169 at $a_0 = \mathsf{e}$. The classifier R_{e} is the carrier-aware singleton relation*

$$R_{\mathsf{e}}(h,k) \Longleftrightarrow A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h,k).$$

Define the addition, multiplication, zero, one, and negation rows by

$$h +_{\mathsf{e}} k := \mathsf{e}, \qquad h \cdot_{\mathsf{e}} k := \mathsf{e}, \qquad 0_{\mathsf{e}} := \mathsf{e}, \qquad 1_{\mathsf{e}} := \mathsf{e}, \qquad -_{\mathsf{e}} h := \mathsf{e}.$$

Equivalently, every binary operation is append-trivial on the singleton endpoint: its operation tree may record two inputs, but its exposed output is the empty history. The tuple $(A_{\mathsf{e}}, R_{\mathsf{e}}, +_{\mathsf{e}}, 0_{\mathsf{e}}, -_{\mathsf{e}}, \cdot_{\mathsf{e}}, 1_{\mathsf{e}})$ is the concrete singleton empty-history $\mathsf{Ring}^{\uparrow}$ instance.

Theorem 43.18 (Singleton empty-history RingUp laws)**.** *The tuple of Definition 43.17 satisfies the $\mathsf{Ring}^{\uparrow}$ algebraic laws: additive abelian-group laws, multiplicative monoid laws, left and right distributivity, left and right zero absorption, and congruence of both operations under R_{e}.*

Proof. The carrier is inhabited by $\mathsf{hsame}(\mathsf{e},\mathsf{e})$. Every displayed operation returns e, so operation closure, the closedness of 0_{e} and 1_{e}, and the closure of additive inverses are all the singleton carrier witness for e.

For the additive laws, both sides of each unit, inverse, associativity, and commutativity comparison reduce to e. The corresponding R_{e} row is therefore assembled from the two singleton endpoint witnesses and reflexivity of hsame. This is the constant-operation specialization of the singleton AbGroup rows in Definition 42.10.

For the multiplicative monoid laws, both products in each unit and associativity comparison again reduce to e. The singleton endpoint witnesses and hsame reflexivity provide the required classifier row, matching the singleton monoid and group rows of Definition 41.5.

For operation congruence, suppose the inputs are paired by R_{e}. The source and target additions are both e, and the source and target multiplications are both e. Thus congruence is the same packed $R_{\mathsf{e}}(\mathsf{e},\mathsf{e})$ witness in both cases.

For distributivity and zero absorption, every term on either side of each law is definitionally e. The endpoint comparisons are consequently supplied by $\mathsf{hsame}(\mathsf{e},\mathsf{e})$, while the classifier endpoint fields are the singleton carrier witnesses for e. Transitivity of hsame is used only to transport any named input endpoint through its carrier witness before repacking the final R_{e} comparison. □

Theorem 43.19 (Singleton empty-history RingUp naming certificate)**.** *The instance of Definition 43.17 supplies a concrete* $\mathsf{NameCert}_{\mathsf{Ring}^\uparrow}$ *package for the one-element ring. Its ten-field fit is: traditional target the one-element ring; BEDC source* BHist*; carrier* A_{e}*; classifier* R_{e}*; stability the singleton transport rows under* hsame*; ledger the constant-operation provenance for* $+_{\mathsf{e}}$*,* 0_{e}*,* $-_{\mathsf{e}}$*,* $\cdot_{\mathsf{e}}$*, and* 1_{e}*; core theorem Definition 43.18; exactness singleton endpoint classification; standard bridge the terminal ring; and consumer boundary the exposed one-endpoint operation table.*

Proof. The source and carrier fields are the BHist singleton predicate A_{e}, and the classifier field is R_{e}. The stability fields follow by transporting every carried endpoint through its witness to e and then using transitivity of hsame to repack the same carrier-aware classifier.

The operation-law fields are exactly Definition 43.18. They include the additive AbGroup part, the multiplicative Monoid part, both distributivity rows, zero absorption, and congruence for the two binary operations.

The ledger records only that each displayed operation tree has endpoint e. Since R_{e} exposes precisely the two endpoint carrier witnesses and their hsame comparison, exactness says that a public endpoint belongs to the certificate exactly when it is the singleton empty-history endpoint. This is the terminal one-element ring table read through BEDC histories. □

43.5 Empty-History Ground Schema Unlock

Definition 43.20 (RingUp empty-history ground instance)**.** *The ground* $\mathsf{Ring}^\uparrow$ *tuple over* BHist *is the singleton empty-history instance*

$$(A_{\mathsf{e}}, R_{\mathsf{e}}, +_{\mathsf{e}}, 0_{\mathsf{e}}, -_{\mathsf{e}}, \cdot_{\mathsf{e}}, 1_{\mathsf{e}})$$

of Definition 43.17. Its carrier is the singleton row A_{e} *at the empty history, its classifier is* R_{e}*, and its displayed operations are fixed by*

$$h +_{\mathsf{e}} k := \mathsf{e}, \qquad -_{\mathsf{e}} h := \mathsf{e}, \qquad 0_{\mathsf{e}} := \mathsf{e},$$

together with

$$h \cdot_{\mathsf{e}} k := \mathsf{e}, \qquad 1_{\mathsf{e}} := \mathsf{e}.$$

Thus every operator row is a concrete BHist *row with endpoint* e*, and every classifier read is the carrier-aware singleton comparison.*

Theorem 43.21 (RingUp empty-history ground laws)**.** *The tuple of Definition 43.20 satisfies the* $\mathsf{Ring}^\uparrow$ *laws: additive abelian-group laws, multiplicative monoid laws, left and right distributivity, left and right zero absorption, and congruence of addition and multiplication under* R_{e}*.*

Proof. The tuple is exactly the singleton empty-history instance of Definition 43.17. Its operation rows, distinguished zero and one rows, negation row, carrier, and classifier are the same displayed rows.

Apply Definition 43.18. That theorem supplies the additive, multiplicative, distributive, zero-absorption, and congruence rows for the same tuple, so no abstract carrier or operator parameter remains to instantiate. □

Theorem 43.22 (RingUp empty-history schema unlock)**.** *Every* $\mathsf{Ring}^\uparrow$ *schema consumer that only requires a concrete ground ring may use the displayed tuple of Definition 43.20. The consumer receives the carrier* A_{e}*, classifier* R_{e}*, addition, negation, zero, multiplication, one, and the law package of Definition 43.21 as concrete* BHist *rows, rather than abstract carrier and operator parameters.*

Proof. Project the ground instance. The carrier, classifier, and five operation rows are all displayed singleton empty-history rows, so a schema consumer can cite them directly.

The law package is supplied by Definition 43.21. Since that theorem is already about the same displayed tuple, substituting it into a ground-ring schema does not introduce a new carrier, a second classifier, or additional operator parameters. □

43.6 The certificate

Definition 43.23 (Ring source specification)**.** *The source is an additive* $\mathsf{AbGroup}^{\uparrow}$ *and multiplicative* $\mathsf{Monoid}^{\uparrow}$ *on the same carrier and classifier.*

Definition 43.24 (Ring pattern specification)**.** *The pattern is expression formation from* $0, 1, +, -, \cdot$.

Definition 43.25 (Ring classifier specification)**.** *The classifier is the shared carrier sameness relation, congruent for both operations.*

Definition 43.26 (Ring stability certificate)**.** *The stability certificate consists of:*

1. *additive abelian-group laws*
2. *multiplicative monoid laws*
3. *addition and multiplication congruence*
4. *left distributivity*
5. *right distributivity*
6. *zero multiplication laws derived or supplied constructively*

Lean4 ✓ `BEDC.Derived.RingUp.ring stability certificate fields`

Theorem 43.27 (Ring additive right inverse)**.** *For BEDC history addition, additive commutativity and the supplied left inverse law imply the matching right inverse law* $x + (-x)\mathsf{hsame}0$.

Proof. Commute $x + (-x)$ to $(-x) + x$, then apply the left inverse law. □

Lean4 ✓ `BEDC.Derived.RingUp.ring add right inverse`

Theorem 43.28 (Ring additive inverse of zero)**.** *For BEDC history addition, additive commutativity, the left-zero law, and the left inverse law imply* $\mathsf{hsame}(-0, 0)$.

Proof. Chain -0 backward through the left-zero equation $0 + (-0)\mathsf{hsame} - 0$, commute $0 + (-0)$ to $(-0) + 0$, and apply the left inverse law at 0. □

Lean4 ✓ `BEDC.Derived.RingUp.ring neg zero`

Theorem 43.29 (Ring duplicate addition collapses to zero)**.** *For BEDC history addition, if an element is the same as its duplicate sum* $a + a$*, then the element is the same as zero.*

Proof. Add the left inverse of a on the left, reassociate to bring $(-a) + a$ together, collapse that pair to zero, and use the left-zero law. □

Lean4 ✓ `BEDC.Derived.RingUp.ring add duplicate eq zero`

Theorem 43.30 (Ring additive duplicate zero exactness)**.** *For BEDC history addition satisfying additive associativity, left zero, left inverse, and addition congruence, every history a satisfies*

$$a\mathsf{hsame}a + a \iff a\mathsf{hsame}0.$$

Proof. The forward implication is exactly the duplicate-addition collapse: apply Definition 43.29 to the hypothesis $a\mathsf{hsame}a + a$.

For the reverse implication, use symmetry of $a\mathsf{hsame}0$ to transport the left summand from a to 0, and use the hypothesis itself to transport the right summand from a to 0 by addition congruence. The resulting comparison $a + a\mathsf{hsame}0 + 0$ reduces by the left-zero law to 0, and transitivity with the original hypothesis gives $a\mathsf{hsame}a + a$. □

Lean4 ✓ `BEDC.Derived.RingUp.ring add duplicate empty iff`

Theorem 43.31 (Ring additive right zero)**.** *For BEDC history addition, additive commutativity and the supplied left-zero law imply the matching right-zero law $x + 0\mathsf{hsame}x$.*

Proof. Commute $x + 0$ to $0 + x$, then apply the left-zero law. □

Lean4 ✓ `BEDC.Derived.RingUp.ring add right zero`

Theorem 43.32 (Ring additive two-sided cancellation)**.** *For BEDC history addition satisfying additive associativity, commutativity, left-zero, left-inverse, and addition congruence, every $a, b, c :$ BHist satisfies both cancellation implications:*

$$a + c\mathsf{hsame}b + c \implies a\mathsf{hsame}b$$

and

$$c + a\mathsf{hsame}c + b \implies a\mathsf{hsame}b.$$

The ten-field fit is: traditional target additive cancellation in a ring; BEDC source $\mathsf{Ring}^{\uparrow}$ *over* BHist *plus* $\mathsf{Group}^{\uparrow}$ *cancellation; carrier* BHist*; classifier* hsame*; stability from additive group laws and addition congruence; ledger the common addend; core theorem this theorem; exactness predicate the two displayed implications; standard bridge ordinary ring additive cancellation; status* ProofTarget*.*

Proof. First derive the additive right-zero law from Theorem 43.31 and the additive right-inverse law from Theorem 43.27. Together with associativity, commutativity, left zero, left inverse, and addition congruence, these are the group-cancellation hypotheses for the additive operation.

For the first implication, read addition as the group operation and apply Theorem 41.116 to the common right summand c. The hypothesis $a + c\mathsf{hsame}b + c$ then yields $a\mathsf{hsame}b$.

For the second implication, apply Theorem 41.66 to the common left summand c. The hypothesis $c + a\mathsf{hsame}c + b$ then yields the same conclusion $a\mathsf{hsame}b$. □

Lean4 ✓ `BEDC.Derived.RingUp.ring additive two sided cancellation`

Theorem 43.33 (Ring negative of sum)**.** *For BEDC history addition and negation satisfying additive associativity, commutativity, left zero, left inverse, and addition congruence, every $a, b :$ BHist satisfies*

$$\mathsf{hsame}(\mathsf{neg}(\mathsf{add}(a, b)), \mathsf{add}(\mathsf{neg}(a), \mathsf{neg}(b))).$$

The ten-field fit is: traditional target additive inverse of a sum in a ring; BEDC source $\mathsf{Ring}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability from additive congruence and additive cancellation; ledger the two addends a, b and the inverse witnesses* $\mathsf{neg}(\mathsf{add}(a, b))$ *and* $\mathsf{add}(\mathsf{neg}(a), \mathsf{neg}(b))$*; core theorem this theorem; exactness the displayed equality; downstream consumer CommRing signed-product normalization and FieldUp denominator inverse normalization; status* ProofTarget*.*

Proof. The common element to cancel is $\mathsf{add}(a, b)$. By Theorem 43.27, the endpoint $\mathsf{neg}(\mathsf{add}(a, b))$ is a right inverse of this common element.

It remains to see that $\mathsf{add}(\mathsf{neg}(a), \mathsf{neg}(b))$ is also a right inverse of $\mathsf{add}(a, b)$. Reassociate the sum $(a + b) + ((-a) + (-b))$, commute the middle terms so that $b + (-b)$ and $a + (-a)$ appear as adjacent pairs, collapse those pairs using the right inverse and left inverse rows, and remove the resulting zeros by the left and right zero laws.

Both endpoints therefore give the same sum with the common left factor $\mathsf{add}(a, b)$. Apply Theorem 43.32 to cancel that factor and obtain the displayed hsame comparison. □

Lean4 ✓ `BEDC.Derived.RingUp.ring neg add`

Theorem 43.34 (Ring additive difference zero exactness)**.** *For BEDC history addition satisfying additive associativity, commutativity, left zero, left inverse, and addition congruence, every x, y : BHist satisfies*

$$x + (-y)\mathsf{hsame}0 \iff x\mathsf{hsame}y.$$

The ten-field fit is: traditional target additive difference exactness; BEDC source $\mathsf{Ring}^{\uparrow}$ over BHist plus the $\mathsf{Group}^{\uparrow}$ cancellation spine already cited by Definition 43.32; carrier BHist; classifier hsame; stability from additive group laws and addition congruence; ledger the hidden signed summand; core theorem this theorem; exactness the displayed iff; standard bridge ordinary ring subtraction exactness; status ProofTarget.

Lean4 ✓ `BEDC.Derived.RingUp.ring additive difference zero exact`

Definition 43.35 (Opposite ring certificate data)**.** *Let C carry a $\mathsf{Ring}^{\uparrow}(C)$ certificate with classifier $\sim_C$, addition $+_C$, zero 0_C, additive inverse operation $-_C$, multiplication $\cdot_C$, and multiplicative identity 1_C. Define the reversed multiplication by*

$$a \cdot_C^{\mathrm{op}} b := b \cdot_C a.$$

The opposite ring data C^{op} have the same carrier C, the same classifier $\sim_C$, the same addition $+_C$, the same zero 0_C, the same additive inverse operation $-_C$, the same multiplicative identity 1_C, and multiplication $\cdot_C^{\mathrm{op}}$.

Theorem 43.36 (Opposite ring certificate)**.** *If the displayed data on C satisfy the $\mathsf{Ring}^{\uparrow}(C)$ certificate obligations, then the data of Definition 43.35 also satisfy the $\mathsf{Ring}^{\uparrow}(C)$ certificate obligations. Thus the same carrier, additive structure, multiplicative identity, and classifier carry a ring certificate with multiplication $\cdot_C^{\mathrm{op}}$.*

Proof. Unpack the $\mathsf{Ring}^{\uparrow}(C)$ obligations through Definition 43.55. The carrier row is unchanged by Definition 43.2. The carrier-and-classifier core is the same NameCert data, so classifier reflexivity, symmetry, transitivity, and carrier transport are copied from Definition 9.7.

The additive source required by Definition 43.23 is unchanged: the $\mathsf{AbGroup}^{\uparrow}$ carrier uses the same $+_C$, 0_C, $-_C$, and $\sim_C$, with the same additive stability and ledger rows. It remains to read the multiplicative source as a $\mathsf{Monoid}^{\uparrow}$ certificate for $\cdot_C^{\mathrm{op}}$. Closure follows from the original multiplication closure applied to the ordered pair (b, a). The opposite left identity row is

$$1_C \cdot_C^{\mathrm{op}} a = a \cdot_C 1_C \sim_C a,$$

which is the original right identity row. The opposite right identity row is

$$a \cdot_C^{\mathrm{op}} 1_C = 1_C \cdot_C a \sim_C a,$$

which is the original left identity row. For associativity, the two opposite bracketings unfold to

$$(a \cdot_C^{\mathrm{op}} b) \cdot_C^{\mathrm{op}} c = c \cdot_C (b \cdot_C a), \qquad a \cdot_C^{\mathrm{op}} (b \cdot_C^{\mathrm{op}} c) = (c \cdot_C b) \cdot_C a.$$

The associativity-under-classifier row in Definition 40.13, applied to the original multiplication at the triple (c, b, a), supplies

$$(c \cdot_C b) \cdot_C a \sim_C c \cdot_C (b \cdot_C a).$$

Classifier symmetry gives the orientation $c \cdot_C (b \cdot_C a) \sim_C (c \cdot_C b) \cdot_C a$ needed to compare the two unfolded opposite bracketings. Multiplication congruence for $\cdot_C^{\mathrm{op}}$ is the original multiplication congruence with the two input comparisons supplied in exchanged order. These are precisely the monoid stability rows of Definition 40.13, hence the multiplicative source satisfies Definition 40.34.

The pattern row of Definition 43.24 is unchanged except that the multiplication node is interpreted by $\cdot_C^{\mathrm{op}}$. The classifier row of Definition 43.25 is unchanged for addition, and the preceding paragraph supplies congruence for the reversed multiplication.

For left distributivity in the opposite data, unfold the reversed product and use original right distributivity:

$$a \cdot_C^{\mathrm{op}} (b +_C c) = (b +_C c) \cdot_C a \sim_C (b \cdot_C a) +_C (c \cdot_C a) = (a \cdot_C^{\mathrm{op}} b) +_C (a \cdot_C^{\mathrm{op}} c).$$

For right distributivity in the opposite data, unfold the reversed product and use original left distributivity:

$$(a +_C b) \cdot_C^{\mathrm{op}} c = c \cdot_C (a +_C b) \sim_C (c \cdot_C a) +_C (c \cdot_C b) = (a \cdot_C^{\mathrm{op}} c) +_C (b \cdot_C^{\mathrm{op}} c).$$

The two zero multiplication rows are exchanged in the same way: $0_C \cdot_C^{\mathrm{op}} a = a \cdot_C 0_C$ is the original right-zero row, and $a \cdot_C^{\mathrm{op}} 0_C = 0_C \cdot_C a$ is the original left-zero row. Together with the copied additive laws and congruence rows, these are exactly the stability fields listed in Definition 43.26.

Finally, the ledger policy of Definition 43.54 uses the same carrier witnesses and the same additive operation trees. A multiplication node with opposite inputs (a, b) records the original multiplication ledger for (b, a). Therefore the carrier, source, pattern, classifier, stability, and ledger rows all satisfy the $\mathsf{Ring}^{\uparrow}(C)$ certificate obligations for the opposite ring data. □

Theorem 43.37 (Ring negation classifier exactness)**.** *For BEDC history addition and negation satisfying additive associativity, commutativity, left zero, left inverse, addition congruence, and additive inverse congruence, every $x, y : \mathsf{BHist}$ satisfies*

$$-x \mathsf{hsame} - y \iff x \mathsf{hsame} y.$$

The ten-field fit is: traditional target additive inverse injectivity in a ring; BEDC source $\mathsf{Ring}^{\uparrow}$ *over* BHist *with the additive* $\mathsf{Group}^{\uparrow}$ *cancellation spine cited by Definition 43.34; carrier* BHist*; classifier* hsame*; stability from addition congruence and additive inverse congruence; ledger the two negated endpoints; core theorem this theorem; exactness the displayed iff; standard bridge ordinary ring additive inverse injectivity; status* $\mathsf{ProofTarget}$*.*

Lean4 ✓ `BEDC.Derived.RingUp.ring negation classifier exactness`

Proof. Assume first that $-x \mathsf{hsame} - y$. By classifier symmetry, $-y \mathsf{hsame} - x$. Addition congruence, with reflexivity on the left summand x, transports this to

$$x + (-y) \mathsf{hsame} x + (-x).$$

The right-inverse law of Definition 43.27 gives $x+(-x)\mathsf{hsame}0$, so transitivity gives $x+(-y)\mathsf{hsame}0$. The forward direction of Definition 43.34 then yields $x\mathsf{hsame}y$.

Conversely, assume $x\mathsf{hsame}y$. The additive inverse congruence field transports this classifier witness directly across negation, giving $-x\mathsf{hsame}-y$. □

Theorem 43.38 (Double-opposite ring certificate data identity)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate satisfying the obligations of Definition 43.55. Present its data by a carrier predicate $\mathcal{C}$, classifier $\sim_R$, addition $+_R$, zero 0_R, additive inverse operation $-_R$, multiplication $\cdot_R$, multiplicative identity 1_R, stability table $\mathcal{S}_R$ as in Definition 43.26, and ledger table $\mathcal{L}_R$ as in Definition 43.54. Let $R^{\mathrm{opop}} = (R^{\mathrm{op}})^{\mathrm{op}}$ be obtained by applying Definition 43.35 twice. Then R^{opop} is a $\mathsf{Ring}^{\uparrow}(R)$ certificate, and its carrier, classifier, additive data, multiplicative identity, multiplication, stability rows, and ledger rows are componentwise identical to those of R: for carried endpoints a, b,*

$$\begin{aligned}
\mathcal{C}^{\mathrm{opop}}(a) &= \mathcal{C}(a), & a \sim_R^{\mathrm{opop}} b &= a \sim_R b,\\
a +_R^{\mathrm{opop}} b &= a +_R b, & 0_R^{\mathrm{opop}} &= 0_R,\\
(-_R)^{\mathrm{opop}}(a) &= -_R a, & 1_R^{\mathrm{opop}} &= 1_R,\\
a \cdot_R^{\mathrm{opop}} b &= a \cdot_R b, & \mathcal{S}_R^{\mathrm{opop}} &= \mathcal{S}_R,\\
\mathcal{L}_R^{\mathrm{opop}} &= \mathcal{L}_R.
\end{aligned}$$

The equalities involving $\mathcal{S}_R$ and $\mathcal{L}_R$ mean equality of the named rows and their displayed endpoint data.

Proof. Because R satisfies the $\mathsf{Ring}^{\uparrow}(R)$ obligations, Definition 43.36 makes R^{op} a certified $\mathsf{Ring}^{\uparrow}(R)$ instance. Applying the same theorem to that certified opposite data makes R^{opop} a certified $\mathsf{Ring}^{\uparrow}(R)$ instance.

It remains to compare the displayed fields. By Definition 43.35, one opposite keeps the carrier, classifier, addition, zero endpoint, additive inverse operation, and multiplicative identity fixed. Two unfoldings therefore give

$$\mathcal{C}^{\mathrm{opop}}(a) = \mathcal{C}(a), \qquad a \sim_R^{\mathrm{opop}} b = a \sim_R b,$$

$$a +_R^{\mathrm{opop}} b = a +_R b, \qquad 0_R^{\mathrm{opop}} = 0_R, \qquad (-_R)^{\mathrm{opop}}(a) = -_R a, \qquad 1_R^{\mathrm{opop}} = 1_R.$$

For multiplication, the first opposite reverses the two inputs and the second opposite reverses them back:

$$a \cdot_R^{\mathrm{opop}} b = b \cdot_R^{\mathrm{op}} a = a \cdot_R b.$$

Thus the raw ring data of the double opposite certificate are the raw ring data of R.

The source row of Definition 43.23 is restored from these identities: the additive $\mathsf{AbGroup}^{\uparrow}$ source is fixed in each opposite, and the multiplicative $\mathsf{Monoid}^{\uparrow}$ source is typed over the restored multiplication and the same identity. The pattern row of Definition 43.24 forms expressions from the same 0_R, 1_R, $+_R$, $-_R$, and restored multiplication. The classifier row of Definition 43.25 is the same relation $\sim_R$, with addition congruence fixed and multiplication congruence read over the restored multiplication.

For the stability table, Definition 43.26 lists the additive abelian-group laws, multiplicative monoid laws, operation congruence, left distributivity, right distributivity, and zero multiplication laws. The additive rows and addition congruence are fixed by each opposite construction. In the multiplicative part, one opposite exchanges the two unit rows, reads associativity with the triple reversed, and exchanges the two congruence inputs; the second opposite performs the same exchanges again, restoring the unit, associativity, and multiplication-congruence rows for $\cdot_R$. The left

and right distributivity rows are exchanged once and then restored, and the two zero multiplication rows are exchanged in the same way. Hence $\mathcal{S}_R^{\mathrm{opop}} = \mathcal{S}_R$ row by row.

Finally, Definition 43.54 records the shared carrier ledger and the operation tree for ring expressions. Carrier, additive, zero, inverse, and unit entries are fixed by each opposite. A multiplication node records the same two operands with their child order exchanged in one opposite reading; the second opposite exchanges that child order again. Therefore every ledger entry of R^{opop} is the corresponding ledger entry of R, so $\mathcal{L}_R^{\mathrm{opop}} = \mathcal{L}_R$. Together with the certified status above, these identities identify the double-opposite ring certificate data with the original ring certificate data. □

Proof. First derive the additive right-zero law from Theorem 43.31 and the additive right-inverse law from Theorem 43.27. These give the removable zero and inverse pairs used on both sides of the equivalence.

For the forward implication, add y to the right of the comparison $x+(-y)\mathsf{hsame}0$. Associativity rewrites $(x+(-y))+y$ as $x+((-y)+y)$, commutativity and the right-inverse law collapse $(-y)+y$ to 0, and the right-zero law removes that terminal zero. The right endpoint $0+y$ reduces to y by the left-zero law, leaving $x\mathsf{hsame}y$.

For the reverse implication, transport $x\mathsf{hsame}y$ through addition congruence against the common summand $-y$. The right side becomes $y+(-y)$, which Theorem 43.27 collapses to 0, yielding $x+(-y)\mathsf{hsame}0$ by transitivity. □

Theorem 43.39 (Ring multiplication zero absorption)**.** *For BEDC history operations satisfying additive associativity, left zero, left inverse, congruence, and both distributive laws, multiplication by zero on either side is internally the same as zero.*

Lean4 ✓ `BEDC.Derived.RingUp.ring mul zero absorption`

Proof. First cancel a duplicated summand $a\mathsf{hsame}a+a$ by adding the left inverse, reassociating, and using the left-zero law. Then apply distributivity to $x\cdot(0+0)$ and $(0+0)\cdot x$, transport along $0+0\mathsf{hsame}0$, and use the duplicate-cancellation step on the two resulting products. □

Theorem 43.40 (Ring zero-classifier factor absorption)**.** *For BEDC history operations satisfying additive associativity, left zero, left inverse, addition congruence, multiplication congruence, and both distributive laws, if* $\mathsf{hsame}(x,0)$*, then every* $y : \mathsf{BHist}$ *satisfies*

$$\mathsf{hsame}(x\cdot y,0)\wedge\mathsf{hsame}(y\cdot x,0).$$

Proof. Invoke Definition 43.39 to obtain the two literal zero-factor absorptions. For the left product, multiplication congruence transports the left factor along $\mathsf{hsame}(x,0)$, comparing $x\cdot y$ with $0\cdot y$. Transitivity with the left zero-factor absorption gives $\mathsf{hsame}(x\cdot y,0)$, using symmetry if the congruence step is read in the opposite direction.

For the right product, multiplication congruence transports the right factor along the same classifier witness, comparing $y\cdot x$ with $y\cdot 0$. Transitivity with the right zero-factor absorption gives $\mathsf{hsame}(y\cdot x,0)$, again using symmetry when the displayed comparison is oriented oppositely. The two transported conclusions form the required conjunction. □

Lean4 ✓ `BEDC.Derived.RingUp.ring zero classifier factor absorption`

Theorem 43.41 (Ring zero-classifier two-sided ideal package)**.** *For BEDC history ring operations satisfying additive associativity, commutativity, left zero, left inverse, addition congruence, multiplication congruence, additive inverse congruence, and both distributive laws, if* $\mathsf{hsame}(x, 0)$ *and* $\mathsf{hsame}(y, 0)$*, then*

$$\mathsf{hsame}(x + y, 0) \wedge \mathsf{hsame}(-x, 0) \wedge \forall z : \mathsf{BHist},\ \mathsf{hsame}(x \cdot z, 0) \wedge \mathsf{hsame}(z \cdot x, 0) \wedge \mathsf{hsame}(x \cdot y, 0).$$

The ten-field fit is: traditional target zero-classifier two-sided ideal closure package; BEDC source $\mathsf{Ring}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability from addition congruence, additive inverse congruence, multiplication congruence, and both distributive laws; ledger the two zero-classifier witnesses and an arbitrary multiplier; core theorem this theorem; exactness the displayed addition, negation, and two-sided multiplication closure; downstream consumer* $\mathsf{Field}^{\uparrow}$ *zero-product exits,* $\mathsf{QuotientRing}^{\uparrow}$ *kernels, and* $\mathsf{Ideal}^{\uparrow}$ *certificates; status* $\mathsf{ProofTarget}$*.*

Proof. First close the zero classifier under addition. Addition congruence transports $x + y$ along $\mathsf{hsame}(x, 0)$ and $\mathsf{hsame}(y, 0)$ to compare it with $0 + 0$, and the left-zero law reduces $0 + 0$ to 0. Transitivity gives $\mathsf{hsame}(x + y, 0)$.

Next close the classifier under additive inverse. Additive inverse congruence transports $\mathsf{hsame}(x, 0)$ to a comparison between $-x$ and -0, while Definition 43.28 identifies -0 with 0. Transitivity gives $\mathsf{hsame}(-x, 0)$.

Finally fix $z : \mathsf{BHist}$. Apply Definition 43.40 to the factor x and multiplier z to obtain $\mathsf{hsame}(x \cdot z, 0)$ and $\mathsf{hsame}(z \cdot x, 0)$. Apply the same theorem with factor x and multiplier y to obtain $\mathsf{hsame}(x \cdot y, 0)$, and package these conclusions with the additive and negative closure witnesses. □

Lean4 ✓ `BEDC.Derived.RingUp.ring zero classifier two sided ideal package`

Theorem 43.42 (Ring zero-classifier square annihilator package)**.** *For BEDC history ring operations satisfying additive associativity, left zero, left inverse, addition congruence, multiplication congruence, and both distributive laws, if* $\mathsf{hsame}(x, 0)$*, then*

$$\mathsf{hsame}(x \cdot x, 0) \wedge \forall c : \mathsf{BHist},\ \mathsf{hsame}((x \cdot x) \cdot c, 0) \wedge \mathsf{hsame}(c \cdot (x \cdot x), 0).$$

The ten-field fit is: traditional target square-zero annihilator package; BEDC source $\mathsf{Ring}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability from multiplication congruence and zero-classifier factor absorption; ledger the original zero-factor witness, the square-zero witness, and the universal multiplier row; core theorem this theorem; exactness the displayed package; downstream consumer* $\mathsf{Field}^{\uparrow}$ *square-apartness and zero-product exit packages; status* $\mathsf{ProofTarget}$*.*

Proof. Apply Definition 43.40 with factor x and multiplier x. Its left component gives the square-zero classifier witness $\mathsf{hsame}(x \cdot x, 0)$.

Now fix an arbitrary multiplier $c : \mathsf{BHist}$. Apply Definition 43.40 again, this time with factor $x \cdot x$ and multiplier c, using the square-zero witness from the first step. The two components give $\mathsf{hsame}((x \cdot x) \cdot c, 0)$ and $\mathsf{hsame}(c \cdot (x \cdot x), 0)$, and packaging them with the square-zero witness is exactly the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.RingUp.ring zero classifier square annihilator package`

Theorem 43.43 (Ring equal-factor difference annihilation)**.** *For BEDC history ring operations satisfying additive associativity, commutativity, left zero, left inverse, addition congruence, multiplication congruence, and both distributive laws, if* $x\mathsf{hsame}y$*, then every* $z : \mathsf{BHist}$ *satisfies*

$$\mathsf{hsame}((x + (-y)) \cdot z, 0) \wedge \mathsf{hsame}(z \cdot (x + (-y)), 0).$$

The ten-field fit is: traditional target ordinary ring difference annihilation; BEDC source $\mathsf{Ring}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability from additive group laws, addition congruence, multiplication congruence, and both distributive laws; ledger the equal-factor witness and the multiplier; core theorem this theorem; exactness additive difference zero exactness feeding zero-factor absorption; standard bridge ordinary ring equal-factor difference annihilation; downstream use FieldUp and RatUp zero-product reasoning; status* $\mathsf{ProofTarget}$*.*

Lean4 ✓ `BEDC.Derived.RingUp.ring equal factor difference annihilation`

Proof. Apply the reverse direction of Definition 43.34 to the classifier witness $x\mathsf{hsame}y$. This turns the displayed difference into a zero-classified factor, namely $x + (-y)\mathsf{hsame}0$.

Now apply Definition 43.40 with factor $x + (-y)$ and multiplier z. The left component gives $\mathsf{hsame}((x+(-y))\cdot z, 0)$, and the right component gives $\mathsf{hsame}(z\cdot(x+(-y)), 0)$; these two components are exactly the displayed conjunction. □

Theorem 43.44 (Ring zero-classifier signed factor absorption)**.** *For BEDC history ring operations satisfying additive associativity, commutativity, left zero, left inverse, addition congruence, multiplication congruence, additive inverse congruence, and both distributive laws, if* $\mathsf{hsame}(x, 0)$*, then every* $y : \mathsf{BHist}$ *satisfies*

$$\mathsf{hsame}((-x)y, 0) \wedge \mathsf{hsame}(y(-x), 0) \wedge \mathsf{hsame}((-x)(-y), 0) \wedge \mathsf{hsame}((-y)(-x), 0).$$

The ten-field fit is: traditional target signed zero-factor absorption in a ring; BEDC source $\mathsf{Ring}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability obligations additive inverse congruence, zero classifier absorption, and both distributive laws; ledger the zero-classifier witness and signed multiplier; core theorem this theorem.*

Proof. First transport the zero-classifier witness through additive inverse. Additive inverse congruence sends $\mathsf{hsame}(x, 0)$ to a comparison between $-x$ and -0, and Definition 43.28 identifies -0 with 0. Transitivity gives $\mathsf{hsame}(-x, 0)$.

Apply Definition 43.40 with factor $-x$ and multiplier y. This yields the two absorptions $\mathsf{hsame}((-x)y, 0)$ and $\mathsf{hsame}(y(-x), 0)$.

Apply the same absorption theorem again with factor $-x$ and multiplier $-y$. Its left and right conclusions are precisely $\mathsf{hsame}((-x)(-y), 0)$ and $\mathsf{hsame}((-y)(-x), 0)$, and the four conclusions package into the stated conjunction. □

Lean4 ✓ `BEDC.Derived.RingUp.ring zero classifier signed factor absorption`

Theorem 43.45 (Ring left-negative product sum vanishes)**.** *For BEDC history operations satisfying additive associativity, left zero, left inverse, operation congruence, and both distributive laws, every pair* x, y *satisfies* $(-x)y + xy\mathsf{hsame}0$*.*

Proof. Apply right distributivity backward to identify $(-x)y+xy$ with $((-x)+x)y$. Transport the left factor across the additive left-inverse law $(-x) + x\mathsf{hsame}0$, then use the left zero-absorption half of multiplication by zero. □

Lean4 ✓ `BEDC.Derived.RingUp.ring mul neg left inverse sum zero`

Theorem 43.46 (Ring right-negative product sum vanishes)**.** *For BEDC history operations satisfying additive associativity, left zero, left inverse, operation congruence, and both distributive laws, every pair* x, y *satisfies* $x(-y) + xy\mathsf{hsame}0$*.*

Proof. Apply left distributivity backward to identify $x(-y) + xy$ with $x((-y) + y)$. Transport the right factor across the additive left-inverse law $(-y) + y\mathsf{hsame}0$, then use the right zero-absorption half of multiplication by zero. □

Lean4 ✓ `BEDC.Derived.RingUp.ring mul neg right inverse sum zero`

Theorem 43.47 (Ring left-negative and right-negative products agree)**.** *For BEDC history operations satisfying additive abelian-group laws, operation congruence, and both distributive laws, the two negative products agree:* $(-x)y\mathsf{hsame}x(-y)$.

Proof. The left-negative and right-negative product sums both collapse to zero after adding the common summand xy on the right. The additive right-zero and right-inverse laws supply the hypotheses for right cancellation in the underlying additive group, so the common summand cancels. □

Lean4 ✓ `BEDC.Derived.RingUp.ring mul neg left right same`

Theorem 43.48 (Ring left-negative product equals negative product)**.** *For BEDC history ring operations satisfying additive associativity, commutativity, left zero, left inverse, operation congruence, and both distributive laws, every pair* x, y *satisfies*

$$\mathsf{hsame}((-x)y, -(xy)).$$

Proof. The left-negative product sum theorem gives $(-x)y + xy\mathsf{hsame}0$. The additive right inverse theorem gives $xy + (-(xy))\mathsf{hsame}0$.

Apply Definition 41.59 with the group operation read as addition, the identity read as 0, and the inverse operation read as negation. The displayed equations are the left-inverse and right-inverse witnesses for xy; Definition 43.31 and Definition 43.27 provide the right identity and right inverse rows required by that GroupUp theorem. □

Lean4 ✓ `BEDC.Derived.RingUp.ring mul neg left eq neg mul`

Theorem 43.49 (Ring right-negative product equals negative product)**.** *For BEDC history ring operations satisfying additive associativity, commutativity, left zero, left inverse, operation congruence, and both distributive laws, every pair* x, y *satisfies*

$$\mathsf{hsame}(x(-y), -(xy)).$$

Proof. Apply left distributivity backward to identify $x(-y) + xy$ with $x((-y) + y)$. Transport the right factor across the additive left-inverse law, use right zero absorption for multiplication, and obtain $x(-y) + xy\mathsf{hsame}0$.

Apply Definition 41.59 in the additive group, with identity 0 and inverse operation given by negation. The new equality is the left-inverse witness for xy, while Definition 43.27 gives the right-inverse witness $xy + (-(xy))\mathsf{hsame}0$; the right identity row comes from Definition 43.31. □

Lean4 ✓ `BEDC.Derived.RingUp.ring mul neg right eq neg mul`

Theorem 43.50 (Ring zero-classifier negated product annihilation)**.** *For BEDC history ring operations satisfying additive associativity, commutativity, left zero, left inverse, addition congruence, multiplication congruence, additive inverse congruence, and both distributive laws, if* $\mathsf{hsame}(x, 0)$*, then every* $y : \mathsf{BHist}$ *satisfies*

$$\mathsf{hsame}(-(xy), 0) \wedge \mathsf{hsame}(-(yx), 0).$$

The ten-field fit is: traditional target negated zero-product annihilation; BEDC source $\mathsf{Ring}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability from signed zero-factor absorption and negative-product identification; ledger the zero-factor witness and the hidden product endpoint; core theorem this theorem; exactness the displayed conjunction; downstream consumer* $\mathsf{Field}^{\uparrow}$ *denominator inverse normalization and zero-product exits; status* $\mathsf{ProofTarget}$*.*

Lean4 ✓ `BEDC.Derived.RingUp.ring zero classifier negated product annihilation`

Proof. Apply Definition 43.44 to the zero-classified factor x and multiplier y. Its first two components give the signed zero-product rows $\mathsf{hsame}((-x)y, 0)$ and $\mathsf{hsame}(y(-x), 0)$.

Apply Definition 43.48 to identify $(-x)y$ with $-(xy)$. Apply Definition 43.49 with the ordered pair (y, x) to identify $y(-x)$ with $-(yx)$.

Use symmetry for the two endpoint identifications where necessary, and then transitivity of hsame with the two signed zero-product rows. This gives $\mathsf{hsame}(-(xy), 0)$ and $\mathsf{hsame}(-(yx), 0)$, which are exactly the displayed conjunction. □

Theorem 43.51 (Ring double-negative product)**.** *For BEDC history ring operations satisfying additive associativity, commutativity, left zero, left inverse, operation congruence, and both distributive laws, every pair* x, y *satisfies*

$$\mathsf{hsame}((-x)(-y), xy).$$

Proof. The left-negative product theorem identifies $(-x)(-y)$ with $-(x(-y))$. The right-negative product theorem identifies $x(-y)$ with $-(xy)$.

Apply Definition 41.60 under the additive-group reading, so the inverse operation is negation and the right identity and right inverse rows are supplied by Definition 43.31 and Definition 43.27. This transports the second equality through the outer inverse. Then Definition 41.57 collapses $-(-(xy))$ to xy under the same additive reading. □

Lean4 ✓ `BEDC.Derived.RingUp.ring mul neg neg eq mul`

Theorem 43.52 (Ring equal-factor signed difference annihilation)**.** *For BEDC history ring operations satisfying additive associativity, commutativity, left zero, left inverse, addition congruence, multiplication congruence, additive inverse congruence, and both distributive laws, if* $x\mathsf{hsame}y$*, then every* $z : \mathsf{BHist}$ *satisfies*

$$\mathsf{hsame}((x+(-y))z, 0) \wedge \mathsf{hsame}(z(x+(-y)), 0) \wedge \mathsf{hsame}((-(x+(-y)))z, 0) \wedge \mathsf{hsame}(z(-(x+(-y))), 0).$$

The ten-field fit is: traditional target signed annihilation of an equal-factor difference; BEDC source $\mathsf{Ring}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability from additive difference exactness, zero-factor absorption, and signed zero-factor absorption; ledger the equality witness, the hidden difference, the sign, and the multiplier; core theorem this theorem; exactness the four displayed zero-classifier rows; downstream consumer* $\mathsf{Field}^{\uparrow}$ *denominator inverse and zero-product packages; status* $\mathsf{ProofTarget}$*.*

Proof. Set $d := x + (-y)$. Apply the reverse direction of Definition 43.34 to the witness $x\mathsf{hsame}y$; this gives $d\mathsf{hsame}0$.

Apply Definition 43.40 to d and multiplier z. This gives the two unsigned products $\mathsf{hsame}(dz, 0)$ and $\mathsf{hsame}(zd, 0)$.

Apply Definition 43.44 to the same zero-classified factor and multiplier. Its first two conjuncts give $\mathsf{hsame}((-d)z, 0)$ and $\mathsf{hsame}(z(-d), 0)$. Substituting $d = x + (-y)$ packages the four displayed zero-classifier rows. □

Lean4 ✓ `BEDC.Derived.RingUp.ring equal factor signed difference annihilation`

Theorem 43.53 (Ring signed square zero ideal package)**.** *For BEDC history ring operations satisfying additive associativity, commutativity, left zero, left inverse, addition congruence, multiplication congruence, additive inverse congruence, and both distributive laws, if* $\mathsf{hsame}(x, 0)$*, then*

$$\mathsf{hsame}((-x)(-x), 0) \wedge \forall c : \mathsf{BHist},\ \mathsf{hsame}(((-x)(-x))c, 0) \wedge \mathsf{hsame}(c((-x)(-x)), 0).$$

The ten-field fit is: traditional target zero ideal closure under signed squares; BEDC source $\mathsf{Ring}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability from signed zero-factor absorption, double-negative product, and zero-classifier factor absorption; ledger the zero witness, signed square endpoint, and arbitrary multiplier; core theorem this theorem; exactness the displayed package; downstream consumer* $\mathsf{Field}^{\uparrow}$ *signed-square and zero-product exits; status* $\mathsf{ProofTarget}$*.*

Proof. Specialize Definition 43.44 with $y = x$. Its third component gives the signed-square zero witness $\mathsf{hsame}((-x)(-x), 0)$. Equivalently, one may orient the same endpoint by combining Definition 43.51 with the ordinary zero-factor package.

Now apply Definition 43.40 with factor $(-x)(-x)$ and multiplier c. The signed-square zero witness supplies the factor premise, and the absorption theorem yields both $\mathsf{hsame}(((-x)(-x))c, 0)$ and $\mathsf{hsame}(c((-x)(-x)), 0)$.

Package the signed-square endpoint together with the universal multiplier statement. This is exactly the displayed zero-ideal consequence. □

Lean4 ✓ `BEDC.Derived.RingUp.ring signed square zero ideal package`

Definition 43.54 (Ring ledger policy)**.** *Record the shared carrier ledger and the operation tree for ring expressions.*

Definition 43.55 ($\mathsf{Ring}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{Ring}^{\uparrow}$*.*

Primitive boundary. $\mathsf{Ring}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Theorem 43.56 (Ring left distributivity over subtraction)**.** *Let R carry a history-level* $\mathsf{Ring}^{\uparrow}$ *certificate with classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, and multiplication $\cdot_R$. Write $x -_R y$ for $x +_R (-_R y)$. For every carried triple a, b, c,*

$$a \cdot_R (b -_R c) \sim_R (a \cdot_R b) -_R (a \cdot_R c).$$

The ten-field fit is: traditional target left distributivity over subtraction; BEDC source $\mathsf{Ring}^{\uparrow}$ *over the carried endpoints of R; carrier the ring carrier; classifier $\sim_R$; stability from the addition congruence and left distributivity fields of Definition 43.26; ledger the three endpoints and the hidden negative summand; core theorem this theorem; exactness the displayed subtraction law; standard bridge ordinary ring distribution over differences; downstream consumer polynomial and module linear-expression normalization; status* $\mathsf{ProofTarget}$*.*

Proof. By the difference abbreviation, the left side is $a \cdot_R (b +_R (-_R c))$. Left distributivity gives

$$a \cdot_R (b +_R (-_R c)) \sim_R (a \cdot_R b) +_R (a \cdot_R (-_R c)).$$

The right-negative product theorem Definition 43.49, read in this certificate, gives

$$a \cdot_R (-_R c) \sim_R -_R(a \cdot_R c).$$

Addition congruence transports this comparison in the right summand while the left summand $a \cdot_R b$ is held fixed. Hence

$$(a \cdot_R b) +_R (a \cdot_R (-_R c)) \sim_R (a \cdot_R b) +_R (-_R(a \cdot_R c)).$$

The final expression is $(a \cdot_R b) -_R (a \cdot_R c)$ by the same difference abbreviation. Transitivity of $\sim_R$ composes the distributivity comparison with the transported sign comparison and yields the displayed law. □

Lean4 ✓ `BEDC.Derived.RingUp.ring left distributivity over subtraction`

Proposition 43.57 (Ring forgets to Monoid certificate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with carrier classifier $\sim_R$, zero 0_R, addition $+_R$, additive inverse $(-)_R$, multiplication $\cdot_R$, and identity 1_R. If the additive operations 0_R, $+_R$, and $(-)_R$, the additive abelian-group stability rows, both distributive rows, the zero-multiplication rows, and every ledger entry whose operation-tree provenance uses a dropped additive constructor are omitted, then the retained carrier, source, monoid pattern, classifier, monoid stability fields, and multiplicative ledger form a $\mathsf{Monoid}^{\uparrow}(R)$ certificate. The carrier R, multiplication $\cdot_R$, identity 1_R, and classifier $\sim_R$ are unchanged.*

Proof. By Definition 43.55, the given certificate supplies carrier, source, pattern, classifier, stability, and ledger data for $\mathsf{Ring}^{\uparrow}(R)$. The retained package keeps exactly the rows whose endpoint claims and expression provenance use only the carrier classifier, multiplication, and the multiplicative identity.

By Definition 43.2, a ring carrier consists of a carrier with classifier, addition, zero, additive inverse, multiplication, one, and ring law fields. Removing the additive coordinates leaves the same carrier R, the same classifier $\sim_R$, the same multiplication $\cdot_R : R \times R \to R$, and the same identity 1_R. These are precisely the carrier data listed in Definition 40.1.

By Definition 43.23, the source side of a ring is an additive $\mathsf{AbGroup}^{\uparrow}$ and a multiplicative $\mathsf{Monoid}^{\uparrow}$ on the same carrier and classifier. Suppressing the additive source leaves the certified multiplicative source over R, $\cdot_R$, 1_R, and $\sim_R$. This is the source required by Definition 40.9.

By Definition 43.24, ring expressions are formed from 0, 1, +, unary minus, and multiplication. Restricting to expressions containing no additive constructor leaves expression formation from 1_R, carried endpoints, and binary multiplication, exactly the monoid pattern of Definition 40.10.

By Definition 43.25, the ring classifier is the shared carrier sameness relation, congruent for both operations. Retaining the relation $\sim_R$ and its multiplication-congruence row gives the classifier required by Definition 40.11. The addition-congruence row mentions the omitted operation and is not a monoid obligation.

For stability, Definition 43.26 lists additive abelian-group laws, multiplicative monoid laws, operation congruence, left distributivity, right distributivity, and zero multiplication laws. The multiplicative monoid laws give associativity and the left and right identity laws for 1_R under $\sim_R$; the retained multiplication-congruence row gives congruence in both arguments. The carrier-classifier rows are unchanged by the projection, so reflexivity and transitivity remain available. Together these are exactly the rows listed in Definition 40.13. The omitted additive, distributive, and zero-multiplication rows mention 0_R, $+_R$, or $(-)_R$, so they have no corresponding $\mathsf{Monoid}^{\uparrow}$ obligation.

Finally, Definition 43.54 records the shared carrier ledger and the operation tree for ring expressions. Removing ledger entries whose provenance uses a dropped additive constructor leaves carrier witnesses, the identity endpoint, and multiplication trees for monoid expressions. This is the ledger policy of Definition 40.33. Hence the retained data satisfy the obligations named in Definition 40.34, with R, $\cdot_R$, 1_R, and $\sim_R$ copied from the original $\mathsf{Ring}^{\uparrow}(R)$ certificate. □

Theorem 43.58 (Ring right distributivity over subtraction)**.** *Let R carry a history-level $\mathsf{Ring}^{\uparrow}$ certificate with classifier $\sim_R$, addition $+_R$, additive inverse $-_R$, and multiplication $\cdot_R$. Write $x -_R y$ for $x +_R (-_R y)$. For every carried triple a, b, c,*

$$(a -_R b) \cdot_R c \sim_R (a \cdot_R c) -_R (b \cdot_R c).$$

The ten-field fit is: traditional target right distributivity over subtraction; BEDC source $\mathsf{Ring}^{\uparrow}$ over the carried endpoints of R; carrier the ring carrier; classifier $\sim_R$; stability from the addition congruence and right distributivity fields of Definition 43.26; ledger the three endpoints and the hidden negative summand; core theorem this theorem; exactness the displayed subtraction law; standard bridge ordinary ring distribution over differences; downstream consumer polynomial and module linear-expression normalization; status ProofTarget.

Proof. By the difference abbreviation, the left side is $(a +_R (-_R b)) \cdot_R c$. Right distributivity gives

$$(a +_R (-_R b)) \cdot_R c \sim_R (a \cdot_R c) +_R ((-_R b) \cdot_R c).$$

The left-negative product theorem Definition 43.48, read in this certificate, gives

$$(-_R b) \cdot_R c \sim_R -_R(b \cdot_R c).$$

Addition congruence transports this comparison in the right summand while the left summand $a \cdot_R c$ is held fixed. Hence

$$(a \cdot_R c) +_R ((-_R b) \cdot_R c) \sim_R (a \cdot_R c) +_R (-_R(b \cdot_R c)).$$

The final expression is $(a \cdot_R c) -_R (b \cdot_R c)$ by the same difference abbreviation. Transitivity of $\sim_R$ composes the distributivity comparison with the transported sign comparison and yields the displayed law. □

Lean4 ✓ `BEDC.Derived.RingUp.ring right distributivity over subtraction`

Proposition 43.59 (Ring forgets to AbGroup certificate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with carrier classifier $\sim_R$, zero 0_R, addition $+_R$, additive inverse $-_R$, multiplication $\cdot_R$, and identity 1_R. If the multiplicative monoid source package, $\cdot_R$, 1_R, the multiplicative monoid stability rows, both distributive rows, the zero-multiplication rows, and every ledger entry whose operation-tree provenance uses a multiplicative constructor are omitted, then the retained carrier, source, additive pattern, classifier, additive stability fields, and additive ledger form an $\mathsf{AbGroup}^{\uparrow}(R)$ certificate. The carrier R, addition $+_R$, zero 0_R, additive inverse $-_R$, and classifier $\sim_R$ are unchanged.*

Proof. By Definition 43.55, the given certificate supplies carrier, source, pattern, classifier, stability, and ledger data for $\mathsf{Ring}^{\uparrow}(R)$. The retained package keeps exactly the rows whose endpoint claims and expression provenance use only the carrier classifier, additive zero, addition, and additive inverse.

By Definition 43.2, a ring carrier consists of a carrier with classifier, addition, zero, additive inverse, multiplication, one, and ring law fields. Removing the multiplicative coordinates leaves

the same carrier R, the same classifier $\sim_R$, the same addition $+_R : R \times R \to R$, the same zero 0_R, and the same additive inverse $-_R$. Reading addition as the abelian-group operation, zero as its identity, and $-_R$ as its inverse operation gives precisely the carrier data required by Definition 42.1.

By Definition 43.23, the source side of a ring is an additive $\mathsf{AbGroup}^{\uparrow}$ and a multiplicative $\mathsf{Monoid}^{\uparrow}$ on the same carrier and classifier. Suppressing the multiplicative source leaves the certified additive $\mathsf{AbGroup}^{\uparrow}$ source over R, $+_R$, 0_R, $-_R$, and $\sim_R$. Unpacking that source through Definition 42.5 gives the certified group carrier plus commutativity field required for the abelian-group source.

By Definition 43.25, the ring classifier is the shared carrier sameness relation, congruent for both operations. Retaining $\sim_R$ and the addition-congruence row gives the classifier required by Definition 42.7. The multiplication-congruence row mentions the omitted operation and has no abelian-group obligation.

By Definition 43.24, ring expressions are formed from 0_R, 1_R, $+_R$, $-_R$, and $\cdot_R$. Restricting to expressions containing no multiplicative constructor leaves carried endpoints, 0_R, addition, and additive inverse. Together with the retained commutativity permission from the additive abelian-group certificate, this is the abelian-group pattern of Definition 42.6.

By Definition 43.26, the stability certificate contains additive abelian-group laws, multiplicative monoid laws, addition and multiplication congruence, distributivity, and zero multiplication laws. The retained additive abelian-group laws supply the group stability fields, commutativity under the classifier, and the compatibility data for commutativity with inverse and operation congruence listed in Definition 42.8. The retained addition-congruence row is the operation-congruence row for the abelian-group operation. The multiplicative monoid rows, multiplication congruence, distributive rows, and zero-multiplication rows all mention $\cdot_R$ or 1_R, so they are not obligations for $\mathsf{AbGroup}^{\uparrow}$.

Finally, Definition 43.54 records the shared carrier ledger and the operation tree for ring expressions. Removing entries whose provenance uses 1_R or $\cdot_R$ leaves carrier witnesses, the additive identity endpoint, addition trees, additive inverse trees, and the commutativity-use records from the additive source. This is the group-expression provenance and commutativity ledger of Definition 42.31. Hence the retained data satisfy the obligations named in Definition 42.32, with R, $+_R$, 0_R, $-_R$, and $\sim_R$ copied from the original $\mathsf{Ring}^{\uparrow}(R)$ certificate. □

Theorem 43.60 (Ring zero absorption from distributivity)**.** *Let R carry a history-level $\mathsf{Ring}^{\uparrow}$ certificate with classifier $\sim_R$, addition $+$, zero endpoint 0_R, and multiplication $\cdot$. Assume the additive component supplies additive left cancellation under $\sim_R$, as obtained from Definition 41.66 for the additive group part of Definition 43.23. If the ring stability fields of Definition 43.26 supply multiplication congruence, left distributivity, and right distributivity, then every endpoint x satisfies*

$$0_R \cdot x \sim_R 0_R \qquad \textit{and} \qquad x \cdot 0_R \sim_R 0_R.$$

Proof. The additive left-zero row gives $0_R + 0_R \sim_R 0_R$. By multiplication congruence, for any x,

$$x \cdot (0_R + 0_R) \sim_R x \cdot 0_R.$$

Left distributivity gives

$$x \cdot (0_R + 0_R) \sim_R (x \cdot 0_R) + (x \cdot 0_R).$$

Writing $u = x \cdot 0_R$, symmetry and transitivity of the classifier give $u \sim_R u + u$. The additive right-zero theorem, Definition 43.31, gives $u + 0_R \sim_R u$, hence

$$u + 0_R \sim_R u + u.$$

Additive left cancellation of the common summand u yields $0_R \sim_R u$, and symmetry gives $x \cdot 0_R \sim_R 0_R$.

For the other side, multiplication congruence gives

$$(0_R + 0_R) \cdot x \sim_R 0_R \cdot x,$$

while right distributivity gives

$$(0_R + 0_R) \cdot x \sim_R (0_R \cdot x) + (0_R \cdot x).$$

Writing $v = 0_R \cdot x$, the same transitivity step gives $v \sim_R v + v$. Again Definition 43.31 gives $v + 0_R \sim_R v$, so

$$v + 0_R \sim_R v + v.$$

Additive left cancellation of the common summand v gives $0_R \sim_R v$, and symmetry gives $0_R \cdot x \sim_R 0_R$. □

Theorem 43.61 (Ring finite expression ledger induction)**.** *Let R carry a history-level* $\mathsf{Ring}^{\uparrow}$ *certificate with carrier C_R, classifier $\sim_R$, addition $+$, multiplication $\cdot$, zero endpoint 0_R, negation $-$, stability rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. Every finite* $\mathsf{Ring}^{\uparrow}$ *expression ledger whose entries are generated from displayed endpoints by the additive rows, multiplicative rows, zero row, negation row, stability rows, and local* NameCert *row admits a constructor-by-constructor BEDC induction. Each induction branch reads only the visible ledger entry and the earlier finite subledgers named by its constructor.*

Consequently any equality, absorption, distributivity, or normal-form read over such a ledger is justified by finite BHist *inspection of the same rows, not by an ambient quotient-ring induction principle or a host algebraic normalizer.*

Proof. Begin with the generating rows. Endpoint entries, the zero endpoint, and named NameCert rows are already visible as finite BHist data, so the base cases require no quotient carrier or ambient equality class.

For the additive, multiplicative, and negation constructors, inspect the displayed operation row that produced the ledger entry. The induction hypotheses are attached to the finite input subledgers, and the stability rows transport the corresponding classifier reads through $+$, $\cdot$, and $-$.

Finally read componentwise hsame transport, displayed Cont replay, and Pkg provenance. These structural rows repack the same finite ledger without adding a host quotient coordinate. Thus the induction remains a BEDC induction over the recorded expression ledger, and every algebraic read stays inside the displayed $\mathsf{Ring}^{\uparrow}$ certificate surface. □

Theorem 43.62 (Ring quotient-free normal-form route)**.** *For the same history-level* $\mathsf{Ring}^{\uparrow}$ *certificate, any normal-form read produced from the finite expression ledger of Definition 43.61 remains a quotient-free route through* BHist*,* Cont*,* Pkg*, classifier stability, and local* NameCert *data. A normal form may cite additive associativity, additive inverse, zero absorption, multiplication stability, and distributivity only as displayed certificate rows over $\sim_R$.*

It cannot be reread as equality in a host quotient ring, equality of quotient representatives, a selected canonical representative, a polynomial normalization algorithm outside the packet, or an ambient algebra theorem over an unrecorded carrier.

Proof. Use the finite expression-ledger induction. Each normal-form step is one of the ledger constructors or one of the displayed stability rows, so its inputs and output are still named histories connected by the carrier classifier.

The zero-absorption theorem above supplies the only multiplication-by-zero simplification used here, and it was derived from distributivity plus additive cancellation inside the same classifier. Additive inverse, associativity, and multiplication stability are read in the same way: as rows of the $\mathsf{Ring}^{\uparrow}$ certificate, not as quotient-ring facts.

The structural rows Cont and Pkg preserve provenance of the normal-form read. Since no row stores a quotient carrier, selected representative, external polynomial normalizer, or ambient ring object, the normal-form route is exactly the finite BEDC route described in the statement. □

Theorem 43.63 (RingUp public singleton operation surface)**.** *For the concrete singleton history ring instance of Definition 43.3, the public surface consists of the singleton carrier A_{e}, the classifier R_{e}, and the five displayed operations*

$$\mathsf{add}(h,k) := \mathsf{append}(h,k), \qquad \mathsf{neg}(h) := \mathsf{e}, \qquad 0 := \mathsf{e},$$

together with

$$\mathsf{mul}(h,k) := \mathsf{append}(h,k), \qquad 1 := \mathsf{e}.$$

On carried endpoints this surface is closed under addition, negation, multiplication, zero, and one; append endpoints have exact singleton classifier readback; multiplication continuations classify exactly through the singleton continuation row; multiplication by zero is absorbed; and the exposed ledger contains only the operation tree plus singleton endpoint witnesses, so the zero-classifier ideal package contributes no hidden endpoint channel.

Proof. The carrier, classifier, and operation rows are those displayed in Definition 43.3. The RingUp laws of Theorem 43.4 supply the additive group rows, multiplicative monoid rows, congruence rows, and both distributivity rows for this same tuple.

Endpoint exactness is read from the singleton classifier lemmas. The append commutation row of Theorem 43.12 exposes no data beyond the two singleton endpoint witnesses, while Theorem 43.15 records that continuation readback after multiplication is again exactly the singleton carrier condition on the continuation input and output.

The zero boundary is public for the same reason. The zero-factor absorption of Theorem 43.39 prevents a zero multiplication branch from producing a visible endpoint, and Theorem 43.41 packages addition, negation, and two-sided multiplication closure for zero-classified inputs. Thus the public ledger exposes precisely the operation tree and the singleton endpoint certificates already named above, with no additional history data available behind the classifier. □

Theorem 43.64 (RingUp singleton operation table exhaustion)**.** *Every public $\mathsf{Ring}^{\uparrow}$ consumer read from the concrete singleton certificate is exhausted by the five operation rows* add, neg, 0, mul, *and* 1, *together with their singleton endpoint witnesses. No read of the public certificate exposes an additional history endpoint, quotient carrier, polynomial row, module row, or non-singleton multiplication table.*

Proof. Begin with the public singleton operation surface of Definition 43.63. It lists the carrier A_{e}, classifier R_{e}, and exactly the five displayed operation rows.

The operation laws come from Definition 43.4. Since every carried endpoint is classified with e, each addition, negation, zero, multiplication, and one read returns the same singleton endpoint witness.

The remaining public boundary does not add a sixth operation row. Definition 43.39 controls the zero-multiplication branch, and Definition 43.41 keeps the zero-classifier package inside the same singleton endpoint. Thus every public consumer read is one of the five operation-table rows. □

Theorem 43.65 (RingUp algebra sibling route)**.** *The singleton public* $\mathsf{Ring}^{\uparrow}$ *surface consumes additive-group rows from chapter 42, multiplicative-unit rows from chapter 40, and commutative specialization rows from chapter 44 before downstream algebra consumers read* $\mathsf{Ring}^{\uparrow}$*. This route exposes the five-operation table without asserting a quotient ring or a non-singleton carrier.*

Proof. Project the public table of Definition 43.64. The additive rows add, neg, and 0 are read through the abelian-group surface, so every additive consumer keeps the $\mathsf{AbGroup}^{\uparrow}$ sibling route.

The multiplicative rows mul and 1 are read through the monoid surface. The singleton classifier and endpoint witnesses keep this multiplicative handoff inside the same finite operation table.

Finally, any commutative specialization is routed through the $\mathsf{CommRing}^{\uparrow}$ sibling before it is exported to downstream algebra. Since the projected data are exactly the five singleton operation rows and their endpoint witnesses, the route introduces no quotient-ring claim and no non-singleton carrier. □

Theorem 43.66 (RingUp singleton public certificate scope)**.** *The public scope of the concrete singleton* $\mathsf{Ring}^{\uparrow}$ *certificate consists of ten fields: the BEDC source* BHist*, the carrier* A_{e}*, the classifier* R_{e}*, stability under singleton transport, the public* add *row, the public* neg *row, the public* 0 *row, the public* mul *row, the public* 1 *row, and the standard bridge to the terminal ring. The five operation fields form the visible ledger table, and their endpoint exactness says precisely that a consumer row is present iff its endpoint is the singleton* e *endpoint.*

Proof. Project the singleton source and algebraic laws from Definition 43.4. The source is the displayed BHist row, while A_{e} and R_{e} give the carrier and classifier over the same endpoint.

Next read the public operation table through Definition 43.63 and Definition 43.64. These rows account for addition, negation, zero, multiplication, and one, and each read carries the singleton endpoint iff supplied by the classifier.

Finally apply Definition 43.39 and Definition 43.41 to keep the zero and multiplication boundary inside the same public table. Repacking these rows with the checked standard bridge exposes the terminal ring and no additional consumer channel. □

Lean4 ✓ `BEDC.Derived.RingUp.RingUp StdBridge`

Closure status for $\mathsf{NameCert}_{\mathsf{Ring}^{\uparrow}}$**.**

Constructive story: The ring surface reuses one empty-history endpoint twice, letting the same singleton carry both the additive and multiplicative roles. A history is admitted only when it is history-equal to e, and the classifier is the corresponding singleton relation, so addition by continuation, negation, zero, multiplication by continuation, and one all land back at the same endpoint. The source is the singleton predicate, the pattern records those operation rows together with distributivity, zero absorption, and the signed-square and subtraction packages, and the ledger keeps every visible singleton aligned with its raw history. Since a one-element history class is inhabited by e and history-equality is an equivalence that preserves the class, the five name-certificate obligations hold without any separate algebraic carrier. A history h lies in the signature gap of a $\mathsf{Ring}^{\uparrow}$ token p when the source-domain accepts h, the signature relation pairs it with an answer history and evidence ledger, and the token-introduction relation names that answer as p; after unfolding, h is history-equal to e and p is the singleton ring element. The public operation surface and terminal bridge expose this same endpoint table to downstream consumers, including the opposite-ring certificate. The chapter registers this two-operation singleton construction under the name $\mathsf{Ring}^{\uparrow}$; addition and multiplication share one classifier on one endpoint, with no polynomial, quotient, field, or non-singleton ring structure introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Ring}^{\uparrow}}$, maturePackageClosed)

Scope closed: This chapter binds the mature singleton RingUp package consisting of the carrier A_{e}, classifier R_{e}, displayed addition, negation, zero, multiplication, one, distributivity, zero-absorption, signed-square and subtraction packages, opposite-ring certificate, and public singleton operation surface.

Formal verification: FormalStatus(NameCert$_{\mathsf{Ring}\uparrow}$, bridgeChecked)

Lean target: `BEDC.Derived.RingUp.RingSingletonEmptyHistory\_laws`

Bridge status: bridgeChecked

Not claimed: It does not close arbitrary non-singleton rings, polynomial rings, fields, modules, quotient-ring theory, or machine-checked standard bridge data.

Upgrade path: No further upgrade: the chapter is at the top of the formal axis.

Chapter 44

A Concrete Naming Certificate for $\mathsf{CommRing}^{\uparrow}$

The commutative ring interface $\mathsf{CommRing}^{\uparrow}$ extends chapter 43 with the commutativity field $a \cdot b = b \cdot a$ for the multiplicative operation under the carrier's classifier. The integer ring from chapter 31 is the canonical concrete instance.

44.1 Carrier definition

Definition 44.1 (CommRing carrier)**.** *Use a ring setup extended with commutativity of multiplication.*

44.2 Concrete singleton history commutative ring instance

Definition 44.2 (Concrete singleton history commutative ring instance)**.** *On the concrete* BHist *carrier, define* $A_{\mathsf{e}}(h) := \mathsf{hsame}(h, \mathsf{e})$ *and*

$$R_{\mathsf{e}}(h, k) := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h, k).$$

The commutative-ring operation tuple is

$$\mathsf{add}(h, k) := \mathsf{append}(h, k), \qquad \mathsf{neg}(h) := \mathsf{e}, \qquad 0 := \mathsf{e},$$

with multiplication and unit

$$\mathsf{mul}(h, k) := \mathsf{append}(h, k), \qquad 1 := \mathsf{e}.$$

Theorem 44.3 (Concrete singleton history commutative ring laws)**.** *The concrete singleton history commutative ring instance of Definition 44.2 has carrier containing* 0*, is closed under addition, negation, and multiplication, has left and right additive zero laws under* R_{e}*, and satisfies multiplicative commutativity under* R_{e}*.*

Proof. The carrier witness $A_{\mathsf{e}}(0)$ is reflexive $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$. For addition and multiplication closure, if $A_{\mathsf{e}}(x)$ and $A_{\mathsf{e}}(y)$ hold, then both inputs are the empty history, so $\mathsf{append}(x, y)$ reduces to e. The negation operation is constantly e, so its closure is immediate from the same reflexive endpoint witness.

For the two additive zero laws, the singleton input witness identifies x with e; after that identification, both $\mathsf{append}(\mathsf{e}, x)$ and $\mathsf{append}(x, \mathsf{e})$ are the empty history, and the classifier packages the two carrier endpoints with reflexive hsame. Multiplicative commutativity is identical: two singleton carrier witnesses identify x and y with e, so the two append products are both e and are related by R_{e}. □

Lean4 ✓ `BEDC.Derived.CommRingUp.concrete singleton history commring laws`

Theorem 44.4 (Concrete singleton history CommRingUp full schema laws)**.** *For the concrete singleton history commutative ring instance of Definition 44.2, the tuple* $(A_{\mathsf{e}}, R_{\mathsf{e}}, \mathsf{add}, 0, \mathsf{neg}, \mathsf{mul}, 1)$ *satisfies the full* $\mathsf{CommRing}^{\uparrow}$ *law package: all* $\mathsf{Ring}^{\uparrow}$ *laws from Theorem 43.4, multiplicative commutativity from Theorem 44.3, and stability of the commutativity row under* R_{e}*-classified replacement of carried inputs. Its certificate fit has ten fields: traditional target the one-element commutative ring; BEDC source* BHist*; carrier* A_{e}*; classifier* R_{e}*; stability obligations the* $\mathsf{Ring}^{\uparrow}$ *package plus commutativity compatibility; ledger append-operation provenance; core theorem Theorem 44.4; exactness singleton endpoint classification; standard bridge the terminal commutative ring; status* $\mathsf{ProofTarget}$*.*

Proof. The $\mathsf{Ring}^{\uparrow}$ part is exactly Theorem 43.4 for the displayed append-operation tuple. It supplies the additive abelian-group laws, multiplicative monoid laws, addition and multiplication congruence, and the two distributive laws over A_{e} and R_{e}.

The commutativity row is exactly Theorem 44.3, read at the same append multiplication. For carried inputs x and y, the singleton endpoint witnesses identify both products $\mathsf{mul}(x, y)$ and $\mathsf{mul}(y, x)$ with e, so the displayed row is an R_{e}-classification.

For compatibility of that row, suppose the two carried inputs are replaced by R_{e}-classified inputs. Multiplication congruence from the $\mathsf{Ring}^{\uparrow}$ package transports $\mathsf{mul}(x, y)$ to the replacement product, and the same congruence transports $\mathsf{mul}(y, x)$ to the reversed replacement product. Compose these transported relations with the commutativity row by symmetry and transitivity of hsame; the carrier fields are preserved by the same singleton endpoint classification, so the commutativity row remains R_{e}-classified after replacement. □

Lean4 ✓ `BEDC.Derived.CommRingUp.concrete singleton history commring full schema laws`

Theorem 44.5 (Concrete singleton history CommRingUp certificate boundary)**.** *For the concrete tuple of Definition 44.2, the carrier-aware classifier* R_{e} *supplies the* $\mathsf{SemanticNameCert}$ *rows. Together with Theorem 44.4, these rows supply the concrete* $\mathsf{CommRing}^{\uparrow}$ *certificate boundary over* BHist *with the following ten fields:*

1. *traditional target: the terminal commutative ring;*
2. *BEDC source: the history carrier* BHist *with source* A_{e}*;*
3. *carrier:* A_{e}*;*
4. *classifier:* R_{e}*;*
5. *stability obligations: the* $\mathsf{Ring}^{\uparrow}$ *package plus multiplicative commutativity compatibility;*
6. *ledger: append-operation provenance for addition and multiplication, constant-operation provenance for negation, and empty-history provenance for* 0 *and* 1*;*
7. *core theorem: Theorem 44.4;*
8. *exactness: singleton endpoint classification by* A_{e} *and* hsame*;*

9. *standard bridge: the ordinary terminal commutative ring;*
10. *status:* ProofTarget.

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingUp concrete to schema`

Proof. Apply Theorem 41.88 to the singleton history carrier A_{e} and classifier R_{e}. It supplies reflexivity, symmetry, transitivity, and carrier transport for the carrier-aware semantic naming certificate.

The operation endpoints are exactly the endpoints displayed in Definition 44.2: append for addition and multiplication, the constant endpoint e for negation, and e for both distinguished constants. Thus the BEDC source, carrier, classifier, ledger, and exactness rows are the concrete rows named in the definition.

The law rows are supplied by Theorem 44.4. That theorem packages the additive, multiplicative, distributive, congruence, and multiplicative-commutativity rows over the same tuple.

Combining the SemanticNameCert rows with the law package gives the displayed ten-field $\mathsf{CommRing}^{\uparrow}$ certificate boundary. The terminal commutative ring is the standard bridge, and the boundary is recorded with status ProofTarget. □

44.3 Concrete singleton empty-history commutative ring instance

Definition 44.6 (Singleton empty-history commutative ring instance)**.** *Let A_{e} be the singleton history source of Definition 36.169 at $a_0 = \mathsf{e}$. Define the classifier*

$$\rho_{\mathsf{e}}(h,k) \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h,k).$$

Define the concrete commutative ring operations by

$$\mathsf{add}(h,k) := \mathsf{e}, \qquad \mathsf{neg}(h) := \mathsf{e}, \qquad 0 := \mathsf{e}, \qquad \mathsf{mul}(h,k) := \mathsf{e}, \qquad 1 := \mathsf{e}.$$

Equip this singleton ring tuple with the multiplicative commutativity field

$$\rho_{\mathsf{e}}(\mathsf{mul}(x,y), \mathsf{mul}(y,x)).$$

The concrete commutative-ring certificate has the following ten fields:

1. *traditional target: the one-element commutative ring;*
2. *BEDC source:* BHist *with the singleton empty-history ring instance;*
3. *carrier: A_{e};*
4. *classifier: ρ_{e};*
5. *stability obligations: the singleton ring laws, multiplicative commutativity, and multiplication-commutativity compatibility;*
6. *ledger: constant-operation provenance for* 0, 1, *addition, negation, and multiplication;*
7. *core theorem: Theorem 44.7;*
8. *exactness: endpoint classification by membership in the singleton carrier and* hsame*;*
9. *standard bridge: the ordinary one-element commutative ring;*
10. *status:* ProofTarget.

Theorem 44.7 (Singleton empty-history commutative ring laws)**.** *The singleton empty-history commutative-ring tuple supplies a concrete* SemanticNameCert *for the carrier* A_{e} *and classifier* ρ_{e}*. Its operation rows include the displayed constant* add*,* neg*, and* mul *endpoints, multiplicative commutativity, both distributive laws, and the left unit row for* 1 *under* ρ_{e}*.*

Proof. The carrier-aware classifier ρ_{e} is a semantic naming certificate. Carrier inhabitance is witnessed by e. Reflexivity uses the given carrier witness and $\mathsf{hsame}(h, h)$; symmetry swaps the endpoint carrier witnesses and uses symmetry of hsame; transitivity composes the hsame components and keeps the outer carrier witnesses. Carrier transport is the right endpoint carrier field of the classifier.

The concrete add, neg, and mul endpoint rows close because all three displayed operations are constant at e. The two carrier witnesses are therefore singleton witnesses for e, and the relation component is reflexive $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$.

The ring-law part is exactly Theorem 43.6 applied to the displayed singleton empty-history operation tuple. This supplies carrier inhabitance, additive abelian-group laws, multiplicative monoid laws, operation congruence, both distributive laws, the unit laws, and zero multiplication laws.

For multiplicative commutativity, both $\mathsf{mul}(x, y)$ and $\mathsf{mul}(y, x)$ are definitionally e. The two endpoint witnesses for ρ_{e} are the singleton carrier witnesses for e, and the relation component is $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.CommRingUp.singleton empty history commring laws`

Proposition 44.8 (CommRing forgets to Ring certificate)**.** *Let* R *carry a* $\mathsf{CommRing}^{\uparrow}(R)$ *certificate. If the multiplication-commutativity row and its commutative-ring-specific ledger entries are omitted from the exported package, the retained carrier, source, ring pattern, classifier, ring stability fields, and ring ledger form a* $\mathsf{Ring}^{\uparrow}(R)$ *certificate. The operations* 0_R*,* 1_R*,* $+_R$*,* $(-)_R$*,* $\cdot_R$*, and the carrier classifier on* R *are unchanged.*

Proof. By Definition 44.59, a commutative-ring certificate supplies the same carrier operations as a ring certificate, together with the extra multiplication-commutativity requirement. Removing only that extra row leaves the carrier data of Definition 43.2: zero, one, addition, additive inverse, multiplication, and the same carrier classifier.

The source, pattern, classifier, stability, and ledger rows retained by this projection are exactly the ring rows. The source still contains the additive abelian-group and multiplicative monoid data required by Definition 43.23; the pattern still generates the ring expression language; and the stability rows still contain the ring congruence, distributivity, zero-multiplication, and unit laws listed in Definition 43.26.

The discarded entries are precisely those whose only role is to witness or record multiplication commutativity. Therefore the retained rows satisfy Definition 43.55 with the same operations and classifier carried by the original $\mathsf{CommRing}^{\uparrow}$ certificate. □

Theorem 44.9 (CommRing singleton negation empty endpoint)**.** *For histories* $h, t : \mathsf{BHist}$ *with* $A_{\mathsf{e}}(h)$*,*

$$\rho_{\mathsf{e}}(\mathsf{CommRingSingletonNeg}(h), t) \iff A_{\mathsf{e}}(t) \wedge \mathsf{hsame}(\mathsf{CommRingSingletonNeg}(h), \mathsf{e}).$$

Proof. The singleton commutative-ring negation endpoint is definitionally e. Unfolding the carrier-aware classifier gives the forward direction directly: the right carrier field is $A_{\mathsf{e}}(t)$ and the left carrier field is the empty endpoint for $\mathsf{CommRingSingletonNeg}(h)$.

For the converse, the same two endpoint facts are the left and right carrier fields. Symmetry of hsame compares t back to e, and transitivity through the negation endpoint supplies the relation component of ρ_{e}. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonClassifier neg empty endpoint iff`

Theorem 44.10 (CommRing singleton empty multiplication context carrier)**.** *For singleton empty-history CommRing histories L and R, the classifier comparison*

$$\rho_{\mathsf{e}}(\mathsf{append}(L, \mathsf{mul}(x, y)), \mathsf{append}(R, out))$$

holds exactly when out lies in the singleton empty carrier.

Proof. The multiplication endpoint of the singleton empty-history CommRing tuple is definitionally e. In the forward direction, the right carrier field of the classifier identifies $\mathsf{append}(R, out)$ with e, and append-empty inversion extracts *out*hsamee.

Conversely, if *out*hsamee, then the carrier witnesses for L and R rebuild the two append endpoints as empty endpoints by append-empty inversion. Transitivity through e compares the endpoints, so the classifier package is recovered. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commringSingletonEmptyClassifier mul context carrier iff`

Theorem 44.11 (CommRing singleton empty operation context carrier package)**.** *For singleton empty-history CommRing histories L and R, the three operation contexts*

$$\mathsf{append}(L, \mathsf{add}(x, y)), \quad \mathsf{append}(L, \mathsf{neg}(x)), \quad \mathsf{append}(L, \mathsf{mul}(x, y))$$

are classified against $\mathsf{append}(R, out)$ *precisely when out lies in the singleton empty carrier.*

Proof. The add, neg, and mul endpoints of the singleton empty-history CommRing tuple are all definitionally e. The forward direction reads the right carrier field of the classifier and applies append-empty inversion to recover *out*hsamee. Conversely, the carrier witnesses for L, R, and *out* rebuild both append endpoints as empty endpoints, and transitivity through e supplies the classifier relation. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commringSingletonEmptyClassifier operation context carrier package`

Theorem 44.12 (CommRing singleton classifier visible-right exclusion)**.** *For histories h, p, q :* BHist*, neither $\rho_{\mathsf{e}}(h, \mathsf{append}(p, \mathsf{e0}(q)))$ nor $\rho_{\mathsf{e}}(h, \mathsf{append}(p, \mathsf{e1}(q)))$ can hold.*

Proof. Unfold the singleton commutative-ring classifier. In either branch, the right carrier field says that the displayed append endpoint is e. The empty-result inversion theorem for append splits this into an empty prefix and an empty visible tail. The latter would identify $\mathsf{e0}(q)$ or $\mathsf{e1}(q)$ with e, contradicting the constructor separation of BHist. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonClassifier append visible right absurd`

Theorem 44.13 (CommRing singleton classifier visible-prefix exclusion)**.** *For histories p, q, h :* BHist*, neither $\rho_{\mathsf{e}}(\mathsf{append}(\mathsf{e0}(p), q), h)$ nor $\rho_{\mathsf{e}}(\mathsf{append}(\mathsf{e1}(p), q), h)$ can hold.*

Proof. Unfold the singleton commutative-ring classifier. In either branch, the left carrier field says that the displayed append endpoint is e. The empty-result inversion theorem for append splits this into an empty visible prefix and an empty suffix. The former would identify $\mathsf{e0}(p)$ or $\mathsf{e1}(p)$ with e, contradicting the constructor separation of BHist. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonClassifier append visible prefix absurd`

Theorem 44.14 (CommRing singleton classifier visible boundary package)**.** *For histories h, p, q : BHist, the singleton commutative-ring classifier has the two-sided visible append boundary exclusion*

$$(\rho_{\mathsf{e}}(h, \mathsf{append}(p, \mathsf{e0}(q))) \to \bot) \wedge (\rho_{\mathsf{e}}(h, \mathsf{append}(p, \mathsf{e1}(q))) \to \bot) \wedge (\rho_{\mathsf{e}}(\mathsf{append}(\mathsf{e0}(p), q), h) \to \bot) \wedge (\rho_{\mathsf{e}}(\mathsf{append}(\mathsf{e1}(p), q),$$

The ten-field fit is: traditional target singleton classifier no-confusion for visible append boundaries; BEDC source singleton $\mathsf{CommRing}^{\uparrow}$ *over* BHist*; carrier A_{e}; classifier ρ_{e}; stability from the two checked classifier exclusions; ledger the visible prefix/tail constructor; core theorem this block; exactness the four displayed impossibility clauses; downstream consumer singleton CommRing certificate boundary and* $\mathsf{Field}^{\uparrow}$ *terminal-object no-confusion; status* $\mathsf{ProofTarget}$.

Proof. The two right-endpoint clauses are exactly the two branches of Definition 44.12. They exclude classifier witnesses whose second endpoint is an append ending in $\mathsf{e0}(q)$ or $\mathsf{e1}(q)$.

The two left-endpoint clauses are exactly the two branches of Definition 44.13. They exclude classifier witnesses whose first endpoint is an append beginning with $\mathsf{e0}(p)$ or $\mathsf{e1}(p)$.

Repack these four one-sided implications in the displayed order. No additional constructor analysis is needed beyond the checked visible-right and visible-prefix exclusions. □

Theorem 44.15 (CommRing singleton carrier visible exclusion)**.** *For every history p : BHist, neither $\mathsf{e0}(p)$ nor $\mathsf{e1}(p)$ lies in the singleton commutative-ring carrier.*

Proof. Unfold the singleton carrier as equality with e. The two generated history constructors are separated from the empty history, so both endpoint carrier witnesses are impossible. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonCarrier visible absurd`

Theorem 44.16 (CommRing singleton carrier visible-head append exclusion)**.** *For histories h, k : BHist, neither $\mathsf{append}(\mathsf{e0}(h), k)$ nor $\mathsf{append}(\mathsf{e1}(h), k)$ lies in the singleton commutative-ring carrier.*

Proof. In either branch, the singleton carrier identifies the displayed append history with e. Empty-result inversion for append then identifies the visible head $\mathsf{e0}(h)$ or $\mathsf{e1}(h)$ with e, contradicting constructor separation for BHist. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonCarrier append visible head absurd`

Theorem 44.17 (CommRing singleton carrier visible-tail append exclusion)**.** *For histories p, q : BHist, neither $\mathsf{append}(p, \mathsf{e0}(q))$ nor $\mathsf{append}(p, \mathsf{e1}(q))$ lies in the singleton commutative-ring carrier.*

Proof. In either branch, the singleton carrier identifies the displayed append history with e. Empty-result inversion for append then identifies the visible tail $\mathsf{e0}(q)$ or $\mathsf{e1}(q)$ with e, contradicting constructor separation for BHist. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonCarrier append visible tail absurd`

Theorem 44.18 (CommRing singleton carrier append commutation)**.** *For histories h, k : BHist,*

$$\mathsf{CommRingSingletonCarrier}(\mathsf{append}(h, k)) \iff \mathsf{CommRingSingletonCarrier}(\mathsf{append}(k, h)).$$

Proof. In either direction, empty-result inversion for append splits the singleton carrier witness into singleton witnesses for the two factors. Reversing the two factors and applying empty-result construction rebuilds the singleton carrier witness for the commuted append. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonCarrier append comm iff`

Theorem 44.19 (CommRing singleton classifier append context cancellation)**.** *For singleton commutative-ring carrier contexts* $L, R : \mathsf{BHist}$ *and histories* $Q, S : \mathsf{BHist}$*,*

$$\rho_{\mathsf{e}}(\mathsf{append}(L, Q), \mathsf{append}(R, S)) \iff \rho_{\mathsf{e}}(Q, S).$$

Proof. In the forward direction, the two classifier carrier fields identify $\mathsf{append}(L, Q)$ and $\mathsf{append}(R, S)$ with e. Empty-result inversion for append splits these into endpoint witnesses for Q and S. Those two recovered carrier witnesses compose with symmetry to give $\mathsf{hsame}(Q, S)$.

Conversely, if $\rho_{\mathsf{e}}(Q, S)$ holds and both contexts are singleton carriers, empty-result construction for append gives singleton carrier witnesses for $\mathsf{append}(L, Q)$ and $\mathsf{append}(R, S)$. Composing the two append carrier witnesses with symmetry gives the classifier relation component between the contextual endpoints. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonClassifier append context cancel iff`

Theorem 44.20 (CommRing singleton classifier append context carrier split)**.** *If the singleton commutative-ring classifier relates two appended endpoints, then all four append factors are singleton carriers:*

$$\rho_{\mathsf{e}}(\mathsf{append}(L, Q), \mathsf{append}(R, S)) \implies A_{\mathsf{e}}(L) \wedge A_{\mathsf{e}}(Q) \wedge A_{\mathsf{e}}(R) \wedge A_{\mathsf{e}}(S).$$

Proof. The classifier supplies singleton-carrier witnesses for $\mathsf{append}(L, Q)$ and $\mathsf{append}(R, S)$. Empty-result inversion for append splits the first witness into carrier witnesses for L and Q, and splits the second witness into carrier witnesses for R and S. Conjunction introduction packages the four factors. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonClassifier append context carrier split`

Theorem 44.21 (CommRing singleton classifier append-left carrier exactness)**.** *For histories* $h, k, out : \mathsf{BHist}$*, the singleton commutative-ring classifier relates the appended left endpoint to* out *exactly when all three visible histories are singleton carriers:*

$$\rho_{\mathsf{e}}(\mathsf{append}(h, k), out) \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge A_{\mathsf{e}}(out).$$

Proof. The forward direction projects the left endpoint carrier from the classifier and applies empty-result inversion for append, yielding singleton carrier witnesses for h and k. The right endpoint carrier is the second classifier field.

Conversely, the carrier witnesses for h and k rebuild a singleton carrier witness for $\mathsf{append}(h, k)$ by empty-result construction. Together with the carrier witness for out, transitivity through e and symmetry give the displayed singleton classifier. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonClassifier append left carrier iff`

Theorem 44.22 (CommRing singleton classifier append-right carrier exactness)**.** *For histories* $h, k, out : \mathsf{BHist}$*, the singleton commutative-ring classifier relates* out *to the appended right endpoint exactly when all three visible histories are singleton carriers:*

$$\rho_{\mathsf{e}}(out, \mathsf{append}(h, k)) \iff A_{\mathsf{e}}(out) \wedge A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

Proof. The forward direction projects the right endpoint carrier from the classifier and splits the append carrier by empty-result inversion. Conversely, singleton carrier witnesses for h and k rebuild the appended right carrier. Together with the carrier witness for *out*, transitivity through e gives the displayed classifier. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonClassifier append right carrier iff`

Theorem 44.23 (CommRing singleton classifier append commuted factors)**.** *For histories* $h, h', k, k' : \mathsf{BHist}$*, if the singleton commutative-ring classifier relates the two appended endpoints*

$$\rho_{\mathsf{e}}(\mathsf{append}(h, k), \mathsf{append}(h', k')),$$

then it also relates the endpoints with the two append factors exchanged:

$$\rho_{\mathsf{e}}(\mathsf{append}(k, h), \mathsf{append}(k', h')).$$

Proof. The classifier gives singleton carrier witnesses for $\mathsf{append}(h, k)$ and $\mathsf{append}(h', k')$. Empty-result inversion for append splits each witness into singleton carrier witnesses for its two factors. Swapping the two factors on each side and applying empty-result construction rebuilds singleton carrier witnesses for $\mathsf{append}(k, h)$ and $\mathsf{append}(k', h')$. Both rebuilt endpoints are therefore classified through e, so transitivity and symmetry of hsame give the displayed singleton classifier. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonClassifier append comm congr`

Theorem 44.24 (CommRing singleton classifier append commutativity compatibility)**.** *For histories* $x, x', y, y' : \mathsf{BHist}$*, if the singleton commutative-ring classifier relates* x *to* x' *and relates* y *to* y'*, then it classifies three append endpoints:*

$$\rho_{\mathsf{e}}(\mathsf{append}(x, y), \mathsf{append}(y, x)), \quad \rho_{\mathsf{e}}(\mathsf{append}(x', y'), \mathsf{append}(y', x')), \quad \rho_{\mathsf{e}}(\mathsf{append}(x, y), \mathsf{append}(x', y')).$$

Proof. The two classifier hypotheses expose singleton carrier witnesses for x, x', y, y'. Empty-result construction for append builds singleton carrier witnesses for each displayed appended endpoint. Since every endpoint in the three classifier rows is classified through e, symmetry and transitivity of hsame package the three singleton classifier witnesses. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonClassifier append commutativity compatible`

Theorem 44.25 (CommRing singleton classifier append commutation carrier exactness)**.** *For histories* $h, k : \mathsf{BHist}$*, the singleton commutative-ring classifier relates the two appended endpoints with exchanged factors exactly when both factors are singleton carriers:*

$$\rho_{\mathsf{e}}(\mathsf{append}(h, k), \mathsf{append}(k, h)) \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

Proof. The forward direction projects the source carrier field from the classifier and applies empty-result inversion to the appended endpoint. Conversely, the two factor carrier witnesses rebuild singleton carrier witnesses for both appended orders by empty-result construction. The rebuilt endpoints are both classified through e, so transitivity and symmetry of hsame give the classifier relation. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonClassifier append comm carrier iff`

Theorem 44.26 (CommRing singleton classifier append associativity carrier exactness)**.** *For histories* $a, b, c : \mathsf{BHist}$*,*

$$\rho_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(a, b), c), \mathsf{append}(a, \mathsf{append}(b, c))) \iff A_{\mathsf{e}}(a) \wedge A_{\mathsf{e}}(b) \wedge A_{\mathsf{e}}(c).$$

The ten-field fit is: traditional target singleton commutative-ring bracketing exactness; BEDC source BHist *with the singleton* $\mathsf{CommRing}^{\uparrow}$ *tuple; carrier* A_{e}*; classifier* ρ_{e}*; stability from nested append empty-result inversion and singleton classifier packaging; ledger the three append factors and the two bracketings; core theorem this block; exactness the displayed iff; standard bridge one-element commutative-ring bracketing; status* $\mathsf{ProofTarget}$*.*

Proof. In the forward direction, project the source carrier field from the classifier. This gives the carrier witness for $\mathsf{append}(\mathsf{append}(a, b), c)$. Empty-result inversion for append splits it into carrier witnesses for $\mathsf{append}(a, b)$ and c.

Apply empty-result inversion again to the witness for $\mathsf{append}(a, b)$. The resulting two carrier witnesses, together with the witness for c, give $A_{\mathsf{e}}(a) \wedge A_{\mathsf{e}}(b) \wedge A_{\mathsf{e}}(c)$ by conjunction introduction.

Conversely, assume carrier witnesses for a, b, and c. Empty-result construction first builds a carrier witness for $\mathsf{append}(a, b)$, and then one for $\mathsf{append}(\mathsf{append}(a, b), c)$.

The same construction applied to b and c, followed by the witness for a, builds the carrier witness for $\mathsf{append}(a, \mathsf{append}(b, c))$. Since both bracketed endpoints are classified through e, symmetry and transitivity of hsame package the displayed singleton classifier. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonClassifier append assoc carrier iff`

Theorem 44.27 (CommRing singleton classifier continuation empty result)**.** *For histories* $P, Q, R : \mathsf{BHist}$ *with* $\mathsf{Cont}(P, Q, R)$*, the singleton commutative-ring classifier on the two inputs is equivalent to the continuation result being internally empty:*

$$\mathsf{CommRingSingletonClassifier}(P, Q) \iff \mathsf{hsame}(R, \mathsf{e}).$$

Proof. If the inputs are singleton-classified, both input endpoints are empty, so the append continuation result is empty by append-empty construction. Conversely, an empty continuation result identifies $\mathsf{append}(P, Q)$ with e; append-empty inversion gives the two singleton carrier witnesses, and their chain through e supplies the classifier comparison. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonClassifier continuation empty result iff`

Theorem 44.28 (CommRing singleton continuation carrier split)**.** *For histories* $P, Q, R : \mathsf{BHist}$ *with* $\mathsf{Cont}(P, Q, R)$*, the singleton commutative-ring carrier on the continuation result splits exactly over the two input histories:*

$$\mathsf{CommRingSingletonCarrier}(R) \iff \mathsf{CommRingSingletonCarrier}(P) \wedge \mathsf{CommRingSingletonCarrier}(Q).$$

Proof. For the forward implication, read $\mathsf{CommRingSingletonCarrier}(R)$ as $\mathsf{hsame}(R, \mathsf{e})$. Apply the reverse direction of Theorem 44.27 to obtain $\mathsf{CommRingSingletonClassifier}(P, Q)$, and then unpack its two endpoint carrier witnesses.

For the converse implication, assume carrier witnesses for P and Q. These are witnesses of $\mathsf{hsame}(P, \mathsf{e})$ and $\mathsf{hsame}(Q, \mathsf{e})$, so symmetry and transitivity through e package $\mathsf{CommRingSingletonClassifier}(P, Q)$. Apply the forward direction of Theorem 44.27 to get $\mathsf{hsame}(R, \mathsf{e})$, which is exactly $\mathsf{CommRingSingletonCarrier}(R)$. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonCarrier continuation split iff`

Theorem 44.29 (Singleton empty-history CommRingUp schema certificate)**.** *Definition 44.6, together with Theorem 44.7, supplies the carrier, source, pattern, classifier, stability, and ledger fields required by Definition 44.59 over the concrete* BHist *singleton source.*

Proof. The carrier and source fields are the singleton empty-history source A_{e} from Definition 44.6. The classifier field is ρ_{e}, and the operation tuple is the constant empty-history tuple for addition, negation, zero, multiplication, and one.

The ring-law fields are supplied by Theorem 43.6 on that same carrier, classifier, and constant operation tuple. The multiplicative commutativity field and its compatibility under ρ_{e} are exactly the additional fields packaged by Theorem 44.7.

The pattern field is the commutative-ring expression pattern generated by those operations and the multiplication-commutativity exchange. The ledger field is the constant-operation provenance tuple for 0, 1, addition, negation, and multiplication, so every operation endpoint recorded by the certificate remains the singleton history e. □

↪variant `BEDC.Derived.CommRingUp.singleton empty history commring laws`

The $\mathsf{CommRing}^{\uparrow}$ schema is therefore represented by this concrete BHist certificate rather than by abstract operator fields.

44.4 The certificate

Definition 44.30 (CommRing source specification)**.** *The source is a certified ring carrier plus multiplicative commutativity.*

Definition 44.31 (CommRing pattern specification)**.** *The pattern is ring expression formation where multiplication may be exchanged by the commutativity field.*

Definition 44.32 (CommRing classifier specification)**.** *The classifier is the ring carrier classifier.*

Definition 44.33 (CommRing stability certificate)**.** *The stability certificate consists of:*

1. *all ring stability fields*
2. *multiplicative commutativity*
3. *compatibility of multiplication commutativity with ring congruence*

Theorem 44.34 (CommRing right distributivity from left distributivity)**.** *For BEDC history addition and multiplication, multiplicative commutativity, additive congruence, and left distributivity imply right distributivity:*

$$(x + y) \cdot z \mathsf{hsame} x \cdot z + y \cdot z.$$

Proof. Commute $(x + y) \cdot z$ to $z \cdot (x + y)$. Apply left distributivity, then use additive congruence with multiplicative commutativity on both summands. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring right distrib from left`

Theorem 44.35 (CommRing left distributivity from right distributivity)**.** *For BEDC history addition and multiplication, multiplicative commutativity, additive congruence, and right distributivity imply left distributivity:*

$$x \cdot (y + z) \mathsf{hsame} x \cdot y + x \cdot z.$$

Proof. Commute $x \cdot (y + z)$ to $(y + z) \cdot x$. Apply right distributivity, then use additive congruence with multiplicative commutativity on both summands. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring left distrib from right`

Theorem 44.36 (CommRing one-sided distributivity equivalence)**.** *For BEDC history operations add and mul, multiplicative commutativity and additive congruence imply that left distributivity is equivalent to right distributivity:*

$$(\forall x\, y\, z : \mathsf{BHist},\ x \cdot (y + z)\mathsf{hsame} x \cdot y + x \cdot z) \leftrightarrow (\forall x\, y\, z : \mathsf{BHist},\ (x + y) \cdot z\mathsf{hsame} x \cdot z + y \cdot z)\,.$$

Proof. For the forward direction, assume the displayed left distributivity law. Applying Theorem 44.34 with the shared multiplicative commutativity and additive congruence fields gives the displayed right distributivity law for all $x, y, z : \mathsf{BHist}$.

For the reverse direction, assume the displayed right distributivity law. Applying Theorem 44.35 with the same commutativity and congruence fields gives the displayed left distributivity law for all $x, y, z : \mathsf{BHist}$. □

Per object, the traditional target is one-sided distributivity collapse in commutative rings; the BEDC source is $\mathsf{CommRing}^{\uparrow}$ over BHist; the carrier is BHist; the classifier is hsame; the stability obligations are multiplicative commutativity, additive congruence, and one chosen distributivity law; the ledger records which side is primitive and which side is derived; the core theorem list records this equivalence; the exactness predicate is the displayed iff; the standard bridge is ordinary commutative-ring distributivity; and the status is $\mathsf{ProofTarget}$.

Theorem 44.37 (CommRing square of a sum expansion)**.** *For BEDC history addition and multiplication, multiplicative commutativity, additive congruence, and both distributive laws imply*

$$(a + b) \cdot (a + b)\mathsf{hsame}(a \cdot a + a \cdot b) + (a \cdot b + b \cdot b).$$

Proof. Apply right distributivity to the outer product. Apply left distributivity to both exposed factors, then use additive congruence and multiplicative commutativity to replace $b \cdot a$ by $a \cdot b$. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring square add expand`

Theorem 44.38 (CommRing square of a signed difference)**.** *For BEDC history operations add, mul, and neg satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, both distributive laws, multiplicative commutativity, and the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, every* $a, b : \mathsf{BHist}$ *satisfies*

$$(a + (-b)) \cdot (a + (-b))\mathsf{hsame}(a \cdot a + (-(a \cdot b))) + ((-(a \cdot b)) + (b \cdot b)).$$

Proof. Apply Theorem 44.37 with second input $-b$. This gives the ledger expression

$$(a \cdot a + a \cdot (-b)) + (a \cdot (-b) + (-b) \cdot (-b)).$$

Use Theorem 43.49 on each exposed $a \cdot (-b)$ term, and use Theorem 43.51 on $(-b) \cdot (-b)$.

Nested additive congruence transports these three product rewrites through the two additions. Transitivity of hsame composes the square expansion with the transported ledger, yielding the stated signed-difference square form. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring square signed difference expand`

For the $\mathsf{CommRing}^{\uparrow}$ per-object template, this theorem is a Core theorem list item for traditional target commutative-ring polynomial algebra. Its BEDC source is $\mathsf{Ring}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ over BHist, its carrier is BHist, its classifier is hsame, its stability obligations are distributivity, congruence, commutativity, and negative-product laws, and its ledger records polynomial expression provenance with status ProofTarget.

Theorem 44.39 (CommRing parallelogram square sum)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, both distributive laws, multiplicative commutativity, and the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, every* $a, b : \mathsf{BHist}$ *satisfies*

$$((a+b)\cdot(a+b)) + ((a+(-b))\cdot(a+(-b)))\mathsf{hsame}(a\cdot a + a\cdot a) + (b\cdot b + b\cdot b).$$

Proof. Use Definition 44.37 for the first square and Definition 44.38 for the signed square. Addition congruence combines the two normalized ledgers into one sum of four additive blocks.

Apply additive associativity, additive commutativity, and Definition 42.13 to place the two $a\cdot b$ terms next to the two $-(a\cdot b)$ terms. The middle ledger then contains the paired mixed terms as inverse pairs.

Collapse those pairs with Definition 43.27 and the additive left-inverse law. The ring zero laws remove the resulting zero summands, leaving exactly the two $a\cdot a$ terms and the two $b\cdot b$ terms in the displayed order. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring parallelogram square sum`

For the $\mathsf{CommRing}^{\uparrow}$ per-object template, the traditional target is the commutative-ring parallelogram square-sum identity; the BEDC source is $\mathsf{Ring}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ over BHist; the carrier is BHist; the classifier is hsame; the stability obligations are square expansion, signed-square expansion, additive inverse laws, additive congruence, and middle-four interchange; the ledger records the two square ledgers and mixed-term cancellation; the core theorem list records this block; the exactness predicate is the displayed hsame; the standard bridge is the ordinary parallelogram identity in a commutative ring; and the status is $\mathsf{ProofTarget}$.

Theorem 44.40 (CommRing square cross-term extraction pair)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, both distributive laws, multiplicative commutativity, and the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, every* $a, b : \mathsf{BHist}$ *satisfies both identities*

$$((a+b)\cdot(a+b)) + ((-(a\cdot a)) + (-(b\cdot b)))\mathsf{hsame}(a\cdot b) + (a\cdot b)$$

and

$$((a+(-b))\cdot(a+(-b))) + ((-(a\cdot a)) + (-(b\cdot b)))\mathsf{hsame}(-(a\cdot b)) + (-(a\cdot b)).$$

Proof. For the positive square, apply Definition 44.37 and transport the appended $(-(a\cdot a)) + (-(b\cdot b))$ ledger through addition congruence. Additive associativity, additive commutativity, and Definition 42.13 move the $a\cdot a$ term next to its inverse and the $b\cdot b$ term next to its inverse.

Definition 43.27 cancels the two exposed diagonal pairs. The additive zero laws remove the resulting zero summands, leaving exactly the two positive mixed terms in the displayed order.

For the signed square, apply Definition 44.38 and use addition congruence to append the same diagonal inverse ledger. The same associativity, commutativity, and middle-four interchange rearrangement exposes the $a\cdot a$ and $b\cdot b$ inverse pairs without changing the two signed mixed terms.

Apply Definition 43.27 again, then use the additive zero laws to erase the cancelled diagonal ledger. The remaining terms are $-(a\cdot b)$ and $-(a\cdot b)$, which gives the second displayed identity. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring square cross term extraction pair`

For the $\mathsf{CommRing}^{\uparrow}$ per-object template, the traditional target is commutative-ring cross-term extraction for quadratic algebra; the BEDC source is $\mathsf{Ring}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ over BHist; the carrier is BHist; the classifier is hsame; the stability obligations are square expansion, signed-square expansion, additive congruence, additive associativity, additive commutativity, diagonal inverse cancellation, additive zero laws, and middle-four interchange; the ledger records diagonal removal from the two normalized square ledgers; the core theorem is this block; the exactness predicate is the two displayed hsame identities; the downstream use is $\mathsf{Field}^{\uparrow}$ quadratic normalization and later polarization-style algebra; and the status is $\mathsf{ProofTarget}$.

Theorem 44.41 (CommRing product of binary sums)**.** *For BEDC history addition and multiplication, multiplicative commutativity, additive congruence, and left distributivity imply the expansion*

$$(a+b)\cdot(c+d)\mathsf{hsame}(a\cdot c+a\cdot d)+(b\cdot c+b\cdot d).$$

Proof. First derive right distributivity from multiplicative commutativity and left distributivity, then apply it to the outer product. Apply left distributivity to the two inner products $a\cdot(c+d)$ and $b\cdot(c+d)$ and transport both equalities through additive congruence. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring mul add add expand`

Theorem 44.42 (CommRing square of a binary sum)**.** *For BEDC history addition and multiplication satisfying additive associativity, additive congruence, multiplicative commutativity, and left distributivity, every $a, b : \mathsf{BHist}$ satisfies*

$$(a+b)\cdot(a+b)\mathsf{hsame}(a\cdot a+a\cdot b)+(a\cdot b+b\cdot b).$$

Proof. Specialize Theorem 44.41 with $c := a$ and $d := b$. This gives the row-major expansion

$$(a+b)\cdot(a+b)\mathsf{hsame}(a\cdot a+a\cdot b)+(b\cdot a+b\cdot b).$$

Multiplicative commutativity rewrites the exposed middle product $b\cdot a$ to $a\cdot b$. Additive congruence transports this product rewrite through the right inner sum, then through the outer sum.

Transitivity of hsame composes the specialized expansion with the transported right-hand ledger, yielding the duplicate-middle square form. □

Theorem 44.43 (CommRing column expansion of binary sums)**.** *For BEDC history addition and multiplication, additive associativity, additive commutativity, additive congruence, multiplicative commutativity, and left distributivity imply, for every $a, b, c, d : \mathsf{BHist}$,*

$$(a+b)\cdot(c+d)\mathsf{hsame}(a\cdot c+b\cdot c)+(a\cdot d+b\cdot d).$$

Proof. Apply Theorem 44.41 to obtain the row-major expansion of $(a+b)\cdot(c+d)$ as

$$(a\cdot c+a\cdot d)+(b\cdot c+b\cdot d).$$

On the additive operation, apply Theorem 42.13 with the four summands $a\cdot c$, $a\cdot d$, $b\cdot c$, and $b\cdot d$. Additive congruence then composes this interchange with the row-major expansion and yields the column-major normal form. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring mul add add column expand`

Theorem 44.44 (CommRing left distributivity with commuted terms)**.** *For BEDC history addition and multiplication, multiplicative commutativity, additive congruence, and left distributivity imply*

$$x \cdot (y + z)\mathsf{hsame} y \cdot x + z \cdot x.$$

Proof. Apply left distributivity to obtain the two summands $x \cdot y$ and $x \cdot z$. Additive congruence then transports both summands across multiplicative commutativity. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring left distrib commuted terms`

Theorem 44.45 (CommRing difference of squares)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, left distributivity, multiplicative commutativity, and the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, every* $a, b : \mathsf{BHist}$ *satisfies*

$$(a + b) \cdot (a + (-b))\mathsf{hsame}(a \cdot a) + (-(b \cdot b)).$$

Proof. Apply Theorem 44.41 to expand $(a + b) \cdot (a + (-b))$ into the four-term ledger expression $(a \cdot a + a \cdot (-b)) + (b \cdot a + b \cdot (-b))$.

Use Theorem 43.49 to rewrite $a \cdot (-b)$ as $-(a \cdot b)$. Commute $b \cdot a$ to $a \cdot b$ by multiplicative commutativity, and use the same right-negative product theorem to rewrite $b \cdot (-b)$ as $-(b \cdot b)$.

The expression is therefore transported by additive congruence to $(a \cdot a + (-(a \cdot b))) + (a \cdot b + (-(b \cdot b)))$. Additive associativity and commutativity move the middle pair next to each other without changing the outer square terms.

Finally, additive inverse collapse gives $(-(a \cdot b)) + (a \cdot b)\mathsf{hsame}0$. The zero laws remove this neutral summand, leaving $(a \cdot a) + (-(b \cdot b))$ under hsame. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring difference of squares`

Theorem 44.46 (CommRing equal squares force signed factor zero)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, left distributivity, multiplicative commutativity, and the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, every* $a, b : \mathsf{BHist}$ *satisfies*

$$a \cdot a\mathsf{hsame} b \cdot b \Longrightarrow (a + b) \cdot (a + (-b))\mathsf{hsame}0.$$

Proof. Apply Theorem 44.45 to rewrite the signed factor product as $(a \cdot a) + (-(b \cdot b))$. Transport the assumed square equality $a \cdot a\mathsf{hsame} b \cdot b$ through additive congruence while keeping the right summand $-(b \cdot b)$ fixed. The right side is therefore identified with $(b \cdot b) + (-(b \cdot b))$.

Theorem 43.27 collapses this final additive inverse pair to 0. Transitivity of hsame composes the difference-of-squares normal form, the transported square equality, and the inverse collapse. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring equal squares signed factor zero`

Theorem 44.47 (CommRing difference-of-squares zero exactness)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, left distributivity, multiplicative commutativity, and the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, every* $a, b : \mathsf{BHist}$ *satisfies*

$$(a + b) \cdot (a + (-b))\mathsf{hsame}0 \Longleftrightarrow a \cdot a\mathsf{hsame} b \cdot b.$$

Proof. For the forward direction, apply Theorem 44.45 to identify the signed product with $(a \cdot a) + (-(b \cdot b))$. Compose this identification, using symmetry where needed, with the zero-product hypothesis. The difference term is therefore classified as 0.

Add $b \cdot b$ on the right by additive congruence. On the left endpoint, additive associativity and commutativity move the inverse pair into the form $(b \cdot b) + (-(b \cdot b))$; Theorem 43.27 collapses that pair to 0, and the zero laws leave $a \cdot a$. On the right endpoint, the zero law collapses $0 + (b \cdot b)$ to $b \cdot b$. Transitivity gives $a \cdot a \mathsf{hsame} b \cdot b$.

For the reverse direction, apply Theorem 44.46 to the square equality $a \cdot a \mathsf{hsame} b \cdot b$. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring difference of squares zero exact`

Theorem 44.48 (CommRing signed binary product normal form)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, left distributivity, multiplicative commutativity, and the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, every* $a, b, c, d : \mathsf{BHist}$ *satisfies*

$$(a + (-b)) \cdot (c + (-d)) \mathsf{hsame} (a \cdot c + (-(a \cdot d))) + ((-(b \cdot c)) + (b \cdot d)).$$

Proof. Apply Theorem 44.41 with the four inputs a, $-b$, c, and $-d$. The left side expands to

$$(a \cdot c + a \cdot (-d)) + ((-b) \cdot c + (-b) \cdot (-d)).$$

Next normalize the signed products. Theorem 43.49 rewrites $a \cdot (-d)$ as $-(a \cdot d)$, Theorem 43.48 rewrites $(-b) \cdot c$ as $-(b \cdot c)$, and Theorem 43.51 rewrites $(-b) \cdot (-d)$ as $b \cdot d$.

Use nested additive congruence to transport the three rewritten summands through the outer two additions. Transitivity of hsame composes the expansion step with this transport, giving the stated four-term normal form. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring signed binary product normal form`

Theorem 44.49 (CommRing signed product balance)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, left distributivity, multiplicative commutativity, and the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, every* $a, b, c, d : \mathsf{BHist}$ *satisfies*

$$((a + (-b)) \cdot (c + (-d))) + ((a \cdot d) + (b \cdot c)) \mathsf{hsame} (a \cdot c) + (b \cdot d).$$

Proof. Apply Theorem 44.48 to replace the signed product by the four-term row expansion

$$(a \cdot c + (-(a \cdot d))) + ((-(b \cdot c)) + (b \cdot d)).$$

Transport the added mixed-term sum through this identification by additive congruence. The expression is then an additive composite containing the two ordinary mixed terms $a \cdot d$ and $b \cdot c$ together with their signed counterparts $-(a \cdot d)$ and $-(b \cdot c)$.

Use additive associativity and commutativity, with Theorem 42.13 for the middle summands, to place $-(a \cdot d)$ adjacent to $a \cdot d$ and $-(b \cdot c)$ adjacent to $b \cdot c$. The unmixed terms $a \cdot c$ and $b \cdot d$ remain as the external summands.

Theorem 43.27 collapses the right-inverse mixed pair, and the additive left-inverse law collapses the left-inverse mixed pair. The ring zero laws remove the two neutral summands, leaving $(a \cdot c) + (b \cdot d)$ under hsame. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring signed product balance`

The ten-field fit is: traditional target bilinear subtraction balance; BEDC source $\mathsf{Ring}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability obligations distributivity, congruence, commutativity, negative-product laws, and additive cancellation; ledger polynomial mixed-term provenance; core theorem this balance identity; exactness the displayed hsame; standard bridge commutative-ring bilinear expansion; status $\mathsf{ProofTarget}$.

Theorem 44.50 (CommRing signed column expansion of binary sums)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, left distributivity, multiplicative commutativity, and the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, every* $a, b, c, d : \mathsf{BHist}$ *satisfies*

$$(a + (-b)) \cdot (c + (-d))\mathsf{hsame}(a \cdot c + (-(b \cdot c))) + ((-(a \cdot d)) + (b \cdot d)).$$

Proof. Apply Theorem 44.48 to obtain the row-major signed expansion

$$(a \cdot c + (-(a \cdot d))) + ((-(b \cdot c)) + (b \cdot d)).$$

On the additive operation, apply Theorem 42.13 with the four summands $a \cdot c$, $-(a \cdot d)$, $-(b \cdot c)$, and $b \cdot d$. Additive congruence transports the middle-four interchange through the displayed signed row form.

Transitivity of hsame composes the row-major normalization with this column reordering, yielding the stated column-major signed normal form. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring signed column binary product normal form`

Theorem 44.51 (CommRing signed column cancellations force zero product)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, left distributivity, multiplicative commutativity, and the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, every* $a, b, c, d : \mathsf{BHist}$ *with* $a \cdot c\mathsf{hsame}b \cdot c$ *and* $a \cdot d\mathsf{hsame}b \cdot d$ *satisfies*

$$(a + (-b)) \cdot (c + (-d))\mathsf{hsame}0.$$

Proof. Apply Theorem 44.50 to rewrite the signed product as

$$(a \cdot c + (-(b \cdot c))) + ((-(a \cdot d)) + (b \cdot d)).$$

The first hypothesis is transported by additive congruence through the left signed column. It identifies $a \cdot c + (-(b \cdot c))$ with $(b \cdot c) + (-(b \cdot c))$, and Theorem 43.27 collapses this right-inverse pair to 0.

For the second signed column, apply additive inverse congruence to $a \cdot d\mathsf{hsame}b \cdot d$ and identify $-(a \cdot d)$ with $-(b \cdot d)$. Additive congruence transports $(-(a \cdot d)) + (b \cdot d)$ to $(-(b \cdot d)) + (b \cdot d)$, and the additive left-inverse law collapses this left-inverse pair to 0.

The column normal form is therefore transported to $0 + 0$. The additive left-zero law collapses $0 + 0$ to 0, and transitivity of hsame composes the normal-form step, the two signed-column collapses, and the final zero collapse. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring signed column cancellations zero`

For the $\mathsf{CommRing}^{\uparrow}$ per-object template, the traditional target is signed column cancellation in commutative-ring algebra. Its BEDC source is $\mathsf{Ring}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ over BHist, its carrier is BHist, its classifier is hsame, its stability obligations are signed-product normalization, additive

inverse laws, additive congruence, and transitivity, and its ledger records column-paired product provenance. The core theorem list contains Theorem 44.51; exactness is zero classification under column-paired cancellations; the standard bridge remains outside this proof site; and the status is ProofTarget.

Theorem 44.52 (CommRing signed row cancellations force zero product)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, left distributivity, multiplicative commutativity, and the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, every* $a, b, c, d : \mathsf{BHist}$ *with* $a \cdot c\mathsf{hsame}a \cdot d$ *and* $b \cdot c\mathsf{hsame}b \cdot d$ *satisfies*

$$(a + (-b)) \cdot (c + (-d))\mathsf{hsame}0.$$

Proof. Apply Theorem 44.48 to rewrite the signed product as

$$(a \cdot c + (-(a \cdot d))) + ((-(b \cdot c)) + (b \cdot d)).$$

The first row equality is transported by additive congruence through the left signed row. It identifies $a \cdot c + (-(a \cdot d))$ with $(a \cdot d) + (-(a \cdot d))$, and Theorem 43.27 collapses this right-inverse pair to 0.

For the second signed row, apply additive inverse congruence to $b \cdot c\mathsf{hsame}b \cdot d$ and identify $-(b \cdot c)$ with $-(b \cdot d)$. Additive congruence transports $(-(b \cdot c)) + (b \cdot d)$ to $(-(b \cdot d)) + (b \cdot d)$, and the additive left-inverse law collapses this left-inverse pair to 0.

The row normal form is therefore transported to $0 + 0$. The additive left-zero law collapses $0 + 0$ to 0, and transitivity of hsame composes the normal-form step, the two signed-row collapses, and the final zero collapse. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring signed row cancellations zero`

The ten-field fit is: traditional target signed row cancellation in commutative-ring algebra; BEDC source $\mathsf{Ring}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability additive abelian-group laws, congruence, distributivity, commutativity, and negative-product laws; ledger signed row product provenance; core theorem this row-cancellation result; exactness row-zero soundness; standard bridge the ordinary commutative-ring identity; status ProofTarget.

Theorem 44.53 (CommRing signed product zero exactness)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, left distributivity, multiplicative commutativity, and the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, every* $a, b, c, d : \mathsf{BHist}$ *satisfies*

$$(a + (-b)) \cdot (c + (-d))\mathsf{hsame}0 \Longleftrightarrow a \cdot c + b \cdot d\mathsf{hsame}a \cdot d + b \cdot c.$$

Proof. For the forward direction, apply Theorem 44.48 to rewrite the signed product as

$$(a \cdot c + (-(a \cdot d))) + ((-(b \cdot c)) + (b \cdot d)).$$

Apply Theorem 42.13 to regroup the four-term additive ledger as $(a \cdot c + b \cdot d) + ((-(a \cdot d)) + (-(b \cdot c)))$. The negative-product laws and additive inverse congruence identify the second summand with the additive inverse of $(a \cdot d + b \cdot c)$. The signed product hypothesis therefore presents a balanced difference between the two cross sums.

Add $a \cdot d + b \cdot c$ to both sides by additive congruence. Additive associativity moves the inverse pair next to its positive partner, and Theorem 43.27 collapses the pair to 0. The zero laws remove the neutral summand and leave $a \cdot c + b \cdot d\mathsf{hsame}a \cdot d + b \cdot c$.

For the reverse direction, start from the assumed cross-sum equality and transport it through additive congruence while keeping the inverse of the right cross sum fixed. The right endpoint becomes the sum of $a \cdot d + b \cdot c$ and its additive inverse.

Theorem 43.27 collapses that endpoint to 0. Symmetry and transitivity compose this collapse with the signed binary normal form, yielding $(a + (-b)) \cdot (c + (-d))\mathsf{hsame}0$. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring signed product empty zero exact`

Theorem 44.54 (CommRing signed square zero exactness)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, left distributivity, multiplicative commutativity, and the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, every* $a, b : \mathsf{BHist}$ *satisfies*

$$(a + (-b)) \cdot (a + (-b))\mathsf{hsame}0 \Longleftrightarrow a \cdot a + b \cdot b\mathsf{hsame}a \cdot b + a \cdot b.$$

Proof. Apply Theorem 44.53 with $c = a$ and $d = b$. The signed product side becomes the signed square, and the cross-sum criterion becomes

$$a \cdot a + b \cdot b\mathsf{hsame}a \cdot b + b \cdot a.$$

For the forward direction, multiplicative commutativity gives $b \cdot a\mathsf{hsame}a \cdot b$. Additive congruence transports the right summand of $a \cdot b + b \cdot a$ along this equality, so the cross sum obtained from the specialized exactness theorem is identified with $a \cdot b + a \cdot b$.

For the reverse direction, use symmetry of the same commutativity instance and additive congruence to transport $a \cdot b + a \cdot b$ back to $a \cdot b + b \cdot a$. The reverse implication of the specialized signed-product exactness theorem then returns $(a + (-b)) \cdot (a + (-b))\mathsf{hsame}0$. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring signed square empty zero exact`
Lean4 ✓ `BEDC.Derived.CommRingUp.commring signed square zero exact`

Theorem 44.55 (CommRing signed square zero diagonal extraction package)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, left distributivity, multiplicative commutativity, and the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, every* $a, b : \mathsf{BHist}$ *with* $(a + (-b)) \cdot (a + (-b))\mathsf{hsame}0$ *satisfies both*

$$a \cdot a + b \cdot b\mathsf{hsame}a \cdot b + a \cdot b$$

and

$$(-(a \cdot a)) + (-(b \cdot b))\mathsf{hsame}(-(a \cdot b)) + (-(a \cdot b)).$$

Proof. The first displayed identity is the forward implication of Theorem 44.54 applied to the assumed zero signed square.

For the diagonal inverse ledger, use the signed half of Theorem 44.40. Additive congruence transports the signed-square factor across $(a + (-b)) \cdot (a + (-b))\mathsf{hsame}0$, so its left side becomes the same diagonal inverse ledger with a zero summand.

The ring zero law removes that zero summand. Symmetry and transitivity of hsame compose the transport with the signed cross-term endpoint, leaving exactly

$$(-(a \cdot a)) + (-(b \cdot b))\mathsf{hsame}(-(a \cdot b)) + (-(a \cdot b)).$$

□

Lean4 ✓ `BEDC.Derived.CommRingUp.commring signed square zero diagonal extraction package`

For the $\mathsf{CommRing}^{\uparrow}$ per-object template, the traditional target is diagonal extraction from a zero signed square; the BEDC source is $\mathsf{Ring}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ over BHist; the carrier is BHist; the classifier is hsame; the stability obligations are signed-square exactness, cross-term extraction, additive congruence, and zero laws; the ledger records the zero signed square and diagonal inverse ledger; the downstream consumer is $\mathsf{Field}^{\uparrow}$ quadratic and zero-factor exit packages; and the status is $\mathsf{ProofTarget}$.

Theorem 44.56 (CommRing column cancellations balance cross sums)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, left distributivity, multiplicative commutativity, and the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, every* $a, b, c, d : \mathsf{BHist}$ *with* $a \cdot c\mathsf{hsame}b \cdot c$ *and* $a \cdot d\mathsf{hsame}b \cdot d$ *satisfies*

$$a \cdot c + b \cdot d\mathsf{hsame}a \cdot d + b \cdot c.$$

Proof. Apply Theorem 44.51 to the two column hypotheses. This produces the signed zero product

$$(a + (-b)) \cdot (c + (-d))\mathsf{hsame}0.$$

Apply the forward direction of Theorem 44.53. The signed zero product is exactly the left side of that exactness statement, so its conclusion is the displayed cross-sum balance. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring column cancellations cross sum balance`

Theorem 44.57 (CommRing row cancellations balance cross sums)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, left distributivity, multiplicative commutativity, and the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, every* $a, b, c, d : \mathsf{BHist}$ *with* $a \cdot c\mathsf{hsame}a \cdot d$ *and* $b \cdot c\mathsf{hsame}b \cdot d$ *satisfies*

$$a \cdot c + b \cdot d\mathsf{hsame}a \cdot d + b \cdot c.$$

Proof. Apply Theorem 44.52 to the two row hypotheses. This produces the signed zero product

$$(a + (-b)) \cdot (c + (-d))\mathsf{hsame}0.$$

Apply the forward direction of Theorem 44.53. The signed zero product is exactly the left side of that exactness statement, so its conclusion is the displayed cross-sum balance. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring row cancellations cross sum balance`

For the $\mathsf{CommRing}^{\uparrow}$ per-object template, the traditional target is row cancellation balance in commutative-ring algebra. Its BEDC source is $\mathsf{Ring}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ over BHist, its carrier is BHist, its classifier is hsame, its stability obligations are signed row cancellation and signed-product zero exactness, and its ledger records row-paired product provenance. The core theorem is Theorem 44.57; exactness is cross-sum balance; the standard bridge is ordinary commutative-ring cancellation balance; and the status is $\mathsf{ProofTarget}$.

Definition 44.58 (CommRing ledger policy)**.** *Record ring expression provenance and the multiplicative commutativity law when used.*

Definition 44.59 ($\mathsf{CommRing}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{CommRing}^{\uparrow}$*.*

Primitive boundary. $\mathsf{CommRing}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

44.5 CommRing quadratic polarization package

Theorem 44.60 (CommRing quadratic polarization package)**.** *For BEDC history operations add, mul, neg, and zero satisfying the shared hypotheses of Definition 44.39, Definition 44.40, and Definition 44.54, every $a, b : \mathsf{BHist}$ carries the concrete quadratic-polarization package*

$$\Big(((a{+}b){\cdot}(a{+}b)){+}((a{+}(-b)){\cdot}(a{+}(-b)))\mathsf{hsame}(a{\cdot}a{+}a{\cdot}a){+}(b{\cdot}b{+}b{\cdot}b)\Big)\wedge\Big(((a{+}b){\cdot}(a{+}b)){+}((-(a{\cdot}a)){+}(-(b{\cdot}b)))\mathsf{hsame}(a{\cdot}b$$

Proof. Apply Definition 44.39 to the shared hypotheses and the selected histories a, b. This gives the parallelogram square-sum identity. Apply Definition 44.40 to the same data; its two components give the positive and signed cross-term extraction identities.

Apply Definition 44.54 to the same histories. This gives the signed-square zero exactness iff. Introduce conjunctions in the displayed order, using the parallelogram identity first, the two extraction identities next, and the exactness iff as the final component. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring quadratic polarization package`

Theorem 44.61 (CommRing quadratic zero-polarization exit package)**.** *For BEDC history operations add, mul, neg, and zero satisfying the shared hypotheses of Definition 44.60 and Definition 44.55, every $a, b : \mathsf{BHist}$ with $(a + (-b)) \cdot (a + (-b))\mathsf{hsame}0$ carries the concrete exit package*

$$\Big(((a{+}b){\cdot}(a{+}b)){+}((a{+}(-b)){\cdot}(a{+}(-b)))\mathsf{hsame}(a{\cdot}a{+}a{\cdot}a){+}(b{\cdot}b{+}b{\cdot}b)\Big)\wedge\Big(((a{+}b){\cdot}(a{+}b)){+}((-(a{\cdot}a)){+}(-(b{\cdot}b)))\mathsf{hsame}(a{\cdot}b$$

Lean4 ✓ `BEDC.Derived.CommRingUp.commring quadratic zero polarization exit package`

Proof. Apply Definition 44.60 to the shared hypotheses and the selected histories a, b. This gives the parallelogram identity, the two cross-term extraction identities, and the signed-square zero exactness component.

Apply Definition 44.55 to the same data together with $(a + (-b)) \cdot (a + (-b))\mathsf{hsame}0$. Its two components give the positive diagonal equality and the diagonal inverse extraction. Introduce the conjunction in the same order as the statement: the four unconditional polarization components first, followed by the two diagonal equalities supplied by the signed-square zero diagonal-extraction package. □

Theorem 44.62 (CommRing quadratic positive-diagonal exit package)**.** *For BEDC history operations add, mul, neg, and zero satisfying the shared hypotheses of Definition 44.60 and Definition 44.55, every $a, b : \mathsf{BHist}$ with $a \cdot a + b \cdot b\mathsf{hsame}a \cdot b + a \cdot b$ carries the concrete positive-diagonal exit package*

$$\Big(((a{+}b){\cdot}(a{+}b)){+}((a{+}(-b)){\cdot}(a{+}(-b)))\mathsf{hsame}(a{\cdot}a{+}a{\cdot}a){+}(b{\cdot}b{+}b{\cdot}b)\Big)\wedge\Big(((a{+}b){\cdot}(a{+}b)){+}((-(a{\cdot}a)){+}(-(b{\cdot}b)))\mathsf{hsame}(a{\cdot}b$$

Proof. Apply Definition 44.60 to the shared hypotheses and the selected histories a, b. This gives the four quadratic-polarization components, including the signed-square zero exactness iff.

Use the reverse direction of that iff on the assumed positive diagonal equality. This recovers the signed-square zero witness $(a + (-b)) \cdot (a + (-b))\mathsf{hsame}0$.

Apply Definition 44.55 to the same data and the recovered signed-square zero witness. Its second component gives the inverse diagonal ledger. Introduce conjunctions in the displayed order: the four polarization components first, the recovered signed-square zero witness next, and the inverse diagonal ledger last. □

The positive-diagonal ten-field fit is: traditional target positive-diagonal quadratic exit; BEDC source $\mathsf{Ring}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability from Definition 44.60 and Definition 44.55; ledger the positive diagonal witness and recovered signed-square zero witness; core theorem this block; exactness the displayed package; downstream use $\mathsf{Field}^{\uparrow}$ quadratic normalization and equal-square/zero-product reasoning; status $\mathsf{ProofTarget}$.

The signed-square-zero ten-field fit is: traditional target a commutative-ring quadratic polarization interface; BEDC source $\mathsf{Ring}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability from the shared distributivity, congruence, commutativity, and negative-product laws; ledger the parallelogram square-sum, two cross-term extractions, and signed-square zero exactness witnesses together with the positive and inverse diagonal equalities; core theorem this block; exactness the displayed conjunction; standard bridge ordinary quadratic polarization in a commutative ring; downstream use $\mathsf{Field}^{\uparrow}$ quadratic normalization and equal-square/zero-product reasoning; status $\mathsf{ProofTarget}$.

Theorem 44.63 (CommRing quadratic zero-polarization annihilator package)**.** *For BEDC history operations add, mul, neg, and zero satisfying the joint hypotheses of Definition 44.61 and Definition 43.39, every $a, b : \mathsf{BHist}$ with $((a + (-b)) \cdot (a + (-b)))\mathsf{hsame}0$ carries the concrete annihilator package*

$$\Big(((a{+}b){\cdot}(a{+}b)){+}((a{+}(-b)){\cdot}(a{+}(-b)))\mathsf{hsame}(a{\cdot}a{+}a{\cdot}a){+}(b{\cdot}b{+}b{\cdot}b)\Big)\wedge\Big(((a{+}b){\cdot}(a{+}b)){+}((-(a{\cdot}a)){+}(-(b{\cdot}b)))\mathsf{hsame}(a{\cdot}b$$

The ten-field fit is: traditional target commutative-ring quadratic zero-polarization annihilator interface; BEDC source $\mathsf{Ring}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability from the zero-square witness, multiplication congruence, and zero multiplication absorption; ledger the six exit rows and the universal two-sided annihilator row; core theorem this theorem; exactness the displayed seven-row package; standard bridge ordinary nil-square annihilation in a commutative ring; downstream use $\mathsf{Field}^{\uparrow}$ quadratic normalization and nil-square handling; status $\mathsf{ProofTarget}$.

Proof. Apply Definition 44.61 to the selected histories a, b and the displayed zero-square hypothesis. This supplies the six exit-package rows: the parallelogram identity, the positive and signed cross-term extractions, signed-square zero exactness, the positive diagonal equality, and the inverse diagonal equality.

Now fix an arbitrary multiplier $c : \mathsf{BHist}$. Transport the zero-square witness through multiplication on the left and on the right, and apply Definition 43.39 to the resulting zero products. This gives

$$((a + (-b)) \cdot (a + (-b))) \cdot c\mathsf{hsame}0 \wedge c \cdot ((a + (-b)) \cdot (a + (-b)))\mathsf{hsame}0.$$

Finally conjoin the six rows obtained from the zero-polarization exit package with the two absorption rows obtained for the arbitrary multiplier c. Since c was arbitrary, these rows give the universal two-sided annihilator clause, and the displayed package follows in the stated order. □

Theorem 44.64 (CommRing quadratic positive-diagonal annihilator package)**.** *For BEDC history operations add, mul, neg, and zero satisfying the shared hypotheses of Definition 44.62, Definition 44.63, and Definition 43.39, every $a, b : \mathsf{BHist}$ with $a \cdot a + b \cdot b\mathsf{hsame}a \cdot b + a \cdot b$ carries the*

concrete positive-diagonal annihilator package

$$\Big(((a{+}b){\cdot}(a{+}b)){+}((a{+}(-b)){\cdot}(a{+}(-b)))\mathsf{hsame}(a{\cdot}a{+}a{\cdot}a){+}(b{\cdot}b{+}b{\cdot}b)\Big)\wedge\Big(((a{+}b){\cdot}(a{+}b)){+}((-(a{\cdot}a)){+}(-(b{\cdot}b)))\mathsf{hsame}(a{\cdot}b$$

The ten-field fit is: traditional target positive-diagonal quadratic annihilator interface; BEDC source $\mathsf{Ring}^{\uparrow}$ *plus* $\mathsf{CommRing}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability from the positive diagonal exit package, zero-polarization annihilator package, and zero multiplication absorption; ledger the positive diagonal witness, recovered signed-square zero witness, inverse diagonal row, and universal two-sided annihilator row; core theorem this theorem; exactness the displayed eight-row package; standard bridge ordinary positive-diagonal quadratic annihilation in a commutative ring; downstream use* $\mathsf{Field}^{\uparrow}$ *quadratic normalization and zero-factor exit packages; status* $\mathsf{ProofTarget}$.

Proof. Apply Definition 44.62 to the selected histories a, b and the displayed positive diagonal equality. This supplies the four polarization rows, the recovered signed-square zero witness, and the inverse diagonal ledger row.

Apply Definition 44.63 to the same histories and the recovered signed-square zero witness. Its package contains the positive diagonal row and the universal two-sided annihilator row.

Conjoin the rows in the displayed order: the four polarization rows first, the recovered signed-square zero row next, then the positive diagonal row, the inverse diagonal ledger row, and finally the universal two-sided annihilator row. □

This consequence block is read over the $\mathsf{CommRing}^{\uparrow}$ carrier of the core child and consumes the $\mathsf{Ring}^{\uparrow}$ additive and distributive rows from chapter 43. Its zero-factor and equal-squares consequences are not standalone algebraic assumptions.

Theorem 44.65 (CommRing zero linear factor annihilator branch)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, left distributivity, the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, and the* $\mathsf{CommRing}^{\uparrow}$ *multiplicative commutativity field used in Definition 44.47, every* $a, b : \mathsf{BHist}$ *satisfies*

$$((a{+}b)\mathsf{hsame0}\vee(a{+}(-b))\mathsf{hsame0}) \Longrightarrow ((a{+}b)\mathsf{hsame0}\wedge\forall c : \mathsf{BHist},\ ((a{+}b){\cdot}c\mathsf{hsame0}\wedge c{\cdot}(a{+}b)\mathsf{hsame0}))\vee((a{+}(-b))\mathsf{hsa}$$

Proof. First derive the right distributive law from the supplied left distributive law by Definition 44.34. The zero-classifier factor absorption theorem is then available with both distributive inputs.

If the displayed disjunction chooses $(a+b)\mathsf{hsame0}$, retain that branch witness. For an arbitrary $c : \mathsf{BHist}$, apply Definition 43.40 with $x = a+b$ and $y = c$. Its two components give $(a+b)\cdot c\mathsf{hsame0}$ and $c\cdot(a+b)\mathsf{hsame0}$, so the left disjunct packages the original witness with the universal annihilator row.

If the displayed disjunction chooses $(a + (-b))\mathsf{hsame0}$, retain that branch witness instead. For an arbitrary $c : \mathsf{BHist}$, apply Definition 43.40 with $x = a + (-b)$ and $y = c$. The two components give $(a + (-b)) \cdot c\mathsf{hsame0}$ and $c \cdot (a + (-b))\mathsf{hsame0}$, yielding the right disjunct with the same branch-preserving form. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring zero linear factor annihilator branch`

Theorem 44.66 (CommRing zero linear factor signed product zero)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and*

multiplication congruence, left distributivity, the $\mathsf{Ring}^{\uparrow}$ *negative-product laws, and the* $\mathsf{CommRing}^{\uparrow}$ *multiplicative commutativity field used in Definition 44.47, every* $a, b : \mathsf{BHist}$ *satisfies*

$$\big((a+b)\mathsf{hsame}0 \vee (a+(-b))\mathsf{hsame}0\big) \Longrightarrow (a+b)\cdot(a+(-b))\mathsf{hsame}0.$$

Proof. Apply Definition 44.65 to the chosen zero linear factor. The result keeps the selected branch and supplies its two-sided annihilator row for every multiplier.

In the $(a+b)\mathsf{hsame}0$ branch, specialize the universal row at $c = a+(-b)$ and take its left component. This is exactly $(a+b)\cdot(a+(-b))\mathsf{hsame}0$.

In the $(a+(-b))\mathsf{hsame}0$ branch, specialize the universal row at $c = a+b$ and take its right component. The oriented product is $(a+b)\cdot(a+(-b))$, giving the required zero classifier. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring zero linear factor signed product zero`

Theorem 44.67 (CommRing zero linear factor commuted signed product zero)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, left distributivity, the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, and the* $\mathsf{CommRing}^{\uparrow}$ *multiplicative commutativity field used in Definition 44.47, every* $a, b : \mathsf{BHist}$ *satisfies*

$$\big((a+b)\mathsf{hsame}0 \vee (a+(-b))\mathsf{hsame}0\big) \Longrightarrow (a+(-b))\cdot(a+b)\mathsf{hsame}0.$$

Proof. Apply Definition 44.65 to the selected zero linear factor. In the $(a+b)\mathsf{hsame}0$ branch, specialize the two-sided annihilator row at $c = a+(-b)$ and take the right multiplication component. In the $(a+(-b))\mathsf{hsame}0$ branch, specialize at $c = a+b$ and take the left multiplication component. Both cases produce the displayed commuted signed product as an empty classifier. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring zero linear factor commuted signed product zero`

Theorem 44.68 (CommRing scoped multiplication commutativity source)**.** *In the concrete* $\mathsf{CommRing}^{\uparrow}$ *zero-linear-factor surface over* BHist*, the multiplicative commutativity input is read only as the* hsame*-stable* BHist *row that reverses the* $\mathsf{Ring}^{\uparrow}$ *multiplication classifier. The zero-linear signed-product consumers may use that row to exchange* $(a+b)\cdot(a+(-b))$ *with* $(a+(-b))\cdot(a+b)$*, but they do not receive an additional host commutative-ring carrier, a quotient classifier, or an inverse operation.*

Proof. Project the $\mathsf{CommRing}^{\uparrow}$ input named in Definition 44.47. Its commutativity field is a classifier row over the same BHist multiplication used by $\mathsf{Ring}^{\uparrow}$, and the surrounding hypotheses already supply the hsame transport needed to keep that row stable.

Apply Definition 44.67. The only new read beyond the $\mathsf{Ring}^{\uparrow}$ zero-linear proof is the displayed reversal of the multiplication classifier. Since the theorem still concludes inside hsame over BHist, the source package contributes no external carrier or field structure. □

Theorem 44.69 (CommRing scoped RingUp dependency source)**.** *Every zero-linear and quadratic consumer in this* $\mathsf{CommRing}^{\uparrow}$ *chapter factors through the already cited* $\mathsf{Ring}^{\uparrow}$ *additive laws, addition and multiplication congruence rows, distributivity rows, and negative-product laws, together with the single scoped commutativity row of Definition 44.68. No consumer in the zero-linear or quadratic packet reads a primitive host commutative ring operation outside those rows.*

Proof. For zero-linear consumers, use Definition 44.65, Definition 44.66, and Definition 44.67. Their hypotheses list exactly the $\mathsf{Ring}^{\uparrow}$ additive, congruence, distributive, and negative-product rows, with the commutativity field used only for the reversed orientation.

For quadratic consumers, use Definition 44.60, Definition 44.73, and Definition 44.75. These package the same zero-linear source rows with the quadratic readback rows, so the quadratic exit has the same scoped dependency surface. □

Theorem 44.70 (CommRing scoped ledger source for FieldUp exits)**.** *The downstream* $\mathsf{Field}^{\uparrow}$ *exit rows referenced by the* $\mathsf{CommRing}^{\uparrow}$ *zero-linear and quadratic packets read only the* Cont *and* Pkg *ledger rows named by those packets: the* $\mathsf{Ring}^{\uparrow}$ *source ledgers, the* $\mathsf{CommRing}^{\uparrow}$ *multiplication-commutativity ledger, the zero-linear annihilator ledgers, and the quadratic readback ledgers. The exit package does not acquire field inverse data, cancellation outside the displayed classifier rows, or a bridge to a standard algebraic carrier.*

Proof. Project the zero-linear ledger from Definition 44.71 and the annihilator packages that follow it. These rows give the Cont witnesses for both signed-product orientations and the Pkg provenance for the $\mathsf{Ring}^{\uparrow}$ and $\mathsf{CommRing}^{\uparrow}$ sources.

Project the quadratic ledger from Definition 44.86 and Definition 44.87. The downstream consumer receives those named rows as its readback surface, so its exit data is confined to the packet ledgers and cannot read inverse, cancellation, or standard-carrier structure absent from them. □

Theorem 44.71 (CommRing zero linear factor two-sided signed product zero)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, addition and multiplication congruence, left distributivity, the* $\mathsf{Ring}^{\uparrow}$ *negative-product laws, and the* $\mathsf{CommRing}^{\uparrow}$ *multiplicative commutativity field used in Definition 44.47, every* $a, b : \mathsf{BHist}$ *satisfies*

$$\big((a+b)\mathsf{hsame0} \vee (a+(-b))\mathsf{hsame0}\big) \Longrightarrow \big((a+b)\cdot(a+(-b))\mathsf{hsame0}\big) \wedge \big((a+(-b))\cdot(a+b)\mathsf{hsame0}\big).$$

Proof. Apply Definition 44.66 to the chosen zero linear factor. This gives the forward signed product $(a+b)\cdot(a+(-b))\mathsf{hsame0}$.

Apply Definition 44.67 to the same branch witness. This gives the commuted signed product $(a+(-b))\cdot(a+b)\mathsf{hsame0}$.

Introduce the conjunction with these two oriented zero-product witnesses as its left and right components. □

Theorem 44.72 (CommRing zero linear factor signed product annihilator package)**.** *For BEDC history operations add, mul, neg, and zero satisfying the same hypotheses as Definition 44.82, every* $a, b : \mathsf{BHist}$ *satisfies*

$$\big((a{+}b)\mathsf{hsame0}{\vee}(a{+}(-b))\mathsf{hsame0}\big) \Longrightarrow ((a+b)\cdot(a+(-b))\mathsf{hsame0} \wedge \forall c : \mathsf{BHist},\ (((a+b)\cdot(a+(-b)))\cdot c\mathsf{hsame0} \wedge c$$

Proof. Let H be the displayed zero-linear-factor hypothesis. Apply Definition 44.66 to H to obtain the signed product-zero witness $(a+b)\cdot(a+(-b))\mathsf{hsame0}$.

Use Definition 44.34 to recover the right distributive row from the supplied left distributive row. Together with the $\mathsf{Ring}^{\uparrow}$ zero-factor absorption theorem, this gives the same two-sided absorption mechanism used in Definition 44.65.

Now instantiate that absorption mechanism with $x = (a+b)\cdot(a+(-b))$. For an arbitrary $c : \mathsf{BHist}$, the product-zero witness gives both $((a+b)\cdot(a+(-b)))\cdot c\mathsf{hsame0}$ and $c\cdot((a+b)\cdot(a+(-b)))\mathsf{hsame0}$. Pair this universal row with the original signed product-zero witness to obtain the displayed package. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring zero linear factor signed product annihilator package`

Theorem 44.73 (CommRing equal-squares signed-product annihilator)**.** *For BEDC history operations add, mul, neg, and zero satisfying the hypotheses of Definition 44.47 and the zero-factor absorption hypotheses of Definition 43.40, every $a, b : \mathsf{BHist}$ satisfies*

$$a \cdot a\mathsf{hsame}b \cdot b \Longrightarrow ((a+b)\cdot(a+(-b))\mathsf{hsame}0 \wedge \forall c : \mathsf{BHist},\ (((a+b)\cdot(a+(-b)))\cdot c\mathsf{hsame}0 \wedge c\cdot((a+b)\cdot(a+(-b))$$

Proof. Let Q be the square-equality hypothesis $a \cdot a\mathsf{hsame}b \cdot b$. Apply the reverse direction of Definition 44.47 to Q. This produces the signed product-zero witness $(a+b)\cdot(a+(-b))\mathsf{hsame}0$.

The zero-factor absorption hypotheses give Definition 43.40 for the signed product $x = (a+b)\cdot(a+(-b))$. For an arbitrary $c : \mathsf{BHist}$, instantiate that theorem at $y = c$.

The two components are $((a+b)\cdot(a+(-b)))\cdot c\mathsf{hsame}0$ and $c\cdot((a+b)\cdot(a+(-b)))\mathsf{hsame}0$. Pair this universal two-sided absorption row with the signed product-zero witness from the equal-squares route. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring equal squares signed product annihilator`

Theorem 44.74 (CommRing equal-squares bilateral signed-product zero)**.** *For BEDC history operations add, mul, neg, and zero satisfying the hypotheses of Definition 44.47, every $a, b : \mathsf{BHist}$ satisfies*

$$a \cdot a\mathsf{hsame}b \cdot b \Longrightarrow \big((a+b)\cdot(a+(-b))\mathsf{hsame}0\big) \wedge \big((a+(-b))\cdot(a+b)\mathsf{hsame}0\big).$$

Proof. Let Q be the square-equality hypothesis $a \cdot a\mathsf{hsame}b \cdot b$. Apply Definition 44.46 to Q to obtain the forward signed-product zero witness $(a+b)\cdot(a+(-b))\mathsf{hsame}0$.

The $\mathsf{CommRing}^{\uparrow}$ multiplicative commutativity field identifies the reversed product $(a+(-b))\cdot(a+b)$ with the forward product $(a+b)\cdot(a+(-b))$. Compose this identification with the forward signed-product zero witness by transitivity of hsame.

The two oriented zero-product witnesses form the required conjunction. □

Theorem 44.75 (CommRing equal-squares commuted signed factor zero)**.** *Under the hypotheses of Definition 44.46, every square equality also annihilates the commuted signed product:*

$$a \cdot a\mathsf{hsame}b \cdot b \Longrightarrow (a+(-b))\cdot(a+b)\mathsf{hsame}0.$$

Proof. Apply multiplicative commutativity to identify $(a+(-b))\cdot(a+b)$ with $(a+b)\cdot(a+(-b))$, then compose with Definition 44.46. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring equal squares commuted signed factor zero`

Theorem 44.76 (CommRing equal-squares commuted signed product annihilator)**.** *Under the hypotheses of Definition 44.75, every square equality gives the commuted signed product as a two-sided annihilator:*

$$a\cdot a\mathsf{hsame}b\cdot b \Longrightarrow (a+(-b))\cdot(a+b)\mathsf{hsame}0 \wedge \forall c, ((a+(-b))\cdot(a+b))\cdot c\mathsf{hsame}0 \wedge c\cdot((a+(-b))\cdot(a+b))\mathsf{hsame}0.$$

Proof. Apply Definition 44.75 to get the commuted signed-product zero witness. Right distributivity follows from left distributivity and multiplicative commutativity, and the ring zero absorption rows then identify multiplication by the zero product on either side with zero. Multiplication congruence transports the zero-product witness through the two multiplier positions. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring equal squares commuted signed product annihilator`

Theorem 44.77 (CommRing equal-squares bilateral signed-product annihilator package)**.** *Under the joint hypotheses of Definition 44.73 and Definition 44.76, every* $a, b : \mathsf{BHist}$ *satisfies*

$$a{\cdot}a\mathsf{hsame}b{\cdot}b \Longrightarrow (((a+b)\cdot(a+(-b))\mathsf{hsame0} \wedge \forall c : \mathsf{BHist},\ (((a+b)\cdot(a+(-b)))\cdot c\mathsf{hsame0} \wedge c\cdot((a+b)\cdot(a+(-b)$$

Proof. Let Q be the square-equality hypothesis $a \cdot a\mathsf{hsame}b \cdot b$.

Apply Definition 44.73 to Q. This gives the forward signed-product zero row together with its universal two-sided multiplier annihilator row.

Apply Definition 44.76 to the same Q. This gives the commuted signed-product zero row together with its universal two-sided multiplier annihilator row.

Introduce the outer conjunction and place the forward package in the left component and the commuted package in the right component. □

Theorem 44.78 (CommRing equal-squares bilateral signed-product context annihilator)**.** *Under the joint hypotheses of Definition 44.77 and Definition 43.39, every* $a, b : \mathsf{BHist}$ *satisfies*

$$a{\cdot}a\mathsf{hsame}b{\cdot}b \Longrightarrow \forall c, d : \mathsf{BHist},\ (((c\cdot((a+b)\cdot(a+(-b))))\cdot d)\mathsf{hsame0} \wedge ((c\cdot((a+(-b))\cdot(a+b)))\cdot d)\mathsf{hsame0})\,.$$

Proof. Let Q be the square-equality hypothesis $a \cdot a\mathsf{hsame}b \cdot b$.

Apply Definition 44.77 to Q. Evaluating the two universal left-multiplier rows at c gives $c \cdot ((a+b)\cdot(a+(-b)))\mathsf{hsame0}$ and $c \cdot ((a+(-b))\cdot(a+b))\mathsf{hsame0}$.

For the forward signed product, multiplication congruence transports the first zero witness through the common right multiplier d, comparing $(c \cdot ((a+b)\cdot(a+(-b))))\cdot d$ with $0 \cdot d$. The corresponding zero-absorption row from Definition 43.39 collapses $0 \cdot d$ to 0.

For the commuted signed product, the same argument transports the second left-multiplier zero witness through d and collapses the endpoint $0 \cdot d$ by zero absorption. These two transported zero witnesses form the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring equal squares bilateral signed product context annihilator`

Theorem 44.79 (CommRing equal-squares bilateral signed-product two-sided context annihilator)**.** *Under the joint hypotheses of Definition 44.77 and Definition 43.39, every* $a, b, c, d : \mathsf{BHist}$ *satisfies the following implication. Writing* $P = (a+b)\cdot(a+(-b))$ *and* $Q = (a+(-b))\cdot(a+b)$*,*

$$a{\cdot}a\mathsf{hsame}b{\cdot}b \Longrightarrow \left(\begin{array}{l} (P\cdot c)\cdot d\mathsf{hsame0} \wedge d\cdot(P\cdot c)\mathsf{hsame0} \wedge (c\cdot P)\cdot d\mathsf{hsame0} \wedge d\cdot(c\cdot P)\mathsf{hsame0} \\ \wedge\ (Q\cdot c)\cdot d\mathsf{hsame0} \wedge d\cdot(Q\cdot c)\mathsf{hsame0} \wedge (c\cdot Q)\cdot d\mathsf{hsame0} \wedge d\cdot(c\cdot Q)\mathsf{hsame0} \end{array}\right).$$

Proof. Let S be the square-equality witness $a \cdot a\mathsf{hsame}b \cdot b$. Apply Definition 44.77 to S. The forward package supplies the universal two-sided rows for P, and the commuted package supplies the universal two-sided rows for Q.

Specializing those universal rows at c gives four zero factors: $P{\cdot}c\mathsf{hsame0}$, $c{\cdot}P\mathsf{hsame0}$, $Q{\cdot}c\mathsf{hsame0}$, and $c \cdot Q\mathsf{hsame0}$.

Apply the two rows of Definition 43.39 to each of these four zero factors with multiplier d. The right-context row gives $(P\cdot c)\cdot d\mathsf{hsame0}$, $(c\cdot P)\cdot d\mathsf{hsame0}$, $(Q\cdot c)\cdot d\mathsf{hsame0}$, and $(c\cdot Q)\cdot d\mathsf{hsame0}$; the left-context row gives $d\cdot(P\cdot c)\mathsf{hsame0}$, $d\cdot(c\cdot P)\mathsf{hsame0}$, $d\cdot(Q\cdot c)\mathsf{hsame0}$, and $d\cdot(c\cdot Q)\mathsf{hsame0}$. These eight witnesses are exactly the displayed context rows. □

The ten-field fit for this theorem is: traditional target full two-sided visible-context annihilation in a commutative ring; BEDC source $\mathsf{Ring}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability from bilateral signed-product annihilation and zero absorption; ledger

square equality plus the two visible context histories; core theorem Definition 44.79; exactness the eight displayed context rows; downstream use by $\mathsf{Field}^{\uparrow}$ zero-product obstruction and localization boundary; status ProofTarget.

Proof. Let H be the displayed zero-linear-factor assumption. Apply Definition 44.65 to H to obtain the branch-preserving annihilator disjunction.

Apply Definition 44.82 to the same assumption H. This yields the paired signed product-zero witness and square equality.

Introduce the final conjunction by placing the branch-preserving disjunction in the first component and the paired product-zero and square-equality certificate in the second component. □

The ten-field fit is: traditional target zero linear factor exact package in a commutative ring; BEDC source $\mathsf{Ring}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability from zero-factor absorption and difference-of-squares exactness; ledger the chosen linear factor, branch annihilator row, and signed-product witness; core theorem Definition 44.83; exactness branch annihilator coverage together with signed product zero and equal squares; standard bridge ordinary commutative-ring square exit; status $\mathsf{ProofTarget}$.

Theorem 44.84 (CommRing zero linear factor branch exact package)**.** *For BEDC history operations add, mul, neg, and zero satisfying the same hypotheses as Definition 44.82, every* $a, b : \mathsf{BHist}$ *satisfies*

$$((a+b)\mathsf{hsame}0 \vee (a+(-b))\mathsf{hsame}0) \Longrightarrow ((((a+b)\mathsf{hsame}0 \wedge \forall c : \mathsf{BHist},\ ((a+b)\cdot c\mathsf{hsame}0 \wedge c\cdot(a+b)\mathsf{hsame}0)) \vee ((a$$

Lean4 ✓ `BEDC.Derived.CommRingUp.commring zero linear factor branch exact package from empty unit`

Proof. Start with the displayed zero-linear-factor disjunction. Apply Definition 44.65 to retain the selected branch and its two-sided annihilator row for every $c : \mathsf{BHist}$.

Apply Definition 44.80 to the same disjunction. This gives the square equality $a \cdot a\mathsf{hsame}b \cdot b$ under the identical hypotheses.

Pair the branch-preserving annihilator package with the square equality. The result is exactly the displayed conjunction, so later selector arguments can consume the chosen linear factor without reconstructing the branch. □

The ten-field fit is: traditional target branch-preserving zero-factor exactness in a commutative ring; BEDC source $\mathsf{Ring}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability from zero-factor absorption and difference-of-squares exactness; ledger the selected linear factor and annihilator row; core theorem this block; exactness the displayed conjunction; downstream consumer $\mathsf{Field}^{\uparrow}$ quadratic and zero-factor exit packages; status $\mathsf{ProofTarget}$.

Theorem 44.85 (CommRing zero linear factor bilateral exact package)**.** *For BEDC history operations add, mul, neg, and zero satisfying the same hypotheses as Definition 44.82, every* $a, b : \mathsf{BHist}$ *satisfies*

$$((a+b)\mathsf{hsame}0 \vee (a+(-b))\mathsf{hsame}0) \Longrightarrow ((((a+b)\mathsf{hsame}0 \wedge \forall c : \mathsf{BHist},\ ((a+b)\cdot c\mathsf{hsame}0 \wedge c\cdot(a+b)\mathsf{hsame}0)) \vee ((a$$

Lean4 ✓ `BEDC.Derived.CommRingUp.commring zero linear factor bilateral exact package`

Proof. Let H be the displayed zero-linear-factor hypothesis. Apply Definition 44.84 to H to obtain the branch-preserving annihilator disjunction together with the square equality $a \cdot a\mathsf{hsame}b \cdot b$.

Apply Definition 44.66 to H. This yields the forward signed product $(a+b)\cdot(a+(-b))\mathsf{hsame}0$.

Apply Definition 44.67 to H. This yields the reversed signed product $(a+(-b))\cdot(a+b)\mathsf{hsame}0$.

Introduce the final conjunction by placing the branch annihilator package first, the forward signed product second, the reversed signed product third, and the square equality fourth. The result is the displayed bilateral certificate. □

The ten-field fit is: traditional target zero linear factor bilateral exact package in a commutative ring; BEDC source $\mathsf{Ring}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability from zero-factor absorption and difference-of-squares exactness; ledger the selected linear factor, branch annihilator row, both signed product orientations, and square equality; core theorem this block; exactness the displayed four-component certificate; downstream consumer $\mathsf{Field}^{\uparrow}$ quadratic and zero-factor exit packages; status $\mathsf{ProofTarget}$.

Theorem 44.86 (CommRing quadratic zero-linear bridge package)**.** *For BEDC history operations add, mul, neg, and zero satisfying the shared hypotheses of Definition 44.60 and Definition 44.85, every $a, b : \mathsf{BHist}$ satisfies*

$$((a{+}b)\mathsf{hsame}0 \vee (a{+}(-b))\mathsf{hsame}0) \Longrightarrow \Big(\Big(\Big(((a+b)\cdot(a+b)) + ((a+(-b))\cdot(a+(-b)))\mathsf{hsame}(a\cdot a + a\cdot a) + (b\cdot b +$$

Proof. Apply Definition 44.60 to the shared hypotheses and the selected histories a, b. This produces the full quadratic-polarization package in the displayed order.

Let H be the zero-linear-factor branch witness. Apply Definition 44.85 to H under the same operation hypotheses. This produces the full bilateral certificate: the selected branch with its two-sided annihilator row, both signed product orientations, and the square equality.

Introduce the final conjunction with the quadratic-polarization package as the first component and the bilateral zero-linear-factor certificate as the second component. The branch witness is consumed only by the bilateral component, so the resulting certificate remains over the same concrete BHist source. □

The ten-field fit is: traditional target a commutative-ring package combining quadratic polarization with zero-linear-factor exactness; BEDC source $\mathsf{Ring}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability from the shared quadratic and zero-factor operation laws; ledger the polarization identities, exact signed-square test, selected linear factor, two-sided annihilator row, bilateral signed products, and square equality; core theorem this block; exactness the displayed combined certificate; downstream use by $\mathsf{Field}^{\uparrow}$ quadratic normalization and zero-factor exit packages; status $\mathsf{ProofTarget}$.

Theorem 44.87 (CommRing zero-linear FieldUp exit consumer surface)**.** *For the concrete $\mathsf{CommRing}^{\uparrow}$ history package over BHist, the zero-linear annihilator branch, signed-product zero rows, equal-squares signed-factor rows, total exact package, bilateral exact package, and quadratic zero-linear bridge package expose exactly the $\mathsf{Field}^{\uparrow}$ consumer surface needed by the phase-exit certificate. The exposed surface consists of the carrier rows inherited from $\mathsf{Ring}^{\uparrow}$ and $\mathsf{CommRing}^{\uparrow}$, the classifier rows supplied by the signed-product package, the zero-factor exactness rows, the quadratic readback rows, and the finite ledger rows consumed by the $\mathsf{Field}^{\uparrow}$ phase-exit certificate. It contains no field inverse row, no division row, and no host polynomial-root datum.*

Proof. First project the zero-linear branch through Definition 44.65 and Definition 44.83. These results place the selected branch, its two-sided annihilator behavior, and its zero-factor exactness inside the finite BHist ledger.

Next project the classifier rows. The signed-product rows of Definition 44.66 and Definition 44.67 give the two orientations, while Definition 44.80 and Definition 44.85 identify the equal-squares row and keep the classifier stable under both signed factors.

Finally apply Definition 44.86. It repacks the quadratic readback rows together with the bilateral zero-linear certificate, so the downstream $\mathsf{Field}^{\uparrow}$ exit sees one concrete carrier, classifier, exactness, readback, and ledger surface over BHist. Since every step is a projection from the listed commutative-ring packages, no inverse, division, or host polynomial-root row is introduced. □

Theorem 44.88 (CommRing singleton empty square exact package)**.** *For the singleton empty-history CommRing tuple of Definition 44.6, every pair* $a, b : \mathsf{BHist}$ *carried by* A_{e} *satisfies*

$$\big((a+b)\cdot(a+(-b))\mathsf{hsame}0\big) \wedge \big(a\cdot a\mathsf{hsame}b\cdot b\big),$$

where $+$, $\cdot$, $-$, *and* 0 *are the displayed singleton operations.*

Proof. Theorem 44.7 supplies the concrete singleton $\mathsf{CommRing}^{\uparrow}$ laws for the operation tuple of Definition 44.6. Since the displayed addition and zero operations are constant at e, the carried inputs identify the sum endpoint with the zero endpoint, giving $(a+b)\mathsf{hsame}0$.

Choose the left branch of the zero-linear-factor disjunction:

$$(a+b)\mathsf{hsame}0 \vee (a+(-b))\mathsf{hsame}0.$$

The same singleton law package supplies the additive, congruence, distributive, negative-product, and multiplicative-commutativity fields needed to instantiate Theorem 44.82.

Applying that theorem to the selected left branch yields the signed product zero witness together with the square equality. These are exactly $((a+b)\cdot(a+(-b))\mathsf{hsame}0)$ and $(a\cdot a\mathsf{hsame}b\cdot b)$ for the singleton empty-history CommRing tuple. □

The ten-field fit is: traditional target one-element commutative-ring square exactness; BEDC source singleton empty-history $\mathsf{CommRing}^{\uparrow}$; carrier A_{e}; classifier ρ_{e}; stability from singleton CommRing laws plus the zero-linear-factor exact package; ledger the selected empty linear factor and signed-product witness; core theorem this block; exactness the paired product-zero and equal-square conclusion; standard bridge the one-element commutative ring; status $\mathsf{ProofTarget}$.

Theorem 44.89 (CommRing singleton empty signed product annihilator package)**.** *For the singleton empty-history CommRing tuple of Definition 44.6, every pair* $a, b : \mathsf{BHist}$ *carried by* A_{e} *satisfies*

$$((a+b)\cdot(a+(-b))\mathsf{hsame}0)\wedge\forall c : \mathsf{BHist},\ ((((a+b)\cdot(a+(-b)))\cdot c\mathsf{hsame}0)\wedge(c\cdot((a+b)\cdot(a+(-b)))\mathsf{hsame}0)),$$

where $+$, $\cdot$, $-$, *and* 0 *are the displayed singleton operations.*

Proof. Theorem 44.7 supplies the concrete singleton $\mathsf{CommRing}^{\uparrow}$ laws for the operation tuple of Definition 44.6. Because the displayed addition and zero operations are constant at e, carriedness of a and b identifies the sum endpoint with the zero endpoint, giving $(a+b)\mathsf{hsame}0$.

Choose the left branch of the zero-linear-factor disjunction:

$$(a+b)\mathsf{hsame}0 \vee (a+(-b))\mathsf{hsame}0.$$

The same singleton law package supplies the additive, congruence, distributive, negative-product, and multiplicative-commutativity fields needed to instantiate Theorem 44.72.

That theorem yields the signed product-zero witness together with the universal two-sided annihilator row for the signed product. Unpacking those two components gives exactly $((a+b)\cdot(a+(-b))\mathsf{hsame}0)$ and, for every $c : \mathsf{BHist}$, both $(((a+b)\cdot(a+(-b)))\cdot c\mathsf{hsame}0)$ and $(c\cdot((a+b)\cdot(a+(-b)))\mathsf{hsame}0)$ for the singleton empty-history CommRing tuple. □

The ten-field fit is: traditional target one-element commutative-ring signed-product annihilator; BEDC source singleton empty-history $\mathsf{CommRing}^{\uparrow}$; carrier A_{e}; classifier ρ_{e}; stability from singleton CommRing laws plus zero-factor absorption; ledger selected empty linear factor and signed-product annihilator row; core theorem this block; exactness product-zero plus universal two-sided annihilation; standard bridge one-element commutative ring; status $\mathsf{ProofTarget}$.

Theorem 44.90 (CommRing singleton empty square and signed-product annihilator package)**.** *For the singleton empty-history CommRing tuple of Definition 44.6, every pair $a, b : \mathsf{BHist}$ carried by A_{e} satisfies*

$$(a{\cdot}a\mathsf{hsame}b{\cdot}b)\wedge((a{+}b){\cdot}(a{+}(-b))\mathsf{hsame}0)\wedge\forall c : \mathsf{BHist},\ ((((a+b)\cdot(a+(-b)))\cdot c\mathsf{hsame}0)\wedge(c\cdot((a+b)\cdot(a+(-b)))\mathsf{h}$$

where $+$, $\cdot$, $-$, and 0 are the displayed singleton operations.

Proof. Apply Theorem 44.88 to the selected histories a, b. This yields the signed-product zero row together with the square-equality row for the singleton empty-history CommRing tuple.

Apply Theorem 44.89 to the same selected histories. This yields the same signed-product zero row and the universal two-sided annihilator row for that signed product.

Introduce the displayed triple conjunction. Use the square row from the square-exact package as the first component, use either signed-product zero row as the second component, and use the universal annihilator row from the signed-product annihilator package as the final component. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commringSingletonEmpty square signed product annihilator package`

The ten-field fit is: traditional target one-element commutative-ring package combining singleton square exactness with signed-product annihilation; BEDC source singleton empty-history $\mathsf{CommRing}^{\uparrow}$; carrier A_{e}; classifier ρ_{e}; stability from the singleton square-exact and signed-product annihilator packages; ledger the equal-square row, signed-product zero row, and universal two-sided annihilator row; core theorem this block; exactness the displayed three-part certificate; downstream use by $\mathsf{Field}^{\uparrow}$ quadratic and zero-factor exit packages; status $\mathsf{ProofTarget}$.

Theorem 44.91 (CommRing singleton empty square endpoint annihilator package)**.** *For the singleton empty-history CommRing tuple of Definition 44.6, every pair $a, b : \mathsf{BHist}$ carried by A_{e} satisfies*

$$(a{\cdot}a\mathsf{hsame}b{\cdot}b)\wedge\forall c : \mathsf{BHist},\ ((((a\cdot a)\cdot c)\mathsf{hsame}0)\wedge(c\cdot(a\cdot a)\mathsf{hsame}0)\wedge(((b\cdot b)\cdot c)\mathsf{hsame}0)\wedge(c\cdot(b\cdot b)\mathsf{hsame}0))\,,$$

where $\cdot$ and 0 are the displayed singleton operations.

Lean4 ✓ `BEDC.Derived.CommRingUp.commringSingletonEmpty square endpoint annihilator package`

Proof. Apply Theorem 44.90 to the selected histories a, b. Its first component gives the required square row $a \cdot a\mathsf{hsame}b \cdot b$.

Next use Theorem 44.7. In the singleton empty-history CommRing tuple, multiplication and zero both select the singleton endpoint, so carriedness identifies $a{\cdot}a$ and $b{\cdot}b$ with the zero endpoint.

Now instantiate the zero-factor absorption mechanism of Theorem 43.40 twice, first with $x = a \cdot a$ and then with $x = b \cdot b$. For an arbitrary multiplier $c : \mathsf{BHist}$, the two instantiations provide both left and right zero-factor rows for the two square endpoints.

Package these outputs as the displayed conjunction: the square-equality row is the first component, and the four universal multiplier rows are the second component. □

The ten-field fit is: traditional target one-element commutative-ring square ideal boundary; BEDC source singleton empty-history $\mathsf{CommRing}^{\uparrow}$; carrier A_{e}; classifier ρ_{e}; stability from singleton laws and zero-factor absorption; ledger carried inputs, two square endpoints, and arbitrary multiplier; core theorem this block; exactness square endpoints are two-sided zero annihilators; downstream consumer $\mathsf{Field}^{\uparrow}$ square-apartness and zero-product exits; status $\mathsf{ProofTarget}$.

44.6 Public closure record

Theorem 44.92 (CommRing singleton public operation surface)**.** *For the concrete singleton history commutative-ring instance of Definition 44.2, the public carrier is A_{e}, the public classifier is R_{e}, and the public operation tuple is*

$$\mathsf{add}(h,k) := \mathsf{append}(h,k), \qquad \mathsf{neg}(h) := \mathsf{e}, \qquad 0 := \mathsf{e},$$

together with

$$\mathsf{mul}(h,k) := \mathsf{append}(h,k), \qquad 1 := \mathsf{e}.$$

Every public expression generated from carried endpoints by 0, 1*, unary negation, addition, and multiplication remains in A_{e}, and any two such expressions are classified by R_{e} against the singleton endpoint* e*.*

Proof. The public carrier, classifier, and operation symbols are exactly the rows displayed in Definition 44.2. The operation closure clauses for addition, negation, multiplication, and the distinguished constants are supplied by Theorem 44.3; the remaining schema rows and replacement stability are supplied by Theorem 44.4.

Proceed by induction on the generated public expression. The constant cases 0 and 1 are the empty endpoint. The negation case uses the constant endpoint e. The addition and multiplication cases use the append endpoint and the singleton append rows Theorems 44.21, 44.22, and 44.11 to keep the visible endpoint inside A_{e}.

For the classifier assertion, the induction hypotheses identify each generated endpoint with e. The append/context cancellation and split rows Theorems 44.19 and 44.20 transport that endpoint classification through public operation contexts, while Theorem 44.24 records the commutative multiplication row on the same singleton surface.

Finally, Theorem 44.5 packages these carrier, classifier, operation, stability, ledger, exactness, and terminal-bridge rows as the concrete $\mathsf{CommRing}^{\uparrow}$ certificate boundary. Thus the instance exposes a public carrier/classifier/operation surface rather than only scoped singleton rows. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingUp StdBridge`

Theorem 44.93 (CommRing singleton concrete schema unlock)**.** *The singleton empty-history $\mathsf{Ring}^{\uparrow}$ carrier A_{e}, classifier R_{e}, zero row, one row, addition row, negation row, and multiplication row, together with the singleton multiplication-commutativity row and the square-package rows displayed in this child file, instantiate the $\mathsf{CommRing}^{\uparrow}$ schema as a concrete BHist carrier. The resulting surface is not merely an abstract operator schema: its carrier is A_{e}, its classifier is R_{e}, and all public ring and commutative multiplication operations are generated by the empty-history package.*

Future Lean targets for this surface should live in BEDC.Derived.CommRingUp *over this concrete carrier, classifier, and operation tuple rather than as parameter-transport schema over an unspecified commutative-ring family.*

Proof. Start with the $\mathsf{Ring}^{\uparrow}$ singleton public surface of Definition 44.92. It identifies the carrier, classifier, zero, one, addition, negation, and multiplication rows as the concrete empty-history package over A_{e} and R_{e}.

Next use the commutative multiplication row Definition 44.24. Because both multiplication orders are append endpoints classified by the same singleton predicate, the commutative-ring multiplication obligation is a row over the displayed BHist carrier, not a transported parameter.

Finally combine the square and zero closure rows of Definition 44.88, Definition 44.90, and Definition 44.91. These rows keep the square-package consumers on the same singleton carrier and classifier, so the $\mathsf{CommRing}^{\uparrow}$ schema is opened by a concrete empty-history certificate surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CommRing}^{\uparrow}}$.

Constructive story: The commutative-ring package keeps the same empty-history singleton used for $\mathsf{Ring}^{\uparrow}$ and asks the multiplication row to ignore the order in which two carried endpoint witnesses are continued. Every admitted history is history-equal to e, every comparison is the singleton classifier, and both $\mathsf{Cont}(a, b, \mathsf{e})$ and $\mathsf{Cont}(b, a, \mathsf{e})$ are pulled back by the same endpoint witnesses. The source is the singleton predicate, the pattern records the existing ring operation table plus this multiplication-swap row, and the ledger keeps visible singleton histories aligned with their raw representatives. Because the singleton class is inhabited and history-equality is an equivalence preserving it, nonemptiness, reflexivity, symmetry, transitivity, and carrier closure all follow from the endpoint structure. A history h lies in the signature gap of a $\mathsf{CommRing}^{\uparrow}$ token p when the source-domain accepts h, the signature relation pairs it with an answer history and evidence ledger, and the token-introduction relation names that answer as p; unfolded, h is history-equal to e and p is the singleton commutative-ring element. The signed-square product and endpoint-annihilator facts, together with the terminal bridge, are direct readbacks of the displayed zero, negation, and singleton multiplication rows. The chapter registers this multiplication-swap singleton package under the name $\mathsf{CommRing}^{\uparrow}$; commutativity is the added endpoint obligation over $\mathsf{Ring}^{\uparrow}$, with no spectra, field-inverse data, or non-singleton commutative-ring family introduced.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CommRing}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The paper-side mature scope is the singleton empty-history carrier A_{e}, classifier R_{e}, public operation tuple, singleton certificate boundary, terminal bridge, and the square/annihilator algebraic packages of Definition 44.90 and Definition 44.91.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CommRing}^{\uparrow}}, \mathsf{bridgeChecked})$

Lean target: `BEDC.Derived.CommRingUp.singleton\_empty\_history\_commring\_laws`

Bridge status: bridgeChecked

Not claimed: This record does not close arbitrary commutative rings, non-singleton examples, spectra, field inverse data, or machine-checked bridge verification.

Upgrade path: no further upgrade – chapter at top of formal axis

44.7 Singleton Cont History Instance for $\mathsf{CommRing}^{\uparrow}$

Definition 44.94 (CommRingUp singleton Cont history instance)**.** *Let A_{e} be the singleton* BHist *carrier whose only accepted endpoint is* e*, and let R_{e} be the classifier that identifies two accepted endpoints exactly when both are* hsame *to* e*. Define addition and multiplication by the same concrete continuation endpoint:*

$$x +_{\mathsf{e}} y := \mathsf{Cont}(x, y, \mathsf{e}), \qquad x \cdot_{\mathsf{e}} y := \mathsf{Cont}(x, y, \mathsf{e}).$$

The zero and one rows are both the displayed empty endpoint e*. The package ledger records the two input endpoints, the append read, the output endpoint, and the singleton classifier witness returning the output to* e*.*

Theorem 44.95 (Singleton Cont commutative-ring laws)**.** *The carrier A_{e} with classifier R_{e}, operations $+_{\mathsf{e}}$ and $\cdot_{\mathsf{e}}$, and constants $0_{\mathsf{e}} = 1_{\mathsf{e}} = \mathsf{e}$ satisfies the* $\mathsf{CommRing}^{\uparrow}$ *law surface. Additive group laws, multiplicative monoid laws, distributivity, and multiplicative commutativity all read back to the singleton endpoint under* hsame*.*

Proof. Every accepted input endpoint is classified with e by R_{e}. The continuation endpoint for either operation is therefore an accepted singleton endpoint and is again classified with e.

For associativity, identity, and inverse rows on addition, both sides of each law are continuation endpoints whose source and target histories classify to e. The additive inverse operation is the constant empty endpoint, so the left and right inverse rows also reduce to the same readback.

The multiplicative identity, associativity, and commutativity rows are identical endpoint-readback arguments, because multiplication uses the same concrete continuation endpoint and its unit is also e.

For distributivity, expand both sides as finite continuation endpoints over accepted singleton histories. Each displayed endpoint returns to e under R_{e}, so the two sides classify together. Repacking these rows gives the commutative-ring law surface without quantified abstract operators. □

Theorem 44.96 (CommRingUp singleton Cont schema source)**.** *The singleton Cont history instance of Definition 44.94 is a concrete* BHist*-anchored source for* $\mathsf{CommRing}^{\uparrow}$*. Future formal targets may use this carrier, classifier, operation table, constants, and endpoint ledger as the ground source instead of proving the commutative-ring schema from arbitrary carrier parameters and abstract binary operations.*

Proof. The definition supplies all rows demanded by the commutative-ring source: carrier, classifier, addition, multiplication, zero, one, and package provenance. The preceding theorem supplies the finite law rows for the same objects.

Thus a consumer can cite the singleton packet directly. No external carrier, parameter family, host equality, or abstract operation table is needed to obtain a concrete $\mathsf{CommRing}^{\uparrow}$ source. □

Definition 44.97 (CommRing left zero-divisor data)**.** *For a BEDC history-level* $\mathsf{CommRing}^{\uparrow}$ *operation tuple with multiplication* $\cdot$ *and zero* 0*, write*

$$\mathsf{ApartZero}_R(x) := (x\mathsf{hsame}0 \to \bot).$$

The strict left zero-divisor predicate is

$$\mathsf{LeftZD}_R(x) := \mathsf{ApartZero}_R(x) \wedge \exists c : \mathsf{BHist},\ \mathsf{ApartZero}_R(c) \wedge x \cdot c\mathsf{hsame}0.$$

Lean4 (definition) `BEDC.Derived.CommRingUp.CommRingApartZero`
Lean4 (definition) `BEDC.Derived.CommRingUp.CommRingLeftZeroDivisor`

Theorem 44.98 (CommRing apart-zero visible pair)**.** *For every history* $h : \mathsf{BHist}$*, both visible constructors are apart from the empty zero history:*

$$\mathsf{ApartZero}_R(\mathsf{E0}(h)) \wedge \mathsf{ApartZero}_R(\mathsf{E1}(h)).$$

Proof. Each conjunct is the corresponding BEDC history no-confusion law: neither an $\mathsf{E0}$-headed history nor an $\mathsf{E1}$-headed history can be history-same as e. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingApartZero visible pair`

Definition 44.99 (CommRing strict two-sided zero-divisor data)**.** *For the same BEDC history-level* $\mathsf{CommRing}^{\uparrow}$ *operation tuple, the strict two-sided zero-divisor predicate is*

$$\mathsf{StrictZD}_R(x) := \mathsf{ApartZero}_R(x) \wedge \exists c : \mathsf{BHist},\ \mathsf{ApartZero}_R(c) \wedge x \cdot c\mathsf{hsame}0 \wedge c \cdot x\mathsf{hsame}0.$$

Lean4 (definition) `BEDC.Derived.CommRingUp.CommRingStrictZeroDivisor`

Theorem 44.100 (CommRing singleton multiplication visible strict zero-divisors)**.** *For every BEDC history* h*, both visible singleton histories* $\mathsf{E0}(h)$ *and* $\mathsf{E1}(h)$ *are strict two-sided zero-divisors for the singleton commutative-ring multiplication:*

$$\mathsf{StrictZD}_{\mathsf{singleton}}(\mathsf{E0}(h)) \wedge \mathsf{StrictZD}_{\mathsf{singleton}}(\mathsf{E1}(h)).$$

Proof. The singleton multiplication sends every pair of histories to e. For $\mathsf{E0}(h)$ use $\mathsf{E1}(h)$ as the displayed annihilator, and for $\mathsf{E1}(h)$ use $\mathsf{E0}(h)$. Constructor disjointness gives the apart-from-zero clauses for both visible histories, while both ordered products reduce to e. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingSingletonMul visible strictZeroDivisor`

Theorem 44.101 (CommRing left zero-divisor strictness from commutativity)**.** *For any BEDC history multiplication mul satisfying multiplicative commutativity under* hsame*, every left zero-divisor carries a two-sided annihilator witness:*

$$\mathsf{LeftZD}_R(x) \Longrightarrow \mathsf{ApartZero}_R(x) \wedge \exists c : \mathsf{BHist},\ \mathsf{ApartZero}_R(c) \wedge x \cdot c\mathsf{hsame}0 \wedge c \cdot x\mathsf{hsame}0.$$

Proof. Unpack the left zero-divisor data. It gives the apartness of x and a witness c with $\mathsf{ApartZero}_R(c)$ and $x \cdot c\mathsf{hsame}0$. Apply multiplicative commutativity to obtain $c \cdot x\mathsf{hsame}x \cdot c$, then compose by transitivity with the displayed left annihilation row. The same witness c therefore supplies both annihilator orientations. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingLeftZeroDivisor strict of mul comm`

Theorem 44.102 (CommRing left zero-divisor strictness iff under commutativity)**.** *For any BEDC history multiplication mul, written as* $\cdot$*, satisfying multiplicative commutativity under* hsame*, every* $x : \mathsf{BHist}$ *satisfies*

$$(\forall uv : \mathsf{BHist},\ u \cdot v\mathsf{hsame}v \cdot u) \Longrightarrow (\mathsf{LeftZD}_R(x) \Longleftrightarrow \mathsf{StrictZD}_R(x)).$$

Proof. For the forward implication, assume $\mathsf{LeftZD}_R(x)$ and the displayed multiplicative commutativity row. Apply Definition 44.101. Its conclusion is the apartness of x together with an apart annihilator c satisfying both $x \cdot c\mathsf{hsame}0$ and $c \cdot x\mathsf{hsame}0$, which is exactly $\mathsf{StrictZD}_R(x)$ by Definition 44.99.

For the reverse implication, unfold $\mathsf{StrictZD}_R(x)$. The strict two-sided data gives $\mathsf{ApartZero}_R(x)$ and a witness $c : \mathsf{BHist}$ with $\mathsf{ApartZero}_R(c)$, $x \cdot c\mathsf{hsame}0$, and $c \cdot x\mathsf{hsame}0$. Dropping the right-annihilation conjunct leaves precisely the apartness of x, the same witness c, its apartness, and $x \cdot c\mathsf{hsame}0$, hence $\mathsf{LeftZD}_R(x)$. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingLeftZeroDivisor strictZeroDivisor of mul comm iff`
Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingLeftZeroDivisor strict iff of mul comm`
Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingLeftZeroDivisor strict expansion iff of mul comm`

Ten-field fit: traditional target left and two-sided zero-divisor collapse in commutative rings; BEDC source $\mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability multiplicative commutativity and transitivity; ledger selected annihilator witness; core theorem Definition 44.102; exactness equivalence of one-sided and two-sided annihilator data; standard bridge ordinary commutative-ring zero divisors; status $\mathsf{ProofTarget}$.

Theorem 44.103 (CommRing zero-divisor product closure)**.** *For BEDC history operations add, mul, neg, and zero satisfying the* $\mathsf{Ring}^{\uparrow}$ *additive abelian-group laws, multiplicative associativity, addition and multiplication congruence, left distributivity, and the* $\mathsf{CommRing}^{\uparrow}$ *multiplicative commutativity field, every* $a, b : \mathsf{BHist}$ *satisfies*

$$\mathsf{LeftZD}_R(a) \Longrightarrow ((a \cdot b)\mathsf{hsame}0 \to \bot) \Longrightarrow \mathsf{LeftZD}_R(a \cdot b).$$

Proof. First derive right distributivity from the supplied left distributivity by Definition 44.34. With this row, the additive group laws, and multiplication congruence, the hypotheses of Definition 43.40 are available.

Unpack $\mathsf{LeftZD}_R(a)$. Its right component gives a history $c : \mathsf{BHist}$ with $\mathsf{ApartZero}_R(c)$ and $a \cdot c\mathsf{hsame}0$. Let P be the displayed proof that $a \cdot b$ is apart from zero.

The same c annihilates $a \cdot b$. Multiplicative associativity gives $(a \cdot b) \cdot c\mathsf{hsame}a \cdot (b \cdot c)$. Multiplicative commutativity gives $b \cdot c\mathsf{hsame}c \cdot b$, and multiplication congruence transports this inside left multiplication by a. Symmetry of associativity then identifies $a \cdot (c \cdot b)$ with $(a \cdot c) \cdot b$.

Apply Definition 43.40 to the zero classifier $a \cdot c\mathsf{hsame}0$ and multiplier b. Its left product component gives $(a \cdot c) \cdot b\mathsf{hsame}0$. Transitivity through the associativity and commutativity rows yields

$$(a \cdot b) \cdot c\mathsf{hsame}0.$$

The strict left zero-divisor data for $a \cdot b$ is therefore the pair consisting of P and the same annihilator witness c with its apart-zero proof and the displayed product-zero classifier. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingLeftZeroDivisor product closed`

Theorem 44.104 (CommRing annihilator product left zero-divisor)**.** *Under the same hypotheses as Definition 44.103, every* $a, b, c : \mathsf{BHist}$ *satisfies*

$$\mathsf{ApartZero}_R(c) \Longrightarrow (a \cdot c\mathsf{hsame}0) \Longrightarrow ((a \cdot b)\mathsf{hsame}0 \to \bot) \Longrightarrow \mathsf{LeftZD}_R(a \cdot b).$$

Proof. Assume $\mathsf{ApartZero}_R(c)$, $a \cdot c\mathsf{hsame}0$, and $P : (a \cdot b)\mathsf{hsame}0 \to \bot$. We reuse the displayed c as the annihilator witness and show that it annihilates $a \cdot b$.

Multiplicative associativity gives $(a \cdot b) \cdot c\mathsf{hsame}a \cdot (b \cdot c)$. Multiplicative commutativity gives $b \cdot c\mathsf{hsame}c \cdot b$, and multiplication congruence transports this comparison inside left multiplication by a. Symmetry of associativity then identifies $a \cdot (c \cdot b)$ with $(a \cdot c) \cdot b$.

As in Definition 44.103, derive right distributivity from Definition 44.34 and use the zero-classifier factor absorption theorem. Applied to $a \cdot c\mathsf{hsame}0$ and the multiplier b, it yields $(a \cdot c) \cdot b\mathsf{hsame}0$. Transitivity through the associativity, commutativity, and congruence chain gives

$$(a \cdot b) \cdot c\mathsf{hsame}0.$$

The strict left zero-divisor data for $a \cdot b$ is the apart-zero component P together with the same witness c, its apart-zero proof, and the displayed product-zero classifier. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingLeftZeroDivisor product closed from annihilator`

Ten-field fit: traditional target nonzero multiple of an element with a nonzero annihilator; BEDC source $\mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability associativity, commutativity, congruence, and zero absorption; ledger selected annihilator witness; core theorem Definition 44.104; exactness explicit witness preservation; standard bridge ordinary commutative-ring zero-divisor propagation; status $\mathsf{ProofTarget}$.

Theorem 44.105 (CommRing strict zero-divisor product closure)**.** *Under the same operation hypotheses as Definition 44.103, every* $a, b : \mathsf{BHist}$ *satisfies*

$$\mathsf{StrictZD}_R(a) \Longrightarrow ((a \cdot b)\mathsf{hsame}0 \to \bot) \Longrightarrow \mathsf{StrictZD}_R(a \cdot b).$$

Proof. Unpack $\mathsf{StrictZD}_R(a)$. The strict witness supplies $c : \mathsf{BHist}$ together with $\mathsf{ApartZero}_R(c)$, $a \cdot c\mathsf{hsame0}$, and $c \cdot a\mathsf{hsame0}$. Let P be the given proof that $a \cdot b$ is apart from zero.

The left annihilation row for the product is the same chain as in Definition 44.103. Multiplicative associativity rewrites $(a \cdot b) \cdot c$ to $a \cdot (b \cdot c)$, commutativity rewrites $b \cdot c$ to $c \cdot b$, and congruence transports the comparison under left multiplication by a.

Associativity in the other direction identifies $a \cdot (c \cdot b)$ with $(a \cdot c) \cdot b$. The zero-classifier factor absorption theorem then sends $a \cdot c\mathsf{hsame0}$ to $(a \cdot c) \cdot b\mathsf{hsame0}$, so transitivity gives

$$(a \cdot b) \cdot c\mathsf{hsame0}.$$

For the right annihilation row, apply the $\mathsf{CommRing}^{\uparrow}$ multiplicative commutativity field to the two histories $(a \cdot b) \cdot c$ and $c \cdot (a \cdot b)$. Transport the displayed zero classifier across this comparison to obtain

$$c \cdot (a \cdot b)\mathsf{hsame0}.$$

Package P, the same apart-zero witness c, its apartness proof, and the two displayed annihilation rows. These are exactly the components of $\mathsf{StrictZD}_R(a \cdot b)$. □

Lean4 ✓ `BEDC.Derived.CommRingUp.commring strict zero divisor empty product closed`

Theorem 44.106 (CommRing left zero-divisor product strict closure)**.** *Under the same operation hypotheses as Definition 44.103, together with the multiplicative commutativity row used in Definition 44.101, every* $a, b : \mathsf{BHist}$ *satisfies*

$$\mathsf{LeftZD}_R(a) \Longrightarrow ((a \cdot b)\mathsf{hsame0} \to \bot) \Longrightarrow \mathsf{StrictZD}_R(a \cdot b).$$

Proof. Assume $\mathsf{LeftZD}_R(a)$ and let $P : (a \cdot b)\mathsf{hsame0} \to \bot$ be the displayed apartness proof for the product. Apply Definition 44.103 to a, b, the left zero-divisor witness for a, and P. This gives $\mathsf{LeftZD}_R(a \cdot b)$ with the preserved annihilator.

Next apply Definition 44.101 to the product $a \cdot b$, using the same multiplicative commutativity row. The result unpacks into the apartness of $a \cdot b$ and a history $c : \mathsf{BHist}$ with $\mathsf{ApartZero}_R(c)$, $(a \cdot b) \cdot c\mathsf{hsame0}$, and $c \cdot (a \cdot b)\mathsf{hsame0}$.

These are precisely the fields of $\mathsf{StrictZD}_R(a \cdot b)$. Repack the apartness component and the two-sided annihilator witness c to obtain the claimed strict product closure. □

Lean4 ✓ `BEDC.Derived.CommRingUp.CommRingLeftZeroDivisor product strict closed`

The ten-field fit for Definition 44.106 is: traditional target nonzero multiple of a left zero-divisor; BEDC source $\mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability from associativity, commutativity, congruence, and zero absorption; ledger the preserved annihilator and product apartness; core theorem Definition 44.106; exactness the two-sided strict witness recovered from the left witness; downstream consumer the $\mathsf{Field}^{\uparrow}$ zero-product obstruction and commutative-ring localization boundary; status $\mathsf{ProofTarget}$.

The ten-field fit for Definition 44.105 is: traditional target strict zero-divisor closure in a commutative ring; BEDC source $\mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability from associativity, commutativity, congruence, and zero absorption; ledger the apartness witness plus both annihilator orientations; core theorem Definition 44.105; exactness the two-sided annihilator witness; standard bridge ordinary commutative-ring zero-divisor closure; status $\mathsf{ProofTarget}$.

Theorem 44.107 (CommRing left zero-divisor two-step product strict closure)**.** *Under the same operation hypotheses as Definition 44.106, every* $a, b, c : \mathsf{BHist}$ *satisfies*

$$\mathsf{LeftZD}_R(a) \Longrightarrow ((a \cdot b)\mathsf{hsame0} \to \bot) \Longrightarrow (((a \cdot b) \cdot c)\mathsf{hsame0} \to \bot) \Longrightarrow \mathsf{StrictZD}_R((a \cdot b) \cdot c).$$

Proof. Assume $\mathsf{LeftZD}_R(a)$ and let $P : (a \cdot b)\mathsf{hsame0} \to \bot$ be the apartness proof for the first product. Apply Definition 44.106 to a, b, the left zero-divisor witness for a, and P. This gives $\mathsf{StrictZD}_R(a \cdot b)$.

Let $Q : ((a \cdot b) \cdot c)\mathsf{hsame0} \to \bot$ be the apartness proof for the second product. Apply Definition 44.105 to the strict zero-divisor $a \cdot b$, the factor c, and Q.

The resulting package is exactly $\mathsf{StrictZD}_R((a \cdot b) \cdot c)$: its apartness component is Q, and its two-sided annihilator witness is the one transported by the cited strict product-closure theorem. □

The ten-field fit for Definition 44.107 is: traditional target iterated nonzero multiple of a zero divisor; BEDC source $\mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability from the two cited product-closure theorems; ledger the two apartness hypotheses and preserved annihilator; core theorem Definition 44.107; exactness the strict two-sided witness for the second product; standard bridge ordinary commutative-ring zero-divisor propagation; status $\mathsf{ProofTarget}$.

Definition 44.108 (CommRing subring-inclusion name certificate)**.** *Let S and T be history-level $\mathsf{CommRing}^{\uparrow}$ packages as in Definition 44.59. Write their carriers and classifiers as $C_S, \sim_S$ and $C_T, \sim_T$, and write their operations as $0_S, 1_S, +_S, -_S, \cdot_S$ and $0_T, 1_T, +_T, -_T, \cdot_T$. For a history map $\iota : \mathsf{BHist} \to \mathsf{BHist}$, define the target image carrier*

$$\mathsf{Im}_\iota(y) \iff \exists x : \mathsf{BHist},\ C_S(x) \wedge \iota(x) \sim_T y.$$

Define the target-image classifier by

$$y \sim_\iota z \iff \mathsf{Im}_\iota(y) \wedge \mathsf{Im}_\iota(z) \wedge y \sim_T z.$$

A subring-inclusion name certificate for ι over T is the naming certificate of Definition 9.6 with source Im_ι, classifier $\sim_\iota$, stability rows inherited from the target $\mathsf{CommRing}^{\uparrow}$ package, and ledger rows recording the carrier reflection, classifier reflection, and operation-preservation data for 0, 1, $+$, and $\cdot$. Its stability component includes target-carrier inclusion, classifier transport, closure under 0_T, 1_T, $+_T$, $-_T$, and $\cdot_T$, and the inherited additive, multiplicative, distributive, congruence, and commutativity laws under $\sim_\iota$.

Theorem 44.109 (CommRing subring inclusion inverse closure)**.** *Let S and T be history-level $\mathsf{CommRing}^{\uparrow}$ packages as in Definition 44.59, with notation as in Definition 44.108. Let $\iota : \mathsf{BHist} \to \mathsf{BHist}$ satisfy carrier reflection, classifier reflection on carried source endpoints, zero preservation $\iota(0_S) \sim_T 0_T$, and addition preservation on carried inputs:*

$$\iota(x +_S u) \sim_T \iota(x) +_T \iota(u).$$

If $\mathsf{Im}_\iota(y)$, then $\mathsf{Im}_\iota(-_T y)$.

Proof. Choose a source witness x for $\mathsf{Im}_\iota(y)$, so $C_S(x)$ and $\iota(x) \sim_T y$. Source inverse closure gives $C_S(-_S x)$. The source left-inverse row gives $(-_S x) +_S x \sim_S 0_S$, and classifier reflection on carried source endpoints transports it to

$$\iota((-_S x) +_S x) \sim_T \iota(0_S).$$

Addition preservation and zero preservation turn this comparison into

$$\iota(-_S x) +_T \iota(x) \sim_T 0_T.$$

Target additive congruence with $\iota(x) \sim_T y$ gives

$$\iota(-_S x) +_T y \sim_T 0_T.$$

The target right-inverse row from Definition 43.27 gives $y +_T (-_T y) \sim_T 0_T$. Together with target additive associativity, the target left-zero law, Definition 43.31, and target addition congruence, Definition 41.59 identifies the two inverse witnesses:

$$\iota(-_S x) \sim_T -_T y.$$

Thus the carried source endpoint $-_S x$ witnesses $\mathsf{Im}_\iota(-_T y)$. The additive inverse row follows from + and 0 preservation, so no separate preservation assumption for $-_S$ is required. □

Theorem 44.110 (CommRing carrier reflection gives subring inclusion)**.** *Let S and T be history-level* $\mathsf{CommRing}^\uparrow$ *packages as in Definition 44.59, with notation as in Definition 44.108. Let* $\iota : \mathsf{BHist} \to \mathsf{BHist}$ *satisfy the following rows:*

1. *Carrier reflection:* $C_S(x) \Longrightarrow C_T(\iota(x))$ *and* $C_T(\iota(x)) \Longrightarrow C_S(x)$ *for every* x*.*
2. *Classifier reflection on carried source endpoints:*

$$C_S(x) \wedge C_S(y) \Longrightarrow (x \sim_S y \Longleftrightarrow \iota(x) \sim_T \iota(y)).$$

3. *Constant preservation:* $\iota(0_S) \sim_T 0_T$ *and* $\iota(1_S) \sim_T 1_T$*.*
4. *Operation preservation for carried inputs:*

$$\iota(x +_S y) \sim_T \iota(x) +_T \iota(y) \qquad \text{and} \qquad \iota(x \cdot_S y) \sim_T \iota(x) \cdot_T \iota(y).$$

Then the image carrier Im_ι *and classifier* $\sim_\iota$ *of Definition 44.108 form a subring-inclusion name certificate over the target package* T*.*

Proof. The target classifier is a carrier naming certificate by Definition 9.7. Hence it supplies reflexivity, symmetry, transitivity, and carrier transport for $\sim_T$. If $\mathsf{Im}_\iota(y)$ is witnessed by a carried source endpoint x with $\iota(x) \sim_T y$, carrier preservation gives $C_T(\iota(x))$, and target carrier transport gives $C_T(y)$. If also $y \sim_T y'$, transitivity gives $\iota(x) \sim_T y'$, so the same source witness proves $\mathsf{Im}_\iota(y')$. The restricted classifier $\sim_\iota$ is a $\mathsf{NameCert}$ on Im_ι. Inhabitedness is witnessed by 0_T: the source certificate carries 0_S, and the constant row gives $\iota(0_S) \sim_T 0_T$. Reflexivity, symmetry, and transitivity are the corresponding target classifier fields, with the image endpoints retained in the first two components of the definition of $\sim_\iota$. Carrier transport for Im_ι is immediate from the right image component of a $\sim_\iota$ witness. The constants are carried by the image for the same reason. The zero row uses 0_S and $\iota(0_S) \sim_T 0_T$; the unit row uses 1_S and $\iota(1_S) \sim_T 1_T$. For addition closure, choose image witnesses x, u for y, z, so $C_S(x)$, $C_S(u)$, $\iota(x) \sim_T y$, and $\iota(u) \sim_T z$. Source additive closure, part of the $\mathsf{Ring}^\uparrow$ component in Definition 43.26, gives $C_S(x +_S u)$. Operation preservation gives

$$\iota(x +_S u) \sim_T \iota(x) +_T \iota(u).$$

Target additive congruence transports the two image comparisons to

$$\iota(x) +_T \iota(u) \sim_T y +_T z.$$

Transitivity gives $\iota(x +_S u) \sim_T y +_T z$, so $x +_S u$ witnesses $\mathsf{Im}_\iota(y +_T z)$. Multiplication closure is identical, using source multiplicative closure, target multiplication congruence, and the product-preservation row.

Closure under target additive inverse is Definition 44.109, applied to the carrier reflection, classifier reflection, zero-preservation, and addition-preservation rows already listed. All remaining $\mathsf{CommRing}^{\uparrow}$ laws restrict from T. Associativity, commutativity of addition, additive inverse laws, multiplicative unit and associativity, distributivity, multiplication congruence, and multiplicative commutativity are target stability rows from Definition 44.33; their endpoints stay inside Im_ι by the closure rows just proved, and their classifier comparisons are exactly the third component of $\sim_\iota$. The reverse carrier and classifier reflection implications are recorded as the exactness part of the inclusion ledger, showing that the target image does not identify carried source endpoints beyond $\sim_S$. These rows supply the source, classifier, stability, and ledger components required by Definition 44.108, hence they induce the advertised subring-inclusion name certificate over T. □

Theorem 44.111 (CommRing subring inclusion transitivity)**.** *Let A, B, and C be history-level $\mathsf{CommRing}^{\uparrow}$ packages as in Definition 44.59. Write their carriers and classifiers as $D_A, \sim_A$, $D_B, \sim_B$, and $D_C, \sim_C$, and write their operations as $0_A, 1_A, +_A, -_A, \cdot_A$, $0_B, 1_B, +_B, -_B, \cdot_B$, and $0_C, 1_C, +_C, -_C, \cdot_C$. Let $\iota : \mathsf{BHist} \to \mathsf{BHist}$ carry a subring-inclusion name certificate from A to B, and let $\kappa : \mathsf{BHist} \to \mathsf{BHist}$ carry a subring-inclusion name certificate from B to C, both in the sense of Definition 44.108. Then the composite history map $\kappa \circ \iota$ carries a subring-inclusion name certificate from A to C of the same form. Its target image carrier is*

$$\mathsf{Im}_{\kappa\circ\iota}(z) \iff \exists x : \mathsf{BHist},\ D_A(x) \wedge \kappa(\iota(x)) \sim_C z,$$

and its target-image classifier is

$$z \sim_{\kappa\circ\iota} w \iff \mathsf{Im}_{\kappa\circ\iota}(z) \wedge \mathsf{Im}_{\kappa\circ\iota}(w) \wedge z \sim_C w.$$

Proof. Unpack the two input inclusion certificates using Definition 44.108. Each one supplies carrier reflection in both directions, classifier reflection on carried source endpoints, preservation of 0 and 1, and preservation of addition and multiplication on carried inputs. By Definition 44.110, it is enough to verify these rows for $\kappa \circ \iota$.

For carrier reflection, if $D_A(x)$ then the carrier-preservation row for ι gives $D_B(\iota(x))$, and the carrier-preservation row for κ gives $D_C(\kappa(\iota(x)))$. Conversely, if $D_C(\kappa(\iota(x)))$, the reverse carrier-reflection row for κ gives $D_B(\iota(x))$, and the reverse row for ι gives $D_A(x)$.

For classifier reflection, fix carried x, y in A. Carrier preservation for ι makes $\iota(x)$ and $\iota(y)$ carried in B. The classifier-reflection row for ι gives

$$x \sim_A y \iff \iota(x) \sim_B \iota(y),$$

and the classifier-reflection row for κ gives

$$\iota(x) \sim_B \iota(y) \iff \kappa(\iota(x)) \sim_C \kappa(\iota(y)).$$

Composing these two equivalences gives the classifier-reflection row for the composite.

For zero preservation, the A-certificate carries 0_A, so carrier preservation for ι makes $\iota(0_A)$ carried in B. The B-certificate carries 0_B. The zero row for ι gives $\iota(0_A) \sim_B 0_B$; applying the classifier-preservation direction for κ gives

$$\kappa(\iota(0_A)) \sim_C \kappa(0_B).$$

The zero row for κ gives $\kappa(0_B) \sim_C 0_C$, and classifier transitivity from Definition 9.8 yields $\kappa(\iota(0_A)) \sim_C 0_C$. The same argument with the unit rows gives $\kappa(\iota(1_A)) \sim_C 1_C$.

For addition preservation, let x, u be carried in A. Source additive closure in the A package gives $D_A(x +_A u)$, hence $D_B(\iota(x +_A u))$. The first inclusion certificate gives

$$\iota(x +_A u) \sim_B \iota(x) +_B \iota(u).$$

The endpoints $\iota(x)$ and $\iota(u)$ are carried in B, so B-addition closure carries $\iota(x) +_B \iota(u)$. Applying classifier preservation for κ gives

$$\kappa(\iota(x +_A u)) \sim_C \kappa(\iota(x) +_B \iota(u)).$$

The addition-preservation row for κ on the carried inputs $\iota(x)$ and $\iota(u)$ gives

$$\kappa(\iota(x) +_B \iota(u)) \sim_C \kappa(\iota(x)) +_C \kappa(\iota(u)).$$

Classifier transitivity composes these two comparisons, giving the addition-preservation row for $\kappa \circ \iota$.

The multiplication row is identical, using multiplicative closure in the A and B packages and the two multiplication-preservation rows:

$$\kappa(\iota(x \cdot_A u)) \sim_C \kappa(\iota(x)) \cdot_C \kappa(\iota(u)).$$

Thus the composite supplies carrier reflection, classifier reflection, constant preservation, and operation preservation in the exact format required by Definition 44.110. Applying that theorem to $\kappa \circ \iota$ gives the displayed image carrier, target-image classifier, stability rows inherited from the C-package, and the composite inclusion ledger. Therefore $\kappa \circ \iota$ carries the required subring-inclusion name certificate over C. □

Theorem 44.112 (CommRing singleton empty identity subring inclusion)**.** *For the singleton empty-history CommRing tuple of Definition 44.6, let $\iota : \mathsf{BHist} \to \mathsf{BHist}$ be the identity history map $\iota(h) := h$. Form the image carrier and target-image classifier of Definition 44.108 with source and target both this singleton package. Then, for every $y, z : \mathsf{BHist}$, the image carrier is exactly the singleton carrier:*

$$\mathsf{Im}_\iota(y) \iff A_{\mathsf{e}}(y).$$

The target-image classifier is exactly the singleton classifier:

$$y \sim_\iota z \iff \rho_{\mathsf{e}}(y, z).$$

Moreover, the identity map carries a subring-inclusion name certificate from the singleton empty-history CommRing package to itself.

Proof. Unfold the identity map and the image carrier. If $\mathsf{Im}_\iota(y)$ is witnessed by x, then the classifier component is $\rho_{\mathsf{e}}(x, y)$, and its target carrier field gives $A_{\mathsf{e}}(y)$.

Conversely, assume $A_{\mathsf{e}}(y)$. Choose $x = y$. The reflexive singleton classifier $\rho_{\mathsf{e}}(y, y)$ is assembled from the two copies of $A_{\mathsf{e}}(y)$ and the reflexive history comparison, so y witnesses $\mathsf{Im}_\iota(y)$.

For the classifier row, the forward direction of $y \sim_\iota z$ projects the third component, namely $\rho_{\mathsf{e}}(y, z)$. In the reverse direction, a classifier witness $\rho_{\mathsf{e}}(y, z)$ supplies the two singleton carrier fields; the image-carrier equivalence just proved turns them into $\mathsf{Im}_\iota(y)$ and $\mathsf{Im}_\iota(z)$, and repacking gives $y \sim_\iota z$.

It remains to verify the rows required by Definition 44.110. Since source and target are the same singleton tuple and ι is the identity map, carrier reflection and classifier reflection are reflexive.

Zero preservation, unit preservation, addition preservation, and multiplication preservation are the same singleton endpoint rows from Definition 44.7.

Applying Definition 44.110 gives the subring-inclusion name certificate for the identity map over the singleton target package. The displayed carrier and classifier rows are the exactness part of that certificate. □

The ten-field fit is: traditional target terminal commutative-ring self-inclusion; BEDC source singleton empty-history $\mathsf{CommRing}^{\uparrow}$; carrier A_{e}; classifier ρ_{e}; stability from Definition 44.7; ledger identity-map provenance; core theorem Definition 44.112; exactness the two displayed iff rows; standard bridge terminal ring identity inclusion; status $\mathsf{ProofTarget}$. $\mathsf{Field}^{\uparrow}$ reads its rational carrier through chapter 37 and its algebraic law surface through chapter 43 and chapter 44 before exporting inverse and affine-operation rows.

Chapter 45

A Concrete Naming Certificate for $\mathsf{Field}^{\uparrow}$

The field interface $\mathsf{Field}^{\uparrow}$ extends chapter 44 with the multiplicative inverse field. The inverse domain is a unary certificate $\mathsf{NonZero}_F(a)$ derived from constructive apartness of a from 0; inverse formation is licensed only by an explicit witness $p : \mathsf{NonZero}_F(a)$. This proof-relevant discipline replaces the classical "$a \neq 0$ implies a invertible" formulation, which would otherwise require LEM. The rational carrier from chapter 37 supplies the candidate carrier and classifier source; a $\mathsf{Field}^{\uparrow}$ certificate is present only when commutative-ring structure, constructive nonzero evidence, inverse closure, inverse laws indexed by nonzero witnesses, and the ledger are supplied over that source.

45.1 Carrier definition

Definition 45.1 (Field carrier)**.** *Use a commutative ring setup extended with a constructive apartness predicate and define* $\mathsf{NonZero}_F(a)$ *as the unary certificate obtained from apartness of* a *from* 0*. The inverse datum has type* $\mathsf{inv}(a, p)$ *for* $p : \mathsf{NonZero}_F(a)$*, so no inverse is formed without the nonzero witness.*

45.2 Concrete singleton empty-history field schema instance

Definition 45.2 (Singleton empty-history field schema instance)**.** *Let* A_{e} *be the singleton history source of Definition 36.169 at* $a_0 = \mathsf{e}$*. Define the classifier*

$$\rho_{\mathsf{e}}(h, k) \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h, k).$$

Take add, neg, 0, mul, *and* 1 *to be the constant empty-history operations of Theorem 44.7. Define* $\mathsf{FieldSingletonNonZero}(h)$ *by*

$$\mathsf{FieldSingletonNonZero}(h) \iff A_{\mathsf{e}}(h) \wedge \mathsf{hsame}(h, \mathsf{e0}(\mathsf{e})).$$

The proof-indexed inverse operation is total on explicit witnesses: $\mathsf{inv}(h, p) := \mathsf{e}$ *for* $p : \mathsf{FieldSingletonNonZero}(h)$*. Theorem 45.33 shows that this witness domain is empty on the singleton carrier.*

Theorem 45.3 (Field singleton carrier visible exclusion)**.** *For every history* $p : \mathsf{BHist}$*, neither visible-headed endpoint lies in the singleton carrier:*

$$\mathsf{FieldSingletonCarrier}(\mathsf{e0}(p)) \to \bot, \qquad \mathsf{FieldSingletonCarrier}(\mathsf{e1}(p)) \to \bot.$$

Proof. Unfold the singleton carrier as equality with e. The closed inductive constructors of BHist separate both $\mathsf{e0}(p)$ and $\mathsf{e1}(p)$ from e, so either carrier witness is impossible. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier visible absurd`

Theorem 45.4 (Field singleton carrier constructor partition)**.** *Every history endpoint is either the empty singleton carrier endpoint, or it has a visible constructor whose singleton carrier witness is impossible:*

$$(h = \mathsf{e} \wedge \mathsf{FieldSingletonCarrier}(h)) \vee (\exists p.\ h = \mathsf{E0}(p) \wedge (\mathsf{FieldSingletonCarrier}(h) \to \bot)) \vee (\exists p.\ h = \mathsf{E1}(p) \wedge (\mathsf{FieldSingletonC$$

Proof. Split on the closed generated-history constructors. The empty branch is carried by reflexivity of hsame at e. In the two visible branches, constructor separation from e turns any singleton carrier witness into a contradiction. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier empty or visible absurd`

Theorem 45.5 (Field singleton classifier visible endpoint exclusion)**.** *For histories $p, q, k : \mathsf{BHist}$, no singleton classifier row can have a visible-headed endpoint on either side:*

$$\begin{aligned} &\rho_{\mathsf{e}}(\mathsf{e0}(p), k) \to \bot, \qquad && \rho_{\mathsf{e}}(\mathsf{e1}(p), k) \to \bot, \\ &\rho_{\mathsf{e}}(k, \mathsf{e0}(q)) \to \bot, \qquad && \rho_{\mathsf{e}}(k, \mathsf{e1}(q)) \to \bot. \end{aligned}$$

Proof. Unfold the singleton classifier into its two carrier fields and classifier comparison. If the visible endpoint is on the left, its left carrier field is one of the two impossible carrier witnesses from Definition 45.3. If the visible endpoint is on the right, the right carrier field gives the same contradiction. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier visible endpoint absurd`

Theorem 45.6 (Field singleton classifier empty endpoints)**.** *For histories $h, k : \mathsf{BHist}$, the singleton field classifier satisfies*

$$\rho_{\mathsf{e}}(h, k) \iff h\mathsf{hsamee} \wedge k\mathsf{hsamee}.$$

Proof. The forward direction unpacks the two carrier fields of $\rho_{\mathsf{e}}(h, k)$; these are precisely the endpoint comparisons $h\mathsf{hsamee}$ and $k\mathsf{hsamee}$.

Conversely, the two endpoint comparisons supply the singleton carrier fields. Composing $h\mathsf{hsamee}$ with the symmetry of $k\mathsf{hsamee}$ gives $h\mathsf{hsame}k$, completing the classifier package. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier empty endpoints iff`

Theorem 45.7 (Field singleton carrier hsame empty transport)**.** *For histories $h, k : \mathsf{BHist}$ with $h\mathsf{hsame}k$, singleton carrier membership of h is exactly empty-endpoint classification of k:*

$$\mathsf{FieldSingletonCarrier}(h) \iff k\mathsf{hsamee}.$$

Proof. Unfold singleton carrier membership as $h\mathsf{hsamee}$. The forward direction composes $k\mathsf{hsame}h$ with $h\mathsf{hsamee}$. The reverse direction composes $h\mathsf{hsame}k$ with $k\mathsf{hsamee}$. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier hsame empty transport iff`

Theorem 45.8 (Field singleton classifier hsame empty transport)**.** *For histories $h, h', k, k' : \mathsf{BHist}$ with $h\mathsf{hsame}h'$ and $k\mathsf{hsame}k'$, the transported singleton classifier on h', k' is equivalent to the three empty-endpoint and comparison facts on h, k:*

$$\mathsf{FieldSingletonClassifier}(h', k') \iff h\mathsf{hsame}\mathsf{e} \wedge k\mathsf{hsame}\mathsf{e} \wedge h\mathsf{hsame}k.$$

Proof. In the forward direction, transport the two classifier carrier fields along $h\mathsf{hsame}h'$ and $k\mathsf{hsame}k'$, and transport the classifier comparison $h'\mathsf{hsame}k'$ back to $h\mathsf{hsame}k$. Conversely, transport the two empty-endpoint facts to h' and k', and compose $h'\mathsf{hsame}h$, $h\mathsf{hsame}k$, and $k\mathsf{hsame}k'$ to obtain the classifier comparison. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier hsame empty transport iff`

Theorem 45.9 (Field singleton classifier hsame empty endpoints)**.** *For histories $h, h', k, k' : \mathsf{BHist}$ with $h\mathsf{hsame}h'$ and $k\mathsf{hsame}k'$, the singleton classifier on h, k is equivalent to the three transported empty-endpoint and comparison facts on h', k':*

$$\mathsf{FieldSingletonClassifier}(h, k) \iff h'\mathsf{hsame}\mathsf{e} \wedge k'\mathsf{hsame}\mathsf{e} \wedge h'\mathsf{hsame}k'.$$

Proof. The forward direction transports the two singleton-carrier endpoints from h, k to h', k' and composes the classifier comparison through the two hsame witnesses. Conversely, transport the endpoints back to h, k and compose $h\mathsf{hsame}h'$, $h'\mathsf{hsame}k'$, and $k'\mathsf{hsame}k$ to rebuild the singleton classifier on h, k. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier hsame empty endpoints iff`

Theorem 45.10 (Field singleton classifier continuation commutativity closure)**.** *For histories $P, Q, L, R : \mathsf{BHist}$, if the singleton field classifier relates P and Q, and the two displayed continuation results satisfy*

$$\mathsf{Cont}(P, Q, L) \qquad \textit{and} \qquad \mathsf{Cont}(Q, P, R),$$

then the singleton field classifier relates L and R.

Proof. The classifier witness identifies both P and Q with e. Transport the two continuation witnesses along these endpoint comparisons and compare them with the canonical continuation $\mathsf{Cont}(\mathsf{e}, \mathsf{e}, \mathsf{e})$. Thus both L and R are singleton-carrier endpoints. Transitivity through e supplies $L\mathsf{hsame}R$, completing the singleton classifier package. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier continuation comm closed`

Theorem 45.11 (Field singleton classifier continuation commutativity iff)**.** *For histories $P, Q, L, R : \mathsf{BHist}$ with continuation ledgers*

$$\mathsf{Cont}(P, Q, L) \qquad \textit{and} \qquad \mathsf{Cont}(Q, P, R),$$

the two displayed continuation results are singleton-classified exactly when the two inputs are singleton-classified:

$$\mathsf{FieldSingletonClassifier}(L, R) \iff \mathsf{FieldSingletonClassifier}(P, Q).$$

Proof. In the first implication, the left result carrier identifies L with e. Transporting $\mathsf{Cont}(P, Q, L)$ to empty result and applying empty-result inversion identifies both P and Q with e, which reconstructs the input classifier.

Conversely, the input classifier identifies both inputs with e. Comparing each displayed continuation with the canonical empty continuation identifies both L and R with e; transitivity through e supplies $L\mathsf{hsame}R$ and hence the result classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier continuation comm iff`

Theorem 45.12 (Field singleton carrier continuation closure)**.** *For histories $P, Q, R : \mathsf{BHist}$, if P and Q are singleton field carrier endpoints and $\mathsf{Cont}(P, Q, R)$, then R is a singleton field carrier endpoint.*

Proof. The carrier witnesses identify P and Q with e. Transport the displayed continuation along these endpoint comparisons and compare it with the canonical right-unit continuation $\mathsf{Cont}(\mathsf{e}, \mathsf{e}, \mathsf{e})$. The resulting determinacy identifies R with e. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier continuation closed`

Theorem 45.13 (Field singleton carrier continuation endpoint split)**.** *For histories $P, Q, R : \mathsf{BHist}$ with $\mathsf{Cont}(P, Q, R)$, the result R is a singleton field carrier endpoint exactly when both inputs are singleton field carrier endpoints:*

$$\mathsf{FieldSingletonCarrier}(R) \iff \mathsf{FieldSingletonCarrier}(P) \wedge \mathsf{FieldSingletonCarrier}(Q).$$

Proof. If R is identified with e, transport the displayed continuation result to e and use empty-result inversion for $\mathsf{Cont}(P, Q, \mathsf{e})$ to identify both endpoints with e. Conversely, when P and Q are both identified with e, compare the displayed continuation with the canonical continuation $\mathsf{Cont}(\mathsf{e}, \mathsf{e}, \mathsf{e})$ to identify R with e. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier continuation endpoint split iff`

Theorem 45.14 (Field singleton carrier continuation right endpoint iff)**.** *For histories $P, Q, R : \mathsf{BHist}$, if P is a singleton field carrier endpoint and $\mathsf{Cont}(P, Q, R)$, then R is a singleton field carrier endpoint exactly when Q is a singleton field carrier endpoint:*

$$\mathsf{FieldSingletonCarrier}(P) \Rightarrow \mathsf{Cont}(P, Q, R) \Rightarrow (\mathsf{FieldSingletonCarrier}(R) \iff \mathsf{FieldSingletonCarrier}(Q)).$$

Proof. The carrier witness for P identifies the left endpoint with e. The displayed continuation therefore has the same result as the right endpoint Q. Transporting singleton-carrier membership along this equality gives the forward implication, while singleton carrier continuation closure gives the reverse implication. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier continuation right endpoint iff`

Theorem 45.15 (Field singleton carrier continuation left endpoint iff)**.** *For histories $P, Q, R : \mathsf{BHist}$, if Q is a singleton field carrier endpoint and $\mathsf{Cont}(P, Q, R)$, then R is a singleton field carrier endpoint exactly when P is a singleton field carrier endpoint:*

$$\mathsf{FieldSingletonCarrier}(Q) \Rightarrow \mathsf{Cont}(P, Q, R) \Rightarrow (\mathsf{FieldSingletonCarrier}(R) \iff \mathsf{FieldSingletonCarrier}(P)).$$

Proof. The carrier witness for Q identifies the right endpoint with e. The displayed continuation therefore has the same result as the left endpoint P. Transporting singleton-carrier membership along this equality gives the forward implication, while singleton carrier continuation closure gives the reverse implication. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier continuation left endpoint iff`

Theorem 45.16 (Field singleton classifier continuation left endpoint transport)**.** *For histories $P, Q, R, S : \mathsf{BHist}$, if Q is a singleton field carrier endpoint and $\mathsf{Cont}(P, Q, R)$, then singleton classification from the result endpoint to S is equivalent to singleton classification from the left endpoint to S:*

$$\mathsf{FieldSingletonCarrier}(Q) \Rightarrow \mathsf{Cont}(P, Q, R) \Rightarrow \big(\mathsf{FieldSingletonClassifier}(R, S) \Longleftrightarrow \mathsf{FieldSingletonClassifier}(P, S)\big).$$

Proof. The carrier witness for Q identifies the continuation tail with e, so the continuation result is internally the same as P. Unfolding the singleton classifier on both sides reduces the comparison to transporting the left carrier field and the endpoint-sameness field along this result equality. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier continuation left endpoint transport iff`

Theorem 45.17 (Field singleton classifier continuation right endpoint transport)**.** *For histories $P, Q, R, S : \mathsf{BHist}$, if P is a singleton field carrier endpoint and $\mathsf{Cont}(P, Q, R)$, then singleton classification from the result endpoint to S is equivalent to singleton classification from the right endpoint to S:*

$$\mathsf{FieldSingletonCarrier}(P) \Rightarrow \mathsf{Cont}(P, Q, R) \Rightarrow \big(\mathsf{FieldSingletonClassifier}(R, S) \Longleftrightarrow \mathsf{FieldSingletonClassifier}(Q, S)\big).$$

Proof. The carrier witness for P identifies the continuation source with e, so the continuation result is internally the same as Q. Unfolding the singleton classifier on both sides transports the source-carrier field and the endpoint-sameness field along this result equality. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier continuation right endpoint transport iff`

Theorem 45.18 (Field singleton classifier continuation two-sided context transport)**.** *For histories $L, R, h, mid, out, S : \mathsf{BHist}$, if L and R are singleton field carrier endpoints, $\mathsf{Cont}(L, h, mid)$, and $\mathsf{Cont}(mid, R, out)$, then singleton classification from out to S is equivalent to singleton classification from h to S:*

$$\mathsf{FieldSingletonCarrier}(L) \Rightarrow \mathsf{FieldSingletonCarrier}(R) \Rightarrow \mathsf{Cont}(L, h, mid) \Rightarrow \mathsf{Cont}(mid, R, out) \Rightarrow (\mathsf{FieldSingletonClass}$$

Proof. The right-context singleton endpoint transports the classifier on out back to the intermediate endpoint mid. The left-context singleton endpoint then transports the classifier on mid back to the exposed history h. Composing the two equivalences gives the displayed classifier equivalence. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier continuation two sided context transport iff`

Theorem 45.19 (Field singleton carrier continuation visible result exclusion)**.** *For histories P, Q, r : BHist, if P and Q are singleton field carrier endpoints, then no continuation from P through Q can have visible result $\mathsf{E0}(r)$ or $\mathsf{E1}(r)$:*

$$\mathsf{FieldSingletonCarrier}(P) \Rightarrow \mathsf{FieldSingletonCarrier}(Q) \Rightarrow (\mathsf{Cont}(P, Q, \mathsf{E0}(r)) \Rightarrow \mathsf{False}) \wedge (\mathsf{Cont}(P, Q, \mathsf{E1}(r)) \Rightarrow \mathsf{False}).$$

Proof. The two singleton carrier witnesses identify the continuation endpoints with e. Continuation result transport compares the displayed continuation with the right-unit continuation at e, forcing its result to be in the singleton carrier. Constructor separation rules out both visible histories $\mathsf{E0}(r)$ and $\mathsf{E1}(r)$ being internally the same as e. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier continuation visible result absurd`

Theorem 45.20 (Field singleton classifier continuation visible result exclusion)**.** *For histories P, Q, r : BHist, if the singleton field classifier relates P and Q, then no continuation from P through Q can have visible result $\mathsf{E0}(r)$ or $\mathsf{E1}(r)$:*

$$\mathsf{FieldSingletonClassifier}(P, Q) \Rightarrow (\mathsf{Cont}(P, Q, \mathsf{E0}(r)) \Rightarrow \mathsf{False}) \wedge (\mathsf{Cont}(P, Q, \mathsf{E1}(r)) \Rightarrow \mathsf{False}).$$

Proof. Unpack the classifier into singleton carrier witnesses for the two endpoints. The preceding carrier exclusion then applies to the same continuation and eliminates both visible result shapes. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier continuation visible result absurd`

Theorem 45.21 (Field singleton classifier continuation endpoint split)**.** *For histories P, Q, R : BHist with $\mathsf{Cont}(P, Q, R)$, $\mathsf{FieldSingletonClassifier}(P, Q)$ is equivalent to $\mathsf{FieldSingletonCarrier}(P) \wedge \mathsf{FieldSingletonCarrier}(Q) \wedge \mathsf{FieldSingletonCarrier}(R)$.*

Proof. The classifier gives the two input carrier fields, and singleton carrier continuation closure gives the result carrier. Conversely, the two input carrier fields identify both endpoints with e, so transitivity through e gives their classifier comparison. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier continuation endpoint split iff`

Theorem 45.22 (Field singleton classifier continuation result classifier)**.** *For histories P, Q, R : BHist, if the singleton field classifier relates P and Q and $\mathsf{Cont}(P, Q, R)$, then the result R is classified with e.*

Proof. Apply singleton carrier continuation closure to the two carrier fields of the classifier witness and the displayed continuation. The result carrier, the reflexive carrier of e, and the same result carrier as the comparison through e assemble the singleton classifier package. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier continuation result classifier`

Theorem 45.23 (Field singleton classifier continuation closure)**.** *For histories P, P', Q, Q', L, R : BHist, if the singleton field classifier relates P with P' and Q with Q', and if*

$$\mathsf{Cont}(P, Q, L) \qquad \textit{and} \qquad \mathsf{Cont}(P', Q', R),$$

then the singleton field classifier relates L and R.

Proof. The two classifier witnesses identify all four inputs with e. Transport each continuation witness along the corresponding pair of endpoint comparisons and compare the result with the canonical continuation $\mathsf{Cont}(\mathsf{e}, \mathsf{e}, \mathsf{e})$. Both L and R are therefore singleton-carried endpoints, and transitivity through e supplies $L\mathsf{hsame}R$. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier continuation closed`

Theorem 45.24 (Field singleton classifier visible-left exclusion)**.** *For histories* $p, q, h : \mathsf{BHist}$*, neither* $\rho_{\mathsf{e}}(\mathsf{append}(p, \mathsf{e0}(q)), h)$ *nor* $\rho_{\mathsf{e}}(\mathsf{append}(p, \mathsf{e1}(q)), h)$ *can hold.*

Proof. Unfold the singleton field classifier. In either case, the left carrier field identifies the displayed append endpoint with e. Empty-result inversion for append then forces the visible right component, either $\mathsf{e0}(q)$ or $\mathsf{e1}(q)$, to be e. The constructors of BHist separate visible endpoints from the empty endpoint, so each case is impossible. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier append visible left absurd`

Theorem 45.25 (Field singleton classifier visible-prefix exclusion)**.** *For histories* $p, q, h : \mathsf{BHist}$*, neither* $\rho_{\mathsf{e}}(\mathsf{append}(\mathsf{e0}(p), q), h)$ *nor* $\rho_{\mathsf{e}}(\mathsf{append}(\mathsf{e1}(p), q), h)$ *can hold.*

Proof. Unfold the singleton field classifier. In either case, the left carrier field identifies the displayed append endpoint with e. Empty-result inversion for append then forces the visible prefix, either $\mathsf{e0}(p)$ or $\mathsf{e1}(p)$, to be e. Constructor separation for BHist rules out both alternatives. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier append visible prefix absurd`

Theorem 45.26 (Field singleton classifier visible right-prefix exclusion)**.** *For histories* $h, p, q : \mathsf{BHist}$*, neither* $\rho_{\mathsf{e}}(h, \mathsf{append}(\mathsf{e0}(p), q))$ *nor* $\rho_{\mathsf{e}}(h, \mathsf{append}(\mathsf{e1}(p), q))$ *can hold.*

Proof. Unfold the singleton field classifier. In either case, the right carrier field identifies the displayed append endpoint with e. Empty-result inversion for append then forces the visible prefix, either $\mathsf{e0}(p)$ or $\mathsf{e1}(p)$, to be e. Constructor separation for BHist rules out both alternatives. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier append visible right prefix absurd`

Theorem 45.27 (Field singleton carrier visible-head append exclusion)**.** *For histories* $h, k : \mathsf{BHist}$*, neither singleton carrier endpoint*

$$\mathsf{FieldSingletonCarrier}(\mathsf{append}(\mathsf{e0}(h), k))$$

nor

$$\mathsf{FieldSingletonCarrier}(\mathsf{append}(\mathsf{e1}(h), k))$$

can hold.

Proof. In either branch, the singleton carrier identifies the displayed append history with e. Empty-result inversion for append then identifies the visible head $\mathsf{e0}(h)$ or $\mathsf{e1}(h)$ with e. The generated history constructors separate both visible heads from the empty history, so both alternatives are impossible. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier append visible head absurd`

Theorem 45.28 (Field singleton carrier visible-tail append exclusion)**.** *For histories p, q : BHist, neither singleton carrier endpoint*

$$\mathsf{FieldSingletonCarrier}(\mathsf{append}(p, \mathsf{e0}(q)))$$

nor

$$\mathsf{FieldSingletonCarrier}(\mathsf{append}(p, \mathsf{e1}(q)))$$

can hold.

Proof. In either branch, the singleton carrier identifies the displayed append history with e. Empty-result inversion for append then identifies the visible tail $\mathsf{e0}(q)$ or $\mathsf{e1}(q)$ with e. Constructor separation for generated histories rules out both visible tails. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier append visible tail absurd`

Definition 45.29 (Classifier-complement singleton nonzero domain)**.** *For the same singleton carrier and classifier, define* $\mathsf{fieldSingletonEmptyNonZero}(h)$ *by*

$$\mathsf{fieldSingletonEmptyNonZero}(h) \iff (\rho_{\mathsf{e}}(h, \mathsf{e}) \to \bot).$$

The multiplication, unit, and proof-indexed inverse are the constant empty-history operations $\mathsf{fieldSingletonEmptyMul}(x, y) := \mathsf{e}$, $\mathsf{fieldSingletonEmptyOne} := \mathsf{e}$, *and* $\mathsf{fieldSingletonEmptyInv}(h, p) := \mathsf{e}$.

Lean4 (definition) `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero`

Theorem 45.30 (Singleton empty nonzero carrier complement)**.** *For every h : BHist, the proof-indexed singleton empty nonzero predicate is exactly the complement of the singleton carrier:*

$$\mathsf{fieldSingletonEmptyNonZero}(h) \iff (\mathsf{FieldSingletonCarrier}(h) \to \mathsf{False}).$$

Proof. For the forward direction, assume p : $\mathsf{fieldSingletonEmptyNonZero}(h)$ and a carrier witness for h. The singleton source is generated at e, so this carrier witness supplies the left endpoint comparison $h\mathsf{hsame}\mathsf{e}$.

The reflexive endpoint $\mathsf{ehsame}\mathsf{e}$ gives the target carrier at e. Together with the comparison from h to e, these data assemble the classifier package $\rho_{\mathsf{e}}(h, \mathsf{e})$, and p sends that package to False.

For the reverse direction, assume q : $\mathsf{FieldSingletonCarrier}(h) \to \mathsf{False}$ and a classifier witness $c : \rho_{\mathsf{e}}(h, \mathsf{e})$. Unpack c and extract its left carrier field for h. Applying q to that carrier field gives the required contradiction, so q is a witness of $\mathsf{fieldSingletonEmptyNonZero}(h)$ by Definition 45.29. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero empty endpoint complement iff`

Theorem 45.31 (Singleton empty nonzero hsame empty complement)**.** *For histories h and k with $h\mathsf{hsame}k$, the proof-indexed singleton empty nonzero predicate at h is exactly the complement of k being empty:*

$$\mathsf{fieldSingletonEmptyNonZero}(h) \iff (\mathsf{hsame}(k, \mathsf{e}) \to \mathsf{False}).$$

Proof. Transport an empty endpoint for k across $h\mathsf{hsame}k$ to obtain an empty endpoint for h, then apply the singleton nonzero obstruction. Conversely, unpack a forbidden classifier witness for h to get $h\mathsf{hsame}\mathsf{e}$, transport that endpoint back across $h\mathsf{hsame}k$, and contradict the displayed complement for k. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero hsame empty complement iff`

This identifies the concrete BHist Field$^{\uparrow}$ schema's proof-indexed nonzero domain with the carrier complement of the singleton empty-classifier instance.

Lemma 45.32 (Singleton raw nonzero endpoint obstruction)**.** *For every h : BHist, the two endpoint witnesses $h$hsamee and $h$hsamee0(e) imply* False.

Proof. Compose the endpoint $h$hsamee in reverse with the endpoint $h$hsamee0(e). This gives an equality ehsamee0(e) inside the closed BHist kernel.

The constructors e and e0(e) are distinct constructors of that inductive type, so constructor no-confusion eliminates the composed endpoint. □

Lean4 ✓ `BEDC.Derived.FieldUp.field singleton nonzero absurd`

Theorem 45.33 (Singleton nonzero endpoint obstruction)**.** *For every h : BHist, a witness p : FieldSingletonNonZero(h) leads to contradiction.*

Proof. Unpack p into its singleton-carrier endpoint $h$hsamee and its zero-head endpoint $h$hsamee0(e). Lemma 45.32 applied to those two fields gives the contradiction. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonNonZero absurd`

Theorem 45.34 (Singleton empty nonzero endpoint obstruction)**.** *For every h : BHist, if $h$hsamee and p : fieldSingletonEmptyNonZero(h), then contradiction follows.*

Proof. The endpoint $h$hsamee supplies the source side of the empty singleton classifier. The empty target is classified by reflexivity, and the same endpoint supplies the classifier equality from h to e. This builds the forbidden classifier input to p. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero empty endpoint absurd`

This block supplies the per-object certificate: traditional target empty inverse domain of the terminal proof-indexed field; BEDC source the concrete BHist singleton field schema; carrier A_{e}; classifier ρ_{e}; stability obligation nonzero contradiction; ledger no nonzero witness; core theorem Theorem 45.33; exactness predicate witness-domain emptiness; standard bridge terminal field; status ProofTarget.

Theorem 45.35 (Singleton nonzero forces the zero-headed empty endpoint)**.** *For every a : BHist, a witness of* FieldSingletonNonZero(a) *forces* ehsamee0(e).

Proof. Unpack the witness into the singleton-carrier endpoint $a$hsamee and the zero-headed endpoint $a$hsamee0(e). Symmetry of the first endpoint and transitivity with the second endpoint give the displayed classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonNonZero empty e0 forced`

Theorem 45.36 (Singleton nonzero hsame target readback)**.** *For histories h, k : BHist, if $h$hsame$k$, then*

$$\mathsf{FieldSingletonNonZero}(h) \iff \mathsf{FieldSingletonCarrier}(k) \wedge k\mathsf{hsamee0}(\mathsf{e}).$$

Proof. Unpack the singleton nonzero witness into its carrier endpoint and its zero-headed endpoint. Symmetry and transitivity of hsame transport both endpoints across $h$hsame$k$. The reverse implication transports the two displayed target endpoints back along the same hsame witness. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonNonZero hsame target readback iff`

Theorem 45.37 (Singleton empty-history field schema laws)**.** *The tuple*

$$(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \mathsf{add}, 0, \mathsf{neg}, \mathsf{mul}, 1, \mathsf{FieldSingletonNonZero}, \mathsf{inv})$$

satisfies the $\mathsf{Field}^{\uparrow}$ *schema laws over the concrete* BHist *singleton carrier.*

Proof. The commutative-ring fields are exactly the fields supplied by Theorem 44.7 for the displayed carrier, classifier, and constant empty-history operations.

The nonzero exclusion at 0 follows from Theorem 45.33 by taking $h = 0$.

Nonzero transport along ρ_{e} is vacuous. Given $\rho_{\mathsf{e}}(h, k)$ and $p : \mathsf{FieldSingletonNonZero}(h)$, Theorem 45.33 gives contradiction; from contradiction one obtains the required witness at k.

Inverse closure is direct because $\mathsf{inv}(h, p)$ is definitionally e, whose carrier endpoint is supplied by the singleton source. Inverse congruence is likewise direct because both displayed inverse endpoints are e, hence are related by ρ_{e}.

The left and right inverse laws have the same proof shape. Each law is indexed by a witness $p : \mathsf{FieldSingletonNonZero}(h)$, but both products are the constant empty-history product and $1 = \mathsf{e}$. The classifier witness is therefore the reflexive singleton endpoint, and no classical inverse is formed outside the proof-indexed domain. □

Lean4 ✓ `BEDC.Derived.FieldUp.singleton empty history field schema laws`

Theorem 45.38 (Singleton empty nonzero visible headed exclusion)**.** *For every history* h : BHist*, both visible-headed histories are in the classifier-complement singleton nonzero predicate:*

$$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{e0}(h)) \wedge \mathsf{fieldSingletonEmptyNonZero}(\mathsf{e1}(h)).$$

Proof. For an e0-headed history, any forbidden classifier witness would include the carrier endpoint $\mathsf{e0}(h)\mathsf{hsamee}$, contradicting constructor disjointness for BHist. The e1-headed case is identical, using the disjointness of e1 from e. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero visible headed`

Theorem 45.39 (Singleton empty nonzero visible cases)**.** *Every history in the classifier-complement singleton nonzero predicate is visible-headed:*

$$\mathsf{fieldSingletonEmptyNonZero}(h) \Rightarrow (\exists t.\ h = \mathsf{e0}(t)) \vee (\exists t.\ h = \mathsf{e1}(t)).$$

Proof. Split on the concrete BHist constructor of h. In the empty case, the reflexive singleton-empty classifier contradicts the nonzero predicate. The e0 and e1 cases directly return their visible tail witnesses. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero visible cases`

Theorem 45.40 (Singleton empty nonzero visible append-right exclusion)**.** *For histories* p, q : BHist*, appending a visible right component gives histories in the classifier-complement singleton nonzero predicate:*

$$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(p, \mathsf{e0}(q))) \wedge \mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(p, \mathsf{e1}(q))).$$

Proof. For either visible right component, a forbidden classifier witness would include a carrier proof identifying the displayed append endpoint with e. Empty-result inversion for append then identifies the visible suffix with e, contradicting constructor separation for BHist. Thus each displayed appended endpoint lies in the complement of the singleton empty classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero append visible right`

Theorem 45.41 (Singleton empty nonzero visible append-left exclusion)**.** *For histories p, q : BHist, appending after a visible left component gives histories in the classifier-complement singleton nonzero predicate:*

$$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(\mathsf{e0}(p), q)) \wedge \mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(\mathsf{e1}(p), q)).$$

Proof. For either visible left component, a forbidden classifier witness would identify the displayed append endpoint with e. Empty-result inversion for append then identifies the visible prefix with e, contradicting constructor separation for BHist. Hence both displayed endpoints lie in the complement of the singleton empty classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero append visible left`

Theorem 45.42 (Singleton empty-classifier append split)**.** *For histories p, q, h : BHist, the singleton empty classifier $\rho_{\mathsf{e}}(\mathsf{append}(p, q), h)$ holds exactly when $p$hsamee, $q$hsamee, and h lies in the singleton carrier A_{e}.*

Proof. Unfold the classifier. In the forward direction, $\rho_{\mathsf{e}}(\mathsf{append}(p, q), h)$ supplies $\mathsf{append}(p, q)$hsamee and the carrier witness for h. Empty-result inversion for append splits the first endpoint into $p$hsamee and $q$hsamee.

Conversely, from $p$hsamee and $q$hsamee, append empty-result inversion reconstructs $\mathsf{append}(p, q)$hsamee. Together with the given carrier witness for h, transitivity through e supplies the classifier equality from $\mathsf{append}(p, q)$ to h. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyClassifier append split empty iff`

Theorem 45.43 (Singleton empty-classifier append right cancellation)**.** *For histories P, Q, R : BHist, if P lies in the singleton empty carrier, then adding P as a common right append context preserves and reflects the singleton empty classifier:*

$$\mathsf{fieldSingletonEmptyCarrier}(P) \Rightarrow (\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(Q, P), \mathsf{append}(R, P)) \Longleftrightarrow \mathsf{fieldSingletonEmp}$$

Proof. In the forward direction, the classifier supplies empty carrier witnesses for both appended endpoints. Empty-result inversion for append splits these witnesses into Qhsamee, Phsamee, and Rhsamee; the witnesses for Q and R rebuild the base classifier, with transitivity through e giving the endpoint comparison.

For the reverse direction, combine the supplied carrier witness for P with the two carrier fields of $\mathsf{fieldSingletonEmptyClassifier}(Q, R)$. Empty-result inversion then rebuilds the carrier witnesses for $\mathsf{append}(Q, P)$ and $\mathsf{append}(R, P)$, and transitivity through e compares the two appended endpoints. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyClassifier append right cancel iff`

Theorem 45.44 (Field singleton classifier append left cancellation)**.** *For histories P, Q, R : BHist, if P lies in the singleton carrier A_{e}, then adding P as a common left append context preserves and reflects the singleton field classifier:*

$$\mathsf{FieldSingletonCarrier}(P) \Rightarrow \big(\mathsf{FieldSingletonClassifier}(\mathsf{append}(P, Q), \mathsf{append}(P, R)) \Longleftrightarrow \mathsf{FieldSingletonClassifier}(Q, R)\big)$$

Proof. In the forward direction, the two appended endpoints are singleton-carried. Empty-result inversion for append splits the left and right endpoint carriers, recovering $Q\mathsf{hsamee}$ and $R\mathsf{hsamee}$. These two carrier witnesses, together with transitivity through e, rebuild $\mathsf{FieldSingletonClassifier}(Q, R)$.

For the reverse direction, the carrier witness for P and the endpoint carriers in $\mathsf{FieldSingletonClassifier}(Q, R)$ rebuild singleton carrier witnesses for $\mathsf{append}(P, Q)$ and $\mathsf{append}(P, R)$. Since both appended endpoints are carried to e, transitivity through e supplies the appended classifier comparison. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier append left cancel iff`

Theorem 45.45 (Field singleton classifier multiplication endpoint)**.** *For histories h, k, out : BHist, classifying the singleton-empty field product endpoint against out is exactly the assertion that out is history-same to* e*:*

$$\rho_{\mathsf{e}}(\mathsf{FieldSingletonMul}(h, k), out) \Longleftrightarrow \mathsf{hsame}(out, \mathsf{e}).$$

Proof. The multiplication endpoint is definitionally e. In the forward direction, the classifier contains the carrier witness for the output endpoint. Conversely, a witness $\mathsf{hsame}(out, \mathsf{e})$ gives the output carrier, the reflexive source carrier at e, and by symmetry the classifier comparison from e to out. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier mul empty endpoint iff`

Theorem 45.46 (Field singleton addition endpoint classifier)**.** *For histories h, k, out : BHist, classifying the singleton-empty field addition endpoint against out is exactly the assertion that out is history-same to* e*:*

$$\rho_{\mathsf{e}}(\mathsf{FieldSingletonAdd}(h, k), out) \Longleftrightarrow \mathsf{hsame}(out, \mathsf{e}).$$

Proof. The addition endpoint is definitionally e. Forward classification exposes the carrier witness for out. Conversely, a witness $\mathsf{hsame}(out, \mathsf{e})$ gives the output carrier, the reflexive source carrier at e, and the symmetric classifier comparison. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonAdd endpoint classifier iff`

Theorem 45.47 (Field singleton neg endpoint classifier iff)**.** *For histories h, out : BHist, classifying the singleton-empty field negative endpoint against out is exactly the assertion that out is history-same to* e*:*

$$\rho_{\mathsf{e}}(\mathsf{FieldSingletonNeg}(h), out) \Longleftrightarrow \mathsf{hsame}(out, \mathsf{e}).$$

Proof. The negative endpoint is definitionally e. Forward classification exposes the carrier witness for out. Conversely, a witness $\mathsf{hsame}(out, \mathsf{e})$ gives the output carrier, the reflexive source carrier at e, and transitivity through e gives the classifier comparison. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonNeg endpoint classifier iff`

Theorem 45.48 (Field singleton concrete operation-table collapse)**.** *In the concrete singleton* $\mathsf{Field}^{\uparrow}$ *instance over* BHist *with carrier* $A_{\mathsf{e}} = \mathsf{FieldSingletonCarrier}$*, classifier* $\rho_{\mathsf{e}} = \mathsf{FieldSingletonClassifier}$*, and concrete operations* $\mathsf{FieldSingletonAdd}$*,* $\mathsf{FieldSingletonMul}$*,* $\mathsf{FieldSingletonNeg}$*,* $\mathsf{FieldSingletonZero}$*,* $\mathsf{FieldSingletonOne}$*, and* $\mathsf{FieldSingletonInv}$*, every displayed operation endpoint lies in* A_{e}*. Moreover, for every* $out : \mathsf{BHist}$ *the classifier rows are exactly the singleton empty-history collapse:*

$$\begin{aligned}
\rho_{\mathsf{e}}(\mathsf{FieldSingletonAdd}(h,k), out) &\iff \mathsf{hsame}(out, \mathsf{e}),\\
\rho_{\mathsf{e}}(\mathsf{FieldSingletonMul}(h,k), out) &\iff \mathsf{hsame}(out, \mathsf{e}),\\
\rho_{\mathsf{e}}(\mathsf{FieldSingletonNeg}(h), out) &\iff \mathsf{hsame}(out, \mathsf{e}),\\
\rho_{\mathsf{e}}(\mathsf{FieldSingletonZero}, out) &\iff \mathsf{hsame}(out, \mathsf{e}),\\
\rho_{\mathsf{e}}(\mathsf{FieldSingletonOne}, out) &\iff \mathsf{hsame}(out, \mathsf{e}),\\
\rho_{\mathsf{e}}(\mathsf{FieldSingletonInv}(h,p), out) &\iff \mathsf{hsame}(out, \mathsf{e}).
\end{aligned}$$

Here $h, k : \mathsf{BHist}$ *and* $p : \mathsf{FieldSingletonNonZero}(h)$*.*

Proof. The multiplication, addition, and negation rows are exactly Theorem 45.45, Theorem 45.46, and Theorem 45.47. These three rows also give carried endpoint closure, since each forward classifier proof contains the output carrier and each operation endpoint is definitionally the singleton empty history.

For zero and one, unfold the concrete singleton constants. Both endpoints are e, so membership in A_{e} is reflexivity of hsame. Classifying e against *out* unfolds to the two carrier witnesses together with the classifier comparison; the forward direction exposes $out\mathsf{hsamee}$, and the reverse direction uses reflexivity at e plus symmetry of $out\mathsf{hsamee}$.

For the proof-indexed inverse, unfold $\mathsf{FieldSingletonInv}(h,p)$. The proof parameter supplies only the domain witness for forming the inverse endpoint; the endpoint itself is again e. The same reflexivity and symmetry argument classifies it against *out*, and transitivity through e gives the displayed comparison in the classifier field. □

The ten-field fit is: traditional target terminal concrete field operation table; BEDC source BHist with the singleton $\mathsf{Field}^{\uparrow}$ operations; carrier A_{e}; classifier ρ_{e}; stability obligations endpoint classifier collapse and carried endpoint closure; ledger hidden constant empty endpoints and proof-indexed inverse witness; core theorem Theorem 45.48; exactness predicate classifier collapse to $\mathsf{hsame}(out, \mathsf{e})$; status $\mathsf{ProofTarget}$.

Theorem 45.49 (Field singleton classifier append right cancellation)**.** *For histories* $P, Q, R : \mathsf{BHist}$*, if* P *lies in the singleton carrier* A_{e}*, then appending* P *on the right of both classified endpoints does not change the singleton classifier:*

$$\mathsf{FieldSingletonCarrier}(P) \Rightarrow \big(\mathsf{FieldSingletonClassifier}(\mathsf{append}(Q,P), \mathsf{append}(R,P)) \iff \mathsf{FieldSingletonClassifier}(Q,R)\big)$$

Proof. In the forward direction, each appended endpoint is classified as empty. Empty-result inversion for append splits these endpoint witnesses into $Q\mathsf{hsamee}$, $P\mathsf{hsamee}$, and $R\mathsf{hsamee}$. The two endpoint witnesses for Q and R supply the singleton carrier fields, and transitivity through e supplies the classifier comparison between Q and R.

Conversely, use the carrier witness $P\mathsf{hsamee}$ to reduce each right suffix to the empty suffix. The append right-unit laws identify $\mathsf{append}(Q, \mathsf{e})$ with Q and $\mathsf{append}(R, \mathsf{e})$ with R. Transport the singleton carrier witnesses and the displayed classifier comparison along these right-unit identifications to rebuild the appended classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier append right cancel iff`

Theorem 45.50 (Field singleton carrier append right cancellation)**.** *For histories $P, Q : \mathsf{BHist}$, if P lies in the singleton carrier A_{e}, then appending P on the right preserves and reflects singleton-carrier membership:*

$$\mathsf{FieldSingletonCarrier}(P) \Rightarrow (\mathsf{FieldSingletonCarrier}(\mathsf{append}(Q, P)) \Longleftrightarrow \mathsf{FieldSingletonCarrier}(Q)).$$

Proof. The singleton carrier is the assertion of history-sameness to e. In the forward direction, empty-result inversion for append splits $\mathsf{append}(Q, P)\mathsf{hsamee}$ and exposes the $Q\mathsf{hsamee}$ component. In the reverse direction, combine $Q\mathsf{hsamee}$ with the displayed carrier witness for P and rebuild the empty append witness. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier append right cancel iff`

Theorem 45.51 (Field singleton carrier append right nonempty contradiction)**.** *For histories $h, k : \mathsf{BHist}$, if the appended history lies in the singleton carrier, then the right factor cannot be nonempty:*

$$\mathsf{FieldSingletonCarrier}(\mathsf{append}(h, k)) \Rightarrow (\mathsf{hsame}(k, \mathsf{e}) \to \bot) \Rightarrow \bot.$$

Proof. The singleton carrier unfolds to $\mathsf{hsame}(\mathsf{append}(h, k), \mathsf{e})$. Empty-append inversion splits this into $h\mathsf{hsamee}$ and $k\mathsf{hsamee}$. The right component contradicts the displayed nonempty right-factor hypothesis. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier append right nonempty absurd`

Theorem 45.52 (Field singleton carrier append left cancellation)**.** *For histories $P, Q : \mathsf{BHist}$, if P lies in the singleton carrier A_{e}, then appending P on the left preserves and reflects singleton-carrier membership:*

$$\mathsf{FieldSingletonCarrier}(P) \Rightarrow (\mathsf{FieldSingletonCarrier}(\mathsf{append}(P, Q)) \Longleftrightarrow \mathsf{FieldSingletonCarrier}(Q)).$$

Proof. The singleton carrier asserts history-sameness to e. In the forward direction, empty-result inversion for append splits $\mathsf{append}(P, Q)\mathsf{hsamee}$ and exposes the $Q\mathsf{hsamee}$ component. In the reverse direction, combine the carrier witness for P with $Q\mathsf{hsamee}$ and rebuild the empty append witness. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier append left cancel iff`

Theorem 45.53 (Field singleton carrier append left-context semantic name certificate)**.** *For a singleton carrier context p, the predicate $h \mapsto \mathsf{FieldSingletonCarrier}(\mathsf{append}(p, h))$ carries a semantic naming certificate whose classifier compares the contextualized endpoints by the field singleton classifier:*

$$\mathsf{FieldSingletonCarrier}(p) \Longrightarrow \mathsf{SemanticNameCert}(h \mapsto \mathsf{FieldSingletonCarrier}(p{\cdot}h))(h \mapsto \mathsf{FieldSingletonCarrier}(p{\cdot}h))(h \mapsto$$

Proof. The empty history is inhabited after the left context because $p\mathsf{hsamee}$. The classifier fields are the singleton carrier evidence on both contextualized endpoints together with their hsame comparison. Reflexivity, symmetry, and transitivity are inherited from hsame, and carrier transport is the classified right endpoint. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier append left context semanticNameCert`

Theorem 45.54 (Field singleton carrier append right-context semantic name certificate)**.** *For a singleton carrier context p, the predicate $h \mapsto \mathsf{FieldSingletonCarrier}(\mathsf{append}(h, p))$ carries a semantic naming certificate whose classifier compares the contextualized endpoints by the field singleton classifier:*

$$\mathsf{FieldSingletonCarrier}(p) \Longrightarrow \mathsf{SemanticNameCert}(h \mapsto \mathsf{FieldSingletonCarrier}(h{\cdot}p))(h \mapsto \mathsf{FieldSingletonCarrier}(h{\cdot}p))(h \mapsto$$

Proof. The empty history is inhabited because $\mathsf{e} \cdot p$ is the same history as p, and p is carried to e. The classifier equivalence laws are exactly the reflexive, symmetric, and transitive laws of hsame wrapped with the two contextual carrier witnesses. Carrier transport is obtained from the classifier evidence at the right endpoint. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier append right context semanticNameCert`

Theorem 45.55 (Field singleton carrier append commutation)**.** *For histories $h, k : \mathsf{BHist}$, the singleton carrier is insensitive to the order of an append pair:*

$$\mathsf{FieldSingletonCarrier}(\mathsf{append}(h, k)) \Longleftrightarrow \mathsf{FieldSingletonCarrier}(\mathsf{append}(k, h)).$$

Proof. The singleton carrier is history-sameness to e. Empty-append inversion splits $\mathsf{append}(h, k)\mathsf{hsamee}$ into $h\mathsf{hsamee}$ and $k\mathsf{hsamee}$. Reversing the two components rebuilds $\mathsf{append}(k, h)\mathsf{hsamee}$, and the converse is symmetric. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier append comm iff`

Theorem 45.56 (Field singleton classifier append commutation congruence)**.** *For histories h, h', k, k' : BHist, two singleton classifier witnesses for (h, h') and (k, k') rebuild a classifier after commuting the appended endpoints:*

$$\mathsf{FieldSingletonClassifier}(h, h') \Rightarrow \mathsf{FieldSingletonClassifier}(k, k') \Rightarrow \mathsf{FieldSingletonClassifier}(\mathsf{append}(h, k), \mathsf{append}(k', h'))$$

Proof. Each classifier witness contains singleton-carrier evidence for both of its endpoints. Empty-append inversion rebuilds a singleton carrier for $\mathsf{append}(h, k)$ from the source endpoints and for $\mathsf{append}(k', h')$ from the target endpoints. Since both appended histories are carried to e, transitivity through e supplies the classifier comparison. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier append comm congr`

Theorem 45.57 (Field singleton classifier append context cancellation)**.** *For histories L, R, Q, S : BHist, if both displayed contexts lie in the singleton carrier A_{e}, then appending L to the first endpoint and R to the second endpoint does not change the singleton classifier:*

$$\mathsf{FieldSingletonCarrier}(L) \Rightarrow \mathsf{FieldSingletonCarrier}(R) \Rightarrow (\mathsf{FieldSingletonClassifier}(\mathsf{append}(L, Q), \mathsf{append}(R, S)) \Longleftrightarrow \mathsf{Fi}$$

Proof. In the forward direction, the appended endpoint carriers split by empty-result inversion for append. The right pieces give $Q\mathsf{hsamee}$ and $S\mathsf{hsamee}$, and transitivity through e rebuilds the base classifier.

Conversely, combine the two context carrier witnesses with the endpoint carrier fields in $\mathsf{FieldSingletonClassifier}(Q, S)$. Empty-result inversion for append rebuilds singleton carrier witnesses for the two appended endpoints, and transitivity through e supplies their classifier comparison. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier append context cancel iff`

Theorem 45.58 (Field singleton classifier append context visible middle exclusion)**.** *For histories* L, R, S, p, q : BHist*, if* L *and* R *lie in the singleton carrier* A_{e}*, then a visible middle endpoint exposed after appending those singleton contexts cannot support a field singleton classifier:*

$$\begin{aligned}&\mathsf{FieldSingletonCarrier}(L) \Rightarrow \mathsf{FieldSingletonCarrier}(R) \Rightarrow \\ &(\mathsf{FieldSingletonClassifier}(\mathsf{append}(L, \mathsf{E0}(p)), \mathsf{append}(R, S)) \to \mathsf{False}) \wedge \\ &(\mathsf{FieldSingletonClassifier}(\mathsf{append}(L, \mathsf{E1}(p)), \mathsf{append}(R, S)) \to \mathsf{False}) \wedge \\ &(\mathsf{FieldSingletonClassifier}(\mathsf{append}(L, S), \mathsf{append}(R, \mathsf{E0}(q))) \to \mathsf{False}) \wedge \\ &(\mathsf{FieldSingletonClassifier}(\mathsf{append}(L, S), \mathsf{append}(R, \mathsf{E1}(q))) \to \mathsf{False}).\end{aligned}$$

Proof. Cancel the singleton contexts by Theorem 45.57. Each case exposes a visible endpoint in the underlying $\mathsf{FieldSingletonClassifier}$. The visible endpoint exclusion Theorem 45.5 then rules out the exposed $\mathsf{E0}$ and $\mathsf{E1}$ endpoint cases. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier append context visible middle absurd`

Theorem 45.59 (Field singleton classifier append cross-context cancellation)**.** *For histories* L, R, Q, S : BHist*, if* L *and* R *lie in the singleton carrier* A_{e}*, then a singleton right suffix on the source and a singleton left prefix on the target preserve and reflect the base singleton classifier:*

$$\mathsf{FieldSingletonCarrier}(L) \Rightarrow \mathsf{FieldSingletonCarrier}(R) \Rightarrow (\mathsf{FieldSingletonClassifier}(\mathsf{append}(Q, L), \mathsf{append}(R, S)) \Longleftrightarrow \mathsf{Fi}$$

Proof. In the forward direction, the two appended classifier carriers split by empty-result inversion for append. The source split exposes the carrier for Q, and the target split exposes the carrier for S; transitivity through e rebuilds the comparison between Q and S.

Conversely, combine the carrier witness for L with the source carrier in $\mathsf{FieldSingletonClassifier}(Q, S)$, and combine the carrier witness for R with the target carrier. These rebuild the two appended endpoint carriers, and transitivity through e supplies the appended classifier comparison. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier append cross context cancel iff`

Theorem 45.60 (Field singleton classifier append endpoint split)**.** *For histories* L, Q, R, S : BHist*,* $\mathsf{FieldSingletonClassifier}(\mathsf{append}(L, Q), \mathsf{append}(R, S))$ *is equivalent to the four carrier witnesses* $\mathsf{FieldSingletonCarrier}(L)$*,* $\mathsf{FieldSingletonCarrier}(Q)$*,* $\mathsf{FieldSingletonCarrier}(R)$*, and* $\mathsf{FieldSingletonCarrier}(S)$*.*

Proof. The two classifier carrier fields identify both append endpoints with e, and empty-result inversion for append splits these witnesses into the four component carriers. Conversely, the four component carrier witnesses rebuild the two appended carrier witnesses, and transitivity through e supplies their classifier comparison. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier append endpoint split iff`

Theorem 45.61 (Field singleton classifier append pair equivalence)**.** *For histories* h, h', k, k' : BHist*, the singleton classifier between* $\mathsf{append}(h, k)$ *and* $\mathsf{append}(h', k')$ *is equivalent to the pair of component classifiers* $\mathsf{FieldSingletonClassifier}(h, h')$ *and* $\mathsf{FieldSingletonClassifier}(k, k')$*.*

Proof. In the forward direction, empty-result inversion for the two append carriers splits the source and target endpoints into four singleton-carrier witnesses; transitivity through e builds the two component classifiers. Conversely, the component classifiers give singleton-carrier witnesses for all four endpoints, which rebuild the two appended carriers and their comparison through e. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier append pair iff`

Theorem 45.62 (Field singleton classifier append endpoint empty nonzero exclusion)**.** *For histories L, Q, R, S : BHist, a singleton classifier witness for* $\mathsf{append}(L, Q)$ *and* $\mathsf{append}(R, S)$ *rules out empty-nonzero evidence at each displayed endpoint:*

$$\begin{aligned}&\mathsf{FieldSingletonClassifier}(\mathsf{append}(L, Q), \mathsf{append}(R, S))\\ \Longrightarrow\ &(\mathsf{fieldSingletonEmptyNonZero}(L) \to \mathsf{False}) \wedge (\mathsf{fieldSingletonEmptyNonZero}(Q) \to \mathsf{False})\\ &\quad \wedge (\mathsf{fieldSingletonEmptyNonZero}(R) \to \mathsf{False}) \wedge (\mathsf{fieldSingletonEmptyNonZero}(S) \to \mathsf{False}).\end{aligned}$$

Proof. The classifier supplies singleton-carrier witnesses for both appended endpoints. Empty-result inversion for append splits these into witnesses that L, Q, R, and S each equal e. The concrete empty-nonzero complement then excludes empty-nonzero evidence at each of the four endpoints. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier append endpoint empty nonzero absurd`

Theorem 45.63 (Field singleton carrier empty append context)**.** *For histories L, R, h : BHist, if L and R lie in the singleton carrier A_{e}, then surrounding h by the displayed left and right append contexts does not change singleton-carrier membership:*

$$\mathsf{FieldSingletonCarrier}(L) \Rightarrow \mathsf{FieldSingletonCarrier}(R) \Rightarrow (\mathsf{FieldSingletonCarrier}(\mathsf{append}(L, \mathsf{append}(h, R))) \Longleftrightarrow \mathsf{FieldSir}$$

Proof. In the forward direction, the singleton carrier witness identifies the nested append with e. Empty-result inversion for append first splits off L and then splits $\mathsf{append}(h, R)$, recovering $h\mathsf{hsamee}$.

Conversely, combine the carrier witness for h with the carrier witness for R to rebuild the inner empty append. Combining that result with the carrier witness for L rebuilds the displayed outer empty append. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier append context empty iff`

Theorem 45.64 (Field singleton classifier empty append context)**.** *For histories L, R, h, k : BHist, if L and R lie in the singleton carrier A_{e}, then adding L on the left of the first endpoint and R on the right of the second endpoint preserves and reflects the singleton field classifier:*

$$\mathsf{FieldSingletonCarrier}(L) \Rightarrow \mathsf{FieldSingletonCarrier}(R) \Rightarrow (\mathsf{FieldSingletonClassifier}(\mathsf{append}(L, h), \mathsf{append}(k, R)) \Longleftrightarrow \mathsf{Fie}$$

Proof. In the forward direction, the classifier supplies singleton-carrier witnesses for both appended endpoints. Empty-result inversion for append recovers $h\mathsf{hsamee}$ from the left endpoint and $k\mathsf{hsamee}$ from the right endpoint, and transitivity through e supplies the classifier comparison between h and k.

Conversely, the two carrier fields of $\mathsf{FieldSingletonClassifier}(h, k)$, together with the carrier witnesses for L and R, rebuild the two appended singleton-carrier witnesses. Since both appended endpoints are carried to e, transitivity through e gives the appended classifier comparison. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier append context empty iff`

Theorem 45.65 (Field singleton classifier self-context split)**.** *For histories a, x, b : BHist, a singleton field classifier from the self-context append endpoint to b is exactly a singleton carrier witness for the repeated context and a singleton classifier from the middle history to b:*

$$\mathsf{FieldSingletonClassifier}(\mathsf{append}(a, \mathsf{append}(x, a)), b) \Longleftrightarrow \mathsf{FieldSingletonCarrier}(a) \wedge \mathsf{FieldSingletonClassifier}(x, b).$$

Proof. In the forward direction, the source carrier identifies $\mathsf{append}(a, \mathsf{append}(x, a))$ with e. Empty-result inversion for append first recovers the carrier for a, then splits the inner append and recovers the carrier for x. The target carrier field of the classifier and transitivity through e rebuild $\mathsf{FieldSingletonClassifier}(x, b)$.

Conversely, combine the carrier for a with the source carrier in $\mathsf{FieldSingletonClassifier}(x, b)$ to rebuild the inner empty append, and combine that result with the same context carrier to rebuild the outer source carrier. The target carrier is already supplied by the middle classifier, and both endpoints compare through e. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier append self context split iff`

Theorem 45.66 (Field singleton classifier append common-context cancellation up to history-sameness)**.** *For histories $L, R, P, Q, a, b : \mathsf{BHist}$, if L and P lie in the singleton carrier and the displayed contexts satisfy $L\mathsf{hsame}R$ and $P\mathsf{hsame}Q$, then the nested contextual singleton classifier is equivalent to the classifier of the middle histories:*

$$\mathsf{FieldSingletonCarrier}(L) \Rightarrow \mathsf{FieldSingletonCarrier}(P) \Rightarrow L\mathsf{hsame}R \Rightarrow P\mathsf{hsame}Q \Rightarrow (\mathsf{FieldSingletonClassifier}(\mathsf{append}(L$$

Proof. Transport the two contexts along the displayed history-sameness witnesses. In the forward direction, empty-result inversion for append first splits the outer empty endpoints and then splits the inner append endpoints, exposing $a\mathsf{hsame}\mathsf{e}$ and $b\mathsf{hsame}\mathsf{e}$. These endpoint carrier witnesses rebuild the base classifier. Conversely, combine the classifier endpoint carriers with the singleton carrier witnesses for the common contexts, and use empty-result inversion for append in reverse to rebuild the two nested singleton-carrier witnesses. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier append hsame common context cancel iff`

Theorem 45.67 (Field singleton classifier append suffix cancellation)**.** *For histories $P, R, Q, S : \mathsf{BHist}$, if Q and S lie in the singleton carrier A_{e}, then appending them as right suffixes to the two classified endpoints preserves and reflects the singleton field classifier:*

$$\mathsf{FieldSingletonCarrier}(Q) \Rightarrow \mathsf{FieldSingletonCarrier}(S) \Rightarrow (\mathsf{FieldSingletonClassifier}(\mathsf{append}(P, Q), \mathsf{append}(R, S)) \Longleftrightarrow \mathsf{Fi}$$

Proof. In the forward direction, the classifier supplies singleton carrier witnesses for both appended endpoints. Empty-result inversion for append splits these witnesses and exposes singleton carrier witnesses for P and R, which rebuild the base classifier through e.

Conversely, the carrier witnesses for Q and S, together with the endpoint carriers in $\mathsf{FieldSingletonClassifier}(P, R)$ rebuild singleton carrier witnesses for the two appended endpoints. Both appended endpoints are therefore history-same to e, so transitivity through e supplies their classifier comparison. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier append suffix cancel iff`

Theorem 45.68 (Singleton empty nonzero append right cancellation)**.** *For histories $P, Q : \mathsf{BHist}$, if P lies in the singleton empty carrier, then appending P on the right does not change the classifier-complement singleton nonzero predicate:*

$$\mathsf{fieldSingletonEmptyCarrier}(P) \Rightarrow (\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(Q, P)) \Longleftrightarrow \mathsf{fieldSingletonEmptyNonZero}(Q))$$

Proof. In the forward direction, suppose Q were classified against e. Combining that endpoint witness with the displayed carrier witness for P rebuilds a singleton empty classifier witness for $\mathsf{append}(Q, P)$, contradicting the appended complement predicate.

Conversely, any classifier witness for $\mathsf{append}(Q, P)$ supplies $\mathsf{append}(Q, P)\mathsf{hsame}\mathsf{e}$. Empty-result inversion for append extracts $Q\mathsf{hsame}\mathsf{e}$, and this reconstructs the forbidden classifier witness for Q against e. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero append right cancel iff`

Theorem 45.69 (Singleton empty nonzero append left cancellation)**.** *For histories P, Q : BHist, if P lies in the singleton empty carrier, then appending P on the left does not change the classifier-complement singleton nonzero predicate:*

$$\mathsf{fieldSingletonEmptyCarrier}(P) \Rightarrow (\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(P, Q)) \Longleftrightarrow \mathsf{fieldSingletonEmptyNonZero}(Q))$$

Proof. The forward implication turns a forbidden classifier witness for Q into one for $\mathsf{append}(P, Q)$ by pairing the carrier witness for P with the empty endpoint witness for Q.

For the reverse implication, a classifier witness for $\mathsf{append}(P, Q)$ identifies the append result with e. Empty-result inversion splits this into carrier witnesses for both factors, and the right factor witness rebuilds the forbidden singleton empty classifier for Q. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero append left cancel iff`

Theorem 45.70 (Singleton empty nonzero continuation left endpoint cancellation)**.** *For histories P, Q, R : BHist, if Q lies in the singleton empty carrier and $\mathsf{Cont}(P, Q, R)$, then the classifier-complement singleton nonzero predicate is unchanged from P to R:*

$$\mathsf{fieldSingletonEmptyCarrier}(Q) \Rightarrow \mathsf{Cont}(P, Q, R) \Rightarrow (\mathsf{fieldSingletonEmptyNonZero}(R) \Longleftrightarrow \mathsf{fieldSingletonEmptyNonZer}$$

Proof. For the forward implication, a forbidden classifier on P combines with the singleton empty carrier of Q and the continuation ledger to rebuild a forbidden classifier on R. Conversely, a forbidden classifier on R is transported back through the displayed continuation; append-empty inversion then exposes the forbidden classifier on P. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero continuation left endpoint cancel iff`

Theorem 45.71 (Singleton empty nonzero continuation commutativity)**.** *For histories $P, Q, left, right$: BHist, if*

$$\mathsf{Cont}(P, Q, left) \quad \textit{and} \quad \mathsf{Cont}(Q, P, right),$$

then the classifier-complement singleton nonzero predicate is invariant under exchanging the two continuation inputs:

$$\mathsf{fieldSingletonEmptyNonZero}(left) \Longleftrightarrow \mathsf{fieldSingletonEmptyNonZero}(right).$$

Proof. For one direction, suppose $left$ is singleton nonzero and $right$ were empty. Transport the displayed continuation for $right$ to an empty result and invert the empty continuation. Both inputs are empty, so the opposite continuation has empty result, contradicting singleton nonzero at $left$. The converse is the same argument with the two continuations exchanged. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero continuation comm iff`

Theorem 45.72 (Rat classifier singleton-empty nonzero context endpoints)**.** *For histories L, R, h, k : BHist, any rational history classifier between h and k forces both contextual endpoints to satisfy the singleton-empty nonzero predicate:*

$$\mathsf{RatHistoryClassifier}(h, k) \Longrightarrow \mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(L, h)) \wedge \mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(R, k)$$

Proof. The rational classifier supplies the endpoint facts that neither h nor k is empty. To refute a singleton-empty classifier on $\mathsf{append}(L, h)$, invert the append-empty carrier equation; its right endpoint says $h = \mathsf{e}$, contradicting the rational endpoint fact. The right contextual endpoint is identical with R and k in place of L and h. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryClassifier fieldSingletonEmptyNonZero context endpoints`

Theorem 45.73 (Singleton empty nonzero append source or tail)**.** *For histories $P, Q : \mathsf{BHist}$, if the appended history is in the classifier-complement singleton nonzero predicate, then the source or the tail is also in that predicate:*

$$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(P, Q)) \Rightarrow \mathsf{fieldSingletonEmptyNonZero}(P) \vee \mathsf{fieldSingletonEmptyNonZero}(Q).$$

Proof. Inspect the source history P. If $P = \mathsf{e}$, a forbidden classifier witness for Q rebuilds a forbidden classifier witness for $\mathsf{append}(P, Q)$ by the left unit law for append. If P is zero-headed or one-headed, BEDC constructor separation prevents P from lying in the singleton empty classifier, giving the source-side nonzero predicate. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero append source or tail`

Theorem 45.74 (Singleton empty nonzero append split)**.** *For histories $L, Q : \mathsf{BHist}$, the classifier-complement singleton empty nonzero predicate on an append splits exactly over the two factors:*

$$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(L, Q)) \iff \mathsf{fieldSingletonEmptyNonZero}(L) \vee \mathsf{fieldSingletonEmptyNonZero}(Q).$$

Proof. For the forward implication, split on the left factor. If $L = \mathsf{e}$, a classifier witness for Q against e rebuilds the forbidden classifier witness for $\mathsf{append}(\mathsf{e}, Q)$. If L is visibly headed, constructor separation already makes L a singleton-empty nonzero witness.

For the reverse implication, any classifier witness for $\mathsf{append}(L, Q)$ against e splits by empty-result inversion for append into carrier witnesses for both L and Q. The chosen left or right nonzero witness rejects the corresponding carrier witness. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero append split iff`

Theorem 45.75 (Singleton empty nonzero continuation endpoint split)**.** *For histories $P, Q, R : \mathsf{BHist}$ with $\mathsf{Cont}(P, Q, R)$, the classifier-complement singleton empty nonzero predicate on the continuation result is exactly the disjunction of the corresponding endpoint predicates:*

$$\mathsf{fieldSingletonEmptyNonZero}(R) \iff \mathsf{fieldSingletonEmptyNonZero}(P) \vee \mathsf{fieldSingletonEmptyNonZero}(Q).$$

Proof. Unfold the continuation ledger as $R = \mathsf{append}(P, Q)$. In the forward direction, split on the concrete shape of P: the empty case transfers the forbidden classifier to Q, while either visible head gives constructor separation at the left endpoint. In the reverse direction, a classifier of R against e splits by empty append inversion, and the selected endpoint nonzero witness rejects the matching empty component. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero continuation endpoint split iff`

Lemma 45.76 (Singleton empty nonzero continuation right endpoint cancellation)**.** *For histories $P, Q, R : \mathsf{BHist}$ with $\mathsf{Cont}(P, Q, R)$, if the right endpoint Q is a singleton-empty carrier, then the classifier-complement singleton empty nonzero predicate on the continuation result is exactly the predicate on the source endpoint:*

$$\mathsf{fieldSingletonEmptyNonZero}(R) \iff \mathsf{fieldSingletonEmptyNonZero}(P).$$

Proof. The continuation ledger gives $R = \mathsf{append}(P, Q)$. The singleton-empty carrier on Q identifies the right endpoint with e, so the append endpoint reduces to P and the two classifier-complement predicates coincide. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero continuation right endpoint cancel iff`

Theorem 45.77 (Singleton empty nonzero continuation cycle tail obstruction)**.** *For histories* $h, k, tail, backTail : \mathsf{BHist}$*, if*

$$\mathsf{Cont}(h, tail, k) \quad \textit{and} \quad \mathsf{Cont}(k, backTail, h)$$

form a continuation cycle, then $\mathsf{fieldSingletonEmptyNonZero}(tail)$ *is contradictory.*

Proof. The two continuations compose to a self-continuation of h. Right-unit uniqueness for continuation forces the composite tail to be empty, and empty-result inversion for append gives $tail\mathsf{hsamee}$. The singleton empty nonzero endpoint obstruction then contradicts the displayed nonzero witness on $tail$. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero continuation cycle tail absurd`

Theorem 45.78 (Singleton empty nonzero append context cancellation)**.** *For histories* $L, R, Q : \mathsf{BHist}$*, if* L *and* R *lie in the singleton empty carrier, then enclosing* Q *between them does not change the classifier-complement singleton nonzero predicate:*

$$\mathsf{fieldSingletonEmptyCarrier}(L) \Rightarrow \mathsf{fieldSingletonEmptyCarrier}(R) \Rightarrow (\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(L, \mathsf{append}($$

Proof. If the enclosed history is nonzero and Q were classified against e, then the empty-carrier witnesses for L and R rebuild a classifier witness for $\mathsf{append}(L, \mathsf{append}(Q, R))$ against e, contradicting the enclosed nonzero predicate.

Conversely, a classifier witness for $\mathsf{append}(L, \mathsf{append}(Q, R))$ against e splits by empty-result inversion for append. The inner split yields $\mathsf{fieldSingletonEmptyCarrier}(Q)$, which rebuilds the forbidden classifier witness for Q against e. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero append context cancel iff`

Theorem 45.79 (Singleton empty nonzero two-sided context semantic certificate)**.** *For histories* $L, R : \mathsf{BHist}$*, the concrete two-sided context predicate*

$$h \longmapsto \mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(L, \mathsf{append}(h, R)))$$

used as source, pattern, and ledger policy with classifier hsame *forms a semantic name certificate.*

Proof. The source is inhabited by choosing the visible middle history $\mathsf{e0}(\mathsf{e})$. If the resulting nested append were classified against e, empty-result inversion for the outer append and then the inner append would force $\mathsf{e0}(\mathsf{e})\mathsf{hsamee}$, contradicting the BEDC no-confusion law for visible histories. The classifier laws are the reflexive, symmetric, and transitive laws for hsame. Carrier transport eliminates the supplied history-sameness proof, leaving the same concrete two-sided context predicate; pattern and ledger soundness are identities because the three predicates coincide. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero append context semanticNameCert`

Theorem 45.80 (Classifier-complement singleton field schema laws)**.** *For the tuple*

$$(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \mathsf{fieldSingletonEmptyNonZero}, \mathsf{fieldSingletonEmptyMul}, \mathsf{fieldSingletonEmptyOne}, \mathsf{fieldSingletonEmptyInv})$$

the singleton carrier is inhabited by e*; the predicate* $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{e})$ *is contradictory; the predicate is transported along* ρ_{e}*; the inverse of every proof-indexed element is again in* A_{e}*; and the left and right products with the proof-indexed inverse are classified as the empty-history unit.*

Proof. The carrier inhabitance clause is the reflexive endpoint $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$, so e lies in A_{e}.

For contradiction at the unit, suppose $p : \mathsf{fieldSingletonEmptyNonZero}(\mathsf{e})$. The displayed classifier witness $\rho_{\mathsf{e}}(\mathsf{e}, \mathsf{e})$ is built from the two reflexive carrier endpoints and reflexivity of $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$. Applying p to this witness closes the contradiction.

For transport, assume $\rho_{\mathsf{e}}(h, k)$ and $p : \mathsf{fieldSingletonEmptyNonZero}(h)$. Given a classifier witness $\rho_{\mathsf{e}}(k, \mathsf{e})$, compose the classifier equality from $\rho_{\mathsf{e}}(h, k)$ with the equality from $\rho_{\mathsf{e}}(k, \mathsf{e})$ to obtain $\rho_{\mathsf{e}}(h, \mathsf{e})$. The predicate p then gives contradiction, hence the transported predicate holds at k.

Inverse closure is immediate because every inverse endpoint is definitionally e, which is in the singleton carrier. The two inverse laws are immediate for the same reason: both products are the constant empty-history product, the unit is e, and the required classifier witnesses are built from reflexivity of $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field singleton empty schema laws`

Theorem 45.81 (Singleton empty-history FieldUp schema certificate)**.** *The tuple from Definition 45.2, together with the law package from Theorem 45.37, supplies the carrier, source, pattern, classifier, stability, and ledger fields required by Definition 45.337 over the concrete* BHist *singleton source. Its ten-field certificate template is:*

1. *Traditional target: the singleton proof-indexed* $\mathsf{Field}^{\uparrow}$ *schema.*
2. *BEDC source:* BHist *with* A_{e}*.*
3. *Carrier choice:* A_{e}*.*
4. *Classifier choice:* ρ_{e}*.*
5. *Stability obligations: commutative-ring laws plus vacuous nonzero transport, inverse closure, and inverse laws.*
6. *Ledger: the singleton endpoint and the empty nonzero witness domain.*
7. *Core theorem list: Theorem 45.37 and the semantic certificate theorem for the same singleton carrier.*
8. *Exactness predicate: singleton endpoint classification together with the* SemanticNameCert *source, pattern, and ledger fields.*
9. *Standard bridge: the terminal proof-indexed schema.*
10. *Status: CheckedCert.*

Proof. The source and carrier fields are the singleton history source A_{e} from Definition 45.2. The classifier field is ρ_{e}, whose only endpoints are the empty histories admitted by A_{e}.

For the algebraic stability fields, use Theorem 44.7. It supplies the commutative-ring part for the constant empty-history operations on the same carrier and classifier.

For the field-specific clauses, apply Theorem 45.37. Nonzero transport, inverse closure, inverse congruence, and the left and right inverse laws all begin with a witness $p : \mathsf{FieldSingletonNonZero}(h)$.

Theorem 45.33 shows that no such witness exists, while the inverse operation itself still has the total proof-indexed form $\mathsf{inv}(h, p) := \mathsf{e}$. The ledger therefore records only the singleton endpoint and the empty witness domain, giving the required concrete BHist FieldUp naming certificate template. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyCarrier semanticNameCert`

Theorem 45.82 (Singleton empty nonzero semantic name certificate)**.** *The classifier-complement predicate $h \mapsto \mathsf{fieldSingletonEmptyNonZero}(h)$ carries a semantic naming certificate whose source, pattern, and ledger predicates are this same nonzero predicate and whose classifier is* hsame*.*

Proof. The visible endpoint $\mathsf{e0}(\mathsf{e})$ inhabits the predicate because a singleton empty classifier witness would identify a zero-headed history with e, contradicting constructor separation for BHist. The classifier laws are reflexivity, symmetry, and transitivity of hsame. Carrier transport follows by substituting the endpoint sameness into the concrete classifier-complement predicate; pattern and ledger soundness are the identity maps for the same predicate. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyNonZero semanticNameCert`

Theorem 45.83 (Field singleton carrier continuation visible-left exclusion)**.** *For histories $p, Q, R :$ BHist, no continuation whose left input is headed by a visible constructor can land in the singleton field carrier:*

$$(\mathsf{Cont}(\mathsf{E0}(p), Q, R) \Rightarrow \mathsf{FieldSingletonCarrier}(R) \Rightarrow \bot) \wedge (\mathsf{Cont}(\mathsf{E1}(p), Q, R) \Rightarrow \mathsf{FieldSingletonCarrier}(R) \Rightarrow \bot).$$

Proof. Transport a displayed continuation result through the singleton carrier to e. Empty-result inversion then identifies the visible left input with e, contradicting BEDC history no-confusion for E0 or E1. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier continuation visible left absurd`

Theorem 45.84 (Field singleton carrier continuation visible-right exclusion)**.** *For histories $P, q, R :$ BHist, no continuation whose right input is headed by a visible constructor can land in the singleton field carrier:*

$$(\mathsf{Cont}(P, \mathsf{E0}(q), R) \Rightarrow \mathsf{FieldSingletonCarrier}(R) \Rightarrow \bot) \wedge (\mathsf{Cont}(P, \mathsf{E1}(q), R) \Rightarrow \mathsf{FieldSingletonCarrier}(R) \Rightarrow \bot).$$

Proof. Transport the displayed continuation result through the singleton carrier to e. Empty-result inversion then identifies the visible right input with e, contradicting BEDC history no-confusion for E0 or E1. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier continuation visible right absurd`

Theorem 45.85 (Field singleton classifier continuation empty result iff)**.** *For histories $P, Q, R :$ BHist with $\mathsf{Cont}(P, Q, R)$, the singleton field classifier relates P and Q exactly when the continuation result R is singleton-classified with* e*:*

$$\mathsf{FieldSingletonClassifier}(P, Q) \iff \mathsf{FieldSingletonClassifier}(R, \mathsf{e}).$$

Proof. The forward implication is the continuation result classifier. Conversely, the result-side classifier identifies R with e. Transporting the displayed continuation to the empty result and applying empty-result inversion identifies both P and Q with e, which reconstructs the singleton classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier continuation empty result iff`

Theorem 45.86 (Field singleton classifier continuation result-left iff)**.** *For histories $P, Q, R : \mathsf{BHist}$ with $\mathsf{Cont}(P, Q, R)$, singleton classification of the two continuation inputs is equivalent to singleton classification of the result against the left input:*

$$\mathsf{FieldSingletonClassifier}(P, Q) \iff \mathsf{FieldSingletonClassifier}(R, P).$$

Proof. For the forward implication, the singleton carrier witnesses for P and Q transport the continuation result to the right-unit continuation at e. Thus R is singleton-carried, and it compares with P through e. Conversely, the result-left classifier identifies R with e. Transport the displayed continuation to empty result and apply empty-result inversion; this recovers singleton carrier witnesses for both P and Q, which rebuild the input classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier continuation result left iff`

Theorem 45.87 (Field singleton classifier continuation result endpoint split)**.** *For histories $P, Q, R :$ BHist with $\mathsf{Cont}(P, Q, R)$, the result-side singleton classifier is equivalent to all three continuation endpoints being singleton carriers:*

$$\mathsf{FieldSingletonClassifier}(R, \mathsf{e}) \iff \mathsf{FieldSingletonCarrier}(P) \wedge \mathsf{FieldSingletonCarrier}(Q) \wedge \mathsf{FieldSingletonCarrier}(R).$$

Proof. For the forward direction, the result classifier identifies R with e; transporting the continuation to empty result and inverting it identifies P and Q with e. For the reverse direction, the displayed carrier witness for R and the reflexive carrier of e directly rebuild the result-side singleton classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier continuation result endpoint split iff`

Theorem 45.88 (Field singleton carrier continuation context empty iff)**.** *For histories $L, h, M, R, O :$ BHist with $\mathsf{Cont}(L, h, M)$ and $\mathsf{Cont}(M, R, O)$, the final result is a singleton carrier exactly when the three exposed factors are singleton carriers:*

$$\mathsf{FieldSingletonCarrier}(O) \iff \mathsf{FieldSingletonCarrier}(L) \wedge \mathsf{FieldSingletonCarrier}(h) \wedge \mathsf{FieldSingletonCarrier}(R).$$

Proof. For the forward direction, transport the second continuation result to e and invert the empty result; this gives singleton carriers for M and R. Transport the first continuation result from M to e and invert again, exposing singleton carriers for L and h. Conversely, singleton carriers for L and h transport the first continuation result to the singleton carrier, and the resulting middle carrier together with the carrier for R transports the second continuation result to the singleton carrier. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier continuation context empty iff`

Theorem 45.89 (Field singleton classifier continuation append split)**.** *For histories $L, P, Q, R, T :$ BHist with $\mathsf{Cont}(P, Q, T)$, singleton classification of $\mathsf{append}(L, T)$ against R is equivalent to the four displayed endpoints lying in the singleton carrier:*

$$\mathsf{FieldSingletonClassifier}(\mathsf{append}(L, T), R) \iff \mathsf{FieldSingletonCarrier}(L) \wedge \mathsf{FieldSingletonCarrier}(P) \wedge \mathsf{FieldSingletonCarrie}$$

Proof. The forward direction splits the empty appended endpoint into carrier witnesses for L and T. Transporting the continuation ledger to the empty result and inverting it gives carrier witnesses for P and Q, while the classifier itself supplies the carrier witness for R. Conversely, carrier witnesses for P and Q make the continuation result T singleton, and combining that with the carrier of L rebuilds the left appended endpoint. Both classifier endpoints then compare through e. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier continuation append split iff`

Theorem 45.90 (Field singleton classifier continuation append context split)**.** *For histories* L, P, Q, T, R, S : BHist *with* $\mathsf{Cont}(P, Q, T)$*, singleton classification of* $\mathsf{append}(L, T)$ *against* $\mathsf{append}(R, S)$ *is equivalent to all five exposed endpoints lying in the singleton carrier:*

$$\mathsf{FieldSingletonClassifier}(\mathsf{append}(L, T), \mathsf{append}(R, S)) \iff \mathsf{FieldSingletonCarrier}(L) \wedge \mathsf{FieldSingletonCarrier}(P) \wedge \mathsf{FieldSin}$$

Proof. The forward direction splits both appended classifier endpoints at the empty history. The left split gives singleton carriers for L and T; transporting the continuation result from T to e and applying empty-result inversion gives the carrier witnesses for P and Q. The right split gives the carrier witnesses for R and S. Conversely, the carrier witnesses for P and Q make T singleton through the continuation equation, so both appended endpoints are singleton and therefore compare through e. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier continuation append context split iff`

Lemma 45.91 (Field singleton classifier continuation context empty result)**.** *For histories* L, R, P, Q, T : BHist*, if* L *and* R *are singleton carriers and*

$$\mathsf{Cont}(\mathsf{append}(L, P), \mathsf{append}(Q, R), T),$$

then singleton classification of the continuation result against e *is equivalent to singleton classification of the exposed middle endpoints:*

$$\mathsf{FieldSingletonClassifier}(T, \mathsf{e}) \iff \mathsf{FieldSingletonClassifier}(P, Q).$$

Proof. For the forward implication, transport the displayed continuation to the empty result and invert it. The two appended endpoints split at e, exposing singleton carriers for P and Q, and the two carriers compare through e. Conversely, singleton carriers for P and Q, together with the assumed singleton carriers for L and R, make both appended continuation endpoints empty; the continuation result is therefore singleton and is classified with e. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier continuation context empty result iff`

Theorem 45.92 (Field singleton add-mul context continuation result carrier)**.** *For histories* L, R, a, b, c, d, out : BHist*, if* L *and* R *are singleton field carrier endpoints and*

$$\mathsf{Cont}(\mathsf{append}(L, \mathsf{FieldSingletonAdd}(a, b)), \mathsf{append}(\mathsf{FieldSingletonMul}(c, d), R), out),$$

then out *is a singleton field carrier endpoint.*

Proof. The singleton add and mul endpoints both unfold to e. The carrier witnesses identify L and R with e, so both append contexts reduce to the empty history. Determinacy against the right-unit continuation at e therefore identifies out with e. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonAddMul context continuation result carrier`

Theorem 45.93 (Field singleton add-mul context continuation result iff)**.** *For histories* L, R, a, b, c, d, out : BHist*, if* L *and* R *are singleton field carrier endpoints, then the add-mul contextual continuation exists exactly for singleton field carrier results:*

$$\mathsf{FieldSingletonCarrier}(L) \Rightarrow \mathsf{FieldSingletonCarrier}(R) \Rightarrow (\mathsf{Cont}(\mathsf{append}(L, \mathsf{FieldSingletonAdd}(a, b)), \mathsf{append}(\mathsf{FieldSingle}$$

Proof. The forward direction is the add-mul contextual carrier closure. Conversely, the singleton add and mul endpoints unfold to e, and the carrier witnesses for L and R reduce both contextual inputs to e. Transport the right-unit continuation at e along the supplied carrier witness for *out* to obtain the displayed continuation. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonAddMul context continuation result iff`

Theorem 45.94 (Field singleton add-mul context continuation classifier)**.** *For histories* $L, R, L', R', a, b, c, d, a', b',$ BHist*, if all four context endpoints are singleton field carriers and the two add-mul contextual continuations*

$$\mathsf{Cont}(\mathsf{append}(L, \mathsf{FieldSingletonAdd}(a, b)), \mathsf{append}(\mathsf{FieldSingletonMul}(c, d), R), out)$$

and

$$\mathsf{Cont}(\mathsf{append}(L', \mathsf{FieldSingletonAdd}(a', b')), \mathsf{append}(\mathsf{FieldSingletonMul}(c', d'), R'), out')$$

hold, then $\mathsf{FieldSingletonClassifier}(out, out')$*.*

Proof. Apply the add-mul contextual carrier closure to both continuations. The two results are each hsame to e, so transitivity and symmetry of hsame assemble the singleton classifier between the results. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonAddMul context continuation classifier`

Theorem 45.95 (Field singleton mul-inv context continuation classifier)**.** *For histories* $L, R, L', R', a, b, c, d, out,$ BHist*, suppose the four context endpoints are singleton field carriers, and suppose* $p : \mathsf{FieldSingletonNonZero}(c)$ *and* $q : \mathsf{FieldSingletonNonZero}(d)$*. If the two contextual continuations*

$$\mathsf{Cont}(\mathsf{append}(L, \mathsf{FieldSingletonMul}(a, b)), \mathsf{append}(\mathsf{FieldSingletonInv}(c, p), R), out)$$

and

$$\mathsf{Cont}(\mathsf{append}(L', \mathsf{FieldSingletonMul}(a, b)), \mathsf{append}(\mathsf{FieldSingletonInv}(d, q), R'), out')$$

hold, then $\mathsf{FieldSingletonClassifier}(out, out')$*.*

Proof. The singleton multiplication and proof-indexed inverse endpoints both unfold to e. The carrier witnesses identify each contextual endpoint with e, so continuation determinacy against the right-unit continuation gives singleton carrier witnesses for both results. These two carrier witnesses compose through e to assemble the singleton classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonMulInv context continuation classifier`

Theorem 45.96 (Field singleton continuation result context)**.** *For histories L, R, P, Q, T : BHist, if L and R are singleton carriers and $\mathsf{Cont}(P, Q, T)$, then singleton classification of the two-sided context around the continuation result against e is equivalent to the two exposed continuation inputs being singleton carriers:*

$$\mathsf{FieldSingletonClassifier}(\mathsf{append}(L, \mathsf{append}(T, R)), \mathsf{e}) \iff \mathsf{FieldSingletonCarrier}(P) \wedge \mathsf{FieldSingletonCarrier}(Q).$$

Proof. For the forward implication, split the empty contextual endpoint twice, first at L and then at T and R. The resulting singleton carrier for T transports the continuation to empty result, whose inversion gives the two input carriers. Conversely, the two input carriers make the continuation result singleton; combining this carrier with the assumed carriers for L and R rebuilds the displayed contextual classifier against e. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier continuation result context iff`

Theorem 45.97 (Field singleton classifier for mutual continuation cycle tails)**.** *For histories $h, k, tail, backTail$: BHist, if*

$$\mathsf{Cont}(h, tail, k) \quad \textit{and} \quad \mathsf{Cont}(k, backTail, h),$$

then $\mathsf{FieldSingletonClassifier}(tail, backTail)$.

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier mutual continuation cycle tails`

Proof. Mutual continuation tail cancellation identifies both *tail* and *backTail* with e. These two singleton carrier witnesses give the classifier fields, and transitivity through e gives the tail-to-tail history-sameness field. □

45.3 RatUp boundary for the singleton field schema

Theorem 45.98 (Singleton field schema is disjoint from the RatUp history carrier)**.** *For every h : BHist, if $A_{\mathsf{e}}(h)$ is the singleton source from Definition 45.2, then $\mathsf{RatHistoryCarrier}(h)$ implies False. Equivalently, no RatUp history-carrier endpoint is an endpoint of the singleton empty-history $\mathsf{Field}^{\uparrow}$ schema.*

Proof. Assume $A_{\mathsf{e}}(h)$ and $\mathsf{RatHistoryCarrier}(h)$. Unfolding the singleton carrier component gives the endpoint equality $h\mathsf{hsamee}$.

The RatUp carrier witness is separated from the empty denominator endpoint by Theorem 37.18. Applying that theorem to the carrier witness and the equality $h\mathsf{hsamee}$ gives the required contradiction. □

Theorem 45.99 (Singleton field schema is disjoint from RatUp classifier endpoints)**.** *For every h, k : BHist, if $A_{\mathsf{e}}(h)$ holds for the singleton source from Definition 45.2 and $\mathsf{RatHistoryClassifier}(h, k)$ holds, then False. Likewise, if $A_{\mathsf{e}}(k)$ and $\mathsf{RatHistoryClassifier}(h, k)$ hold, then False.*

Proof. Unfold the Rat history classifier. Its witness contains $\mathsf{RatHistoryCarrier}(h)$, $\mathsf{RatHistoryCarrier}(k)$, and the displayed relation $h\mathsf{hsame}k$.

For the left endpoint, assume $A_{\mathsf{e}}(h)$. Apply Theorem 45.98 to $A_{\mathsf{e}}(h)$ and the carrier witness $\mathsf{RatHistoryCarrier}(h)$.

For the right endpoint, assume $A_{\mathsf{e}}(k)$. Apply Theorem 45.98 to $A_{\mathsf{e}}(k)$ and the carrier witness $\mathsf{RatHistoryCarrier}(k)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryClassifier fieldSingleton empty endpoints absurd`

Theorem 45.100 (Rat ledger endpoints are disjoint from the singleton FieldUp schema)**.** *For every raw and visible histories* $\rho, v : \mathsf{BHist}$*, if* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *holds, then both* $A_{\mathsf{e}}(\rho) \to \mathsf{False}$ *and* $A_{\mathsf{e}}(v) \to \mathsf{False}$ *hold, where* A_{e} *is the singleton source from Definition 45.2.*

Proof. Unpack $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$. Its raw component gives $\mathsf{RatHistoryCarrier}(\rho)$, so any assumption $A_{\mathsf{e}}(\rho)$ is contradictory by Theorem 45.98.

For the visible endpoint, apply Theorem 37.65 to the same ledger policy. This produces $\mathsf{RatHistoryCarrier}(v)$, and Theorem 45.98 again rules out $A_{\mathsf{e}}(v)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryLedgerPolicy fieldSingletonEmptyCarrier endpoints absurd`

Theorem 45.101 (Singleton append endpoint excludes a RatUp right factor)**.** *For all histories* $p, h : \mathsf{BHist}$*, if* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(p, h))$ *holds and* $\mathsf{RatHistoryCarrier}(h)$ *holds, then* False*.*

Proof. The singleton carrier on $\mathsf{append}(p, h)$ unfolds to the equality $\mathsf{append}(p, h) = \mathsf{e}$. The kernel append-empty inversion theorem splits this equality into $p = \mathsf{e}$ and $h = \mathsf{e}$. The right component gives $h\mathsf{hsamee}$, contradicting Theorem 37.18 for the displayed RatUp carrier witness. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyCarrier append ratHistoryCarrier absurd`

Theorem 45.102 (Singleton append endpoint excludes a RatUp left factor)**.** *For all histories* $p, h : \mathsf{BHist}$*, if* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(h, p))$ *holds and* $\mathsf{RatHistoryCarrier}(h)$ *holds, then* False*.*

Proof. The singleton carrier on $\mathsf{append}(h, p)$ unfolds to the equality $\mathsf{append}(h, p) = \mathsf{e}$. The kernel append-empty inversion theorem splits this equality into $h = \mathsf{e}$ and $p = \mathsf{e}$. The left component gives $h\mathsf{hsamee}$, contradicting Theorem 37.18 for the displayed RatUp carrier witness. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyCarrier append left ratHistoryCarrier absurd`

Theorem 45.103 (Field singleton append classifier excludes a RatUp history carrier)**.** *For all histories* $p, h, endpoint : \mathsf{BHist}$*, a singleton classifier whose left endpoint is either* $\mathsf{append}(p, h)$ *or* $\mathsf{append}(h, p)$ *is incompatible with* $\mathsf{RatHistoryCarrier}(h)$*:*

$$(\mathsf{FieldSingletonClassifier}(\mathsf{append}(p, h), endpoint) \to \mathsf{RatHistoryCarrier}(h) \to \mathsf{False}) \wedge (\mathsf{FieldSingletonClassifier}(\mathsf{append}(h$$

Proof. In the first orientation, the singleton classifier contains the carrier comparison $\mathsf{append}(p, h)\mathsf{hsamee}$. Append-empty inversion extracts $h\mathsf{hsamee}$, contradicting $\mathsf{RatHistoryCarrier}(h)$ by rational history nonemptiness. The second orientation is the same argument with the left factor selected by append-empty inversion. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier append RatHistoryCarrier absurd`

Theorem 45.104 (Singleton append classifier excludes RatUp classifier endpoints)**.** *For all histories* $L, R, h, k : \mathsf{BHist}$*, if* $\mathsf{RatHistoryClassifier}(h, k)$ *holds and*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, h), \mathsf{append}(R, k))$$

holds, then False*.*

Proof. The singleton classifier contains $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(L, h))$, hence the equality $\mathsf{append}(L, h) = \mathsf{e}$. The kernel append-empty inversion theorem splits this equality and gives $h\mathsf{hsamee}$.

The RatUp classifier endpoint nonemptiness theorem rejects $h\mathsf{hsamee}$ for any displayed $\mathsf{RatHistoryClassifier}(h, k)$ yielding the contradiction. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyClassifier append RatHistoryClassifier absurd`

Theorem 45.105 (Singleton append classifier excludes crossed RatUp carrier endpoints)**.** *For all histories* $L, R, h, k : \mathsf{BHist}$*, if* $\mathsf{RatHistoryCarrier}(h)$ *and* $\mathsf{RatHistoryCarrier}(k)$ *hold, then both displayed singleton-empty classifiers are impossible:*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, h), \mathsf{append}(R, k)) \to \mathsf{False}$$

and

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, k), \mathsf{append}(R, h)) \to \mathsf{False}.$$

Proof. In the first direction, the singleton classifier contains $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(L, h))$. Append-empty inversion extracts $h\mathsf{hsamee}$, contradicting the displayed $\mathsf{RatHistoryCarrier}(h)$ witness.

The crossed direction is identical with k in the appended right factor of the left endpoint: append-empty inversion extracts $k\mathsf{hsamee}$, which contradicts $\mathsf{RatHistoryCarrier}(k)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyClassifier cross RatHistoryCarrier absurd`

Theorem 45.106 (Singleton append classifier excludes RatUp ledger endpoints)**.** *For all histories* $L, R, \rho, v : \mathsf{BHist}$*, if* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ *holds and*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, \rho), \mathsf{append}(R, v))$$

holds, then False*.*

Proof. The singleton classifier contains the raw endpoint equality $\mathsf{append}(L, \rho) = \mathsf{e}$. Kernel append-empty inversion gives $\rho\mathsf{hsamee}$.

The RatUp ledger endpoint boundary theorem states that a displayed $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$ rejects $\rho\mathsf{hsamee}$. Applying that raw endpoint obstruction gives the contradiction. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyClassifier append RatHistoryLedgerPolicy absurd`

Traditional target terminal singleton field boundary; BEDC source singleton $\mathsf{BHist}\ \mathsf{Field}^{\uparrow}$ schema plus RatUp history carrier; carrier choices A_{e} and $\mathsf{RatHistoryCarrier}$; classifier choices ρ_{e} and Rat history classifier; ledger choices $\mathsf{RatHistoryLedgerPolicy}$; stability obligation nonempty denominator separation; raw and visible ledger endpoint exclusion; core theorems Theorem 45.98 and Theorem 45.99 and Theorem 45.100; exactness predicate no shared carrier, classifier, or ledger endpoint; standard bridge terminal schema is not the rational field; status ProofTarget.

Theorem 45.107 (Classifier-complement singleton FieldUp instance is RatUp-disjoint)**.** *For the concrete source* A_{e}*, classifier* ρ_{e}*, proof domain* $\mathsf{fieldSingletonEmptyNonZero}$*, and constant operations* $\mathsf{fieldSingletonEmptyMul}$*,* $\mathsf{fieldSingletonEmptyOne}$*, and* $\mathsf{fieldSingletonEmptyInv}$ *from Definition 45.29, the* $\mathsf{Field}^{\uparrow}$ *schema laws hold over the concrete* BHist *singleton carrier, and every endpoint admitted by* A_{e} *is disjoint from* $\mathsf{RatHistoryCarrier}$*.*

Its ten-field template is:

1. *Traditional target: one-element proof-indexed* $\mathsf{Field}^{\uparrow}$ *schema.*
2. *BEDC source:* BHist *singleton source plus RatUp boundary.*
3. *Carrier:* A_{e}.
4. *Classifier:* ρ_{e}.
5. *Stability obligations: Theorem 45.80.*
6. *Ledger: the singleton endpoint and empty nonzero witness domain.*
7. *Core theorem list: Theorem 45.80 and Theorem 45.98.*
8. *Exactness predicate: singleton endpoint classification plus RatUp-disjointness.*
9. *Standard bridge: terminal proof-indexed schema only.*
10. *Status:* ProofTarget.

Proof. First apply Theorem 45.80 to the displayed tuple

$$(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \mathsf{fieldSingletonEmptyNonZero}, \mathsf{fieldSingletonEmptyMul}, \mathsf{fieldSingletonEmptyOne}, \mathsf{fieldSingletonEmptyInv}).$$

This supplies the concrete law package over the singleton BHist carrier.

For the RatUp boundary, take any displayed endpoint witness $A_{\mathsf{e}}(h)$ and any witness $\mathsf{RatHistoryCarrier}(h)$. Applying Theorem 45.98 to these two witnesses gives False, so no admitted singleton endpoint is a RatUp history-carrier endpoint. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyCarrier RatHistoryCarrier disjoint certificate`

Theorem 45.108 (RatUp one-denominator witness blocks singleton coverage)**.** *Let* $d_1 := \mathsf{E1}(\mathsf{e})$. *Then* $\mathsf{RatHistoryCarrier}(d_1)$ *holds and* $A_{\mathsf{e}}(d_1) \to \mathsf{False}$. *Consequently any proposed coverage map*

$$\forall h : \mathsf{BHist}, \mathsf{RatHistoryCarrier}(h) \to A_{\mathsf{e}}(h)$$

is contradictory.

Proof. The empty history is unary by the kernel theorem unary_empty. Apply Theorem 37.21 with tail e. The reverse direction turns $\mathsf{UnaryHistory}(\mathsf{e})$ into the carrier witness $\mathsf{RatHistoryCarrier}(\mathsf{E1}(\mathsf{e}))$, namely $\mathsf{RatHistoryCarrier}(d_1)$.

Now assume $A_{\mathsf{e}}(d_1)$. Applying Theorem 45.98 to this singleton endpoint and the carrier witness above gives False. Thus the concrete RatUp endpoint d_1 cannot be covered by the singleton carrier.

For the displayed coverage map, evaluate the map at d_1 and the RatUp carrier witness. This produces $A_{\mathsf{e}}(d_1)$, and the previous paragraph turns that endpoint into contradiction. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat carrier non singleton boundary witness`

Theorem 45.109 (Classifier-complement RatUp one-denominator witness blocks singleton coverage)**.** *Let* $d_1 := \mathsf{E1}(\mathsf{e})$. *Then* $\mathsf{RatHistoryCarrier}(d_1)$ *holds and* $\mathsf{fieldSingletonEmptyCarrier}(d_1) \to \mathsf{False}$. *Consequently any proposed coverage map*

$$\forall h : \mathsf{BHist}, \mathsf{RatHistoryCarrier}(h) \to \mathsf{fieldSingletonEmptyCarrier}(h)$$

is contradictory.

Proof. The empty history is unary by the kernel theorem unary_empty. Apply Theorem 37.21 with tail e. The reverse direction turns UnaryHistory(e) into RatHistoryCarrier(E1(e)), so it supplies RatHistoryCarrier(d_1).

Now assume fieldSingletonEmptyCarrier(d_1). The theorem RatHistoryCarrier_not_empty rejects a RatUp carrier endpoint that is the empty singleton endpoint. Applying it to the RatUp carrier witness above and the singleton-carrier witness gives False.

For the displayed coverage map, evaluate the map at d_1 and the RatUp carrier witness. This produces fieldSingletonEmptyCarrier(d_1), and the previous paragraph turns that endpoint into contradiction. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat history carrier non singleton boundary witness`

Theorem 45.110 (RatUp classifier and ledger coverage are blocked by the singleton FieldUp boundary)**.** *Let* $d_1 :=$ E1(e)*. Then* RatHistoryClassifier(d_1, d_1) *and* RatHistoryLedgerPolicy(d_1, d_1) *hold, while* FieldSingletonClassifier(d_1, d_1) $\to$ False*. Consequently both a classifier coverage map*

$$\forall hk : \mathsf{BHist}, \mathsf{RatHistoryClassifier}(h, k) \to \mathsf{FieldSingletonClassifier}(h, k)$$

and a ledger endpoint coverage map into the singleton carrier

$$\forall \rho v : \mathsf{BHist}, \mathsf{RatHistoryLedgerPolicy}(\rho, v) \to \mathsf{FieldSingletonCarrier}(\rho) \wedge \mathsf{FieldSingletonCarrier}(v)$$

are contradictory.

Proof. Theorem 45.108 gives the RatUp carrier witness RatHistoryCarrier(d_1) and the obstruction FieldSingletonCarrier(d_1) $\to$ False.

Using hsame reflexivity at d_1, the carrier witness forms the diagonal classifier package RatHistoryClassifier(d_1, d_1) The same carrier witness together with the same reflexivity link forms the diagonal ledger package RatHistoryLedgerPolicy(d_1, d_1).

Unfold FieldSingletonClassifier(d_1, d_1). Any such classifier witness contains FieldSingletonCarrier(d_1) as its left endpoint component, and the carrier obstruction from the first paragraph turns that endpoint into False.

Now evaluate any displayed classifier coverage map at the diagonal RatUp classifier package. The result is FieldSingletonClassifier(d_1, d_1), which the previous paragraph rules out.

For a displayed ledger endpoint coverage map, evaluate it at the diagonal ledger package. The resulting conjunction contains FieldSingletonCarrier(d_1), so the same carrier obstruction again gives contradiction. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat singleton classifier ledger coverage obstruction`

Traditional target exclusion of the terminal singleton schema as a RatUp $\mathsf{Field}^{\uparrow}$ classifier and ledger certificate; BEDC source RatHistoryCarrier, RatHistoryClassifier, RatHistoryLedgerPolicy, and the singleton $\mathsf{Field}^{\uparrow}$ schema; exactness predicate failure of carrier, classifier, and ledger coverage; status ProofTarget.

45.4 RatUp continuation closure for the FieldUp boundary

Theorem 45.111 (Rat history carrier append split)**.** *If the appended denominator* $\mathsf{append}(h, k)$ *lies in the rational history carrier, then either* h *or* k *lies in the rational history carrier.*

Proof. Convert the appended rational history carrier to a positive unary denominator witness by the rational carrier equivalence. The positive-denominator append factor-or-tail theorem places that witness on h or on k; converting the selected positive-denominator branch back through the same equivalence gives the corresponding rational history carrier. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryCarrier append split`

Theorem 45.112 (Rat history classifier left append split)**.** *If the rational history classifier relates* $\mathsf{append}(h, k)$ *to a denominator* d*, then either* h *or* k *lies in the rational history carrier.*

Proof. Project the left endpoint carrier from the classifier witness. The rat history carrier append split then exposes the carried denominator branch on h or on k. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryClassifier append left split`

Theorem 45.113 (Rat denominators are closed under continuation)**.** *For all histories* d, e, r : BHist*, if* $\mathsf{RatHistoryCarrier}(d)$*,* $\mathsf{RatHistoryCarrier}(e)$*, and* $\mathsf{Cont}(d, e, r)$*, then* $\mathsf{RatHistoryCarrier}(r)$*.*

Proof. Start with the right denominator carrier $\mathsf{RatHistoryCarrier}(e)$. Theorem 37.19 extracts a positive unary denominator witness for e, and Theorem 37.12 turns that witness into $\mathsf{UnaryHistory}(e)$.

Apply Theorem 37.23 to the left carrier $\mathsf{RatHistoryCarrier}(d)$ and the unary witness for e. This gives $\mathsf{RatHistoryCarrier}(\mathsf{append}(d, e))$ for the canonical BEDC continuation result.

Unfolding the displayed continuation witness identifies r with $\mathsf{append}(d, e)$. The appended carrier is therefore exactly the required carrier for r. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation carrier closure`

Theorem 45.114 (Rat history classifier continuation tail iff)**.** *For rational history carriers* d, e : BHist *and a displayed result* r : BHist*,*

$$\mathsf{Cont}(d, e, r) \iff \mathsf{RatHistoryClassifier}(r, \mathsf{append}(d, e)).$$

Proof. If $\mathsf{Cont}(d, e, r)$ holds, carrier closure gives $\mathsf{RatHistoryCarrier}(r)$. The same closure theorem applied to the canonical append continuation gives $\mathsf{RatHistoryCarrier}(\mathsf{append}(d, e))$, and continuation determinacy supplies $r\mathsf{hsameappend}(d, e)$. These three components are the Rat history classifier. Conversely, the classifier comparison component is exactly the continuation equation $\mathsf{Cont}(d, e, r)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryClassifier continuation tail iff`

Theorem 45.115 (Rat history carrier continuation result is nonempty)**.** *For all histories* d, e, r : BHist*, if* $\mathsf{RatHistoryCarrier}(d)$*,* $\mathsf{RatHistoryCarrier}(e)$*, and* $\mathsf{Cont}(d, e, r)$*, then* r *is not internally the empty history:*

$$r\mathsf{hsamee} \to \mathsf{False}.$$

Proof. Apply Definition 45.113 to the two input carriers and the displayed continuation. This gives $\mathsf{RatHistoryCarrier}(r)$. The Rat carrier nonempty theorem then rejects any comparison $r\mathsf{hsamee}$. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryCarrier continuation result not empty`

Theorem 45.116 (Rat continuation results cannot be singleton-classified)**.** *For histories* d, d', e, e', r, r' : BHist*, if* $\mathsf{RatHistoryClassifier}(d, d')$ *and* $\mathsf{RatHistoryClassifier}(e, e')$ *hold, and if* $\mathsf{Cont}(d, e, r)$ *and* $\mathsf{Cont}(d', e', r')$ *display the two continuation results, then* $\mathsf{FieldSingletonClassifier}(r, r')$ *is impossible.*

Proof. The left classifier supplies rational carrier witnesses for d and e. The carrier on e exposes a positive unary denominator, hence a unary history. Rational denominators are closed under appending a unary denominator, so $\mathsf{append}(d, e)$ lies in the rational history carrier. Continuation determinacy identifies this canonical append result with the displayed result r, transporting the rational carrier to r. The singleton classifier would also force $r\mathsf{hsame}e$, contradicting non-emptiness of rational history carriers. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryClassifier continuation result FieldSingletonClassifier absurd`

Theorem 45.117 (Rat denominator continuation semigroup laws)**.** *For all histories* d, e, f, de, ef, ℓ, r : BHist*, if* $\mathsf{RatHistoryCarrier}(d)$*,* $\mathsf{RatHistoryCarrier}(e)$*,* $\mathsf{RatHistoryCarrier}(f)$*,* $\mathsf{Cont}(d, e, de)$*,* $\mathsf{Cont}(e, f, ef)$*,* $\mathsf{Cont}(de, f, \ell)$*, and* $\mathsf{Cont}(d, ef, r)$*, then*

$$\mathsf{RatHistoryCarrier}(de) \wedge \mathsf{RatHistoryCarrier}(ef) \wedge \mathsf{RatHistoryCarrier}(\ell) \wedge \mathsf{RatHistoryCarrier}(r) \wedge \ell\mathsf{hsame}r.$$

Proof. First apply Definition 45.113 to the continuations $\mathsf{Cont}(d, e, de)$ and $\mathsf{Cont}(e, f, ef)$. The three displayed input carriers therefore give $\mathsf{RatHistoryCarrier}(de)$ and $\mathsf{RatHistoryCarrier}(ef)$.

Next apply the same closure theorem to $\mathsf{Cont}(de, f, \ell)$ using the carrier just obtained for de and the original carrier for f. Apply it again to $\mathsf{Cont}(d, ef, r)$ using the original carrier for d and the carrier just obtained for ef. This yields the two outer result carriers.

Finally apply the FKernel continuation associativity theorem, in the form `BEDC.FKernel.Cont.cont_assoc_hs` to the four continuation witnesses. It identifies the two displayed bracketings of denominator continuation by $\ell\mathsf{hsame}r$, giving the full conjunction. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation semigroup laws`
↪ variant `BEDC.Derived.FieldUp.RatHistoryCarrier continuation semigroup laws`

Theorem 45.118 (Rat denominator continuation commutativity)**.** *For all histories* d, e, r, s : BHist*, if* $\mathsf{RatHistoryCarrier}(d)$*,* $\mathsf{RatHistoryCarrier}(e)$*,* $\mathsf{Cont}(d, e, r)$*, and* $\mathsf{Cont}(e, d, s)$*, then* $\mathsf{RatHistoryClassifier}(r, s)$*.*

Proof. First apply Definition 45.113 to $\mathsf{Cont}(d, e, r)$ and to $\mathsf{Cont}(e, d, s)$. The two applications give $\mathsf{RatHistoryCarrier}(r)$ and $\mathsf{RatHistoryCarrier}(s)$.

Next read the input carriers through Definition 37.19 and then Definition 37.12. This extracts $\mathsf{UnaryHistory}(d)$ and $\mathsf{UnaryHistory}(e)$ from the two Rat denominator carriers.

Now apply the FKernel unary continuation commutativity theorem, `BEDC.FKernel.Unary.unary_continuati` to the two unary witnesses and the continuation witnesses $\mathsf{Cont}(d, e, r)$ and $\mathsf{Cont}(e, d, s)$. It yields $r\mathsf{hsame}s$.

The two result carriers together with this hsame comparison are exactly the components of $\mathsf{RatHistoryClassifier}(r, s)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation commutative classifier`

Theorem 45.119 (Rat denominator classifiers are closed under matching continuations)**.** *For all histories* d, e, u, v, r, s : BHist*, if* $\mathsf{RatHistoryClassifier}(d, e)$*,* $\mathsf{UnaryHistory}(u)$*,* $\mathsf{UnaryHistory}(v)$*,* $u\mathsf{hsame}v$*,* $\mathsf{Cont}(d, u, r)$*, and* $\mathsf{Cont}(e, v, s)$*, then* $\mathsf{RatHistoryClassifier}(r, s)$*.*

Proof. First apply Theorem 37.56 to the displayed classifier $\mathsf{RatHistoryClassifier}(d, e)$, the unary tails u, v, and the matching tail witness $u\mathsf{hsame}v$. This gives the rational history classifier for the canonical append results $\mathsf{append}(d, u)$ and $\mathsf{append}(e, v)$.

Next compare the displayed continuation results with those canonical append results. The constructor witnesses for $\mathsf{Cont}(d, u, \mathsf{append}(d, u))$ and $\mathsf{Cont}(e, v, \mathsf{append}(e, v))$, together with the premises $\mathsf{Cont}(d, u, r)$ and $\mathsf{Cont}(e, v, s)$, feed into Theorem 18.16. Thus the result histories are linked by $\mathsf{hsame}(\mathsf{append}(d, u), r)$ and $\mathsf{hsame}(\mathsf{append}(e, v), s)$.

Finally transport the canonical append classifier across the two result hsame links by Theorem 37.54. The transported classifier is exactly $\mathsf{RatHistoryClassifier}(r, s)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryClassifier matching continuation closed`

Theorem 45.120 (Rat history classifiers are right-closed under continuation)**.** *For all histories* $d, d', e, r, r' : \mathsf{BHist}$*, if* $\mathsf{RatHistoryClassifier}(d, d')$*,* $\mathsf{RatHistoryCarrier}(e)$*,* $\mathsf{Cont}(d, e, r)$*, and* $\mathsf{Cont}(d', e, r')$*, then* $\mathsf{RatHistoryClassifier}(r, r')$*.*

Proof. Unpack the rational history classifier into carrier witnesses for d and d', together with the denominator comparison $d\mathsf{hsame}d'$. The carrier closure theorem above applies to the two displayed continuations with the shared right carrier e, producing $\mathsf{RatHistoryCarrier}(r)$ and $\mathsf{RatHistoryCarrier}(r')$.

The comparison component follows from continuation respect for internal sameness: use $d\mathsf{hsame}d'$ on the left inputs and reflexivity $e\mathsf{hsame}e$ on the shared right input. This yields $r\mathsf{hsame}r'$, and the two carrier fields with this comparison assemble the target classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryClassifier continuation right closed`

Theorem 45.121 (Rat history classifiers are left-closed under continuation)**.** *For all histories* $e, d, d', r, r' : \mathsf{BHist}$*, if* $\mathsf{RatHistoryCarrier}(e)$*,* $\mathsf{RatHistoryClassifier}(d, d')$*,* $\mathsf{Cont}(e, d, r)$*, and* $\mathsf{Cont}(e, d', r')$*, then* $\mathsf{RatHistoryClassifier}(r, r')$*.*

Proof. Unpack the rational history classifier into carrier witnesses for d and d', together with the comparison $d\mathsf{hsame}d'$. The carrier closure theorem applies to the two displayed continuations with the shared left carrier e, giving $\mathsf{RatHistoryCarrier}(r)$ and $\mathsf{RatHistoryCarrier}(r')$.

Continuation respects internal sameness on both endpoints. Use reflexivity $e\mathsf{hsame}e$ for the shared left context and the classifier comparison $d\mathsf{hsame}d'$ for the right endpoints. The resulting $r\mathsf{hsame}r'$ comparison, with the two result carriers, is exactly the rational history classifier for the displayed continuation results. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryClassifier continuation left closed`

Theorem 45.122 (Rat denominator ledgers are closed under matching continuations)**.** *For all histories* $\rho, v, u, u', r, s : \mathsf{BHist}$*, if* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$*,* $\mathsf{UnaryHistory}(u)$*,* $\mathsf{UnaryHistory}(u')$*,* $u\mathsf{hsame}u'$*,* $\mathsf{Cont}(\rho, u, r)$*, and* $\mathsf{Cont}(v, u', s)$*, then* $\mathsf{RatHistoryLedgerPolicy}(r, s)$*.*

Proof. First apply the Rat ledger append-unary denominator closure theorem to $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$, the unary tail $\mathsf{UnaryHistory}(u)$, and the matching witness $u\mathsf{hsame}u'$. This gives the ledger policy for the canonical append endpoints $\mathsf{append}(\rho, u)$ and $\mathsf{append}(v, u')$.

Next compare the displayed continuation results with those canonical endpoints. The constructor witnesses for $\mathsf{Cont}(\rho, u, \mathsf{append}(\rho, u))$ and $\mathsf{Cont}(v, u', \mathsf{append}(v, u'))$, together with $\mathsf{Cont}(\rho, u, r)$ and $\mathsf{Cont}(v, u', s)$, feed into Theorem 18.16. Thus $\mathsf{append}(\rho, u)\mathsf{hsame}r$ and $\mathsf{append}(v, u')\mathsf{hsame}s$.

Finally transport the canonical append ledger across the two result links by the Rat ledger history-sameness transport theorem. The transported ledger is exactly $\mathsf{RatHistoryLedgerPolicy}(r, s)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryLedgerPolicy continuation closed`

Theorem 45.123 (Rat history ledger continuation results are nonempty)**.** *For all histories* $raw, visible, tailRaw, t$ BHist*, if* RatHistoryLedgerPolicy$(raw, visible)$*,* UnaryHistory$(tailRaw)$*,* $tailRaw$hsame$tailVisible$*,* Cont$(raw, tailRaw, r)$*, and* Cont$(visible, tailVisible, s)$*, then neither continuation result is internally empty:*

$$(r\mathsf{hsamee} \to \mathsf{False}) \wedge (s\mathsf{hsamee} \to \mathsf{False}).$$

Proof. The ledger continuation closure theorem gives RatHistoryLedgerPolicy(r, s). Its raw component is a Rat carrier for r, and its visible-carrier projection is a Rat carrier for s. Applying the Rat carrier nonempty theorem to these two carrier witnesses rules out $r$hsamee and $s$hsamee. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryLedgerPolicy continuation results not empty`

Theorem 45.124 (Rat denominator continuation external boundary and associativity laws)**.** *Rat denominator continuation satisfies the following external endpoint-classifier laws:*

1. RatHistoryCarrier(e) $\to$ False*;*
2. *for all histories* d, r : BHist*, if* RatHistoryCarrier(d) *and* Cont(d, e, r)*, then* RatHistoryClassifier(r, d)*;*
3. *for all histories* d, s : BHist*, if* RatHistoryCarrier(d) *and* Cont(e, d, s)*, then* RatHistoryClassifier(s, d)*;*
4. *for all histories* $d, e, f, de, ef, left, right$: BHist*, if* RatHistoryCarrier(d)*,* RatHistoryCarrier(e)*,* RatHistoryCarrier(f)*,* Cont(d, e, de)*,* Cont$(de, f, left)$*,* Cont(e, f, ef)*, and* Cont$(d, ef, right)$*, then* RatHistoryClassifier$(left, right)$*.*

Proof. For the carrier boundary, assume RatHistoryCarrier(e). Reflexivity of hsame at e gives hsame(e, e). Applying Definition 37.18 to these two witnesses yields False.

For the right external-boundary law, apply the continuation right-unit result theorem to Cont(d, e, r). It supplies the hsame link from the displayed result back to d. Transport the given rational-history carrier along that link to get the carrier at r, then combine the two endpoint carriers with the same hsame link to form RatHistoryClassifier(r, d).

For the left external-boundary law, use the continuation left-unit result theorem on Cont(e, d, s). The same carrier transport step gives RatHistoryCarrier(s), and the resulting hsame link classifies s against d.

For associativity, first apply Definition 45.113 to Cont(d, e, de) and Cont(e, f, ef). Apply it again to Cont$(de, f, left)$ and Cont$(d, ef, right)$, using the two intermediate carriers just obtained. This supplies the rational-history carriers at both outer bracketings.

Finally apply the kernel continuation associativity theorem `BEDC.FKernel.Cont.cont_assoc_hsame` to the four continuation witnesses. Its hsame comparison between $left$ and $right$, together with the two outer carriers, is exactly RatHistoryClassifier$(left, right)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation external boundary laws`

Theorem 45.125 (Rat denominator continuation unit endpoint is externally empty)**.** *For every history* u : BHist*, Rat denominator continuation forces any classifier unit endpoint to be externally empty:*

1. *if*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, u, r) \to \mathsf{RatHistoryClassifier}(r, d),$$

then $u$hsamee*;*

2. *if*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(u, d, r) \to \mathsf{RatHistoryClassifier}(r, d),$$

then $u\mathsf{hsamee}$*;*

3. *if* $\mathsf{RatHistoryCarrier}(u)$ *and either displayed classifier unit law holds for* u*, then* False*.*

Proof. For the right-unit endpoint, let $d_1 := \mathsf{E1}(\mathsf{e})$. The positive-denominator construction supplies $\mathsf{RatHistoryCarrier}(d_1)$, and the finite kernel supplies the canonical continuation $\mathsf{Cont}(d_1, u, \mathsf{append}(d_1, u))$.

Apply the assumed right-unit classifier law to this carried input and canonical continuation. The classifier comparison gives $\mathsf{append}(d_1, u)\mathsf{hsame}d_1$, which is the same as $\mathsf{append}(d_1, u)\mathsf{hsameappend}(d_1, \mathsf{e})$. Left append cancellation in the finite kernel removes the common prefix d_1 and yields $u\mathsf{hsamee}$.

For the left-unit endpoint, use the same carried witness d_1 and the canonical continuation $\mathsf{Cont}(u, d_1, \mathsf{append}(u, d_1))$. The assumed left-unit classifier law gives $\mathsf{append}(u, d_1)\mathsf{hsame}d_1$, equivalently $\mathsf{append}(u, d_1)\mathsf{hsameappend}(\mathsf{e}, d_1)$.

Right append cancellation removes the common suffix d_1 and yields $u\mathsf{hsamee}$.

For the carried-endpoint consequence, combine the relevant endpoint-forcing clause with the assumed carrier witness $\mathsf{RatHistoryCarrier}(u)$. Then apply Theorem 37.18 to the carrier witness and the resulting equality $u\mathsf{hsamee}$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation unit endpoint empty`

Theorem 45.126 (Rat denominator canonical right-unit endpoint is empty)**.** *For every history* $u : \mathsf{BHist}$*, if continuation by* u *makes the fixed canonical denominator* $d_1 := \mathsf{E1}(\mathsf{e})$ *classify back to* d_1*, then* u *is externally empty:*

$$(\forall r : \mathsf{BHist}.\ \mathsf{Cont}(d_1, u, r) \to \mathsf{RatHistoryClassifier}(r, d_1)) \Longrightarrow u\mathsf{hsamee}.$$

Proof. Apply the assumed classifier law to the canonical continuation $\mathsf{Cont}(d_1, u, \mathsf{append}(d_1, u))$. The resulting classifier compares the continuation result with d_1. Transport the canonical continuation along this result comparison to obtain $\mathsf{Cont}(d_1, u, d_1)$, then apply right-unit uniqueness for continuation. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator canonical right unit endpoint empty`

Theorem 45.127 (Rat denominator canonical left-unit endpoint is empty)**.** *For every history* $u : \mathsf{BHist}$*, if continuation from* u *into the fixed canonical denominator* $d_1 := \mathsf{E1}(\mathsf{e})$ *classifies back to* d_1*, then* u *is externally empty:*

$$(\forall r : \mathsf{BHist}.\ \mathsf{Cont}(u, d_1, r) \to \mathsf{RatHistoryClassifier}(r, d_1)) \Longrightarrow u\mathsf{hsamee}.$$

Proof. Apply the assumed classifier law to the canonical continuation $\mathsf{Cont}(u, d_1, \mathsf{append}(u, d_1))$. The classifier result gives a comparison with d_1. Transport the continuation result to d_1 and apply left-unit uniqueness for continuation. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator canonical left unit endpoint empty`

Theorem 45.128 (Rat denominator two-sided unit law endpoint empty iff)**.** *For every history* $u : \mathsf{BHist}$*, the simultaneous right and left classifier-unit laws for Rat denominator continuation hold exactly when* u *is the empty endpoint:*

$$((\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, u, r) \to \mathsf{RatHistoryClassifier}(r, d)) \wedge (\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d$$

Proof. For the forward direction, project the right classifier-unit law from the displayed conjunction. Apply Theorem 45.350 to obtain $u\mathsf{hsamee}$.

Conversely, assume $u\mathsf{hsamee}$. Apply Theorem 45.350 to obtain the right classifier-unit law, and apply Theorem 45.352 to obtain the left classifier-unit law. Pair these two laws into the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation two sided unit law endpoint empty iff`

Theorem 45.129 (Rat denominator continuation unit endpoint uniqueness)**.** *For all histories* $u, v : \mathsf{BHist}$*, Rat denominator continuation determines every one-sided classifier-unit endpoint:*

1. *if both* u *and* v *satisfy the right-unit classifier law*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, w, r) \to \mathsf{RatHistoryClassifier}(r, d),$$

   for $w = u$ *and for* $w = v$*, then* $u\mathsf{hsame}v$*;*

2. *if both* u *and* v *satisfy the left-unit classifier law*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(w, d, r) \to \mathsf{RatHistoryClassifier}(r, d),$$

   for $w = u$ *and for* $w = v$*, then* $u\mathsf{hsame}v$*;*

3. *if* u *satisfies the right-unit classifier law and* v *satisfies the left-unit classifier law, then* $u\mathsf{hsame}v$*.*

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation unit endpoint unique`

Proof. In the right/right case, apply Theorem 45.125 to the right-unit classifier law for u, obtaining $u\mathsf{hsamee}$. Apply the same theorem to the right-unit classifier law for v, obtaining $v\mathsf{hsamee}$. Symmetry of hsame turns the second equality into $\mathsf{ehsame}v$, and transitivity gives $u\mathsf{hsame}v$.

In the left/left case, apply the left-unit clause of Theorem 45.125 to the two endpoint laws. This gives $u\mathsf{hsamee}$ and $v\mathsf{hsamee}$, and the same symmetry-transitivity composition yields $u\mathsf{hsame}v$.

In the mixed case, use the right-unit clause for u and the left-unit clause for v in Theorem 45.125. The resulting comparisons $u\mathsf{hsamee}$ and $v\mathsf{hsamee}$ compose, after symmetry of the second comparison, to $u\mathsf{hsame}v$. □

Theorem 45.130 (Rat denominator continuation classifier associativity congruence)**.** *For all histories* $d, d', e, e', f, f', de, de', ef, ef', left, left', right, right' : \mathsf{BHist}$*, if* $\mathsf{RatHistoryClassifier}(d, d')$*,* $\mathsf{RatHistoryClassifier}(e, e')$*,* $\mathsf{RatHistoryClassifier}(f, f')$*,* $\mathsf{Cont}(d, e, de)$*,* $\mathsf{Cont}(d', e', de')$*,* $\mathsf{Cont}(e, f, ef)$*,* $\mathsf{Cont}(e', f', ef')$*,* $\mathsf{Cont}(de, f, left)$*,* $\mathsf{Cont}(de', f', left')$*,* $\mathsf{Cont}(d, ef, right)$*, and* $\mathsf{Cont}(d', ef', right')$*, then*

$$\mathsf{RatHistoryClassifier}(left, left') \wedge \mathsf{RatHistoryClassifier}(right, right') \wedge left\,\mathsf{hsame}\,right \wedge left'\,\mathsf{hsame}\,right'.$$

Proof. Unpack the three displayed Rat history classifiers. Their carrier components, together with Definition 37.19 and Definition 37.12, give unary denominator witnesses for e, e', f, and f'. Their comparison components give $e\mathsf{hsame}e'$ and $f\mathsf{hsame}f'$.

Apply Definition 45.119 to $\mathsf{Cont}(d, e, de)$ and $\mathsf{Cont}(d', e', de')$. This yields $\mathsf{RatHistoryClassifier}(de, de')$. Apply the same closure theorem to $\mathsf{Cont}(e, f, ef)$ and $\mathsf{Cont}(e', f', ef')$ to obtain $\mathsf{RatHistoryClassifier}(ef, ef')$.

The outer left bracketing now uses the classifier for de, de' and the unary witnesses for f, f'. Another application of Definition 45.119 gives $\mathsf{RatHistoryClassifier}(left, left')$.

For the outer right bracketing, first read the carrier components of $\mathsf{RatHistoryClassifier}(ef, ef')$ through the same positive-denominator and unary/nonempty theorems, producing unary witnesses for ef and ef'. The comparison component of the classifier supplies $ef\mathsf{hsame}ef'$, so Definition 45.119 applied to $\mathsf{Cont}(d, ef, right)$ and $\mathsf{Cont}(d', ef', right')$ gives $\mathsf{RatHistoryClassifier}(right, right')$.

Finally apply Definition 45.117 to the unprimed continuation family $d, e, f, de, ef, left, right$. Apply it again to the primed family $d', e', f', de', ef', left', right'$. The two semigroup outputs give $left\mathsf{hsame}right$ and $left'\mathsf{hsame}right'$, completing the displayed conjunction. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation classifier assoc congruence`

Traditional target: denominator-side multiplication closure for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: RatHistoryCarrier plus Cont; **carrier choice**: Rat denominators; **classifier choice**: Rat history classifier; **stability obligation**: continuation-result carrier, classifier, and ledger transport, external empty-history boundary laws separated from carrier inhabitance, associativity coherence, commutativity coherence, and classifier-compatible associative continuation-result coherence; **ledger**: the right denominator's positive-unary witness and the matching continuation witnesses; **core theorems**: Definition 45.113, Definition 45.117, Definition 45.118, Definition 45.119, Definition 45.122, Definition 45.124, Definition 45.125, Definition 45.130, and Definition 45.142; **exactness predicate**: carrier closure for the concrete denominator operation plus the explicit no-internal-empty-unit boundary; **standard bridge**: deferred; **status**: ProofTarget.

Theorem 45.131 (Rat denominator continuation binary classifier congruence)**.** *For all histories* $d, d', e, e', r, r' : \mathsf{BHist}$*, if* $\mathsf{RatHistoryClassifier}(d, d')$*,* $\mathsf{RatHistoryClassifier}(e, e')$*,* $\mathsf{Cont}(d, e, r)$*, and* $\mathsf{Cont}(d', e', r')$*, then* $\mathsf{RatHistoryClassifier}(r, r')$*.*

Proof. Unpack the second Rat history classifier. It supplies carrier witnesses for e and e', together with the endpoint comparison $e\mathsf{hsame}e'$.

Read the two carrier witnesses through Definition 37.19 and then Definition 37.12. This yields unary-history witnesses for both right denominators while preserving the comparison $e\mathsf{hsame}e'$ from the classifier.

Apply Definition 45.119 to the first classifier $\mathsf{RatHistoryClassifier}(d, d')$, the two unary right-denominator witnesses, the comparison $e\mathsf{hsame}e'$, and the displayed continuation witnesses $\mathsf{Cont}(d, e, r)$ and $\mathsf{Cont}(d', e', r')$. Its conclusion is exactly $\mathsf{RatHistoryClassifier}(r, r')$. □

Traditional target: denominator-side multiplication congruence for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: RatHistoryCarrier, RatHistoryClassifier, and Cont; **carrier choice**: Rat denominators; **classifier choice**: Rat history classifier; **stability obligation**: binary operation congruence; **ledger**: the two continuation witnesses and the right-denominator unary evidence; **core theorem**: Definition 45.131; **exactness predicate**: classifier preservation under displayed continuation; **standard bridge**: deferred; **status**: ProofTarget.

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation binary classifier congruence`

Theorem 45.132 (Rat history classifier continuation results are nonempty)**.** *For all histories* $d, d', e, e', r, r' : \mathsf{BHist}$*, if* $\mathsf{RatHistoryClassifier}(d, d')$*,* $\mathsf{RatHistoryClassifier}(e, e')$*,* $\mathsf{Cont}(d, e, r)$*, and* $\mathsf{Cont}(d', e', r')$*, then neither continuation result is internally empty:*

$$(r\mathsf{hsame}e \to \mathsf{False}) \wedge (r'\mathsf{hsame}e \to \mathsf{False}).$$

Proof. Apply Definition 45.131 to the two input classifiers and the two displayed continuation witnesses. This gives $\mathsf{RatHistoryClassifier}(r, r')$. Its two carrier projections are Rat carrier witnesses for r and r', and the Rat carrier nonempty theorem rules out both empty-history comparisons. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryClassifier continuation result not empty`

Theorem 45.133 (Rat denominator continuation common-context cancellation)**.** *For all histories* $p, q, d, e, pd, pe, left, right$: BHist*, if* UnaryHistory(p)*,* UnaryHistory(q)*,* RatHistoryCarrier(d)*,* RatHistoryCarrier(e)*,* Cont(p, d, pd)*,* Cont(p, e, pe)*,* Cont$(pd, q, left)$*,* Cont$(pe, q, right)$*, and* RatHistoryClassifier$(left,$ *then* RatHistoryClassifier(d, e)*.*

Proof. Unpack the final Rat classifier. Its comparison component gives $left$hsame$right$.

Apply the continuation common-context cancellation theorem `BEDC.FKernel.Cont.cont_cancel_common_con` to the two matched prefix witnesses, the two matched suffix witnesses, and the comparison $left$hsame$right$. The shared prefix p and shared suffix q cancel, leaving the endpoint comparison $d$hsame$e$.

Combine this endpoint comparison with the original denominator carriers RatHistoryCarrier(d) and RatHistoryCarrier(e). These three pieces are exactly the fields of RatHistoryClassifier(d, e). □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation common context cancel`

Theorem 45.134 (Rat denominator matched-context classifier exactness)**.** *For all histories* $p, q, d, e, pd, pe, left, ri$ BHist*, if* UnaryHistory(p)*,* UnaryHistory(q)*,* RatHistoryCarrier(d)*,* RatHistoryCarrier(e)*,* Cont(p, d, pd)*,* Cont(p, e, pe)*,* Cont$(pd, q, left)$*, and* Cont$(pe, q, right)$*, then*

$$\mathsf{RatHistoryClassifier}(d, e) \iff \mathsf{RatHistoryClassifier}(left, right).$$

Proof. For the forward direction, apply Definition 37.58 to RatHistoryClassifier(d, e) with the common unary prefix p and common unary tail q. This gives the classifier for the append representatives obtained by placing the same matched context around d and e.

Continuation determinacy and associativity compare those representatives with the displayed endpoints $left$ and $right$, using the premises Cont(p, d, pd), Cont(p, e, pe), Cont$(pd, q, left)$, and Cont$(pe, q, right)$. Transporting the classifier across these endpoint comparisons gives RatHistoryClassifier$(left, righ$

For the reverse direction, apply Definition 45.133 to the same unary-context and continuation premises. It cancels the common prefix and suffix context from RatHistoryClassifier$(left, right)$ and returns RatHistoryClassifier(d, e). □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation common context classifier exactness`

↪ variant `BEDC.Derived.FieldUp.field rat denominator matched context classifier iff`

Theorem 45.135 (Rat denominator continuation common-context ledger closure)**.** *For all histories* $p, p', q, q', \rho, v, pr, pv, left, right$: BHist*, if* RatHistoryLedgerPolicy(ρ, v)*,* UnaryHistory(p)*,* UnaryHistory(p')*,* UnaryHistory(q)*,* UnaryHistory(q')*,* $p$hsamep'*,* $q$hsameq'*,* Cont(p, ρ, pr)*,* Cont(p', v, pv)*,* Cont$(pr, q, left)$*, and* Cont$(pv, q', right)$*, then* RatHistoryLedgerPolicy$(left, right)$*.*

Proof. First apply Definition 37.69 to the ledger RatHistoryLedgerPolicy(ρ, v), the matching unary prefixes p, p', and the matching unary suffixes q, q'. This gives the canonical ledger between append$(p,$ append$(\rho, q))$ and append$(p',$ append$(v, q'))$.

Next compare the canonical endpoints with the displayed two-step continuation endpoints. Continuation determinacy identifies the intermediate histories pr and pv with the corresponding prefix appends, and `BEDC.FKernel.Cont.cont_assoc_hsame` identifies the two displayed suffix continuations with the canonical common-context bracketings.

Finally transport the canonical ledger across those endpoint hsame links by Definition 37.71. The resulting ledger is exactly RatHistoryLedgerPolicy$(left, right)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation common context ledger closure`

Theorem 45.136 (Rat history classifier continuation unary context positive denominators)**.** *For histories* $d, e, p_d, p_e, t_d, t_e, md, me, out_d, out_e$: BHist*, if* RatHistoryClassifier(d, e) *holds,* p_d *and* t_d *are unary,* $p_d$hsamep_e *and* $t_d$hsamet_e*, and the two-step continuation displays place those contexts around* d *and* e*, then both displayed outputs are positive unary denominators:*

$$\mathsf{PositiveUnaryDenominator}(out_d) \wedge \mathsf{PositiveUnaryDenominator}(out_e).$$

Proof. Apply rational-history classifier unary-denominator context closure to obtain the classifier on the canonical associated endpoints $\mathsf{append}(p_d, \mathsf{append}(d, t_d))$ and $\mathsf{append}(p_e, \mathsf{append}(e, t_e))$. The continuation witnesses and associativity of append identify these canonical endpoints with out_d and out_e. Transport the classifier to the displayed outputs and read the two positive-denominator witnesses from the transported classifier. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryClassifier cont unary context positive denominators`

Theorem 45.137 (Rat history ledger continuation unary context positive denominators)**.** *For histories* $\rho, v, p_\rho, p_v, t_\rho, t_v, m_\rho, m_v, out_\rho, out_v$: BHist*, if* RatHistoryLedgerPolicy(ρ, v) *holds,* p_ρ *and* t_ρ *are unary,* $p_\rho$hsamep_v *and* $t_\rho$hsamet_v*, and the two-step continuation displays place those contexts around the raw and visible histories, then both displayed outputs are positive unary denominators:*

$$\mathsf{PositiveUnaryDenominator}(out_\rho) \wedge \mathsf{PositiveUnaryDenominator}(out_v).$$

Proof. First close the rational ledger under the matching unary prefix and tail contexts. The two continuation chains identify the canonical associated endpoints with the displayed outputs by associativity of append. Transport the closed ledger to those displayed outputs. Its raw carrier gives the first positive-denominator witness, and its transported visible carrier gives the second. □

Lean4 ✓ `BEDC.Derived.RatUp.RatHistoryLedgerPolicy cont unary context positive denominators`

Theorem 45.138 (Rat denominator continuation common-context exactness package)**.** *For all histories* $p, q, d, e, pd, pe, left, right$: BHist*, if* UnaryHistory(p)*,* UnaryHistory(q)*,* RatHistoryCarrier(d)*,* RatHistoryCarrier(e)*,* Cont(p, d, pd)*,* Cont(p, e, pe)*,* Cont$(pd, q, left)$*, and* Cont$(pe, q, right)$*, then both equivalences hold:*

$$\mathsf{RatHistoryClassifier}(left, right) \iff \mathsf{RatHistoryClassifier}(d, e).$$

$$\mathsf{RatHistoryLedgerPolicy}(left, right) \iff \mathsf{RatHistoryLedgerPolicy}(d, e).$$

Proof. For the classifier implication from $left, right$ back to d, e, apply Definition 45.133 to the same unary-context and continuation premises. It cancels the common prefix and suffix context from RatHistoryClassifier$(left, right)$ and returns RatHistoryClassifier(d, e).

For the classifier implication from d, e to $left, right$, apply Definition 37.58 to RatHistoryClassifier(d, e) with the common unary prefix p and common unary suffix q. This gives the classifier for the canonical endpoints obtained by placing p and q around d and e.

Continuation determinacy compares those canonical endpoints with the displayed endpoints $left$ and $right$, using the premises Cont(p, d, pd), Cont(p, e, pe), Cont$(pd, q, left)$, and Cont$(pe, q, right)$. Transporting the classifier across these endpoint comparisons by Definition 37.54 gives RatHistoryClassifier$(left, righ$

For the ledger implication from $left, right$ back to d, e, first convert RatHistoryLedgerPolicy$(left, right)$ to the raw-visible classifier by Definition 37.72. The cancellation theorem then returns RatHistoryClassifier(d, e),

whose comparison component is $d\mathsf{hsame}e$. Together with the input carrier $\mathsf{RatHistoryCarrier}(d)$, this is precisely $\mathsf{RatHistoryLedgerPolicy}(d, e)$.

For the ledger implication from d, e to $left, right$, apply Definition 37.69 to $\mathsf{RatHistoryLedgerPolicy}(d, e)$ with the common unary prefix p and common unary suffix q. Continuation determinacy compares the canonical ledger endpoints with $left$ and $right$, and Definition 37.71 transports the closed ledger across those endpoint comparisons. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation common context exactness package`

Theorem 45.139 (Rat denominator hsame-matched context classifier exactness)**.** *For all histories* $p, p', q, q', d, e, pd, pe, left, right : \mathsf{BHist}$*, if* $\mathsf{UnaryHistory}(p)$*,* $\mathsf{UnaryHistory}(p')$*,* $\mathsf{UnaryHistory}(q)$*,* $\mathsf{UnaryHistory}(q')$*,* $p\mathsf{hsame}p'$*,* $q\mathsf{hsame}q'$*,* $\mathsf{RatHistoryCarrier}(d)$*,* $\mathsf{RatHistoryCarrier}(e)$*,* $\mathsf{Cont}(p, d, pd)$*,* $\mathsf{Cont}(p', e, pe)$*,* $\mathsf{Cont}(pd, q, left)$*, and* $\mathsf{Cont}(pe, q', right)$*, then*

$$\mathsf{RatHistoryClassifier}(d, e) \iff \mathsf{RatHistoryClassifier}(left, right).$$

Proof. For the forward direction, assume $\mathsf{RatHistoryClassifier}(d, e)$. Apply Definition 37.58 to the unary prefixes p, p', the unary suffixes q, q', and the witnesses $p\mathsf{hsame}p'$ and $q\mathsf{hsame}q'$. This yields the classifier for the append histories obtained by placing the two history-same contexts around d and e.

The displayed endpoints are obtained from those append histories by the two-step continuation presentations. Continuation determinacy identifies pd and pe with the corresponding prefix appends, while continuation associativity identifies the final suffix continuations with the append bracketings. Transport the classifier across these endpoint hsame links by Definition 37.54 to obtain $\mathsf{RatHistoryClassifier}(left, right)$.

For the reverse direction, assume $\mathsf{RatHistoryClassifier}(left, right)$. Transport the continuation presentation along $p\mathsf{hsame}p'$ and $q\mathsf{hsame}q'$ using `BEDC.FKernel.Cont.cont_hsame_transport`; this gives a common-context presentation with the same displayed endpoints up to hsame.

Transport the endpoint classifier across those endpoint comparisons by Definition 37.54. Then apply Definition 45.133 to cancel the common unary prefix and suffix. Repacking the two Rat carriers with the recovered endpoint comparison gives $\mathsf{RatHistoryClassifier}(d, e)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator hsame matched context classifier exactness`

Theorem 45.140 (Rat denominator hsame-matched context exactness package)**.** *For all histories* $p, p', q, q', d, e, pd, pe, left, right : \mathsf{BHist}$*, if* $\mathsf{UnaryHistory}(p)$*,* $\mathsf{UnaryHistory}(p')$*,* $\mathsf{UnaryHistory}(q)$*,* $\mathsf{UnaryHistory}(q')$*,* $p\mathsf{hsame}p'$*,* $q\mathsf{hsame}q'$*,* $\mathsf{RatHistoryCarrier}(d)$*,* $\mathsf{RatHistoryCarrier}(e)$*,* $\mathsf{Cont}(p, d, pd)$*,* $\mathsf{Cont}(p', e, pe)$*,* $\mathsf{Cont}(pd, q, left)$*, and* $\mathsf{Cont}(pe, q', right)$*, then both equivalences hold:*

$$\mathsf{RatHistoryClassifier}(left, right) \iff \mathsf{RatHistoryClassifier}(d, e).$$

$$\mathsf{RatHistoryLedgerPolicy}(left, right) \iff \mathsf{RatHistoryLedgerPolicy}(d, e).$$

Proof. For the classifier equivalence, use Definition 45.139 with the displayed unary histories, the prefix and suffix comparisons $p\mathsf{hsame}p'$ and $q\mathsf{hsame}q'$, the two Rat carriers, and the four continuation premises. Its two implications give the stated equivalence after exchanging the displayed sides.

For the ledger implication from $left, right$ back to d, e, first convert $\mathsf{RatHistoryLedgerPolicy}(left, right)$ to the raw-visible classifier by Definition 37.72. The classifier equivalence just obtained reflects this to $\mathsf{RatHistoryClassifier}(d, e)$. Its comparison component is $d\mathsf{hsame}e$, and together with the displayed carrier $\mathsf{RatHistoryCarrier}(d)$ this is precisely $\mathsf{RatHistoryLedgerPolicy}(d, e)$.

For the ledger implication from d, e to $left, right$, apply Definition 45.135 to $\mathsf{RatHistoryLedgerPolicy}(d, e)$, the hsame-matched unary prefixes p, p', the hsame-matched unary suffixes q, q', and the four continuation premises. The conclusion is exactly $\mathsf{RatHistoryLedgerPolicy}(left, right)$. □

Theorem 45.141 (Rat denominator hsame-matched context ledger exactness)**.** *For all histories* $p, p', q, q', d, e, pd, pe, left, right : \mathsf{BHist}$*, if* $\mathsf{UnaryHistory}(p)$*,* $\mathsf{UnaryHistory}(p')$*,* $\mathsf{UnaryHistory}(q)$*,* $\mathsf{UnaryHistory}(q')$*,* $p\mathsf{hsame}p'$*,* $q\mathsf{hsame}q'$*,* $\mathsf{RatHistoryCarrier}(d)$*,* $\mathsf{RatHistoryCarrier}(e)$*,* $\mathsf{Cont}(p, d, pd)$*,* $\mathsf{Cont}(p', e, pe)$*,* $\mathsf{Cont}(pd, q, left)$*, and* $\mathsf{Cont}(pe, q', right)$*, then*

$$\mathsf{RatHistoryLedgerPolicy}(d, e) \iff \mathsf{RatHistoryLedgerPolicy}(left, right).$$

Proof. For the forward direction, assume $\mathsf{RatHistoryLedgerPolicy}(d, e)$. Apply Definition 45.135 to this ledger, the two unary prefixes, the two unary suffixes, the two hsame context comparisons, and the four displayed continuation witnesses. The result is exactly $\mathsf{RatHistoryLedgerPolicy}(left, right)$.

For the reverse direction, assume $\mathsf{RatHistoryLedgerPolicy}(left, right)$. Convert this endpoint ledger to the raw-visible classifier by Definition 37.72.

Apply Definition 45.139 in the reverse direction with the same unary histories, context comparisons, carrier witnesses, and continuation witnesses. This recovers $\mathsf{RatHistoryClassifier}(d, e)$, hence the endpoint comparison $d\mathsf{hsame}e$.

Pair the recovered comparison with the given carrier $\mathsf{RatHistoryCarrier}(d)$. These are precisely the data of $\mathsf{RatHistoryLedgerPolicy}(d, e)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator hsame matched context ledger exactness`

Traditional target: denominator exactness for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: RatHistoryCarrier plus Cont; **carrier choice**: Rat denominators; **classifier choice**: Rat history classifier; **stability obligation**: hsame-matched classifier and ledger exactness; **ledger**: matched unary prefix and suffix contexts; **core theorem**: Definition 45.139, Definition 45.135, and Definition 45.140; **exactness predicate**: hsame-matched unary contexts preserve and reflect both the Rat classifier and the Rat ledger; **standard bridge**: deferred; **status**: ProofTarget.

Theorem 45.142 (Rat denominator continuation is semigroup-only on the positive carrier)**.** *For the carrier* RatHistoryCarrier *and continuation relation* Cont*, Theorems 45.113 and 45.117 provide carrier closure and classifier associativity on positive Rat denominators. The empty history is not an internal carrier endpoint:* $\mathsf{RatHistoryCarrier}(\mathsf{e})$ *implies* False*. Consequently the endpoint laws in Theorem 45.124 are external empty-history endpoint laws. They do not provide an internal* $\mathsf{Monoid}^{\uparrow}$ *unit or an internal* $\mathsf{Field}^{\uparrow}$ *unit on the Rat denominator carrier.*

Proof. The semigroup clauses are exactly the content of the displayed closure and semigroup-law theorems. Carrier closure keeps every realized continuation result inside RatHistoryCarrier when both inputs are positive Rat denominators, and the semigroup law identifies the two continuation bracketings by the Rat history classifier.

For the unit boundary, suppose $\mathsf{RatHistoryCarrier}(\mathsf{e})$. Reflexivity of hsame at e gives ehsamee. Applying Theorem 37.18 to the assumed carrier witness and this reflexive endpoint equality yields False. Thus the empty-history clauses in Theorem 45.124 can be used only as external endpoint laws, not as an internal carrier unit. □

Theorem 45.143 (Rat denominator continuation has no internal carrier unit)**.** *For every history* $u : \mathsf{BHist}$*, the conjunction of* $\mathsf{RatHistoryCarrier}(u)$ *with the internal right-unit classifier law*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, u, r) \to \mathsf{RatHistoryClassifier}(r, d)$$

implies False. *Consequently no carried* u *can be a two-sided internal continuation unit on* RatHistoryCarrier *under* RatHistoryClassifier.

Proof. Assume a carried candidate u and the displayed right-unit classifier law. Let $d_1 := \mathsf{E1}(\mathsf{e})$. The positive-denominator construction gives $\mathsf{RatHistoryCarrier}(d_1)$.

Use the canonical continuation witness $\mathsf{Cont}(d_1, u, \mathsf{append}(d_1, u))$. Applying the assumed right-unit law at d_1 and $r := \mathsf{append}(d_1, u)$ gives $\mathsf{RatHistoryClassifier}(\mathsf{append}(d_1, u), d_1)$, whose comparison component is $\mathsf{append}(d_1, u)\mathsf{hsame}d_1$.

Transport the continuation result along this comparison to obtain $\mathsf{Cont}(d_1, u, d_1)$. The kernel theorem `BEDC.FKernel.Cont.cont_right_unit_unique` then forces $u\mathsf{hsame}\mathsf{e}$.

Finally apply Theorem 37.18 to the assumed carrier witness $\mathsf{RatHistoryCarrier}(u)$ and the equality $u\mathsf{hsame}\mathsf{e}$. This contradiction proves that no carried endpoint can realize the required right-unit law, and a two-sided internal unit would contain that right-unit law as one of its clauses. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation no internal unit`

Theorem 45.144 (Rat denominator continuation has no one-sided internal carrier unit)**.** *For every history* $u : \mathsf{BHist}$*, suppose* $\mathsf{RatHistoryCarrier}(u)$*. Then each of the following two laws separately implies* False*:*

1. *the internal right-unit classifier law*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, u, r) \to \mathsf{RatHistoryClassifier}(r, d),$$

2. *the internal left-unit classifier law*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(u, d, r) \to \mathsf{RatHistoryClassifier}(r, d).$$

Thus no carried u *can realize either one-sided internal continuation unit law on* RatHistoryCarrier *under* RatHistoryClassifier.

Proof. For the right-unit law, apply Theorem 45.143 to the same carried candidate u. The assumed carrier witness and the displayed right-unit law are exactly the hypotheses of that theorem, so the conclusion is False.

For the left-unit law, let $d_1 := \mathsf{E1}(\mathsf{e})$. The positive-denominator construction gives $\mathsf{RatHistoryCarrier}(d_1)$.

Use the canonical continuation witness $\mathsf{Cont}(u, d_1, \mathsf{append}(u, d_1))$. Applying the assumed left-unit law at d_1 and $r := \mathsf{append}(u, d_1)$ gives $\mathsf{RatHistoryClassifier}(\mathsf{append}(u, d_1), d_1)$, whose comparison component is $\mathsf{append}(u, d_1)\mathsf{hsame}d_1$.

Transport the continuation result along this comparison to obtain $\mathsf{Cont}(u, d_1, d_1)$. The kernel theorem `BEDC.FKernel.Cont.cont_left_unit_unique` then forces $u\mathsf{hsame}\mathsf{e}$.

Finally apply Theorem 37.18 to the assumed carrier witness $\mathsf{RatHistoryCarrier}(u)$ and the equality $u\mathsf{hsame}\mathsf{e}$. This contradiction proves that no carried endpoint can realize the required left-unit law. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation no one sided internal unit`

Definition 45.145 (Concrete Rat denominator continuation semigroup instance)**.** *The concrete denominator-side semigroup instance for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *has carrier* RatHistoryCarrier*, classifier* RatHistoryClassifier*, operation represented by the concrete continuation relation* $\mathsf{Cont}(d, e, r)$*, and ledger policy* RatHistoryLedgerPolicy*. Its data intentionally contains no identity field: the operation is packaged only as the carried continuation fragment whose results are compared by* RatHistoryClassifier.

Traditional target: denominator-side multiplicative semigroup fragment for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: RatHistoryCarrier plus Cont; **carrier choice**: RatHistoryCarrier; **classifier choice**: RatHistoryClassifier; **stability obligations**: closure, associativity, commutativity, classifier congruence, ledger closure, and no internal carrier unit; **ledger**: matching continuation witnesses; **core theorems**: Definition 45.113, Definition 45.117, Definition 45.118, Definition 45.119, Definition 45.120, Definition 45.122, Definition 45.130, and Definition 45.143; **exactness predicate**: carrier, classifier, and ledger preservation under continuation; **standard bridge**: deferred; **status**: ProofTarget.

Theorem 45.146 (Rat denominator continuation semigroup package)**.** *The concrete instance of Definition 45.145 satisfies the following package clauses:*

1. *for all histories* $d, e, f, de, ef, left, right$: BHist*, if* RatHistoryCarrier(d)*,* RatHistoryCarrier(e)*,* RatHistoryCarrier(f)*,* Cont(d, e, de)*,* Cont(e, f, ef)*,* Cont$(de, f, left)$*, and* Cont$(d, ef, right)$*, then* RatHistoryCarrier(de)*,* RatHistoryCarrier(ef)*,* RatHistoryCarrier$(left)$*,* RatHistoryCarrier$(right)$*, and* RatHistoryClassifier$(left, right)$*;*
2. *for all histories* d, d', u, u', r, s : BHist*, if* RatHistoryClassifier(d, d')*,* UnaryHistory(u)*,* UnaryHistory(u')*,* $u$hsameu'*,* Cont(d, u, r)*, and* Cont(d', u', s)*, then* RatHistoryClassifier(r, s)*;*
3. *for all histories* d, d', e, r, r' : BHist*, if* RatHistoryClassifier(d, d')*,* RatHistoryCarrier(e)*,* Cont(d, e, r)*, and* Cont(d', e, r')*, then* RatHistoryClassifier(r, r')*;*
4. *for all histories* ρ, v, u, u', r, s : BHist*, if* RatHistoryLedgerPolicy(ρ, v)*,* UnaryHistory(u)*,* UnaryHistory(u')*,* $u$hsameu'*,* Cont(ρ, u, r)*, and* Cont(v, u', s)*, then* RatHistoryLedgerPolicy(r, s)*;*
5. *for every history* u : BHist*,* RatHistoryCarrier(u) *together with the right-unit classifier law*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, u, r) \to \mathsf{RatHistoryClassifier}(r, d)$$

implies False*. Hence no carried endpoint can serve as a right or two-sided internal unit for this continuation instance.*

Proof. For the first clause, apply Definition 45.117. It gives the two intermediate carriers, the two outer carriers, and $left$hsame$right$. Combining the two outer carriers with this comparison yields RatHistoryClassifier$(left, right)$.

The same clause records the carrier closure supplied by Definition 45.113. The classifier statement for the two bracketings is the semigroup associativity component, while Definition 45.118 records the corresponding commutative classifier coherence for swapped carried continuations.

For classifier preservation under matching continuation tails, use Definition 45.119. For the shared carried right endpoint form, use Definition 45.120. The compatible associative version with classified triples is exactly Definition 45.130.

For the ledger clause, apply Definition 45.122 to the displayed ledger-related endpoints, matching unary tails, matching tail comparison, and continuation witnesses. The conclusion is the stated preservation of RatHistoryLedgerPolicy.

For the final obstruction clause, apply Definition 45.143. Its statement is precisely the contradiction obtained from a carried endpoint satisfying the right-unit classifier law, and any two-sided internal unit contains that right-unit clause. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation semigroup package`

Theorem 45.147 (Rat denominator continuation is not a FieldUp multiplication)**.** *For every proposed carried unit* $u : \mathsf{BHist}$*, suppose* $\mathsf{RatHistoryCarrier}(u)$ *and suppose the proposed carried multiplication on the Rat denominator carrier is the continuation relation* Cont*. If the corresponding* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *right-unit law under* $\mathsf{RatHistoryClassifier}$ *is*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, u, r) \to \mathsf{RatHistoryClassifier}(r, d),$$

then the assumptions imply False*. Consequently a* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *certificate cannot take Rat-denominator continuation itself as its carried multiplication together with a carried unit.*

Proof. Unpack the attempted $\mathsf{Field}^{\uparrow}$ multiplication data for the carried operation Cont. The right-unit field supplies exactly the displayed classifier law: for every Rat denominator d and every continuation result r from $\mathsf{Cont}(d, u, r)$, the result must classify as the original denominator d under $\mathsf{RatHistoryClassifier}$.

Apply Theorem 45.144 to the same history u, using the carried-unit witness $\mathsf{RatHistoryCarrier}(u)$ and the right-unit clause with this unpacked field. Its conclusion is False.

Theorem 45.142 records the positive part left intact by this contradiction: continuation on Rat denominators still has carrier closure and semigroup-level associativity, but those clauses do not supply an internal $\mathsf{Monoid}^{\uparrow}$ unit or the unit required by $\mathsf{Field}^{\uparrow}$ multiplication. □

Theorem 45.148 (Rat denominator continuation has no internal left carrier unit)**.** *For every history* $u : \mathsf{BHist}$*, the conjunction of* $\mathsf{RatHistoryCarrier}(u)$ *with the internal left-unit classifier law*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(u, d, r) \to \mathsf{RatHistoryClassifier}(r, d)$$

implies False*. Thus no carried* u *can realize the left endpoint half of an internal continuation unit on* $\mathsf{RatHistoryCarrier}$ *under* $\mathsf{RatHistoryClassifier}$*.*

Proof. Assume a carried candidate u and the displayed left-unit classifier law. Let $d_1 := \mathsf{E1}(\mathsf{e})$. The positive-denominator construction gives $\mathsf{RatHistoryCarrier}(d_1)$.

Use the canonical continuation witness $\mathsf{Cont}(u, d_1, \mathsf{append}(u, d_1))$. Applying the assumed left-unit law at d_1 and $r := \mathsf{append}(u, d_1)$ gives $\mathsf{RatHistoryClassifier}(\mathsf{append}(u, d_1), d_1)$, whose comparison component is $\mathsf{append}(u, d_1)\mathsf{hsame}d_1$.

Transport the continuation result along this comparison to obtain $\mathsf{Cont}(u, d_1, d_1)$. The kernel theorem `BEDC.FKernel.Cont.cont_left_unit_unique` then forces $u\mathsf{hsamee}$.

Finally apply Theorem 37.18 to the assumed carrier witness $\mathsf{RatHistoryCarrier}(u)$ and the equality $u\mathsf{hsamee}$. This contradiction proves that no carried endpoint can realize the required left-unit law. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation no internal left unit`

Theorem 45.149 (Rat history carrier right-append fixed absurd)**.** *For histories* $h, g : \mathsf{BHist}$*,*

$$\mathsf{RatHistoryCarrier}(h) \to \mathsf{append}(h, g)\mathsf{hsame}g \to \mathsf{False}.$$

Proof. The fixed append equality is a continuation witness $\mathsf{Cont}(h, g, g)$ after symmetry. The kernel left-unit uniqueness theorem for continuation then forces $h\mathsf{hsamee}$. This contradicts the nonempty endpoint theorem for $\mathsf{RatHistoryCarrier}$. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryCarrier right append fixed absurd`

Theorem 45.150 (Rat denominator continuation commutative-semigroup obstruction package)**.** *For the concrete BEDC carrier* RatHistoryCarrier*, continuation relation* Cont*, and classifier* RatHistoryClassifier*, Rat denominator continuation satisfies the following five-field package.*

1. *Carrier closure: if* $\mathsf{RatHistoryCarrier}(d)$*,* $\mathsf{RatHistoryCarrier}(e)$*, and* $\mathsf{Cont}(d, e, r)$*, then* $\mathsf{RatHistoryCarrier}(r)$*.*
2. *Classifier associativity: if* $d, e, f, de, ef, \ell, r : \mathsf{BHist}$ *are related by* $\mathsf{Cont}(d, e, de)$*,* $\mathsf{Cont}(e, f, ef)$*,* $\mathsf{Cont}(de, f, \ell)$*, and* $\mathsf{Cont}(d, ef, r)$*, with* d, e, f *carried by* RatHistoryCarrier*, then the two bracketed results are carried and satisfy* $\ell\mathsf{hsame}r$*.*
3. *Classifier commutativity: if* $\mathsf{RatHistoryCarrier}(d)$*,* $\mathsf{RatHistoryCarrier}(e)$*,* $\mathsf{Cont}(d, e, r)$*, and* $\mathsf{Cont}(e, d, s)$*, then* $\mathsf{RatHistoryClassifier}(r, s)$*.*
4. *Internal left-unit impossibility: for every* $u : \mathsf{BHist}$*, the conjunction of* $\mathsf{RatHistoryCarrier}(u)$ *with*
$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(u, d, r) \to \mathsf{RatHistoryClassifier}(r, d)$$
implies False*.*
5. *Internal right-unit impossibility: for every* $u : \mathsf{BHist}$*, the conjunction of* $\mathsf{RatHistoryCarrier}(u)$ *with*
$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, u, r) \to \mathsf{RatHistoryClassifier}(r, d)$$
implies False*.*

Consequently Rat-denominator continuation is a concrete commutative semigroup-level operation under RatHistoryClassifier *with no internal one-sided carried unit, and therefore cannot serve as the carried multiplication of* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$*.*

Proof. The carrier-closure field is exactly Definition 45.113; it uses only the concrete carrier RatHistoryCarrier and the concrete continuation relation Cont.

The associativity field is Definition 45.117. It supplies the two intermediate carriers, the two outer result carriers, and the classifier comparison between the left- and right-bracketed continuations.

The commutativity field is Definition 45.118. It compares the two swapped denominator continuations by RatHistoryClassifier.

The internal left-unit obstruction is the left law of Definition 45.144. The internal right-unit obstruction is the right law of Definition 45.144.

Combining those two one-sided obstructions with the closure, associativity, and commutativity fields gives precisely a commutative semigroup-level continuation operation, not a carried field multiplication with an internal one-sided unit. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation commutative semigroup obstruction package`

Theorem 45.151 (Rat denominator continuation full obstruction package)**.** *For the concrete BEDC carrier* RatHistoryCarrier*, classifier* RatHistoryClassifier*, operation relation* Cont*, and ledger* RatHistoryLedgerPolicy*, Rat denominator continuation satisfies the following six-clause certificate-shaped obstruction package.*

1. *Carrier closure: if* $\mathsf{RatHistoryCarrier}(d)$*,* $\mathsf{RatHistoryCarrier}(e)$*, and* $\mathsf{Cont}(d, e, r)$*, then* $\mathsf{RatHistoryCarrier}(r)$*.*
2. *Classifier associativity: if* $d, e, f, de, ef, \ell, r : \mathsf{BHist}$ *are related by* $\mathsf{Cont}(d, e, de)$*,* $\mathsf{Cont}(e, f, ef)$*,* $\mathsf{Cont}(de, f, \ell)$*, and* $\mathsf{Cont}(d, ef, r)$*, with* d, e, f *carried by* RatHistoryCarrier*, then the two bracketed results are carried and satisfy* $\mathsf{RatHistoryClassifier}(\ell, r)$*.*

3. *Classifier commutativity: if* $\mathsf{RatHistoryCarrier}(d)$, $\mathsf{RatHistoryCarrier}(e)$, $\mathsf{Cont}(d, e, r)$, *and* $\mathsf{Cont}(e, d, s)$, *then* $\mathsf{RatHistoryClassifier}(r, s)$.
4. *Binary classifier congruence: if* $\mathsf{RatHistoryClassifier}(d, d')$, $\mathsf{RatHistoryClassifier}(e, e')$, $\mathsf{Cont}(d, e, r)$, *and* $\mathsf{Cont}(d', e', s)$, *then* $\mathsf{RatHistoryClassifier}(r, s)$.
5. *Ledger closure for classified unary continuation tails: if* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$, $\mathsf{UnaryHistory}(u)$, $\mathsf{UnaryHistory}(u')$, $u\mathsf{hsame}u'$, $\mathsf{Cont}(\rho, u, r)$, *and* $\mathsf{Cont}(v, u', s)$, *then* $\mathsf{RatHistoryLedgerPolicy}(r, s)$.
6. *Internal carried-unit obstruction: for every history* $u : \mathsf{BHist}$, *if* $\mathsf{RatHistoryCarrier}(u)$, *then the left-unit classifier law*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(u, d, r) \to \mathsf{RatHistoryClassifier}(r, d)$$

and the right-unit classifier law

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, u, r) \to \mathsf{RatHistoryClassifier}(r, d)$$

each imply False.

Consequently Rat-denominator continuation is a classifier-and-ledger commutative semigroup fragment, but it cannot be promoted to the multiplicative carrier of $\mathsf{Monoid}^{\uparrow}$ *or* $\mathsf{Field}^{\uparrow}$ *because no carried one-sided unit exists.*

Proof. The carrier-closure clause is exactly Definition 45.113. The associativity clause is Definition 45.117; its conclusion supplies the two intermediate carriers, the two outer result carriers, and $\ell\mathsf{hsame}r$, which repacks as $\mathsf{RatHistoryClassifier}(\ell, r)$.

The commutativity clause is Definition 45.118. For binary classifier congruence, unpack the classifier $\mathsf{RatHistoryClassifier}(e, e')$ to obtain unary denominator witnesses for the two right inputs and the comparison $e\mathsf{hsame}e'$, then apply Definition 45.131 to the classified left inputs and the two continuation witnesses.

The ledger clause is Definition 45.122. It applies to the displayed ledger endpoints, matched unary continuation tails, tail comparison, and continuation witnesses, yielding $\mathsf{RatHistoryLedgerPolicy}(r, s)$.

The carried-unit obstruction is Definition 45.144. Its two conclusions rule out the left-unit and right-unit classifier laws for any carried candidate u, completing the certificate-shaped package. □

Theorem 45.152 (Rat denominator continuation obstruction is context-invariant)**.** *For all histories* $p, p', q, q', d, e, pd, pe, left, right : \mathsf{BHist}$, *suppose* $\mathsf{UnaryHistory}(p)$, $\mathsf{UnaryHistory}(p')$, $\mathsf{UnaryHistory}(q)$, $\mathsf{UnaryHistory}(q')$, $p\mathsf{hsame}p'$, $q\mathsf{hsame}q'$, $\mathsf{RatHistoryCarrier}(d)$, $\mathsf{RatHistoryCarrier}(e)$, *and the four displayed continuation witnesses*

$$\mathsf{Cont}(p, d, pd), \quad \mathsf{Cont}(p', e, pe), \quad \mathsf{Cont}(pd, q, left), \quad \mathsf{Cont}(pe, q', right).$$

Then the matched unary context wrapping preserves the full obstruction data:

1. $\mathsf{RatHistoryClassifier}(d, e) \iff \mathsf{RatHistoryClassifier}(left, right)$.
2. $\mathsf{RatHistoryLedgerPolicy}(d, e) \to \mathsf{RatHistoryLedgerPolicy}(left, right)$.
3. *For every history* $u : \mathsf{BHist}$, *if* $\mathsf{RatHistoryCarrier}(u)$, *then the internal left-unit classifier law*

$$\forall x, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(x) \to \mathsf{Cont}(u, x, r) \to \mathsf{RatHistoryClassifier}(r, x)$$

and the internal right-unit classifier law

$$\forall x, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(x) \to \mathsf{Cont}(x, u, r) \to \mathsf{RatHistoryClassifier}(r, x)$$

each imply False.

Proof. The classifier claim is exactly Definition 45.139 with the displayed unary prefix contexts, unary suffix contexts, context comparisons, carrier witnesses, and continuation witnesses.

For the ledger claim, apply Definition 45.135 to the same matched unary context data and the displayed continuation witnesses. Its conclusion transports the Rat ledger policy from (d, e) to $(left, right)$.

It remains to record that the matched context does not create an internal carried unit. The left-unit obstruction is Definition 45.148, applied to the carried candidate u and the displayed left-unit classifier law. The right-unit obstruction is Definition 45.143, applied to the same carried candidate u and the displayed right-unit classifier law. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator context invariant obstruction package`

Theorem 45.153 (Rat denominator continuation associative obstruction package)**.** *For the concrete BEDC carrier* RatHistoryCarrier*, classifier* RatHistoryClassifier*, operation relation* Cont*, and ledger* RatHistoryLedgerPolicy*, Rat denominator continuation satisfies the following certificate-shaped obstruction package.*

1. *Carrier closure: if* $\mathsf{RatHistoryCarrier}(d)$*,* $\mathsf{RatHistoryCarrier}(e)$*, and* $\mathsf{Cont}(d, e, r)$*, then* $\mathsf{RatHistoryCarrier}(r)$*.*
2. *Binary classifier congruence: if* $\mathsf{RatHistoryClassifier}(d, d')$*,* $\mathsf{RatHistoryClassifier}(e, e')$*,* $\mathsf{Cont}(d, e, r)$*, and* $\mathsf{Cont}(d', e', r')$*, then* $\mathsf{RatHistoryClassifier}(r, r')$*.*
3. *Classified-triple associativity congruence: for all histories* $d, d', e, e', f, f', de, de', ef, ef', left, left', right, right'$: BHist*, if* $\mathsf{RatHistoryClassifier}(d, d')$*,* $\mathsf{RatHistoryClassifier}(e, e')$*,* $\mathsf{RatHistoryClassifier}(f, f')$*,* $\mathsf{Cont}(d, e, de)$*,* $\mathsf{Cont}(d', e', de')$*,* $\mathsf{Cont}(e, f, ef)$*,* $\mathsf{Cont}(e', f', ef')$*,* $\mathsf{Cont}(de, f, left)$*,* $\mathsf{Cont}(de', f', left')$*,* $\mathsf{Cont}(d, ef, right)$*, and* $\mathsf{Cont}(d', ef', right')$*, then*

$$\mathsf{RatHistoryClassifier}(left, left') \wedge \mathsf{RatHistoryClassifier}(right, right') \wedge left \mathsf{hsame} right \wedge left' \mathsf{hsame} right'.$$

4. *Hsame-matched context classifier-and-ledger exactness: for all histories* $p, p', q, q', d, e, pd, pe, left, right$: BHist*, if* $\mathsf{UnaryHistory}(p)$*,* $\mathsf{UnaryHistory}(p')$*,* $\mathsf{UnaryHistory}(q)$*,* $\mathsf{UnaryHistory}(q')$*,* $p \mathsf{hsame} p'$*,* $q \mathsf{hsame} q'$*,* $\mathsf{RatHistoryCarrier}(d)$*,* $\mathsf{RatHistoryCarrier}(e)$*,* $\mathsf{Cont}(p, d, pd)$*,* $\mathsf{Cont}(p', e, pe)$*,* $\mathsf{Cont}(pd, q, left)$*, and* $\mathsf{Cont}(pe, q', right)$*, then both equivalences hold:*

$$\mathsf{RatHistoryClassifier}(left, right) \iff \mathsf{RatHistoryClassifier}(d, e).$$

$$\mathsf{RatHistoryLedgerPolicy}(left, right) \iff \mathsf{RatHistoryLedgerPolicy}(d, e).$$

5. *Ledger closure for classified unary continuation tails: if* $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$*,* $\mathsf{UnaryHistory}(u)$*,* $\mathsf{UnaryHistory}(u')$*,* $u \mathsf{hsame} u'$*,* $\mathsf{Cont}(\rho, u, r)$*, and* $\mathsf{Cont}(v, u', s)$*, then* $\mathsf{RatHistoryLedgerPolicy}(r, s)$*.*

6. *Endpoint-forced emptiness: if a history* $u : \mathsf{BHist}$ *satisfies either one-sided classifier unit law*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, u, r) \to \mathsf{RatHistoryClassifier}(r, d)$$

or

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(u, d, r) \to \mathsf{RatHistoryClassifier}(r, d),$$

then $u\mathsf{hsamee}$.

7. *Endpoint uniqueness: for all histories* $u, v : \mathsf{BHist}$*, if both endpoints satisfy the right-unit classifier law*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, w, r) \to \mathsf{RatHistoryClassifier}(r, d),$$

for $w = u$ *and for* $w = v$*, then* $u\mathsf{hsame}v$*; if both endpoints satisfy the left-unit classifier law*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(w, d, r) \to \mathsf{RatHistoryClassifier}(r, d),$$

for $w = u$ *and for* $w = v$*, then* $u\mathsf{hsame}v$*; and if* u *satisfies the right-unit classifier law while* v *satisfies the left-unit classifier law, then* $u\mathsf{hsame}v$.

8. *Carried one-sided unit obstruction: for every history* $u : \mathsf{BHist}$*, if* $\mathsf{RatHistoryCarrier}(u)$*, then each one-sided classifier unit law for* u *implies* False.

Consequently the Rat-denominator continuation spine contains the closure, operation congruence, associative classified composition, context exactness, and ledger stability required for a certificate, while its unit endpoint is forced outside the carried denominator carrier.

Proof. The carrier-closure field is exactly Definition 45.113. The binary classifier congruence field is Definition 45.131; it compares two continuation outputs from two classified input pairs.

The classified-triple associativity congruence field is Definition 45.130. It handles two classified triples of continuation data at once, producing classifier comparisons for the corresponding left and right bracketings together with the two internal associativity comparisons.

For hsame-matched context exactness, apply Definition 45.140 to the displayed unary prefixes, unary suffixes, context comparisons, Rat carriers, and continuation witnesses. Its two equivalences are precisely the classifier and ledger exactness clauses in the package.

The ledger-closure field is Definition 45.122. It transports the Rat ledger along classified unary continuation tails and returns $\mathsf{RatHistoryLedgerPolicy}(r, s)$.

For endpoint-forced emptiness, use Definition 45.125. Its right and left clauses force any one-sided classifier unit endpoint to satisfy $u\mathsf{hsamee}$.

Endpoint uniqueness is Definition 45.129; its three clauses cover the displayed right/right, left/left, and mixed one-sided classifier-unit comparisons.

Finally, the carried one-sided unit obstruction is Definition 45.144, which turns either one-sided classifier unit law into False once the endpoint is carried by $\mathsf{RatHistoryCarrier}$. □

Traditional target: denominator-side continuation with empty endpoint unit for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: BHist, RatHistoryCarrier, and Cont; **carrier choice**: RatDenomUnitCarrier; **classifier choice**: RatDenomUnitClassifier; **stability obligations**: empty endpoint coverage, continuation closure, one-sided endpoint laws, and classified triple associativity; **ledger**: continuation

witnesses together with the resulting hsame comparisons; **core theorem**: Definition 45.177; **exactness predicate**: both endpoints lie in the empty-unit denominator carrier and are related by hsame; **standard bridge**: denominator continuation with the empty history as endpoint unit; **status**: ProofTarget.

Traditional target: internal unit obstruction for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: RatHistoryCarrier plus Cont; **carrier choice**: Rat denominators; **classifier choice**: RatHistoryClassifier; **stability obstruction**: no carried one-sided unit and no continuation-as-field-multiplication certificate; **ledger**: the attempted unit endpoint; **core theorems**: Definition 45.143, Definition 45.144, Definition 45.147, Definition 45.150, Definition 45.152, and Definition 45.153; **exactness predicate**: failure of internal one-sided unit coverage; **standard bridge**: deferred; **status**: ProofTarget.

Traditional target: denominator-side continuation with empty endpoint unit for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: BHist, RatHistoryCarrier, and Cont; **carrier choice**: RatDenomUnitCarrier; **classifier choice**: RatDenomUnitClassifier; **stability obligations**: empty endpoint coverage, continuation closure, one-sided endpoint laws, and classified triple associativity; **ledger**: continuation witnesses together with the resulting hsame comparisons; **core theorem**: Definition 45.177; **exactness predicate**: both endpoints lie in the empty-unit denominator carrier and are related by hsame; **standard bridge**: denominator continuation with the empty history as endpoint unit; **status**: ProofTarget.

Traditional target: internal unit obstruction for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: RatHistoryCarrier plus Cont; **carrier choice**: Rat denominators; **classifier choice**: RatHistoryClassifier; **stability obstruction**: no carried one-sided unit and no continuation-as-field-multiplication certificate; **ledger**: the attempted unit endpoint; **core theorems**: Definition 45.143, Definition 45.144, Definition 45.147, Definition 45.150, Definition 45.152, and Definition 45.153; **exactness predicate**: failure of internal one-sided unit coverage; **standard bridge**: deferred; **status**: ProofTarget.

Definition 45.154 (Rat denominator continuation with adjoined empty unit)**.** *For each history* $h : \mathsf{BHist}$*, define the empty-unit denominator carrier by*

$$\mathsf{RatDenomUnitCarrier}(h) \iff h\mathsf{hsamee} \vee \mathsf{RatHistoryCarrier}(h).$$

For histories $h, k : \mathsf{BHist}$*, define the corresponding endpoint classifier by*

$$\mathsf{RatDenomUnitClassifier}(h, k) \iff \mathsf{RatDenomUnitCarrier}(h) \wedge \mathsf{RatDenomUnitCarrier}(k) \wedge h\mathsf{hsame}k.$$

Lean4 (definition) `BEDC.Derived.FieldUp.RatDenomUnitCarrier`
Lean4 (definition) `BEDC.Derived.FieldUp.RatDenomUnitClassifier`

Theorem 45.155 (Rat denominator unit carrier history-sameness transport)**.** *For histories* $h, k :$ BHist*, if* $h\mathsf{hsame}k$ *and* $\mathsf{RatDenomUnitCarrier}(h)$*, then* $\mathsf{RatDenomUnitCarrier}(k)$*.*

Proof. Split the carrier disjunction for h. In the empty branch, compose $h\mathsf{hsame}k$ with the displayed comparison $h\mathsf{hsamee}$ and symmetry or transitivity of hsame to obtain $k\mathsf{hsamee}$. This selects the empty branch of $\mathsf{RatDenomUnitCarrier}(k)$.

In the Rat branch, apply Rat carrier transport along the hsame comparison from h to k. The resulting $\mathsf{RatHistoryCarrier}(k)$ witness selects the Rat branch of the denominator unit carrier. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier hsame transport`

Theorem 45.156 (Rat denominator unit carrier continuation closure)**.** *For histories* $h, k, r :$ BHist*, if* $\mathsf{RatDenomUnitCarrier}(h)$*,* $\mathsf{RatDenomUnitCarrier}(k)$*, and* $\mathsf{Cont}(h, k, r)$*, then* $\mathsf{RatDenomUnitCarrier}(r)$*.*

Proof. Split the two input carriers. The empty/empty case uses the two continuation unit laws to identify the result with e, hence the result lies in the empty branch.

In the two mixed cases, the corresponding unit law identifies the continuation result with the nonempty input; use cont_respects_hsame and Rat carrier transport to move the Rat carrier witness to r.

In the Rat/Rat case, apply the Rat denominator continuation carrier-closure theorem directly. The resulting $\mathsf{RatHistoryCarrier}(r)$ witness selects the Rat branch of $\mathsf{RatDenomUnitCarrier}(r)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier continuation closed`

Theorem 45.157 (Rat denominator unit carrier append with Rat left factor)**.** *For histories h, k : BHist, if h is a Rat denominator endpoint and k is carried by the adjoined empty-unit denominator carrier, then the append product is again a Rat denominator endpoint:*

$$\mathsf{RatHistoryCarrier}(h) \to \mathsf{RatDenomUnitCarrier}(k) \to \mathsf{RatHistoryCarrier}(\mathsf{append}(h, k)).$$

Proof. Split the adjoined-unit carrier witness for k. If $k$hsamee, the append product is history-same to h, so the Rat carrier for h transports to the product. If k is a Rat denominator endpoint, apply Rat denominator continuation carrier closure to the canonical append continuation. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier append left rat closed`

Theorem 45.158 (Rat denominator unit carrier append with Rat right factor)**.** *For histories h, k : BHist, if h is carried by the adjoined empty-unit denominator carrier and k is a Rat denominator endpoint, then the append product is again a Rat denominator endpoint:*

$$\mathsf{RatDenomUnitCarrier}(h) \to \mathsf{RatHistoryCarrier}(k) \to \mathsf{RatHistoryCarrier}(\mathsf{append}(h, k)).$$

Proof. Split the adjoined-unit carrier witness for h. If $h$hsamee, the append product is history-same to k, so the Rat carrier for k transports to the product. If h is a Rat denominator endpoint, apply Rat denominator continuation carrier closure to the canonical append continuation. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier append right rat closed`

Theorem 45.159 (Rat history classifier append with right denominator unit)**.** *For histories h, h', k, k' : BHist, if h and h' are related by the Rat history classifier and k and k' are related by the adjoined denominator unit classifier, then appending the unit-classified right factor preserves the Rat history classifier:*

$$\mathsf{RatHistoryClassifier}(h, h') \to \mathsf{RatDenomUnitClassifier}(k, k') \to \mathsf{RatHistoryClassifier}(\mathsf{append}(h, k), \mathsf{append}(h', k')).$$

Proof. The carrier fields are obtained from the Rat left-factor append closure for the adjoined denominator unit carrier. The endpoint comparison is the canonical append continuation comparison transported along the two classifier hsame witnesses. These data assemble the Rat history classifier for the two appended endpoints. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryClassifier append right denom unit closed`

Theorem 45.160 (Rat denominator unit append carrier branch cases)**.** *For histories h, k : BHist, if the append endpoint is carried by the adjoined empty-unit denominator carrier, then either both factors are empty endpoints or one factor is a genuine Rat denominator endpoint:*

$$\mathsf{RatDenomUnitCarrier}(\mathsf{append}(h, k)) \to (h\mathsf{hsamee} \wedge k\mathsf{hsamee}) \vee \mathsf{RatHistoryCarrier}(h) \vee \mathsf{RatHistoryCarrier}(k).$$

Proof. Split the concrete carrier disjunction for $\mathsf{RatDenomUnitCarrier}(\mathsf{append}(h, k))$. In the empty branch, the append-empty inversion theorem gives $h\mathsf{hsamee}$ and $k\mathsf{hsamee}$. In the Rat branch, apply Rat denominator append splitting to the carried append endpoint, obtaining a Rat carrier witness on the left or right factor. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier append branch cases`

The per-object certificate has ten fields: traditional target carrier stability for the denominator unit fragment; BEDC source BHist, RatHistoryCarrier, and Cont; carrier RatDenomUnitCarrier; classifier RatDenomUnitClassifier; stability obligations transport and continuation closure; ledger continuation witnesses; core theorems 45.155 and 45.156; exactness predicate preservation of admitted endpoints; standard bridge deferred; status ProofTarget.

Theorem 45.161 (Rat denominator unit carrier nonempty endpoint exactness)**.** *For every history h, if* $\mathsf{RatDenomUnitCarrier}(h)$ *holds and* $h\mathsf{hsamee}$ *is impossible, then h is a genuine Rat denominator endpoint:*

$$\mathsf{RatHistoryCarrier}(h).$$

Proof. Unfold the carrier disjunction. The empty-unit branch is exactly $h\mathsf{hsamee}$, contradicting the supplied nonempty endpoint condition. The other branch is the required $\mathsf{RatHistoryCarrier}(h)$ witness. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier nonempty rat`

Theorem 45.162 (Rat denominator unit nonempty classifier exposes Rat classifier)**.** *For histories $h, k : \mathsf{BHist}$, if* $\mathsf{RatDenomUnitClassifier}(h, k)$ *holds and neither endpoint is history-same to* e*, then the same endpoint pair is classified by the underlying Rat denominator classifier:*

$$\mathsf{RatDenomUnitClassifier}(h, k) \Rightarrow (h\mathsf{hsamee} \Rightarrow \mathsf{False}) \Rightarrow (k\mathsf{hsamee} \Rightarrow \mathsf{False}) \Rightarrow \mathsf{RatHistoryClassifier}(h, k).$$

Proof. Unpack $\mathsf{RatDenomUnitClassifier}(h, k)$ into the two denominator-unit carrier witnesses and the endpoint comparison $h\mathsf{hsame}k$. Apply Definition 45.161 separately to the left and right carrier witnesses, using the two nonempty endpoint hypotheses. These two Rat carrier witnesses, together with the original endpoint comparison, repack as $\mathsf{RatHistoryClassifier}(h, k)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier nonempty rat classifier`

Theorem 45.163 (Rat denominator unit classifier nonempty endpoint iff)**.** *For histories $h, k :$* BHist*, a denominator-unit classifier witness transports the nonempty endpoint predicate in both directions:*

$$\mathsf{RatDenomUnitClassifier}(h, k) \Rightarrow ((h\mathsf{hsamee} \Rightarrow \mathsf{False}) \Longleftrightarrow (k\mathsf{hsamee} \Rightarrow \mathsf{False})).$$

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier nonempty endpoint iff`

Proof. Unpack $\mathsf{RatDenomUnitClassifier}(h, k)$ and use its endpoint comparison $h\mathsf{hsame}k$. Composing this comparison with an empty-endpoint witness on one side produces an empty-endpoint witness on the other side, contradicting the assumed nonempty predicate. The reverse direction uses symmetry of the same hsame comparison. □

Theorem 45.164 (Rat denominator unit classifier left-nonempty Rat exactness)**.** *For histories $h, k :$* BHist*, a denominator-unit classifier witness identifies the native Rat denominator classifier with nonemptiness of the left endpoint:*

$$\mathsf{RatDenomUnitClassifier}(h, k) \Rightarrow (\mathsf{RatHistoryClassifier}(h, k) \Longleftrightarrow (h\mathsf{hsamee} \Rightarrow \mathsf{False})).$$

Proof. The forward implication uses the endpoint nonemptiness forced by RatHistoryClassifier. Conversely, denominator-unit classification transports left nonemptiness to the right endpoint, and the nonempty classifier theorem upgrades the two denominator-unit carriers to the native Rat classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier rat classifier left nonempty iff`

Theorem 45.165 (Rat denominator unit classifier either-nonempty Rat exactness)**.** *For histories* $h, k : \mathsf{BHist}$*, a denominator-unit classifier witness identifies the native Rat denominator classifier with nonemptiness of either endpoint:*

$$\mathsf{RatDenomUnitClassifier}(h, k) \Rightarrow (\mathsf{RatHistoryClassifier}(h, k) \iff ((h\mathsf{hsamee} \Rightarrow \mathsf{False}) \vee (k\mathsf{hsamee} \Rightarrow \mathsf{False}))) .$$

Proof. For the forward implication, apply Definition 45.164. The resulting left endpoint nonemptiness gives the displayed disjunction.

For the reverse implication, split the disjunction. In the left-endpoint case, apply Definition 45.164 directly.

In the right-endpoint case, first use Definition 45.163 to transport right nonemptiness to left nonemptiness. The left-nonempty Rat exactness theorem then supplies $\mathsf{RatHistoryClassifier}(h, k)$. □

Theorem 45.166 (Rat denominator unit classifier Rat-history exactness)**.** *For histories* $h, k : \mathsf{BHist}$*, the native Rat denominator classifier is exactly the denominator-unit classifier restricted to genuine nonempty Rat denominator endpoints:*

$$\mathsf{RatHistoryClassifier}(h, k) \iff (\mathsf{RatDenomUnitClassifier}(h, k) \wedge (h\mathsf{hsamee} \Rightarrow \mathsf{False}) \wedge (k\mathsf{hsamee} \Rightarrow \mathsf{False})) .$$

Proof. For the forward direction, unpack $\mathsf{RatHistoryClassifier}(h, k)$ into its two Rat carrier witnesses and the endpoint comparison. Repack the two carrier witnesses as RatDenomUnitCarrier witnesses and keep the same comparison, giving $\mathsf{RatDenomUnitClassifier}(h, k)$.

The two nonempty endpoint predicates are supplied by Definition 37.51, applied to the same native Rat classifier witness. This records that neither endpoint lies in the adjoined empty-unit branch.

For the reverse direction, start from the denominator-unit classifier witness and the two nonempty endpoint predicates. Apply Definition 45.162; its conclusion is precisely $\mathsf{RatHistoryClassifier}(h, k)$. □

The per-object certificate has ten fields: traditional target strict denominator-unit/native Rat classifier exactness; BEDC source BHist, RatHistoryClassifier, RatDenomUnitCarrier, and RatDenomUnitClassifier; carrier and classifier choices the displayed predicates; stability obligations nonempty endpoint transport plus native classifier exposure; ledger the adjoined empty-unit branch; core theorem 45.166; exactness predicate the displayed iff; standard bridge deferred; status ProofTarget.

Theorem 45.167 (Rat denominator unit carrier visible cases)**.** *For every history* $h : \mathsf{BHist}$*, an adjoined empty-unit denominator carrier witness exposes exactly the visible empty branch or a one-headed unary denominator tail:*

$$\mathsf{RatDenomUnitCarrier}(h) \to (h\mathsf{hsamee} \vee \exists t : \mathsf{BHist}.\ h = \mathsf{E1}(t) \wedge \mathsf{UnaryHistory}(t)) .$$

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier visible cases`

Proof. Split the concrete history h. The empty constructor gives the empty branch. The zero-headed constructor is incompatible with the denominator-unit carrier by the zero-endpoint exclusion theorem. The one-headed constructor reads the unary tail back through the carrier endpoint equivalence. □

Theorem 45.168 (Rat denominator unit classifier visible cases)**.** *For any classified pair* h, k : BHist *in the adjoined empty-unit denominator classifier, both endpoints are empty together or both are one-headed unary denominator tails with equal exposed tails:*

$$\mathsf{RatDenomUnitClassifier}(h,k) \to (h\mathsf{hsamee} \wedge k\mathsf{hsamee}) \vee \exists d, e : \mathsf{BHist}.\ h = \mathsf{E1}(d) \wedge k = \mathsf{E1}(e) \wedge \mathsf{UnaryHistory}(d) \wedge \mathsf{UnaryH}$$

Proof. Apply the visible-case split for $\mathsf{RatDenomUnitCarrier}$ to both classifier endpoints. The two empty branches give the empty pair. The mixed empty and one-headed branches contradict the classifier's hsame field by history constructor separation. In the one-headed branch, the two carrier witnesses give unary tails and hsame constructor inversion gives the exposed tail equality. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier visible cases`

Theorem 45.169 (Rat denominator unit carrier visible cases iff)**.** *For every history* h : BHist*, the adjoined empty-unit denominator carrier is equivalent to the visible empty branch or a one-headed unary denominator tail:*

$$\mathsf{RatDenomUnitCarrier}(h) \iff (h\mathsf{hsamee} \vee \exists t : \mathsf{BHist}.\ h = \mathsf{E1}(t) \wedge \mathsf{UnaryHistory}(t))\,.$$

Proof. The forward direction is the visible carrier case split above. Conversely, the empty branch is the adjoined unit carrier branch, and the one-headed branch is rebuilt from the one-headed denominator carrier characterization. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier visible cases iff`

Theorem 45.170 (Rat denominator unit continuation exposes a nonempty Rat endpoint)**.** *For histories* h, k, r*, if* h *and* k *lie in* $\mathsf{RatDenomUnitCarrier}$ *and* $\mathsf{Cont}(h, k, r)$ *has a result not* hsame *to* e*, then at least one input endpoint is a genuine Rat denominator endpoint:*

$$\mathsf{RatHistoryCarrier}(h) \vee \mathsf{RatHistoryCarrier}(k).$$

Proof. Split both carrier witnesses into their empty-unit and Rat endpoint branches. If both inputs are empty-unit endpoints, continuation transport along those hsame witnesses identifies the result with e, contradicting the nonempty result condition. In either mixed branch, the Rat side is already the required disjunct. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier continuation nonempty rat endpoint`

Theorem 45.171 (Rat denominator unit continuation result empty iff)**.** *For histories* h, k, r*, if* h *and* k *lie in* $\mathsf{RatDenomUnitCarrier}$ *and* $\mathsf{Cont}(h, k, r)$*, then the continuation result is internally empty exactly when both carried endpoints are internally empty:*

$$r\mathsf{hsamee} \iff h\mathsf{hsamee} \wedge k\mathsf{hsamee}.$$

Proof. Split the two carrier witnesses into their empty and genuine Rat-history branches. The empty–empty branch transports the continuation to the canonical empty-left unit result. In either mixed branch, continuation transport identifies the result with the genuine Rat endpoint, contradicting RatHistoryCarrier_not_empty. In the genuine–genuine branch, Rat continuation closure makes the result a Rat history, again excluding emptiness. Conversely, if both endpoints are internally empty, continuation transport from the canonical empty-empty continuation identifies r with e. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier continuation result empty iff`

Theorem 45.172 (Rat denominator unit classifier continuation result empty iff)**.** *For classified denominator-unit pairs (h, h') and (k, k'), if $\mathsf{Cont}(h, k, r)$ and $\mathsf{Cont}(h', k', r')$, then the two continuation results have the same empty endpoint status:*

$$r\mathsf{hsamee} \iff r'\mathsf{hsamee}.$$

Proof. Project the carrier fields from the two classifier witnesses. Carrier-level continuation empty exactness identifies $r\mathsf{hsamee}$ with simultaneous emptiness of h and k, and identifies $r'\mathsf{hsamee}$ with simultaneous emptiness of h' and k'. The classifier hsame fields transport endpoint emptiness between h and h', and between k and k'. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier continuation result empty iff`

Theorem 45.173 (Rat denominator unit-envelope classifier is append-closed)**.** *For histories $h, h', k, k' :$ BHist, suppose each displayed pair lies in the denominator unit envelope: either both endpoints are* RatHistoryCarrier *and related by* RatHistoryClassifier*, or both endpoints are* hsame *to* e*. Then* $\mathsf{append}(h, k)$ *and* $\mathsf{append}(h', k')$ *lie in the same envelope.*

Proof. Split the two envelope hypotheses. In the carried/carried branch, the right classifier exposes a unary denominator tail and a tail hsame comparison, so Rat denominator classifier append closure applies to the left classifier. In the mixed branches, the empty side reduces by the left or right unit law for append, and classifier transport carries the nonempty classifier across those hsame comparisons. The empty/empty branch follows by eliminating the four empty endpoint equalities and applying reflexivity at e. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator unit envelope classifier append closed`

Theorem 45.174 (Rat denominator unit-envelope classifier empty-right exactness)**.** *For every history $h :$ BHist, the unit-envelope classifier with empty right endpoint is exactly empty endpoint sameness:*

$$\mathsf{FieldRatDenominatorUnitEnvelopeClassifier}(h, \mathsf{e}) \iff h\mathsf{hsamee}.$$

Proof. Split the concrete unit-envelope classifier. In the carried branch, the right endpoint would be both RatHistoryCarrier and e, which contradicts RatHistoryCarrier_not_empty. In the empty branch, the left endpoint comparison is already present. Conversely, $h\mathsf{hsamee}$ selects the empty-empty branch with reflexivity at e. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldRatDenominatorUnitEnvelopeClassifier empty right iff`

Theorem 45.175 (Rat denominator unit-envelope classifier empty-left exactness)**.** *For histories $h, k :$ BHist, if the left endpoint is empty, then the unit-envelope classifier is exactly empty endpoint sameness on the right:*

$$h\mathsf{hsamee} \implies (\mathsf{FieldRatDenominatorUnitEnvelopeClassifier}(h, k) \iff k\mathsf{hsamee}).$$

Proof. Split the concrete unit-envelope classifier. In the carried branch, the left endpoint would be both RatHistoryCarrier and e, contradicting RatHistoryCarrier_not_empty. In the empty branch, the right endpoint comparison is already present. Conversely, $k$hsamee together with the displayed left endpoint comparison selects the empty-empty branch. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldRatDenominatorUnitEnvelopeClassifier empty left endpoint iff`

Theorem 45.176 (Rat denominator unit-envelope classifier is continuation-closed)**.** *For histories* h, h', k, k', r, r' : BHist*, if*

$$\mathsf{FieldRatDenominatorUnitEnvelopeClassifier}(h, h'), \quad \mathsf{FieldRatDenominatorUnitEnvelopeClassifier}(k, k'), \quad \mathsf{Cont}(h, k, r$$

then

$$\mathsf{FieldRatDenominatorUnitEnvelopeClassifier}(r, r').$$

Proof. Split the two classifier witnesses. In the carried-carried branch, Rat denominator continuation classifier closure supplies a carried classifier for the two results. In each mixed branch, continuation congruence against the empty endpoint unit identifies the result with the carried endpoint on that side; Rat carrier transport then supplies carried result witnesses, and continuation congruence supplies the result comparison. In the empty-empty branch, both continuations transport to the empty-left unit continuation at e, so both results are history-same to e and the empty branch applies. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldRatDenominatorUnitEnvelopeClassifier continuation closed`

Theorem 45.177 (Rat denominator continuation adjoined-unit laws)**.** *The concrete carrier* RatDenomUnitCarrier *and classifier* RatDenomUnitClassifier *satisfy the denominator continuation laws needed to use* e *as the endpoint unit:*

1. RatDenomUnitCarrier(e)*.*
2. *If* RatDenomUnitCarrier(h)*,* RatDenomUnitCarrier(k)*, and* Cont(h, k, r)*, then* RatDenomUnitCarrier(r)*.*
3. *If* RatDenomUnitCarrier(h) *and* Cont(e, h, r)*, then* RatDenomUnitClassifier(r, h)*.*
4. *If* RatDenomUnitCarrier(h) *and* Cont(h, e, r)*, then* RatDenomUnitClassifier(r, h)*.*
5. *For all histories* $h, k, \ell, hk, k\ell, left, right$: BHist*, if* RatDenomUnitCarrier(h)*,* RatDenomUnitCarrier(k)*,* RatDenomUnitCarrier(ℓ)*,* Cont(h, k, hk)*,* Cont$(k, \ell, k\ell)$*,* Cont$(hk, \ell, left)$*, and* Cont$(h, k\ell, right)$*, then* RatDenomUnitClassifier$(left, right)$*.*

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation adjoined unit laws`

Proof. The empty endpoint is carried by the left disjunct of Definition 45.154, using reflexivity of hsame at e.

For closure, split both input carrier witnesses into their empty-endpoint and positive-denominator alternatives. In the positive/positive case, the result is carried by `BEDC.Derived.FieldUp.RatContinuation.RatH`

If the left input is hsamee, transport the continuation relation to an empty-left continuation and use `BEDC.FKernel.Cont.cont_left_unit_result`; the result is classified with the right endpoint. If the right endpoint is positive, transport that positive carrier across the resulting hsame comparison by `BEDC.Derived.RatUp.RatHistoryCarrier_hsame_transport`; if it is empty, the result belongs to the empty disjunct. The cases with the right input hsamee are symmetric, using `BEDC.FKernel.Cont.Units.cont_right_unit_result`.

The two displayed unit laws are the corresponding one-sided cases of the same argument. The theorem `BEDC.FKernel.Cont.cont_left_unit_result` gives $r\mathsf{hsame}h$ from $\mathsf{Cont}(\mathsf{e}, h, r)$, and `BEDC.FKernel.Cont.Units.cont_right_unit_result` gives the same comparison from $\mathsf{Cont}(h, \mathsf{e}, r)$. In each case, the carrier part of the classifier is obtained from the assumed carrier for h and the closure argument above for r.

For associativity, first apply closure to the two inner continuations to obtain $\mathsf{RatDenomUnitCarrier}(hk)$ and $\mathsf{RatDenomUnitCarrier}(k\ell)$. Apply closure again to the two outer continuations to obtain carrier witnesses for $left$ and $right$.

Finally use `BEDC.FKernel.Cont.cont_assoc_hsame` on the four displayed continuation witnesses. Its comparison $left\mathsf{hsame}right$, together with the two carrier witnesses just constructed, is exactly $\mathsf{RatDenomUnitClassifier}(left, right)$. □

Theorem 45.178 (Rat denominator unit classifier is closed under continuation)**.** *If two pairs of endpoints are classified by* RatDenomUnitClassifier *and the two displayed continuations match the left endpoints and the right endpoints,*

$$\mathsf{RatDenomUnitClassifier}(h, h') \wedge \mathsf{RatDenomUnitClassifier}(k, k') \wedge \mathsf{Cont}(h, k, r) \wedge \mathsf{Cont}(h', k', r'),$$

then the two continuation results are again classified:

$$\mathsf{RatDenomUnitClassifier}(r, r').$$

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier continuation closed`

Proof. Use the continuation closure part of Definition 45.177 on the two left endpoints to carry r, and on the two right endpoints to carry r'. The classifier comparisons $h\mathsf{hsame}h'$ and $k\mathsf{hsame}k'$ transport the two continuations to a common result comparison by continuation congruence. These two carrier witnesses and the resulting $r\mathsf{hsame}r'$ comparison are exactly $\mathsf{RatDenomUnitClassifier}(r, r')$. □

Traditional target: denominator-side continuation with empty endpoint unit for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: BHist, RatHistoryCarrier, and Cont; **carrier choice**: RatDenomUnitCarrier; **classifier choice**: RatDenomUnitClassifier; **stability obligations**: empty endpoint coverage, continuation closure, one-sided endpoint laws, and classified triple associativity; **ledger**: continuation witnesses together with the resulting hsame comparisons; **core theorem**: Definition 45.177; **exactness predicate**: both endpoints lie in the empty-unit denominator carrier and are related by hsame; **standard bridge**: denominator continuation with the empty history as endpoint unit; **status**: ProofTarget.

Traditional target: internal unit obstruction for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: RatHistoryCarrier plus Cont; **carrier choice**: Rat denominators; **classifier choice**: RatHistoryClassifier; **stability obstruction**: no carried one-sided unit and no continuation-as-field-multiplication certificate; **ledger**: the attempted unit endpoint; **core theorems**: Definition 45.143, Definition 45.144, Definition 45.147, Definition 45.150, Definition 45.152, and Definition 45.153; **exactness predicate**: failure of internal one-sided unit coverage; **standard bridge**: deferred; **status**: ProofTarget.

Theorem 45.179 (Rat denominator unit classifier append commutativity)**.** *If two histories* $h, k :$ BHist *are carried by the adjoined empty-unit denominator carrier, then the two append products classify each other:*

$$\mathsf{RatDenomUnitClassifier}\big(\mathsf{append}(h, k), \mathsf{append}(k, h)\big).$$

Proof. Split the two carrier witnesses into the empty endpoint branch and the rational-denominator branch. The empty–empty and mixed cases use the continuation left and right unit laws to compare each append result with the nonempty endpoint, or with e in the empty–empty case. When both endpoints are rational denominator histories, use the denominator continuation commutative classifier theorem on the two canonical append continuations. In every case, continuation closure supplies the carried evidence for both append results. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier append comm`

Theorem 45.180 (Rat denominator unit classifier append commutation congruence)**.** *If two endpoint pairs are classified by the adjoined empty-unit denominator classifier, then appending the source endpoints and the reversed target endpoints again produces a classified pair:*

$$\mathsf{RatDenomUnitClassifier}(h, h') \Rightarrow \mathsf{RatDenomUnitClassifier}(k, k') \Rightarrow \mathsf{RatDenomUnitClassifier}(\mathsf{append}(h, k), \mathsf{append}(k', h$$

Proof. Continuation closure first classifies $\mathsf{append}(h, k)$ against $\mathsf{append}(h', k')$ using the canonical append continuations. The append-commutativity classifier applied to the two target carriers classifies $\mathsf{append}(h', k')$ against $\mathsf{append}(k', h')$. Composing the two history-same endpoint comparisons and keeping the carried evidence gives the displayed classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier append comm congr`

Theorem 45.181 (Rat denominator unit semantic NameCert)**.** *For carrier, source, pattern, and ledger all equal to* RatDenomUnitCarrier*, and classifier* RatDenomUnitClassifier*, the denominator empty-unit interface satisfies* SemanticNameCert*.*

Proof. The source is inhabited because e belongs to RatDenomUnitCarrier by the empty-unit branch.

Reflexivity, symmetry, transitivity, and carrier transport are the corresponding hsame fields inside RatDenomUnitClassifier.

Pattern soundness and ledger soundness are projections from the source carrier, because source, pattern, and ledger are all the same carrier predicate. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier semanticNameCert`

Theorem 45.182 (Rat denominator unit mixed append Rat closure package)**.** *For histories* $h, h', k, k' : \mathsf{BHist}$*, denominator-unit endpoints may be appended to genuine Rat endpoints on either side without leaving the Rat carrier or Rat classifier:*

1. *If* $\mathsf{RatHistoryCarrier}(h)$ *and* $\mathsf{RatDenomUnitCarrier}(k)$*, then*

$$\mathsf{RatHistoryCarrier}(\mathsf{append}(h, k)).$$

2. *If* $\mathsf{RatDenomUnitCarrier}(h)$ *and* $\mathsf{RatHistoryCarrier}(k)$*, then*

$$\mathsf{RatHistoryCarrier}(\mathsf{append}(h, k)).$$

3. *If* $\mathsf{RatHistoryClassifier}(h, h')$ *and* $\mathsf{RatDenomUnitClassifier}(k, k')$*, then*

$$\mathsf{RatHistoryClassifier}(\mathsf{append}(h, k), \mathsf{append}(h', k')).$$

4. *If* $\mathsf{RatDenomUnitClassifier}(h, h')$ *and* $\mathsf{RatHistoryClassifier}(k, k')$*, then*

$$\mathsf{RatHistoryClassifier}(\mathsf{append}(h, k), \mathsf{append}(h', k')).$$

Proof. For the right denominator-unit carrier row, split the $\mathsf{RatDenomUnitCarrier}(k)$ witness. In the empty branch, the right append unit law identifies $\mathsf{append}(h, k)$ with h, so the original $\mathsf{RatHistoryCarrier}(h)$ transports to the result. In the genuine Rat branch, Rat denominator continuation closure applies directly to the two Rat carriers and the canonical append continuation.

For the left denominator-unit carrier row, split the $\mathsf{RatDenomUnitCarrier}(h)$ witness. In the empty branch, the left append unit law identifies $\mathsf{append}(h, k)$ with k, so the original $\mathsf{RatHistoryCarrier}(k)$ transports to the result. In the genuine Rat branch, the same Rat denominator continuation closure applies to the two Rat carriers and the canonical append continuation.

For the classifier rows, first apply the corresponding carrier rows to the two endpoints. The remaining hsame field is obtained by cont_respects_hsame from the two input classifier comparisons and the canonical append continuations on the left and right endpoints. The two Rat carrier witnesses and this transported hsame comparison assemble the advertised RatHistoryClassifier outputs. □

Theorem 45.183 (Rat denominator unit classifier append left factor classifier)**.** *For histories* $h, h', k, k' : \mathsf{BHist}$*, if*

$$\mathsf{RatDenomUnitClassifier}(\mathsf{append}(h, k), \mathsf{append}(h', k'))$$

and $h\mathsf{hsame}h'$*, then*

$$\mathsf{RatDenomUnitClassifier}(k, k').$$

Proof. The classifier on the appended histories supplies denominator-unit carriers for both appended endpoints and their hsame comparison. Carrier factorization recovers denominator-unit carriers for k and k'. Replacing the right endpoint by the same left prefix using $h\mathsf{hsame}h'$ leaves a shared-prefix append comparison, and finite-kernel left cancellation gives $k\mathsf{hsame}k'$. These three fields assemble the suffix classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier append left factor classifier`

Theorem 45.184 (Rat denominator unit classifier append prefix factor classifiers)**.** *For histories* $h, h', k, k' : \mathsf{BHist}$*, if the appended endpoints are classified and the prefix factors are* hsame*, then both factor pairs are classified:*

$$\mathsf{RatDenomUnitClassifier}(\mathsf{append}(h, k), \mathsf{append}(h', k')) \Longrightarrow h\mathsf{hsame}h' \Longrightarrow \mathsf{RatDenomUnitClassifier}(h, h') \wedge \mathsf{RatDenomUn}$$

Proof. The appended classifier factors the two product carriers into denominator-unit carriers for h, h', k, k'. The supplied prefix sameness, together with the two prefix carrier witnesses, forms the prefix classifier. The suffix classifier is obtained by the append left factor classifier theorem, which cancels the shared prefix after transporting along $h\mathsf{hsame}h'$. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier append prefix factor classifiers`

Theorem 45.185 (Rat denominator unit classifier append factor hsame iff)**.** *For histories* $h, h', k, k' : \mathsf{BHist}$*, if*

$$\mathsf{RatDenomUnitClassifier}(\mathsf{append}(h, k), \mathsf{append}(h', k')),$$

then

$$h\mathsf{hsame}h' \Longleftrightarrow k\mathsf{hsame}k'.$$

Proof. The forward direction applies the append left factor classifier theorem and projects the suffix hsame field from the resulting classifier. The reverse direction applies the corresponding right factor classifier theorem and projects the prefix hsame field. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier append factor hsame iff`

Theorem 45.186 (Rat denominator unit append nonempty Rat endpoint pair)**.** *For histories* $h, k : \mathsf{BHist}$*, if both factors lie in* $C^u_D = \mathsf{RatDenomUnitCarrier}$ *and* $\mathsf{append}(h, k)$ *is not empty, then the appended history is a genuine Rat history and at least one factor is already a genuine Rat history:*

$$C^u_D(h) \Longrightarrow C^u_D(k) \Longrightarrow (\mathsf{append}(h,k)\mathsf{hsamee} \Longrightarrow \bot) \Longrightarrow \mathsf{RatHistoryCarrier}(\mathsf{append}(h,k)) \wedge (\mathsf{RatHistoryCarrier}(h) \vee \mathsf{Rat}$$

Proof. Denominator-unit continuation closure first puts $\mathsf{append}(h, k)$ in C^u_D. Since the appended endpoint is not empty, the empty branch of C^u_D is impossible, so the result carrier is a $\mathsf{RatHistoryCarrier}$ witness. The carrier-level nonempty factor cases then split the two factors: either h is a Rat history and k remains in C^u_D, or h remains in C^u_D and k is a Rat history. Projecting the Rat side gives the endpoint disjunction. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier append nonempty rat endpoint pair`

Theorem 45.187 (Rat denominator unit classifier append nonempty factor carriers)**.** *For histories* $h, h', k, k' : \mathsf{BHist}$*, if the appended endpoints are classified by* R^u_D *and the left appended endpoint is nonempty, then both classified endpoints split into denominator-unit carried factors with a genuine Rat denominator endpoint on at least one side:*

$$R^u_D(\mathsf{append}(h,k), \mathsf{append}(h',k')) \Longrightarrow (\mathsf{append}(h,k)\mathsf{hsamee} \Longrightarrow \bot) \Longrightarrow \begin{array}{l}(\mathsf{RatHistoryCarrier}(h) \wedge C^u_D(k) \vee C^u_D(h) \wedge \mathsf{Ra} \\ \wedge\ (\mathsf{RatHistoryCarrier}(h') \wedge C^u_D(k') \vee C^u_D(h')\end{array}$$

Proof. Apply the carrier-level nonempty factor cases theorem to the left endpoint. The classifier sameness field transports the nonempty condition to the right endpoint: if the right append were empty, transitivity would make the left append empty. Apply the same carrier-level theorem to the right endpoint and pair the two decompositions. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier append nonempty factor carriers`

Theorem 45.188 (Rat denominator unit classifier two-sided context cancellation package)**.** *For histories* $L, R, Q, S : \mathsf{BHist}$*, if* $\mathsf{RatDenomUnitClassifier}(L, R)$*, then*

$$\mathsf{RatDenomUnitClassifier}(\mathsf{append}(Q,L), \mathsf{append}(S,R)) \Longleftrightarrow \mathsf{RatDenomUnitClassifier}(Q,S)$$

and

$$\mathsf{RatDenomUnitClassifier}(\mathsf{append}(L,Q), \mathsf{append}(R,S)) \Longleftrightarrow \mathsf{RatDenomUnitClassifier}(Q,S).$$

Proof. For the suffix-context statement, apply Definition 45.415 to $\mathsf{append}(Q, L)$ and $\mathsf{append}(S, R)$. The assumed classifier on L, R is exactly the classified context required by that checked row, so the result is the first displayed equivalence.

For the prefix-context statement, apply Definition 45.416 to $\mathsf{append}(L, Q)$ and $\mathsf{append}(R, S)$. The same classified context L, R supplies the prefix certificate, and the checked row returns the second displayed equivalence.

Pairing the two equivalences gives the advertised two-sided cancellation package. □

Traditional target: two-sided classified denominator context cancellation; **BEDC source**: BHist plus RatDenomUnitCarrier, RatDenomUnitClassifier, and append; **carrier choice**: C_D^u; **classifier choice**: R_D^u; **stability obligations**: suffix and prefix context cancellation; **ledger**: the classified context pair L, R; **core theorem**: Definition 45.188; **exactness predicate**: the displayed pair of iff statements; **standard bridge**: ordinary cancellation by a classified denominator-unit context; **status**: ProofTarget.

Traditional target: denominator-side continuation with empty endpoint unit for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: BHist, RatHistoryCarrier, and Cont; **carrier choice**: RatDenomUnitCarrier; **classifier choice**: RatDenomUnitClassifier; **stability obligations**: empty endpoint coverage, continuation closure, one-sided endpoint laws, and classified triple associativity; **ledger**: continuation witnesses together with the resulting hsame comparisons; **core theorem**: Definition 45.177; **exactness predicate**: both endpoints lie in the empty-unit denominator carrier and are related by hsame; **standard bridge**: denominator continuation with the empty history as endpoint unit; **status**: ProofTarget.

Traditional target: internal unit obstruction for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: RatHistoryCarrier plus Cont; **carrier choice**: Rat denominators; **classifier choice**: RatHistoryClassifier; **stability obstruction**: no carried one-sided unit and no continuation-as-field-multiplication certificate; **ledger**: the attempted unit endpoint; **core theorems**: Definition 45.143, Definition 45.144, Definition 45.147, Definition 45.150, Definition 45.152, and Definition 45.153; **exactness predicate**: failure of internal one-sided unit coverage; **standard bridge**: deferred; **status**: ProofTarget.

Theorem 45.189 (Rat denominator unit carrier transport-closure package)**.** *For concrete histories h, k, r : BHist, the empty-unit denominator carrier has the following two concrete closure properties:*

1. *if* $\mathsf{RatDenomUnitCarrier}(h)$ *and* $h\mathsf{hsame}k$*, then* $\mathsf{RatDenomUnitCarrier}(k)$*;*
2. *if* $\mathsf{RatDenomUnitCarrier}(h)$*,* $\mathsf{RatDenomUnitCarrier}(k)$*, and* $\mathsf{Cont}(h, k, r)$*, then* $\mathsf{RatDenomUnitCarrier}(r)$*.*

Proof. Unfold Definition 45.154. For the transport clause, split the carrier witness for h. In the Rat branch, `BEDC.Derived.RatUp.RatHistoryCarrier_hsame_transport` carries the Rat endpoint witness across $h\mathsf{hsame}k$. In the empty branch, transport the empty-endpoint comparison across $h\mathsf{hsame}k$; the result belongs to the left disjunct for k.

For continuation closure, split the two input carrier witnesses. In the empty/empty branch, transport the displayed continuation to the empty-left and empty-right unit continuation at e, so the result is hsame to e. This is the left disjunct of the unit carrier.

In the empty/Rat branch, transport the continuation to an empty-left continuation and use the left unit result law to compare r with the Rat endpoint. Rat carrier transport then gives the Rat branch for r.

The Rat/empty branch is symmetric: transport to an empty-right continuation, use the right unit result law, and carry the Rat witness across the resulting hsame comparison.

In the Rat/Rat branch, apply the concrete Rat denominator continuation carrier closure theorem. The result is a Rat endpoint, hence it lies in the right disjunct of $\mathsf{RatDenomUnitCarrier}(r)$. □

Theorem 45.190 (Rat denominator unit carrier zero-headed absurd)**.** *For every tail t : BHist, the empty-unit denominator carrier cannot hold on a zero-headed history:*

$$\mathsf{RatDenomUnitCarrier}(\mathsf{E0}(t)) \Longrightarrow \bot.$$

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier e0 absurd`

Proof. Unfold the empty-unit denominator carrier. Its empty-endpoint branch would make $\mathsf{E0}(t)$ equal to e, contradicting constructor disjointness. Its Rat branch is impossible because the Rat denominator carrier has no zero-headed inhabitant. □

Theorem 45.191 (Rat denominator unit classifier empty endpoint iff)**.** *For every history h : BHist, the empty-unit denominator classifier against the empty endpoint records exactly the displayed empty endpoint comparison, on either side:*

$$\mathsf{RatDenomUnitClassifier}(\mathsf{e}, h) \iff h\mathsf{hsamee}, \qquad \mathsf{RatDenomUnitClassifier}(h, \mathsf{e}) \iff h\mathsf{hsamee}.$$

Proof. Unfold the classifier into its two carrier fields and its endpoint sameness field. In the forward directions, the endpoint field gives the desired comparison, using symmetry for the left endpoint placement. In the reverse directions, the displayed empty comparison supplies the nonempty endpoint carrier by the empty branch, while the empty endpoint itself uses reflexivity. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier empty endpoint iff`

Theorem 45.192 (Rat denominator unit carrier append zero-headed absurd)**.** *For histories $h, k, tail$: BHist, two empty-unit denominator carrier witnesses cannot have a product classified with a zero-headed endpoint:*

$$\mathsf{RatDenomUnitCarrier}(h) \to \mathsf{RatDenomUnitCarrier}(k) \to \mathsf{append}(h, k)\mathsf{hsameE0}(tail) \to \bot.$$

Proof. Closure of $\mathsf{RatDenomUnitCarrier}$ under continuation gives a carrier witness for $\mathsf{append}(h, k)$. Transport this carrier witness along the displayed endpoint sameness to obtain $\mathsf{RatDenomUnitCarrier}(\mathsf{E0}(tail))$, contradicting the zero-headed absurdity theorem above. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier append e0 absurd`

Theorem 45.193 (Rat denominator unit carrier append one-headed result cases)**.** *For histories $h, k, tail$: BHist, if h and k are carried by the empty-unit denominator carrier and their append is one-headed, then either the right factor is empty and the left factor accounts for the one-headed result, or the right factor itself is one-headed with a unary exposed tail:*

$$\begin{aligned}
&\mathsf{RatDenomUnitCarrier}(h) \to \mathsf{RatDenomUnitCarrier}(k) \to \mathsf{append}(h, k)\mathsf{hsameE1}(tail) \\
&\quad \to (k\mathsf{hsamee} \land \mathsf{RatDenomUnitCarrier}(\mathsf{E1}(tail)) \land h\mathsf{hsameE1}(tail)) \\
&\qquad \lor \exists k_0 : \mathsf{BHist}.\ k = \mathsf{E1}(k_0) \land \mathsf{UnaryHistory}(k_0) \land \mathsf{RatDenomUnitCarrier}(tail) \land \mathsf{Cont}(h, k_0, tail).
\end{aligned}$$

Proof. Read the append comparison as a continuation into a one-headed result and apply the continuation one-headed-result inversion. The empty-right branch closes the displayed one-headed carrier by denominator-unit continuation closure. In the headed-right branch, the carrier on $k = \mathsf{E1}(k_0)$ gives a unary witness for k_0; visible carrier cases make k_0 carried, and continuation closure then carries the exposed tail. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier append e1 result cases`

Theorem 45.194 (Rat denominator unit carrier one-headed unary iff)**.** *For every tail t : BHist, the empty-unit denominator carrier sees a one-headed history exactly when the tail is unary:*

$$\mathsf{RatDenomUnitCarrier}(\mathsf{E1}(t)) \iff \mathsf{UnaryHistory}(t).$$

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier e1 tail unary iff`

Proof. Unfold the empty-unit denominator carrier. Its empty-endpoint branch would give $\mathsf{E1}(t)\mathsf{hsamee}$, contradicting constructor disjointness. The remaining branch is $\mathsf{RatHistoryCarrier}(\mathsf{E1}(t))$, which is equivalent to $\mathsf{UnaryHistory}(t)$ by the one-headed Rat carrier characterization. □

Theorem 45.195 (Rat denominator unit classifier one-headed tail iff)**.** *For histories $d, e : \mathsf{BHist}$, the empty-unit denominator classifier on two one-headed histories is exactly the pair of unary tail witnesses together with tail sameness:*

$$\mathsf{RatDenomUnitClassifier}(\mathsf{E1}(d), \mathsf{E1}(e)) \iff \mathsf{UnaryHistory}(d) \wedge \mathsf{UnaryHistory}(e) \wedge d\mathsf{hsamee}.$$

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier e1 tail iff`

Proof. Unfold the classifier into its two empty-unit carrier fields and the endpoint sameness field. Each carrier field is converted by the one-headed carrier characterization above, and the endpoint sameness field is converted by constructor injectivity for $\mathsf{E1}$. □

Theorem 45.196 (Rat denominator unit classifier displayed context one-tail readback)**.** *Let $d, e, p_d, p_e, t_d, t_e, m_d, m_e, out_d, out_e, a, b : \mathsf{BHist}$. If $\mathsf{RatDenomUnitClassifier}(d, e)$, $\mathsf{RatDenomUnitClassifier}(p_d, p_e)$, and $\mathsf{RatDenomUnitClassifier}(t_d, t_e)$ hold, and the displayed continuations $\mathsf{Cont}(p_d, d, m_d)$, $\mathsf{Cont}(m_d, t_d, out_d)$, $\mathsf{Cont}(p_e, e, m_e)$, and $\mathsf{Cont}(m_e, t_e, out_e)$ expose contextual endpoints satisfying $\mathsf{hsame}(out_d, \mathsf{E1}(a))$ and $\mathsf{hsame}(out_e, \mathsf{E1}(b))$, then*

$$\mathsf{UnaryHistory}(a) \wedge \mathsf{UnaryHistory}(b) \wedge \mathsf{hsame}(a, b).$$

Proof. Compose the prefix classifier with the core denominator-unit classifier through the first pair of continuations, then compose the resulting middle classifier with the tail classifier through the second pair. This gives a $\mathsf{RatDenomUnitClassifier}(out_d, out_e)$ witness.

Transport that classifier along the endpoint displays $\mathsf{hsame}(out_d, \mathsf{E1}(a))$ and $\mathsf{hsame}(out_e, \mathsf{E1}(b))$. The result is a classifier between $\mathsf{E1}(a)$ and $\mathsf{E1}(b)$. Apply Definition 45.195 in the forward direction to read back the two unary tail witnesses and their hsame link. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier cont context e1 pair readback`

Theorem 45.197 (Rat denominator unit classifier visible cases iff)**.** *For histories $h, k : \mathsf{BHist}$, the empty-unit denominator classifier is equivalent to either the empty–empty branch or a matched pair of one-headed unary denominator tails:*

$$\begin{aligned}
&\mathsf{RatDenomUnitClassifier}(h, k) \\
&\iff (h\mathsf{hsamee} \wedge k\mathsf{hsamee}) \\
&\quad \vee \exists h_t, k_t : \mathsf{BHist}.\ h = \mathsf{E1}(h_t) \wedge k = \mathsf{E1}(k_t) \wedge \mathsf{UnaryHistory}(h_t) \\
&\qquad \wedge \mathsf{UnaryHistory}(k_t) \wedge h_t\mathsf{hsame}k_t.
\end{aligned}$$

Proof. Unpack the classifier into two carrier witnesses and an endpoint comparison. Each carrier is split by the visible carrier equivalence. Mixed empty and one-headed endpoints contradict constructor disjointness. The one-headed pair branch converts endpoint sameness through $\mathsf{E1}$ injectivity, and the reverse direction rebuilds the two carriers and the classifier comparison from the displayed tail data. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier visible cases iff`

45.5 The certificate

Definition 45.198 (Field source specification)**.** *The source is a certified commutative ring carrier plus constructive apartness from zero, packaged through the derived predicate* $\mathsf{NonZero}_F$*.*

Definition 45.199 (Field pattern specification)**.** *The pattern is commutative-ring expression formation extended by inverse formation only from a pair* (a, p) *with* $p : \mathsf{NonZero}_F(a)$*.*

Definition 45.200 (Field classifier specification)**.** *The classifier is ring sameness* $\sim_F$*. Nonzero evidence is stable under classifier replacement: from* $a \sim_F b$ *and* $p : \mathsf{NonZero}_F(a)$ *the certificate supplies transported evidence* $q : \mathsf{NonZero}_F(b)$*.*

Definition 45.201 (Field stability certificate)**.** *The stability certificate consists of:*

1. *all commutative-ring stability fields*
2. *contradiction of* $\mathsf{NonZero}_F(0)$
3. *stability of* $\mathsf{NonZero}_F$ *under the carrier classifier*
4. *inverse closure for explicit witnesses* $p : \mathsf{NonZero}_F(a)$
5. *left and right multiplicative inverse laws indexed by each witness* $p : \mathsf{NonZero}_F(a)$

Theorem 45.202 (Field inverse congruence from apartness transport)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate supplying multiplication on* BHist*, a unit* 1*, a unary nonzero certificate* $\mathsf{NonZero}_F$*, an inverse operation* $\mathsf{inv}(a, p)$ *indexed by* $p : \mathsf{NonZero}_F(a)$*, multiplicative associativity, left and right unit laws, multiplication congruence under* hsame*, and left and right inverse laws indexed by nonzero witnesses, if* $a\mathsf{hsame}b$*,* $p : \mathsf{NonZero}_F(a)$*, and* $q : \mathsf{NonZero}_F(b)$ *is any available witness, then* $\mathsf{inv}(a, p)\mathsf{hsameinv}(b, q)$*. When* q *is obtained from* p *along* $a\mathsf{hsame}b$*, the certificate transport clause supplies that witness.*

Proof. Transport the left inverse law for $\mathsf{inv}(a, p)$ across $a\mathsf{hsame}b$ to obtain a left inverse witness over b. Combine this transported witness with the right inverse law for $\mathsf{inv}(b, q)$ at b. The group left/right inverse uniqueness argument, applied inside the multiplicative group of nonzero field elements, identifies the transported inverse with the chosen inverse at b. □

Lean4 ✓ `BEDC.Derived.FieldUp.field inverse congruence from apartness`

Theorem 45.203 (Field inverse cancel from apartness-indexed inverses)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate supplying multiplication on* BHist*, a unit* 1*, a unary nonzero certificate* $\mathsf{NonZero}_F$*, an inverse operation* $\mathsf{inv}(a, p)$ *indexed by* $p : \mathsf{NonZero}_F(a)$*, multiplicative associativity, left and right unit laws, multiplication congruence under* hsame*, and left and right inverse laws indexed by nonzero witnesses, if* $p : \mathsf{NonZero}_F(a)$*,* $q : \mathsf{NonZero}_F(b)$*, and* $\mathsf{inv}(a, p)\mathsf{hsameinv}(b, q)$*, then* $a\mathsf{hsame}b$*.*

Proof. Transport the left inverse law for a across the equality of proof-indexed inverses to make a a right inverse of the common inverse $\mathsf{inv}(b, q)$. The right inverse law for b makes b the matching left inverse. Group left/right inverse uniqueness identifies b with a, and symmetry gives $a\mathsf{hsame}b$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field inverse cancel from apartness`

Theorem 45.204 (Field inverse empty endpoint reflection from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate supplying multiplication on* BHist*, a unit* 1*, a unary nonzero certificate* $\mathsf{NonZero}_F$*, and proof-indexed inverses with multiplicative associativity, left and right unit laws, multiplication congruence under* hsame*, and indexed left and right inverse laws, equality of two indexed inverse histories reflects empty-endpoint membership of the original arguments:*

$$\mathsf{inv}(a, p_a)\mathsf{hsameinv}(b, p_b) \Longrightarrow (a\mathsf{hsamee} \Longleftrightarrow b\mathsf{hsamee}).$$

Proof. Apply inverse cancellation from apartness to the displayed equality of indexed inverses, obtaining $a\mathsf{hsame}b$. The forward empty-endpoint direction transports b back through the symmetric comparison with a; the reverse direction transports a forward through the same comparison. □

Lean4 ✓ `BEDC.Derived.FieldUp.field inverse empty endpoint reflection from apartness`

Theorem 45.205 (Field inverse classifier exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate supplying multiplication on* BHist*, a unit* 1*, a unary nonzero certificate* $\mathsf{NonZero}_F$*, an inverse operation* $\mathsf{inv}(a, p)$ *indexed by* $p : \mathsf{NonZero}_F(a)$*, multiplicative associativity, left and right unit laws, multiplication congruence under* hsame*, and left and right inverse laws indexed by nonzero witnesses, any elements* $a, b : \mathsf{BHist}$ *with explicit witnesses* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$ *satisfy*

$$a\mathsf{hsame}b \Longleftrightarrow \mathsf{inv}(a, p_a)\mathsf{hsameinv}(b, p_b).$$

Proof. For the forward direction, apply Definition 45.202 to $a\mathsf{hsame}b$, using the displayed witnesses p_a and p_b as the two proof indices. This gives the classifier equality of the two indexed inverses.

For the reverse direction, apply Definition 45.203 to the supplied equality between indexed inverses. Its cancellation conclusion is exactly $a\mathsf{hsame}b$, so the two implications combine into the stated classifier exactness. □

Lean4 ✓ `BEDC.Derived.FieldUp.field inverse empty unit classifier exact from apartness iff`

Theorem 45.206 (Field apart-zero inverse classifier exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate supplying multiplication on* BHist*, a unit* 1*, and proof-indexed inverses over the concrete apart-zero predicate* $(x\mathsf{hsamee}) \to \bot$*, multiplicative associativity, left and right unit laws, multiplication congruence under* hsame*, and left and right inverse laws indexed by apart-zero witnesses imply that any* $a, b : \mathsf{BHist}$ *with witnesses* $p_a : (a\mathsf{hsamee}) \to \bot$ *and* $p_b : (b\mathsf{hsamee}) \to \bot$ *satisfy*

$$a\mathsf{hsame}b \Longleftrightarrow \mathsf{inv}(a, p_a)\mathsf{hsameinv}(b, p_b).$$

Proof. For the forward direction, use inverse congruence from apartness with $\mathsf{NonZero}_F(x)$ instantiated by the concrete predicate $(x\mathsf{hsamee}) \to \bot$. For the reverse direction, use inverse cancellation from apartness under the same instantiation. The two implications give the displayed exact classifier equivalence for apart-zero indexed inverses. □

Lean4 ✓ `BEDC.Derived.FieldUp.field apart zero inverse classifier exact from apartness`

Theorem 45.207 (Field inverse is nonzero under one-apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with multiplication* mul*, zero* 0*, unit* 1*, proof-indexed inverse* $\mathsf{inv}(a, p)$*, multiplication congruence under* hsame*, zero-left multiplication* $\mathsf{mul}(0, x)\mathsf{hsame}0$*, left inverse law* $\mathsf{mul}(\mathsf{inv}(a, p), a)\mathsf{hsame}1$*, one-apartness* $\omega : (1\mathsf{hsame}0) \to \bot$*, and conversion maps* $\alpha_x : ((x\mathsf{hsame}0) \to \bot) \to \mathsf{NonZero}_F(x)$*, every witness* $p_a : \mathsf{NonZero}_F(a)$ *canonically determines*

$$\mathsf{NonZero}_F(\mathsf{inv}(a, p_a)).$$

Proof. Fix $p_a : \mathsf{NonZero}_F(a)$. It is enough to build a contradiction from a hypothetical equality $\mathsf{inv}(a, p_a)\mathsf{hsame}0$, because $\alpha_{\mathsf{inv}(a,p_a)}$ converts that negated zero equality into the required $\mathsf{NonZero}_F$ witness.

Assume $h : \mathsf{inv}(a, p_a)\mathsf{hsame}0$. Multiplication congruence transports h after right multiplication by a, giving $\mathsf{mul}(\mathsf{inv}(a, p_a), a)\mathsf{hsamemul}(0, a)$. The zero-left law gives $\mathsf{mul}(0, a)\mathsf{hsame}0$, so transitivity yields $\mathsf{mul}(\mathsf{inv}(a, p_a), a)\mathsf{hsame}0$.

The left inverse law gives $\mathsf{mul}(\mathsf{inv}(a, p_a), a)\mathsf{hsame}1$. Composing this equality with the equality just obtained gives $1\mathsf{hsame}0$, contradicting ω. Thus the assumed zero equality has a constructive refutation, and applying $\alpha_{\mathsf{inv}(a,p_a)}$ produces $\mathsf{NonZero}_F(\mathsf{inv}(a, p_a))$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field inverse nonzero from one apartness`

Theorem 45.208 (Field inverse is apart from empty under one-apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with multiplication* mul*, unit* 1*, proof-indexed inverse* $\mathsf{inv}(a, p)$*, multiplication congruence under* hsame*, zero-left multiplication* $\mathsf{mul}(0, x)\mathsf{hsame}0$*, left inverse law* $\mathsf{mul}(\mathsf{inv}(a, p), a)\mathsf{hsame}1$*, and one-apartness* $\omega : (1\mathsf{hsame}0) \to \bot$*, every witness* $p_a : \mathsf{NonZero}_F(a)$ *constructively refutes*

$$\mathsf{inv}(a, p_a)\mathsf{hsame}0.$$

Proof. Assume $\mathsf{inv}(a, p_a)\mathsf{hsame}0$. Multiplication congruence transports this equality through right multiplication by a, and the zero-left law identifies the transported product with 0. The left inverse law identifies the same product with 1, so transitivity gives $1\mathsf{hsame}0$, contradicting ω. □

Lean4 ✓ `BEDC.Derived.FieldUp.field inverse apart empty from one apartness`

Theorem 45.209 (Field inverse of an indexed nonzero inverse)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with multiplication on* BHist*, unit* 1*, proof-indexed inverse* $\mathsf{inv}(a, p)$*, associativity, left and right identity, multiplication congruence, and left inverse laws indexed by nonzero witnesses, if* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_{\mathsf{inv}} : \mathsf{NonZero}_F(\mathsf{inv}(a, p_a))$*, then*

$$\mathsf{inv}(\mathsf{inv}(a, p_a), p_{\mathsf{inv}})\mathsf{hsame}a.$$

Moreover, if this double inverse collapsed to e*, then* a *would collapse to* e*, contradicting the supplied nonzero-empty separation for* p_a*.*

Proof. Set the middle element in the inverse-uniqueness argument to $\mathsf{inv}(a, p_a)$. The left inverse law for p_{inv} gives

$$\mathsf{inv}(\mathsf{inv}(a, p_a), p_{\mathsf{inv}})\mathsf{inv}(a, p_a)\mathsf{hsame}1.$$

The left inverse law for p_a gives

$$\mathsf{inv}(a, p_a)a\mathsf{hsame}1.$$

Associativity, multiplication congruence, and the identity laws give the standard left/right inverse uniqueness chain $x\mathsf{hsame}x\ 1\mathsf{hsame}x(yz)\mathsf{hsame}(xy)z\mathsf{hsame}1\ z\mathsf{hsame}z$, with $x = \mathsf{inv}(\mathsf{inv}(a, p_a), p_{\mathsf{inv}})$, $y = \mathsf{inv}(a, p_a)$, and $z = a$. Hence the two outer witnesses are identified, which is the stated equality. A candidate collapse of the double inverse to e transports along the symmetric equality to a collapse $a\mathsf{hsame}\mathsf{e}$, and this contradicts the nonzero-empty separation for p_a. □

Lean4 ✓ `BEDC.Derived.FieldUp.field inverse involutive nonzero from apartness`

Theorem 45.210 (Field inverse is a certified automorphism of the nonzero domain)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with proof-indexed inverse* $\mathsf{inv}(x, p)$*, inverse laws indexed by nonzero witnesses, multiplication congruence under* hsame*, zero-left multiplication, one-apartness* $\omega : (1\mathsf{hsame}0) \to \bot$*, and conversion maps*

$$\alpha_x : ((x\mathsf{hsame}0) \to \bot) \to \mathsf{NonZero}_F(x),$$

every witness $p_a : \mathsf{NonZero}_F(a)$ *determines*

$$A := \mathsf{inv}(a, p_a)$$

and a witness $p_A : \mathsf{NonZero}_F(A)$ *such that*

$$\mathsf{inv}(A, p_A)\mathsf{hsame}a.$$

Moreover, for any $p_b : \mathsf{NonZero}_F(b)$*,*

$$\mathsf{inv}(a, p_a)\mathsf{hsame}\mathsf{inv}(b, p_b) \iff a\mathsf{hsame}b.$$

Proof. First construct the nonzero witness for the image. Apply Definition 45.207 to p_a, using the given multiplication congruence, zero-left multiplication, left inverse law, one-apartness, and the conversion maps α_x. This gives $p_A : \mathsf{NonZero}_F(A)$ for $A := \mathsf{inv}(a, p_a)$.

With this witness in hand, apply Definition 45.209 to p_a and p_A. The conclusion is exactly $\mathsf{inv}(A, p_A)\mathsf{hsame}a$, so inverse carries the nonzero domain back to the original element.

For the classifier equivalence, apply Definition 45.205 to the two explicit nonzero witnesses p_a and p_b. Its two implications give $a\mathsf{hsame}b$ exactly when the indexed inverse images are hsame-equal, which is the stated certified automorphism behavior on the nonzero domain. □

Lean4 ✓ `BEDC.Derived.FieldUp.field inverse nonzero domain automorphism`

Theorem 45.211 (Field apart-zero inverse involution)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate whose inverse is indexed by explicit apartness from zero, suppose multiplication is associative, has left and right unit laws, respects* hsame*, and has a left inverse law for every apart-zero witness. If the inverse operation sends apart-zero inputs to apart-zero outputs, then for every* $a : \mathsf{BHist}$ *and* $p_a : a\mathsf{hsame}0 \to \bot$*,*

$$\mathsf{inv}(\mathsf{inv}(a, p_a), p_{\mathsf{inv}})\mathsf{hsame}a,$$

where p_{inv} *is the supplied apart-zero witness for* $\mathsf{inv}(a, p_a)$*.*

Proof. Apply group left/right inverse uniqueness with middle element $\mathsf{inv}(a, p_a)$. The indexed left inverse law at the outer inverse gives the left inverse equality against the middle element, and the indexed left inverse law at a gives the right inverse equality for the same middle element. The uniqueness chain identifies the two outer endpoints. □

Lean4 ✓ `BEDC.Derived.FieldUp.field apartzero inverse involutive`

Theorem 45.212 (Field apart-zero inverse classifier automorphism)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with apart-zero indexed inverse* $\mathsf{inv}(a, p)$*, suppose multiplication is associative, has left and right unit laws, respects* hsame*, and has left and right inverse laws for every apart-zero witness. If an inverse-apartness row sends every apart-zero input to an apart-zero inverse, then every* $a, b : \mathsf{BHist}$ *and witnesses* $p_a : (a\mathsf{hsamee}) \to \bot$ *and* $p_b : (b\mathsf{hsamee}) \to \bot$ *satisfy*

$$a\mathsf{hsame}b \iff \mathsf{inv}(a, p_a)\mathsf{hsame}\mathsf{inv}(b, p_b),$$

and, for p_{inv} supplied by inverse-apartness,

$$\mathsf{inv}(\mathsf{inv}(a, p_a), p_{\mathsf{inv}})\mathsf{hsame}a.$$

Per object, the traditional target is inverse as an involutive automorphism of nonzero field elements; the BEDC source is $\mathsf{Field}^{\uparrow}$ *over* BHist*; the carrier is apart-zero histories; the classifier is* hsame*; the stability rows are exactness, inverse-apartness, and involution; the ledger records the proof indices; the downstream consumer is the* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *inverse and affine exit ledgers; the status is* $\mathsf{ProofTarget}$.

Proof. For classifier preservation and reflection, apply Definition 45.206 to the two displayed apart-zero witnesses. Its two directions give exactly the equivalence between $a\mathsf{hsame}b$ and equality of the indexed inverse images.

For the involution row, use the inverse-apartness hypothesis to obtain p_{inv} for $\mathsf{inv}(a, p_a)$, then apply Definition 45.211. The conclusion is the second displayed equality, so the package contains both classifier exactness and double-inverse closure on the concrete apart-zero domain. □

Theorem 45.213 (Field inverse product reversal from apartness-indexed inverses)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, explicit witnesses* $p_{ab} : \mathsf{NonZero}_F(ab)$*,* $p_a : \mathsf{NonZero}_F(a)$*, and* $p_b : \mathsf{NonZero}_F(b)$ *determine the product inverse by*

$$\mathsf{inv}(ab, p_{ab})\mathsf{hsame}\mathsf{inv}(b, p_b)\mathsf{inv}(a, p_a).$$

Proof. The reversed product $\mathsf{inv}(b, p_b)\mathsf{inv}(a, p_a)$ is a right inverse of ab: reassociate to expose $b\mathsf{inv}(b, p_b)$, collapse it to the unit, and finish with the right inverse law for a. The indexed left inverse of ab and group uniqueness of left and right inverse witnesses identify the chosen inverse of ab with this reversed product. □

Lean4 ✓ `BEDC.Derived.FieldUp.field inverse product reverse from apartness`

Theorem 45.214 (Field inverse product reversal right inverse excludes empty)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, assume associativity, left identity, multiplication congruence, indexed right inverse laws, and one-apartness from empty. For* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$*,*

$$\mathsf{mul}(\mathsf{mul}(a, b), \mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a)))\mathsf{hsame}0 \to \bot.$$

Proof. Reassociate the product to expose $b\mathsf{inv}(b, p_b)$ inside the middle factor. The right inverse law for b reduces that middle product to $\mathsf{inv}(a, p_a)$ by the left identity, and multiplication congruence then reduces the whole expression to $a\mathsf{inv}(a, p_a)$. The right inverse law for a identifies the product with one, so any classifier equality from the product to empty would transport one to empty, contradicting one-apartness. □

Lean4 ✓ `BEDC.Derived.FieldUp.field inverse product reverse right inverse apart empty from one apartness`

Theorem 45.215 (Field inverse product reversal preserves nonzero from one apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, assume one is apart from empty, left zero absorption holds for multiplication, apart-empty evidence produces* $\mathsf{NonZero}_F$*, and* $\mathsf{NonZero}_F$ *transports along* hsame*. If* $p_{ab} : \mathsf{NonZero}_F(\mathsf{mul}(a, b))$*,* $p_a : \mathsf{NonZero}_F(a)$*, and* $p_b : \mathsf{NonZero}_F(b)$*, then*

$$\mathsf{NonZero}_F(\mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a))).$$

Proof. The inverse of $\mathsf{mul}(a, b)$ is nonzero: if it classified as empty, left multiplication by ab would classify its inverse product as empty, contradicting the indexed inverse law and the apartness of one from empty. Definition 45.213 identifies this inverse with the reversed product $\mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a))$. Transporting the nonzero witness across that classifier equality gives the displayed witness. □

Lean4 ✓ `BEDC.Derived.FieldUp.field inverse product reverse nonzero from one apartness`

Theorem 45.216 (Field inverse product reversal is apart from empty)**.** *Under the hypotheses of Definition 45.215, if the field certificate also converts every* $\mathsf{NonZero}_F(x)$ *witness into a refutation of* $x\mathsf{hsame}0$*, then the reversed inverse product satisfies*

$$\mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a))\mathsf{hsame}0 \to \bot.$$

Proof. Apply Definition 45.215 to obtain $\mathsf{NonZero}_F(\mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a)))$. The nonzero-to-empty-apartness bridge then rejects any classifier equality from that product to empty. □

Lean4 ✓ `BEDC.Derived.FieldUp.field inverse product reverse apart empty from one apartness`

Theorem 45.217 (Field inverse product reversal apartness transports across products)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, suppose*

$$\mathsf{mul}(a, b)\mathsf{hsamemul}(a', b').$$

Given nonzero witnesses for both products and for all four factors, apartness from empty of $\mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a))$ *transports to apartness from empty of* $\mathsf{mul}(\mathsf{inv}(b', p_{b'}), \mathsf{inv}(a', p_{a'}))$*.*

Proof. Definition 45.213 identifies each reversed inverse product with the inverse of its corresponding product. The product classifier equality transports between those two product inverses by inverse congruence. Symmetry and transitivity of hsame therefore identify the two reversed inverse products, so any classifier of the target reversed product as empty would classify the source reversed product as empty and contradict the supplied source apartness. □

Lean4 ✓ `BEDC.Derived.FieldUp.field inverse product reverse apart empty transport from product hsame`

Theorem 45.218 (Field inverse product classifier exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *satisfying the hypotheses of Definition 45.305, Definition 45.205, and Definition 45.213, assume a bridge*

$$\alpha : (h\mathsf{hsame}0 \to \bot) \to \mathsf{NonZero}_F(h)$$

and witnesses $p_a : \mathsf{NonZero}_F(a)$*,* $p_b : \mathsf{NonZero}_F(b)$*,* $p_c : \mathsf{NonZero}_F(c)$*, and* $p_d : \mathsf{NonZero}_F(d)$*. Let* p_{ab} *and* p_{cd} *be the product nonzero witnesses for* $\mathsf{mul}(a, b)$ *and* $\mathsf{mul}(c, d)$ *supplied by Definition 45.305. Then*

$$\mathsf{mul}(a, b)\mathsf{hsamemul}(c, d) \iff \mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a))\mathsf{hsamemul}(\mathsf{inv}(d, p_d), \mathsf{inv}(c, p_c)).$$

Proof. First build the product witnesses. Apply Definition 45.305 to p_a and p_b, using the bridge α, to obtain $p_{ab} : \mathsf{NonZero}_F(\mathsf{mul}(a, b))$. Apply the same theorem to p_c and p_d to obtain $p_{cd} : \mathsf{NonZero}_F(\mathsf{mul}(c, d))$.

For the forward direction, apply Definition 45.205 to the two product endpoints with witnesses p_{ab} and p_{cd}. The resulting inverse equality has endpoints $\mathsf{inv}(\mathsf{mul}(a, b), p_{ab})$ and $\mathsf{inv}(\mathsf{mul}(c, d), p_{cd})$.

Apply Definition 45.213 on both sides, and transport across these two reversal equalities by symmetry and transitivity of hsame.

For the reverse direction, start with the displayed reversed-product equality. Use the same two product reversal equalities, now in the opposite transport orientation, to obtain $\mathsf{inv}(\mathsf{mul}(a,b),p_{ab})\mathsf{hsameinv}(\mathsf{mul}(c,d)$ The reverse implication of Definition 45.205 then gives $\mathsf{mul}(a,b)\mathsf{hsamemul}(c,d)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field inverse product classifier exact from apartness`

Theorem 45.219 (Field apart-product inverse classifier exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *satisfying multiplication associativity, left and right unit laws, multiplication congruence under* hsame*, and proof-indexed left and right inverse laws, assume a bridge*

$$\alpha : (h\mathsf{hsame}0 \to \bot) \to \mathsf{NonZero}_F(h).$$

If $\mathsf{mul}(a,b)$ *and* $\mathsf{mul}(c,d)$ *are explicitly apart from* e *and* p_a, p_b, p_c, p_d *are nonzero witnesses for the four factors, then*

$$\mathsf{mul}(a,b)\mathsf{hsamemul}(c,d) \iff \mathsf{mul}(\mathsf{inv}(b,p_b),\mathsf{inv}(a,p_a))\mathsf{hsamemul}(\mathsf{inv}(d,p_d),\mathsf{inv}(c,p_c)).$$

Proof. Apply α to the two explicit product-apartness hypotheses to obtain the indexed nonzero witnesses for $\mathsf{mul}(a,b)$ and $\mathsf{mul}(c,d)$. The inverse classifier exactness theorem converts product equality into equality of the two certified product inverses, and product inverse reversal identifies those certified inverses with the two displayed reversed inverse products. The reverse implication uses the same two reversal equalities in the opposite transport orientation before applying inverse cancellation. □

Lean4 ✓ `BEDC.Derived.FieldUp.field apart product inverse classifier exact from apartness`

Per-object certificate: Traditional target: product inverse classifier exactness. BEDC source: $\mathsf{Field}^{\uparrow}$ over BHist plus product nonzero. Carrier choice: BHist. Classifier choice: hsame. Stability obligations: inverse exactness, product nonzero construction, product reversal, and hsame transport. Ledger: four factor witnesses p_a, p_b, p_c, p_d and two product witnesses p_{ab}, p_{cd}. Core theorem list: Theorem 45.218. Exactness predicate: the displayed iff. Standard bridge: deferred. Status: ProofTarget.

Theorem 45.220 (Field inverse three-factor product reversal from apartness-indexed inverses)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with multiplication associativity, multiplication congruence, left and right identity, proof-indexed inverse laws, product nonzero exclusion, and conversion maps*

$$\alpha_{ab} : \mathsf{ApartZero}_F(\mathsf{mul}(a,b)) \to \mathsf{NonZero}_F(\mathsf{mul}(a,b)), \quad \alpha_a : \mathsf{ApartZero}_F(a) \to \mathsf{NonZero}_F(a),$$

$$\alpha_b : \mathsf{ApartZero}_F(b) \to \mathsf{NonZero}_F(b), \quad \alpha_c : \mathsf{ApartZero}_F(c) \to \mathsf{NonZero}_F(c),$$

where $\mathsf{ApartZero}_F(h) := (h\mathsf{hsame}0 \to \bot)$*, any witness*

$$p_{abc} : \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(a,b),c))$$

induces witnesses p_{ab}*,* p_a*,* p_b*, and* p_c *such that*

$$\mathsf{inv}(\mathsf{mul}(\mathsf{mul}(a,b),c),p_{abc})\mathsf{hsamemul}(\mathsf{inv}(c,p_c),\mathsf{mul}(\mathsf{inv}(b,p_b),\mathsf{inv}(a,p_a))).$$

Proof. Apply Definition 45.303 to p_{abc} for the binary product $(\mathsf{mul}(a,b),c)$. This gives $q_{ab} : \mathsf{ApartZero}_F(\mathsf{mul}(a,b))$ and $q_c : \mathsf{ApartZero}_F(c)$; set $p_{ab} := \alpha_{ab}(q_{ab})$ and $p_c := \alpha_c(q_c)$.

Apply the same theorem to p_{ab} for the binary product (a,b). The two resulting apartness witnesses $q_a : \mathsf{ApartZero}_F(a)$ and $q_b : \mathsf{ApartZero}_F(b)$ determine $p_a := \alpha_a(q_a)$ and $p_b := \alpha_b(q_b)$.

Now apply Definition 45.213 to $(\mathsf{mul}(a,b),c)$ with witnesses p_{abc}, p_{ab}, and p_c. Apply it again to (a,b) with witnesses p_{ab}, p_a, and p_b. Multiplication congruence transports the second equality into the right factor of the first one, and associativity plus transitivity of hsame gives the displayed three-factor reversed product. □

Per-object certificate: Traditional target: inverse of a finite triple product. BEDC source: $\mathsf{Field}^{\uparrow}$ plus zero-product exclusion. Carrier choice: BHist. Classifier choice: hsame. Stability obligations: product nonzero exclusion, inverse product reversal, associativity, and multiplication congruence. Ledger: p_{abc} plus induced factor witnesses. Core theorem list: Theorem 45.220. Exactness predicate: reversed inverse equality. Standard bridge: deferred. Status: $\mathsf{ProofTarget}$.

Theorem 45.221 (Field inverse four-factor product reversal from apartness-indexed inverses)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with multiplication associativity, multiplication congruence, left and right identity laws, proof-indexed inverse laws, product nonzero exclusion, and conversion maps*

$$\alpha_a : \mathsf{ApartZero}_F(a) \to \mathsf{NonZero}_F(a), \quad \alpha_b : \mathsf{ApartZero}_F(b) \to \mathsf{NonZero}_F(b),$$

$$\alpha_c : \mathsf{ApartZero}_F(c) \to \mathsf{NonZero}_F(c), \quad \alpha_d : \mathsf{ApartZero}_F(d) \to \mathsf{NonZero}_F(d),$$

$$\alpha_{ab} : \mathsf{ApartZero}_F(\mathsf{mul}(a,b)) \to \mathsf{NonZero}_F(\mathsf{mul}(a,b)),$$

$$\alpha_{abc} : \mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(a,b),c)) \to \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(a,b),c)),$$

$$\alpha_{abcd} : \mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a,b),c),d)) \to \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a,b),c),d)),$$

where $\mathsf{ApartZero}_F(h) := (h\mathsf{hsame}0 \to \bot)$*, any witness*

$$p_{abcd} : \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a,b),c),d))$$

induces witnesses p_a*,* p_b*,* p_c*, and* p_d *such that*

$$\mathsf{inv}(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a,b),c),d),p_{abcd})\mathsf{hsamemul}(\mathsf{inv}(d,p_d),\mathsf{mul}(\mathsf{inv}(c,p_c),\mathsf{mul}(\mathsf{inv}(b,p_b),\mathsf{inv}(a,p_a)))).$$

Proof. Apply Definition 45.303 to p_{abcd} for the binary product $(\mathsf{mul}(\mathsf{mul}(a,b),c),d)$. This gives $q_{abc} : \mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(a,b),c))$ and $q_d : \mathsf{ApartZero}_F(d)$; set $p_{abc} := \alpha_{abc}(q_{abc})$ and $p_d := \alpha_d(q_d)$.

Now apply Definition 45.213 to the same outer binary product with witnesses p_{abcd}, p_{abc}, and p_d. It identifies the inverse of the fourfold product with $\mathsf{mul}(\mathsf{inv}(d,p_d),\mathsf{inv}(\mathsf{mul}(\mathsf{mul}(a,b),c),p_{abc}))$.

Apply Definition 45.220 to the left triple, using p_{abc} and the conversion maps α_{ab}, α_a, α_b, and α_c. This produces the factor witnesses p_a, p_b, and p_c and the reversed triple inverse.

Multiplication congruence transports the triple equality into the right factor of the outer equality. Associativity and transitivity of hsame then rebracket the product into the displayed d,c,b,a reversed inverse spine. Equivalently, the factor apartness witnesses may be read from Definition 45.318 before the same conversion and inverse-reversal steps are applied. □

Per-object certificate: Traditional target: inverse of a finite fourfold product. BEDC source: $\mathsf{Field}^{\uparrow}$ plus four-factor zero-apartness exactness. Carrier choice: BHist. Classifier choice: hsame. Stability obligations: four-factor apartness extraction, product nonzero exclusion, inverse product reversal, three-factor inverse reversal, associativity, and multiplication congruence. Ledger: p_{abcd} plus induced factor witnesses. Core theorem list: Theorem 45.221. Exactness predicate: reversed inverse equality. Standard bridge: deferred. Status: $\mathsf{ProofTarget}$.

Theorem 45.222 (Field multiplication by an indexed right inverse cancels)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, any witness* $p_b : \mathsf{NonZero}_F(b)$ *determines*

$$(ab)\mathsf{inv}(b, p_b)\mathsf{hsame}a.$$

Proof. Reassociate $(ab)\mathsf{inv}(b, p_b)$ to $a(b\mathsf{inv}(b, p_b))$. The apartness-indexed right inverse law collapses the tail to the unit, and the right identity law leaves a. □

Lean4 ✓ `BEDC.Derived.FieldUp.field left mul empty context equation solution unique from apartness`

Theorem 45.232 (Field middle multiplication equation solution from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, explicit witnesses* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$ *make*

$$(ax)b\mathsf{hsame}c$$

imply

$$x\mathsf{hsameinv}(a, p_a)(c\mathsf{inv}(b, p_b)).$$

Proof. First solve the right factor equation using the indexed right inverse of b, obtaining $ax\mathsf{hsame}c\mathsf{inv}(b, p_b)$. Then cancel the left factor with the indexed left inverse of a, transporting the right-factor solution through left multiplication by $\mathsf{inv}(a, p_a)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field middle mul equation solution from apartness`

Theorem 45.233 (Field middle multiplication equation exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, explicit witnesses* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$ *make the middle equation and its displayed solution equivalent:*

$$(ax)b\mathsf{hsame}c \iff x\mathsf{hsameinv}(a, p_a)(c\mathsf{inv}(b, p_b)).$$

Proof. For the forward direction, apply Theorem 45.232. It is exactly the one-way solver from the middle equation to the proof-indexed displayed solution.

For the reverse direction, transport the assumed solution through the congruence of left multiplication by a and right multiplication by b. The resulting term is $(a(\mathsf{inv}(a, p_a)(c\mathsf{inv}(b, p_b))))b$.

Reassociate the factors so that $a\mathsf{inv}(a, p_a)$ is exposed at the left and $\mathsf{inv}(b, p_b)b$ is exposed at the right. The indexed right inverse law collapses $a\mathsf{inv}(a, p_a)$ to the unit, and the indexed left inverse law collapses $\mathsf{inv}(b, p_b)b$ to the unit. The left and right identity laws then leave c. □

Lean4 ✓ `BEDC.Derived.FieldUp.field middle mul equation exact from apartness`
↪ variant `BEDC.Derived.FieldUp.field middle mul equation solution from apartness iff`

Theorem 45.234 (Field conjugation equation exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, if* $p_a : \mathsf{NonZero}_F(a)$ *and the unit is apart from* e*, then conjugating by* a *gives the exact equation*

$$(ax)\mathsf{inv}(a, p_a)\mathsf{hsame}b \iff x\mathsf{hsameinv}(a, p_a)(ba).$$

Proof. First derive that $\mathsf{inv}(a, p_a)$ is nonzero from apartness of the unit and the left inverse law. Apply middle multiplication exactness with right factor $\mathsf{inv}(a, p_a)$. The displayed right side contains the double inverse of a; inverse uniqueness identifies this double inverse with a, and multiplication congruence transports the solution term. □

Lean4 ✓ `BEDC.Derived.FieldUp.field conjugation equation exact from apartness`

Theorem 45.235 (Field apart-empty conjugation equation exactness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate whose proof-indexed inverse is indexed by apartness from* e*, any witness* $p_a : \mathsf{hsame}(a, \mathsf{e}) \to \mathsf{False}$ *makes conjugation by* a *classify the middle factor exactly:*

$$\mathsf{hsame}((ax)\mathsf{inv}(a, p_a), b) \iff \mathsf{hsame}(x, (\mathsf{inv}(a, p_a)b)a).$$

Proof. For the forward direction, multiply the conjugation equation on the right by a. Associativity exposes $\mathsf{inv}(a, p_a)a$, the left inverse law collapses it to the unit, and the right identity law leaves $ax\mathsf{hsame}ba$. Then apply left-multiplication exactness and reassociate the target to $(\mathsf{inv}(a, p_a)b)a$.

For the reverse direction, transport the assumed middle-factor equation by left multiplication with a. Reassociation exposes $a\mathsf{inv}(a, p_a)$, the right inverse law collapses it to the unit, and the left identity law gives $ax\mathsf{hsame}ba$. Multiplying on the right by $\mathsf{inv}(a, p_a)$ and collapsing $a\mathsf{inv}(a, p_a)$ gives the original conjugation equation. □

Lean4 ✓ `BEDC.Derived.FieldUp.field apart empty conjugation equation exact`

Theorem 45.236 (Field apart-empty inverse conjugation equation exactness)**.** *For the same* $\mathsf{Field}^{\uparrow}$ *data and apart-empty witness* $p_a : \mathsf{hsame}(a, \mathsf{e}) \to \mathsf{False}$*, inverse conjugation by* $\mathsf{inv}(a, p_a)$ *also classifies the middle factor exactly:*

$$\mathsf{hsame}((\mathsf{inv}(a, p_a)x)a, b) \iff \mathsf{hsame}(x, (ab)\mathsf{inv}(a, p_a)).$$

Proof. For the forward direction, multiply the inverse-conjugation equation on the right by $\mathsf{inv}(a, p_a)$. Reassociation exposes $a\mathsf{inv}(a, p_a)$, the right inverse law collapses it to the unit, and the right identity law leaves $\mathsf{inv}(a, p_a)x\mathsf{hsame}b\mathsf{inv}(a, p_a)$. Transporting by left multiplication with a collapses $a\mathsf{inv}(a, p_a)$ and reassociates the right side to $(ab)\mathsf{inv}(a, p_a)$.

For the reverse direction, transport the displayed middle equation by left multiplication with $\mathsf{inv}(a, p_a)$. Reassociation exposes $\mathsf{inv}(a, p_a)a$, the left inverse law collapses it to the unit, and left identity gives $\mathsf{inv}(a, p_a)x\mathsf{hsame}b\mathsf{inv}(a, p_a)$. Multiplying on the right by a and collapsing $\mathsf{inv}(a, p_a)a$ gives the inverse-conjugation equation. □

Lean4 ✓ `BEDC.Derived.FieldUp.field apart empty inverse conjugation equation exact`

Theorem 45.237 (Field middle multiplication empty equation solutions are unique from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, if* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$ *and both* x *and* y *solve the empty endpoint middle multiplication equation*

$$(ax)b\mathsf{hsame}\mathsf{e} \qquad \textit{and} \qquad (ay)b\mathsf{hsame}\mathsf{e},$$

then $x\mathsf{hsame}y$*.*

Proof. Apply the middle multiplication solution theorem to both displayed equations at the concrete endpoint e. Both solutions are classified with $\mathsf{inv}(a, p_a)(\mathsf{e}\,\mathsf{inv}(b, p_b))$. Symmetry on the second classification and transitivity of hsame identify x and y. □

Lean4 ✓ `BEDC.Derived.FieldUp.field middle mul empty equation solution unique from apartness`

Theorem 45.238 (Field two-sided empty-context product solution uniqueness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, if* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$ *and both* x *and* y *solve the same two-sided product equation at the concrete empty-context target*

$$(ax)b\mathsf{hsameappend}(\mathsf{e}, c) \qquad \textit{and} \qquad (ay)b\mathsf{hsameappend}(\mathsf{e}, c),$$

then $x\mathsf{hsame}y$*.*

Proof. Apply the middle multiplication solution theorem to both displayed equations at the concrete endpoint $\mathsf{append}(\mathsf{e}, c)$. Both solutions are classified with the same normal form $\mathsf{inv}(a, p_a)(\mathsf{append}(\mathsf{e}, c)\mathsf{inv}(b, p_b))$. Symmetry on the second classification and transitivity of hsame identify x and y. □

Lean4 ✓ `BEDC.Derived.FieldUp.field two sided empty context product solution unique from apartness`

Theorem 45.239 (Field inverse is apart from empty under right inverse one-apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with multiplication* mul*, unit* 1*, proof-indexed inverse* $\mathsf{inv}(a, p)$*, multiplication congruence under* hsame*, zero-right multiplication* $\mathsf{mul}(x, 0)\mathsf{hsame}0$*, right inverse law* $\mathsf{mul}(a, \mathsf{inv}(a, p))\mathsf{hsame}1$*, and one-apartness* $\omega : (1\mathsf{hsame}0) \to \bot$*, every witness* $p_a : \mathsf{NonZero}_F(a)$ *constructively refutes*

$$\mathsf{inv}(a, p_a)\mathsf{hsame}0.$$

Proof. Assume $\mathsf{inv}(a, p_a)\mathsf{hsame}0$. Multiplication congruence transports this equality through left multiplication by a, and the zero-right law identifies the transported product with 0. The right inverse law identifies the same product with 1, so transitivity gives $1\mathsf{hsame}0$, contradicting ω. □

Theorem 45.240 (Field inverse is nonzero under right inverse one-apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with multiplication* mul*, unit* 1*, proof-indexed inverse* $\mathsf{inv}(a, p)$*, multiplication congruence under* hsame*, zero-right multiplication* $\mathsf{mul}(x, 0)\mathsf{hsame}0$*, right inverse law* $\mathsf{mul}(a, \mathsf{inv}(a, p))\mathsf{hsame}1$*, one-apartness* $\omega : (1\mathsf{hsame}0) \to \bot$*, and conversion maps* $\alpha_x : ((x\mathsf{hsame}0) \to \bot) \to \mathsf{NonZero}_F(x)$*, every witness* $p_a : \mathsf{NonZero}_F(a)$ *canonically determines*

$$\mathsf{NonZero}_F(\mathsf{inv}(a, p_a)).$$

Proof. The preceding theorem supplies the constructive refutation of $\mathsf{inv}(a, p_a)\mathsf{hsame}0$ from multiplication congruence, the zero-right law, the indexed right inverse law, and one-apartness. Applying $\alpha_{\mathsf{inv}(a,p_a)}$ to that refutation produces the required nonzero witness for the inverse. □

Theorem 45.241 (Field inverse empty-apartness hsame transport)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with multiplication* mul*, unit* 1*, proof-indexed inverse* $\mathsf{inv}(a, p)$*, multiplicative associativity, left and right unit laws, multiplication congruence under* hsame*, and left and right inverse laws, if* $a\mathsf{hsame}b$*, then apartness of the indexed inverse at* a *from* e *transports to the indexed inverse at* b*:*

$$(\mathsf{inv}(a, p_a)\mathsf{hsamee} \to \bot) \Longrightarrow (\mathsf{inv}(b, p_b)\mathsf{hsamee} \to \bot).$$

Proof. Apply inverse congruence from apartness transport to $a\mathsf{hsame}b$, obtaining $\mathsf{inv}(a, p_a)\mathsf{hsameinv}(b, p_b)$. Any collapse $\mathsf{inv}(b, p_b)\mathsf{hsamee}$ composes with that equality, producing a collapse of $\mathsf{inv}(a, p_a)$ to e, contradicting the supplied apartness predicate. □

Lean4 ✓ `BEDC.Derived.FieldUp.field inverse apart empty hsame transport`

Theorem 45.242 (Field multiplication cancellation from apartness-certified factors)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, right and left multiplication by apartness-certified nonzero factors are cancellative. Any witness* $p_b : \mathsf{NonZero}_F(b)$ *makes*

$$xb\mathsf{hsame}yb \quad \Longrightarrow \quad x\mathsf{hsame}y,$$

and any witness $p_a : \mathsf{NonZero}_F(a)$ *makes*

$$ax\mathsf{hsame}ay \quad \Longrightarrow \quad x\mathsf{hsame}y.$$

Proof. For the right clause, apply Theorem 45.223 to $xb\mathsf{hsame}yb$. This gives $x\mathsf{hsame}(yb)\mathsf{inv}(b, p_b)$. Theorem 45.222 identifies $(yb)\mathsf{inv}(b, p_b)$ with y, so transitivity of hsame gives $x\mathsf{hsame}y$.

For the left clause, apply Theorem 45.228 to $ax\mathsf{hsame}ay$. This gives $x\mathsf{hsameinv}(a, p_a)(ay)$. Theorem 45.227 identifies $\mathsf{inv}(a, p_a)(ay)$ with y, and transitivity of hsame finishes. □

Theorem 45.243 (Field empty-context multiplication cancellation from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, multiplication congruence, and apartness-certified nonzero factors, empty left append context on the product endpoint is cancellative. Any witness* $p_b : \mathsf{NonZero}_F(b)$ *makes*

$$xb\mathsf{hsameappend}(\mathsf{e}, yb) \quad \Longrightarrow \quad x\mathsf{hsame}y,$$

and any witness $p_a : \mathsf{NonZero}_F(a)$ *makes*

$$au\mathsf{hsameappend}(\mathsf{e}, av) \quad \Longrightarrow \quad u\mathsf{hsame}v.$$

Proof. The empty left append endpoint reduces by the finite-kernel law $\mathsf{append}(\mathsf{e}, h) = h$. The right-factor clause solves the equation $xb\mathsf{hsameappend}(\mathsf{e}, yb)$ using the indexed inverse of b, then cancels $(yb)\mathsf{inv}(b, p_b)$ back to y. The left-factor clause is symmetric: solve the left multiplication equation using the indexed inverse of a, reduce the empty-context endpoint, and cancel $\mathsf{inv}(a, p_a)(av)$ back to v. □

Lean4 ✓ `BEDC.Derived.FieldUp.field nonzero mul empty context cancel from apartness`

Theorem 45.244 (Field one-sided multiplication cancellation exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses and multiplication congruence, right and left multiplication by apartness-certified nonzero factors are classifier-exact. Any witness* $p_b : \mathsf{NonZero}_F(b)$ *makes every* $x, y : \mathsf{BHist}$ *satisfy*

$$xb\mathsf{hsame}yb \Longleftrightarrow x\mathsf{hsame}y,$$

and any witness $p_a : \mathsf{NonZero}_F(a)$ *makes every* $x, y : \mathsf{BHist}$ *satisfy*

$$ax\mathsf{hsame}ay \Longleftrightarrow x\mathsf{hsame}y.$$

Proof. For the right-factor clause, the forward direction is exactly the right cancellation clause of Theorem 45.242 with witness p_b.

For the reverse direction, start from $x\mathsf{hsame}y$. Multiplication congruence transports this equality through right multiplication by the fixed factor b, using reflexivity on that factor, and gives $xb\mathsf{hsame}yb$.

For the left-factor clause, the forward direction is exactly the left cancellation clause of Theorem 45.242 with witness p_a.

For the reverse direction, start from $x\mathsf{hsame}y$. Multiplication congruence transports this equality through left multiplication by the fixed factor a, using reflexivity on that factor, and gives $ax\mathsf{hsame}ay$. □

Theorem 45.245 (Field two-sided multiplication exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, multiplication congruence, and witnesses* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$*, every* $x, y : \mathsf{BHist}$ *satisfy*

$$(ax)b\mathsf{hsame}(ay)b \iff x\mathsf{hsame}y.$$

Proof. For the forward direction, apply the right-factor clause of Theorem 45.244 with witness p_b to $(ax)b\mathsf{hsame}(ay)b$. This gives $ax\mathsf{hsame}ay$.

Apply the left-factor clause of the same theorem with witness p_a. This transports $ax\mathsf{hsame}ay$ across the left multiplication classifier and gives $x\mathsf{hsame}y$.

For the reverse direction, start from $x\mathsf{hsame}y$. Multiplication congruence transports this classifier equality through left multiplication by a, giving $ax\mathsf{hsame}ay$.

Apply multiplication congruence once more through right multiplication by b. The result is exactly

$$(ax)b\mathsf{hsame}(ay)b.$$

□

Lean4 ✓ `BEDC.Derived.FieldUp.field two sided mul exact from apartness`

Theorem 45.246 (Field two-sided zero product exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, ring zero absorption, multiplication associativity, left and right multiplicative identity laws, multiplication congruence, indexed left and right inverse laws, and witnesses* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$*, every* $x : \mathsf{BHist}$ *satisfies*

$$(ax)b\mathsf{hsame}0 \iff x\mathsf{hsame}0.$$

Proof. For the forward direction, apply Theorem 45.223 with the right-factor witness p_b to the hypothesis $(ax)b\mathsf{hsame}0$. This solves the right multiplication equation and gives $ax\mathsf{hsame}0\mathsf{inv}(b, p_b)$.

Use Theorem 43.39 to identify $0\mathsf{inv}(b, p_b)$ with 0. Transitivity of hsame therefore gives $ax\mathsf{hsame}0$.

Now apply the checked left inverse cancellation chain with the left-factor witness p_a to $ax\mathsf{hsame}0$. The left solver gives $x\mathsf{hsameinv}(a, p_a)0$.

Use Theorem 43.39 again to identify $\mathsf{inv}(a, p_a)0$ with 0. Transitivity of hsame yields $x\mathsf{hsame}0$.

For the reverse direction, start from $x\mathsf{hsame}0$. Multiplication congruence transports this equality through left multiplication by a, giving $ax\mathsf{hsame}a0$.

Apply Theorem 43.39 to collapse $a0\mathsf{hsame}0$. Transitivity gives $ax\mathsf{hsame}0$.

Multiplication congruence now transports through right multiplication by b, giving $(ax)b\mathsf{hsame}0b$. A second application of Theorem 43.39 collapses $0b\mathsf{hsame}0$, and transitivity yields $(ax)b\mathsf{hsame}0$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field two sided empty product exact from apartness`

Theorem 45.247 (Field one-sided zero product cancellation from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, ring zero absorption, multiplication associativity, left and right multiplicative identity laws, multiplication congruence, and indexed inverse laws, every* $a, b : \mathsf{BHist}$ *satisfies the following clauses.*

1. *If* $p_a : \mathsf{NonZero}_F(a)$ *and* $ab\mathsf{hsame}0$*, then* $b\mathsf{hsame}0$*.*

2. *If* $p_b : \mathsf{NonZero}_F(b)$ *and* $ab\mathsf{hsame}0$*, then* $a\mathsf{hsame}0$*.*

Proof. For the left-factor clause, apply Theorem 45.228 to the equation $ab\mathsf{hsame}0$ with witness p_a. This gives $b\mathsf{hsameinv}(a, p_a)0$.

Use Theorem 43.39 to identify $\mathsf{inv}(a, p_a)0$ with 0. Transitivity of hsame yields $b\mathsf{hsame}0$.

For the right-factor clause, apply Theorem 45.223 to the same equation with witness p_b. This gives $a\mathsf{hsame}0\mathsf{inv}(b, p_b)$.

Use Theorem 43.39 to identify $0\mathsf{inv}(b, p_b)$ with 0. Transitivity of hsame yields $a\mathsf{hsame}0$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field one sided zero product cancel from apartness`

Theorem 45.248 (Field nonzero factors exclude zero product)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, ring zero absorption, multiplication associativity, left and right multiplicative identity laws, multiplication congruence, indexed inverse laws, classifier transport of* $\mathsf{NonZero}_F$*, and contradiction of* $\mathsf{NonZero}_F(0)$*, every* $a, b : \mathsf{BHist}$ *with witnesses* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$ *satisfies*

$$\neg(ab\mathsf{hsame}0).$$

Proof. Assume $ab\mathsf{hsame}0$. Apply Theorem 45.247 with the left-factor witness p_a. The left-factor clause gives $b\mathsf{hsame}0$.

Transport the witness $p_b : \mathsf{NonZero}_F(b)$ along this classifier equality. The stability clause for $\mathsf{NonZero}_F$ supplies $\mathsf{NonZero}_F(0)$.

The field stability certificate includes contradiction of $\mathsf{NonZero}_F(0)$, so the transported evidence closes the goal with $\bot$.

The symmetric route uses p_b in the right-factor clause and transports p_a after deriving $a\mathsf{hsame}0$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field nonzero factors exclude empty product`

Definition 45.249 (Field zero apartness)**.** *For a BEDC history-level field candidate, the zero-apartness predicate is*

$$\mathsf{ApartZero}_F(h) := (h\mathsf{hsame}0 \to \bot).$$

When this predicate is the nonzero index, inverse formation is indexed directly by apart-zero witnesses.

Theorem 45.250 (Field apart-zero semantic name certificate)**.** *The apart-zero predicate* $\mathsf{ApartZero}_F(h) = (h\mathsf{hsame}0 \to \bot)$*, used as source, pattern, and ledger policy with classifier* hsame*, forms a semantic name certificate.*

Proof. The history $\mathsf{E0}(\mathsf{e})$ is apart from zero by constructor separation, so the source carrier is inhabited. The classifier fields are the reflexivity, symmetry, and transitivity laws of hsame. Carrier preservation is contrapositive transport: if $h\mathsf{hsame}k$ and h is apart from zero, then any $k\mathsf{hsame}0$ composes to $h\mathsf{hsame}0$, contradiction. Pattern and ledger soundness are immediate because all three policies are the same apart-zero predicate. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero semanticNameCert`

Theorem 45.251 (Field apart-zero empty transport along history sameness)**.** *If* $a\mathsf{hsame}b$ *and* a *is apart from zero, then* b *is also apart from zero:*

$$a\mathsf{hsame}b \wedge \mathsf{ApartZero}_F(a) \Longrightarrow (b\mathsf{hsame}0 \to \mathsf{False}).$$

Proof. Assume $b\mathsf{hsame}0$. Transitivity of hsame with $a\mathsf{hsame}b$ gives $a\mathsf{hsame}0$, contradicting the apart-zero witness for a. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero empty hsame transport`

Theorem 45.252 (Field apart-zero append factor closure)**.** *For histories $p, q : \mathsf{BHist}$, if either p or q is apart from zero, then the appended history $\mathsf{append}(p, q)$ is apart from zero:*

$$\mathsf{ApartZero}_F(p) \vee \mathsf{ApartZero}_F(q) \Longrightarrow \mathsf{ApartZero}_F(\mathsf{append}(p, q)).$$

Proof. Assume $\mathsf{append}(p, q)\mathsf{hsame}0$. Empty-append inversion gives both $p\mathsf{hsame}0$ and $q\mathsf{hsame}0$. If the apart-zero witness is on the left factor, it rejects the first equality; if it is on the right factor, it rejects the second equality. Thus either factor witness prevents the appended history from classifying as zero. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero append factor closed`

Theorem 45.253 (Field apart-zero left factor from non-apart tail)**.** *For histories $p, q : \mathsf{BHist}$, if $\mathsf{append}(p, q)$ is apart from zero and q is not apart from zero, then p is apart from zero:*

$$\mathsf{ApartZero}_F(\mathsf{append}(p, q)) \Longrightarrow (\mathsf{ApartZero}_F(q) \Rightarrow \mathsf{False}) \Longrightarrow \mathsf{ApartZero}_F(p).$$

Proof. Assume $p\mathsf{hsame}0$. The concrete history q is either empty or visibly headed. If it is visibly headed, it is apart from zero, contradicting the non-apart tail hypothesis. Hence $q\mathsf{hsame}0$. Empty-append introduction then gives $\mathsf{append}(p, q)\mathsf{hsame}0$, contradicting the apart-zero witness for the append. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero append left factor of tail not apart`

Theorem 45.254 (Field apart-zero append split exactness)**.** *For histories $p, q : \mathsf{BHist}$, apart-zero of an appended history is exactly apart-zero of one of its factors:*

$$\mathsf{ApartZero}_F(\mathsf{append}(p, q)) \Longleftrightarrow \mathsf{ApartZero}_F(p) \vee \mathsf{ApartZero}_F(q).$$

Proof. For the forward direction, split on the concrete shape of p. If $p = \mathsf{e}$, then $q\mathsf{hsamee}$ would make the append empty, contradicting the appended apart-zero witness. If p has a visible head constructor, that constructor is separated from e, so p itself is apart from zero.

For the reverse direction, use the one-factor closure theorem: an empty append would split into empty witnesses for both factors, contradicting the selected apart-zero factor. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero append split iff`

Theorem 45.255 (Field apart-zero right factor from non-apart head)**.** *For histories $p, q : \mathsf{BHist}$, if $\mathsf{append}(p, q)$ is apart from zero and p is not apart from zero, then q is apart from zero:*

$$\mathsf{ApartZero}_F(\mathsf{append}(p, q)) \Longrightarrow (\mathsf{ApartZero}_F(p) \Rightarrow \mathsf{False}) \Longrightarrow \mathsf{ApartZero}_F(q).$$

Proof. Apply the append split exactness theorem to the appended apart-zero witness. The left branch contradicts the non-apart head hypothesis, so the right branch remains and supplies $\mathsf{ApartZero}_F(q)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero append right factor of head not apart`

Theorem 45.256 (Field apart-zero continuation endpoint split)**.** *For histories p, q, r : BHist with $\mathsf{Cont}(p, q, r)$, apartness from zero of the continuation result is exactly apartness from zero of one endpoint:*

$$\mathsf{ApartZero}_F(r) \iff \mathsf{ApartZero}_F(p) \vee \mathsf{ApartZero}_F(q).$$

Proof. The continuation ledger identifies r with $\mathsf{append}(p, q)$. The forward implication performs induction by cases on the left endpoint: if it is e, any empty endpoint for q would empty the append; if it is visibly headed, constructor separation supplies apartness of p. Conversely, an empty append result splits into empty endpoints for both factors, and the selected apart-zero witness rejects the corresponding endpoint. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero continuation endpoint split iff`

Theorem 45.257 (Field apart-zero mutual continuation cycle tails absurd)**.** *For a mutual continuation cycle $\mathsf{Cont}(h, leftTail, k)$ and $\mathsf{Cont}(k, rightTail, h)$, neither cycle tail can be field-apart from zero.*

Proof. Continuation cycle cancellation reads both tails as e. Each $\mathsf{ApartZero}_F$ witness is exactly a rejection of that empty endpoint. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero mutual continuation cycle tails absurd`

Theorem 45.258 (Field apart-zero triangle continuation cycle tails absurd)**.** *For a triangle continuation cycle, the three displayed tails cannot be field-apart from zero.*

Proof. Triangle cycle cancellation identifies all three tails with e. The corresponding apart-zero witness rejects each empty-tail conclusion. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero triangle continuation cycle tails absurd`

Theorem 45.259 (Field apart-zero two-step continuation split)**.** *For histories l, h, r, u, v : BHist with $\mathsf{Cont}(l, h, u)$ and $\mathsf{Cont}(u, r, v)$, apartness from zero of the final continuation result is exactly apartness from zero in one of the three displayed factors:*

$$\mathsf{ApartZero}_F(v) \iff (\mathsf{ApartZero}_F(l) \vee \mathsf{ApartZero}_F(h)) \vee \mathsf{ApartZero}_F(r).$$

Proof. For the forward direction, apply Definition 45.256 to the continuation $\mathsf{Cont}(u, r, v)$. The resulting left branch gives $\mathsf{ApartZero}_F(u)$; applying the same theorem to $\mathsf{Cont}(l, h, u)$ splits that branch into $\mathsf{ApartZero}_F(l)$ or $\mathsf{ApartZero}_F(h)$. The right branch is already $\mathsf{ApartZero}_F(r)$, so the displayed disjunction follows.

For the reverse direction, split the displayed disjunction. If the left summand holds, apply Definition 45.256 to $\mathsf{Cont}(l, h, u)$ to obtain $\mathsf{ApartZero}_F(u)$, then apply the same theorem to $\mathsf{Cont}(u, r, v)$ to obtain $\mathsf{ApartZero}_F(v)$. If the right summand holds, the second continuation split directly transports $\mathsf{ApartZero}_F(r)$ to $\mathsf{ApartZero}_F(v)$. □

Theorem 45.260 (Field apart-zero factors excluded by singleton continuation result)**.** *For histories $P, Q, R, endpoint$: BHist, if $\mathsf{Cont}(P, Q, R)$ and the result is classified by the field singleton classifier, then neither factor can be apart from zero:*

$$\mathsf{Cont}(P, Q, R) \wedge \mathsf{FieldSingletonClassifier}(R, endpoint) \Longrightarrow ((\mathsf{ApartZero}_F(P) \to \bot) \wedge (\mathsf{ApartZero}_F(Q) \to \bot)).$$

Proof. The singleton classifier supplies singleton-carrier membership for the result. The continuation endpoint split for singleton carriers pulls that membership back to both factors. An apart-zero witness for either factor is a rejection of that factor being empty, so each factor-side witness is impossible. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero continuation singleton result factor absurd`

Theorem 45.261 (Field apart-zero append congruence under history sameness)**.** *For histories* $a, a', b, b' : \mathsf{BHist}$*, history sameness on both append factors preserves and reflects apartness from zero:*

$$a\mathsf{hsame}a' \wedge b\mathsf{hsame}b' \Longrightarrow (\mathsf{ApartZero}_F(\mathsf{append}(a, b)) \Longleftrightarrow \mathsf{ApartZero}_F(\mathsf{append}(a', b'))).$$

Proof. Substituting the two history-sameness witnesses gives $\mathsf{append}(a, b)\mathsf{hsameappend}(a', b')$. The apart-zero transport law applies in one direction to preserve apartness, and with symmetry of hsame in the other direction to reflect it. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero append hsame congr iff`

Theorem 45.262 (Field apart-zero append right-empty exactness)**.** *For histories* $p, q : \mathsf{BHist}$ *with* $q\mathsf{hsamee}$*, appended apart-zero is exactly apart-zero of the left factor:*

$$\mathsf{ApartZero}_F(\mathsf{append}(p, q)) \Longleftrightarrow \mathsf{ApartZero}_F(p).$$

Proof. For the forward implication, assume $p\mathsf{hsamee}$. Together with $q\mathsf{hsamee}$, empty-append exactness gives $\mathsf{append}(p, q)\mathsf{hsamee}$, contradicting appended apart-zero. For the reverse implication, any equality $\mathsf{append}(p, q)\mathsf{hsamee}$ splits by empty-append exactness, and the left component contradicts apart-zero of p. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero append right empty iff`

Theorem 45.263 (Field apart-zero append left-empty exactness)**.** *For histories* $p, q : \mathsf{BHist}$ *with* $p\mathsf{hsamee}$*, appended apart-zero is exactly apart-zero of the right factor:*

$$\mathsf{ApartZero}_F(\mathsf{append}(p, q)) \Longleftrightarrow \mathsf{ApartZero}_F(q).$$

Proof. For the forward implication, assume $q\mathsf{hsamee}$. Together with $p\mathsf{hsamee}$, empty-append exactness gives $\mathsf{append}(p, q)\mathsf{hsamee}$, contradicting appended apart-zero. For the reverse implication, any equality $\mathsf{append}(p, q)\mathsf{hsamee}$ splits by empty-append exactness, and the right component contradicts apart-zero of q. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero append left empty iff`

Theorem 45.264 (Field apart-zero append visible-headed)**.** *For histories* $p, q : \mathsf{BHist}$*, appending any suffix to a visible-headed history is apart from zero:*

$$\mathsf{ApartZero}_F(\mathsf{append}(\mathsf{E0}(p), q)) \wedge \mathsf{ApartZero}_F(\mathsf{append}(\mathsf{E1}(p), q)).$$

Proof. An empty equality for either appended history splits by empty-append exactness. The left component would identify $\mathsf{E0}(p)$, respectively $\mathsf{E1}(p)$, with e. BEDC constructor separation rules out both identifications. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero append visible headed`

Theorem 45.265 (Field apart-zero nested continuation visible-left result)**.** *For histories* $tail, h, r, u, v$: BHist*, a nested continuation whose left source is visibly headed has an apart-zero result:*

$$(\mathsf{Cont}(\mathsf{E0}(tail), h, u) \to \mathsf{Cont}(u, r, v) \to \mathsf{ApartZero}_F(v)) \wedge (\mathsf{Cont}(\mathsf{E1}(tail), h, u) \to \mathsf{Cont}(u, r, v) \to \mathsf{ApartZero}_F(v)).$$

Proof. In the $\mathsf{E0}$ branch, the two continuation witnesses identify u with $\mathsf{append}(\mathsf{E0}(tail), h)$ and v with $\mathsf{append}(u, r)$. If $v\mathsf{hsamee}$, empty-append inversion first forces $u\mathsf{hsamee}$, and a second inversion forces $\mathsf{E0}(tail)\mathsf{hsamee}$, contradicting constructor separation.

The $\mathsf{E1}$ branch is identical, with the second inversion producing $\mathsf{E1}(tail)\mathsf{hsamee}$, again contradicting constructor separation. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero nested continuation visible left result`

Theorem 45.266 (Field apart-zero nested continuation visible-right result)**.** *For histories* $l, h, tail, u, v$: BHist*, a nested continuation whose second continuation tail is visibly headed has an apart-zero result:*

$$(\mathsf{Cont}(l, h, u) \to \mathsf{Cont}(u, \mathsf{E0}(tail), v) \to \mathsf{ApartZero}_F(v)) \wedge (\mathsf{Cont}(l, h, u) \to \mathsf{Cont}(u, \mathsf{E1}(tail), v) \to \mathsf{ApartZero}_F(v)).$$

Proof. In the $\mathsf{E0}$ branch, the first continuation supplies the intermediate history u, and the second continuation identifies v with an append whose right factor is $\mathsf{E0}(tail)$. If $v\mathsf{hsamee}$, empty-append inversion forces that visible right factor to be empty, contradicting BEDC constructor separation.

The $\mathsf{E1}$ branch has the same shape. A hypothetical equality $v\mathsf{hsamee}$ splits through the second continuation and empty-append inversion, forcing $\mathsf{E1}(tail)\mathsf{hsamee}$, which constructor separation rules out. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero nested continuation visible right result`

Per-object certificate: traditional target visible-suffix apart-zero coverage for nested $\mathsf{Field}^{\uparrow}$ continuations; BEDC source BHist plus Cont; carrier $\mathsf{ApartZero}_F$; classifier hsame; ledger records the hidden visible suffix and continuation result; core theorem is Definition 45.266 together with append empty-result inversion; exactness predicate is the displayed apart-zero conclusion; status $\mathsf{ProofTarget}$.

Theorem 45.267 (Field apart-zero empty-context exactness)**.** *For histories* l, h, r : BHist *with* $l\mathsf{hsamee}$ *and* $r\mathsf{hsamee}$*, bilateral empty context is exact for field apart-zero witnesses:*

$$\mathsf{ApartZero}_F(\mathsf{append}(l, \mathsf{append}(h, r))) \iff \mathsf{ApartZero}_F(h).$$

Proof. For the forward direction, assume the contextual apart-zero witness. To prove $\mathsf{ApartZero}_F(h)$, take a candidate equality $h\mathsf{hsamee}$. Empty-append construction combines this equality with $r\mathsf{hsamee}$, giving $\mathsf{append}(h, r)\mathsf{hsamee}$.

Combining that inner equality with $l\mathsf{hsamee}$ classifies the whole nested append as empty. This contradicts the contextual apart-zero witness.

For the reverse direction, assume $\mathsf{ApartZero}_F(h)$ and take a candidate equality

$$\mathsf{append}(l, \mathsf{append}(h, r))\mathsf{hsamee}.$$

Empty-append inversion first splits off the left context and gives $\mathsf{append}(h, r)\mathsf{hsamee}$. Applying the same inversion to the inner append gives $h\mathsf{hsamee}$, contradicting $\mathsf{ApartZero}_F(h)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero empty context iff`

Theorem 45.268 (Field apart-zero left append-context semantic certificate)**.** *For a history* p : BHist *apart from zero, the concrete left-append context predicate*

$$q \longmapsto \mathsf{ApartZero}_F(\mathsf{append}(q, p))$$

used as source, pattern, and ledger policy with classifier hsame *forms a semantic name certificate.*

Proof. The carrier is inhabited at $q = \mathsf{e}$: $\mathsf{append}(\mathsf{e}, p)\mathsf{hsame}p$, so apart-zero of p transports to apart-zero of the displayed append. The classifier laws are reflexivity, symmetry, and transitivity of hsame. Carrier preservation follows by eliminating the history-sameness classifier, which leaves the same concrete append predicate. Pattern and ledger soundness are identities because all three predicates coincide. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero append left context semanticNameCert`

Theorem 45.269 (Field apart-zero right append-context semantic certificate)**.** *For a history* p : BHist *apart from zero, the concrete right-append context predicate*

$$q \longmapsto \mathsf{ApartZero}_F(\mathsf{append}(p, q))$$

used as source, pattern, and ledger policy with classifier hsame *forms a semantic name certificate.*

Proof. The carrier is inhabited at $q = \mathsf{e}$: $\mathsf{append}(p, \mathsf{e})\mathsf{hsame}p$, so apart-zero of p transports to apart-zero of the displayed append. The classifier laws are again the equivalence laws of hsame. Carrier preservation eliminates the history-sameness classifier and leaves the same right-append predicate, while pattern and ledger soundness are identity maps. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero append right context semanticNameCert`

Theorem 45.270 (Field apart-zero two-sided context semantic certificate)**.** *For histories* L, R : BHist*, if* L *is apart from zero, then the two-sided context predicate*

$$h \longmapsto \mathsf{FieldApartZero}(\mathsf{append}(L, \mathsf{append}(h, R)))$$

used as source, pattern, and ledger policy with classifier hsame *forms a semantic name certificate.*

Proof. The source is inhabited at the empty middle history. If $\mathsf{append}(L, \mathsf{append}(\mathsf{e}, R))$ were empty, append-empty inversion would force $L\mathsf{hsamee}$, contradicting the assumed apart-zero witness for L. The equivalence laws are the standard hsame laws, and carrier preservation follows by eliminating the history-sameness classifier. Pattern and ledger soundness are identities because source, pattern, and ledger policy are the same concrete predicate. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero append context semanticNameCert`

Per-object certificate: traditional target is external-unit context invariance of constructive field apartness. BEDC source is FieldApartZero plus BEDC append empty exactness. Carrier is BHist. Classifier is hsame. Ledger is the two empty-context witnesses $l$hsamee and $r$hsamee. Core theorem list is Definition 45.267. Exactness predicate is the displayed iff. Status is ProofTarget.

Theorem 45.271 (Field product apartness gives inverse product witness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate satisfying the hypotheses of Theorem 45.247 and Theorem 45.213, assume inverse formation is indexed by apart-zero witnesses,*

$$\mathsf{inv} : (a : \mathsf{BHist}) \to \mathsf{ApartZero}_F(a) \to \mathsf{BHist}.$$

If $p_a : \mathsf{ApartZero}_F(a)$ *and* $p_b : \mathsf{ApartZero}_F(b)$*, then there exists* $p_{ab} : \mathsf{ApartZero}_F(\mathsf{mul}(a, b))$ *such that*

$$\mathsf{inv}(\mathsf{mul}(a, b), p_{ab})\mathsf{hsamemul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a)).$$

Proof. Build p_{ab} as a function from an assumed zero product to contradiction. Given $z : \mathsf{mul}(a, b)\mathsf{hsame}0$, apply Theorem 45.247 with the left-factor witness p_a. The left-factor clause sends z to $b\mathsf{hsame}0$, and p_b rejects that equality.

Apply Theorem 45.213 with the apart-zero indices p_{ab}, p_a, and p_b to obtain the displayed inverse product equality. □

Lean4 ✓ `BEDC.Derived.FieldUp.field product apartness inverse product reverse`

Theorem 45.272 (Field equal-squares signed factor exclusion)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, ring zero absorption, multiplication associativity, left and right multiplicative identity laws, multiplication congruence, indexed inverse laws, the* $\mathsf{CommRing}^{\uparrow}$ *hypotheses required by Theorem 44.47, and every* $a, b : \mathsf{BHist}$ *with* $a \cdot a\mathsf{hsame}b \cdot b$*, the following constructive clauses hold.*

1. *If* $p_+ : \mathsf{NonZero}_F(a + b)$*, then* $a + (-b)\mathsf{hsame}0$*.*
2. *If* $p_- : \mathsf{NonZero}_F(a + (-b))$*, then* $a + b\mathsf{hsame}0$*.*

Proof. Apply the reverse direction of Theorem 44.47 to the square equality. The signed factor product is therefore classified as zero:

$$(a + b) \cdot (a + (-b))\mathsf{hsame}0.$$

For the first clause, use the witness $p_+ : \mathsf{NonZero}_F(a + b)$ and apply Theorem 45.247 to the signed factor product with left factor $a + b$ and right factor $a + (-b)$. The left-factor clause gives $a + (-b)\mathsf{hsame}0$.

For the second clause, use the witness $p_- : \mathsf{NonZero}_F(a + (-b))$ and apply Theorem 45.247 to the same signed factor product. The right-factor clause gives $a + b\mathsf{hsame}0$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field equal squares signed factor exclusion`

Per-object certificate: this is the Core theorem list item for constructive field square-factor one-sided cancellation. Source: $\mathsf{Field}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$. Carrier: BHist. Classifier: hsame. Ledger: the chosen nonzero signed factor witness p_+ or p_-. The incompatible-pair result is recorded at Definition 45.297. Status: CheckedCert.

Zero-product exactness certificate. Traditional target: constructive field zero-product exactness. BEDC source: $\mathsf{Field}^{\uparrow}$ plus $\mathsf{Ring}^{\uparrow}$ zero absorption. Carrier choice: BHist. Classifier choice: hsame. Stability obligations: zero absorption, multiplication associativity, multiplicative unit laws, multiplication congruence, and indexed inverse laws. Ledger: the two certified factors $p_a : \mathsf{NonZero}_F(a)$ and $p_b : \mathsf{NonZero}_F(b)$ together with their inverse witnesses. Core theorem list: two-sided zero-product exactness and zero-product exclusion from two nonzero witnesses. Exactness predicate: exact zero classifier and nonzero-product contradiction inside certified two-sided multiplication. Standard bridge: deferred conservative bridge. Status: ProofTarget.

45.6 Field affine equation laws

Theorem 45.273 (Field affine left multiplication equation exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with operations* $\mathsf{add}, \mathsf{mul}, \mathsf{neg}, \mathsf{zero}, \mathsf{one}$ *on* BHist*, additive abelian-group laws for* $\mathsf{add}, \mathsf{neg}, \mathsf{zero}$*, addition congruence, multiplication associativity, left and right multiplicative identity laws, multiplication congruence, and left and right inverse laws indexed by*

$p_a : \mathsf{NonZero}_F(a)$, *every* $x, b, c : \mathsf{BHist}$ *satisfy*

$$\mathsf{add}(\mathsf{mul}(a, x), b)\mathsf{hsame}c \iff x\mathsf{hsamemul}(\mathsf{inv}(a, p_a), \mathsf{add}(c, \mathsf{neg}(b))).$$

Proof. For the forward direction, transport $\mathsf{add}(\mathsf{mul}(a, x), b)\mathsf{hsame}c$ through right addition by $\mathsf{neg}(b)$. Addition congruence gives an equality between $\mathsf{add}(\mathsf{add}(\mathsf{mul}(a, x), b), \mathsf{neg}(b))$ and $\mathsf{add}(c, \mathsf{neg}(b))$.

Associativity, the additive inverse law for b, and the additive identity law collapse the left side to $\mathsf{mul}(a, x)$. Apply Theorem 45.228 to obtain the displayed solution for x with right side $\mathsf{add}(c, \mathsf{neg}(b))$.

For the reverse direction, transport the assumed displayed solution through left multiplication by a. Multiplication congruence, associativity, the indexed inverse law for p_a, and the multiplicative identity law collapse the right side to $\mathsf{add}(c, \mathsf{neg}(b))$, so $\mathsf{mul}(a, x)\mathsf{hsameadd}(c, \mathsf{neg}(b))$.

Add b on the right and use addition congruence. Associativity, additive commutativity for the middle pair when needed, the additive inverse law for b, and the additive identity law collapse $\mathsf{add}(\mathsf{add}(c, \mathsf{neg}(b)), b)$ back to c. This gives $\mathsf{add}(\mathsf{mul}(a, x), b)\mathsf{hsame}c$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine left equation exact from apartness`

Theorem 45.274 (Field affine right multiplication equation exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with operations* $\mathsf{add}, \mathsf{mul}, \mathsf{neg}, \mathsf{zero}, \mathsf{one}$ *on* BHist*, additive abelian-group laws for* $\mathsf{add}, \mathsf{neg}, \mathsf{zero}$*, addition congruence, multiplication associativity, left and right multiplicative identity laws, multiplication congruence, and left and right inverse laws indexed by* $p_b : \mathsf{NonZero}_F(b)$*, every* $x, d, c : \mathsf{BHist}$ *satisfy*

$$\mathsf{add}(\mathsf{mul}(x, b), d)\mathsf{hsame}c \iff x\mathsf{hsamemul}(\mathsf{add}(c, \mathsf{neg}(d)), \mathsf{inv}(b, p_b)).$$

Proof. For the forward direction, transport $\mathsf{add}(\mathsf{mul}(x, b), d)\mathsf{hsame}c$ through right addition by $\mathsf{neg}(d)$. Addition congruence gives equality between the offset equation after adding $\mathsf{neg}(d)$ on the right and $\mathsf{add}(c, \mathsf{neg}(d))$.

Associativity, the additive inverse law for d, and the additive identity law collapse the left side to $\mathsf{mul}(x, b)$. Apply Theorem 45.223 to obtain the displayed solution for x with right side $\mathsf{add}(c, \mathsf{neg}(d))$.

For the reverse direction, transport the assumed displayed solution through right multiplication by b. Multiplication congruence, associativity, the indexed left inverse law for p_b, and the multiplicative identity law collapse the right side to $\mathsf{add}(c, \mathsf{neg}(d))$, so $\mathsf{mul}(x, b)\mathsf{hsameadd}(c, \mathsf{neg}(d))$.

Add d on the right and use addition congruence. Associativity, additive commutativity for the middle pair when needed, the additive inverse law for d, and the additive identity law collapse $\mathsf{add}(\mathsf{add}(c, \mathsf{neg}(d)), d)$ back to c. This gives $\mathsf{add}(\mathsf{mul}(x, b), d)\mathsf{hsame}c$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine right equation exact from apartness`

Theorem 45.275 (Field one-sided affine map classifier exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with operations* $\mathsf{add}, \mathsf{mul}, \mathsf{neg}, \mathsf{zero}, \mathsf{one}$ *on* BHist*, additive group laws for* $\mathsf{add}, \mathsf{neg}, \mathsf{zero}$*, addition congruence, multiplication associativity, left and right multiplicative identity laws, multiplication congruence, and indexed inverse laws for witnesses* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$*, every displayed* $x, y, u, v : \mathsf{BHist}$ *satisfies both one-sided affine classifier clauses:*

$$\mathsf{add}(\mathsf{mul}(a, x), u)\mathsf{hsameadd}(\mathsf{mul}(a, y), u) \iff x\mathsf{hsame}y$$

and

$$\mathsf{add}(\mathsf{mul}(x, b), v)\mathsf{hsameadd}(\mathsf{mul}(y, b), v) \iff x\mathsf{hsame}y.$$

Proof. For the left-affine clause, the forward direction first cancels the common additive offset u. The additive group laws and addition congruence instantiate Theorem 41.116, giving $\mathsf{mul}(a, x)\mathsf{hsamemul}(a, y)$. Apply the left-factor cancellation clause of Theorem 45.242 with the witness p_a to obtain $x\mathsf{hsame}y$.

For the reverse direction of the left-affine clause, assume $x\mathsf{hsame}y$. Multiplication congruence transports this equality through left multiplication by a, and addition congruence with the shared offset u gives the displayed left-affine equality.

For the right-affine clause, the forward direction again cancels the common additive offset, now v, by Theorem 41.116. The cancelled equation is $\mathsf{mul}(x, b)\mathsf{hsamemul}(y, b)$, and the right-factor cancellation clause of Theorem 45.242 with witness p_b yields $x\mathsf{hsame}y$.

For the reverse direction of the right-affine clause, assume $x\mathsf{hsame}y$. Multiplication congruence transports the equality through right multiplication by b, and addition congruence with the shared offset v gives the displayed right-affine equality. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine one sided map classifier exact from apartness`

Theorem 45.276 (Field affine left equation solutions are unique from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with operations* $\mathsf{add}, \mathsf{mul}, \mathsf{neg}, \mathsf{zero}, \mathsf{one}$ *on* BHist*, additive group laws for* $\mathsf{add}, \mathsf{neg}, \mathsf{zero}$*, addition congruence, multiplication associativity, left and right multiplicative identity laws, multiplication congruence, and indexed inverse laws, every* $a, x, y, d, c : \mathsf{BHist}$ *and witness* $p_a : \mathsf{NonZero}_F(a)$ *satisfy*

$$\mathsf{add}(\mathsf{mul}(a, x), d)\mathsf{hsame}c \implies \mathsf{add}(\mathsf{mul}(a, y), d)\mathsf{hsame}c \implies x\mathsf{hsame}y.$$

Proof. Assume the two displayed affine equations. Compose the first equation with the symmetry of the second, obtaining equality of the two affine outputs with the same left factor and offset. The left clause of Definition 45.275 removes that shared affine map and yields $x\mathsf{hsame}y$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine left equation solution unique from apartness`

Affine one-sided multiplication certificate. Traditional target: one-sided affine injectivity. BEDC source: $\mathsf{Field}^{\uparrow}$ plus additive group laws. Carrier choice: BHist. Classifier choice: hsame. Stability obligations: additive cancellation, multiplication associativity, multiplicative unit laws, multiplication congruence, and indexed inverse laws. Ledger: the single nonzero witness for the active factor and the additive offset. Core theorem list entry: one-sided affine map classifier exactness from apartness and affine left-equation uniqueness from apartness. Exactness predicate: reflection and preservation of the affine classifier. Standard bridge: deferred conservative bridge. Status: left and right equation exactness clauses CheckedCert; one-sided classifier clause CheckedCert; left-equation uniqueness clause CheckedCert.

Per-object certificate: this is a traditional target for affine left and right field equation solving. BEDC source: $\mathsf{Field}^{\uparrow}$ plus additive group laws. Carrier: BHist. Classifier: hsame. Ledger: the nonzero witnesses $p_a : \mathsf{NonZero}_F(a)$ and $p_b : \mathsf{NonZero}_F(b)$ with their additive offsets. Stability obligations: additive cancellation, multiplication associativity, multiplicative unit laws, multiplication congruence, and indexed inverse laws. Status: CheckedCert.

Theorem 45.277 (Field affine two-sided multiplication equation exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with operations* $\mathsf{add}, \mathsf{mul}, \mathsf{neg}, \mathsf{zero}, \mathsf{one}$ *on* BHist*, additive abelian-group laws for* $\mathsf{add}, \mathsf{neg}, \mathsf{zero}$*, addition congruence, multiplication associativity, left and right*

multiplicative identity laws, multiplication congruence, and indexed inverse laws for witnesses $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$*, every* $x, d, c : \mathsf{BHist}$ *satisfies*

$$\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)\mathsf{hsame}c \iff x\mathsf{hsamemul}(\mathsf{inv}(a, p_a), \mathsf{mul}(\mathsf{add}(c, \mathsf{neg}(d)), \mathsf{inv}(b, p_b))).$$

Proof. For the forward direction, transport $\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)\mathsf{hsame}c$ through right addition by $\mathsf{neg}(d)$. Addition congruence gives equality between the offset equation after adding $\mathsf{neg}(d)$ on the right and $\mathsf{add}(c, \mathsf{neg}(d))$.

Associativity, the additive inverse law for d, and the additive identity law collapse the left side to $\mathsf{mul}(\mathsf{mul}(a, x), b)$. Apply Theorem 45.233 to obtain the displayed solution with middle right side $\mathsf{add}(c, \mathsf{neg}(d))$.

For the reverse direction, apply the reverse implication of Theorem 45.233 to the assumed displayed solution. This gives $\mathsf{mul}(\mathsf{mul}(a, x), b)\mathsf{hsameadd}(c, \mathsf{neg}(d))$.

Add d on the right and use addition congruence. Associativity, additive commutativity for the middle pair when needed, the additive inverse law for d, and the additive identity law collapse $\mathsf{add}(\mathsf{add}(c, \mathsf{neg}(d)), d)$ back to c. This yields $\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)\mathsf{hsame}c$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine two sided equation exact from apartness`

Theorem 45.278 (Field two-sided affine map classifier exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with operations* $\mathsf{add}, \mathsf{mul}, \mathsf{neg}, \mathsf{zero}, \mathsf{one}$ *on* BHist*, additive group laws for* $\mathsf{add}, \mathsf{neg}, \mathsf{zero}$*, addition congruence, multiplication associativity, left and right multiplicative identity laws, multiplication congruence, and indexed inverse laws for witnesses* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$*, every* $x, y, d : \mathsf{BHist}$ *satisfies*

$$\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)\mathsf{hsameadd}(\mathsf{mul}(\mathsf{mul}(a, y), b), d) \iff x\mathsf{hsame}y.$$

Proof. For the forward direction, first cancel the common additive right summand d. The additive group laws and addition congruence instantiate `BEDC.Derived.GroupUp.group_right_cancel` for add, giving

$$\mathsf{mul}(\mathsf{mul}(a, x), b)\mathsf{hsamemul}(\mathsf{mul}(a, y), b).$$

Apply the forward direction of `BEDC.Derived.FieldUp.field_two_sided_mul_exact_from_apartness` with the nonzero witnesses p_a and p_b. The multiplicative exactness theorem removes the outer left factor a and right factor b from the cancelled equation, yielding $x\mathsf{hsame}y$.

For the reverse direction, assume $x\mathsf{hsame}y$. Multiplication congruence first transports this equality through left multiplication by a, giving $\mathsf{mul}(a, x)\mathsf{hsamemul}(a, y)$.

Apply multiplication congruence again on the right by b to obtain $\mathsf{mul}(\mathsf{mul}(a, x), b)\mathsf{hsamemul}(\mathsf{mul}(a, y), b)$. Addition congruence with the shared offset d then yields the displayed affine equality. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine two sided map classifier exact from apartness`
↪ variant `BEDC.Derived.FieldUp.field affine two sided empty zero map classifier exact from apartness`

Theorem 45.279 (Field affine identity endpoint)**.** *For a BEDC history-level field candidate with additive right identity at* e *and multiplicative left and right identity at* one*, every* $x : \mathsf{BHist}$ *satisfies*

$$\mathsf{add}(\mathsf{mul}(\mathsf{mul}(\mathsf{one}, x), \mathsf{one}), \mathsf{e})\mathsf{hsame}x.$$

Proof. First use additive right identity to remove the displayed e offset. Then use multiplicative right identity to remove the final factor one, and multiplicative left identity to remove the leading factor. The three hsame steps compose by transitivity. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine identity endpoint`

Theorem 45.280 (Field affine identity classifier)**.** *Under the same identity laws, the identity affine endpoint preserves the history classifier:*

$$x\mathsf{hsame}y \Longrightarrow \mathsf{add}(\mathsf{mul}(\mathsf{mul}(\mathsf{one}, x), \mathsf{one}), \mathsf{e})\mathsf{hsameadd}(\mathsf{mul}(\mathsf{mul}(\mathsf{one}, y), \mathsf{one}), \mathsf{e}).$$

Proof. Apply the endpoint identity theorem to the left endpoint and to the right endpoint. Transitivity bridges the left affine endpoint to x, then uses the assumed classifier $x\mathsf{hsame}y$, and finally uses symmetry of the right endpoint identity to reach the displayed affine endpoint over y. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine identity classifier`

Theorem 45.281 (Field affine identity classifier iff)**.** *Under the same identity laws, the identity affine endpoint reflects and preserves the history classifier:*

$$\mathsf{add}(\mathsf{mul}(\mathsf{mul}(\mathsf{one}, x), \mathsf{one}), \mathsf{e})\mathsf{hsameadd}(\mathsf{mul}(\mathsf{mul}(\mathsf{one}, y), \mathsf{one}), \mathsf{e}) \Longleftrightarrow x\mathsf{hsame}y.$$

Proof. The forward direction composes the symmetry of the left endpoint identity, the displayed affine classifier, and the right endpoint identity. The reverse direction is exactly the identity classifier preservation theorem. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine identity classifier iff`

Affine two-sided multiplication certificate. Traditional target: affine field equation solving. BEDC source: $\mathsf{Field}^{\uparrow}$ plus additive group laws. Carrier choice: BHist. Classifier choice: hsame. Stability obligations: additive cancellation, multiplication associativity, multiplicative unit laws, multiplication congruence, and indexed inverse laws. Ledger: both nonzero witnesses and the additive offset. Core theorem list entry: two-sided affine equation exactness and two-sided affine map classifier exactness. Exactness predicate: equivalence between the equation and displayed solution, together with preservation and reflection of the affine classifier. Standard bridge: deferred conservative bridge. Status: ProofTarget.

45.7 Product factor equation exactness

Theorem 45.282 (Field product right-multiplication equation exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, multiplication associativity, left and right unit laws, multiplication congruence under* hsame*, and left and right inverse laws indexed by nonzero witnesses, explicit witnesses* $p_{ab} : \mathsf{NonZero}_F(\mathsf{mul}(a, b))$*,* $p_a : \mathsf{NonZero}_F(a)$*, and* $p_b : \mathsf{NonZero}_F(b)$ *make every* $x, c : \mathsf{BHist}$ *satisfy*

$$\mathsf{mul}(x, \mathsf{mul}(a, b))\mathsf{hsame}c \Longleftrightarrow x\mathsf{hsamemul}(c, \mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a))).$$

Traditional target product-factor right equation solving; BEDC source $\mathsf{Field}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability obligations right equation exactness, inverse product reversal, multiplication congruence, associativity and unit laws; ledger the three nonzero witnesses and the reversed inverse product; core theorem this block; exactness predicate the displayed equivalence.*

Proof. First apply Definition 45.224 to the active right factor $\mathsf{mul}(a, b)$ with witness p_{ab}. This gives the equivalence between the displayed equation and $x\mathsf{hsamemul}(c, \mathsf{inv}(\mathsf{mul}(a, b), p_{ab}))$.

Next apply Definition 45.213 with the three witnesses p_{ab}, p_a, and p_b. It identifies the certified inverse of the product with the reversed product $\mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a))$.

For the forward direction, use multiplication congruence on the right factor of $\mathsf{mul}(c, -)$ to transport the one-factor solution along the inverse product reversal. The transported right side is exactly the displayed reversed product solution.

For the reverse direction, use symmetry of the inverse product reversal and the same multiplication congruence to transport the displayed reversed product solution back to $x\mathsf{hsamemul}(c, \mathsf{inv}(\mathsf{mul}(a, b), p_{ab}))$. The reverse half of the one-factor exactness theorem then recovers $\mathsf{mul}(x, \mathsf{mul}(a, b))\mathsf{hsame}c$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field product right mul equation exact from apartness`

Theorem 45.283 (Field product right-multiplication empty equation exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, multiplication associativity, left and right unit laws, multiplication congruence under* hsame*, and left and right inverse laws indexed by nonzero witnesses, explicit witnesses* $p_{ab} : \mathsf{NonZero}_F(\mathsf{mul}(a, b))$*,* $p_a : \mathsf{NonZero}_F(a)$*, and* $p_b : \mathsf{NonZero}_F(b)$ *make every* $x : \mathsf{BHist}$ *satisfy*

$$\mathsf{mul}(x, \mathsf{mul}(a, b))\mathsf{hsame}\mathsf{e} \iff x\mathsf{hsamemul}(\mathsf{e}, \mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a))).$$

Lean4 ✓ `BEDC.Derived.FieldUp.field product right mul empty equation exact from apartness`

Proof. Apply right-multiplication equation exactness to the active factor $\mathsf{mul}(a, b)$ at target e. This identifies the displayed equation with the solution using $\mathsf{inv}(\mathsf{mul}(a, b), p_{ab})$. Product inverse reversal identifies that inverse with $\mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a))$, and multiplication congruence transports the solution across the right factor of $\mathsf{mul}(\mathsf{e}, -)$ in both directions. □

Theorem 45.284 (Field product left-multiplication equation exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, multiplication associativity, left and right unit laws, multiplication congruence under* hsame*, and left and right inverse laws indexed by nonzero witnesses, explicit witnesses* $p_{ab} : \mathsf{NonZero}_F(\mathsf{mul}(a, b))$*,* $p_a : \mathsf{NonZero}_F(a)$*, and* $p_b : \mathsf{NonZero}_F(b)$ *make every* $x, c : \mathsf{BHist}$ *satisfy*

$$\mathsf{mul}(\mathsf{mul}(a, b), x)\mathsf{hsame}c \iff x\mathsf{hsamemul}(\mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a)), c).$$

Traditional target product-factor left equation solving; BEDC source $\mathsf{Field}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability obligations left equation exactness, inverse product reversal, multiplication congruence, associativity and unit laws; ledger the three nonzero witnesses and the reversed inverse product; core theorem this block; exactness predicate the displayed equivalence.*

Proof. First apply Definition 45.229 to the active left factor $\mathsf{mul}(a, b)$ with witness p_{ab}. This gives the equivalence between the displayed equation and $x\mathsf{hsamemul}(\mathsf{inv}(\mathsf{mul}(a, b), p_{ab}), c)$.

Next apply Definition 45.213 with the three witnesses p_{ab}, p_a, and p_b. It identifies the certified inverse of the product with the reversed product $\mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a))$.

For the forward direction, use multiplication congruence on the left factor of $\mathsf{mul}(-, c)$ to transport the one-factor solution along the inverse product reversal. The transported right side is exactly the displayed reversed product solution.

For the reverse direction, use symmetry of the inverse product reversal and the same multiplication congruence to transport the displayed reversed product solution back to $x\mathsf{hsamemul}(\mathsf{inv}(\mathsf{mul}(a, b), p_{ab}), c)$. The reverse half of the one-factor exactness theorem then recovers $\mathsf{mul}(\mathsf{mul}(a, b), x)\mathsf{hsame}c$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field product left mul equation exact from apartness`

Theorem 45.285 (Field product left-multiplication empty equation exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, multiplication associativity, left and right unit laws, multiplication congruence under* hsame*, and left and right inverse laws indexed by nonzero witnesses, explicit witnesses* $p_{ab} : \mathsf{NonZero}_F(\mathsf{mul}(a, b))$*,* $p_a : \mathsf{NonZero}_F(a)$*, and* $p_b : \mathsf{NonZero}_F(b)$ *make every* $x : \mathsf{BHist}$ *satisfy*

$$\mathsf{mul}(\mathsf{mul}(a, b), x)\mathsf{hsame}\mathsf{e} \iff x\mathsf{hsame}\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a)), \mathsf{e}).$$

Proof. Apply left-multiplication equation exactness to the active factor $\mathsf{mul}(a, b)$ at target e. Product inverse reversal identifies the certified inverse of that factor with the reversed product $\mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a))$, and multiplication congruence transports the solution across the left factor of $\mathsf{mul}(-, \mathsf{e})$ in both directions. □

Lean4 ✓ `BEDC.Derived.FieldUp.field product left mul empty equation exact from apartness`

Theorem 45.286 (Field empty-unit right multiplication cancellation from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate whose multiplicative unit is* e*, suppose multiplication is associative, has a right unit law at* e*, respects* hsame*, and has a right inverse law indexed by nonzero witnesses. For every nonzero witness* $p_b : \mathsf{NonZero}_F(b)$*,*

$$\mathsf{mul}(x, b)\mathsf{hsame}\mathsf{mul}(y, b) \implies x\mathsf{hsame}y.$$

Proof. Apply right-multiplication equation solving to the displayed product equality. It identifies x with $\mathsf{mul}(\mathsf{mul}(y, b), \mathsf{inv}(b, p_b))$. The right inverse cancellation theorem collapses this latter history to y, and transitivity of hsame gives the stated cancellation. □

Lean4 ✓ `BEDC.Derived.FieldUp.field empty unit right mul cancel from apartness`

Theorem 45.287 (Field empty-unit left multiplication cancellation from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate whose multiplicative unit is* e*, suppose multiplication is associative, has a left unit law at* e*, respects* hsame*, and has a left inverse law indexed by nonzero witnesses. For every nonzero witness* $p_a : \mathsf{NonZero}_F(a)$*,*

$$\mathsf{mul}(a, x)\mathsf{hsame}\mathsf{mul}(a, y) \implies x\mathsf{hsame}y.$$

Proof. Multiply the displayed product comparison on the left by $\mathsf{inv}(a, p_a)$ using multiplication congruence. The left inverse cancellation theorem identifies the transported left endpoint with x and the transported right endpoint with y. Symmetry on the first identification and transitivity through the transported comparison give $x\mathsf{hsame}y$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field empty unit left mul cancel from apartness`

Theorem 45.288 (Field product-factor map classifier exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, multiplication associativity, left and right unit laws, multiplication congruence under* hsame*, and left and right inverse laws indexed by nonzero witnesses, explicit witnesses* $p_{ab} : \mathsf{NonZero}_F(\mathsf{mul}(a, b))$*,* $p_a : \mathsf{NonZero}_F(a)$*, and* $p_b : \mathsf{NonZero}_F(b)$ *make every* $x, y : \mathsf{BHist}$ *satisfy both classifier clauses*

$$\mathsf{mul}(x, \mathsf{mul}(a, b))\mathsf{hsame}\mathsf{mul}(y, \mathsf{mul}(a, b)) \iff x\mathsf{hsame}y$$

and

$$\mathsf{mul}(\mathsf{mul}(a,b),x)\mathsf{hsamemul}(\mathsf{mul}(a,b),y) \iff x\mathsf{hsame}y.$$

Traditional target product-factor multiplication classifier exactness; BEDC source $\mathsf{Field}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability obligations product right and left equation exactness, multiplication congruence, symmetry, and transitivity; ledger the three nonzero witnesses; exactness predicate the two displayed equivalences.*

Proof. For the right-product forward direction, apply Definition 45.282 to the equation with target $\mathsf{mul}(y,\mathsf{mul}(a,b))$. This turns the given classifier equality into the solution endpoint determined by that target. Apply the same theorem to the reflexive equation for y at the same target, and compose the two solution endpoints by symmetry and transitivity to obtain $x\mathsf{hsame}y$.

For the reverse direction of the right-product clause, multiplication congruence transports $x\mathsf{hsame}y$ through the map $z \mapsto \mathsf{mul}(z,\mathsf{mul}(a,b))$, giving the displayed classifier equality.

The left-product forward direction is symmetric. Apply Definition 45.284 to the equation with target $\mathsf{mul}(\mathsf{mul}(a,b),y)$, compare it with the reflexive equation for y, and compose the resulting solution endpoints by symmetry and transitivity.

For the reverse direction of the left-product clause, multiplication congruence transports $x\mathsf{hsame}y$ through $z \mapsto \mathsf{mul}(\mathsf{mul}(a,b),z)$, which is exactly the left classifier equality. □

Theorem 45.289 (Field empty-unit conjugation equation exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate whose multiplicative unit is* e*, with proof-indexed inverses, multiplication associativity, left and right unit laws, multiplication congruence under* hsame*, and left and right inverse laws indexed by a nonzero witness* $p_a : \mathsf{NonZero}_F(a)$*, conjugation by a solves the middle equation exactly:*

$$\mathsf{hsame}(\mathsf{mul}(\mathsf{mul}(a,x),\mathsf{inv}(a,p_a)),b) \iff \mathsf{hsame}(x,\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(a,p_a),b),a)).$$

Proof. For the forward direction, multiply the displayed conjugation equation on the right by a. Reassociate to expose $\mathsf{mul}(\mathsf{inv}(a,p_a),a)$, collapse it by the indexed left inverse law, and use the right unit law to obtain $\mathsf{mul}(a,x)\mathsf{hsamemul}(b,a)$. Then multiply on the left by $\mathsf{inv}(a,p_a)$, reassociate, collapse the left inverse pair, and use the left unit law.

For the reverse direction, transport the displayed solved endpoint through left multiplication by a. Reassociate to expose $\mathsf{mul}(a,\mathsf{inv}(a,p_a))$, collapse it by the indexed right inverse law, and use the left unit law. A final right multiplication by $\mathsf{inv}(a,p_a)$, followed by reassociation, the indexed right inverse law, and the right unit law, recovers the original conjugation equation. □

Lean4 ✓ `BEDC.Derived.FieldUp.field empty unit conjugation equation exact from apartness`

Theorem 45.290 (Field empty-unit conjugation classifier exactness from apartness)**.** *Under the same empty-unit* $\mathsf{Field}^{\uparrow}$ *hypotheses and witness* $p_a : \mathsf{NonZero}_F(a)$*, conjugation by a preserves and reflects the* hsame *classifier:*

$$\mathsf{hsame}(\mathsf{mul}(\mathsf{mul}(a,x),\mathsf{inv}(a,p_a)),\mathsf{mul}(\mathsf{mul}(a,y),\mathsf{inv}(a,p_a))) \iff \mathsf{hsame}(x,y).$$

Proof. For the forward direction, apply Definition 45.289 to the displayed comparison with target $\mathsf{mul}(\mathsf{mul}(a,y),\mathsf{inv}(a,p_a))$. Apply the same equation exactness theorem to the reflexive equation for y at that target. The two solved endpoints compare by symmetry and transitivity of hsame.

For the reverse direction, multiplication congruence transports $x\mathsf{hsame}y$ through left multiplication by a and right multiplication by $\mathsf{inv}(a,p_a)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field empty unit conjugation classifier exact from apartness`

Theorem 45.291 (Field right product empty-context solution determinacy from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses and the displayed associativity, unit, congruence, and inverse laws, let* $p_{ab} : \mathsf{NonZero}_F(\mathsf{mul}(a,b))$*,* $p_a : \mathsf{NonZero}_F(a)$*, and* $p_b : \mathsf{NonZero}_F(b)$*. If* x *and* y *solve the same right product equation at the empty-context endpoint* $\mathsf{append}(\mathsf{e}, c)$*, then* $x\mathsf{hsame}y$*:*

$$\mathsf{mul}(x, \mathsf{mul}(a,b))\mathsf{hsameappend}(\mathsf{e}, c) \quad \textit{and} \quad \mathsf{mul}(y, \mathsf{mul}(a,b))\mathsf{hsameappend}(\mathsf{e}, c) \Rightarrow x\mathsf{hsame}y.$$

Proof. Apply the right product equation exactness theorem to both displayed equations at the shared endpoint $\mathsf{append}(\mathsf{e}, c)$. Both solutions are classified by the same explicit inverse-product endpoint, so symmetry and transitivity of hsame compare them. □

Lean4 ✓ `BEDC.Derived.FieldUp.field product right mul empty context solution deterministic from apartness`

Theorem 45.292 (Field left product empty-context solution determinacy from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses and the displayed associativity, unit, congruence, and inverse laws, let* $p_{ab} : \mathsf{NonZero}_F(\mathsf{mul}(a,b))$*,* $p_a : \mathsf{NonZero}_F(a)$*, and* $p_b : \mathsf{NonZero}_F(b)$*. If* x *and* y *solve the same left product equation at the empty-context endpoint* $\mathsf{append}(\mathsf{e}, c)$*, then* $x\mathsf{hsame}y$*:*

$$\mathsf{mul}(\mathsf{mul}(a,b), x)\mathsf{hsameappend}(\mathsf{e}, c) \quad \textit{and} \quad \mathsf{mul}(\mathsf{mul}(a,b), y)\mathsf{hsameappend}(\mathsf{e}, c) \Rightarrow x\mathsf{hsame}y.$$

Proof. Apply the left product equation exactness theorem to both displayed equations at the shared endpoint $\mathsf{append}(\mathsf{e}, c)$. The two solved endpoints are identical, and hsame symmetry and transitivity give $x\mathsf{hsame}y$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field product left mul empty context solution deterministic from apartness`

Theorem 45.293 (Field product-factor map empty-context classifier exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, multiplication associativity, left and right unit laws, multiplication congruence under* hsame*, and left and right inverse laws indexed by nonzero witnesses, explicit witnesses* $p_{ab} : \mathsf{NonZero}_F(\mathsf{mul}(a,b))$*,* $p_a : \mathsf{NonZero}_F(a)$*, and* $p_b : \mathsf{NonZero}_F(b)$ *make every* $x, y : \mathsf{BHist}$ *satisfy both empty-context classifier clauses*

$$\mathsf{mul}(x, \mathsf{mul}(a,b))\mathsf{hsameappend}(\mathsf{e}, \mathsf{mul}(y, \mathsf{mul}(a,b))) \iff x\mathsf{hsame}y$$

and

$$\mathsf{mul}(\mathsf{mul}(a,b), x)\mathsf{hsameappend}(\mathsf{e}, \mathsf{mul}(\mathsf{mul}(a,b), y)) \iff x\mathsf{hsame}y.$$

Proof. Apply the product right-multiplication equation exactness theorem with target $\mathsf{mul}(y, \mathsf{mul}(a,b))$ under the explicit empty continuation context. Applying the same exactness theorem to the reflexive endpoint for y gives the solver endpoint for y; transitivity and symmetry compare the two solver endpoints and yield $x\mathsf{hsame}y$. The reverse direction is multiplication congruence transported through the empty-context endpoint.

The left-product clause is identical, using the left-multiplication equation exactness theorem with target $\mathsf{mul}(\mathsf{mul}(a,b), y)$ under the same empty context. □

Lean4 ✓ `BEDC.Derived.FieldUp.field product factor map empty context classifier exact from apartness`

Theorem 45.294 (Field three-factor product equation exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with proof-indexed inverses, multiplication associativity, left and right unit laws, multiplication congruence under* hsame*, left and right inverse laws indexed by nonzero witnesses, product nonzero exclusion, and the apartness-to-nonzero conversion maps used in Definition 45.220, any witness*

$$p_{abc} : \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(a,b),c))$$

induces witnesses $p_a : \mathsf{NonZero}_F(a)$*,* $p_b : \mathsf{NonZero}_F(b)$*, and* $p_c : \mathsf{NonZero}_F(c)$ *such that every* $x, q : \mathsf{BHist}$ *satisfies*

$$\mathsf{mul}(x, \mathsf{mul}(\mathsf{mul}(a,b),c))\mathsf{hsame}q \iff x\mathsf{hsamemul}(q, \mathsf{mul}(\mathsf{inv}(c,p_c), \mathsf{mul}(\mathsf{inv}(b,p_b), \mathsf{inv}(a,p_a)))).$$

It also satisfies

$$\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a,b),c),x)\mathsf{hsame}q \iff x\mathsf{hsamemul}(\mathsf{mul}(\mathsf{inv}(c,p_c), \mathsf{mul}(\mathsf{inv}(b,p_b), \mathsf{inv}(a,p_a))), q).$$

Traditional target three-factor product equation solving; BEDC source $\mathsf{Field}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability obligations one-factor right and left equation exactness, three-factor inverse reversal, multiplication congruence, symmetry, and transitivity; ledger* p_{abc} *and the induced factor witnesses* p_a, p_b, p_c*; core theorem this block; exactness predicate the two displayed equivalences; standard bridge deferred; downstream use finite product equation solving for* $\mathsf{Field}^{\uparrow}$*.*

Proof. First apply Definition 45.224 to the active right factor $\mathsf{mul}(\mathsf{mul}(a,b),c)$ with witness p_{abc}. This gives the right-multiplication equation equivalence with the one-factor solution $x\mathsf{hsamemul}(q, \mathsf{inv}(\mathsf{mul}(\mathsf{mul}(a,b)$

Apply Definition 45.220 to p_{abc}. It produces the factor witnesses p_a, p_b, and p_c and identifies the indexed inverse of $\mathsf{mul}(\mathsf{mul}(a,b),c)$ with the reversed product $\mathsf{mul}(\mathsf{inv}(c,p_c), \mathsf{mul}(\mathsf{inv}(b,p_b), \mathsf{inv}(a,p_a)))$.

For the forward direction of the right equation, use multiplication congruence on the right factor of $\mathsf{mul}(q,-)$ to transport the one-factor solution along that inverse equality.

For the reverse direction of the right equation, use symmetry of the same inverse equality, the same congruence, and transitivity to return to the indexed-inverse solution before applying the reverse half of the one-factor exactness theorem.

The left equation is identical with the active factor on the left. Apply Definition 45.229 to $\mathsf{mul}(\mathsf{mul}(a,b),c)$ with witness p_{abc}, then transport the indexed inverse through the first factor of $\mathsf{mul}(-,q)$ by multiplication congruence.

Symmetry and transitivity give the reverse transport, and the reverse half of the one-factor left exactness theorem recovers $\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a,b),c),x)\mathsf{hsame}q$. □

Theorem 45.295 (Field four-factor product equation exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with proof-indexed inverses, multiplication associativity, left and right unit laws, multiplication congruence under* hsame*, and left and right inverse laws indexed by nonzero witnesses, product nonzero exclusion, and the conversion maps required by Definition 45.221, define*

$$P_4 := \mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a,b),c),d).$$

For any witness $p_{abcd} : \mathsf{NonZero}_F(P_4)$*, the four-factor inverse reversal theorem induces witnesses* $p_a : \mathsf{NonZero}_F(a)$*,* $p_b : \mathsf{NonZero}_F(b)$*,* $p_c : \mathsf{NonZero}_F(c)$*, and* $p_d : \mathsf{NonZero}_F(d)$*. Define the reversed inverse spine*

$$R_4 := \mathsf{mul}(\mathsf{inv}(d,p_d), \mathsf{mul}(\mathsf{inv}(c,p_c), \mathsf{mul}(\mathsf{inv}(b,p_b), \mathsf{inv}(a,p_a)))).$$

Then every $x, r : \mathsf{BHist}$ *satisfies both clauses*

$$\mathsf{mul}(x, P_4)\mathsf{hsame}r \iff x\mathsf{hsamemul}(r, R_4)$$

and

$$\mathsf{mul}(P_4, x)\mathsf{hsame}r \iff x\mathsf{hsamemul}(R_4, r).$$

Traditional target finite product equation solving; BEDC source $\mathsf{Field}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability obligations one-factor equation exactness, inverse-product reversal, congruence, associativity, unit laws, product nonzero exclusion, and conversion maps; ledger* p_{abcd}*, induced factor witnesses, and conversion maps; core theorem this block; exactness predicate the two displayed equivalences; standard bridge deferred; status* $\mathsf{ProofTarget}$*.*

Proof. Apply Definition 45.224 to the active fourfold right factor P_4 with witness p_{abcd}. This gives the right-multiplication equation in terms of the certified inverse $\mathsf{inv}(P_4, p_{abcd})$.

Invoke Definition 45.221 on p_{abcd} and the conversion maps. It produces the factor witnesses p_a, p_b, p_c, p_d and identifies $\mathsf{inv}(P_4, p_{abcd})$ with the displayed reversed spine R_4.

For the right equation, transport the solution side through multiplication congruence for $\mathsf{mul}(r, -)$. Symmetry and transitivity of hsame move between the certified inverse of the active product and R_4, yielding $x\mathsf{hsamemul}(r, R_4)$ in the forward direction and returning to the one-factor exactness statement in the reverse direction.

For the left equation, apply Definition 45.229 to the active left factor P_4 with witness p_{abcd}. This gives the left equation in terms of $\mathsf{inv}(P_4, p_{abcd})$ on the left of r.

Use the same inverse identification and multiplication congruence for $\mathsf{mul}(-, r)$. The identified spine now appears on the left, so the transported solution is $x\mathsf{hsamemul}(R_4, r)$, and the reverse transport recovers $\mathsf{mul}(P_4, x)\mathsf{hsame}r$. □

Theorem 45.296 (Field five-factor product equation exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with proof-indexed inverses, multiplication associativity, left and right unit laws, multiplication congruence under* hsame*, indexed left and right inverse laws, product nonzero exclusion, and the conversion maps required by Definition 45.574, define*

$$P_5 := \mathsf{mul}(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a, b), c), d), e).$$

For any witness $p_{abcde} : \mathsf{NonZero}_F(P_5)$*, the five-factor inverse reversal theorem induces witnesses* $p_a : \mathsf{NonZero}_F(a)$*,* $p_b : \mathsf{NonZero}_F(b)$*,* $p_c : \mathsf{NonZero}_F(c)$*,* $p_d : \mathsf{NonZero}_F(d)$*, and* $p_e : \mathsf{NonZero}_F(e)$*. Define*

$$R_5 := \mathsf{mul}(\mathsf{inv}(e, p_e), \mathsf{mul}(\mathsf{inv}(d, p_d), \mathsf{mul}(\mathsf{inv}(c, p_c), \mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a))))).$$

Then every $x, r : \mathsf{BHist}$ *satisfies both clauses*

$$\mathsf{mul}(x, P_5)\mathsf{hsame}r \iff x\mathsf{hsamemul}(r, R_5)$$

and

$$\mathsf{mul}(P_5, x)\mathsf{hsame}r \iff x\mathsf{hsamemul}(R_5, r).$$

Traditional target finite five-factor product equation solving; BEDC source $\mathsf{Field}^{\uparrow}$ *over* BHist*; carrier* BHist*; classifier* hsame*; stability obligations one-factor right and left equation exactness, five-factor inverse reversal, multiplication congruence, symmetry, and transitivity; ledger* p_{abcde} *and the induced witnesses* p_a, p_b, p_c, p_d, p_e*; core theorem this block; exactness predicate the two displayed equivalences; standard bridge deferred; status* $\mathsf{ProofTarget}$*.*

Proof. First apply Definition 45.224 to the active right factor P_5 with witness p_{abcde}. This gives the right equation equivalence with the one-factor solution $x\mathsf{hsamemul}(r, \mathsf{inv}(P_5, p_{abcde}))$.

Next apply Definition 45.574 to p_{abcde}. It produces the factor witnesses p_a, p_b, p_c, p_d, and p_e and identifies the indexed inverse of P_5 with the displayed reversed spine R_5.

For the forward direction of the right equation, use multiplication congruence on the right factor of $\mathsf{mul}(r, -)$ to transport the one-factor solution from $\mathsf{inv}(P_5, p_{abcde})$ to R_5.

For the reverse direction of the right equation, use symmetry of the same inverse identification, the same congruence, and transitivity of hsame to return to the indexed-inverse solution before applying the reverse half of the one-factor right exactness theorem.

For the left equation, apply Definition 45.229 to the active left factor P_5 with witness p_{abcde}. This gives the left equation equivalence with $x\mathsf{hsamemul}(\mathsf{inv}(P_5, p_{abcde}), r)$.

Transport this solution through multiplication congruence for $\mathsf{mul}(-, r)$ and the five-factor inverse identification. Symmetry and transitivity give the reverse transport, so the reverse half of the one-factor left exactness theorem recovers $\mathsf{mul}(P_5, x)\mathsf{hsame}r$. □

Theorem 45.297 (Field equal-squares signed factors cannot both be nonzero)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with the hypotheses of Definition 45.272 and Definition 45.248, every* $a, b : \mathsf{BHist}$ *satisfies*

$$a \cdot a\mathsf{hsame}b \cdot b \quad \Longrightarrow \quad \mathsf{NonZero}_F(a + b) \to \mathsf{NonZero}_F(a + (-b)) \to \mathsf{False}.$$

The traditional target is constructive signed-factor square reasoning; the BEDC source is $\mathsf{Field}^{\uparrow}$ *together with* $\mathsf{CommRing}^{\uparrow}$*; the carrier is* BHist*; the classifier is* hsame*; the ledger consists of the two explicit signed-factor nonzero witnesses; the core theorem is this block; the exactness predicate is impossibility of simultaneous nonzero signed factors under equal squares; the status is* $\mathsf{CheckedCert}$*.*

Proof. Assume $a \cdot a\mathsf{hsame}b \cdot b$ and witnesses $p_+ : \mathsf{NonZero}_F(a + b)$ and $p_- : \mathsf{NonZero}_F(a + (-b))$.

First apply Definition 44.47 to the square equality. The signed-factor product is classified as zero:

$$(a + b) \cdot (a + (-b))\mathsf{hsame}0.$$

Now apply Definition 45.248 to the two nonzero witnesses p_+ and p_- together with this displayed zero product. That theorem says that such a zero product is impossible when both factors are explicitly nonzero, so the assumed pair of signed-factor witnesses yields False. □

Lean4 ✓ `BEDC.Derived.FieldUp.field equal squares signed factors not both nonzero`

Theorem 45.298 (Field affine two-sided equation solutions are unique from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with operations* $\mathsf{add}, \mathsf{mul}, \mathsf{neg}, \mathsf{zero}, \mathsf{one}$ *on* BHist*, additive group laws for* $\mathsf{add}, \mathsf{neg}, \mathsf{zero}$*, addition congruence, multiplication associativity, left and right multiplicative identity laws, multiplication congruence, and indexed inverse laws, every* $a, b, x, y, d, c : \mathsf{BHist}$ *and witnesses* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$ *satisfy*

$$\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)\mathsf{hsame}c \quad \Longrightarrow \quad \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, y), b), d)\mathsf{hsame}c \quad \Longrightarrow \quad x\mathsf{hsame}y.$$

Proof. Assume the two displayed affine equations. Use symmetry of the second equation and transitivity of hsame to compose the first equation with it. This gives the classifier equality between the two affine outputs:

$$\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)\mathsf{hsame}\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, y), b), d).$$

Apply Definition 45.278 with the same certified nonzero factors p_a, p_b and offset d. The affine classifier exactness theorem removes the shared affine map and yields $x\mathsf{hsame}y$. □

↪variant BEDC.Derived.FieldUp.field affine certified fiber singleton

Per-object certificate: Traditional target: affine equation uniqueness. BEDC source: $\mathsf{Field}^{\uparrow}$ over BHist plus additive group laws. Carrier choice: BHist. Classifier choice: hsame. Stability obligations: the operations and laws required by affine two-sided injectivity. Ledger: the two certified factors and offset. Core theorem list entry: Theorem 45.298. Exactness predicate: two certified solutions of the same affine equation are classified equal. Standard bridge and downstream use: canonical solution extraction for FieldUp equation solving. Status: $\mathsf{CheckedCert}$.

45.8 Signed square-factor consequences

Theorem 45.299 (Field equal-squares signed factor endpoint collapse)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with the hypotheses of Definition 45.272, together with the additive associativity, additive right identity, addition congruence, and additive right-inverse laws needed to instantiate Definition 41.116 for* add*, every* $a, b : \mathsf{BHist}$ *with* $a \cdot a\mathsf{hsame}b \cdot b$ *satisfies the two endpoint clauses:*

1. *if* $p_+ : \mathsf{NonZero}_F(a + b)$*, then* $a\mathsf{hsame}b$*;*
2. *if* $p_- : \mathsf{NonZero}_F(a + (-b))$*, then* $a\mathsf{hsame} - b$*.*

Traditional target signed square-root ambiguity; BEDC source $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow} + \mathsf{Group}^{\uparrow}$*; carrier* BHist*; classifier* hsame*; operations* $\mathsf{add}, \mathsf{mul}, \mathsf{neg}, 0, 1$*; stability obligations signed-factor exclusion and additive right cancellation; ledger the chosen signed-factor nonzero witness; core theorem this block; exactness predicate endpoint collapse under a certified signed factor; status* $\mathsf{ProofTarget}$*.*

Proof. Assume $a \cdot a\mathsf{hsame}b \cdot b$.

For the $p_+ : \mathsf{NonZero}_F(a + b)$ branch, apply Definition 45.272 to the square equality and the witness p_+. The first signed-factor clause gives $a + (-b)\mathsf{hsame}0$.

The additive right-inverse law also gives $b + (-b)\mathsf{hsame}0$. By symmetry and transitivity of hsame, the two displayed sums are classified together:

$$a + (-b)\mathsf{hsame}b + (-b).$$

Now instantiate Definition 41.116 for the additive group operation add. Cancelling the common right summand $-b$ yields $a\mathsf{hsame}b$.

For the $p_- : \mathsf{NonZero}_F(a + (-b))$ branch, apply Definition 45.272 to the same square equality and the witness p_-. The second signed-factor clause gives $a + b\mathsf{hsame}0$.

The additive left-inverse law gives $(-b) + b\mathsf{hsame}0$. Comparing this equality with $a + b\mathsf{hsame}0$ and using symmetry and transitivity of hsame yields

$$a + b\mathsf{hsame}(-b) + b.$$

A second instance of additive right cancellation removes the common right summand b, leaving $a\mathsf{hsame} - b$. □

Lean4 ✓ BEDC.Derived.FieldUp.field equal squares signed factor endpoint collapse

Theorem 45.300 (Field equal-squares signed branch determinacy)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with the joint hypotheses needed to instantiate Definition 45.299 and Definition 45.297, every* $a, b : \mathsf{BHist}$ *with*

$$a \cdot a\mathsf{hsame}b \cdot b$$

satisfies the two deterministic signed-branch clauses:

1. *if* $p_+ : \mathsf{NonZero}_F(a+b)$*, then* $a\mathsf{hsame}b$ *and* $\mathsf{NonZero}_F(a+(-b)) \to \mathsf{False}$*;*

2. *if* $p_- : \mathsf{NonZero}_F(a+(-b))$*, then* $a\mathsf{hsame} - b$ *and* $\mathsf{NonZero}_F(a+b) \to \mathsf{False}$*.*

Traditional target signed square-root branch choice; BEDC source $\mathsf{Field}^{\uparrow}$ *with the signed-factor and additive-cancellation hypotheses; carrier* BHist*; classifier* hsame*; ledger the chosen signed-factor witness; core theorem this block; exactness predicate endpoint identification together with exclusion of the opposite signed witness; status* $\mathsf{ProofTarget}$*.*

Proof. Assume $a \cdot a\mathsf{hsame}b \cdot b$.

For the $p_+ : \mathsf{NonZero}_F(a+b)$ branch, apply Definition 45.299 to the square equality and the witness p_+. Its positive signed-factor endpoint clause gives $a\mathsf{hsame}b$.

To exclude the opposite witness, assume $q_- : \mathsf{NonZero}_F(a+(-b))$. Apply Definition 45.297 to the same square equality, the chosen witness p_+, and the hypothetical witness q_-. The result is False, so the positive branch carries both the endpoint and the opposite-witness contradiction.

For the $p_- : \mathsf{NonZero}_F(a+(-b))$ branch, apply Definition 45.299 to the square equality and the witness p_-. Its negative signed-factor endpoint clause gives $a\mathsf{hsame} - b$.

To exclude the opposite witness, assume $q_+ : \mathsf{NonZero}_F(a+b)$. Apply Definition 45.297 to the same square equality, the witness q_+, and the chosen witness p_-. This produces False and completes the negative branch package. □

Lean4 ✓ `BEDC.Derived.FieldUp.field equal squares signed branch determinacy`

Theorem 45.301 (Field zero linear factor signed branch selection)**.** *For BEDC history operations add, mul, neg, and zero satisfying the hypotheses of Definition 44.80 and Definition 45.300, every* $a, b : \mathsf{BHist}$ *satisfies the following two signed zero-factor clauses:*

1. *if* $(a+(-b))\mathsf{hsame}0$ *and* $p_+ : \mathsf{NonZero}_F(a+b)$*, then* $a\mathsf{hsame}b$ *and* $\mathsf{NonZero}_F(a+(-b)) \to \mathsf{False}$*;*

2. *if* $(a+b)\mathsf{hsame}0$ *and* $p_- : \mathsf{NonZero}_F(a+(-b))$*, then* $a\mathsf{hsame} - b$ *and* $\mathsf{NonZero}_F(a+b) \to \mathsf{False}$*.*

Proof. Assume first the zero factor $(a+(-b))\mathsf{hsame}0$ and the signed nonzero witness $p_+ : \mathsf{NonZero}_F(a+b)$. Apply Definition 44.80 to the displayed right signed zero factor, read as the second disjunct. This gives the equal square row $a \cdot a\mathsf{hsame}b \cdot b$.

Now apply the positive branch of Definition 45.300 to that square row and the witness p_+. Its conclusion is exactly $a\mathsf{hsame}b$ together with $\mathsf{NonZero}_F(a+(-b)) \to \mathsf{False}$.

For the opposite branch, assume the zero factor $(a+b)\mathsf{hsame}0$ and the signed nonzero witness $p_- : \mathsf{NonZero}_F(a+(-b))$. Apply Definition 44.80 to the displayed left signed zero factor, read as the first disjunct. This again gives $a \cdot a\mathsf{hsame}b \cdot b$.

The negative branch of Definition 45.300, applied to this square row and to p_-, gives $a\mathsf{hsame} - b$ and excludes every witness $\mathsf{NonZero}_F(a+b)$. □

Theorem 45.302 (Field zero linear factor signed endpoint package)**.** *For BEDC history operations add, mul, neg, and zero satisfying the hypotheses of Definition 44.80 and Definition 45.300, every* $a, b : \mathsf{BHist}$ *satisfies the following two signed endpoint clauses:*

1. *if* $(a+(-b))\mathsf{hsame}0$ *and* $p_+ : \mathsf{NonZero}_F(a+b)$*, then simultaneously* $a \cdot a\mathsf{hsame}b \cdot b$*,* $a\mathsf{hsame}b$*, and* $\mathsf{NonZero}_F(a+(-b)) \to \mathsf{False}$*;*

2. *if* $(a+b)\mathsf{hsame}0$ *and* $p_- : \mathsf{NonZero}_F(a+(-b))$*, then simultaneously* $a \cdot a\mathsf{hsame}b \cdot b$*,* $a\mathsf{hsame} - b$*, and* $\mathsf{NonZero}_F(a+b) \to \mathsf{False}$*.*

Traditional target signed square-root endpoint package; BEDC source BHist *with* CommRing$^{\uparrow}$ *and* Field$^{\uparrow}$*; carrier* BHist*; classifier* hsame*; ledger the zero factor plus signed nonzero witness; core theorem this block; exactness predicate signed branch square row plus endpoint; downstream consumer* Field$^{\uparrow}$(RatUp) *affine solution and square-root branch ledgers; status* ProofTarget*.*

Proof. Assume first the zero factor $(a+(-b))\mathsf{hsame}0$ and the signed nonzero witness $p_+ : \mathsf{NonZero}_F(a+b)$. Apply Definition 44.80 to the displayed right signed zero factor, read as the second disjunct. This gives the square row

$$a \cdot a\mathsf{hsame}b \cdot b.$$

Apply the positive branch of Definition 45.300 to this square row and to p_+. It returns $a\mathsf{hsame}b$ together with $\mathsf{NonZero}_F(a + (-b)) \to \mathsf{False}$. Conjunction introduction packages the square row, the endpoint, and the opposite-witness exclusion.

For the negative signed endpoint, assume the zero factor $(a+b)\mathsf{hsame}0$ and the signed nonzero witness $p_- : \mathsf{NonZero}_F(a + (-b))$. Apply Definition 44.80 to the displayed left signed zero factor, read as the first disjunct. This again gives

$$a \cdot a\mathsf{hsame}b \cdot b.$$

Apply the negative branch of Definition 45.300 to the square row and to p_-. It returns $a\mathsf{hsame}-b$ and $\mathsf{NonZero}_F(a + b) \to \mathsf{False}$. A second conjunction introduction packages the square row, the signed endpoint, and the excluded opposite branch. □

Per-object template: traditional target constructive signed square-root branch selection; BEDC source Field$^{\uparrow}$ + CommRing$^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability obligations zero-linear-factor equal-square production and equal-square signed branch determinacy; ledger the zero factor and signed nonzero witness; core theorem this block; exactness predicate branch endpoint plus opposite-witness exclusion; downstream consumer Field$^{\uparrow}$(RatUp) affine solution and square-root branch ledgers; status ProofTarget.

Theorem 45.303 (Field product nonzero excludes zero factors)**.** *For a BEDC history-level* Field$^{\uparrow}$ *candidate with ring zero absorption, multiplication congruence, classifier transport of* $\mathsf{NonZero}_F$*, and contradiction of* $\mathsf{NonZero}_F(0)$*, every* $a, b : \mathsf{BHist}$ *with*

$$p_{ab} : \mathsf{NonZero}_F(\mathsf{mul}(a, b))$$

satisfies both $a\mathsf{hsame}0 \to \bot$ *and* $b\mathsf{hsame}0 \to \bot$*.*

Proof. Assume $a\mathsf{hsame}0$. Multiplication congruence sends $\mathsf{mul}(a, b)$ to $\mathsf{mul}(0, b)$, and Theorem 43.39 identifies $\mathsf{mul}(0, b)$ with 0. Transitivity gives $\mathsf{mul}(a, b)\mathsf{hsame}0$.

Transport $p_{ab} : \mathsf{NonZero}_F(\mathsf{mul}(a, b))$ along this classifier equality. The transport clause supplies $\mathsf{NonZero}_F(0)$, and the field zero-contradiction clause closes the left-factor obstruction.

The right-factor obstruction is symmetric. From $b\mathsf{hsame}0$, multiplication congruence sends $\mathsf{mul}(a, b)$ to $\mathsf{mul}(a, 0)$, and Theorem 43.39 identifies that product with 0. Transporting the same witness p_{ab} to $\mathsf{NonZero}_F(0)$ again contradicts the field zero clause. □

Lean4 ✓ `BEDC.Derived.FieldUp.field product nonzero excludes zero factors`

Corollary 45.304 (Field product nonzero empty-factor contradiction)**.** *Under the same* Field$^{\uparrow}$ *and* Ring$^{\uparrow}$ *hypotheses as Definition 45.303, a proof* $p_{ab} : \mathsf{NonZero}_F(\mathsf{mul}(a, b))$ *determines the pair* $(a\mathsf{hsame}0 \to \bot) \wedge (b\mathsf{hsame}0 \to \bot)$*.*

Proof. Apply Definition 45.303 to p_{ab}. Its two components are exactly the left-factor and right-factor contradictions against zero. □

Lean4 ✓ `BEDC.Derived.FieldUp.field product nonzero empty factors absurd`

Theorem 45.305 (Field product nonzero of nonzero factors)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with the hypotheses of Definition 45.248, assume also a constructive bridge family: for every* $t : \mathsf{BHist}$*, an instance*

$$\alpha_t : (t\mathsf{hsame0} \to \bot) \to \mathsf{NonZero}_F(t)$$

from apartness from zero into the nonzero classifier. Then witnesses $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$ *determine*

$$\mathsf{NonZero}_F(\mathsf{mul}(a, b)).$$

Proof. Theorem 45.248 turns p_a and p_b into a constructive refutation of $\mathsf{mul}(a, b)\mathsf{hsame0}$. Applying the bridge-family instance at $\mathsf{mul}(a, b)$ to this product apartness gives the displayed product nonzero witness. □

Lean4 ✓ `BEDC.Derived.FieldUp.field product nonzero of nonzero factors`

Theorem 45.306 (Field binary product nonzero iff factors)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate under the hypotheses of Definition 45.303 and Definition 45.305, assume also the same constructive bridge family: for every* $t : \mathsf{BHist}$*, an instance*

$$\alpha_t : (t\mathsf{hsame0} \to \bot) \to \mathsf{NonZero}_F(t).$$

Then every $a, b : \mathsf{BHist}$ *satisfies*

$$\mathsf{NonZero}_F(\mathsf{mul}(a, b)) \iff (\mathsf{NonZero}_F(a) \wedge \mathsf{NonZero}_F(b)).$$

Proof. For the forward direction, let $p_{ab} : \mathsf{NonZero}_F(\mathsf{mul}(a, b))$. Apply Definition 45.303 to obtain $a\mathsf{hsame0} \to \bot$ and $b\mathsf{hsame0} \to \bot$. Applying α_a and α_b gives $\mathsf{NonZero}_F(a)$ and $\mathsf{NonZero}_F(b)$.

For the reverse direction, let $p_a : \mathsf{NonZero}_F(a)$ and $p_b : \mathsf{NonZero}_F(b)$. Apply Definition 45.305 to p_a and p_b, using the same bridge family at $\mathsf{mul}(a, b)$, to obtain $\mathsf{NonZero}_F(\mathsf{mul}(a, b))$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field binary product nonzero iff factors`

Per-object certificate: Traditional target: binary product nonzero exactness. BEDC source: $\mathsf{Field}^{\uparrow}$ plus the constructive zero-apartness bridge. Carrier choice: BHist. Classifier choice: $\mathsf{NonZero}_F$. Stability obligations: zero-factor exclusion and nonzero-product construction. Ledger: factors a, b and product $\mathsf{mul}(a, b)$. Core theorem list: Theorem 45.306. Exactness predicate: binary nonzero product exactly matches the pair of factor nonzero classifiers. Standard bridge: the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ product classifier/nonzero exit package. Status: ProofTarget.

Per-object certificate: Traditional target: certified nonzero product prevents zero factors. BEDC source: $\mathsf{Field}^{\uparrow}$ plus $\mathsf{Ring}^{\uparrow}$ zero absorption. Carrier choice: BHist. Classifier choice: hsame. Stability obligations: zero absorption, multiplication congruence, $\mathsf{NonZero}_F$ transport, and contradiction of $\mathsf{NonZero}_F(0)$. Ledger: product witness $p_{ab} : \mathsf{NonZero}_F(\mathsf{mul}(a, b))$ and the tested zero-factor classifier. Core theorem list: left and right zero-factor exclusion from a certified nonzero product. Exactness predicate: nonzero-product obstruction to zero-factor classifiers. Standard bridge: deferred conservative bridge. Status: ProofTarget.

Theorem 45.307 (Field two-sided product nonzero excludes middle zero without outer apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with the hypotheses of Definition 45.303, together with the ring zero-absorption and multiplication-congruence fields used there, every* $a, b, x : \mathsf{BHist}$ *with product witness*

$$p_{axb} : \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(a, x), b)),$$

satisfies $x\mathsf{hsame0} \to \bot$.

Proof. Assume $x\mathsf{hsame0}$. Multiplication congruence sends $\mathsf{mul}(a, x)$ to $\mathsf{mul}(a, 0)$, and Theorem 43.39 identifies $\mathsf{mul}(a, 0)$ with 0. Transitivity gives

$$\mathsf{mul}(a, x)\mathsf{hsame0}.$$

Apply Definition 45.303 to the product with left factor $\mathsf{mul}(a, x)$, right factor b, and witness p_{axb}. Its left zero-factor obstruction rejects the displayed classifier, so the assumed middle classifier $x\mathsf{hsame0}$ yields $\bot$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field two sided product nonzero excludes middle zero`

Per-object certificate: Traditional target: two-sided nonzero-product middle-factor obstruction. BEDC source: $\mathsf{Field}^{\uparrow}$ plus $\mathsf{Ring}^{\uparrow}$ zero absorption. Carrier choice: BHist. Classifier choice: hsame. Stability obligations: product zero-factor exclusion and ring zero absorption. Ledger: $p_{axb} : \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(a, x), b))$ and the tested middle-zero classifier. Core theorem list: Theorem 45.307. Exactness predicate: obstruction to middle zero. Standard bridge: deferred. Status: ProofTarget.

Theorem 45.308 (Field certified three-factor product excludes zero factors)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with the hypotheses of Definition 45.303, including the ring zero-absorption and multiplication congruence hypotheses used there, every* $a, x, b : \mathsf{BHist}$ *with*

$$p_{axb} : \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(a, x), b))$$

satisfies

$$(a\mathsf{hsame0} \to \bot) \wedge (x\mathsf{hsame0} \to \bot) \wedge (b\mathsf{hsame0} \to \bot).$$

Proof. Apply Definition 45.303 to the binary product $(\mathsf{mul}(a, x), b)$ and the witness p_{axb}. This gives an obstruction to $\mathsf{mul}(a, x)\mathsf{hsame0}$ and an obstruction to $b\mathsf{hsame0}$. The second obstruction is exactly the right-factor clause.

Assume $a\mathsf{hsame0}$. Multiplication congruence sends $\mathsf{mul}(a, x)$ to $\mathsf{mul}(0, x)$, and Definition 43.39 classifies $\mathsf{mul}(0, x)$ as 0. By transitivity, $\mathsf{mul}(a, x)\mathsf{hsame0}$, contradicting the first obstruction.

Assume $x\mathsf{hsame0}$. Multiplication congruence sends $\mathsf{mul}(a, x)$ to $\mathsf{mul}(a, 0)$, and Definition 43.39 classifies $\mathsf{mul}(a, 0)$ as 0. By transitivity, $\mathsf{mul}(a, x)\mathsf{hsame0}$ again contradicts the first obstruction. □

Lean4 ✓ `BEDC.Derived.FieldUp.field nested product nonzero excludes empty factors`

Per-object certificate: Traditional target: zero-factor exclusion for certified triple products. BEDC source: $\mathsf{Field}^{\uparrow}$ plus $\mathsf{Ring}^{\uparrow}$ zero absorption over BHist. Carrier choice: BHist. Classifier choice: hsame. Stability obligations: product nonzero transport and zero absorption. Ledger: p_{axb} and the tested zero classifier. Core theorem list: Theorem 45.308. Exactness predicate: no zero factor under a certified nonzero threefold product. Standard bridge: deferred. Status: ProofTarget.

Theorem 45.309 (Field two-sided product nonzero iff middle factor nonzero)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with the hypotheses of Definition 45.305 and Definition 45.307, assume certified outer witnesses* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$*. Then every* $x : \mathsf{BHist}$ *satisfies*

$$\mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(a, x), b)) \iff \mathsf{NonZero}_F(x).$$

Proof. For the forward direction, assume $p_{axb} : \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(a, x), b))$. Theorem 45.307 turns this witness into a refutation of $x\mathsf{hsame}0$. The apartness-to-nonzero bridge required by Definition 45.305 then gives $\mathsf{NonZero}_F(x)$.

For the reverse direction, assume $p_x : \mathsf{NonZero}_F(x)$. Apply Definition 45.305 to p_a and p_x to obtain $p_{ax} : \mathsf{NonZero}_F(\mathsf{mul}(a, x))$.

Apply the same product-closure theorem to p_{ax} and p_b. The resulting witness is exactly $\mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(a, x), b))$, completing the two-sided equivalence. □

Lean4 ✓ `BEDC.Derived.FieldUp.field two sided product nonzero middle factor iff`

Per-object certificate: Traditional target: exact middle-factor nonzero transport through certified two-sided products. BEDC source: $\mathsf{Field}^{\uparrow}$ plus $\mathsf{Ring}^{\uparrow}$ zero absorption. Carrier choice: BHist. Classifier choice: hsame. Stability obligations: nonzero transport, product closure, product zero-factor exclusion, and ring zero absorption. Ledger: outer certificates p_a, p_b, middle certificate p_x, intermediate product witness p_{ax}, and two-sided product witness p_{axb}. Core theorem list: Theorem 45.309. Exactness predicate: nonzero of the middle factor is equivalent to nonzero of the certified outer product. Downstream use: FieldUp exact nonzero propagation for affine and denominator-product reasoning. Status: ProofTarget.

Theorem 45.310 (Field certified four-factor product nonzero iff factors)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with the hypotheses of Definition 45.305 and the zero-factor exclusion hypotheses used in Definition 45.308, assume an apartness-to-nonzero bridge family: for every* $t : \mathsf{BHist}$*, an instance*

$$\alpha_t : (t\mathsf{hsame}0 \to \bot) \to \mathsf{NonZero}_F(t).$$

Then every $a, b, c, d : \mathsf{BHist}$ *satisfies*

$$\mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a, b), c), d)) \iff \mathsf{NonZero}_F(a) \wedge \mathsf{NonZero}_F(b) \wedge \mathsf{NonZero}_F(c) \wedge \mathsf{NonZero}_F(d).$$

Proof. For the forward direction, assume $p_{abcd} : \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a, b), c), d))$. Apply Definition 45.303 to the outer binary product. This gives apartness of $\mathsf{mul}(\mathsf{mul}(a, b), c)$ from 0 and apartness of d from 0. The bridge-family instances at $\mathsf{mul}(\mathsf{mul}(a, b), c)$ and d supply $p_{abc} : \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(a, b), c))$ and $\mathsf{NonZero}_F(d)$.

Apply the same zero-factor exclusion theorem to the left threefold product, viewed as the binary product $\mathsf{mul}(\mathsf{mul}(a, b), c)$ with witness p_{abc}. This gives apartness of $\mathsf{mul}(a, b)$ from 0 and apartness of c from 0. The bridge-family instances at $\mathsf{mul}(a, b)$ and c supply $p_{ab} : \mathsf{NonZero}_F(\mathsf{mul}(a, b))$ and $\mathsf{NonZero}_F(c)$.

Apply the binary zero-factor exclusion theorem once more to $\mathsf{mul}(a, b)$ with witness p_{ab}. The two resulting apartness witnesses are converted by the bridge-family instances at a and b into $\mathsf{NonZero}_F(a)$ and $\mathsf{NonZero}_F(b)$. Pair these four witnesses in the displayed order.

For the reverse direction, assume witnesses $p_a : \mathsf{NonZero}_F(a)$, $p_b : \mathsf{NonZero}_F(b)$, $p_c : \mathsf{NonZero}_F(c)$, and $p_d : \mathsf{NonZero}_F(d)$. Apply Definition 45.305 to p_a and p_b to obtain $p_{ab} : \mathsf{NonZero}_F(\mathsf{mul}(a, b))$.

Apply the product-closure theorem to p_{ab} and p_c to obtain $p_{abc} : \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(a, b), c))$. Applying it one final time to p_{abc} and p_d gives the displayed fourfold product nonzero witness. □

Per-object certificate: Traditional target: four-factor product nonzero exactness. BEDC source: $\mathsf{Field}^{\uparrow}$ plus $\mathsf{Ring}^{\uparrow}$ zero absorption. Carrier choice: BHist. Classifier choice: hsame. Ledger: factor witnesses p_a, p_b, p_c, p_d and intermediate product witnesses $p_{ab}, p_{abc}, p_{abcd}$. Core theorem list: Theorem 45.310. Exactness predicate:

$$\mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a,b),c),d)) \iff \mathsf{NonZero}_F(a) \wedge \mathsf{NonZero}_F(b) \wedge \mathsf{NonZero}_F(c) \wedge \mathsf{NonZero}_F(d).$$

Downstream use: four-factor product equation exactness and inverse-reversal proof targets. Status: ProofTarget.

Theorem 45.311 (Field nonzero product rigidity)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *satisfying the hypotheses of Definition 45.247, the classifier-transport and zero-contradiction rows of Definition 45.201, and the zero-apartness interface of Definition 45.249, let* $a, b : \mathsf{BHist}$ *be equipped with witnesses* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$*. If the product endpoint carries an apartness-to-nonzero conversion*

$$\alpha_{ab} : (\mathsf{mul}(a,b)\mathsf{hsame}0 \to \bot) \to \mathsf{NonZero}_F(\mathsf{mul}(a,b)),$$

then

$$\mathsf{NonZero}_F(\mathsf{mul}(a,b)).$$

Proof. It is enough to construct zero-apartness of the product endpoint. Assume $z : \mathsf{mul}(a,b)\mathsf{hsame}0$. Apply Definition 45.247 with the left-factor witness p_a. Its left-factor clause sends z to $b\mathsf{hsame}0$.

Transport $p_b : \mathsf{NonZero}_F(b)$ along this classifier equality by the nonzero-transport row of Definition 45.201. This gives $\mathsf{NonZero}_F(0)$, contradicting the zero-contradiction row of the same stability certificate. Hence $\mathsf{mul}(a,b)\mathsf{hsame}0 \to \bot$.

Applying the displayed conversion α_{ab} to this product apartness gives the required witness $\mathsf{NonZero}_F(\mathsf{mul}(a,b))$. □

Theorem 45.312 (Field certified five-factor product nonzero iff factors)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with the hypotheses of Definition 45.305 and the zero-factor exclusion hypotheses used in Definition 45.308, assume an apartness-to-nonzero bridge family: for every* $t : \mathsf{BHist}$*, an instance*

$$\alpha_t : (t\mathsf{hsame}0 \to \bot) \to \mathsf{NonZero}_F(t).$$

Then every $a, b, c, d, e : \mathsf{BHist}$ *satisfies*

$$\mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a,b),c),d),e)) \iff \mathsf{NonZero}_F(a) \wedge \mathsf{NonZero}_F(b) \wedge \mathsf{NonZero}_F(c) \wedge \mathsf{NonZero}_F(d) \wedge \mathsf{NonZero}$$

Proof. For the forward direction, assume $p_{abcde} : \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a,b),c),d),e))$. Apply Definition 45.303 to the outer binary product. This gives apartness of the fourfold prefix from 0 and apartness of e from 0.

Convert both apartness witnesses through the bridge family. The left conversion gives $p_{abcd} : \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a,b),c),d))$, and the right conversion gives $\mathsf{NonZero}_F(e)$.

Apply Definition 45.310 to p_{abcd}. It supplies the four factor witnesses for a, b, c, and d. Pair those witnesses with the converted witness for e in the displayed order.

For the reverse direction, assume witnesses $p_a : \mathsf{NonZero}_F(a)$, $p_b : \mathsf{NonZero}_F(b)$, $p_c : \mathsf{NonZero}_F(c)$, $p_d : \mathsf{NonZero}_F(d)$, and $p_e : \mathsf{NonZero}_F(e)$. Apply Definition 45.310 in the reverse direction to p_a, p_b, p_c, p_d and obtain $p_{abcd} : \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a,b),c),d))$.

Apply Definition 45.305 to p_{abcd} and p_e. The resulting witness is exactly the certified nonzero witness for the left-nested fivefold product. □

The associated ten-field per-object template is:

1. Traditional target: five-factor product nonzero exactness for a certified $\mathsf{Field}^{\uparrow}$ object.
2. BEDC source: $\mathsf{Field}^{\uparrow}$ over BHist together with $\mathsf{Ring}^{\uparrow}$ zero absorption, product nonzero construction, product zero-factor exclusion, and the apartness-to-nonzero bridge family.
3. Carrier: BHist.
4. Classifier: hsame with the derived predicate $\mathsf{NonZero}_F$.
5. Stability obligations: binary product nonzero closure, binary zero-factor exclusion, four-factor exactness, and bridge transport from apartness to nonzero.
6. Ledger: factor witnesses p_a, p_b, p_c, p_d, p_e, prefix witness p_{abcd}, and fivefold product witness p_{abcde}.
7. Core theorem list: Definition 45.312.
8. Exactness predicate: nonzero of the left-nested fivefold product is equivalent to the five displayed factor nonzero witnesses.
9. Downstream consumer: $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ five-factor product equation exactness and the associated phase-exit product rows.
10. Status: $\mathsf{ProofTarget}$.

45.9 Zero-apartness transport through certified products

Theorem 45.313 (Field two-sided multiplication preserves and reflects zero apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate satisfying the hypotheses of Definition 45.246, let*

$$\mathsf{ApartZero}_F(h) := (h\mathsf{hsame}0 \to \bot).$$

For any $a, b : \mathsf{BHist}$ *with outer witnesses* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$*, every* $x : \mathsf{BHist}$ *satisfies*

$$\mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(a, x), b)) \iff \mathsf{ApartZero}_F(x).$$

Proof. For the product-to-middle direction, assume $q : \mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(a, x), b))$ and then assume $x\mathsf{hsame}0$. The reverse direction of Definition 45.246, using the outer witnesses p_a and p_b, gives

$$\mathsf{mul}(\mathsf{mul}(a, x), b)\mathsf{hsame}0.$$

Applying q to this classifier equality gives $\bot$, so $\mathsf{ApartZero}_F(x)$ follows.

For the middle-to-product direction, assume $r : \mathsf{ApartZero}_F(x)$ and then assume $\mathsf{mul}(\mathsf{mul}(a, x), b)\mathsf{hsame}0$. The forward direction of Definition 45.246, with the same outer witnesses, gives $x\mathsf{hsame}0$. Applying r to this classifier equality gives $\bot$, so the certified two-sided product is apart from zero. □

Lean4 ✓ `BEDC.Derived.FieldUp.field two sided product apartzero exact`

Theorem 45.314 (Field two-sided empty-product solution uniqueness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate satisfying the same additive, multiplicative, congruence, distributivity, and*

inverse hypotheses as Definition 45.246, let $a, b : \mathsf{BHist}$ *carry nonzero witnesses* p_a, p_b*. If two middle histories* x, y *both solve the empty two-sided product equation*

$$\mathsf{mul}(\mathsf{mul}(a, x), b)\mathsf{hsamee}, \qquad \mathsf{mul}(\mathsf{mul}(a, y), b)\mathsf{hsamee},$$

then $x\mathsf{hsame}y$*.*

Proof. Apply the two-sided empty-product exactness theorem separately to the two displayed empty-product witnesses. It identifies both x and y with e. Transitivity through the symmetric second comparison gives $x\mathsf{hsame}y$. □

Theorem 45.315 (Field two-sided empty-product fiber independence)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate satisfying the same additive, multiplicative, congruence, distributivity, and inverse hypotheses as Definition 45.246, let* $a, b, c, d : \mathsf{BHist}$ *carry nonzero witnesses* $p_a : \mathsf{NonZero}_F(a)$*,* $p_b : \mathsf{NonZero}_F(b)$*,* $p_c : \mathsf{NonZero}_F(c)$*, and* $p_d : \mathsf{NonZero}_F(d)$*. If* $x, y : \mathsf{BHist}$ *satisfy*

$$\mathsf{mul}(\mathsf{mul}(a, x), b)\mathsf{hsamee} \qquad \textit{and} \qquad \mathsf{mul}(\mathsf{mul}(c, y), d)\mathsf{hsamee},$$

then $x\mathsf{hsame}y$*.*

Proof. Apply the two-sided empty-product exactness theorem to the first displayed witness with the certified outer pair (a, b) and witnesses p_a, p_b. This classifies the middle history as $x\mathsf{hsamee}$.

Apply the same exactness theorem to the second displayed witness with the certified outer pair (c, d) and witnesses p_c, p_d. This classifies the second middle history as $y\mathsf{hsamee}$.

Symmetry turns the second comparison into $\mathsf{ehsame}y$. Transitivity through the common empty endpoint gives $x\mathsf{hsame}y$, so the empty-product fiber is independent of the chosen certified outer factors. □

Per-object certificate: Traditional target: two-sided empty-product fiber uniqueness and independence. BEDC source: $\mathsf{Field}^{\uparrow}$ over BHist. Carrier choice: BHist. Classifier choice: hsame. Stability obligation: two-sided zero-product exactness. Ledger: the two certified outer-factor pairs and the two empty-product witnesses. Core theorem list: Theorem 45.314 and Theorem 45.315. Exactness predicate: all certified two-sided empty-product fibers classify to the singleton empty endpoint. Status: $\mathsf{ProofTarget}$.

Theorem 45.316 (Field binary product zero-apartness exactness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *satisfying the hypotheses of Definition 45.247, including the ring zero-absorption and multiplication-congruence hypotheses used there, define*

$$\mathsf{ApartZero}_F(h) := (h\mathsf{hsame}0 \to \bot).$$

For any $a, b : \mathsf{BHist}$ *equipped with explicit maps* $\alpha_a : \mathsf{ApartZero}_F(a) \to \mathsf{NonZero}_F(a)$ *and* $\alpha_b : \mathsf{ApartZero}_F(b) \to \mathsf{NonZero}_F(b)$*, one has*

$$\mathsf{ApartZero}_F(\mathsf{mul}(a, b)) \iff \mathsf{ApartZero}_F(a) \wedge \mathsf{ApartZero}_F(b).$$

Proof. For the product-to-left direction, assume $q : \mathsf{ApartZero}_F(\mathsf{mul}(a, b))$ and then assume $a\mathsf{hsame}0$. Multiplication congruence transports this classifier equality through right multiplication by b, giving $\mathsf{mul}(a, b)\mathsf{hsamemul}(0, b)$. Theorem 43.39 classifies $\mathsf{mul}(0, b)$ as 0, so transitivity gives $\mathsf{mul}(a, b)\mathsf{hsame}0$. Applying q gives $\bot$.

For the product-to-right direction, assume again $q : \mathsf{ApartZero}_F(\mathsf{mul}(a, b))$ and then assume $b\mathsf{hsame}0$. Multiplication congruence transports this classifier equality through left multiplication

by a, giving $\mathsf{mul}(a,b)\mathsf{hsamemul}(a,0)$. Theorem 43.39 classifies $\mathsf{mul}(a,0)$ as 0, so transitivity gives $\mathsf{mul}(a,b)\mathsf{hsame0}$. Applying q gives $\bot$.

For the factor-to-product direction, assume $r_a : \mathsf{ApartZero}_F(a)$ and $r_b : \mathsf{ApartZero}_F(b)$. Convert them to nonzero witnesses $p_a := \alpha_a(r_a)$ and $p_b := \alpha_b(r_b)$, and assume $\mathsf{mul}(a,b)\mathsf{hsame0}$.

Apply Definition 45.247 to the zero product. With p_a it returns $b\mathsf{hsame0}$, which r_b sends to contradiction. Symmetrically, the witness p_b would return $a\mathsf{hsame0}$ and close by r_a; the paired factor ledger is therefore stable on both sides. This proves $\mathsf{ApartZero}_F(\mathsf{mul}(a,b))$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field binary product apartzero exact`

Per-object certificate: Traditional target: product nonzero exactness. BEDC source: $\mathsf{Field}^{\uparrow}$ + $\mathsf{Ring}^{\uparrow}$. Carrier choice: BHist. Classifier choice: hsame. Ledger: the two factor apartness witnesses. Core theorem this block: Theorem 45.316. Exactness predicate: binary product zero-apartness. Standard bridge: deferred. Status: ProofTarget.

Theorem 45.317 (Field three-factor product zero-apartness exactness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *satisfying the hypotheses of Definition 45.316, define*

$$\mathsf{ApartZero}_F(h) := (h\mathsf{hsame0} \to \bot).$$

For any $a, x, b : \mathsf{BHist}$ *equipped with explicit conversion maps*

$$\alpha_a : \mathsf{ApartZero}_F(a) \to \mathsf{NonZero}_F(a), \quad \alpha_x : \mathsf{ApartZero}_F(x) \to \mathsf{NonZero}_F(x), \quad \alpha_b : \mathsf{ApartZero}_F(b) \to \mathsf{NonZero}_F(b),$$

$$\alpha_{ax} : \mathsf{ApartZero}_F(\mathsf{mul}(a,x)) \to \mathsf{NonZero}_F(\mathsf{mul}(a,x)), \quad \alpha_{axb} : \mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(a,x),b)) \to \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}($$

one has

$$\mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(a,x),b)) \iff \mathsf{ApartZero}_F(a) \wedge \mathsf{ApartZero}_F(x) \wedge \mathsf{ApartZero}_F(b).$$

Proof. For the forward direction, assume $q : \mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(a,x),b))$. Apply Definition 45.316 first to the binary product $(\mathsf{mul}(a,x),b)$, using the conversion maps α_{ax} and α_b. Its forward implication gives both $\mathsf{ApartZero}_F(\mathsf{mul}(a,x))$ and $\mathsf{ApartZero}_F(b)$.

Apply Definition 45.316 again to the binary product (a,x), using α_a and α_x. The apartness of $\mathsf{mul}(a,x)$ just obtained yields $\mathsf{ApartZero}_F(a)$ and $\mathsf{ApartZero}_F(x)$. Together with $\mathsf{ApartZero}_F(b)$, these are exactly the three factor witnesses on the right-hand side.

For the reverse direction, assume witnesses $r_a : \mathsf{ApartZero}_F(a)$, $r_x : \mathsf{ApartZero}_F(x)$, and $r_b : \mathsf{ApartZero}_F(b)$. Apply Definition 45.316 to (a,x) and use its reverse implication with r_a and r_x to build $r_{ax} : \mathsf{ApartZero}_F(\mathsf{mul}(a,x))$.

Now apply the same binary exactness theorem to $(\mathsf{mul}(a,x),b)$, using α_{ax} and α_b. Its reverse implication combines r_{ax} with r_b, producing $\mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(a,x),b))$. The displayed conversion map α_{axb} records the corresponding full product witness interface for downstream certificates. □

Per-object certificate: Traditional target: threefold product nonzero exactness. BEDC source: $\mathsf{Field}^{\uparrow}$ plus $\mathsf{Ring}^{\uparrow}$ zero absorption. Carrier choice: BHist. Classifier choice: hsame. Ledger: the factor apartness witnesses and product conversion maps. Exactness predicate: threefold zero-apartness equivalence. Status: ProofTarget.

Theorem 45.318 (Field four-factor product zero-apartness exactness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *satisfying the hypotheses of Definition 45.316, define*

$$\mathsf{ApartZero}_F(h) := (h\mathsf{hsame0} \to \bot).$$

For any $a, x, b, c : \mathsf{BHist}$ *equipped with explicit conversion maps*

$$\alpha_a : \mathsf{ApartZero}_F(a) \to \mathsf{NonZero}_F(a), \quad \alpha_x : \mathsf{ApartZero}_F(x) \to \mathsf{NonZero}_F(x), \quad \alpha_b : \mathsf{ApartZero}_F(b) \to \mathsf{NonZero}_F(b),$$

$$\alpha_{ax} : \mathsf{ApartZero}_F(\mathsf{mul}(a, x)) \to \mathsf{NonZero}_F(\mathsf{mul}(a, x)), \quad \alpha_{bc} : \mathsf{ApartZero}_F(\mathsf{mul}(b, c)) \to \mathsf{NonZero}_F(\mathsf{mul}(b, c)),$$

one has

$$\mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(a, x), \mathsf{mul}(b, c))) \iff \mathsf{ApartZero}_F(a) \wedge \mathsf{ApartZero}_F(x) \wedge \mathsf{ApartZero}_F(b) \wedge \mathsf{ApartZero}_F(c).$$

Proof. For the forward direction, assume $q : \mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(a, x), \mathsf{mul}(b, c)))$. Apply Definition 45.316 first to the outer binary product $(\mathsf{mul}(a, x), \mathsf{mul}(b, c))$, using the conversion maps α_{ax} and α_{bc}. Its forward implication gives both $\mathsf{ApartZero}_F(\mathsf{mul}(a, x))$ and $\mathsf{ApartZero}_F(\mathsf{mul}(b, c))$.

Apply the same binary exactness theorem to (a, x) with α_a and α_x. The first pair-product apartness witness yields $\mathsf{ApartZero}_F(a)$ and $\mathsf{ApartZero}_F(x)$.

Apply binary exactness once more to (b, c) with α_b and α_c. The second pair-product apartness witness yields $\mathsf{ApartZero}_F(b)$ and $\mathsf{ApartZero}_F(c)$. These four witnesses are exactly the right-hand side.

For the reverse direction, assume witnesses $r_a : \mathsf{ApartZero}_F(a)$, $r_x : \mathsf{ApartZero}_F(x)$, $r_b : \mathsf{ApartZero}_F(b)$, and $r_c : \mathsf{ApartZero}_F(c)$. Apply Definition 45.316 to (a, x) and use its reverse implication with r_a and r_x to build $r_{ax} : \mathsf{ApartZero}_F(\mathsf{mul}(a, x))$.

Apply binary exactness to (b, c) in the same way. The witnesses r_b and r_c build $r_{bc} : \mathsf{ApartZero}_F(\mathsf{mul}(b, c))$.

Finally apply binary exactness to the outer product $(\mathsf{mul}(a, x), \mathsf{mul}(b, c))$, using α_{ax} and α_{bc}. Its reverse implication combines r_{ax} and r_{bc} into $\mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(a, x), \mathsf{mul}(b, c)))$. □

Per-object certificate: Traditional target: fourfold product nonzero exactness. BEDC source: $\mathsf{Field}^{\uparrow} + \mathsf{Ring}^{\uparrow}$. Carrier choice: BHist. Classifier choice: hsame. Ledger: the four factor witnesses plus the pair-product conversion maps for $\mathsf{mul}(a, x)$ and $\mathsf{mul}(b, c)$. Exactness predicate: fourfold zero-apartness equivalence. Status: $\mathsf{ProofTarget}$.

Theorem 45.319 (Field four-factor product inverse reversal from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *satisfying the hypotheses of Definition 45.316, Definition 45.318, Definition 45.213, and Definition 45.202, including multiplication congruence, associativity, and transitivity for* hsame*, let* $\mathsf{ApartZero}_F(h) := (h\mathsf{hsame0} \to \bot)$*. For any* $a, x, b, c : \mathsf{BHist}$ *equipped with conversion maps*

$$\alpha_a : \mathsf{ApartZero}_F(a) \to \mathsf{NonZero}_F(a), \quad \alpha_x : \mathsf{ApartZero}_F(x) \to \mathsf{NonZero}_F(x),$$

$$\alpha_b : \mathsf{ApartZero}_F(b) \to \mathsf{NonZero}_F(b), \quad \alpha_c : \mathsf{ApartZero}_F(c) \to \mathsf{NonZero}_F(c),$$

$$\alpha_{ax} : \mathsf{ApartZero}_F(\mathsf{mul}(a, x)) \to \mathsf{NonZero}_F(\mathsf{mul}(a, x)), \quad \alpha_{bc} : \mathsf{ApartZero}_F(\mathsf{mul}(b, c)) \to \mathsf{NonZero}_F(\mathsf{mul}(b, c)),$$

$$\alpha_{axbc} : \mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(a, x), \mathsf{mul}(b, c))) \to \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(a, x), \mathsf{mul}(b, c))),$$

any witness

$$q : \mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(a, x), \mathsf{mul}(b, c)))$$

determines induced witnesses p_a*,* p_x*,* p_b*,* p_c*,* p_{ax}*,* p_{bc}*, and* p_{axbc} *such that*

$$\mathsf{inv}(\mathsf{mul}(\mathsf{mul}(a, x), \mathsf{mul}(b, c)), p_{axbc})\mathsf{hsamemul}(\mathsf{mul}(\mathsf{inv}(c, p_c), \mathsf{inv}(b, p_b)), \mathsf{mul}(\mathsf{inv}(x, p_x), \mathsf{inv}(a, p_a))).$$

Proof. Apply Definition 45.318 to q. The forward implication yields apartness witnesses $q_a : \mathsf{ApartZero}_F(a)$, $q_x : \mathsf{ApartZero}_F(x)$, $q_b : \mathsf{ApartZero}_F(b)$, and $q_c : \mathsf{ApartZero}_F(c)$. Set $p_a := \alpha_a(q_a)$, $p_x := \alpha_x(q_x)$, $p_b := \alpha_b(q_b)$, and $p_c := \alpha_c(q_c)$.

Use the reverse implication of Definition 45.316 on (a, x) to build $q_{ax} : \mathsf{ApartZero}_F(\mathsf{mul}(a, x))$ from q_a and q_x. Use it again on (b, c) to build $q_{bc} : \mathsf{ApartZero}_F(\mathsf{mul}(b, c))$ from q_b and q_c. Set $p_{ax} := \alpha_{ax}(q_{ax})$, $p_{bc} := \alpha_{bc}(q_{bc})$, and $p_{axbc} := \alpha_{axbc}(q)$.

Apply Definition 45.213 to the outer product with witnesses p_{axbc}, p_{ax}, and p_{bc}. Apply the same theorem to (a, x) with p_{ax}, p_a, and p_x, and to (b, c) with p_{bc}, p_b, and p_c.

Multiplication congruence transports the two pair-product inverse equalities into the right-hand side of the outer equality. The comparison of inverse proof indices is supplied by Definition 45.202, and associativity together with transitivity of hsame gives the displayed $(c, b)(x, a)$ reversed product. □

45.10 Field square apartness inverse descent

Theorem 45.320 (Field square apartness inverse descent)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate satisfying the hypotheses of Definition 45.303 and Definition 45.213, plus the canonical product-apartness witness construction of Definition 45.271, together with the proof-index comparison supplied by Definition 45.202, let* $\mathsf{ApartZero}_F(h)$ *mean* $h\mathsf{hsame}0 \to \bot$. *For every* $a : \mathsf{BHist}$, *assume explicit conversion maps*

$$\alpha_a : \mathsf{ApartZero}_F(a) \to \mathsf{NonZero}_F(a), \quad \alpha_{aa} : \mathsf{ApartZero}_F(\mathsf{mul}(a, a)) \to \mathsf{NonZero}_F(\mathsf{mul}(a, a)).$$

Any witness

$$p_{a^2} : \mathsf{ApartZero}_F(\mathsf{mul}(a, a))$$

canonically induces a witness $p_a : \mathsf{ApartZero}_F(a)$. *With this induced apartness witness and the displayed conversions, the proof-indexed inverse satisfies*

$$\mathsf{inv}(\mathsf{mul}(a, a), \alpha_{aa}(p_{a^2}))\mathsf{hsamemul}(\mathsf{inv}(a, \alpha_a(p_a)), \mathsf{inv}(a, \alpha_a(p_a))).$$

Proof. Construct p_a as a function from an assumed classifier $a\mathsf{hsame}0$ to contradiction. Multiplication congruence sends $\mathsf{mul}(a, a)$ to $\mathsf{mul}(0, a)$, and ring zero absorption classifies $\mathsf{mul}(0, a)$ as 0. Transitivity gives $\mathsf{mul}(a, a)\mathsf{hsame}0$.

Apply the square apartness witness p_{a^2} to this classifier equality. This closes the assumed zero classifier for a, so the function just built is the induced witness $p_a : \mathsf{ApartZero}_F(a)$.

Next apply Definition 45.271 to the two factor witnesses p_a and p_a, using α_a for both factor indices and α_{aa} for the product index. This supplies the canonical product apartness witness

$$p'_{a^2} : \mathsf{ApartZero}_F(\mathsf{mul}(a, a))$$

and the indexed inverse equality

$$\mathsf{inv}(\mathsf{mul}(a, a), \alpha_{aa}(p'_{a^2}))\mathsf{hsamemul}(\mathsf{inv}(a, \alpha_a(p_a)), \mathsf{inv}(a, \alpha_a(p_a))).$$

It remains to compare the supplied square witness with the canonical product witness. Use Definition 45.202 with reflexivity on $\mathsf{mul}(a, a)$, the witness p_{a^2} on the source side, and p'_{a^2} on the target side. This identifies

$$\mathsf{inv}(\mathsf{mul}(a, a), \alpha_{aa}(p_{a^2}))\mathsf{hsameinv}(\mathsf{mul}(a, a), \alpha_{aa}(p'_{a^2})).$$

Transitivity with the canonical product equality gives the displayed inverse descent identity. □

Lean4 ✓ `BEDC.Derived.FieldUp.field square apartness inverse descent`

Theorem 45.321 (Field square nonzero gives one-sided multiplication exactness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate satisfying the hypotheses of Definition 45.303, Definition 45.229, and Definition 45.224, let* $\mathsf{ApartZero}_F(h)$ *mean* $h\mathsf{hsame}0 \to \bot$*. For every* $a : \mathsf{BHist}$*, assume an explicit conversion map*

$$\alpha_a : \mathsf{ApartZero}_F(a) \to \mathsf{NonZero}_F(a).$$

For every witness

$$p_{a^2} : \mathsf{NonZero}_F(\mathsf{mul}(a, a)),$$

let $r_a : \mathsf{ApartZero}_F(a)$ *be the first zero-factor obstruction induced by zero-factor exclusion, and set* $p_a := \alpha_a(r_a)$*. Then every* $c, x : \mathsf{BHist}$ *satisfies both one-sided multiplication exactness clauses:*

$$\mathsf{mul}(a, x)\mathsf{hsame}c \iff x\mathsf{hsamemul}(\mathsf{inv}(a, p_a), c)$$

and

$$\mathsf{mul}(x, a)\mathsf{hsame}c \iff x\mathsf{hsamemul}(c, \mathsf{inv}(a, p_a)).$$

Proof. Apply Definition 45.303 to p_{a^2} with both product entries instantiated by a. The first factor clause gives $r_a : \mathsf{ApartZero}_F(a)$.

Convert this apartness witness by the displayed map, setting $p_a := \alpha_a(r_a) : \mathsf{NonZero}_F(a)$. This is the proof index available to the inverse and cancellation laws for the factor a.

For the left multiplication clause, invoke Definition 45.229 with this induced witness p_a. Its displayed equivalence is exactly $\mathsf{mul}(a, x)\mathsf{hsame}c$ if and only if $x\mathsf{hsamemul}(\mathsf{inv}(a, p_a), c)$.

For the right multiplication clause, invoke Definition 45.224 with the same induced witness p_a. Its displayed equivalence is exactly $\mathsf{mul}(x, a)\mathsf{hsame}c$ if and only if $x\mathsf{hsamemul}(c, \mathsf{inv}(a, p_a))$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field square nonzero one sided mul exact`

Theorem 45.322 (Field square nonzero gives two-sided same-factor multiplication exactness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate satisfying the hypotheses of Definition 45.303 and Definition 45.233, let* $\mathsf{ApartZero}_F(h)$ *mean* $h\mathsf{hsame}0 \to \bot$*. For every* $a : \mathsf{BHist}$*, assume an explicit conversion map*

$$\alpha_a : \mathsf{ApartZero}_F(a) \to \mathsf{NonZero}_F(a).$$

For every $c, x : \mathsf{BHist}$ *and witness*

$$p_{a^2} : \mathsf{NonZero}_F(\mathsf{mul}(a, a)),$$

let $r_a : \mathsf{ApartZero}_F(a)$ *be the first zero-factor obstruction induced by zero-factor exclusion, and set* $p_a := \alpha_a(r_a)$*. Then the square-scaled equation with the same certified factor on both sides satisfies*

$$\mathsf{mul}(\mathsf{mul}(a, x), a)\mathsf{hsame}c \iff x\mathsf{hsamemul}(\mathsf{inv}(a, p_a), \mathsf{mul}(c, \mathsf{inv}(a, p_a))).$$

Proof. Apply Definition 45.303 to p_{a^2} with both product entries instantiated by a. Its first zero-factor obstruction gives $r_a : \mathsf{ApartZero}_F(a)$.

Convert this obstruction by the displayed map, setting $p_a := \alpha_a(r_a) : \mathsf{NonZero}_F(a)$. This single proof index is shared by the left and right occurrences of the same multiplier a.

Instantiate Definition 45.233 with both outer factors equal to a and with both outer nonzero witnesses equal to p_a. The resulting middle multiplication exactness equivalence is exactly the displayed square-scaled equation solver. □

Lean4 ✓ `BEDC.Derived.FieldUp.field square nonzero two sided mul exact`

Per-object certificate: Traditional target: square inverse descent. BEDC source: $\mathsf{Field}^{\uparrow}$ plus $\mathsf{Ring}^{\uparrow}$. Carrier choice: BHist. Classifier choice: hsame. Stability obligations: zero absorption, multiplication congruence, apartness transport, and proof-indexed inverse laws. Ledger: the square apartness witness and induced factor witness. Core theorem list entry: Theorem 45.320 and Theorem 45.322. Exactness predicate: square apartness descends to the factor inverse and square nonzero supplies the same-factor two-sided equation solver. Standard bridge: deferred conservative bridge. Status: ProofTarget.

45.11 Concrete Rat denominator continuation instance

Definition 45.323 (Concrete Rat denominator continuation instance)**.** *The concrete denominator-side continuation instance for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *has carrier, classifier, operation, continuation witness, and ledger predicate*

$$C_D(h) \iff \mathsf{RatHistoryCarrier}(h),$$

$$R_D(h,k) \iff \mathsf{RatHistoryClassifier}(h,k),$$

$$\mu_D(h,k) := \mathsf{append}(h,k),$$

with the canonical continuation witness $\mathsf{Cont}(h,k,\mu_D(h,k))$ *and ledger predicate* RatHistoryLedgerPolicy*. The empty history* e *is an external classifier-unit endpoint for the operation and is not a carried denominator.*

Theorem 45.324 (Rat denominator append concrete instance laws)**.** *For histories* $d, d', e, e', f, \rho, v :$ BHist*, the concrete function data of Definition 45.323, with* $\mu_D(h,k) := \mathsf{append}(h,k)$*, satisfy the following append laws.*

1. *If* $C_D(d)$ *and* $C_D(e)$*, then* $C_D(\mu_D(d,e))$*.*
2. *If* $C_D(d)$ *and* $C_D(e)$*, then* $R_D(\mu_D(d,e), \mu_D(e,d))$*.*
3. *If* $C_D(d)$*,* $C_D(e)$*, and* $C_D(f)$*, then* $R_D(\mu_D(\mu_D(d,e),f), \mu_D(d, \mu_D(e,f)))$*.*
4. *If* $R_D(d,d')$ *and* $R_D(e,e')$*, then* $R_D(\mu_D(d,e), \mu_D(d',e'))$*.*
5. *If* $\mathsf{RatHistoryLedgerPolicy}(\rho,v)$*,* $C_D(e)$*, and* $R_D(e,e')$*, then* $\mathsf{RatHistoryLedgerPolicy}(\mu_D(\rho,e), \mu_D(v,e'))$*.*
6. *No carried history* $u : \mathsf{BHist}$ *can satisfy either one-sided classifier-unit law*

$$\forall x : \mathsf{BHist}.\ C_D(x) \to R_D(\mu_D(x,u), x)$$

or

$$\forall x : \mathsf{BHist}.\ C_D(x) \to R_D(\mu_D(u,x), x).$$

Proof. Unfold C_D, R_D, and μ_D. The operation is ordinary history append, so the first five clauses are the concrete append package proved for RatHistoryCarrier, RatHistoryClassifier, and RatHistoryLedgerPolicy.

Carrier closure uses the carried denominator closure of append. The commutative classifier clause uses the unary append commutativity theorem inside the two carried histories.

Associativity compares the two append bracketings by append associativity and then repacks the result into R_D. Binary classifier congruence and ledger closure are the corresponding Rat denominator append-closure clauses for the classifier and ledger predicates.

For a one-sided carried unit, pass from the displayed append law to its canonical continuation instance using $\mathsf{Cont}(x, u, \mu_D(x, u))$ or $\mathsf{Cont}(u, x, \mu_D(u, x))$. Then Definition 45.125 forces $u\mathsf{hsamee}$, while Definition 37.18 rules out a carried empty denominator. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator append concrete instance laws`

Theorem 45.325 (Rat denominator continuation concrete instance laws)**.** *For histories $d, d', e, e', f, \rho, v, de, ed, ef$, BHist, the relational continuation data of Definition 45.323 satisfy the following laws.*

1. *If $C_D(d)$, $C_D(e)$, and $\mathsf{Cont}(d, e, de)$, then $C_D(de)$.*
2. *If $C_D(d)$, $C_D(e)$, $\mathsf{Cont}(d, e, de)$, and $\mathsf{Cont}(e, d, ed)$, then $R_D(de, ed)$.*
3. *If $C_D(d)$, $C_D(e)$, $C_D(f)$, $\mathsf{Cont}(d, e, de)$, $\mathsf{Cont}(e, f, ef)$, $\mathsf{Cont}(de, f, left)$, and $\mathsf{Cont}(d, ef, right)$, then $R_D(left, right)$.*
4. *If $R_D(d, d')$, $R_D(e, e')$, $\mathsf{Cont}(d, e, de)$, and $\mathsf{Cont}(d', e', dep)$, then $R_D(de, dep)$.*
5. *If $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$, $C_D(e)$, $R_D(e, e')$, $\mathsf{Cont}(\rho, e, rhoe)$, and $\mathsf{Cont}(v, e', vep)$, then $\mathsf{RatHistoryLedgerPolicy}(rhoe, vep)$.*
6. *No carried history $u : \mathsf{BHist}$ can satisfy either one-sided classifier-unit law*

$$\forall x, r : \mathsf{BHist}.\ C_D(x) \to \mathsf{Cont}(x, u, r) \to R_D(r, x)$$

or

$$\forall x, r : \mathsf{BHist}.\ C_D(x) \to \mathsf{Cont}(u, x, r) \to R_D(r, x).$$

Proof. Unfold C_D and R_D. The relational presentation leaves each output history named by its Cont witness instead of replacing it by append at the statement level.

Carrier closure is Definition 45.113. The commutative classifier clause is Definition 45.118 applied to the two displayed continuations.

Associativity uses Definition 45.117 on the four continuation witnesses. The theorem supplies the carried intermediate results and the history-sameness comparison needed to read the two bracketings as classifier-equivalent.

For binary classifier congruence, unpack $R_D(d, d')$ and $R_D(e, e')$. The right input classifier supplies the matching denominator comparison required by Definition 45.119, and the two displayed continuations give $R_D(de, dep)$.

The ledger clause applies Definition 45.122 to $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$, the carried and classified right tail, and the two displayed continuations.

Finally, Definition 45.125 says that any one-sided classifier-unit endpoint is hsame to e, and its carried endpoint clause rules out such a history inside $\mathsf{RatHistoryCarrier}$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation concrete instance laws`

Theorem 45.326 (Rat denominator append-continuation endpoint bridge)**.** *For the concrete data of Definition 45.323, if $C_D(h)$ and $C_D(k)$, then every history $r : \mathsf{BHist}$ satisfies the endpoint classifier bridge*

$$\mathsf{Cont}(h,k,r) \iff R_D(r,\mu_D(h,k)).$$

Thus the canonical append endpoint $\mu_D(h,k)$ and any displayed continuation endpoint r are identified exactly at the denominator classifier surface.

Proof. Unfold C_D, R_D, and μ_D only to read them as RatHistoryCarrier, RatHistoryClassifier, and append. With the two carrier hypotheses in place, Definition 45.114 gives, for every history r, exactly $\mathsf{Cont}(h,k,r) \iff R_D(r,\mu_D(h,k))$.

At the canonical endpoint, the same bridge reads the canonical continuation witness as the reflexive denominator classifier comparison $R_D(\mu_D(h,k),\mu_D(h,k))$. □

Theorem 45.327 (Rat denominator append-relational unit-law equivalence)**.** *For the concrete data of Definition 45.323, every history $u : \mathsf{BHist}$ satisfying $C_D(u)$ has the following two one-sided unit-law equivalences:*

$$(\forall x : \mathsf{BHist}.\ C_D(x) \to R_D(\mu_D(x,u),x)) \iff (\forall x,r : \mathsf{BHist}.\ C_D(x) \to \mathsf{Cont}(x,u,r) \to R_D(r,x))$$

and

$$(\forall x : \mathsf{BHist}.\ C_D(x) \to R_D(\mu_D(u,x),x)) \iff (\forall x,r : \mathsf{BHist}.\ C_D(x) \to \mathsf{Cont}(u,x,r) \to R_D(r,x))\,.$$

Thus the functional append presentation and the relational continuation presentation carry exactly the same one-sided internal-unit obstruction for a carried denominator endpoint.

Proof. Fix $u : \mathsf{BHist}$ with $C_D(u)$.

For the right-unit forward direction, assume the append family $\forall x.\ C_D(x) \to R_D(\mu_D(x,u),x)$. Given x, r, $C_D(x)$, and $\mathsf{Cont}(x,u,r)$, apply Definition 45.326 to the carried pair (x,u). This classifies the displayed endpoint r with the canonical append endpoint $\mu_D(x,u)$. The assumed append family classifies $\mu_D(x,u)$ with x, and classifier transitivity gives $R_D(r,x)$.

For the right-unit reverse direction, assume the relational family $\forall x,r.\ C_D(x) \to \mathsf{Cont}(x,u,r) \to R_D(r,x)$. At each carried x, use the canonical continuation witness $\mathsf{Cont}(x,u,\mu_D(x,u))$ from Definition 45.323. Applying the relational family to this witness gives $R_D(\mu_D(x,u),x)$.

The left-unit equivalence is identical with the inputs reversed. The forward direction compares any displayed $\mathsf{Cont}(u,x,r)$ endpoint to the canonical append endpoint $\mu_D(u,x)$ by Definition 45.326, then composes with the assumed append left-unit row by classifier transitivity. The reverse direction applies the relational left-unit family to the canonical witness $\mathsf{Cont}(u,x,\mu_D(u,x))$. □

This theorem fits the ten-field per-object template as follows: traditional target append/Cont unit-law equivalence for strict denominator multiplication support; BEDC source BHist together with Cont, RatHistoryCarrier, and RatHistoryClassifier; carrier C_D; classifier R_D; stability obligation endpoint bridge plus classifier transitivity; ledger RatHistoryLedgerPolicy; core theorem Definition 45.327; exactness the displayed iff pair; standard bridge strict denominator semigroup interface; status ProofTarget.

For the ten-field exit certificate of Definition 45.585, this theorem occupies only the denominator endpoint-identification part of the classifier and stability rows. The traditional target, BEDC source, carrier, ledger, core theorem list, exactness predicate, standard bridge, and status rows are supplied by their named concrete certificates, while the append and relational denominator laws remain the checked packages of Definition 45.324 and Definition 45.325.

Definition 45.328 (Concrete Rat denominator strict semigroup interface)**.** *The denominator multiplication interface carried by the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *continuation data is the triple*

$$C_D(h) := \mathsf{RatHistoryCarrier}(h),$$

$$R_D(h,k) := \mathsf{RatHistoryClassifier}(h,k),$$

and

$$\mu_D(h,k) := \mathsf{append}(h,k).$$

It is a strict denominator semigroup interface: the operation is the canonical append endpoint, the classifier is the Rat denominator history classifier, and the carried endpoints are exactly the Rat denominator histories. The interface has no carried unit endpoint. The empty history is only an external classifier endpoint, and no $u : \mathsf{BHist}$ *with* $C_D(u)$ *can act as a one-sided unit for the carried denominator multiplication.*

Theorem 45.329 (Rat denominator carried unit obstruction package)**.** *For the concrete strict denominator semigroup interface of Definition 45.328, every* $u : \mathsf{BHist}$ *with* $C_D(u)$ *satisfies the following four impossibility rows:*

1. *the functional right-unit family*

$$\forall x : \mathsf{BHist}.\ C_D(x) \to R_D(\mu_D(x,u),x)$$

implies False*;*

2. *the functional left-unit family*

$$\forall x : \mathsf{BHist}.\ C_D(x) \to R_D(\mu_D(u,x),x)$$

implies False*;*

3. *the relational right-unit family*

$$\forall x, r : \mathsf{BHist}.\ C_D(x) \to \mathsf{Cont}(x,u,r) \to R_D(r,x)$$

implies False*;*

4. *the relational left-unit family*

$$\forall x, r : \mathsf{BHist}.\ C_D(x) \to \mathsf{Cont}(u,x,r) \to R_D(r,x)$$

implies False*.*

The ten-field template represented by this certificate is: traditional target strict denominator semigroup support; BEDC source BHist *with* Cont*,* $\mathsf{RatHistoryCarrier}$*, and* $\mathsf{RatHistoryClassifier}$*; carrier* C_D*; classifier* R_D*; stability append/*Cont *endpoint bridge plus classifier transitivity; ledger* $\mathsf{RatHistoryLedgerPolicy}$*; core theorem this package; exactness the four impossibility rows; standard bridge strict non-unital denominator multiplication; status* $\mathsf{ProofTarget}$*.*

Proof. Fix $u : \mathsf{BHist}$ with $C_D(u)$.

For the two functional rows, clause 6 of Definition 45.324 states that a carried history cannot satisfy either one-sided append classifier-unit law. Applying that clause to u and the displayed functional right-unit or left-unit family yields False.

For the two relational rows, clause 6 of Definition 45.325 gives the same contradiction for a carried history satisfying either one-sided Cont-based classifier-unit law. Applying it to the displayed relational right-unit or left-unit family yields False.

Finally, Definition 45.327 records that the append presentation and the relational continuation presentation express the same one-sided carried-unit boundary. The right-unit equivalence links the first and third rows, and the left-unit equivalence links the second and fourth rows, so the four contradictions are one certificate-level obstruction for the concrete denominator interface. □

45.12 Rat denominator append-continuation semigroup ledger bridge

Theorem 45.330 (Rat denominator append-continuation strict semigroup non-monoid bridge)**.** *For the concrete data of Definition 45.323, the append presentation* (C_D, R_D, μ_D) *and the relational* Cont *presentation determine the same strict commutative semigroup-with-ledger over* $\mathsf{RatHistoryCarrier}$*, not an internal carried monoid. The common structure has the following form.*

1. *The carrier is* $C_D(h)$*, equivalently* $\mathsf{RatHistoryCarrier}(h)$*, and the classifier is* $R_D(h, k)$*, equivalently* $\mathsf{RatHistoryClassifier}(h, k)$*.*
2. *The append presentation supplies carrier closure, commutative classifier, associativity up to* R_D*, binary classifier congruence, and ledger closure for* $\mathsf{RatHistoryLedgerPolicy}$ *under right carried tails.*
3. *The relational* Cont *presentation supplies the same five rows with every product endpoint named by a continuation witness.*
4. *The endpoint bridge identifies every relational product endpoint with the corresponding append endpoint at the* R_D *classifier surface, so the five append rows and the five relational rows transport into one another.*
5. *For every carried history* $u : \mathsf{BHist}$ *with* $C_D(u)$*, neither presentation admits a one-sided classifier unit. In the append presentation, neither*

$$\forall x : \mathsf{BHist}.\ C_D(x) \to R_D(\mu_D(x, u), x)$$

nor

$$\forall x : \mathsf{BHist}.\ C_D(x) \to R_D(\mu_D(u, x), x)$$

can hold. In the relational presentation, neither

$$\forall x, r : \mathsf{BHist}.\ C_D(x) \to \mathsf{Cont}(x, u, r) \to R_D(r, x)$$

nor

$$\forall x, r : \mathsf{BHist}.\ C_D(x) \to \mathsf{Cont}(u, x, r) \to R_D(r, x)$$

can hold.

Proof. The append rows are exactly the first five clauses of Definition 45.324: closure of C_D, commutativity at the classifier, associativity at the classifier, binary classifier congruence, and ledger closure for RatHistoryLedgerPolicy.

The relational rows are the matching five clauses of Definition 45.325. They use the same carrier, classifier, and ledger predicate, but leave each product endpoint as a named Cont result.

The identification of the two presentations is Definition 45.326. Its endpoint bridge transports each append output to the corresponding continuation endpoint and transports each continuation endpoint back to the append output at the R_D classifier surface.

It remains to record why the common object is strict. The one-sided unit clauses in the append and relational packages both feed into Definition 45.125, which forces any such endpoint to be hsamee. Definition 37.18 then excludes this endpoint from RatHistoryCarrier. Hence no carried denominator supplies an internal one-sided classifier unit, so the shared denominator structure is a strict semigroup-with-ledger rather than a carried monoid. □

Per-object template: traditional target strict denominator multiplication support for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, Cont, RatHistoryCarrier, RatHistoryClassifier, and RatHistoryLedgerPolicy; carrier choice: C_D; classifier choice: R_D; stability obligations: carrier closure, commutative classifier, associativity, binary classifier congruence, ledger closure, and carried unit obstruction; ledger: denominator multiplication provenance through RatHistoryLedgerPolicy; core theorem: Definition 45.330; exactness predicate: append and Cont endpoint bridge; standard bridge: deferred; status ProofTarget.

Theorem 45.331 (Rat denominator append-continuation final-exit obstruction guard)**.** *For the concrete data of Definition 45.323 and the final row inventory package of Theorem 45.773, the Phase Algebra Hierarchy consumer receives both the final selector-row inventory and the strict denominator guard. Explicitly, for every carried denominator* $u : \mathsf{BHist}$ *with* $C_D(u)$*, the append presentation gives both*

$$(\forall x : \mathsf{BHist}.\ C_D(x) \to R_D(\mu_D(x, u), x)) \to \mathsf{False}$$

and

$$(\forall x : \mathsf{BHist}.\ C_D(x) \to R_D(\mu_D(u, x), x)) \to \mathsf{False}.$$

The relational presentation gives both

$$(\forall x, r : \mathsf{BHist}.\ C_D(x) \to \mathsf{Cont}(x, u, r) \to R_D(r, x)) \to \mathsf{False}$$

and

$$(\forall x, r : \mathsf{BHist}.\ C_D(x) \to \mathsf{Cont}(u, x, r) \to R_D(r, x)) \to \mathsf{False}.$$

Thus the final $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *row inventory and the denominator obstruction arrive as one consumable guard: later algebra may use the selector exit rows, but may not read the denominator semigroup as a carried multiplication with a one-sided internal classifier unit.*

Proof. The positive inventory is supplied by Theorem 45.773. It packages the selector inverse-domain coverage row, the selector row-stability row, the complete selector obstruction certificate, and the selector-chain boundary rows for the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object.

The strict denominator rows are supplied by Theorem 45.330. Its append half gives closure, commutative classifier, associativity, congruence, ledger closure, and the two displayed denials of one-sided append classifier units.

For the relational half, use the same bridge theorem together with the no-one-sided-unit rows formalized by BEDC.Derived.FieldUp.field_rat_denominator_continuation_commutative_semigroup_obstruction_pa Those rows deny both carried relational laws with endpoints named by Cont.

Combining these two cited packages gives the advertised guard. The Phase Algebra Hierarchy consumer may carry the final selector-row inventory forward, while the denominator side remains a strict commutative semigroup-with-ledger and not a carried monoid. □

Per-object template: traditional target final-exit denominator obstruction guard for $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source BHist, Cont, RatHistoryCarrier, RatHistoryClassifier, RatHistoryLedgerPolicy, and the final selector rows; carrier choice: C_D; classifier choice: R_D; stability obligations: final selector-row coverage plus strict append and relational carried-unit obstruction; ledger: denominator multiplication provenance through RatHistoryLedgerPolicy; core theorem: Definition 45.331; exactness predicate: shared append and Cont endpoint bridge with one-sided-unit denial; standard bridge: Phase Algebra Hierarchy consumer for $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; status ProofTarget.

Lean4 ✓ `BEDC.Derived.FieldUp.field two sided product apartzero exact from apartness`

Lean4 ✓ `BEDC.Derived.FieldUp.field binary product apartzero exact from apartness`

Theorem 45.332 (Field square zero rejects nonzero factor)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with the hypotheses of Definition 45.247, together with classifier transport of* $\mathsf{NonZero}_F$ *and contradiction of* $\mathsf{NonZero}_F(0)$*, every* $a : \mathsf{BHist}$ *satisfying*

$$\mathsf{mul}(a, a)\mathsf{hsame0}$$

has $\mathsf{NonZero}_F(a) \to \bot$*. Moreover, for*

$$\mathsf{ApartZero}_F(h) := (h\mathsf{hsame0} \to \bot),$$

the same displayed square-zero classifier refutes $\mathsf{ApartZero}_F(\mathsf{mul}(a, a))$*.*

Proof. Assume $z : \mathsf{mul}(a, a)\mathsf{hsame0}$ and $p_a : \mathsf{NonZero}_F(a)$. Apply Definition 45.247 to z with the left-factor witness p_a. The left-factor clause returns $a\mathsf{hsame0}$.

Transport p_a along this classifier equality. The classifier-transport stability for $\mathsf{NonZero}_F$ gives a witness of $\mathsf{NonZero}_F(0)$.

The field certificate supplies contradiction of $\mathsf{NonZero}_F(0)$, so the transported witness closes the nonzero-factor clause with $\bot$.

For the apartness clause, take $q : \mathsf{ApartZero}_F(\mathsf{mul}(a, a))$. Since $\mathsf{ApartZero}_F(h)$ means $h\mathsf{hsame0} \to \bot$, direct application of q to the displayed square-zero classifier z gives $\bot$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field square zero rejects factor nonzero`

Theorem 45.333 (Field square nonzero iff factor nonzero)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate satisfying the hypotheses of Definition 45.303 and Definition 45.305, including a constructive bridge family*

$$\alpha_t : (t\mathsf{hsame0} \to \bot) \to \mathsf{NonZero}_F(t),$$

every $a : \mathsf{BHist}$ *satisfies*

$$\mathsf{NonZero}_F(\mathsf{mul}(a, a)) \iff \mathsf{NonZero}_F(a).$$

Proof. For the forward direction, assume $p_{aa} : \mathsf{NonZero}_F(\mathsf{mul}(a, a))$. Apply Definition 45.303 to the square product with both factors equal to a. The left-factor clause gives $a\mathsf{hsame}0 \to \bot$.

Apply the bridge-family instance α_a to this apartness witness. The result is $\mathsf{NonZero}_F(a)$.

For the reverse direction, assume $p_a : \mathsf{NonZero}_F(a)$. Apply Definition 45.305 to the same witness p_a in both factor slots. The resulting product witness is exactly $\mathsf{NonZero}_F(\mathsf{mul}(a, a))$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field square nonzero iff factor nonzero`

Per-object certificate: Traditional target: square inverse descent. BEDC source: $\mathsf{Field}^{\uparrow}$ plus $\mathsf{Ring}^{\uparrow}$. Carrier choice: BHist. Classifier choice: hsame. Stability obligations: zero absorption, multiplication congruence, apartness transport, and proof-indexed inverse laws. Ledger: the square apartness witness, induced factor witness, and square-zero classifier. Core theorem list entries: Theorem 45.320 and Theorem 45.332, together with Theorem 45.333. Exactness predicate: square apartness descends to the factor inverse, square-zero classification rejects nonzero factors, and

$$\mathsf{NonZero}_F(\mathsf{mul}(a, a)) \iff \mathsf{NonZero}_F(a).$$

Standard bridge: deferred conservative bridge. Status: $\mathsf{ProofTarget}$.

45.13 Field square apartness inverse descent

Theorem 45.334 (Field square-certified two-sided affine exactness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate satisfying the hypotheses of Definition 45.321, Definition 45.277, and Definition 45.278, let*

$$\mathsf{ApartZero}_F(h) := (h\mathsf{hsame}0 \to \bot).$$

For $a, b : \mathsf{BHist}$*, assume explicit conversion maps*

$$\alpha_a : \mathsf{ApartZero}_F(a) \to \mathsf{NonZero}_F(a), \quad \alpha_b : \mathsf{ApartZero}_F(b) \to \mathsf{NonZero}_F(b).$$

With square witnesses

$$p_{a^2} : \mathsf{NonZero}_F(\mathsf{mul}(a, a)), \quad p_{b^2} : \mathsf{NonZero}_F(\mathsf{mul}(b, b)),$$

let $r_a : \mathsf{ApartZero}_F(a)$ *and* $r_b : \mathsf{ApartZero}_F(b)$ *be the first zero-factor obstructions induced by zero-factor exclusion, and set* $p_a := \alpha_a(r_a)$ *and* $p_b := \alpha_b(r_b)$*. Then for every* $c, d, x, y : \mathsf{BHist}$ *both clauses hold:*

$$\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)\mathsf{hsame}c \iff x\mathsf{hsamemul}(\mathsf{inv}(a, p_a), \mathsf{mul}(\mathsf{add}(c, \mathsf{neg}(d)), \mathsf{inv}(b, p_b)))$$

and

$$\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)\mathsf{hsameadd}(\mathsf{mul}(\mathsf{mul}(a, y), b), d) \iff x\mathsf{hsame}y.$$

Proof. Apply Definition 45.303 to p_{a^2} with both product entries instantiated by a. As in Definition 45.321, the first factor clause gives $r_a : \mathsf{ApartZero}_F(a)$. Convert it by the displayed map, setting $p_a := \alpha_a(r_a) : \mathsf{NonZero}_F(a)$.

Apply the same zero-factor exclusion theorem to p_{b^2} with both product entries instantiated by b. The first factor clause gives $r_b : \mathsf{ApartZero}_F(b)$. Convert it by the displayed map, setting $p_b := \alpha_b(r_b) : \mathsf{NonZero}_F(b)$.

With these two induced witnesses, invoke Definition 45.277. Its equivalence is exactly the stated solution formula for $\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)\mathsf{hsame}c$.

For the classifier exactness clause, invoke Definition 45.278 with the same witnesses p_a and p_b and the same offset d. This removes the common certified affine map and yields precisely $\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)\mathsf{hsameadd}(\mathsf{mul}(\mathsf{mul}(a, y), b), d)$ if and only if $x\mathsf{hsame}y$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field square certified two sided affine exact`

The per-object certificate records traditional target affine equation uniqueness under square-certified factors; BEDC source $\mathsf{Field}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability obligations square nonzero descent and affine classifier exactness; ledger the two square witnesses, conversions, offset, and target; core theorem Definition 45.335; exactness predicate same-target solution uniqueness; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.335 (Field square-certified affine equation solutions are unique)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate satisfying the hypotheses of Definition 45.303 and Definition 45.278, let*

$$\mathsf{ApartZero}_F(h) := (h\mathsf{hsame}0 \to \bot).$$

For $a, b : \mathsf{BHist}$*, assume explicit conversion maps*

$$\alpha_a : \mathsf{ApartZero}_F(a) \to \mathsf{NonZero}_F(a), \quad \alpha_b : \mathsf{ApartZero}_F(b) \to \mathsf{NonZero}_F(b).$$

With square witnesses

$$p_{a^2} : \mathsf{NonZero}_F(\mathsf{mul}(a, a)), \quad p_{b^2} : \mathsf{NonZero}_F(\mathsf{mul}(b, b)),$$

for every $c, d, x, y : \mathsf{BHist}$*, if*

$$\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)\mathsf{hsame}c$$

and

$$\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, y), b), d)\mathsf{hsame}c,$$

then $x\mathsf{hsame}y$*.*

Lean4 ✓ `BEDC.Derived.FieldUp.field square certified affine solution unique`

Proof. Apply Definition 45.303 to p_{a^2} with both product entries instantiated by a. The first zero-factor obstruction gives $r_a : \mathsf{ApartZero}_F(a)$, and the conversion map gives $p_a := \alpha_a(r_a) : \mathsf{NonZero}_F(a)$.

Apply the same descent to p_{b^2} with both product entries instantiated by b. This gives $r_b : \mathsf{ApartZero}_F(b)$ and hence $p_b := \alpha_b(r_b) : \mathsf{NonZero}_F(b)$.

Let the two displayed hypotheses be e_x and e_y. By symmetry of hsame applied to e_y and transitivity of hsame with e_x, obtain

$$\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)\mathsf{hsame}\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, y), b), d).$$

Invoke Definition 45.278 with the certified factors p_a and p_b and the same offset d. The classifier exactness theorem cancels the common two-sided affine map, yielding $x\mathsf{hsame}y$. □

Definition 45.336 (Field ledger policy)**.** *Record the ring ledger and the* $\mathsf{NonZero}_F$ *witness used for each inverse.*

Definition 45.337 ($\mathsf{Field}^{\uparrow}$ certificate obligations)**.** *For the concrete target* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$*, a certificate must provide the following rows as a single obligation record.*

1. *Source and carrier: the rational-history source on* BHist *with carrier* $\mathsf{RatHistoryCarrier}$*.*
2. *Classifier and pattern:* $\mathsf{RatHistoryClassifier}$ *and the continuation pattern* Cont *over* BHist*.*
3. *Ring base: the* $\mathsf{CommRing}^{\uparrow}$ *additive, multiplicative, commutativity, distributivity, operation-congruence, and ring-ledger rows.*

4. *Apartness and inverse data:* $\mathsf{NonZero}_F$ *apartness from zero, transport of nonzero evidence, inverse closure, inverse classifier exactness, and left and right inverse laws indexed by nonzero witnesses.*
5. *Product data: the two-sided zero-product rows and the certified nonzero-product contradiction rows.*
6. *Denominator tuple:* (RatDenomUnitCarrier, RatDenomUnitClassifier, append, e, RatHistoryCarrier) *with its multiplicative, unit, closure, classifier, and ledger rows.*
7. *Contextual denominator data: the action* Γ*, its envelope and normalized-support rows, and the context-pair monoid rows for pair product, unit-pair action, composition, and strict-support readback.*
8. *Affine source:* AffAut_F *with the packaged affine* $\mathsf{Group}^{\uparrow}$ *rows used by the field certificate.*
9. *Ledger and exactness data: ring expression ledger rows, inverse witness ledger rows, denominator ledger rows, contextual-pair ledger rows, affine coefficient ledger rows, coverage, soundness, completeness, exact zero classification, denominator exactness, contextual-action exactness, context-pair exactness, and affine classifier exactness.*
10. *Status: the record status field, instantiated here as* ProofTarget.

Lean4 (definition) `BEDC.Derived.FieldUp.FieldCertificateObligations`

Theorem 45.338 (Field certificate obligations expose Rat denominator rows)**.** *Every* FieldCertificateObligations *record projects the Rat carrier row* RatHistoryCarrier(carrier)*, the Rat classifier row* RatHistoryClassifier(carrier, classifi *the denominator row* RatDenomUnitCarrier(denominatorTuple)*, and the contextual denominator row* RatDenomUnitClassifier(denominatorTuple, contextualData)*. It also projects the four source, base, affine, and status assembly equations*

$$\begin{aligned}\mathsf{hsame}(\mathsf{source}, \mathsf{append}(\mathsf{carrier}, \mathsf{classifier})),\\ \mathsf{hsame}(\mathsf{ringBase}, \mathsf{append}(\mathsf{productData}, \mathsf{inverseData})),\\ \mathsf{hsame}(\mathsf{affineSource}, \mathsf{append}(\mathsf{contextualData}, \mathsf{ledgerExactness})),\\ \mathsf{hsame}(\mathsf{status}, \mathsf{append}(\mathsf{source}, \mathsf{affineSource})).\end{aligned}$$

Proof. Unfold the certificate-obligation record. Its surface is the nested conjunction whose first four fields are exactly the Rat carrier, Rat classifier, denominator carrier, and contextual denominator classifier rows.

The remaining conjunctive fields are the four displayed assembly equations. Projecting the nested conjunction in order gives all eight rows without adding any extra carrier, classifier, or ledger hypothesis. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldCertificateObligations rat denominator rows`

Per-object certificate record.

1. Traditional target: constructive field.
2. BEDC source: $\mathsf{Rat}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ data.
3. Carrier choice: the $\mathsf{Rat}^{\uparrow}$ carrier with $\mathsf{NonZero}_F(a)$ derived from apartness from 0.
4. Classifier choice: the rational classifier plus $\mathsf{NonZero}_F$ transport.

5. Stability obligations: commutative-ring laws, contradiction of $\mathsf{NonZero}_F(0)$, nonzero transport, inverse closure, and inverse laws indexed by nonzero witnesses.
6. Ledger: ring expression tree plus the $\mathsf{NonZero}_F$ witness for each inverse.
7. Core theorem list: inverse closure, left inverse, right inverse, nonzero stability, inverse congruence from apartness transport, inverse involution under explicit nonzero evidence, right-multiplication equation solving, right-multiplication equation exactness, left-multiplication equation solving, left-multiplication equation exactness, middle multiplication equation solving, middle multiplication equation exactness, two-sided multiplication exactness, two-sided zero-product exactness, zero-product exclusion from two nonzero witnesses, signed-factor apartness exclusivity, affine left equation exactness, affine right equation exactness, two-sided affine equation exactness, one-sided affine map classifier exactness, two-sided affine map classifier exactness, affine automorphism package, product-witness independence, denominator row laws, denominator contextual action certificate, Definition 45.470, Definition 45.475, Definition 45.473, Definition 45.478, Definition 45.487, Definition 45.568, Definition 45.570, Definition 45.490, Definition 45.524, Definition 45.558, and distributivity inherited from $\mathsf{CommRing}^{\uparrow}$.
8. 9. Standard bridge: deferred conservative bridge.
10. Status: ProofTarget.

Theorem 45.339 (RatUp FieldUp certificate record absorbs selector-independent exit)**.** *For the certificate-obligation record of Definition 45.337, for Definition 45.617, for the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, for histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, for selectors* $s, t, u, v : \mathsf{BMark}$*, and for contexts* $L, R, r : \mathsf{BHist}$*, if* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *certificate record contains, as one record-level row family, every row of Definition 45.763 and every row of Definition 45.764. This family includes the selector-pair strict exit rows, the bracketing obstruction rows, both selected final boundaries, and the componentwise* $\mathsf{RatHistoryClassifier}$ *selector rows.*

Proof. Instantiate Definition 45.763 with the displayed denominator tuple, histories, carrier witnesses, selectors s, t, u, v, contexts L, R, r, and the given $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ witness. This supplies the selector-pair strict exit rows, the bracketing obstruction rows, and the selected final-boundary rows for the concrete exit object.

Instantiate Definition 45.764 with the same tuple, witnesses, selectors, contexts, and support witness. This supplies both selected final boundaries together with the componentwise R^u_D and $\mathsf{RatHistoryClassifier}$ selector rows.

The ledger fields of Definition 45.337 already name the denominator ledger, contextual-pair ledger, and coverage rows. The exactness fields name denominator exactness, contextual-action

exactness, context-pair exactness, and classifier exactness. Package the two instantiated row families under those fields, using the selector pairs and contexts as the ledger indices.

The result is a single $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ record-level final exit certificate: the traditional target is the $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ record-level final exit certificate, the BEDC source is BHist, BMark, and RatUp, the carrier and classifier rows are the denominator and rational classifier rows, the ledger is selector pairs plus contexts, and the downstream consumer is the Phase Algebra Hierarchy exit criterion. □

Theorem 45.340 (RatUp FieldUp certificate record absorbs final row inventory)**.** *For the certificate-obligation record of Definition 45.337, for the concrete exit object of Definition 45.617, for the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, for histories* $h, k, \ell : \mathsf{BHist}$ *with carrier witnesses* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, for selectors* $s, t, u, v, w, z : \mathsf{BMark}$*, and for contexts* $L, R, r : \mathsf{BHist}$*, if* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *certificate record contains the complete final row inventory of Definition 45.773. That record-level inventory consists of selector inverse-domain coverage, selector row-stability transport, the complete selector exit obstruction, and the selector-chain final boundary rows.*

Proof. Instantiate Definition 45.773 with the displayed concrete exit object, denominator tuple, histories, carrier witnesses, selectors s, t, u, v, w, z, contexts L, R, r, and the $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ witness. This gives the four row families as one final inventory for the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object.

Next apply Definition 45.339 to the same denominator tuple, histories, carrier witnesses, selectors s, t, u, v, contexts L, R, r, and support witness. This places the complete selector exit obstruction and the selected final-boundary rows inside the certificate-obligation record as record-level rows.

It remains to place the selector inverse-domain coverage, selector row-stability transport, and selector-chain final boundary rows in the same record. Definition 45.337 supplies the denominator ledger, contextual-pair ledger, coverage field, denominator exactness, contextual-action exactness, context-pair exactness, and classifier exactness fields. Use the selector sextuple and contexts as ledger indices, and store the remaining row families from the final inventory under those ledger and exactness fields.

The record therefore consumes the full inventory without adding a second exit object or changing the source package. Conjunction introduction identifies the record-level obstruction rows, inverse-domain rows, row-transport rows, and selector-chain rows as one certificate-record data family. □

Per-object template: traditional target final $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ record-level row inventory; BEDC source BHist, BMark, and $\mathsf{RatUpFieldSource}_F$; carrier $\mathsf{RatHistoryCarrier}$ and C^u_D; classifier $\mathsf{RatHistoryClassifier}$ and R^u_D; stability obligations final inventory coverage and record absorption; ledger selectors plus contexts; core theorem this block; exactness final row inventory as certificate-record data; standard bridge deferred; status $\mathsf{ProofTarget}$.

Primitive boundary. $\mathsf{Field}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Remark 45.341 (Zero-axiom encoding note)**.** *Explicit apartness witnesses support inverse formation without LEM-based* $a \neq 0$ *reasoning.*

Theorem 45.342 (Field certificate forgets to CommRing certificate)**.** *Let $\mathcal{F}$ be a BEDC history-level $\mathsf{Field}^{\uparrow}(F)$ certificate with carrier C_F, classifier R_F, operations add_F, zero_F, neg_F, mul_F, and one_F, nonzero predicate $\mathsf{NonZero}_F$, and proof-indexed inverse $\mathsf{inv}_F(a,p)$ for $p : \mathsf{NonZero}_F(a)$. If $\mathcal{F}$ satisfies the field source, pattern, classifier, stability, ledger, and obligation rows of Definition 45.198, Definition 45.199, Definition 45.200, Definition 45.201, Definition 45.336, and Definition 45.337, then*

$$\mathcal{F}_{\mathsf{CommRing}} := (C_F, R_F, \mathsf{add}_F, \mathsf{zero}_F, \mathsf{neg}_F, \mathsf{mul}_F, \mathsf{one}_F)$$

is a $\mathsf{CommRing}^{\uparrow}(F)$ source package in the sense of Definition 44.30, Definition 44.31, Definition 44.32, and Definition 44.33. It has the same carrier, classifier, additive operation, zero, additive inverse, multiplication, and unit as $\mathcal{F}$; the nonzero apartness row and all proof-indexed inverse rows are not used by this reduct.

Proof. Unpack the field source row. By Definition 45.198, a field source is already a certified commutative-ring carrier together with the additional constructive apartness predicate. Selecting the commutative-ring coordinate gives the same carrier C_F and does not change any BEDC history endpoint.

Unpack the field pattern row. By Definition 45.199, the field pattern is commutative-ring expression formation with one added formation rule for $\mathsf{inv}_F(a,p)$ when $p : \mathsf{NonZero}_F(a)$. Restricting to expressions with no inverse node leaves exactly the commutative-ring pattern from Definition 44.31, using the original add_F, neg_F, mul_F, zero_F, and one_F rows.

Unpack the classifier row. By Definition 45.200, the field classifier is ring sameness R_F together with transport of $\mathsf{NonZero}_F$ along that classifier. The $\mathsf{CommRing}^{\uparrow}(F)$ classifier requires only the ring classifier, so the projected classifier is exactly the same R_F.

Unpack the stability row. The first item of Definition 45.201 is all commutative-ring stability fields. These are precisely the closure, congruence, additive, multiplicative, distributive, and multiplicative-commutativity rows listed in Definition 44.33. The remaining field rows concern $\mathsf{NonZero}_F(0)$, nonzero transport, inverse closure, and the left and right inverse laws indexed by nonzero witnesses; none is required for the commutative-ring certificate.

Finally, Definition 45.336 records the ring ledger together with the nonzero witness used for each inverse. Selecting the ring ledger and omitting inverse-witness entries gives the commutative-ring ledger for the same operations and classifier. Thus every $\mathsf{CommRing}^{\uparrow}(F)$ row is a coordinate of $\mathcal{F}$, and the displayed tuple is the required forgetful certificate. □

Corollary 45.343 (Field certificate forgets to Ring certificate)**.** *Let $\mathcal{F}$ be a BEDC history-level $\mathsf{Field}^{\uparrow}(F)$ certificate with scalar carrier C_F, classifier R_F, operations $+_F$, 0_F, $(-)_F$, mul_F, and 1_F, nonzero predicate $\mathsf{NonZero}_F$, and proof-indexed inverse $\mathsf{inv}_F(a,p)$ for $p : \mathsf{NonZero}_F(a)$. If $\mathcal{F}$ satisfies the field source, pattern, classifier, stability, ledger, and obligation rows of Definition 45.198, Definition 45.199, Definition 45.200, Definition 45.201, Definition 45.336, and Definition 45.337, then the composite reduct obtained by first applying Definition 45.342 and then applying Definition 44.8 is a $\mathsf{Ring}^{\uparrow}(F)$ certificate. Its carrier is C_F, its classifier is R_F, and its operations are $+_F$, 0_F, $(-)_F$, mul_F, and 1_F.*

Proof. Apply Definition 45.342 to $\mathcal{F}$. The resulting commutative-ring reduct keeps the carrier C_F, the classifier R_F, addition $+_F$, zero 0_F, additive inverse $(-)_F$, multiplication mul_F, and unit 1_F. The rows involving $\mathsf{NonZero}_F$ and the proof-indexed inverse operation are omitted, because they are not part of the $\mathsf{CommRing}^{\uparrow}(F)$ obligations.

Now apply Definition 44.8 to this $\mathsf{CommRing}^{\uparrow}(F)$ certificate. That projection removes only the multiplication-commutativity row and the commutative-ring-specific ledger entries, while retaining

the carrier, source, ring pattern, classifier, ring stability fields, and ring ledger. By Definition 43.55, those retained rows are precisely a $\mathsf{Ring}^{\uparrow}(F)$ certificate.

Both projections are coordinate projections. The first does not alter the carrier or any of $+_F$, 0_F, $(-)_F$, mul_F, and 1_F, and the second projection states that the same operations and carrier classifier are unchanged. Therefore the composite reduct is the required $\mathsf{Ring}^{\uparrow}(F)$ certificate over the original scalar carrier, classifier, and ring operations. □

Theorem 45.344 (Preserved strict zero-divisor pair obstructs FieldUp)**.** *Let R be a BEDC history-level* $\mathsf{CommRing}^{\uparrow}$ *package over* BHist *with zero* 0*, unit* 1*, multiplication* $\cdot$*, classifier* hsame*, and apart-zero predicate* $\mathsf{ApartZero}_R(x) := (x\mathsf{hsame}0 \to \bot)$ *as in Definition 44.97. Let $\mathcal{F}$ be a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate satisfying Definition 45.337 with the same zero, unit, multiplication, and classifier on the displayed histories. Assume its apartness-preservation row is*

$$\alpha : \forall x : \mathsf{BHist},\ \mathsf{ApartZero}_R(x) \to \mathsf{NonZero}_F(x).$$

Then every $a, b : \mathsf{BHist}$ satisfies

$$\mathsf{ApartZero}_R(a) \wedge \mathsf{ApartZero}_R(b) \wedge a \cdot b\mathsf{hsame}0 \Longrightarrow \mathsf{False}.$$

Proof. Assume such a pair exists. Unpack its three components as $q_a : \mathsf{ApartZero}_R(a)$, $q_b : \mathsf{ApartZero}_R(b)$, and $z : a \cdot b\mathsf{hsame}0$.

Apartness preservation converts the first two components into field nonzero witnesses

$$p_a := \alpha(a)(q_a) : \mathsf{NonZero}_F(a), \qquad p_b := \alpha(b)(q_b) : \mathsf{NonZero}_F(b).$$

Because the field candidate preserves the same multiplication, zero, and classifier on these endpoints, the ring classifier row z is also the field zero-product row for a and b. The product data in Definition 45.337 supplies the hypotheses consumed by Definition 45.248. Applying that theorem to p_a, p_b, and z gives False, contradicting existence of the displayed pair. Thus a field candidate with the stated preserved coordinates cannot exist over a commutative-ring package carrying such witnesses. □

Corollary 45.345 (Strict zero divisor obstructs FieldUp)**.** *Under the same preservation hypotheses, if $a : \mathsf{BHist}$ satisfies $\mathsf{StrictZD}_R(a)$ in the sense of Definition 44.99, then no $\mathsf{Field}^{\uparrow}$ certificate satisfying Definition 45.337 preserves the same 0, 1, multiplication, classifier, and apartness over that commutative-ring package.*

Proof. Unpack $\mathsf{StrictZD}_R(a)$. It gives $\mathsf{ApartZero}_R(a)$ and a history $b : \mathsf{BHist}$ with $\mathsf{ApartZero}_R(b)$, $a \cdot b\mathsf{hsame}0$, and $b \cdot a\mathsf{hsame}0$. The first three of these components form the preserved strict zero-divisor pair excluded by Definition 45.344. Therefore any $\mathsf{Field}^{\uparrow}$ certificate with the stated preservation rows yields False. □

45.14 Rat denominator empty-unit continuation monoid instance

Definition 45.346 (Rat denominator empty-unit continuation monoid instance)**.** *The empty-unit denominator continuation monoid data for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *are the concrete tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D)$ *defined by*

$$C^u_D(h) \Longleftrightarrow \mathsf{RatDenomUnitCarrier}(h),$$

$$R^u_D(h, k) \Longleftrightarrow \mathsf{RatDenomUnitClassifier}(h, k),$$

$$\mu^u_D(h,k) := \mathsf{append}(h,k),$$

and $e^u_D := \mathsf{e}$. *For every pair of histories* $h,k : \mathsf{BHist}$, *the multiplication is equipped with the canonical continuation witness*

$$\mathsf{Cont}(h,k,\mathsf{append}(h,k)).$$

Theorem 45.347 (Rat denominator empty-unit continuation monoid laws)**.** *The concrete tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D)$ *of Definition 45.346 satisfies the denominator empty-unit continuation monoid laws:*

1. *The unit is carried:* $C^u_D(e^u_D)$.
2. *The multiplication is closed: if* $C^u_D(h)$ *and* $C^u_D(k)$, *then* $C^u_D(\mu^u_D(h,k))$.
3. *The left and right unit products are classified with their endpoint: for every* h *with* $C^u_D(h)$, $R^u_D(\mu^u_D(e^u_D,h),h)$ *and* $R^u_D(\mu^u_D(h,e^u_D),h)$.
4. *The multiplication is associative under* R^u_D: *if* $C^u_D(h)$, $C^u_D(k)$, *and* $C^u_D(\ell)$, *then* $R^u_D(\mu^u_D(\mu^u_D(h,k),\ell),\mu^u_D(h,\mu^u_D(k,$
5. *The multiplication respects classified endpoints: if* $R^u_D(h,h')$ *and* $R^u_D(k,k')$, *then* $R^u_D(\mu^u_D(h,k),\mu^u_D(h',k'))$.

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator empty unit continuation monoid laws`

Proof. Unfold C^u_D, R^u_D, μ^u_D, and e^u_D. The displayed multiplication is the external append operation, so each product carries the canonical continuation witness $\mathsf{Cont}(h,k,\mathsf{append}(h,k))$.

The carried empty unit, append closure, and the two one-sided unit classifications are exactly the first four clauses of Definition 45.177 applied to those canonical continuation witnesses.

For associativity, use the same adjoined-unit theorem with the four canonical continuation witnesses for the two inner and two outer products. Its fifth clause gives the classifier comparison between the two bracketed append results.

It remains to show multiplication congruence. From $R^u_D(h,h')$ and $R^u_D(k,k')$, unfold the classifier to obtain the four carried endpoint witnesses together with $h\mathsf{hsame}h'$ and $k\mathsf{hsame}k'$. Apply Definition 12.3 to the two hsame comparisons; append closure for C^u_D supplies the two carried product witnesses. These three pieces are exactly $R^u_D(\mu^u_D(h,k),\mu^u_D(h',k'))$.

Thus the denominator continuation fields are concrete BEDC data: carrier $\mathsf{RatDenomUnitCarrier}$, classifier $\mathsf{RatDenomUnitClassifier}$, multiplication append, and unit e, with no abstract operator field being used. □

Theorem 45.348 (Rat denominator unit carrier empty context exactness)**.** *For histories* $p,q,h : \mathsf{BHist}$, *if* $p\mathsf{hsame}\mathsf{e}$ *and* $q\mathsf{hsame}\mathsf{e}$, *then adding those empty endpoint contexts does not change membership in the empty-unit denominator carrier:*

$$\mathsf{RatDenomUnitCarrier}(\mathsf{append}(p,\mathsf{append}(h,q))) \iff \mathsf{RatDenomUnitCarrier}(h).$$

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier empty context iff`

Proof. Eliminate the two empty-context sameness witnesses. The right append with e reduces to h, and the left append by e is identified with h by the append left-unit law. Transport the concrete $\mathsf{RatDenomUnitCarrier}$ predicate along that history-sameness comparison in both directions. □

Theorem 45.349 (Rat denominator unit classifier empty context strict support iff)**.** *For histories* $p,q,p',q',h,k : \mathsf{BHist}$, *assume* $p\mathsf{hsame}\mathsf{e}$, $q\mathsf{hsame}\mathsf{e}$, $p'\mathsf{hsame}\mathsf{e}$, *and* $q'\mathsf{hsame}\mathsf{e}$. *If the empty-unit denominator classifier relates the two context-enlarged endpoints,*

$$\mathsf{RatDenomUnitClassifier}(\mathsf{append}(p,\mathsf{append}(h,q)),\mathsf{append}(p',\mathsf{append}(k,q'))),$$

then strict rational support is the same on the exposed endpoints:

$$\mathsf{RatHistoryCarrier}(h) \iff \mathsf{RatHistoryCarrier}(k).$$

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier empty context rat carrier iff`

Proof. Apply Definition 45.405 to the four empty-context witnesses and the displayed classifier. This yields the core classifier $\mathsf{RatDenomUnitClassifier}(h, k)$. Its final field is $h\mathsf{hsame}k$, so $\mathsf{RatHistoryCarrier}$ transports from h to k; using the symmetric hsame comparison gives the reverse implication. □

45.15 Rat denominator unit endpoint exactness

Theorem 45.350 (Rat denominator continuation right-unit endpoint iff empty)**.** *For every history $u : \mathsf{BHist}$, the right-unit classifier law is equivalent to external emptiness:*

$$(\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, u, r) \to \mathsf{RatHistoryClassifier}(r, d)) \iff u\mathsf{hsame}\mathsf{e}.$$

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation right unit law endpoint empty iff`

Proof. For the forward direction, apply Theorem 45.125 to the displayed right-unit classifier law. Its first endpoint-forcing clause returns $u\mathsf{hsame}\mathsf{e}$.

Conversely, assume $u\mathsf{hsame}\mathsf{e}$, a carrier witness $\mathsf{RatHistoryCarrier}(d)$, and a displayed continuation $\mathsf{Cont}(d, u, r)$. Transport the second continuation endpoint along $u\mathsf{hsame}\mathsf{e}$ to obtain a continuation presentation $\mathsf{Cont}(d, \mathsf{e}, r)$ with the same displayed result. The right external-boundary law in Theorem 45.124 then yields $\mathsf{RatHistoryClassifier}(r, d)$. □

Theorem 45.351 (Rat denominator continuation right-unit visible endpoint exclusion)**.** *For every pair of histories $u, p : \mathsf{BHist}$, if u satisfies the right-unit classifier law for Rat denominator continuation, then u cannot be history-same to either visible endpoint over p:*

$$(\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, u, r) \to \mathsf{RatHistoryClassifier}(r, d)) \Longrightarrow (\mathsf{hsame}(u, \mathsf{E0}(p)) \to \mathsf{False}) \wedge (\mathsf{hs}$$

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation right unit law visible endpoint absurd`

Proof. Test the law on the concrete Rat carrier $\mathsf{E1}(\mathsf{e})$ and the displayed continuation $\mathsf{Cont}(\mathsf{E1}(\mathsf{e}), u, \mathsf{E1}(\mathsf{e}) \cdot u)$. The classifier result collapses the continuation result back to $\mathsf{E1}(\mathsf{e})$, so continuation right-unit uniqueness gives $u\mathsf{hsame}\mathsf{e}$. Composing either visible presentation of u with this empty endpoint contradicts BEDC history constructor no-confusion for $\mathsf{E0}$ and $\mathsf{E1}$. □

Theorem 45.352 (Rat denominator continuation left-unit endpoint iff empty)**.** *For every history $u : \mathsf{BHist}$, the left-unit classifier law is equivalent to external emptiness:*

$$(\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(u, d, r) \to \mathsf{RatHistoryClassifier}(r, d)) \iff u\mathsf{hsame}\mathsf{e}.$$

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation left unit law endpoint empty iff`

Proof. For the forward direction, apply Theorem 45.125 to the displayed left-unit classifier law. Its second endpoint-forcing clause returns $u\mathsf{hsamee}$.

Conversely, assume $u\mathsf{hsamee}$, a carrier witness $\mathsf{RatHistoryCarrier}(d)$, and a displayed continuation $\mathsf{Cont}(u, d, r)$. Transport the first continuation endpoint along $u\mathsf{hsamee}$ to obtain $\mathsf{Cont}(\mathsf{e}, d, r)$. The left external-boundary law in Theorem 45.124 classifies the displayed result as $\mathsf{RatHistoryClassifier}(r, d)$. □

Theorem 45.353 (Rat denominator left-unit result is not empty)**.** *For histories $u, d, r : \mathsf{BHist}$, suppose u satisfies the Rat-denominator left-unit classifier law:*

$$\forall x, y : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(x) \to \mathsf{Cont}(u, x, y) \to \mathsf{RatHistoryClassifier}(y, x).$$

If $\mathsf{RatHistoryCarrier}(d)$ and $\mathsf{Cont}(u, d, r)$, then $\mathsf{hsame}(r, \mathsf{e})$ implies contradiction.

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation left unit law result not empty`

Proof. Apply the displayed left-unit classifier law to the concrete carried denominator d and continuation $\mathsf{Cont}(u, d, r)$. The resulting $\mathsf{RatHistoryClassifier}(r, d)$ exposes a Rat carrier witness on r, and Rat carrier histories cannot be internally the same as e. □

Lemma 45.354 (Rat denominator left-unit results classify together)**.** *For histories $u, d, r, s : \mathsf{BHist}$, suppose u satisfies the Rat-denominator left-unit classifier law. If $\mathsf{RatHistoryCarrier}(d)$, $\mathsf{Cont}(u, d, r)$, and $\mathsf{Cont}(u, d, s)$, then $\mathsf{RatHistoryClassifier}(r, s)$.*

Proof. Apply the left-unit classifier law to both displayed continuations. This gives $\mathsf{RatHistoryClassifier}(r, d)$ and $\mathsf{RatHistoryClassifier}(s, d)$. The carrier fields supply Rat carrier witnesses for r and s, and the two hsame comparisons compose through d to classify r with s. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation left unit result classifier`

Theorem 45.355 (Rat denominator e1 left-unit law is impossible)**.** *For every tail history $t : \mathsf{BHist}$, the one-headed candidate $\mathsf{E1}(t)$ cannot satisfy the Rat-denominator left-unit classifier law:*

$$(\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(\mathsf{E1}(t), d, r) \to \mathsf{RatHistoryClassifier}(r, d)) \to \mathsf{False}.$$

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation e1 left unit law absurd`

Proof. The left-unit endpoint equivalence forces $\mathsf{E1}(t)\mathsf{hsamee}$ from the displayed classifier law. Constructor separation for BHist rejects any equality between a one-headed history and the empty history. □

Theorem 45.356 (Rat denominator visible left-unit law is impossible)**.** *For every history $u : \mathsf{BHist}$, if u is history-same to a visible zero-headed or one-headed history, then u cannot satisfy the Rat-denominator left-unit classifier law:*

$$((\exists t : \mathsf{BHist}.\ u\mathsf{hsameE0}(t)) \vee (\exists t : \mathsf{BHist}.\ u\mathsf{hsameE1}(t))) \to (\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(u, d, r) \to \mathsf{Ra}$$

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator continuation visible left unit law absurd`

Proof. The left-unit endpoint equivalence forces $u\mathsf{hsamee}$. In the visible zero-headed branch, transitivity gives $\mathsf{E0}(t)\mathsf{hsamee}$, contradicting constructor separation. In the one-headed branch, the same argument gives $\mathsf{E1}(t)\mathsf{hsamee}$, again impossible by constructor separation. □

Theorem 45.357 (Rat denominator e1-probe classifier endpoint empty)**.** *For every history* u : BHist*, if the one-headed denominator probe classifies the displayed product with its endpoint,*

$$\mathsf{RatHistoryClassifier}(\mathsf{append}(u, \mathsf{E1}(\mathsf{e})), \mathsf{E1}(\mathsf{e})),$$

then $u\mathsf{hsamee}$*.*

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator e1 probe classifier endpoint empty`

Proof. Use the canonical continuation witness $\mathsf{Cont}(u, \mathsf{E1}(\mathsf{e}), \mathsf{append}(u, \mathsf{E1}(\mathsf{e})))$. The classifier supplies history sameness between its result and $\mathsf{E1}(\mathsf{e})$, so continuation result transport gives $\mathsf{Cont}(u, \mathsf{E1}(\mathsf{e}), \mathsf{E1}(\mathsf{e}))$. The left-unit uniqueness law for continuation then forces $u\mathsf{hsamee}$. □

Theorem 45.358 (Rat denominator right e1-probe classifier endpoint empty)**.** *For every history* u : BHist*, if the fixed one-headed denominator probe on the left classifies the displayed product with its endpoint,*

$$\mathsf{RatHistoryClassifier}(\mathsf{append}(\mathsf{E1}(\mathsf{e}), u), \mathsf{E1}(\mathsf{e})),$$

then $u\mathsf{hsamee}$*.*

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator right e1 probe classifier endpoint empty`

Proof. Use the canonical continuation witness $\mathsf{Cont}(\mathsf{E1}(\mathsf{e}), u, \mathsf{append}(\mathsf{E1}(\mathsf{e}), u))$. The classifier supplies history sameness between its result and $\mathsf{E1}(\mathsf{e})$, so continuation result transport gives $\mathsf{Cont}(\mathsf{E1}(\mathsf{e}), u, \mathsf{E1}(\mathsf{e}))$. The right-unit uniqueness law for continuation then forces $u\mathsf{hsamee}$. □

Theorem 45.359 (Rat history classifier right append carrier obstruction)**.** *For all histories* d, u : BHist*, if* $\mathsf{RatHistoryCarrier}(u)$ *holds, then*

$$\mathsf{RatHistoryClassifier}(\mathsf{append}(d, u), d) \to \mathsf{False}.$$

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryClassifier append right carrier absurd`

Proof. Use the canonical continuation $\mathsf{Cont}(d, u, \mathsf{append}(d, u))$. The classifier equality transports this continuation result to d, giving $\mathsf{Cont}(d, u, d)$. Right-unit uniqueness forces $u\mathsf{hsamee}$, contradicting the displayed $\mathsf{RatHistoryCarrier}(u)$ witness. □

Theorem 45.360 (Rat history classifier left append carrier obstruction)**.** *For all histories* u, d : BHist*, if* $\mathsf{RatHistoryCarrier}(u)$ *holds, then*

$$\mathsf{RatHistoryClassifier}(\mathsf{append}(u, d), d) \to \mathsf{False}.$$

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryClassifier append left carrier absurd`

Proof. Use the canonical continuation $\mathsf{Cont}(u, d, \mathsf{append}(u, d))$. The classifier equality transports this continuation result to d, giving $\mathsf{Cont}(u, d, d)$. Left-unit uniqueness forces $u\mathsf{hsamee}$, contradicting the displayed $\mathsf{RatHistoryCarrier}(u)$ witness. □

Theorem 45.361 (Rat denominator external unit separation package)**.** *For the concrete denominator carrier, classifier, and continuation operation given by*

$$C_D(h) \iff \mathsf{RatHistoryCarrier}(h),$$

$$R_D(h, k) \iff \mathsf{RatHistoryClassifier}(h, k),$$

with operation represented by Cont*, every history* u : BHist *satisfies the following three clauses.*

1. *The right classifier-unit law*

$$\forall d, r : \mathsf{BHist}.\ C_D(d) \to \mathsf{Cont}(d, u, r) \to R_D(r, d)$$

is equivalent to $u\mathsf{hsamee}$.

2. *The left classifier-unit law*

$$\forall d, r : \mathsf{BHist}.\ C_D(d) \to \mathsf{Cont}(u, d, r) \to R_D(r, d)$$

is equivalent to $u\mathsf{hsamee}$.

3. *If* $C_D(u)$ *holds, then either one-sided classifier-unit law displayed above implies* False.

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator external unit separation package`

Proof. The displayed definitions of C_D and R_D identify the right classifier-unit law with the concrete law in Definition 45.350. That theorem gives the first equivalence exactly.

The same unpacking identifies the left classifier-unit law with the concrete law in Definition 45.352. That theorem gives the second equivalence.

For the carried exclusion, assume $C_D(u)$. This is precisely $\mathsf{RatHistoryCarrier}(u)$. The right one-sided law contradicts Definition 45.143, while the left one-sided law contradicts Definition 45.148.

Equivalently, either endpoint equivalence first yields $u\mathsf{hsamee}$, and then Definition 37.18 excludes the simultaneous carried witness. Thus the empty endpoint is external to the positive Rat denominator carrier even though it is exact for the classifier-unit boundary laws. □

Theorem 45.362 (Rat denominator external unit endpoint disjunction uniqueness)**.** *For histories* $u, v : \mathsf{BHist}$*, suppose each endpoint satisfies at least one of the two one-sided denominator classifier-unit laws:*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, u, r) \to \mathsf{RatHistoryClassifier}(r, d)$$

or

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(u, d, r) \to \mathsf{RatHistoryClassifier}(r, d),$$

and similarly with v *in place of* u*. Then* $u\mathsf{hsame}v$.

Proof. Case-split the two endpoint alternatives. The right/right, left/left, and right/left branches are the three clauses of the endpoint uniqueness theorem. The left/right branch is the symmetric form of the right/left branch applied with the two endpoints exchanged. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator external unit endpoint disjunction unique`

Theorem 45.363 (Rat denominator external unit normal form)**.** *For every history* $u : \mathsf{BHist}$*, write* $R(u)$ *for the right classifier-unit law*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, u, r) \to \mathsf{RatHistoryClassifier}(r, d)$$

and write $L(u)$ *for the left classifier-unit law*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(u, d, r) \to \mathsf{RatHistoryClassifier}(r, d).$$

Then $R(u)$*,* $L(u)$*,* $R(u) \vee L(u)$*, and* $u\mathsf{hsamee}$ *are pairwise equivalent: each of the four propositions implies each of the other three. Moreover,*

$$\mathsf{RatHistoryCarrier}(u) \to (R(u) \vee L(u)) \to \mathsf{False}.$$

Proof. The right endpoint law is equivalent to $u\mathsf{hsamee}$ by Definition 45.350. The left endpoint law is equivalent to $u\mathsf{hsamee}$ by Definition 45.352. Thus $R(u)$ and $L(u)$ each factor through the same external empty endpoint, and the empty endpoint returns both one-sided laws by the reverse directions.

For the disjunction, assume $R(u) \vee L(u)$. Constructive case analysis reduces the right case to the right endpoint theorem and the left case to the left endpoint theorem, so either branch gives $u\mathsf{hsamee}$. Conversely, $u\mathsf{hsamee}$ gives both $R(u)$ and $L(u)$, hence gives the displayed disjunction. Factoring every implication through $u\mathsf{hsamee}$ gives the pairwise equivalence of all four propositions.

For the carried exclusion, assume $\mathsf{RatHistoryCarrier}(u)$ and $R(u) \vee L(u)$. In the right branch, the no-internal-unit theorem Definition 45.143 gives False. In the left branch, the no-internal-left-unit theorem Definition 45.148 gives False. Equivalently, this is the carried exclusion clause of Definition 45.361 applied to the displayed one-sided law. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator external unit normal form`

Theorem 45.364 (Rat denominator external unit uniqueness and carrier separation)**.** *For histories $u, v : \mathsf{BHist}$, write $R(w)$ for the right classifier-unit law*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, w, r) \to \mathsf{RatHistoryClassifier}(r, d)$$

and write $L(w)$ for the left classifier-unit law

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(w, d, r) \to \mathsf{RatHistoryClassifier}(r, d).$$

If $R(u) \vee L(u)$ and $R(v) \vee L(v)$, then $u\mathsf{hsame}v$, $\mathsf{RatHistoryCarrier}(u) \to \mathsf{False}$, and $\mathsf{RatHistoryCarrier}(v) \to \mathsf{False}$.

Proof. Assume the two endpoint disjunction witnesses. Apply Definition 45.362 to these witnesses to obtain $u\mathsf{hsame}v$.

For u, use the carried-exclusion clause of Definition 45.363. Composing that clause with the assumed witness $R(u) \vee L(u)$ yields $\mathsf{RatHistoryCarrier}(u) \to \mathsf{False}$.

The same argument at v, now using the assumed witness $R(v) \vee L(v)$, yields $\mathsf{RatHistoryCarrier}(v) \to \mathsf{False}$. The three conclusions are therefore available as a single consumable boundary row. □

Traditional target: external denominator unit normal form; **BEDC source**: RatHistoryCarrier, RatHistoryClassifier, and Cont; **carrier**: Rat denominators; **classifier**: Rat history classifier; **stability obligation**: endpoint-unit exactness; **ledger**: the displayed continuation witness; **core theorem**: Definition 45.363; **exactness predicate**: one-sided unit laws coincide with external emptiness; **standard bridge**: deferred; **status**: ProofTarget.

Traditional target: external unit boundary for the Rat denominator continuation fragment; **BEDC source**: RatHistoryCarrier, RatHistoryClassifier, and Cont; **carrier**: C_D; **classifier**: R_D; **stability obligation**: endpoint exactness plus carried-unit exclusion; **ledger**: continuation witness; **core theorem**: Definition 45.361; **exactness predicate**: external-unit iff empty plus no internal carried unit; **standard bridge**: deferred; **status**: ProofTarget.

Traditional target: denominator-side continuation unit endpoint classification for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: RatHistoryCarrier, RatHistoryClassifier, and Cont; **carrier choice**: Rat denominators; **classifier choice**: Rat history classifier; **stability obligation**: endpoint-unit exactness; **ledger**: the displayed continuation witness; **core theorems**: Definition 45.350 and Definition 45.352; **exactness predicate**: right and left unit endpoint laws are each equivalent to external emptiness; **standard bridge**: deferred; **status**: ProofTarget.

Definition 45.365 (Rat denominator external-unit predicate)**.** *For a history* $u : \mathsf{BHist}$*, let* $U_D(u)$ *denote the proposition*

$$U_D(u) :\Longleftrightarrow (\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, u, r) \to \mathsf{RatHistoryClassifier}(r, d)) \vee (\forall d, r : \mathsf{BHist}.\ \mathsf{RatHisto}$$

Theorem 45.366 (Rat denominator external-unit classifier disjointness)**.** *For all histories* $u, d : \mathsf{BHist}$*,*

$$U_D(u) \to (\mathsf{RatHistoryClassifier}(u, d) \vee \mathsf{RatHistoryClassifier}(d, u)) \to \mathsf{False}.$$

Proof. Unfold $U_D(u)$. A witness for this predicate is exactly one of the two one-sided denominator classifier-unit laws displayed in Definition 45.363. That normal form turns either alternative into the endpoint equality $u\mathsf{hsamee}$.

It remains to compare this endpoint equality with the displayed classifier branch. If $\mathsf{RatHistoryClassifier}(u, d)$ holds, project its left endpoint witness. This gives $\mathsf{RatHistoryCarrier}(u)$, and Definition 37.18 contradicts it together with $u\mathsf{hsamee}$.

If $\mathsf{RatHistoryClassifier}(d, u)$ holds, project its right endpoint witness. This again gives $\mathsf{RatHistoryCarrier}(u)$, so the same carrier nonemptiness theorem contradicts the endpoint equality. Hence no external unit selected by the concrete denominator unit predicate can occur as either endpoint of a Rat denominator classifier edge. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator external unit classifier disjointness`

Theorem 45.367 (Rat denominator external-unit predicate boundary package)**.** *For histories* $u, v, d : \mathsf{BHist}$*, if* $U_D(u)$ *and* $U_D(v)$*, then the following four boundary clauses hold:*

1. $u\mathsf{hsame}v$*;*
2. $\mathsf{RatHistoryCarrier}(u) \to \mathsf{False}$*;*
3. $\mathsf{RatHistoryCarrier}(v) \to \mathsf{False}$*;*
4. $(\mathsf{RatHistoryClassifier}(u, d) \vee \mathsf{RatHistoryClassifier}(d, u)) \to \mathsf{False}$*.*

Proof. Unfold $U_D(u)$ and $U_D(v)$ only to expose the two endpoint-unit disjunction witnesses. Apply Definition 45.364 to these two witnesses. This gives the uniqueness clause $u\mathsf{hsame}v$ and the two carrier-exclusion clauses for u and v.

It remains to rule out classifier edges touching the chosen external unit. Apply Definition 45.366 to the original witness $U_D(u)$. The resulting implication is exactly the displayed Rat-classifier disjointness row for the pair (u, d). □

Traditional target: external unit classifier separation for the concrete Rat denominator fragment; **BEDC source**: RatHistoryCarrier, RatHistoryClassifier, and Cont; **carrier**: Rat denominators; **classifier**: Rat history classifier; **stability obligation**: endpoint-unit normal form plus carrier nonemptiness; **ledger**: the chosen one-sided unit law and classifier endpoint; **core theorem**: Definition 45.366; **exactness predicate**: classifier-disjointness from Rat denominator endpoints; **standard bridge**: deferred; **status**: ProofTarget.

45.16 Concrete Rat denominator external-unit package

Theorem 45.368 (Rat denominator concrete continuation is cancellative and unitless)**.** *For the concrete data* C_D*,* R_D*, and* μ_D *of Definition 45.323, the denominator-side fragment consumed by the* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *certificate has the following form.*

1. *C_D, R_D, and μ_D form the carried commutative semigroup fragment: multiplication closes on carried denominators, commutativity and associativity hold up to R_D, binary classifier congruence is respected in both inputs, and the Rat history ledger is closed under classified carried right tails.*

2. *For all histories $p, q, d, e, pd, pe, left, right$: BHist, if $\mathsf{UnaryHistory}(p)$, $\mathsf{UnaryHistory}(q)$, $C_D(d)$, $C_D(e)$, $\mathsf{Cont}(p, d, pd)$, $\mathsf{Cont}(p, e, pe)$, $\mathsf{Cont}(pd, q, left)$, and $\mathsf{Cont}(pe, q, right)$, then the common unary context is exact for both the classifier and the ledger:*

$$R_D(left, right) \iff R_D(d, e).$$

$$\mathsf{RatHistoryLedgerPolicy}(left, right) \iff \mathsf{RatHistoryLedgerPolicy}(d, e).$$

3. *For every endpoint u : BHist, if either one-sided classifier-unit law*

$$\forall d, r : \mathsf{BHist}.\ C_D(d) \to \mathsf{Cont}(d, u, r) \to R_D(r, d)$$

or

$$\forall d, r : \mathsf{BHist}.\ C_D(d) \to \mathsf{Cont}(u, d, r) \to R_D(r, d)$$

holds, then $u\mathsf{hsamee}$. If also $C_D(u)$, then False.

Proof. Unfold the concrete data of Definition 45.323, so that C_D is $\mathsf{RatHistoryCarrier}$, R_D is $\mathsf{RatHistoryClassifier}$, and μ_D is append with its canonical continuation witness.

The semigroup fragment is exactly Definition 45.325. Its clauses give carrier closure, commutativity, associativity, binary classifier congruence, and ledger closure for the displayed concrete operation.

For the common-context clause, apply Definition 45.138 to the two unary contexts and the four displayed continuation witnesses. After the same unfolding of C_D and R_D, its two conclusions are precisely the classifier cancellation equivalence and the ledger exactness equivalence in the statement.

For the endpoint obstruction, use Definition 45.350 for the right-unit classifier law and Definition 45.352 for the left-unit classifier law. Either case yields $u\mathsf{hsamee}$. If a carrier witness $C_D(u)$ is also present, unfold C_D and apply Definition 37.18 to that witness and the comparison $u\mathsf{hsamee}$, giving False. □

Theorem 45.369 (Rat denominator continuation exact external-unit package)**.** *For the concrete Rat denominator continuation data (C_D, R_D, μ_D) of Definition 45.323, the following package holds.*

1. *If $C_D(d)$ and $C_D(e)$, then $C_D(\mu_D(d, e))$.*

2. *If $C_D(d)$ and $C_D(e)$, then $R_D(\mu_D(d, e), \mu_D(e, d))$.*

3. *If $C_D(d)$, $C_D(e)$, and $C_D(f)$, then $R_D(\mu_D(\mu_D(d, e), f), \mu_D(d, \mu_D(e, f)))$.*

4. *If $R_D(d, d')$ and $R_D(e, e')$, then $R_D(\mu_D(d, e), \mu_D(d', e'))$.*

5. *If $\mathsf{RatHistoryLedgerPolicy}(\rho, v)$, $C_D(e)$, and $R_D(e, e')$, then $\mathsf{RatHistoryLedgerPolicy}(\mu_D(\rho, e), \mu_D(v, e'))$.*

6. *For every endpoint u : BHist,*

$$(\forall d, r : \mathsf{BHist}.\ C_D(d) \to \mathsf{Cont}(d, u, r) \to R_D(r, d)) \iff u\mathsf{hsamee}.$$

7. *For every endpoint* $u : \mathsf{BHist}$,

$$(\forall d, r : \mathsf{BHist}.\ C_D(d) \to \mathsf{Cont}(u, d, r) \to R_D(r, d)) \iff u\mathsf{hsamee}.$$

8. *If* $C_D(u)$, *then neither displayed one-sided classifier-unit law can hold for* u.

9. *If* u *and* v *each satisfy either displayed one-sided classifier-unit law, then* $u\mathsf{hsame}v$.

Proof. Unfold the concrete names C_D, R_D, and μ_D only as needed. The first five clauses are exactly the first law group in Definition 45.325: carrier closure, commutative classifier, associative classifier, binary classifier congruence, and ledger closure.

For the right external-unit exactness clause, read C_D as $\mathsf{RatHistoryCarrier}$ and R_D as $\mathsf{RatHistoryClassifier}$. Apply Definition 45.350 to the displayed right-unit law.

For the left external-unit exactness clause, use the same identifications and apply Definition 45.352.

For carried-endpoint exclusion, suppose $C_D(u)$ and one of the displayed one-sided classifier-unit laws holds. The corresponding exactness clause gives $u\mathsf{hsamee}$. Since $C_D(u)$ is $\mathsf{RatHistoryCarrier}(u)$, rational history carrier nonemptiness, Definition 37.18, contradicts $u\mathsf{hsamee}$.

Finally, take two one-sided classifier-unit endpoints u and v. The right/right, left/left, and right/left cases are the three clauses of Definition 45.129. The left/right case follows by applying the mixed clause in the opposite order and then using symmetry of hsame. □

Traditional target: denominator-side continuation package for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ with an external unit endpoint; **BEDC source**: $\mathsf{RatHistoryCarrier}$, $\mathsf{RatHistoryClassifier}$, Cont, append, and $\mathsf{RatHistoryLedgerPolicy}$; **carrier choice**: C_D from Definition 45.323; **classifier choice**: R_D from Definition 45.323; **stability obligation**: carrier closure, commutative classifier, associative classifier, classifier congruence, ledger closure, and endpoint uniqueness; **ledger**: the Rat history ledger policy transported through μ_D; **core theorem**: Definition 45.369; **exactness predicate**: the right and left external-unit iff clauses identifying the endpoint with e; **standard bridge**: deferred; **status**: $\mathsf{ProofTarget}$.

Rat denominator external-unit envelope law spine. The denominator envelope used at the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ boundary is the concrete history carrier $C^*_D(h) \equiv \mathsf{RatHistoryCarrier}(h) \vee h\mathsf{hsamee}$, with classifier R^*_D given by the guarded carried Rat classifier branch or the empty-empty endpoint branch. The product is the BEDC history append operation, and the displayed endpoint is $e^*_D = \mathsf{e}$.

The checked law package for this envelope consists of carrier inhabitance, append closure, associativity under R^*_D, the left and right endpoint unit laws, and binary classifier congruence. On carried denominators the guarded branch restricts back to the positive-denominator Rat classifier, while the empty branch supplies the external endpoint. The one-sided unit uniqueness and unit equivalence clauses recorded below use this same law spine together with the nonemptiness of carried Rat denominators.

Definition 45.370 (Rat denominator external-unit envelope)**.** *The Rat denominator external-unit envelope over the concrete continuation instance of Definition 45.323 has carrier, classifier, operation, and unit*

$$C^*_D(h) \iff \mathsf{RatHistoryCarrier}(h) \vee h\mathsf{hsamee},$$

$$R^*_D(h, k) \iff (\mathsf{RatHistoryCarrier}(h) \wedge \mathsf{RatHistoryCarrier}(k) \wedge \mathsf{RatHistoryClassifier}(h, k)) \vee (h\mathsf{hsamee} \wedge k\mathsf{hsamee}),$$

$$\mu^*_D(h, k) := \mathsf{append}(h, k),$$

with external unit $e^*_D := \mathsf{e}$. *The first classifier branch is the original Rat denominator classifier guarded by carried denominator evidence. The second branch is the single external endpoint clause, so mixed carried-empty pairs are not classified merely by adjoining* e^*_D.

Theorem 45.371 (Rat denominator external-unit envelope classifier normal form)**.** *For the explicit envelope of Definition 45.370 and the adjoined empty-unit classifier of Definition 45.154, the following normal forms coincide:*

1. *For every history* $h : \mathsf{BHist}$,

$$C^*_D(h) \iff \mathsf{RatDenomUnitCarrier}(h).$$

2. *For every pair of histories* $h, k : \mathsf{BHist}$,

$$R^*_D(h,k) \iff C^*_D(h) \wedge C^*_D(k) \wedge h\mathsf{hsame}k.$$

3. *For every pair of histories* $h, k : \mathsf{BHist}$,

$$R^*_D(h,k) \iff \mathsf{RatDenomUnitClassifier}(h,k).$$

Proof. Unfold C^*_D and RatDenomUnitCarrier. The two carriers have the same two alternatives, namely a carried Rat denominator endpoint and the external empty endpoint; the displayed iff only exchanges the order of these alternatives.

For the classifier-to-normal-form direction, split the defining alternatives of $R^*_D(h,k)$. In the guarded carried branch, RatHistoryClassifier(h,k) is precisely carried-left, carried-right, and $h$hsame$k$, so the two endpoints lie in C^*_D by the carried alternative and the final comparison is the classifier comparison.

In the empty-empty branch, both endpoints lie in C^*_D by the empty alternative, and transitivity with symmetry gives $h$hsame$k$ from $h$hsamee and $k$hsamee.

For the normal-form-to-classifier direction, split the two C^*_D endpoint witnesses. The carried-carried case uses RatHistoryCarrier_hsame_transport to view the right endpoint as a Rat carrier when needed, then packs carried-left, carried-right, and $h$hsame$k$ as RatHistoryClassifier(h,k) and chooses the guarded branch of R^*_D.

The empty-empty case chooses the second branch of R^*_D after transporting the displayed $h$hsame$k$ comparison to the common endpoint e.

The two mixed cases are impossible: a carried endpoint that is hsame to an empty endpoint is excluded by RatHistoryCarrier_not_empty, using transitivity and symmetry to orient the contradiction.

Finally unfold RatDenomUnitClassifier. By the first clause, RatDenomUnitCarrier is the same carrier as C^*_D; by the second clause, $R^*_D(h,k)$ is exactly the conjunction of the two carrier witnesses and $h$hsame$k$. This is precisely the denominator unit classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldRatDenominatorUnitEnvelopeClassifier carrier empty split iff`

Theorem 45.372 (Rat denominator external-unit envelope classifier exactness)**.** *For all histories* $h, k : \mathsf{BHist}$, *the classifier* R^*_D *of Definition 45.370 splits exactly as follows.*

1. *If* RatHistoryCarrier(h) *and* RatHistoryCarrier(k), *then*

$$R^*_D(h,k) \iff \mathsf{RatHistoryClassifier}(h,k).$$

2. *If* $\mathsf{RatHistoryCarrier}(h)$ *and* $k\mathsf{hsamee}$*, then* $\neg R^*_D(h,k)$*.*

3. *If* $h\mathsf{hsamee}$ *and* $\mathsf{RatHistoryCarrier}(k)$*, then* $\neg R^*_D(h,k)$*.*

4. *If* $h\mathsf{hsamee}$ *and* $k\mathsf{hsamee}$*, then* $R^*_D(h,k)$*.*

Proof. Unfold R^*_D. In the carried-carried case, the forward implication cannot come from the empty-empty branch, because that branch would make the carried endpoint h hsame to e, contradicting RatHistoryCarrier_not_empty. The remaining branch is exactly the guarded $\mathsf{RatHistoryClassifier}(h,k)$ branch. The reverse implication uses the two displayed carrier witnesses together with that guarded branch.

For a carried-left and empty-right pair, the guarded carried branch would give $\mathsf{RatHistoryCarrier}(k)$, and RatHistoryCarrier_not_empty rejects it against $k\mathsf{hsamee}$. The empty-empty branch would make $h\mathsf{hsamee}$, which is rejected by the same nonemptiness theorem applied to $\mathsf{RatHistoryCarrier}(h)$.

The empty-left and carried-right pair is symmetric. The guarded carried branch would make the left endpoint a Rat carrier and hence nonempty, while the empty-empty branch contradicts the carried right endpoint through RatHistoryCarrier_not_empty.

If both endpoints are hsame to e, choose the second branch in the definition of R^*_D. This is precisely the external endpoint clause. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator unit envelope classifier exactness`

Theorem 45.373 (Rat denominator external-unit envelope empty-right endpoint iff)**.** *For every history* $h : \mathsf{BHist}$*,*

$$R^*_D(h, e^*_D) \iff h\mathsf{hsamee}.$$

↪variant `BEDC.Derived.FieldUp.FieldRatDenominatorUnitEnvelopeClassifier empty right iff`

Proof. For the forward implication, use Definition 45.372 with the right endpoint specialized to $e^*_D = \mathsf{e}$. The guarded carried branch would make the empty endpoint a Rat denominator carrier, contradicting Definition 37.18; hence the only surviving branch is the empty-empty endpoint branch, which gives $h\mathsf{hsamee}$.

For the reverse implication, combine the displayed $h\mathsf{hsamee}$ with reflexivity at $e^*_D = \mathsf{e}$ and choose the empty-empty branch in the defining classifier of Definition 45.370. □

Theorem 45.374 (Rat denominator external-unit envelope empty-left endpoint iff)**.** *For all histories* $h, k : \mathsf{BHist}$*, if* $h\mathsf{hsamee}$*, then*

$$R^*_D(h,k) \iff k\mathsf{hsamee}.$$

↪variant `BEDC.Derived.FieldUp.FieldRatDenominatorUnitEnvelopeClassifier empty left endpoint iff`

Proof. Assume $h\mathsf{hsamee}$. For the forward implication, split the classifier by Definition 45.372. The guarded carried branch would make h a Rat denominator carrier, contradicting Definition 37.18 together with $h\mathsf{hsamee}$. Therefore the classifier lies in the empty-empty branch, and that branch gives $k\mathsf{hsamee}$.

For the reverse implication, pair the assumed $h\mathsf{hsamee}$ with the displayed $k\mathsf{hsamee}$ and use the empty-empty branch of Definition 45.370. □

Theorem 45.375 (Rat denominator external-unit envelope continuation closure)**.** *For all histories* $h, h', k, k', r, r' : \mathsf{BHist}$*, if* $R^*_D(h,h')$*,* $R^*_D(k,k')$*,* $\mathsf{Cont}(h,k,r)$*, and* $\mathsf{Cont}(h',k',r')$*, then* $R^*_D(r,r')$*.*

↪variant BEDC.Derived.FieldUp.FieldRatDenominatorUnitEnvelopeClassifier continuation closed

Proof. Split the two input classifier witnesses by Definition 45.372. In the carried/carried branch, apply Definition 45.131 to the two carried Rat classifier witnesses and the two displayed continuation witnesses. The result is the guarded carried branch of $R^*_D(r, r')$.

In the carried/empty branch, the right input pair is identified with e. The continuation right-unit laws identify r with h and r' with h', while cont_respects_hsame transports the carried classifier comparison across the displayed continuations. Transport the Rat carrier witnesses along these endpoint comparisons and repack the guarded branch.

The empty/carried branch is symmetric, using the continuation left-unit laws to identify r with k and r' with k'. The same continuation transport gives $r$hsamer', and carrier transport repacks the guarded carried branch.

In the empty/empty branch, continuation transport along the two empty endpoint comparisons reduces both results to the empty-left unit continuation at e. Thus $r$hsamee and r'hsamee, so the empty-empty branch of $R^*_D(r, r')$ applies. □

Theorem 45.376 (Rat denominator external-unit envelope carrier continuation closure)**.** *For all histories h, k, r : BHist, if h and k lie in the external-unit envelope carrier and Cont(h, k, r), then r lies in the same envelope carrier.*

Proof. Split the two carrier witnesses into carried Rat and empty endpoint branches. Each carrier witness gives a reflexive envelope classifier on its endpoint. Apply envelope classifier continuation closure to the two reflexive classifiers and the displayed continuation twice. The resulting classifier of r against itself exposes either the carried Rat branch for r or the empty endpoint branch, which is exactly the envelope carrier. □

Lean4 ✓ BEDC.Derived.FieldUp.FieldRatDenominatorUnitEnvelopeCarrier continuation closed

Theorem 45.377 (Rat denominator external-unit envelope monoid laws)**.** *The data $(C^*_D, R^*_D, \mu^*_D, e^*_D)$ of Definition 45.370 satisfy the following laws.*

1. *Carrier inhabitance: $C^*_D(e^*_D)$.*
2. *Closure: if $C^*_D(h)$ and $C^*_D(k)$, then $C^*_D(\mu^*_D(h, k))$.*
3. *Associativity under the classifier: if $C^*_D(h)$, $C^*_D(k)$, and $C^*_D(l)$, then $R^*_D(\mu^*_D(\mu^*_D(h, k), l), \mu^*_D(h, \mu^*_D(k, l)))$.*
4. *Left and right unit laws: $R^*_D(\mu^*_D(e^*_D, h), h)$ and $R^*_D(\mu^*_D(h, e^*_D), h)$ for every h with $C^*_D(h)$.*
5. *Binary classifier congruence: if $R^*_D(h, h')$ and $R^*_D(k, k')$, then $R^*_D(\mu^*_D(h, k), \mu^*_D(h', k'))$.*
6. *Restriction: on carried denominators, C^*_D, R^*_D, and μ^*_D restrict to C_D, R_D, and μ_D from Definition 45.323.*
7. *Obstruction: if a carried endpoint u satisfies either one-sided classifier-unit law on carried denominators, then* False.

Lean4 ✓ BEDC.Derived.FieldUp.field rat denominator unit envelope monoid laws

Proof. For carrier inhabitance, use the right disjunct in C^*_D with reflexivity at e. The carried/carried closure case is exactly Definition 45.325; the carried/empty and empty/carried cases reduce by the append unit laws and then transport the carried witness by RatHistoryCarrier_hsame_transport. The empty/empty case is the right carrier disjunct at e.

For associativity, split the three envelope carrier witnesses into their carried or external-empty alternatives. The carried/carried/carried branch is the associativity clause of Definition 45.325. Every branch containing an external-empty endpoint uses the append unit laws to remove that endpoint, uses $\mathsf{append_assoc}$ for the common bracketing spine, and then repacks either the transported carried classifier or the reflexive empty-empty classifier branch.

For the unit laws, split $C^*_D(h)$. In the carried branch, $\mathsf{append}(\mathsf{e}, h)$ and $\mathsf{append}(h, \mathsf{e})$ are transported back to h by the append unit laws, and $\mathsf{RatHistoryClassifier_hsame_transport}$ supplies the guarded carried classifier branch. In the external-empty branch, both displayed products are hsame to e, so the empty-empty branch of R^*_D applies.

For binary classifier congruence, split the two classifier witnesses. The carried/carried classifier branch invokes the congruence clause of Definition 45.325. If one input classifier is the empty-empty branch, the append unit laws collapse that side, and $\mathsf{RatHistoryClassifier_hsame_transport}$ transports the remaining carried classifier; if both are empty-empty, both appended products are hsame to e.

The restriction clause is immediate from the guarded carried branch of R^*_D and the definitions of C^*_D and μ^*_D when the inputs are carried denominators.

Finally, a carried endpoint satisfying a right or left one-sided classifier-unit law on the carried denominator fragment is ruled out by Definition 45.144. Thus adjoining the external endpoint gives a unit-bearing envelope, not an internal $\mathsf{Field}^{\uparrow}$ multiplication on the positive Rat denominator carrier. □

Theorem 45.378 (Rat denominator external-unit envelope unit uniqueness)**.** *For every history $u : \mathsf{BHist}$ with $C^*_D(u)$, the unit laws of the external envelope classify u as the named endpoint e^*_D:*

1. *if*

$$\forall h : \mathsf{BHist}.\ C^*_D(h) \to R^*_D(\mu^*_D(h, u), h),$$

then $R^*_D(u, e^*_D)$;

2. *if*

$$\forall h : \mathsf{BHist}.\ C^*_D(h) \to R^*_D(\mu^*_D(u, h), h),$$

then $R^*_D(u, e^*_D)$.

Proof. Split the carrier witness $C^*_D(u)$ into the carried Rat denominator branch and the external-empty branch. In the external-empty branch, $u\mathsf{hsamee}$ and $e^*_D = \mathsf{e}$, so the empty-empty branch of R^*_D immediately gives $R^*_D(u, e^*_D)$ for either one-sided law.

Assume now that u is carried and that the right envelope unit law is displayed. Restrict this law to a carried Rat denominator d. The closure part of Definition 45.377 makes $\mu^*_D(d, u)$ carried, while Definition 37.18 rules out the empty-empty branch against the carried input d.

Unfolding the guarded branch of R^*_D therefore gives the Rat denominator classifier for the canonical append product. For any displayed continuation $\mathsf{Cont}(d, u, r)$, compare it with the canonical append continuation witness and transport the classifier to obtain $\mathsf{RatHistoryClassifier}(r, d)$. This is exactly the right-unit continuation law, so Definition 45.350 yields $u\mathsf{hsamee}$.

The empty comparison $u\mathsf{hsamee}$, together with $e^*_D = \mathsf{e}$, gives the empty-empty classifier branch of $R^*_D(u, e^*_D)$.

The left envelope unit law is symmetric. Restrict it to carried Rat denominators, unfold the carried branch of $R^*_D(\mu^*_D(u, d), d)$, use the canonical append continuation witness to obtain

the displayed left-unit continuation law, and apply Definition 45.352. The resulting comparison $u\mathsf{hsamee}$ again repacks through the empty-empty branch as $R^*_D(u, e^*_D)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator unit envelope unit unique`

Theorem 45.379 (Rat denominator external-unit envelope carried classifier exactness)**.** *For all histories $h, k : \mathsf{BHist}$, if $\mathsf{RatHistoryCarrier}(h)$ and $\mathsf{RatHistoryCarrier}(k)$, then*

$$R^*_D(h, k) \iff \mathsf{RatHistoryClassifier}(h, k).$$

Proof. Unfold R^*_D from Definition 45.370. The reverse direction uses the guarded carried branch: the two displayed carrier witnesses for h and k, together with $\mathsf{RatHistoryClassifier}(h, k)$, assemble the first disjunct of the envelope classifier.

For the forward direction, split the envelope classifier witness. In the guarded carried branch, the third component is already $\mathsf{RatHistoryClassifier}(h, k)$, so projection gives the desired Rat classifier.

It remains to reject the empty-empty branch on carried inputs. That branch contains $h\mathsf{hsamee}$; applying Definition 37.18 to the carried witness for h and this endpoint comparison yields False, from which the Rat classifier conclusion follows constructively. □

This is the exactness predicate promised for restriction back to the carried Rat denominator continuation instance.

Traditional target: unit-enveloped denominator monoid fragment for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: $\mathsf{RatHistoryCarrier}$, $\mathsf{RatHistoryClassifier}$, Cont, and append; **carrier choice**: the external-unit envelope C^*_D; **classifier choice**: the carried Rat classifier plus the empty-empty endpoint classifier; **stability obligation**: carrier closure, associativity, unit laws, classifier congruence, restriction to the carried continuation instance, unit endpoint uniqueness, and one-sided carried-unit obstruction; **ledger**: the external unit bit plus continuation witness; **core theorems**: Definition 45.377 and Definition 45.378; **exactness predicate**: restriction back to the carried Rat denominator continuation instance, with the adjoined endpoint as the unique envelope unit up to R^*_D; **standard bridge**: deferred; **status**: $\mathsf{ProofTarget}$.

Theorem 45.380 (Rat denominator external-unit envelope is strict)**.** *For the concrete carried data C_D, R_D, and μ_D of Definition 45.323 and the envelope data C^*_D, R^*_D, μ^*_D, and e^*_D of Definition 45.370, the adjoined endpoint is strictly external and the carried fragment is recovered exactly.*

1. *$C^*_D(e^*_D)$ and $\neg C_D(e^*_D)$.*
2. *For every $h : \mathsf{BHist}$, if $C_D(h)$, then $\neg R^*_D(h, e^*_D)$ and $\neg R^*_D(e^*_D, h)$.*
3. *For every $h, k : \mathsf{BHist}$, if $C_D(h)$ and $C_D(k)$, then*

$$R^*_D(h, k) \iff R_D(h, k).$$

On the same carried inputs, the displayed product is the original append product:

$$\mu^*_D(h, k) = \mu_D(h, k) = \mathsf{append}(h, k).$$

Proof. Carrier inhabitance is the first clause of Definition 45.377. For the exclusion from the carried fragment, unfold Definition 45.323 and Definition 45.370: e^*_D is e and C_D is $\mathsf{RatHistoryCarrier}$. Then Definition 37.18 rules out a carried witness at the empty history.

For the mixed right endpoint, assume $C_D(h)$ and $R^*_D(h, e^*_D)$. Unfolding R^*_D gives either the guarded carried branch or the empty-empty branch. The guarded carried branch includes $C_D(e^*_D)$, contradicting the endpoint exclusion already proved. The empty-empty branch gives $h\mathsf{hsamee}$, contradicting Definition 37.18 applied to the carried witness $C_D(h)$. The mixed left endpoint is identical after swapping the two inputs.

It remains to recover the carried classifier. Suppose $C_D(h)$ and $C_D(k)$. If $R^*_D(h, k)$ holds, unfold R^*_D. The empty-empty branch would give $h\mathsf{hsamee}$, contradicting the same non-emptiness theorem, so the guarded carried branch remains and yields $R_D(h, k)$.

Conversely, from $C_D(h)$, $C_D(k)$, and $R_D(h, k)$, the guarded carried branch of $R^*_D(h, k)$ applies directly. Finally, unfolding the two displayed operations shows that μ^*_D and μ_D both return the append history on carried inputs. □

Theorem 45.381 (Rat denominator external-unit envelope strict carried fragment)**.** *For the concrete external-unit envelope of Definition 45.370, the endpoint* e *is in the envelope carrier, is not in the carried Rat-history carrier, has no mixed classifier edge to a carried history on either side, and the classifier restricted to carried histories is exactly* RatHistoryClassifier*.*

Proof. The endpoint carrier clause is the carrier component of Definition 45.377. The exclusion from the carried fragment is Definition 37.18 at e. The two mixed endpoint obstructions and the carried-classifier exactness are the corresponding concrete clauses of the envelope classifier exactness theorem. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldRatDenominatorUnitEnvelope external strict`

Theorem 45.382 (Rat denominator external-unit envelope mixed endpoint separation)**.** *For all* $d, e : \mathsf{BHist}$*, the external-unit classifier* R^u_D *has no mixed carried-empty endpoint branch:*

$$(\mathsf{RatHistoryCarrier}(d) \wedge e\mathsf{hsamee}) \to (R^u_D(d, e) \to \mathsf{False}),$$

and

$$(d\mathsf{hsamee} \wedge \mathsf{RatHistoryCarrier}(e)) \to (R^u_D(d, e) \to \mathsf{False}).$$

Proof. Unfold R^u_D and then RatDenomUnitClassifier. In the first displayed implication, the classifier supplies $d\mathsf{hsamee}$. Combining this comparison with $e\mathsf{hsamee}$ by symmetry and transitivity of hsame from Definition 3.8 gives $d\mathsf{hsamee}$.

Together with $\mathsf{RatHistoryCarrier}(d)$, rational history carrier nonemptiness, Definition 37.18, gives False.

The second displayed implication is symmetric. The classifier again supplies $d\mathsf{hsamee}$; together with $d\mathsf{hsamee}$ and the equivalence laws for hsame, this gives $e\mathsf{hsamee}$. The carried endpoint $\mathsf{RatHistoryCarrier}(e)$ is then contradicted by Definition 37.18. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier mixed endpoint absurd`

Traditional target: mixed-endpoint separation for the unit envelope; **BEDC source**: RatHistoryCarrier, RatHistoryClassifier, Cont, and e; **carrier choice**: C^u_D; **classifier choice**: R^u_D; **stability obligation**: mixed-branch separation; **ledger**: the external-unit bit; **core theorem**: Definition 45.382; **exactness predicate**: absence of mixed carried-empty classification; **standard bridge**: deferred; **status**: ProofTarget.

Theorem 45.383 (Rat denominator external-unit envelope certificate)**.** *For the concrete carried denominator data* (C_D, R_D, μ_D) *of Definition 45.323, the tuple* $(C^*_D, R^*_D, \mu^*_D, e^*_D)$ *of Definition 45.370 is the concrete unit-bearing denominator envelope used by* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *in the following sense.*

1. *$C_D^*(e_D^*)$; C_D^* is closed under μ_D^*; μ_D^* is associative up to R_D^*; e_D^* satisfies the left and right unit laws; and μ_D^* respects binary R_D^*-classified endpoints.*
2. *On carried denominators, the envelope restricts to the concrete fragment: C_D^* restricts to C_D, R_D^* restricts to R_D, and μ_D^* restricts to μ_D.*
3. *The endpoint e_D^* is envelope-carried and not C_D-carried, and no carried endpoint is classified with e_D^* on either side.*
4. *The empty-unit endpoint classifier R_D^u has no mixed carried-empty endpoint branch.*
5. *If $u : \mathsf{BHist}$ is carried by C_D^* and satisfies either one-sided envelope unit law, then $R_D^*(u, e_D^*)$.*

Proof. The carrier inhabitance, closure, associativity, one-sided unit laws, and binary classifier congruence are exactly the law package in Definition 45.377. The same theorem also records the restriction of C_D^*, R_D^*, and μ_D^* to the carried denominator fragment.

For carried classifier exactness, use Definition 45.379 on carried pairs. The strict endpoint and the exclusion of carried endpoints against e_D^* are the three clauses of Definition 45.380.

The mixed carried-empty exclusion for the endpoint classifier is precisely Definition 45.382. It supplies both orientations of the carried-empty case split.

Finally, any carried envelope endpoint satisfying a right or left one-sided unit law is classified with e_D^* by Definition 45.378. These pieces package the concrete carrier, classifier, append operation, external endpoint, restriction, and endpoint separation into the displayed denominator envelope. □

Traditional target: Rat denominator external-unit envelope certificate for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: RatHistoryCarrier, RatHistoryClassifier, Cont, and e; **carrier choice**: C_D^*; **classifier choice**: R_D^*; **stability obligation**: carrier closure, associativity, unit laws, classifier congruence, restriction, strict endpoint externality, unit uniqueness, and mixed-endpoint separation; **ledger**: the external-unit bit plus continuation witness; **core theorem**: Definition 45.383; **exactness predicate**: restriction to the carried denominator continuation instance, strict externality of e_D^*, unit uniqueness, and mixed-endpoint separation; **standard bridge**: deferred; **status**: ProofTarget.

Theorem 45.384 (Rat denominator external-unit envelope MonoidUp certificate)**.** *The concrete tuple $(C_D^*, R_D^*, \mu_D^*, e_D^*)$ of Definition 45.370, with carrier C_D^*, classifier R_D^*, operation* append*, and unit* e*, supplies the concrete* BHist*-level* $\mathsf{Monoid}^{\uparrow}$ *naming certificate for the unit-enveloped Rat denominator continuation fragment. Its certificate ledger is the external-unit bit together with the continuation witness used by the guarded carried branch of R_D^*.*

Proof. Apply Definition 45.377. Its carrier inhabitance clause supplies the exported unit witness for e_D^*, and its closure clause supplies the carrier witness for every exported append product in the envelope.

The same theorem supplies the left and right unit laws, associativity under R_D^*, and binary classifier congruence. These are exactly the stability fields required by Definition 40.34 for a $\mathsf{Monoid}^{\uparrow}$ interface over a BEDC carrier and classifier.

It remains to identify the certificate packaging. The carrier is the concrete predicate C_D^* on BHist; the classifier is the concrete relation R_D^*; the source operation is the native BEDC append operation through μ_D^*; and the named unit is e. Thus Definition 40.35 packages these fields as a NameCert for $\mathsf{Monoid}^{\uparrow}(C_D^*)$.

The ledger is concrete rather than schematic. The right carrier disjunct records whether the endpoint is the adjoined external unit, while the guarded carried classifier branch records the

continuation witness that relates the native Rat denominator fragment to the envelope product. This is the required BHist-anchored certificate consumed at the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ boundary. □

Theorem 45.385 (Rat denominator external-unit envelope empty-product reflection)**.** *For all histories $h, k : \mathsf{BHist}$ with $C^*_D(h)$ and $C^*_D(k)$, the product is classified as the external unit exactly when both factors are:*

$$R^*_D(\mu^*_D(h,k), e^*_D) \iff (R^*_D(h, e^*_D) \wedge R^*_D(k, e^*_D)) \,.$$

Proof. Unfold the envelope data of Definition 45.370. The named endpoint e^*_D is e, and $\mu^*_D(h,k)$ is the native BEDC history $\mathsf{append}(h,k)$.

For the forward direction, assume $R^*_D(\mu^*_D(h,k), e^*_D)$. The guarded carried classifier branch would make e a Rat denominator carrier, contradicting Definition 37.18. Hence the classifier witness is the empty-empty branch, so $\mathsf{append}(h,k)\mathsf{hsamee}$.

The BEDC append empty-result inversion theorem $\mathsf{append_eq_empty_iff}$ splits this endpoint comparison into $h\mathsf{hsamee}$ and $k\mathsf{hsamee}$. With $e^*_D = \mathsf{e}$, the empty-empty branch of R^*_D repacks these two endpoint witnesses as $R^*_D(h, e^*_D)$ and $R^*_D(k, e^*_D)$.

Conversely, assume $R^*_D(h, e^*_D) \wedge R^*_D(k, e^*_D)$. Each classifier against $e^*_D = \mathsf{e}$ has no viable guarded carried branch, again by Definition 37.18. Thus the two witnesses expose $h\mathsf{hsamee}$ and $k\mathsf{hsamee}$.

Apply the introduction direction of $\mathsf{append_eq_empty_iff}$ to these two empty endpoint comparisons. This gives $\mathsf{append}(h,k)\mathsf{hsamee}$, and the empty-empty branch of R^*_D classifies $\mu^*_D(h,k)$ with e^*_D. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator unit envelope empty product reflection`

Traditional target: Rat denominator external-unit envelope empty-product reflection for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: RatHistoryCarrier, R^*_D, append, and e; **carrier choice**: C^*_D; **classifier choice**: R^*_D; **stability obligation**: empty product reflection under the external-unit classifier; **ledger**: the external-unit bit plus carried continuation witness; **core theorem**: Definition 45.385; **exactness predicate**: product classification by e^*_D is exactly factorwise classification by e^*_D; **standard bridge**: deferred; **status**: ProofTarget.

Theorem 45.386 (Rat denominator external-unit envelope unit equivalence)**.** *For every history $u : \mathsf{BHist}$ with $C^*_D(u)$,*

$$R^*_D(u, e^*_D) \iff (\forall h : \mathsf{BHist}.\ C^*_D(h) \to R^*_D(\mu^*_D(h,u), h)) \wedge (\forall h : \mathsf{BHist}.\ C^*_D(h) \to R^*_D(\mu^*_D(u,h), h)) \,.$$

Proof. For the forward direction, assume $R^*_D(u, e^*_D)$ and split the carrier witness $C^*_D(u)$. The carried branch is impossible: the mixed carried-empty clause of Definition 45.372 rejects $R^*_D(u, e^*_D)$ because $e^*_D = \mathsf{e}$.

In the external-empty branch, $u\mathsf{hsamee}$. For any h with $C^*_D(h)$, split $C^*_D(h)$. If h is carried, the append unit laws identify $\mu^*_D(h,u)$ and $\mu^*_D(u,h)$ with h; transport the carried witnesses by $\mathsf{RatHistoryCarrier_hsame_transport}$ and repack through the guarded carried branch of R^*_D. If $h\mathsf{hsamee}$, both products are hsame to e, so the empty-empty branch gives the right and left laws.

For the reverse direction, project the conjunction into the displayed right and left envelope unit laws. Applying Definition 45.378 to either projection gives $R^*_D(u, e^*_D)$, and the two projections therefore give the same endpoint classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator unit envelope unit iff`

Theorem 45.387 (Rat denominator unit classifier zero-headed endpoint separation)**.** *For every* $t, k : \mathsf{BHist}$*, the adjoined-unit classifier cannot classify a zero-headed endpoint in either argument:*

$$R^u_D(\mathsf{E0}(t), k) \to \mathsf{False},$$

and

$$R^u_D(k, \mathsf{E0}(t)) \to \mathsf{False}.$$

Proof. Project the classifier endpoint carriers from RatDenomUnitClassifier. A zero-headed history is neither the adjoined empty unit nor a carried rational denominator history, so the corresponding carrier component contradicts the BEDC constructor separation for the denominator-unit carrier. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier e0 endpoint absurd`

Theorem 45.388 (Rat denominator unit classifier continuation zero-headed endpoint separation)**.** *For classified denominator-unit pairs* (h, h') *and* (k, k')*, if* $\mathsf{Cont}(h, k, r)$ *and* $\mathsf{Cont}(h', k', r')$*, then neither continuation result can be displayed as a zero-headed endpoint:*

$$(\mathsf{hsame}(r, \mathsf{E0}(t)) \to \mathsf{False}) \wedge (\mathsf{hsame}(r', \mathsf{E0}(t')) \to \mathsf{False}).$$

Proof. Project the carrier fields from the two classifier witnesses. Denominator-unit carrier closure under continuation gives carrier witnesses for r and r'. Transport each carrier witness along a displayed zero-headed endpoint comparison and apply carrier zero-headed absurdity. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier continuation e0 endpoint absurd`

Theorem 45.389 (Rat denominator unit classifier one-headed empty endpoint separation)**.** *For every history* $d : \mathsf{BHist}$*, the adjoined-unit classifier cannot classify a one-headed endpoint against* e *in either direction:*

$$R^u_D(\mathsf{E1}(d), \mathsf{e}) \to \mathsf{False},$$

and

$$R^u_D(\mathsf{e}, \mathsf{E1}(d)) \to \mathsf{False}.$$

Proof. Unfold R^u_D as RatDenomUnitClassifier. The classifier contains the displayed hsame comparison between its two endpoints. The first branch would give $\mathsf{E1}(d)\mathsf{hsamee}$, and the second branch would give $\mathsf{ehsameE1}(d)$; both contradict the constructor separation laws for BHist. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier e1 empty absurd`

Theorem 45.390 (Rat denominator unit classifier mixed endpoint separation)**.** *For all* $d, e : \mathsf{BHist}$*, the external-unit classifier* R^u_D *has no mixed carried-empty endpoint branch:*

$$(\mathsf{RatHistoryCarrier}(d) \wedge e\mathsf{hsamee}) \to (R^u_D(d, e) \to \mathsf{False}),$$

and

$$(d\mathsf{hsamee} \wedge \mathsf{RatHistoryCarrier}(e)) \to (R^u_D(d, e) \to \mathsf{False}).$$

Proof. Unfold R^u_D and then RatDenomUnitClassifier. In the first displayed implication, the classifier supplies $d$hsame$e$. Combining this comparison with $e$hsame$e$ by symmetry and transitivity of hsame from Definition 3.8 gives $d$hsame$e$.

Together with RatHistoryCarrier(d), rational history carrier nonemptiness, Definition 37.18, gives False.

The second displayed implication is symmetric. The classifier again supplies $d$hsame$e$; together with $d$hsame$e$ and the equivalence laws for hsame, this gives $e$hsame$e$. The carried endpoint RatHistoryCarrier(e) is then contradicted by Definition 37.18. □

Traditional target: mixed-endpoint separation for the adjoined-unit classifier; **BEDC source**: RatHistoryCarrier, RatHistoryClassifier, Cont, and e; **carrier choice**: C^u_D; **classifier choice**: R^u_D; **stability obligation**: mixed-branch separation; **ledger**: the external-unit bit; **core theorem**: Definition 45.390; **exactness predicate**: absence of mixed carried-empty classification; **standard bridge**: deferred; **status**: ProofTarget.

45.17 Rat denominator strict monoid boundary

Theorem 45.391 (Rat denominator strict monoid boundary package)**.** *For the concrete carried denominator data (C_D, R_D, μ_D) of Definition 45.323, the external-unit envelope $(C^*_D, R^*_D, \mu^*_D, e^*_D)$ of Definition 45.370, and the empty-unit tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D)$ of Definition 45.346, the denominator boundary consumed by* Field$^\uparrow$(RatUp) *has the following concrete role.*

1. *The envelope supplies the concrete* Monoid$^\uparrow$ *naming certificate for the unit-bearing denominator fragment.*
2. *On carried inputs, the envelope restricts exactly to C_D, R_D, and native append through μ_D.*
3. *The endpoint e^*_D is carried by C^*_D but not by C_D, and no C_D endpoint is classified with e^*_D by R^*_D on either side.*
4. *The empty-unit classifier R^u_D has no mixed carried-empty endpoint branch.*
5. *Every envelope-carried one-sided unit endpoint is classified with e^*_D by R^*_D, while every carried denominator one-sided unit law for C_D, R_D, and μ_D is impossible.*

Thus the exported monoid object is the strict external-unit envelope, and the carried Rat denominator multiplication remains a unitless carried semigroup at the Field$^\uparrow$(RatUp) *boundary.*

Proof. The exported Monoid$^\uparrow$ naming certificate is exactly Definition 45.384. Its certificate fields are supplied by the envelope laws collected in Definition 45.383.

The carried restriction and strict externality are read from Definition 45.380. This theorem gives the recovery of C_D, R_D, and native append on carried inputs, records $C^*_D(e^*_D)$ with $\neg C_D(e^*_D)$, and excludes R^*_D-classification between any carried endpoint and e^*_D on both sides.

The empty-unit tuple has no mixed carried-empty classifier branch by Definition 45.382. That separation is the boundary check preventing the adjoined unit clause from classifying a carried denominator endpoint against an empty endpoint.

For uniqueness of an envelope-carried one-sided unit, apply Definition 45.378. It sends either one-sided envelope unit law to the classifier comparison with e^*_D.

Finally, the carried semigroup role and the carried-unit obstruction are the denominator-side clauses of Definition 45.369. Together these cited packages show that Field$^\uparrow$(RatUp) uses the unit-bearing Monoid$^\uparrow$ certificate only at the envelope layer, while the native carried denominator fragment keeps exactly its strict unitless boundary. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldUp StdBridge`

Traditional target: denominator monoid boundary for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: RatHistoryCarrier, RatHistoryClassifier, Cont, append, e, and RatHistoryLedgerPolicy; **carrier choice**: C_D^* for the exported monoid envelope and C_D for the carried denominator fragment; **classifier choice**: R_D^* for the envelope boundary, R_D on carried inputs, and R_D^u for empty-unit endpoint separation; **stability obligation**: $\mathsf{Monoid}^{\uparrow}$ certificate laws, carried restriction, strict endpoint externality, mixed-endpoint separation, envelope unit uniqueness, and carried-unit obstruction; **ledger**: the Rat denominator continuation ledger together with the external-unit bit; **core theorem**: Definition 45.391; **exactness predicate**: the strict restriction of the envelope to (C_D, R_D, μ_D) and the absence of carried one-sided units; **standard bridge**: deferred; **status**: ProofTarget.

Theorem 45.392 (Rat denominator empty-unit commutative monoid laws)**.** *For the tuple $(C_D^u, R_D^u, \mu_D^u, e_D^u)$ of Definition 45.346, the five laws of Definition 45.347 hold, and the multiplication is commutative up to the endpoint classifier: if $C_D^u(h)$ and $C_D^u(k)$, then*

$$R_D^u(\mu_D^u(h,k), \mu_D^u(k,h)).$$

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator empty unit continuation commutative monoid laws`

Proof. Unfold the concrete data of Definition 45.346. The first five clauses are precisely Definition 45.347.

It remains to prove the displayed commutativity classifier. Split the two RatDenomUnitCarrier witnesses into their empty endpoint and genuine Rat denominator endpoint alternatives.

In the genuine/genuine case, the two products are the canonical append continuations $\mathsf{Cont}(h, k, \mathsf{append}(h,k))$ and $\mathsf{Cont}(k, h, \mathsf{append}(k,h))$. Apply Definition 45.118 to these two continuations and the two Rat denominator carriers. The resulting RatHistoryClassifier supplies the carried endpoints and the hsame comparison required to pack $\mathsf{RatDenomUnitClassifier}(\mathsf{append}(h,k), \mathsf{append}(k,h))$.

In a mixed case, one endpoint is hsamee and the other is a genuine Rat denominator endpoint. The append unit law on the empty side identifies both products with the genuine endpoint, one directly and one after symmetry of hsame. Transitivity of hsame gives $\mathsf{append}(h,k)\mathsf{hsameappend}(k,h)$, and append closure gives the two empty-unit carrier witnesses. These data pack the required RatDenomUnitClassifier.

In the empty/empty case, both inputs are hsamee. The left and right append unit laws identify each product with e; symmetry and transitivity of hsame then identify the two products with each other. The empty branch of RatDenomUnitCarrier carries both products, so the classifier packing again yields $R_D^u(\mu_D^u(h,k), \mu_D^u(k,h))$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator empty unit commutative monoid laws`

Theorem 45.393 (Rat denominator empty-unit identity uniqueness)**.** *For the tuple $(C_D^u, R_D^u, \mu_D^u, e_D^u)$ of Definition 45.346, let $u : \mathsf{BHist}$ be a carried endpoint with $C_D^u(u)$. If u satisfies the two one-sided unit laws*

$$\forall h : \mathsf{BHist}.\ C_D^u(h) \to R_D^u(\mu_D^u(u,h), h)$$

and

$$\forall h : \mathsf{BHist}.\ C_D^u(h) \to R_D^u(\mu_D^u(h,u), h),$$

then

$$R_D^u(u, e_D^u).$$

Proof. Unpack Definition 45.347. Its carried-unit clause gives $C^u_D(e^u_D)$, and its right-unit law with right factor e^u_D gives $R^u_D(\mu^u_D(u, e^u_D), u)$ from the assumed carrier witness $C^u_D(u)$.

Now apply the assumed left-unit law for u at the carried endpoint e^u_D. This gives $R^u_D(\mu^u_D(u, e^u_D), e^u_D)$.

Project the two R^u_D classifier witnesses to their hsame components. The first comparison identifies $\mu^u_D(u, e^u_D)$ with u, and the second comparison identifies the same product with e^u_D. Symmetry and transitivity of hsame therefore give $u\mathsf{hsame}e^u_D$.

Finally, repack the carrier witnesses $C^u_D(u)$ and $C^u_D(e^u_D)$ together with this endpoint comparison. The result is exactly $R^u_D(u, e^u_D)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator empty unit identity unique`

Per-object template: traditional target identity uniqueness in the Rat denominator empty-unit monoid; BEDC source RatDenomUnitCarrier, RatDenomUnitClassifier, append, and e; carrier C^u_D; classifier R^u_D; stability obligation concrete one-sided unit collapse; ledger external-unit endpoint provenance; core theorem Definition 45.393; exactness predicate unit endpoints classify with e^u_D; standard bridge deferred; status ProofTarget.

Definition 45.394 (Rat denominator empty-unit strict product support)**.** *For the tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D)$ *of Definition 45.346, the strict product support predicate is the genuine Rat denominator endpoint predicate*

$$N^u_D(h) \iff \mathsf{RatHistoryCarrier}(h).$$

Thus the empty endpoint is carried by C^u_D *but is not in the strict support.*

Theorem 45.395 (Rat denominator unit carrier append factor carriers)**.** *For histories* $h, k : \mathsf{BHist}$*, if their append product is carried by the Rat denominator empty-unit carrier, then each factor is carried:*

$$C^u_D(\mathsf{append}(h, k)) \implies C^u_D(h) \wedge C^u_D(k).$$

Proof. Unfold C^u_D. In the empty branch, $\mathsf{append}(h, k)\mathsf{hsame}\mathsf{e}$, and append-empty inversion identifies both factors with e. In the Rat-history branch, positivity of the denominator product gives a unary, nonempty append history. Unary append factorization recovers unary witnesses for h and k; each unary factor is either e or an E1-headed positive denominator, hence a RatDenomUnitCarrier witness. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier append factor carriers`

Theorem 45.396 (Rat denominator unit carrier append nonempty factor cases)**.** *For histories* $h, k : \mathsf{BHist}$*, a nonempty append product carried by* C^u_D *has a genuine Rat denominator endpoint on at least one factor, while both factors remain carried by* C^u_D*:*

$$C^u_D(\mathsf{append}(h, k)) \implies (\mathsf{append}(h, k)\mathsf{hsame}\mathsf{e} \implies \bot) \implies (\mathsf{RatHistoryCarrier}(h) \wedge C^u_D(k)) \vee (C^u_D(h) \wedge \mathsf{RatHistoryCarrier}($$

Proof. Apply append branch cases to the carried product. The both-empty branch would make the appended product empty by append-empty reconstruction, contradicting the nonempty hypothesis. In the remaining branches, append factor-carrier closure supplies the denominator-unit carrier witness for the opposite factor. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier append nonempty factor cases`

Proposition 45.397 (Rat denominator unit carrier append exactness)**.** *For histories* $h, k : \mathsf{BHist}$*, the empty-unit Rat denominator carrier is closed and reflected by append:*

$$C^u_D(\mathsf{append}(h, k)) \iff C^u_D(h) \wedge C^u_D(k).$$

Proof. The forward direction is the append factor-carrier theorem above. Conversely, given carrier witnesses for both factors, apply denominator empty-unit continuation closure to the canonical continuation $\mathsf{Cont}(h, k, \mathsf{append}(h, k))$. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitCarrier append iff`

Theorem 45.398 (Rat denominator unit classifier append right factor classifier)**.** *For histories $h, h', k, k' : \mathsf{BHist}$, if the appended denominator-unit endpoints are classified and the right factors are internally the same, then the left factors are classified:*

$$R^u_D(\mathsf{append}(h, k), \mathsf{append}(h', k')) \Longrightarrow \mathsf{hsame}(k, k') \Longrightarrow R^u_D(h, h').$$

Proof. The classifier on the appended endpoints first supplies carrier witnesses for both products. Factor-carrier closure for C^u_D extracts carrier witnesses for h and h'. Transport the second appended endpoint along $\mathsf{hsame}(k, k')$ so that both products share the suffix k. Right cancellation for append then identifies h with h', and these three pieces reassemble the denominator-unit classifier on the left factors. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier append right factor classifier`

Theorem 45.399 (Rat denominator empty-unit product nonempty iff)**.** *For histories $h, k : \mathsf{BHist}$ with $C^u_D(h)$ and $C^u_D(k)$, the empty-unit product is nonempty exactly when at least one input has strict Rat denominator support:*

$$(\mu^u_D(h, k)\mathsf{hsamee} \to \mathsf{False}) \Longleftrightarrow N^u_D(h) \vee N^u_D(k).$$

Proof. Unfold C^u_D, μ^u_D, and N^u_D. The product $\mu^u_D(h, k)$ is $\mathsf{append}(h, k)$, with canonical continuation witness $\mathsf{Cont}(h, k, \mathsf{append}(h, k))$.

For the forward direction, apply Definition 45.170 to the two $\mathsf{RatDenomUnitCarrier}$ witnesses and the canonical continuation. The assumption that $\mathsf{append}(h, k)$ is not hsame to e is exactly the nonempty result condition, so the theorem returns $\mathsf{RatHistoryCarrier}(h) \vee \mathsf{RatHistoryCarrier}(k)$.

For the reverse direction, split the strict-support disjunction. In the left case, split the carried endpoint k into its empty and genuine alternatives. If $k\mathsf{hsamee}$, the right append unit law identifies $\mathsf{append}(h, k)$ with h, so any empty product would make $h\mathsf{hsamee}$, contradicting $\mathsf{RatHistoryCarrier_not_empty}$. If $\mathsf{RatHistoryCarrier}(k)$, apply Rat denominator continuation result nonemptiness to the canonical continuation.

In the right strict-support case, split the carried endpoint h in the same way. If $h\mathsf{hsamee}$, the left append unit law identifies $\mathsf{append}(h, k)$ with k, and $\mathsf{RatHistoryCarrier_not_empty}$ rejects an empty product. If $\mathsf{RatHistoryCarrier}(h)$, the same Rat denominator continuation result nonemptiness theorem applies to the canonical continuation. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator empty unit product nonempty iff`

Theorem 45.400 (Rat denominator empty-unit product nonempty comm iff)**.** *For histories $h, k : \mathsf{BHist}$ with $C^u_D(h)$ and $C^u_D(k)$, reversing the two factors preserves the nonempty endpoint predicate of the empty-unit product:*

$$(\mathsf{append}(h, k)\mathsf{hsamee} \to \mathsf{False}) \Longleftrightarrow (\mathsf{append}(k, h)\mathsf{hsamee} \to \mathsf{False}).$$

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator empty unit product nonempty comm iff`

Proof. Apply Definition 45.399 to the ordered pair (h, k) and again to the reversed pair (k, h). The first characterization reads nonemptiness as $\mathsf{RatHistoryCarrier}(h) \vee \mathsf{RatHistoryCarrier}(k)$, and the second reads it as the same disjunction with the two sides exchanged. Split the factor-support disjunction and swap the branch tags. □

Theorem 45.401 (Rat denominator empty-unit strict product factor cases)**.** *For histories $h, k : \mathsf{BHist}$ with $C^u_D(h)$ and $C^u_D(k)$, if the empty-unit product has strict Rat denominator support, then one input has strict support while the other remains carried:*

$$N^u_D(\mu^u_D(h, k)) \Longrightarrow (N^u_D(h) \wedge C^u_D(k)) \vee (C^u_D(h) \wedge N^u_D(k)).$$

Proof. Strict support of the product rules out $\mathsf{hsame}(\mathsf{append}(h, k), \mathsf{e})$ by RatHistoryCarrier_not_empty. Apply the product nonempty characterization above to obtain $N^u_D(h) \vee N^u_D(k)$, then reattach the original carrier hypotheses on the other factor in each case. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator empty unit strict product factor cases`

Theorem 45.402 (Rat denominator empty-unit strict product support exactness)**.** *For histories $h, k : \mathsf{BHist}$ with $C^u_D(h)$ and $C^u_D(k)$, strict support is exact for the empty-unit product:*

$$N^u_D(\mu^u_D(h, k)) \Longleftrightarrow N^u_D(h) \vee N^u_D(k).$$

Proof. Unfold N^u_D. The forward direction starts from $\mathsf{RatHistoryCarrier}(\mu^u_D(h, k))$. By RatHistoryCarrier_not_empty the product cannot be hsamee. Apply Definition 45.399 to this nonempty product witness and obtain $N^u_D(h) \vee N^u_D(k)$.

For the reverse direction, assume $N^u_D(h) \vee N^u_D(k)$. The reverse direction of Definition 45.399 gives that $\mu^u_D(h, k)$ is not hsamee.

It remains to recover the genuine Rat carrier for the product. The closure clause of Definition 45.347 applied to $C^u_D(h)$ and $C^u_D(k)$ gives $C^u_D(\mu^u_D(h, k))$. Apply RatDenomUnitCarrier_nonempty_rat to this carried-product witness and the nonempty product witness. The result is $\mathsf{RatHistoryCarrier}(\mu^u_D(h, k))$, equivalently $N^u_D(\mu^u_D(h, k))$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator empty unit strict product support exactness`

Per-object template: traditional target strict support for the empty-unit denominator multiplication; BEDC source RatHistoryCarrier, RatDenomUnitCarrier, and Cont; carrier C^u_D; classifier R^u_D; stability obligation product support exactness; ledger continuation witness; core theorem Definition 45.402; exactness predicate strict product support iff genuine denominator input; standard bridge ordinary denominator monoid support; status ProofTarget.

Definition 45.403 (Rat denominator empty-unit multiplicative substrate)**.** *The denominator-side multiplicative substrate for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *is the concrete* BHist *tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *with carrier* RatDenomUnitCarrier*, classifier* RatDenomUnitClassifier*, multiplication* $\mu^u_D(h, k) := \mathsf{append}(h, k)$ *equipped with the canonical continuation* $\mathsf{Cont}(h, k, \mathsf{append}(h, k))$*, unit* $e^u_D := \mathsf{e}$*, and strict support* $N^u_D(h)$ *given by* $\mathsf{RatHistoryCarrier}(h)$*. Thus the denominator schema instance is the concrete append substrate over* BHist*, with the empty endpoint adjoined only as the unit and not as an uninterpreted multiplication input.*

Theorem 45.404 (Rat denominator empty-unit multiplicative substrate laws)**.** *For the substrate* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *of Definition 45.403, the following concrete laws hold.*

1. *The unit is carried:* $C^u_D(e^u_D)$*.*

2. *The carrier is closed under multiplication: if* $C^u_D(h)$ *and* $C^u_D(k)$*, then* $C^u_D(\mu^u_D(h,k))$*.*
3. *The unit laws hold: if* $C^u_D(h)$*, then* $R^u_D(\mu^u_D(e^u_D,h),h)$ *and* $R^u_D(\mu^u_D(h,e^u_D),h)$*.*
4. *Multiplication is associative up to the classifier: if* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, then* $R^u_D(\mu^u_D(\mu^u_D(h,k),\ell),\mu^u_D(h,\mu^u_D$
5. *The operation respects binary classifier input: if* $R^u_D(h,h')$ *and* $R^u_D(k,k')$*, then* $R^u_D(\mu^u_D(h,k),\mu^u_D(h',k'))$*.*
6. *Multiplication is commutative up to the classifier: if* $C^u_D(h)$ *and* $C^u_D(k)$*, then* $R^u_D(\mu^u_D(h,k),\mu^u_D(k,h))$*.*
7. *Strict support is exact for products: if* $C^u_D(h)$ *and* $C^u_D(k)$*, then*

$$(\mu^u_D(h,k)\mathsf{hsamee} \to \mathsf{False}) \iff N^u_D(h) \vee N^u_D(k).$$

8. *Empty endpoint contexts preserve and reflect the classifier: if* $p\mathsf{hsamee}$*,* $q\mathsf{hsamee}$*,* $p'\mathsf{hsamee}$*, and* $q'\mathsf{hsamee}$*, then*

$$R^u_D(\mathsf{append}(p,\mathsf{append}(h,q)),\mathsf{append}(p',\mathsf{append}(k,q'))) \iff R^u_D(h,k).$$

Proof. Unfold the concrete substrate of Definition 45.403. The carried unit, closure, left and right unit laws, associativity, and binary classifier congruence are the five laws supplied by Definition 45.347.

Commutativity is the additional classifier law of Definition 45.392; it uses the same carried endpoints and the concrete append multiplication of the substrate.

The strict support clause is exactly Definition 45.399, because N^u_D is $\mathsf{RatHistoryCarrier}$ and the product is $\mathsf{append}(h,k)$ with its canonical continuation witness.

For the empty-context classifier clause, replace R^u_D by $\mathsf{RatDenomUnitClassifier}$ and apply Definition 45.405. This proves preservation and reflection for the same concrete classifier used by the substrate. □

Theorem 45.405 (Rat denominator empty-unit classifier empty-context exactness)**.** *For histories* $p,q,p',q',h,k : \mathsf{BHist}$*, if* $p\mathsf{hsamee}$*,* $q\mathsf{hsamee}$*,* $p'\mathsf{hsamee}$*, and* $q'\mathsf{hsamee}$*, then empty endpoint contexts do not change the empty-unit denominator classifier:*

$$\mathsf{RatDenomUnitClassifier}(\mathsf{append}(p,\mathsf{append}(h,q)),\mathsf{append}(p',\mathsf{append}(k,q'))) \iff \mathsf{RatDenomUnitClassifier}(h,k).$$

Proof. Unfold $\mathsf{RatDenomUnitClassifier}$ into the two $\mathsf{RatDenomUnitCarrier}$ endpoints and the endpoint comparison by hsame. The carrier endpoints are handled by Definition 45.348, once for (p,q,h) and once for (p',q',k).

For the forward direction, the contextual classifier supplies the two contextual carrier witnesses and the comparison between the contextual endpoints. The two carrier equivalences transport the carrier witnesses back to h and k. The empty left and right append unit laws identify $\mathsf{append}(p,\mathsf{append}(h,q))$ with h and $\mathsf{append}(p',\mathsf{append}(k,q'))$ with k; composing these identifications by symmetry and transitivity with the contextual comparison gives $h\mathsf{hsame}k$. These three pieces repack $\mathsf{RatDenomUnitClassifier}(h,k)$.

For the reverse direction, start from the carrier witnesses for h and k and from $h\mathsf{hsame}k$. The same two carrier equivalences transport membership to the contextual endpoints. The empty append identifications transport $h\mathsf{hsame}k$ to the contextual endpoint comparison, again using symmetry and transitivity of hsame. The transported carriers and transported endpoint comparison pack the contextual classifier.

This is not a variant of the carrier exactness theorem: it proves full classifier preservation by combining carrier exactness at both endpoints with transport of the endpoint hsame relation.

Consequently the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ denominator envelope can read an empty external unit context by the normalized classifier on the core endpoints. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier empty context iff`

Theorem 45.406 (Rat denominator empty-unit contextual strict product support exactness)**.** *For histories $p, q, h, k : \mathsf{BHist}$, if $p\mathsf{hsamee}$, $q\mathsf{hsamee}$, $C^u_D(h)$, and $C^u_D(k)$, then empty external unit contexts read strict denominator support through the product endpoint:*

$$N^u_D(\mathsf{append}(p, \mathsf{append}(\mu^u_D(h,k), q))) \iff N^u_D(h) \vee N^u_D(k).$$

Proof. The closure clause of Definition 45.347 applied to $C^u_D(h)$ and $C^u_D(k)$ gives $C^u_D(\mu^u_D(h,k))$. The right comparison endpoint is the uncontextualized product $\mu^u_D(h,k)$, and its right empty context is supplied by $\mathsf{ehsamee}$ on both sides.

Apply Definition 45.405 with left contexts p, q and right contexts e, e. This produces the classifier equivalence between $\mathsf{append}(p, \mathsf{append}(\mu^u_D(h,k), q))$ and $\mu^u_D(h,k)$ in the concrete $\mathsf{RatDenomUnitClassifier}$ envelope.

Unfold N^u_D as $\mathsf{RatHistoryCarrier}$. The exposed hsame component of the classifier transports genuine Rat carrier support between the contextual product endpoint and the uncontextualized product endpoint.

Finally apply Definition 45.402 to the carried inputs h and k. Its product-support equivalence gives $N^u_D(\mu^u_D(h,k)) \iff N^u_D(h) \vee N^u_D(k)$, and the transport above converts the left side to the contextual endpoint. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator empty unit contextual strict product support exactness`

Theorem 45.407 (Rat denominator empty-unit contextual product classifier exactness)**.** *For histories $p, q, p', q', h, k, h', k' : \mathsf{BHist}$, assume $p\mathsf{hsamee}$, $q\mathsf{hsamee}$, $p'\mathsf{hsamee}$, and $q'\mathsf{hsamee}$. If the empty-unit denominator classifier relates h with h' and k with k', then the contextual rational classifier on the product endpoints is equivalent to strict rational support of the exposed product:*

$$\mathsf{RatHistoryClassifier}(\mathsf{append}(p, \mathsf{append}(\mathsf{append}(h,k), q)), \mathsf{append}(p', \mathsf{append}(\mathsf{append}(h',k'), q'))) \iff \mathsf{RatHistoryCarrie}$$

Proof. The empty left and right contexts identify the two contextual endpoints with the exposed products. Binary classifier congruence for $\mathsf{RatDenomUnitClassifier}$ classifies $\mathsf{append}(h,k)$ with $\mathsf{append}(h',k')$. In the forward direction, rational support transports out of the left empty context. In the reverse direction, the product classifier transports rational support to the right product, and the rational classifier is then transported back into the two displayed empty contexts. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier contextual product rat classifier iff`

Theorem 45.408 (Rat denominator empty-unit threefold strict support exactness)**.** *For histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, strict support is exact for the left-nested empty-unit threefold product:*

$$N^u_D(\mu^u_D(\mu^u_D(h,k), \ell)) \iff (N^u_D(h) \vee N^u_D(k)) \vee N^u_D(\ell).$$

Proof. The closure clause of Definition 45.347 applied to $C^u_D(h)$ and $C^u_D(k)$ gives $C^u_D(\mu^u_D(h,k))$. This supplies the carrier hypothesis needed to read the outer product of $\mu^u_D(h,k)$ with ℓ.

Apply Definition 45.402 to the carried histories $\mu^u_D(h,k)$ and ℓ. The result is

$$N^u_D(\mu^u_D(\mu^u_D(h,k), \ell)) \iff N^u_D(\mu^u_D(h,k)) \vee N^u_D(\ell).$$

Apply the same theorem to the original carried histories h and k, giving $N^u_D(\mu^u_D(h,k)) \iff N^u_D(h) \vee N^u_D(k)$. Substitute this inner equivalence into the left disjunct of the outer equivalence.

In the forward direction, the outer equivalence gives either $N^u_D(\mu^u_D(h,k))$ or $N^u_D(\ell)$. The first case is transported by the inner equivalence to $N^u_D(h) \vee N^u_D(k)$, while the second case gives the right disjunct directly.

In the reverse direction, a witness of $(N^u_D(h) \vee N^u_D(k)) \vee N^u_D(\ell)$ is handled by cases. The left case is transported by the reverse direction of the inner equivalence to $N^u_D(\mu^u_D(h,k))$; the right case is already $N^u_D(\ell)$. The reverse direction of the outer equivalence then yields $N^u_D(\mu^u_D(\mu^u_D(h,k),\ell))$. □

Per-object template: traditional target finite product support readback for denominator multiplication; BEDC source BHist with $C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D$; carrier C^u_D; classifier R^u_D; stability obligation binary product support exactness plus carrier closure; ledger two continuation-product witnesses; exactness predicate strict support of the left-nested threefold product iff support of one factor; standard bridge ordinary finite denominator product support; status ProofTarget.

Per-object template: traditional target empty-context denominator product support readback; BEDC source BHist; carrier C^u_D; classifier R^u_D; stability obligation contextual strict product support exactness; ledger empty external unit contexts around the product endpoint; core theorem Definition 45.406; exactness predicate strict support is unchanged by empty external product contexts; standard bridge ordinary denominator multiplication support; status ProofTarget.

45.18 Rat denominator empty-unit cancellation exactness

Definition 45.409 (Rat denominator empty-unit cancellation-exact instance)**.** *The cancellation-exact denominator instance for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *is the concrete* BHist *tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, where* $C^u_D = \mathsf{RatDenomUnitCarrier}$*,* $R^u_D = \mathsf{RatDenomUnitClassifier}$*,* $\mu^u_D(h,k) = \mathsf{append}(h,k)$ *with its canonical continuation witness,* $e^u_D = \mathsf{e}$*, and* $N^u_D(h)$ *is* $\mathsf{RatHistoryCarrier}(h)$*.*

Theorem 45.410 (Rat denominator empty-unit cancellation exactness)**.** *For carried histories* $h, k, t : \mathsf{BHist}$ *in the instance of Definition 45.409, classifier cancellation by the common carried factor is exact on both sides:*

$$R^u_D(\mu^u_D(h,t), \mu^u_D(k,t)) \iff R^u_D(h,k),$$

and

$$R^u_D(\mu^u_D(t,h), \mu^u_D(t,k)) \iff R^u_D(h,k).$$

Proof. For the two forward directions, use the carried hypotheses for h, k, and t and apply Definition 45.431. Its right-cancellation field gives the first implication, and its left-cancellation field gives the second implication.

For the reverse direction on the right, start from $R^u_D(h,k)$. Reflexivity for the carried factor gives $R^u_D(t,t)$, and the binary classifier congruence field in Definition 45.392 combines the two classifier witnesses to obtain $R^u_D(\mu^u_D(h,t), \mu^u_D(k,t))$.

For the reverse direction on the left, use the same reflexivity witness $R^u_D(t,t)$ as the first classifier input and the assumed $R^u_D(h,k)$ as the second classifier input. The same binary congruence field then gives $R^u_D(\mu^u_D(t,h), \mu^u_D(t,k))$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator empty unit right multiplication classifier exactness`

Per-object template: traditional target cancellation exactness in the denominator monoid boundary; BEDC source RatDenomUnitCarrier, RatDenomUnitClassifier, Cont, and append; carrier C^u_D; classifier R^u_D; stability obligation two-sided classifier preservation and reflection; ledger the common carried denominator factor; core theorem Definition 45.410; exactness predicate classifier iff after common denominator multiplication; standard bridge cancellative commutative denominator monoids; status ProofTarget.

This is a concrete BHist tuple law for future Lean rounds, not an abstract operator schema.

Definition 45.411 (Rat denominator empty-unit right multiplication context)**.** *For a carried context t : BHist with $C^u_D(t)$, define the concrete right multiplication map on the empty-unit denominator carrier by*

$$R_t(h) := \mu^u_D(h, t).$$

The carrier, classifier, and multiplication are the same concrete BHist *data used in Definition 45.409.*

Definition 45.412 (Rat denominator empty-unit left multiplication context)**.** *For a carried context t : BHist with $C^u_D(t)$, define the concrete left multiplication map on the empty-unit denominator carrier by*

$$L_t(h) := \mu^u_D(t, h).$$

The carrier, classifier, and multiplication are the same concrete BHist *data used in Definition 45.346.*

Theorem 45.413 (Rat denominator empty-unit left multiplication classifier exactness)**.** *For histories h, k, t : BHist, if $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(t)$, then left multiplication by t preserves and reflects the empty-unit denominator classifier:*

$$R^u_D(\mu^u_D(t, h), \mu^u_D(t, k)) \Longleftrightarrow R^u_D(h, k).$$

Proof. For the forward direction, use the left-cancellation clause packaged in Definition 45.431 with the three carrier hypotheses. It reads the displayed comparison after common left multiplication by t back as the endpoint classifier $R^u_D(h, k)$.

For the reverse direction, use $C^u_D(t)$ to obtain reflexivity $R^u_D(t, t)$. The binary classifier congruence field in Definition 45.347, or the same congruence field as packaged in Definition 45.431, combines $R^u_D(t, t)$ with $R^u_D(h, k)$ and yields $R^u_D(\mu^u_D(t, h), \mu^u_D(t, k))$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator empty unit left multiplication classifier exactness`

Per-object template: traditional target left multiplication by a fixed denominator-unit factor; BEDC source RatDenomUnitCarrier, RatDenomUnitClassifier, Cont, and append; carrier C^u_D; classifier R^u_D; stability obligation left-context classifier exactness; ledger fixed left-context continuation witness; core theorem Definition 45.413; exactness predicate preservation and reflection of the classifier under L_t; standard bridge cancellative commutative denominator monoids; status ProofTarget.

This is the left-context companion to the right-cancellation law Definition 45.432 inside the concrete empty-unit denominator boundary.

Theorem 45.414 (Rat history classifier append left denominator unit closure)**.** *For histories h, h', k, k' : BHist, if* RatDenomUnitClassifier(h, h') *and* RatHistoryClassifier(k, k')*, then*

$$\mathsf{RatHistoryClassifier}(\mathsf{append}(h, k), \mathsf{append}(h', k')).$$

Proof. The denominator-unit carrier on h and the Rat carrier on k close the left appended endpoint as a Rat history carrier; the same argument closes the right endpoint from h' and k'. The classifier comparisons for the two factors are respected by the canonical append continuations, giving the required history sameness between the appended endpoints. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatHistoryClassifier append left denom unit closed`

Theorem 45.415 (Rat denominator unit classifier append-context cancellation)**.** *For histories L, R, Q, S : BHist, if $R^u_D(L, R)$, then appending the classified suffixes L and R preserves and reflects the empty-unit denominator classifier:*

$$R^u_D(\mathsf{append}(Q, L), \mathsf{append}(S, R)) \iff R^u_D(Q, S).$$

Proof. For the forward direction, unpack the displayed classifier. Product-carrier factorization gives carried witnesses for Q and S. The suffix classifier gives $L\mathsf{hsame}R$, so the right displayed endpoint can be transported to the common suffix L; right append cancellation then gives $Q\mathsf{hsame}S$.

For the reverse direction, classifier closure under continuation appends the two carried suffix witnesses to the two carried endpoints. The endpoint classifier and suffix classifier identify the two appended histories. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier append context cancel iff`

Theorem 45.416 (Rat denominator unit classifier append left context cancellation)**.** *For histories L, R, Q, S : BHist, if $\mathsf{RatDenomUnitClassifier}(L, R)$, then appending the classified prefixes L and R preserves and reflects the empty-unit denominator classifier:*

$$\mathsf{RatDenomUnitClassifier}(\mathsf{append}(L, Q), \mathsf{append}(R, S)) \iff \mathsf{RatDenomUnitClassifier}(Q, S).$$

Proof. For the forward direction, factor the two appended carrier witnesses to recover carried witnesses for Q and S. Transport the right displayed endpoint along $R\mathsf{hsame}L$ so both endpoints have common prefix L, then apply left append cancellation to obtain $Q\mathsf{hsame}S$.

For the reverse direction, close the two appended endpoints by denominator-unit continuation closure. Continuation respect for the classified prefixes and classified suffixes gives the endpoint comparison. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitClassifier append left context cancel iff`

Definition 45.417 (Rat denominator empty-unit bilateral multiplication context)**.** *For carried contexts l, r : BHist with $C^u_D(l)$ and $C^u_D(r)$, define the concrete two-sided carried-context map over the empty-unit denominator carrier by*

$$B_{l,r}(h) := \mu^u_D(\mu^u_D(l, h), r).$$

Here the carrier is C^u_D, the classifier is R^u_D, and multiplication is the concrete operation $\mu^u_D(h, k) := \mathsf{append}(h, k)$ from Definition 45.346.

Theorem 45.418 (Rat denominator empty-unit bilateral multiplication classifier exactness)**.** *For histories h, k, l, r : BHist, if $C^u_D(h)$, $C^u_D(k)$, $C^u_D(l)$, and $C^u_D(r)$, then the two-sided carried-context map of Definition 45.417 preserves and reflects the empty-unit denominator classifier:*

$$R^u_D(B_{l,r}(h), B_{l,r}(k)) \iff R^u_D(h, k).$$

Proof. First use carrier closure from Definition 45.347. The carried hypotheses for l, h, and k give carried witnesses for $\mu^u_D(l,h)$ and $\mu^u_D(l,k)$; together with $C^u_D(r)$, they put both right-multiplied endpoints inside the scope of the denominator cancellation exactness theorem.

For the forward direction, unfold $B_{l,r}$ to read the assumed comparison as the right multiplication comparison of $\mu^u_D(l,h)$ and $\mu^u_D(l,k)$ by the common carried context r. Apply Definition 45.410; its reflection direction gives $R^u_D(\mu^u_D(l,h), \mu^u_D(l,k))$.

Now apply Definition 45.413 with the carried left context l. Its reflection direction converts the last classifier witness into $R^u_D(h,k)$.

For the reverse direction, begin with $R^u_D(h,k)$. The preservation direction of Definition 45.413 gives $R^u_D(\mu^u_D(l,h), \mu^u_D(l,k))$.

Apply the right-hand preservation direction of Definition 45.410 with the common carried context r. After folding the definition of $B_{l,r}$, the result is exactly $R^u_D(B_{l,r}(h), B_{l,r}(k))$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator empty unit bilateral multiplication classifier exactness`

Per-object template: traditional target bilateral denominator-context exactness; BEDC source RatDenomUnitCarrier, RatDenomUnitClassifier, Cont, and append; carrier C^u_D; classifier R^u_D; stability obligation two-sided carried-context classifier exactness; ledger the two carried context continuation witnesses; core theorem Definition 45.418; exactness predicate $R^u_D(B_{l,r}(h), B_{l,r}(k)) \iff R^u_D(h,k)$; standard bridge cancellative commutative denominator monoids; status ProofTarget.

Theorem 45.419 (Rat denominator empty-unit context action support exactness)**.** *For histories* $h, k, t, p, q, p', q' : \mathsf{BHist}$*, assume* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(t)$*, and* $p\mathsf{hsamee}$*,* $q\mathsf{hsamee}$*,* $p'\mathsf{hsamee}$*, and* $q'\mathsf{hsamee}$*. The concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *satisfies the following context-action boundary laws.*

1. *Right multiplication by the fixed factor* t *is classifier exact:*

$$R^u_D(\mu^u_D(h,t), \mu^u_D(k,t)) \iff R^u_D(h,k).$$

2. *Left multiplication by the fixed factor* t *is classifier exact:*

$$R^u_D(\mu^u_D(t,h), \mu^u_D(t,k)) \iff R^u_D(h,k).$$

3. *Empty external endpoint contexts are classifier exact:*

$$R^u_D(\mathsf{append}(p, \mathsf{append}(h,q)), \mathsf{append}(p', \mathsf{append}(k,q'))) \iff R^u_D(h,k).$$

4. *Empty external endpoint contexts preserve and reflect strict support:*

$$N^u_D(\mathsf{append}(p, \mathsf{append}(h,q))) \iff N^u_D(h)$$

and

$$N^u_D(\mathsf{append}(p', \mathsf{append}(k,q'))) \iff N^u_D(k).$$

5. *Strict support is exact under the two fixed-factor multiplication actions:*

$$N^u_D(\mu^u_D(h,t)) \iff N^u_D(h) \vee N^u_D(t)$$

and

$$N^u_D(\mu^u_D(t,h)) \iff N^u_D(t) \vee N^u_D(h).$$

Proof. The first classifier equivalence is exactly Definition 45.410 applied to the carried histories h, k, and t.

The second classifier equivalence is exactly Definition 45.413 with the same three carried endpoints.

For the empty external contexts, unfold R^u_D as RatDenomUnitClassifier and apply Definition 45.405 to the four endpoint equalities $p$hsamee, $q$hsamee, p'hsamee, and q'hsamee.

For strict support under empty contexts, unfold N^u_D as RatHistoryCarrier. The endpoint equalities identify $\mathsf{append}(p, \mathsf{append}(h, q))$ with h and $\mathsf{append}(p', \mathsf{append}(k, q'))$ with k by the same empty-context endpoint equivalence used in Definition 45.348. Transport RatHistoryCarrier along those hsame comparisons in both directions.

The two fixed-factor support equivalences are the two orientations of Definition 45.402, first for (h, t) and then for (t, h). □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator empty unit context action support exactness`

Theorem 45.420 (Rat denominator contextual action empty-context classifier transport)**.** *For histories h, h', l, r : BHist, if $C^u_D(l)$ and $C^u_D(r)$ hold and $R^u_D(h, h')$, then the bilateral empty-context action preserves the denominator classifier:*

$$R^u_D(\Gamma_{\mathsf{e},\mathsf{e},l,r}(h), \Gamma_{\mathsf{e},\mathsf{e},l,r}(h')).$$

Proof. Classify l with itself and r with itself by reflexivity of hsame. Apply continuation closure of R^u_D first to the left product $\mathsf{append}(l, h)$ versus $\mathsf{append}(l, h')$, and then to the right product with r. The empty external contexts are removed by the denominator unit classifier empty-context equivalence in both directions. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitContextualAction empty context hsame transport`

Per-object template: traditional target denominator context action for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source RatDenomUnitCarrier, RatDenomUnitClassifier, RatHistoryCarrier, Cont, append, and e; carrier C^u_D; classifier R^u_D; stability obligations classifier exactness and support exactness; ledger fixed factor and empty external contexts; core theorem Definition 45.419; exactness predicate preservation and reflection of classifier plus strict support; standard bridge cancellative denominator monoids with adjoined unit; status ProofTarget.

Theorem 45.421 (Rat denominator empty-unit bilateral multiplication support exactness)**.** *For histories h, l, r : BHist with $C^u_D(h)$, $C^u_D(l)$, and $C^u_D(r)$, the bilateral context map of Definition 45.417 satisfies*

$$N^u_D(B_{l,r}(h)) \iff N^u_D(l) \vee N^u_D(h) \vee N^u_D(r).$$

Proof. Unfold $B_{l,r}$ as $\mu^u_D(\mu^u_D(l, h), r)$. Carrier closure for the empty-unit denominator product gives $C^u_D(\mu^u_D(l, h))$ from the carried hypotheses on l and h, so the outer product lies in the scope of strict product support exactness.

Apply Definition 45.402 to $\mu^u_D(\mu^u_D(l, h), r)$. This identifies $N^u_D(B_{l,r}(h))$ with $N^u_D(\mu^u_D(l, h)) \vee N^u_D(r)$.

Apply the same strict-product support exactness theorem to the inner product $\mu^u_D(l, h)$. This identifies the inner support term with $N^u_D(l) \vee N^u_D(h)$.

For the forward direction, combine the two displayed equivalences. If the outer support witness lands in the right component, obtain $N^u_D(r)$. If it lands in the left component, use the inner equivalence and distinguish the l and h cases. Reassociate the resulting constructive disjunction as $N^u_D(l) \vee N^u_D(h) \vee N^u_D(r)$.

For the reverse direction, start from $N^u_D(l) \vee N^u_D(h) \vee N^u_D(r)$. The r case supplies the right component of the outer strict-product equivalence. The l and h cases first supply $N^u_D(\mu^u_D(l,h))$ by the reverse direction of the inner equivalence, and then supply $N^u_D(B_{l,r}(h))$ by the reverse direction of the outer equivalence. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator empty unit bilateral multiplication support exactness`

Per-object template: traditional target bilateral denominator-context support exactness; BEDC source RatDenomUnitCarrier, RatHistoryCarrier, Cont, append, and e; carrier C^u_D; classifier R^u_D; stability obligation strict-support exactness under two-sided carried contexts; ledger the two continuation witnesses; core theorem Definition 45.421; exactness predicate $N^u_D(B_{l,r}(h)) \iff N^u_D(l) \vee N^u_D(h) \vee N^u_D(r)$; standard bridge cancellative denominator monoids with adjoined unit; status ProofTarget.

Definition 45.422 (Rat denominator empty-unit contextual commutative instance)**.** *The concrete empty-unit contextual commutative instance over* BHist *uses the carrier* $C^u_D :=$ RatDenomUnitCarrier*, the classifier* $R^u_D :=$ RatDenomUnitClassifier*, multiplication* $\mu^u_D(h,k) :=$ $\mathsf{append}(h,k)$*, and unit* $e^u_D :=$ e*. Its admissible external left and right contexts are exactly the histories history-same to the empty endpoint, written* $p$hsamee *and* $q$hsamee*.*

Theorem 45.423 (Rat denominator empty-unit contextual commutativity)**.** *For histories* $p, q, p', q', h, k :$ BHist*, if* $p$hsamee*,* $q$hsamee*,* p'hsamee*,* q'hsamee*,* $C^u_D(h)$*, and* $C^u_D(k)$*, then denominator multiplication commutes inside the admissible empty external contexts:*

$$R^u_D(\mathsf{append}(p, \mathsf{append}(\mu^u_D(h,k), q)), \mathsf{append}(p', \mathsf{append}(\mu^u_D(k,h), q'))).$$

Proof. Apply Definition 45.392 to the two carrier hypotheses $C^u_D(h)$ and $C^u_D(k)$. The commutativity clause gives the core classifier

$$R^u_D(\mu^u_D(h,k), \mu^u_D(k,h)).$$

Now use the reverse direction of Definition 45.405 with the four endpoint hypotheses $p$hsamee, $q$hsamee, p'hsamee, and q'hsamee. It transports the core classifier through the two empty left contexts and the two empty right contexts.

Since the contextual instance of Definition 45.422 has $\mu^u_D(x,y) = \mathsf{append}(x,y)$ and $R^u_D =$ RatDenomUnitClassifier, the transported classifier is exactly the displayed empty-context commutativity statement. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator empty unit contextual commutativity`

Theorem 45.424 (Rat denominator external-unit envelope commutative monoid laws)**.** *For the tuple* $(C^*_D, R^*_D, \mu^*_D, e^*_D)$ *of Definition 45.370, all laws of Definition 45.377 hold, and the envelope multiplication is commutative up to its endpoint classifier: whenever* $C^*_D(h)$ *and* $C^*_D(k)$*,*

$$R^*_D(\mu^*_D(h,k), \mu^*_D(k,h)).$$

Proof. The carrier inhabitance, closure, associativity, left and right unit laws, binary classifier congruence, carried restriction, and carried one-sided unit obstruction are exactly the fields supplied by Definition 45.377.

It remains to prove the displayed commutativity classifier. Split the two carrier witnesses $C^*_D(h)$ and $C^*_D(k)$ into their carried Rat denominator alternatives and their external-empty alternatives.

In the carried/carried case, $\mu^*_D(h,k)$ and $\mu^*_D(k,h)$ are the canonical append continuations of the two carried denominators in opposite orders. Apply Definition 45.118 to these two continuations. The carried classifier exactness theorem Definition 45.379 then repacks the resulting RatHistoryClassifier as the required R^*_D comparison.

In the carried/empty case, the append right-unit and left-unit laws identify $\mu^*_D(h,k)$ and $\mu^*_D(k,h)$ with the same carried endpoint h, up to hsame. The envelope classifier normal form, Definition 45.371, turns those two endpoint comparisons and the transported carried witness into $R^*_D(\mu^*_D(h,k), \mu^*_D(k,h))$.

The empty/carried case is symmetric. The same append unit laws identify the two products with the carried endpoint k, and the same normal form converts the two transported carrier witnesses and the resulting hsame comparison into the envelope classifier.

In the empty/empty case, both products are hsame to e by the append unit laws and transitivity of hsame. Since $e^*_D = \mathsf{e}$, the empty branch of R^*_D classifies the two products directly. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator unit envelope commutative monoid laws`

Per-object template: traditional target commutative denominator monoid boundary for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source RatHistoryCarrier, RatHistoryClassifier, Cont, append, and e; carrier C^*_D; classifier R^*_D; stability obligation monoid laws plus commutativity; ledger external-unit bit plus continuation witness; core theorem Definition 45.424; exactness predicate envelope commutativity over the strict carried restriction; standard bridge deferred; status ProofTarget.

Definition 45.425 (Rat denominator external-unit envelope strict support)**.** *For the tuple $(C^*_D, R^*_D, \mu^*_D, e^*_D)$ of Definition 45.370, the strict support predicate is the genuine Rat denominator endpoint predicate*

$$N^*_D(h) \iff \mathsf{RatHistoryCarrier}(h).$$

Thus the external endpoint is carried by C^*_D but does not enter the strict denominator support.

Theorem 45.426 (Rat denominator external-unit envelope strict support laws)**.** *For histories $h, k : \mathsf{BHist}$ with $C^*_D(h)$ and $C^*_D(k)$, the strict support predicate of Definition 45.425 satisfies:*

1. $R^*_D(h,k) \to (N^*_D(h) \iff N^*_D(k))$.
2. $N^*_D(\mu^*_D(h,k)) \iff N^*_D(h) \vee N^*_D(k)$.
3. *Together with Definition 45.424, these clauses give a concrete* BHist *multiplicative-support boundary for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$.

Proof. Unfold C^*_D, R^*_D, μ^*_D, and N^*_D. The carrier assumptions split each input into a genuine Rat denominator endpoint or an external empty endpoint.

For support transport along the classifier, split the defining alternatives of $R^*_D(h,k)$. In the guarded carried branch, both strict-support predicates are exactly the displayed RatHistoryCarrier witnesses, so the two directions are projections. In the empty-empty branch, any strict-support witness for either endpoint contradicts RatHistoryCarrier_not_empty after composing its endpoint comparison with the branch comparison to e.

For product support, first consider the carried/carried branch. The canonical continuation witness for $\mathsf{append}(h,k)$ and carried denominator closure give $\mathsf{RatHistoryCarrier}(\mu^*_D(h,k))$, while the right side holds by either input support.

In the carried/empty branch, the append right-unit law identifies $\mu^*_D(h,k)$ with h. Transport $\mathsf{RatHistoryCarrier}(h)$ across this hsame comparison by RatHistoryCarrier_hsame_transport, and the left disjunct supplies the reverse implication. The empty/carried branch is symmetric, using the append left-unit law and the right strict-support disjunct.

In the empty/empty branch, the append unit laws identify $\mu^*_D(h,k)$ with e. Therefore product strict support is impossible by RatHistoryCarrier_not_empty, and both input strict-support predicates are impossible by the same theorem. This proves the displayed product equivalence.

The final clause only packages these two support laws with the already stated commutative monoid laws: the monoid theorem supplies the algebraic envelope, and the present theorem supplies the exact descent of genuine denominator support through classifier transport and multiplication. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator unit envelope strict support laws`

Theorem 45.427 (Rat denominator external-unit envelope product strict-support congruence)**.** *For histories $h, h', k, k' : \mathsf{BHist}$ with $C^*_D(h)$, $C^*_D(h')$, $C^*_D(k)$, $C^*_D(k')$, $R^*_D(h,h')$, and $R^*_D(k,k')$, the products have equivalent strict support:*

$$N^*_D(\mu^*_D(h,k)) \Longleftrightarrow N^*_D(\mu^*_D(h',k')).$$

Proof. First build the product endpoints inside the envelope. The closure clauses of Definition 45.377 applied to $C^*_D(h)$ and $C^*_D(k)$ give a carrier witness for $\mu^*_D(h,k)$, and the same clauses applied to $C^*_D(h')$ and $C^*_D(k')$ give a carrier witness for $\mu^*_D(h',k')$.

Next compare the two products. The binary classifier-congruence clause of Definition 45.377, applied to $R^*_D(h,h')$ and $R^*_D(k,k')$, gives $R^*_D(\mu^*_D(h,k), \mu^*_D(h',k'))$.

Finally transport strict support across that product classifier. The classifier-transport clause of Definition 45.426, used with the two product carrier witnesses, yields the displayed equivalence of N^*_D for the two products. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator unit envelope product strict support congruence`

Per-object template: traditional target product strict-support congruence for the concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ denominator envelope; BEDC source BHist, RatHistoryCarrier, R^*_D, μ^*_D, and append; carrier C^*_D; classifier R^*_D; stability obligation factorwise classifier congruence; ledger external-unit bit plus carried continuation witness; core theorem Definition 45.427; exactness predicate product strict support invariant under factorwise classification; standard bridge deferred; status ProofTarget.

Theorem 45.428 (Rat denominator external-unit envelope support-unit no-confusion)**.** *For every history $h : \mathsf{BHist}$ with $C^*_D(h)$,*

$$N^*_D(h) \Longleftrightarrow (R^*_D(h, e^*_D) \to \mathsf{False}).$$

For histories $h, k : \mathsf{BHist}$ with $C^*_D(h)$ and $C^*_D(k)$,

$$(R^*_D(\mu^*_D(h,k), e^*_D) \to \mathsf{False}) \Longleftrightarrow N^*_D(h) \vee N^*_D(k).$$

Proof. Unfold the carrier C^*_D at h. In the carried branch, $N^*_D(h)$ is exactly the displayed $\mathsf{RatHistoryCarrier}(h)$ witness. A classifier comparison $R^*_D(h, e^*_D)$ would be a mixed carried-empty endpoint comparison, because $e^*_D = \mathsf{e}$; by Definition 45.372 and Definition 37.18 this branch is impossible.

In the empty branch, $h\mathsf{hsamee}$. Since $e^*_D = \mathsf{e}$, the empty-empty classifier branch gives $R^*_D(h, e^*_D)$. The same endpoint comparison also rules out $N^*_D(h)$ by Definition 37.18. Thus the strict support predicate is exactly the failure of classification as the adjoined unit.

For the product clause, first use the carrier closure in Definition 45.424 to view $\mu^*_D(h,k)$ as an envelope-carried history. Applying the first clause to this product rewrites failure of $R^*_D(\mu^*_D(h,k), e^*_D)$ as $N^*_D(\mu^*_D(h,k))$.

Finally apply the second support law of Definition 45.426, which identifies $N_D^*(\mu_D^*(h,k))$ with $N_D^*(h) \vee N_D^*(k)$. The two equivalences compose to give the displayed product no-confusion statement. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator unit envelope support unit no confusion`

Per-object template: downstream target $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ denominator support boundary; BEDC source RatHistoryCarrier, RatHistoryClassifier, Cont, append, and e; carrier C_D^*; classifier R_D^*; stability obligation strict support transport and product support exactness; ledger external-unit bit plus continuation witness; core theorem Definition 45.426; exactness predicate genuine Rat denominator support descends through R_D^* and μ_D^*; standard bridge $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ denominator support boundary; status ProofTarget.

45.19 Rat denominator external-unit envelope cancellation exactness

Theorem 45.429 (Rat denominator external-unit envelope cancellation exactness)**.** *For the tuple $(C_D^*, R_D^*, \mu_D^*, e_D^*)$ of Definition 45.370 and the strict support predicate N_D^* of Definition 45.425, strict common factors cancel exactly at the envelope classifier. For histories h, k, t : BHist, if $C_D^*(h)$, $C_D^*(k)$, $C_D^*(t)$, and $N_D^*(t)$, then*

$$R_D^*(\mu_D^*(h,t), \mu_D^*(k,t)) \Longleftrightarrow R_D^*(h,k),$$

and

$$R_D^*(\mu_D^*(t,h), \mu_D^*(t,k)) \Longleftrightarrow R_D^*(h,k).$$

Proof. Unfold the envelope tuple and the strict support predicate. The hypothesis $N_D^*(t)$ identifies the common factor as a genuine RatHistoryCarrier endpoint, so multiplication by t remains in the carried Rat denominator branch after applying the append continuation closure used by the envelope laws.

For the forward right-cancellation direction, split the carrier witnesses for h and k into carried denominator and external empty branches.

In the carried/carried branch, all three factors lie in RatDenomUnitCarrier, and the displayed envelope classifier is read as the corresponding empty-unit classifier by Definition 45.379. Apply Definition 45.431 to cancel the strict common factor. The resulting carried denominator classifier is then packed back into $R_D^*(h,k)$ through the carried branch of the envelope classifier.

In a mixed branch, one of h and k is external while the other is carried. Because t has strict support, the product on the carried side has a RatHistoryCarrier witness, while the product on the external side is classified with the same carried continuation only through a mixed external-carried alternative. The classifier normal form and Definition 45.372, together with RatHistoryCarrier_not_empty, rule out such a product classifier. Hence the antecedent of the forward implication cannot hold in the mixed cases.

In the external/external branch, both h and k are classified with $e_D^* = \mathsf{e}$. The two products are classified with the common carried continuation of t by the one-sided unit laws, and the conclusion $R_D^*(h,k)$ is the empty branch of the envelope classifier.

The forward left-cancellation direction is the same case split with the common strict factor placed on the left. The carried/carried case uses the left cancellation field of Definition 45.431; the mixed cases are excluded by the same classifier exactness and RatHistoryCarrier_not_empty argument; the external/external case packs the empty branch directly.

For the reverse directions, assume $R^*_D(h,k)$. The carrier hypothesis on t gives reflexivity $R^*_D(t,t)$, and the multiplication congruence field of Definition 45.424 combines $R^*_D(h,k)$ with this reflexive common factor. Placing the reflexive factor on the right gives $R^*_D(\mu^*_D(h,t),\mu^*_D(k,t))$; placing it on the left gives $R^*_D(\mu^*_D(t,h),\mu^*_D(t,k))$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator unit envelope cancellation exactness`

Traditional target: cancellative denominator envelope for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: BHist, RatHistoryCarrier, RatDenomUnitCarrier, RatDenomUnitClassifier, Cont, and append; **carrier**: C^*_D; **classifier**: R^*_D; **multiplication**: μ^*_D; **unit**: e^*_D; **ledger**: external-unit bit plus common denominator continuation witness; **core theorem**: Definition 45.429; **exactness predicate**: strict-factor cancellation; **standard bridge**: ordinary denominator cancellation; **status**: LeanChecked.

Theorem 45.430 (Rat denominator external-unit envelope exact FieldUp boundary)**.** *For the concrete tuple $(C^*_D, R^*_D, \mu^*_D, e^*_D)$ of Definition 45.370 and the strict support predicate N^*_D of Definition 45.425, the external-unit envelope supplies the exact* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *denominator boundary. Namely, the tuple carries the commutative monoid laws, restricts to the carried Rat denominator continuation fragment, separates mixed carried and external endpoints, has e^*_D as the unique external unit, transports strict support along R^*_D, computes product strict support exactly by $N^*_D(\mu^*_D(h,k)) \iff N^*_D(h) \vee N^*_D(k)$ for carried envelope inputs, and satisfies exact left and right cancellation by every strict common factor t:*

$$N^*_D(t) \to \big(R^*_D(\mu^*_D(h,t),\mu^*_D(k,t)) \iff R^*_D(h,k)\big),$$

and

$$N^*_D(t) \to \big(R^*_D(\mu^*_D(t,h),\mu^*_D(t,k)) \iff R^*_D(h,k)\big),$$

for all $h,k,t : \mathsf{BHist}$ carried by C^*_D.

Proof. The algebraic denominator envelope is supplied by Definition 45.424. Its underlying certificate data are exactly the carrier restriction to the concrete Rat denominator fragment, the carried classifier and multiplication restriction, and the mixed-endpoint separation recorded by Definition 45.383.

The external endpoint is pinned down by Definition 45.378: any carried envelope endpoint satisfying either one-sided unit law is classified with e^*_D. This supplies the unique external unit field of the boundary.

The strict-support fields come from Definition 45.426. Its first clause transports N^*_D across R^*_D-classified endpoints, and its second clause gives the exact product support equivalence for μ^*_D.

Finally, Definition 45.429 supplies the two displayed cancellation equivalences whenever the common factor has strict support. Combining these four packages gives the stated concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ denominator boundary without any further structure. □

Traditional target: exact denominator boundary for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: BHist, RatHistoryCarrier, RatHistoryClassifier, RatDenomUnitCarrier, RatDenomUnitClassifier, Cont, append, and e; **carrier**: C^*_D; **classifier**: R^*_D; **multiplication**: μ^*_D; **unit**: e^*_D; **ledger**: external-unit bit plus denominator continuation witness; **core theorem**: Definition 45.430; **exactness predicate**: carried-fragment restriction, mixed-endpoint separation, unique external unit, strict-support transport, product support exactness, and strict-factor cancellation; **standard bridge**: concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ denominator boundary; **status**: ProofTarget.

Theorem 45.431 (Rat denominator empty-unit cancellative commutative monoid package)**.** *For the tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D)$ *of Definition 45.346, the laws of Definition 45.392 hold. Moreover, for carried histories* $h, k, q : \mathsf{BHist}$*, the endpoint classifier is cancellative on both sides:*

$$C^u_D(h) \wedge C^u_D(k) \wedge C^u_D(q) \wedge R^u_D(\mu^u_D(h,q), \mu^u_D(k,q)) \to R^u_D(h,k),$$

and

$$C^u_D(h) \wedge C^u_D(k) \wedge C^u_D(q) \wedge R^u_D(\mu^u_D(q,h), \mu^u_D(q,k)) \to R^u_D(h,k).$$

Proof. Unfold the concrete data of Definition 45.346. The algebraic fields are exactly the commutative monoid laws supplied by Definition 45.392.

For right cancellation, split the three $\mathsf{RatDenomUnitCarrier}$ witnesses for h, k, and q into empty endpoint and genuine Rat denominator endpoint alternatives.

In the genuine/genuine/genuine branch, the two classified products are displayed continuation endpoints with the same genuine right context q. Apply Definition 45.133 with empty unary prefix and common suffix q, then use Definition 45.134 to read the obtained comparison as the denominator classifier $R^u_D(h,k)$.

If the common right factor q is empty, the one-sided unit laws from Definition 45.347 identify $\mu^u_D(h,q)$ with h and $\mu^u_D(k,q)$ with k. Transporting the displayed classifier across those endpoint identifications gives $R^u_D(h,k)$.
