If one of h and k is empty and the other is genuine, the displayed product classifier forces a mixed endpoint comparison after the same unit reduction on the empty side. The empty-unit endpoint exactness clauses from section 45.15 separate the empty endpoint from the genuine denominator endpoint, so the only classifiable mixed case is the one already carrying the comparison needed for $R^u_D(h,k)$.

The empty/empty branch is immediate: both endpoints are hsamee, and the definition of $\mathsf{RatDenomUnitClassifier}$ packs the two carried witnesses with the resulting hsame comparison.

Left cancellation follows from right cancellation and commutativity. Apply Definition 45.392 to commute both displayed left products into right products, use the right-cancellation clause just proved, and transport the classifier back along the same commutativity comparisons. □

Traditional target: cancellative commutative denominator monoid for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: $\mathsf{RatHistoryCarrier}$, $\mathsf{RatDenomUnitCarrier}$, Cont, and append; **carrier**: C^u_D; **classifier**: R^u_D; **stability obligations**: monoid laws, commutativity, and cancellation; **ledger**: external empty-unit provenance; **core theorem**: Definition 45.431; **exactness predicate**: cancellative endpoint classification; **standard bridge**: ordinary positive-denominator multiplication with adjoined unit; **status**: $\mathsf{ProofTarget}$.

Theorem 45.432 (Rat denominator empty-unit right cancellation)**.** *For the tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D)$ *of Definition 45.346, right multiplication by a carried empty-unit denominator endpoint is exact for the classifier. For all histories* $h, k, t : \mathsf{BHist}$*, if* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(t)$*, and*

$$R^u_D(\mu^u_D(h,t), \mu^u_D(k,t)),$$

then

$$R^u_D(h,k).$$

Proof. Unfold the data of Definition 45.346. Thus μ^u_D is append, C^u_D is $\mathsf{RatDenomUnitCarrier}$, and R^u_D is $\mathsf{RatDenomUnitClassifier}$.

First consider the branch where t is the empty endpoint. The right-unit clause in Definition 45.347 classifies $\mathsf{append}(h,t)$ with h and $\mathsf{append}(k,t)$ with k. Transport the displayed classifier across these two right-unit classifications, using symmetry and transitivity of hsame inside $\mathsf{RatDenomUnitClassifier}$, to obtain $\mathsf{RatDenomUnitClassifier}(h,k)$.

Now consider the branch where t is a genuine Rat denominator endpoint. If one of h and k is empty and the other is genuine, the displayed product classifier is a mixed carried-empty endpoint after cancelling the visible append presentation; this contradicts Definition 45.382. The empty/empty subcase packs the classifier directly from the two empty endpoint witnesses.

It remains to handle the genuine/genuine subcase. The products $\mu^u_D(h,t)$ and $\mu^u_D(k,t)$ are the canonical append continuation endpoints with common suffix t. Apply Definition 45.133 with the empty prefix, the common suffix t, and the two canonical continuation witnesses for $\mathsf{Cont}(h,t,\mathsf{append}(h,t))$ and $\mathsf{Cont}(k,t,\mathsf{append}(k,t))$. The result is $\mathsf{RatHistoryClassifier}(h,k)$, and the original carrier hypotheses repack it as $\mathsf{RatDenomUnitClassifier}(h,k)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator empty unit right cancel`

Per-object template: traditional target cancellation in the denominator monoid boundary; BEDC source $\mathsf{RatDenomUnitCarrier}$, $\mathsf{RatDenomUnitClassifier}$, Cont, and append; carrier C^u_D; classifier R^u_D; stability obligation right cancellation; ledger the common suffix continuation witness; core theorem Definition 45.432; exactness predicate cancellation of a shared denominator factor; standard bridge ordinary cancellative commutative monoids; status $\mathsf{ProofTarget}$.

Theorem 45.433 (Rat denominator empty-unit FieldUp multiplicative subcertificate)**.** *For the tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D)$ of Definition 45.346 and the strict support predicate N^u_D of Definition 45.394, the FieldUp denominator side over* BHist *carries the following concrete multiplicative subcertificate.*

1. *The empty-unit commutative monoid laws hold for $(C^u_D, R^u_D, \mu^u_D, e^u_D)$, including commutativity up to R^u_D.*
2. *For all carried histories $h, k : \mathsf{BHist}$, strict support of the product is exact:*
$$(\mu^u_D(h,k)\mathsf{hsamee} \to \mathsf{False}) \Longleftrightarrow N^u_D(h) \vee N^u_D(k).$$
3. *For every carried history $u : \mathsf{BHist}$, if u satisfies both one-sided unit laws against all carried histories, then*
$$R^u_D(u, e^u_D).$$
4. *For all carried histories $h, k, t : \mathsf{BHist}$, classifier equality is cancellative for a common carried factor on the right and on the left:*
$$R^u_D(\mu^u_D(h,t), \mu^u_D(k,t)) \to R^u_D(h,k),$$
and
$$R^u_D(\mu^u_D(t,h), \mu^u_D(t,k)) \to R^u_D(h,k).$$

Proof. The first field is exactly the concrete commutative monoid boundary of Definition 45.392. It anchors the carrier, classifier, multiplication, and empty unit in the BHist tuple rather than in an abstract monoid variable.

The strict-support field is supplied by Definition 45.399. Its predicate is the N^u_D introduced in Definition 45.394, so the empty endpoint remains carried while the genuine Rat denominator endpoint is the only strict support source.

The unit field is Definition 45.393. It takes an arbitrary carried two-sided unit witness u and classifies it against the distinguished endpoint e_D^u.

The cancellation field is the two-sided classifier cancellation package of Definition 45.431. Together these clauses are not a variant of any single source theorem: the block composes the carrier and classifier laws, the strict support predicate, unit uniqueness, and both cancellation directions into the concrete denominator multiplicative boundary required by the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit criterion. □

Traditional target: FieldUp multiplicative denominator subcertificate for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: BHist, RatDenomUnitCarrier, RatDenomUnitClassifier, RatHistoryCarrier, Cont, and append; **carrier**: C_D^u; **classifier**: R_D^u; **stability obligations**: commutative monoid laws, strict support exactness, unit uniqueness, and two-sided cancellation; **ledger**: empty-unit endpoint provenance plus shared denominator continuation witness; **core theorem**: Definition 45.433; **exactness predicate**: concrete carried denominator products classify exactly through the empty-unit boundary; **standard bridge**: ordinary positive-denominator multiplication with an adjoined empty unit; **status**: ProofTarget.

Theorem 45.434 (Rat denominator external-unit FieldUp concrete instance unlock)**.** *The concrete* BHist *tuple* $(C_D^*, R_D^*, \mu_D^*, e_D^*, N_D^*)$*, with* $\mu_D^*(h,k) := \mathsf{append}(h,k)$*,* $e_D^* := \mathsf{e}$*, and strict support*

$$N_D^*(h) \iff \mathsf{RatHistoryCarrier}(h),$$

supplies the external-unit denominator instance required by the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *multiplicative schema. Concretely, the tuple carries:*

1. *commutative monoid laws for* $(C_D^*, R_D^*, \mu_D^*, e_D^*)$*;*
2. *strict-support transport along* R_D^* *and exact product support for* μ_D^**;*
3. *support-unit no-confusion at the external endpoint* e_D^**;*
4. *the exact* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *external-unit denominator boundary;*
5. *the cancellative commutative monoid package;*
6. *right cancellation for a common carried denominator factor;*
7. *the multiplicative subcertificate that repacks the denominator-side fields needed by the* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *exit criterion.*

Proof. The underlying monoid part is the concrete external-unit envelope of Definition 45.424. It fixes the displayed carrier, classifier, append multiplication, and empty unit, and it includes commutativity at the endpoint classifier.

The strict-support fields are those of Definition 45.426. They transport N_D^* across R_D^* and compute product support through μ_D^* exactly. The support-unit obstruction is supplied next by Definition 45.428.

The FieldUp denominator boundary is then the exact external-unit boundary of Definition 45.430. This packages the support transport, product-support exactness, and exact cancellation boundary for strict carried factors.

The cancellative algebraic layer is supplied by Definition 45.431, and the concrete right-cancellation row is Definition 45.432. These rows provide the ordinary cancellative commutative monoid package and the common right-factor cancellation required by the denominator side.

Finally, Definition 45.433 repackages the monoid laws, strict support, unit field, and cancellation fields as the multiplicative subcertificate. Hence the displayed BHist tuple supplies the concrete external-unit denominator instance for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$. □

Theorem 45.435 (Rat denominator empty-unit strict-support FieldUp subcertificate)**.** *For the tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *of Definition 45.346 and the strict support predicate* N^u_D *of Definition 45.394, the FieldUp denominator side over* BHist *carries the following concrete strict-support subcertificate.*

1. *The empty-unit commutative monoid laws hold for* $(C^u_D, R^u_D, \mu^u_D, e^u_D)$*, including commutativity up to* R^u_D*.*
2. *For all carried histories* $h, k : \mathsf{BHist}$*, classifier transport preserves and reflects strict support:*
$$R^u_D(h, k) \to (N^u_D(h) \iff N^u_D(k)).$$
3. *For all carried histories* $h, k : \mathsf{BHist}$*, strict support is exact for the product:*
$$N^u_D(\mu^u_D(h, k)) \iff N^u_D(h) \vee N^u_D(k).$$
4. *For every carried history* $u : \mathsf{BHist}$*, if* u *satisfies both one-sided unit laws against all carried histories, then*
$$R^u_D(u, e^u_D).$$
5. *For all carried histories* $h, k, t : \mathsf{BHist}$*, classifier equality is cancellative for a common carried factor on the right and on the left:*
$$R^u_D(\mu^u_D(h, t), \mu^u_D(k, t)) \to R^u_D(h, k),$$
and
$$R^u_D(\mu^u_D(t, h), \mu^u_D(t, k)) \to R^u_D(h, k).$$
6. *For histories* $p, q, p', q', h, k : \mathsf{BHist}$*, empty endpoint contexts preserve and reflect the classifier: if* $p\mathsf{hsamee}$*,* $q\mathsf{hsamee}$*,* $p'\mathsf{hsamee}$*, and* $q'\mathsf{hsamee}$*, then*
$$R^u_D(\mathsf{append}(p, \mathsf{append}(h, q)), \mathsf{append}(p', \mathsf{append}(k, q'))) \iff R^u_D(h, k).$$

Proof. The first field is exactly the concrete commutative monoid boundary of Definition 45.392. It anchors the carrier, classifier, multiplication, and empty unit in the BHist tuple rather than in an abstract monoid variable.

For support transport, unfold R^u_D as RatDenomUnitClassifier and N^u_D as RatHistoryCarrier. A classifier witness supplies the endpoint hsame comparison between h and k; applying RatHistoryCarrier_hsame_trans in both directions gives $N^u_D(h) \iff N^u_D(k)$.

The product support field is supplied by Definition 45.402. Its predicate is the N^u_D introduced in Definition 45.394, so the empty endpoint remains carried while the genuine Rat denominator endpoint is the only strict support source.

The unit field is Definition 45.393. It takes an arbitrary carried two-sided unit witness u and classifies it against the distinguished endpoint e^u_D.

The cancellation field is the two-sided classifier cancellation package of Definition 45.431.

The empty-context field is exactly the preservation-and-reflection theorem Definition 45.405. It uses the same classifier $R^u_D = \mathsf{RatDenomUnitClassifier}$ and the same append operation as the tuple.

Together these clauses compose the carrier and classifier laws, strict-support transport, product support exactness, unit uniqueness, cancellation, and empty-context classifier exactness into the concrete denominator boundary required by the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit criterion. □

Traditional target: FieldUp strict-support denominator subcertificate for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: BHist, RatDenomUnitCarrier, RatDenomUnitClassifier, RatHistoryCarrier, Cont, and append; **carrier**: C^u_D; **classifier**: R^u_D; **stability obligations**: commutative monoid laws, strict support transport, product support exactness, unit uniqueness, two-sided cancellation, and empty-context classifier exactness; **ledger**: empty-unit endpoint provenance plus shared denominator continuation witness; **core theorem**: Definition 45.435; **exactness predicate**: genuine denominator support is invariant under the classifier and exact under empty-unit products; **standard bridge**: ordinary positive-denominator multiplication with an adjoined empty unit; **status**: ProofTarget.

Theorem 45.436 (Rat denominator empty-unit contextual multiplication classifier exactness)**.** *For histories p, q, p', q', h, k, t : BHist, if $p$hsamee, $q$hsamee, p'hsamee, q'hsamee, $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(t)$, then fixed denominator multiplication is classifier-exact inside empty external contexts on both sides:*

$$R^u_D(\mathsf{append}(p, \mathsf{append}(\mu^u_D(h,t), q)), \mathsf{append}(p', \mathsf{append}(\mu^u_D(k,t), q'))) \iff R^u_D(h,k),$$

and

$$R^u_D(\mathsf{append}(p, \mathsf{append}(\mu^u_D(t,h), q)), \mathsf{append}(p', \mathsf{append}(\mu^u_D(t,k), q'))) \iff R^u_D(h,k).$$

Proof. For the right multiplication law, apply Definition 45.405 to the four hypotheses $p$hsamee, $q$hsamee, p'hsamee, and q'hsamee. This strips the empty external contexts from the displayed classifier and leaves the comparison $R^u_D(\mu^u_D(h,t), \mu^u_D(k,t))$.

The carried hypotheses $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(t)$ now match the input of Definition 45.410. That theorem identifies the stripped comparison with $R^u_D(h,k)$, giving the first equivalence.

For the left multiplication law, the same empty-context exactness theorem again removes the external histories and leaves $R^u_D(\mu^u_D(t,h), \mu^u_D(t,k))$.

The same carrier hypotheses then match Definition 45.413, which identifies this stripped comparison with $R^u_D(h,k)$. This gives the second equivalence. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator empty unit contextual multiplication classifier exactness`

1. Traditional target: contextual multiplication classifier exactness for the denominator side of $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$.
2. BEDC source: BHist, RatDenomUnitCarrier, RatDenomUnitClassifier, Cont, and append.
3. Carrier: C^u_D.
4. Classifier: R^u_D.
5. Stability obligations: empty external contexts preserve and reflect the classifier, and fixed denominator multiplication preserves and reflects the classifier on both sides.
6. Ledger: four empty external context witnesses and one carried fixed denominator factor.

7. Core theorem: Definition 45.436.
8. Exactness predicate: classifier equivalence before and after fixed denominator multiplication inside empty external contexts.
9. Standard bridge: ordinary denominator multiplication with an adjoined empty unit and empty endpoint contexts.
10. Status: ProofTarget.

Theorem 45.437 (Rat denominator FieldUp multiplicative certificate boundary)**.** *Let the denominator carrier, classifier, multiplication, unit, and strict support be the concrete* BHist *data*

$$C_D^*(h), \qquad R_D^*(h,k), \qquad \mu_D^*(h,k) := \mathsf{append}(h,k), \qquad e_D^* := \mathsf{e}, \qquad N_D^*(h) := \mathsf{RatHistoryCarrier}(h).$$

This tuple supplies the denominator-side multiplicative certificate boundary for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$*: envelope classifier exactness, monoid laws, commutativity, strict-support transport, product-support exactness, empty-unit identity uniqueness, and carried-endpoint cancellation all hold for the displayed* BHist *denominator package.*

Proof. The carrier, classifier, operation, and unit are the external-unit envelope data of Definition 45.370. Its classifier boundary is exactly Definition 45.372.

The algebraic envelope comes from two checked components. The monoid laws are those of Definition 45.377, and the commutative law is supplied by Definition 45.424.

The strict support named in the statement is the support predicate of Definition 45.426. That theorem gives both classifier transport for N_D^* and the exact product law

$$N_D^*(\mu_D^*(h,k)) \Longleftrightarrow N_D^*(h) \vee N_D^*(k).$$

The empty endpoint is controlled by Definition 45.393, which identifies any carried two-sided identity with $e_D^* = \mathsf{e}$ through the endpoint classifier. The carried cancellation part is the cancellation field of Definition 45.431, read on the same denominator append operation and the same empty endpoint.

Combining these clauses gives a single concrete denominator-side multiplicative boundary for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$, with no abstract carrier or classifier left to choose. □

Theorem 45.438 (Rat denominator FieldUp contextual multiplicative boundary)**.** *Let the denominator-side empty-unit tuple for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *be the concrete* BHist *data*

$$(C_D^u, R_D^u, \mu_D^u, e_D^u, N_D^u) = (\mathsf{RatDenomUnitCarrier}, \mathsf{RatDenomUnitClassifier}, \mathsf{append}, \mathsf{e}, \mathsf{RatHistoryCarrier}).$$

Equivalently, $\mu_D^u(h,k) = \mathsf{append}(h,k)$*,* $e_D^u = \mathsf{e}$*, and* $N_D^u(h) = \mathsf{RatHistoryCarrier}(h)$*. The FieldUp denominator-side contextual multiplicative boundary holds for this tuple:*

1. *empty external contexts preserve and reflect* R_D^u*;*
2. *right multiplication by any carried denominator factor is classifier-exact;*
3. *left multiplication by any carried denominator factor is classifier-exact;*
4. *the combined two-sided contextual statement is exactly Definition 45.436.*

Proof. The displayed tuple is the concrete cancellation-exact denominator instance of Definition 45.409. Thus the carrier, classifier, append multiplication, empty endpoint, and strict support are already fixed by the BHist denominator package.

For empty external contexts, apply Definition 45.405. It strips and restores empty histories on both sides of the denominator classifier, so context insertion by e preserves and reflects R^u_D.

For fixed-factor multiplication, apply Definition 45.410 and Definition 45.413. These give classifier exactness after right and left multiplication by any carried denominator factor.

Finally, combine the empty-context exactness with the two fixed-factor exactness laws through Definition 45.436. That theorem is precisely the packaged two-sided contextual multiplication boundary for the displayed FieldUp denominator tuple. □

Traditional target: contextual multiplicative denominator boundary for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: BHist, RatDenomUnitCarrier, RatDenomUnitClassifier, Cont, and append; **carrier**: C^u_D; **classifier**: R^u_D; **stability obligations**: empty-context classifier exactness plus right- and left-factor multiplication exactness; **ledger**: empty external context witnesses and one carried denominator factor; **core theorem**: Definition 45.436; **exactness predicate**: classifier preservation and reflection after fixed denominator multiplication inside empty external contexts; **standard bridge**: ordinary denominator multiplication with an adjoined empty unit and empty endpoint contexts; **status**: ProofTarget.

Theorem 45.439 (Rat denominator FieldUp multiplicative certificate obligation coverage)**.** *For the concrete tuple $(C^*_D, R^*_D, \mu^*_D, e^*_D, N^*_D)$ of Definition 45.437, the multiplicative* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *certificate rows are covered by the displayed* BHist *denominator data:*

1. *carrier closure and unit inhabitation for C^*_D and e^*_D;*
2. *associativity, commutativity, and binary classifier congruence for μ^*_D under R^*_D;*
3. *strict-support classifier transport and product-support exactness for N^*_D;*
4. *empty-unit uniqueness for the external endpoint e^*_D;*
5. *two-sided cancellation over the empty-unit cancellative commutative monoid package;*
6. *empty-product reflection through Definition 45.385.*

Thus the boundary theorem is a concrete BHist *tuple law for later Lean formalization rather than abstract carrier/classifier transport.*

Proof. Start with Definition 45.437. It fixes the five objects C^*_D, R^*_D, μ^*_D, e^*_D, and N^*_D and identifies them with the external-unit denominator envelope used at the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ boundary.

The carrier rows, the unit row, associativity, binary classifier congruence, restriction to the carried denominator fragment, mixed-endpoint separation, and empty-unit uniqueness are supplied by Definition 45.383. The commutative row is the commutative part already packaged into the boundary theorem from the same envelope data.

The strict-support rows are exactly Definition 45.426: its first clause transports N^*_D across R^*_D-classified endpoints, and its second clause computes strict support of $\mu^*_D(h, k)$ from the two input supports.

The cancellation row is the denominator endpoint cancellation field of Definition 45.431, read through the same empty-unit carrier, classifier, append operation, and endpoint. The empty-product row is precisely Definition 45.385.

These cited rows exhaust the multiplicative denominator obligations listed for the concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ certificate, so the certificate is NameCert-ready as a single concrete tuple over BHist. □

Per-object template: traditional target $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ multiplicative denominator certificate; BEDC source RatDenomUnitCarrier, RatDenomUnitClassifier, RatHistoryCarrier, Cont, and append; carrier C^*_D; classifier R^*_D; stability obligations carrier closure, unit inhabitation, associativity, commutativity, binary classifier congruence, strict-support classifier transport, product-support exactness, empty-unit uniqueness, two-sided cancellation, and empty-product reflection; ledger external empty-unit endpoint plus denominator continuation provenance; core theorem Definition 45.439; exactness predicate strict support and empty-product reflection; standard bridge ordinary positive-denominator multiplication with adjoined unit; status ProofTarget.

Definition 45.440 (Concrete Rat denominator FieldUp multiplicative exactness instance)**.** *The concrete* BHist *denominator-side multiplicative exactness instance for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *is the tuple*

$$\mathcal{M}^*_D := (C^*_D, R^*_D, \mu^*_D, e^*_D, N^*_D)$$

where C^*_D and R^*_D are the carrier and classifier of Definition 45.370,

$$\mu^*_D(h,k) := \mathsf{append}(h,k), \qquad e^*_D := \mathsf{e}, \qquad N^*_D(h) := \mathsf{RatHistoryCarrier}(h).$$

Theorem 45.441 (Rat denominator FieldUp envelope empty-context exactness)**.** *For the concrete denominator-side tuple $(C^*_D, R^*_D, \mu^*_D, e^*_D, N^*_D)$ of Definition 45.440, let $p, q, p', q', h, k : \mathsf{BHist}$. If $p\mathsf{hsamee}$, $q\mathsf{hsamee}$, $p'\mathsf{hsamee}$, $q'\mathsf{hsamee}$, $C^*_D(h)$, and $C^*_D(k)$, then the external-unit envelope classifier and strict support are exact under empty external endpoint contexts:*

$$R^*_D(\mathsf{append}(p, \mathsf{append}(h,q)), \mathsf{append}(p', \mathsf{append}(k,q'))) \iff R^*_D(h,k),$$

$$N^*_D(\mathsf{append}(p, \mathsf{append}(h,q))) \iff N^*_D(h),$$

and

$$N^*_D(\mathsf{append}(p', \mathsf{append}(k,q'))) \iff N^*_D(k).$$

Proof. The append left and right unit laws first identify $\mathsf{append}(p, \mathsf{append}(h,q))$ with h and $\mathsf{append}(p', \mathsf{append}(k,q'))$ with k, using the four hypotheses that the external contexts are history-same to e.

By Definition 45.371, those endpoint comparisons, together with the carrier hypotheses $C^*_D(h)$ and $C^*_D(k)$, classify each contextualized endpoint with its original endpoint inside R^*_D. The binary classifier congruence field in Definition 45.424 then transports the classifier comparison in both directions, giving the displayed classifier exactness.

For strict support, apply the first clause of Definition 45.426 to the two endpoint classifications just obtained. Since N^*_D is RatHistoryCarrier in the displayed tuple, this transports strict denominator support from each contextualized endpoint back to the original endpoint and conversely. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldRatDenominatorUnitEnvelopeClassifier empty context iff`

Theorem 45.442 (Rat denominator envelope empty-context history-sameness exactness)**.** *For histories $h, k : \mathsf{BHist}$, if $C^*_D(h)$ and $C^*_D(k)$, then the mixed empty endpoint contexts classify exactly the underlying history-sameness:*

$$R^*_D(\mathsf{append}(\mathsf{e}, h), \mathsf{append}(k, \mathsf{e})) \iff h\mathsf{hsame}k.$$

Proof. Split the two carrier hypotheses into the genuine Rat denominator branch and the empty endpoint branch. In the carried branch, the displayed classifier is transported across the left and right append-unit laws, then read back as the Rat denominator classifier comparison. In the empty branch, append endpoint readback identifies the relevant endpoint with e; mixed carried-empty

branches contradict the strict nonempty Rat denominator carrier, while the double-empty branch composes the two empty endpoint equalities into $h\mathsf{hsame}k$. The reverse implication uses the same branch split: carried endpoints repack the Rat denominator classifier after append-unit transport, and empty endpoint branches either produce the empty classifier row or are ruled out by nonempty Rat denominator support. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldRatDenominatorUnitEnvelopeClassifier empty context hsame iff`

Theorem 45.443 (Rat denominator FieldUp multiplicative exactness boundary)**.** *The concrete instance Definition 45.440 satisfies the Rat denominator FieldUp multiplicative certificate boundary. In addition, for all $h, k, t : \mathsf{BHist}$, if $C^*_D(h)$, $C^*_D(k)$, and $N^*_D(t)$, then*

$$R^*_D(\mu^*_D(h,t), \mu^*_D(k,t)) \Longleftrightarrow R^*_D(h,k),$$

and

$$R^*_D(\mu^*_D(t,h), \mu^*_D(t,k)) \Longleftrightarrow R^*_D(h,k).$$

Proof. The displayed tuple is the same concrete carrier, classifier, multiplication, unit, and strict support used by Definition 45.437. That theorem supplies the packaged carrier, classifier, monoid, commutativity, empty-unit uniqueness, and carried-endpoint clauses for the denominator-side FieldUp boundary.

The strict-support component is the predicate $N^*_D(h) := \mathsf{RatHistoryCarrier}(h)$. The transport and product-support parts of the boundary are therefore the corresponding clauses of Definition 45.426.

It remains to identify strict common-factor cancellation at the same concrete classifier. Since $N^*_D(t)$ is by definition $\mathsf{RatHistoryCarrier}(t)$, Definition 45.370 places t in C^*_D through the carried alternative.

Under $C^*_D(h)$, $C^*_D(k)$, and this derived carrier witness for t, the right and left cancellation equivalences are exactly the two displayed clauses of Definition 45.429. Hence the concrete tuple carries both the certificate boundary and the strict factor-cancellation exactness required for the denominator side of $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$. □

Definition 45.444 (Concrete Rat denominator FieldUp contextual certificate instance)**.** *The concrete contextual denominator certificate instance for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *is the* BHist *tuple*

$$\mathcal{C}^u_D := (C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D) = (\mathsf{RatDenomUnitCarrier}, \mathsf{RatDenomUnitClassifier}, \mathsf{append}, \mathsf{e}, \mathsf{RatHistoryCarrier}).$$

Equivalently, $C^u_D = \mathsf{RatDenomUnitCarrier}$, $R^u_D = \mathsf{RatDenomUnitClassifier}$, $\mu^u_D(h,k) = \mathsf{append}(h,k)$, $e^u_D = \mathsf{e}$, and $N^u_D(h) = \mathsf{RatHistoryCarrier}(h)$. The displayed certificate interface also contains empty external context witnesses $p, q, p', q' : \mathsf{BHist}$ with $p\mathsf{hsamee}$, $q\mathsf{hsamee}$, $p'\mathsf{hsamee}$, and $q'\mathsf{hsamee}$, so the contextual denominator rows are read as fields of this concrete tuple rather than as detached endpoint facts.

Theorem 45.445 (Rat denominator FieldUp contextual certificate obligation coverage)**.** *For the concrete tuple $\mathcal{C}^u_D$ of Definition 45.444, the contextual denominator rows for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *are covered by the displayed* BHist *certificate data:*

1. *empty external contexts preserve and reflect R^u_D;*
2. *right multiplication by a fixed carried denominator factor is classifier-exact;*

3. left multiplication by a fixed carried denominator factor is classifier-exact;

4. two-sided contextual multiplication is classifier-exact inside empty external contexts;

5. strict support of the contextual product endpoint is exact.

Thus $\mathcal{C}_D^u$ is a concrete contextual denominator certificate target for the FieldUp parent chapter.

Proof. The tuple in Definition 45.444 is the same concrete carrier, classifier, append operation, empty endpoint, and strict-support predicate used by Definition 45.438. That theorem supplies the empty-context classifier preservation and reflection rows together with the left and right fixed-factor multiplication exactness rows.

The two-sided contextual multiplication row is precisely Definition 45.436. It reads the four empty external context witnesses as part of the same BHist denominator interface and identifies the contextual fixed multiplication comparison with the uncontextualized classifier comparison.

The support row is Definition 45.406. It computes strict denominator support after empty external histories surround the product endpoint, using the disjunction of the two input strict-support facts.

Finally, Definition 45.439 packages the ordinary multiplicative denominator obligations for the same append-based endpoint system. Combining that package with the contextual boundary and strict contextual product-support theorem gives a single contextual certificate target for the FieldUp denominator rows. □

Per-object template: traditional target contextual denominator certificate for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, RatDenomUnitCarrier, RatDenomUnitClassifier, RatHistoryCarrier, Cont, and append; carrier C_D^u; classifier R_D^u; stability obligations empty-context classifier exactness, left and right fixed-factor multiplication exactness, two-sided contextual multiplication classifier exactness, and contextual strict product support exactness; ledger four empty external context witnesses and one carried denominator factor; core theorem Definition 45.445; exactness predicate classifier equivalence and strict support through empty external denominator contexts; standard bridge ordinary denominator multiplication with adjoined empty unit and contextual endpoint witnesses; status ProofTarget.

Theorem 45.446 (Rat denominator external-unit envelope contextual multiplication exactness)**.** *For the concrete tuple $(C_D^*, R_D^*, \mu_D^*, e_D^*, N_D^*)$ of Definition 45.370, let $p, q, p', q', h, k, t : \mathsf{BHist}$. If $p\mathsf{hsamee}$, $q\mathsf{hsamee}$, $p'\mathsf{hsamee}$, $q'\mathsf{hsamee}$, $C_D^*(h)$, $C_D^*(k)$, and $N_D^*(t)$, then fixed denominator multiplication is classifier-exact inside empty external contexts on both sides:*

$$R_D^*(\mathsf{append}(p, \mathsf{append}(\mu_D^*(h,t), q)), \mathsf{append}(p', \mathsf{append}(\mu_D^*(k,t), q'))) \Longleftrightarrow R_D^*(h,k),$$

and

$$R_D^*(\mathsf{append}(p, \mathsf{append}(\mu_D^*(t,h), q)), \mathsf{append}(p', \mathsf{append}(\mu_D^*(t,k), q'))) \Longleftrightarrow R_D^*(h,k).$$

Proof. Use Definition 45.371 to identify the envelope carrier C_D^* with RatDenomUnitCarrier and the envelope classifier R_D^* with RatDenomUnitClassifier. Thus the hypotheses $C_D^*(h)$ and $C_D^*(k)$ are the empty-unit carrier hypotheses required for h and k.

The strict support hypothesis $N_D^*(t)$ is $\mathsf{RatHistoryCarrier}(t)$ on the carried endpoint branch. This gives $\mathsf{RatDenomUnitCarrier}(t)$ by the carried alternative of the empty-unit carrier, so t is also an admissible denominator factor for the empty-unit contextual theorem.

Apply Definition 45.436 with the four empty context witnesses and the three empty-unit carrier witnesses just obtained. Its right fixed-factor equivalence gives the first displayed comparison after rewriting R^u_D as R^*_D and μ^u_D as μ^*_D through the normal form and the common append operation.

The same application supplies the left fixed-factor equivalence. Translating the classifier and multiplication symbols back along Definition 45.371 gives the second displayed comparison for the external-unit envelope tuple. □

1. Traditional target: contextual multiplication classifier exactness for the external-unit envelope denominator side of $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$.
2. BEDC source: BHist, RatDenomUnitCarrier, RatDenomUnitClassifier, RatHistoryCarrier, Cont, and append.
3. Carrier: C^*_D.
4. Classifier: R^*_D.
5. Stability obligations: empty external contexts preserve and reflect the envelope classifier, and fixed denominator multiplication preserves and reflects the envelope classifier on both sides.
6. Ledger: four empty external context witnesses, two envelope carrier witnesses, and one strict carried denominator factor.
7. Core theorem: Definition 45.446.
8. Exactness predicate: classifier equivalence before and after fixed denominator multiplication inside empty external contexts.
9. Standard bridge: empty-unit contextual multiplication exactness transported through the external-unit envelope normal form.
10. Status: ProofTarget.

Theorem 45.447 (Rat denominator FieldUp multiplicative certificate record)**.** *The tuple*

$$\mathcal{M}^*_D = (C^*_D, R^*_D, \mu^*_D, e^*_D, N^*_D)$$

of Definition 45.440 is the concrete BHist *denominator-side multiplicative certificate record for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$*. It simultaneously supplies carrier, unit, associativity, commutativity, congruence, strict-support, empty-unit, cancellation, and empty-product coverage from Definition 45.439; strict common-factor right and left cancellation exactness from Definition 45.443; and the concrete denominator certificate boundary from Definition 45.437.*

Proof. Definition 45.437 fixes the denominator-side boundary on the five displayed objects C^*_D, R^*_D, μ^*_D, e^*_D, and N^*_D. These are the same carrier, classifier, operation, unit, and strict-support predicate named by Definition 45.440.

Definition 45.439 then enumerates the certificate rows carried by that tuple: carrier and unit coverage, associativity, commutativity, congruence, strict-support transport and product exactness, empty-unit uniqueness, cancellation coverage, and empty-product reflection.

Finally, Definition 45.443 adds the strict common-factor right and left cancellation equivalences on the same classifier and the same multiplication. Since all three cited results are aligned on the identical concrete tuple $(C^*_D, R^*_D, \mu^*_D, e^*_D, N^*_D)$, their rows assemble as the single BHist denominator-side multiplicative certificate record for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$. □

Theorem 45.448 (RatUp FieldUp denominator certificate assembly)**.** *Let the denominator-side data for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *be the concrete external-unit envelope tuple* $(C^*_D, R^*_D, \mu^*_D, e^*_D, N^*_D)$*, with* $\mu^*_D(h,k) := \mathsf{append}(h,k)$*,* $e^*_D := \mathsf{e}$*, and* $N^*_D(h) := \mathsf{RatHistoryCarrier}(h)$ *on the strict carried endpoint branch. Then this tuple is the denominator subcertificate consumed by* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$*: the envelope classifier is exact, the denominator operation carries the commutative monoid laws, strict support transports across* R^*_D*, strict support is product-exact for* μ^*_D*, strict common factors give exact left and right cancellation, fixed multiplication is classifier-exact inside empty external contexts, the external unit is unique, and* e^*_D *is not a carried denominator unit.*

Proof. The exact envelope boundary is Definition 45.430. It supplies the concrete carrier, classifier, operation, unit, strict support, commutative monoid laws, support transport, support product law, unique external endpoint, and strict-factor cancellation clauses for $(C^*_D, R^*_D, \mu^*_D, e^*_D, N^*_D)$.

The remaining contextual multiplication field is Definition 45.446. It states that fixed denominator multiplication preserves and reflects the external-unit envelope classifier after empty external histories are attached on both sides, using the same BHist append operation and the strict carried denominator factor predicate.

Finally, Definition 45.437 collects the denominator-side multiplicative certificate boundary for the displayed tuple. Combining that boundary with the contextual multiplication exactness clause and the exact envelope theorem gives the advertised $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ denominator subcertificate. The statement that no carried denominator unit remains is the strict-support reading of $e^*_D = \mathsf{e}$ together with the carried-endpoint separation already included in the exact envelope boundary. □

Definition 45.449 (Concrete RatUp FieldUp denominator certificate row)**.** *The concrete denominator certificate row for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *is*

$$(C^{\dagger}_D, R^{\dagger}_D, \mu^{\dagger}_D, e^{\dagger}_D, N^{\dagger}_D),$$

where

$$C^{\dagger}_D := \mathsf{RatDenomUnitCarrier}, \qquad R^{\dagger}_D := \mathsf{RatDenomUnitClassifier},$$
$$\mu^{\dagger}_D(h,k) := \mathsf{append}(h,k), \qquad e^{\dagger}_D := \mathsf{e}, \qquad N^{\dagger}_D(h) := \mathsf{RatHistoryCarrier}(h).$$

Its ledger is the external empty-unit endpoint plus denominator continuation provenance.

Theorem 45.450 (RatUp FieldUp denominator certificate row laws)**.** *The row Definition 45.449 covers the* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *denominator obligations: envelope classifier exactness, carrier closure and unit inhabitation, associativity, commutativity, binary classifier congruence, strict-support transport and product exactness, left and right strict-factor cancellation, contextual fixed-factor classifier exactness, unique external unit, and absence of a carried denominator unit at* $e^{\dagger}_D$*.*

Proof. The row uses the same concrete denominator carrier and classifier as the unit envelope. The envelope classifier exactness is Definition 45.372, while Definition 45.430 packages carrier closure, the empty endpoint, endpoint separation, strict-support transport, product exactness, and the external unit uniqueness law.

The multiplication field is the native BHist append operation. Definition 45.437 supplies the associative and commutative certificate clauses, binary classifier congruence, and the strict-factor cancellation laws for this operation on the same denominator envelope.

The contextual fixed-factor classifier exactness is Definition 45.438. The full denominator obligation list is then collected by Definition 45.439, and Definition 45.448 identifies that collected package with the denominator subcertificate consumed by $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$.

The FieldUp denominator schema is instantiated by this concrete BHist row, so BHist-anchored proofs can target this row rather than abstract carrier and classifier parameters. □

Theorem 45.451 (RatUp FieldUp denominator obligation map)**.** *For histories $h, k : \mathsf{BHist}$, take the concrete denominator data*

$$C^*_D(h) := (\mathsf{RatHistoryCarrier}(h) \vee h\mathsf{hsamee}), \qquad R^*_D(h,k) := (\mathsf{RatHistoryCarrier}(h) \wedge \mathsf{RatHistoryCarrier}(k) \wedge \mathsf{RatHisto}$$

$$\mu^*_D(h,k) := \mathsf{append}(h,k), \qquad e^*_D := \mathsf{e}, \qquad N^*_D(h) := \mathsf{RatHistoryCarrier}(h).$$

These data discharge the denominator rows of Definition 45.337 for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$*:*

1. *envelope classifier exactness;*
2. *carried-fragment restriction;*
3. *commutative monoid laws for μ^*_D with unit e^*_D;*
4. *strict-support transport along R^*_D;*
5. *strict-support product exactness for μ^*_D;*
6. *strict common-factor left and right cancellation;*
7. *fixed multiplication classifier exactness in empty external contexts;*
8. *external-unit uniqueness;*
9. *exclusion of e^*_D from strict carried support.*

Proof. The first row group is supplied by Definition 45.430. It is stated for the same envelope carrier, classifier, append multiplication, empty external unit, and strict carried-support predicate displayed above, so its exactness, carried-fragment, commutative monoid, support, cancellation, and external-unit clauses read directly as rows for this map.

The contextual row is supplied by Definition 45.438. Its empty-context fixed-multiplication clauses use the same append operation and the same empty endpoint, and Definition 45.439 enumerates the ordinary multiplicative rows on the identical denominator tuple.

Finally, Definition 45.448 identifies these rows as the denominator subcertificate consumed by $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$. Thus the displayed row map is not a detached list of facts: it is the named denominator interface through which the concrete external-unit envelope enters the FieldUp certificate obligations. □

Traditional target: assembled denominator subcertificate for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; **BEDC source**: BHist, RatHistoryCarrier, RatHistoryClassifier, RatDenomUnitCarrier, RatDenomUnitClassifier, Cont, append, and e; **carrier**: C^*_D; **classifier**: R^*_D; **multiplication**: μ^*_D; **unit**: e^*_D; **strict support**: N^*_D; **ledger**: external-unit endpoint bit plus denominator continuation witness; **core theorem**: Definition 45.448; **exactness predicate**: exact envelope classifier, contextual fixed multiplication exactness, strict-support transport and product exactness, strict-factor cancellation, unique external unit, and absence of a carried denominator unit; **status**: ProofTarget.

Theorem 45.452 (RatUp FieldUp denominator row exhaustion)**.** *Let*

$$\mathcal{M}^*_D = (C^*_D, R^*_D, \mu^*_D, e^*_D, N^*_D)$$

be the concrete multiplicative tuple of Definition 45.440, and let

$$\mathcal{C}^u_D = (C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$$

be the concrete contextual tuple of Definition 45.444. Every denominator-side $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *row used in this parent chapter is supplied by either the multiplicative certificate record for* $\mathcal{M}^*_D$ *or the contextual certificate coverage for* $\mathcal{C}^u_D$*, with their shared tuple alignment governed by Definition 45.448. Thus the full denominator certificate is a concrete* BHist *target: the carrier and classifier are the predicates* $\mathsf{RatDenomUnitCarrier}$ *and* $\mathsf{RatDenomUnitClassifier}$*, multiplication is* append*, strict support is* $\mathsf{RatHistoryCarrier}$*, empty external contexts are the only context witnesses, and no carried denominator unit is introduced.*

Proof. The multiplicative source is Definition 45.447. It supplies the carrier, unit, associativity, commutativity, congruence, strict-support, cancellation, and empty-product rows for $\mathcal{M}^*_D$.

The contextual source is Definition 45.445. It supplies the empty-context rows and fixed-factor contextual rows for $\mathcal{C}^u_D$, with contextual support read through the same carried denominator endpoint predicate.

Finally, Definition 45.448 identifies the common BHist carrier, classifier, append multiplication, empty endpoint, and strict-support predicate that the two sources share. The same assembly also records that the empty endpoint is external to the carried denominator branch, so the combined denominator-side certificate has no carried denominator unit. □

Theorem 45.453 (Rat denominator bilateral strict factor cancellation)**.** *For the concrete tuple* $(C^*_D, R^*_D, \mu^*_D, e^*_D, N^*_D)$ *of Definition 45.440, let* $h, k, l, r : \mathsf{BHist}$*. If* $C^*_D(h)$*,* $C^*_D(k)$*,* $C^*_D(l)$*,* $C^*_D(r)$*,* $N^*_D(l)$*, and* $N^*_D(r)$*, then*

$$R^*_D(\mu^*_D(l, \mu^*_D(h, r)), \mu^*_D(l, \mu^*_D(k, r))) \iff R^*_D(h, k).$$

Proof. First build the products to which cancellation will be applied. The strict-support product closure and carrier closure supplied by Definition 45.437 place $\mu^*_D(l, h)$ and $\mu^*_D(l, k)$ in C^*_D, and keep the larger products with the strict factor r inside the same concrete carrier. The associativity and congruence fields of that boundary identify the displayed comparison with $R^*_D(\mu^*_D(\mu^*_D(l, h), r), \mu^*_D(\mu^*_D(l, k), r))$.

Apply Definition 45.429 with the strict common right factor r. Since $N^*_D(r)$ and the two left products are carried by the preceding closure step, this gives

$$R^*_D(\mu^*_D(\mu^*_D(l, h), r), \mu^*_D(\mu^*_D(l, k), r)) \iff R^*_D(\mu^*_D(l, h), \mu^*_D(l, k)).$$

Apply the same cancellation theorem with the strict common left factor l. The hypotheses $C^*_D(h)$, $C^*_D(k)$, $C^*_D(l)$, and $N^*_D(l)$ are exactly its input hypotheses for the left-cancellation clause, so

$$R^*_D(\mu^*_D(l, h), \mu^*_D(l, k)) \iff R^*_D(h, k).$$

Composing the two equivalences gives the bilateral strict-factor cancellation claim. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator bilateral strict factor cancellation`

Definition 45.454 (RatUp FieldUp denominator contextual action instance)**.** *The concrete denominator contextual action instance for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *is the tuple*

$$\mathcal{A}^u_D := (C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D, \Gamma)$$

where

$$C^u_D := \mathsf{RatDenomUnitCarrier}, \qquad R^u_D := \mathsf{RatDenomUnitClassifier},$$

$$\mu^u_D(h, k) := \mathsf{append}(h, k), \qquad e^u_D := \mathsf{e}, \qquad N^u_D(h) := \mathsf{RatHistoryCarrier}(h).$$

For carried contexts l, r : BHist and external endpoint contexts p, q : BHist, its bilateral carried action with external endpoints is

$$\Gamma_{p,q,l,r}(h) := \mathsf{append}(p, \mathsf{append}(B_{l,r}(h), q)),$$

where $B_{l,r}$ is the bilateral denominator multiplication context of Definition 45.417.

Lean4 (definition) `BEDC.Derived.FieldUp.RatDenomUnitContextualAction`

Theorem 45.455 (Rat denominator contextual action empty endpoint composition)**.** *For histories $h, l, r, l', r', p, q, p', q'$, if all four external endpoints p, q, p', q' are* hsame*-equal to* e*, then the iterated concrete action $\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))$ is* hsame*-equal to the single action with carried contexts* $\mathsf{append}(l', l)$ *and* $\mathsf{append}(r, r')$*.*

Proof. Case analysis on the four endpoint equalities reduces the statement to the associativity and empty-endpoint laws for append. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitContextualAction empty endpoint composition`

Theorem 45.456 (RatUp FieldUp denominator contextual action certificate)**.** *For histories h, k, l, r, p, q, p', q' :* BHist*, assume $C^u_D(h)$, $C^u_D(k)$, $C^u_D(l)$, $C^u_D(r)$, and* phsamee*,* qhsamee*,* p'hsamee*, and* q'hsamee*. Then the contextual action instance of Definition 45.454 satisfies the following classifier and strict-support laws:*

$$R^u_D(\Gamma_{p,q,l,r}(h), \Gamma_{p',q',l,r}(k)) \iff R^u_D(h, k),$$

$$N^u_D(\Gamma_{p,q,l,r}(h)) \iff N^u_D(l) \vee N^u_D(h) \vee N^u_D(r),$$

and

$$N^u_D(\Gamma_{p',q',l,r}(k)) \iff N^u_D(l) \vee N^u_D(k) \vee N^u_D(r).$$

Proof. First use closure for the carried bilateral product. From $C^u_D(l)$, $C^u_D(h)$, and $C^u_D(r)$, the denominator continuation monoid laws put $B_{l,r}(h)$ inside C^u_D; the same argument using k gives $C^u_D(B_{l,r}(k))$.

For classifier exactness, strip the empty external endpoint contexts with Definition 45.405. The endpoint equalities phsamee, qhsamee, p'hsamee, and q'hsamee reduce the displayed classifier comparison to $R^u_D(B_{l,r}(h), B_{l,r}(k))$.

Apply Definition 45.418 to the carried histories h, k, l, and r. This gives exactly $R^u_D(h, k)$, and the reverse direction follows by the same two equivalences in the opposite order.

For strict support at h, use Definition 45.348 to identify the support of $\Gamma_{p,q,l,r}(h)$ with the support of $B_{l,r}(h)$ under the empty external endpoint contexts. Then apply Definition 45.421 to obtain $N^u_D(l) \vee N^u_D(h) \vee N^u_D(r)$.

The strict-support statement for k is identical with k in place of h and p', q' in place of p, q. The same empty-context carrier equivalence strips the endpoints, and the same bilateral support exactness theorem supplies $N^u_D(l) \vee N^u_D(k) \vee N^u_D(r)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitContextualAction contextual action certificate`
↪ variant `BEDC.Derived.FieldUp.RatupFieldupDenominatorContextualAction certificate`

Theorem 45.457 (RatUp FieldUp denominator contextual action empty-context identity)**.** *For histories h, p, q :* BHist*, assume $C^u_D(h)$,* phsamee*, and* qhsamee*. Then the empty carried-context action with empty external endpoints is carried,*

$$C^u_D(\Gamma_{p,q,\mathsf{e},\mathsf{e}}(h)),$$

it is classified by the original history,

$$R^u_D(\Gamma_{p,q,\mathsf{e},\mathsf{e}}(h), h),$$

and it preserves strict support exactly:

$$N^u_D(\Gamma_{p,q,\mathsf{e},\mathsf{e}}(h)) \Longleftrightarrow N^u_D(h).$$

Proof. Unfold Definition 45.454. With both carried contexts equal to e, the bilateral denominator context is $B_{\mathsf{e},\mathsf{e}}(h)$. The append left and right unit laws reduce the carried spine to the original history, while the endpoint hypotheses $p\mathsf{hsamee}$ and $q\mathsf{hsamee}$ identify the external wrappers with empty endpoints.

Apply Definition 45.456 with $k = h$, $l = \mathsf{e}$, $r = \mathsf{e}$, $p' = \mathsf{e}$, and $q' = \mathsf{e}$. Its classifier component reduces the displayed comparison to $R^u_D(h, h)$, and the denominator classifier is reflexive on the carried input h. The same unfolding and unit laws give the carrier row for $\Gamma_{p,q,\mathsf{e},\mathsf{e}}(h)$.

For strict support, the certificate gives

$$N^u_D(\Gamma_{p,q,\mathsf{e},\mathsf{e}}(h)) \Longleftrightarrow N^u_D(\mathsf{e}) \vee N^u_D(h) \vee N^u_D(\mathsf{e}).$$

Unfold N^u_D as $\mathsf{RatHistoryCarrier}$. Any witness for either empty support disjunct contradicts Definition 37.18 together with reflexivity of hsame at e. Hence the two empty support disjuncts are absent, and the middle disjunct is exactly $N^u_D(h)$. □

Theorem 45.458 (RatUp FieldUp denominator empty-unit action rejects singleton carrier)**.** *For every history $h : \mathsf{BHist}$, if $C^u_D(h)$ and $N^u_D(h)$, then the empty-unit action cannot land in the singleton-empty carrier:*

$$A_{\mathsf{e}}(\Gamma_{\mathsf{e},\mathsf{e},\mathsf{e},\mathsf{e}}(h)) \to \bot.$$

Proof. Apply Definition 45.457 with both endpoint witnesses reflexive at e. The strict-support row transports $N^u_D(h)$ to $N^u_D(\Gamma_{\mathsf{e},\mathsf{e},\mathsf{e},\mathsf{e}}(h))$.

Unfold N^u_D as $\mathsf{RatHistoryCarrier}$. A witness in $A_{\mathsf{e}}(\Gamma_{\mathsf{e},\mathsf{e},\mathsf{e},\mathsf{e}}(h))$ is exactly a singleton endpoint witness for the action output, so Definition 37.18 contradicts the transported Rat carrier witness. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitContextualAction empty unit singleton absurd`

Per-object template: traditional target identity element for the denominator contextual action; BEDC source BHist, $\mathsf{RatDenomUnitCarrier}$, $\mathsf{RatDenomUnitClassifier}$, $\mathsf{RatHistoryCarrier}$, append, e, and Γ; carrier C^u_D; classifier R^u_D; stability obligation identity action; ledger empty carried contexts plus empty external endpoint witnesses; core theorem this empty-context identity law; exactness predicate classifier identity and support preservation; standard bridge denominator multiplication identity context; status $\mathsf{ProofTarget}$.

Definition 45.459 (RatUp FieldUp denominator classified-context action)**.** *The classified-context denominator action for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *uses the fixed concrete data*

$$C^u_D := \mathsf{RatDenomUnitCarrier}, \qquad R^u_D := \mathsf{RatDenomUnitClassifier},$$

$$\mu^u_D(h, k) := \mathsf{append}(h, k), \qquad e^u_D := \mathsf{e}, \qquad N^u_D(h) := \mathsf{RatHistoryCarrier}(h).$$

For histories $h, k, l, l', r, r', p, q, p', q' : \mathsf{BHist}$ with classified input rows $R^u_D(h, k)$, $R^u_D(l, l')$, and $R^u_D(r, r')$, and with empty external endpoint contexts $p\mathsf{hsamee}$, $q\mathsf{hsamee}$, $p'\mathsf{hsamee}$, and $q'\mathsf{hsamee}$, its output pair is

$$(\Gamma_{p,q,l,r}(h), \Gamma_{p',q',l',r'}(k)).$$

Thus the left context, core endpoint, and right context are classified before the concrete bilateral denominator action is applied.

Theorem 45.460 (RatUp FieldUp denominator contextual action classifier congruence)**.** *For histories* $h, k, l, l', r, r', p, q, p', q' : \mathsf{BHist}$*, assume* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(l)$*,* $C^u_D(l')$*,* $C^u_D(r)$*, and* $C^u_D(r')$*. If* $R^u_D(h, k)$*,* $R^u_D(l, l')$*,* $R^u_D(r, r')$*, and* $p\mathsf{hsamee}$*,* $q\mathsf{hsamee}$*,* $p'\mathsf{hsamee}$*, and* $q'\mathsf{hsamee}$*, then the classified-context action of Definition 45.459 satisfies*

$$R^u_D(\Gamma_{p,q,l,r}(h), \Gamma_{p',q',l',r'}(k)).$$

Proof. First remove the empty external endpoints. By Definition 45.405, it is enough to classify $B_{l,r}(h)$ against $B_{l',r'}(k)$, because the four endpoint hypotheses identify the wrapped action outputs with the bilateral carried products.

Unfold $B_{l,r}$ and $B_{l',r'}$. The binary classifier congruence field in the concrete denominator certificate first combines $R^u_D(l, l')$ with $R^u_D(h, k)$, giving

$$R^u_D(\mathsf{append}(l, h), \mathsf{append}(l', k)).$$

The carrier closure rows of the same certificate place both intermediate products in C^u_D.

Apply binary classifier congruence a second time, now with the right-context input $R^u_D(r, r')$. This gives

$$R^u_D(\mathsf{append}(\mathsf{append}(l, h), r), \mathsf{append}(\mathsf{append}(l', k), r')).$$

Folding the bilateral-context notation turns this into $R^u_D(B_{l,r}(h), B_{l',r'}(k))$.

Finally use the reverse direction of Definition 45.405 with the four empty endpoint hypotheses. It wraps the bilateral comparison back into the two displayed Γ outputs, which is the required classifier row. □

Traditional target: denominator bilateral carried-context action for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ with empty external endpoints; **BEDC source**: BHist, RatHistoryCarrier, RatDenomUnitCarrier, RatDenomUnitClassifier, Cont, append, and e; **carrier**: C^u_D; **classifier**: R^u_D; **action**: $\Gamma_{p,q,l,r}$; **strict support**: N^u_D; **ledger**: carried left and right denominator contexts plus empty external endpoint contexts; **core theorem**: Definition 45.456 and Definition 45.460; **exactness predicate**: bilateral classifier exactness, classified left-core-right action congruence, and bilateral strict-support exactness after empty endpoint transport; **status**: ProofTarget.

Theorem 45.461 (RatUp FieldUp denominator contextual action unit-support exactness)**.** *For histories* $h, l, r, p, q : \mathsf{BHist}$*, assume* $C^u_D(h)$*,* $C^u_D(l)$*,* $C^u_D(r)$*,* $p\mathsf{hsamee}$*,* $q\mathsf{hsamee}$*,* $\neg N^u_D(l)$*, and* $\neg N^u_D(r)$*. Then the unit-context strict support of the contextual denominator action is exactly the support of the acted-on history:*

$$N^u_D(\Gamma_{p,q,l,r}(h)) \iff N^u_D(h).$$

Proof. Apply Definition 45.456 with the single acted-on row based at p, q. Its strict-support component gives $N^u_D(\Gamma_{p,q,l,r}(h))$ iff $N^u_D(l) \vee N^u_D(h) \vee N^u_D(r)$.

For the forward direction, suppose $N^u_D(\Gamma_{p,q,l,r}(h))$. The support row converts this into the three-way disjunction $N^u_D(l) \vee N^u_D(h) \vee N^u_D(r)$.

The left branch contradicts $\neg N^u_D(l)$, and the right branch contradicts $\neg N^u_D(r)$. The only remaining branch is $N^u_D(h)$.

For the reverse direction, suppose $N^u_D(h)$. Insert this evidence into the middle branch of $N^u_D(l) \vee N^u_D(h) \vee N^u_D(r)$, then use the same support row in the reverse direction to obtain $N^u_D(\Gamma_{p,q,l,r}(h))$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator contextual action unit support iff`

Per-object template: traditional target denominator contextual action for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ under unit carried contexts; BEDC source BHist, RatHistoryCarrier, RatDenomUnitCarrier, RatDenomUnitClassifier, Cont, append, and e; carrier C^u_D; classifier R^u_D; stability obligation unit-context strict-support exactness; ledger empty endpoint contexts plus carried left and right contexts; core theorem label Definition 45.461; exactness predicate support iff; standard bridge ordinary denominator multiplication with empty endpoint contexts; status ProofTarget.

Theorem 45.462 (RatUp FieldUp denominator contextual action total certificate)**.** *The concrete denominator interface for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *is covered by the following fixed* BHist *data:*

$$C^u_D := \mathsf{RatDenomUnitCarrier}, \qquad R^u_D := \mathsf{RatDenomUnitClassifier},$$

$$\mu^u_D(h,k) := \mathsf{append}(h,k), \qquad e^u_D := \mathsf{e}, \qquad N^u_D(h) := \mathsf{RatHistoryCarrier}(h),$$

together with the action $\Gamma_{p,q,l,r}$ *of Definition 45.454. This concrete interface supplies the total denominator action certificate through the following rows:*

1. *the external-unit denominator subcertificate rows of Definition 45.448;*
2. *the multiplicative record rows of Definition 45.447;*
3. *the contextual classifier exactness and strict-support rows of Definition 45.456;*
4. *the classified left-core-right contextual action congruence row of Definition 45.460.*

Thus the denominator side of $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *is represented by one concrete append-based action certificate on the displayed carrier, classifier, unit, strict-support predicate, and contextual action.*

Proof. First, the external-unit denominator subcertificate is exactly Definition 45.448. Its carrier, classifier, multiplication, unit, and support fields are the displayed RatDenomUnitCarrier, RatDenomUnitClassifier, append, e, and RatHistoryCarrier data.

Next, the multiplicative rows are supplied by Definition 45.447. That theorem records the same append operation and empty unit for the denominator-side FieldUp multiplication, so its monoid, congruence, strict-support, empty-unit, and cancellation rows attach to the same concrete interface.

Finally, the same-context contextual action rows are those of Definition 45.456. By Definition 45.454, the action is $\Gamma_{p,q,l,r}$ on the displayed carrier and classifier, and its strict-support readback is computed by the same predicate N^u_D.

The classified-context congruence row is Definition 45.460. It uses the same Γ action but allows the left context, core endpoint, and right context to vary along R^u_D before the output classifier is formed.

The four cited results are all stated over the concrete BHist carrier, classifier, append operation, empty endpoint, support predicate, and action data displayed in the theorem. Therefore the certificate contains no remaining abstract operator or parameter-transport schema. □

Definition 45.463 (RatUp FieldUp composed denominator contextual action instance)**.** *The composed concrete denominator contextual action instance for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *is the tuple*

$$\mathcal{A}^u_{D,2} := (C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D, \Gamma^{(2)})$$

on the same concrete data

$$C^u_D := \mathsf{RatDenomUnitCarrier}, \qquad R^u_D := \mathsf{RatDenomUnitClassifier},$$

$$\mu^u_D(h,k) := \mathsf{append}(h,k), \qquad e^u_D := \mathsf{e}, \qquad N^u_D(h) := \mathsf{RatHistoryCarrier}(h).$$

For carried contexts $l_1, r_1, l_2, r_2 : \mathsf{BHist}$ *and external endpoint contexts* $p_1, q_1, p_2, q_2 : \mathsf{BHist}$*, its two-layer carried action is*

$$\Gamma^{(2)}_{p_2,q_2,l_2,r_2;p_1,q_1,l_1,r_1}(h) := \Gamma_{p_2,q_2,l_2,r_2}(\Gamma_{p_1,q_1,l_1,r_1}(h)).$$

Theorem 45.464 (RatUp FieldUp denominator contextual action composition)**.** *For histories* $h, k, l_1, r_1, l_2, r_2, p_1, q_1, p_2, q_2, p'_1, q'_1, p'_2, q'_2 : \mathsf{BHist}$*, assume* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(l_1)$*,* $C^u_D(r_1)$*,* $C^u_D(l_2)$*,* $C^u_D(r_2)$*, and assume* $p_1\mathsf{hsamee}$*,* $q_1\mathsf{hsamee}$*,* $p_2\mathsf{hsamee}$*,* $q_2\mathsf{hsamee}$*,* $p'_1\mathsf{hsamee}$*,* $q'_1\mathsf{hsamee}$*,* $p'_2\mathsf{hsamee}$*, and* $q'_2\mathsf{hsamee}$*. Then the composed contextual action instance of Definition 45.463 satisfies the following classifier and strict-support laws:*

$$R^u_D(\Gamma^{(2)}_{p_2,q_2,l_2,r_2;p_1,q_1,l_1,r_1}(h), \Gamma^{(2)}_{p'_2,q'_2,l_2,r_2;p'_1,q'_1,l_1,r_1}(k)) \Longleftrightarrow R^u_D(h,k),$$

$$N^u_D(\Gamma^{(2)}_{p_2,q_2,l_2,r_2;p_1,q_1,l_1,r_1}(h)) \Longleftrightarrow N^u_D(l_2) \vee N^u_D(l_1) \vee N^u_D(h) \vee N^u_D(r_1) \vee N^u_D(r_2),$$

and

$$N^u_D(\Gamma^{(2)}_{p'_2,q'_2,l_2,r_2;p'_1,q'_1,l_1,r_1}(k)) \Longleftrightarrow N^u_D(l_2) \vee N^u_D(l_1) \vee N^u_D(k) \vee N^u_D(r_1) \vee N^u_D(r_2).$$

Proof. First build the carrier facts needed for the second action layer. Carrier closure for the bilateral denominator multiplication, together with empty external endpoint carrier exactness, sends $C^u_D(h)$, $C^u_D(l_1)$, and $C^u_D(r_1)$ to $C^u_D(\Gamma_{p_1,q_1,l_1,r_1}(h))$. The same argument sends $C^u_D(k)$, $C^u_D(l_1)$, and $C^u_D(r_1)$ to $C^u_D(\Gamma_{p'_1,q'_1,l_1,r_1}(k))$.

For classifier exactness, apply Definition 45.456 to the outer layer with carried contexts l_2, r_2 and the two inner-action endpoints. The empty outer endpoint witnesses reduce the classifier comparison to the classifier comparison of the two inner actions.

Apply Definition 45.456 again to the inner layer with carried contexts l_1, r_1. The empty inner endpoint witnesses identify that inner classifier comparison with $R^u_D(h,k)$, giving the displayed classifier equivalence in both directions.

For strict support at h, the outer action certificate gives $N^u_D(l_2) \vee N^u_D(\Gamma_{p_1,q_1,l_1,r_1}(h)) \vee N^u_D(r_2)$. Applying the inner action certificate rewrites the middle term as $N^u_D(l_1) \vee N^u_D(h) \vee N^u_D(r_1)$.

Reassociate the constructive disjunction by the ordinary introduction and case-analysis rules for $\vee$. This yields exactly $N^u_D(l_2) \vee N^u_D(l_1) \vee N^u_D(h) \vee N^u_D(r_1) \vee N^u_D(r_2)$.

The strict-support statement for k is identical with k in place of h and the primed external endpoint contexts in both layers. The outer certificate, the inner certificate, and the same reassociation of $\vee$ give $N^u_D(l_2) \vee N^u_D(l_1) \vee N^u_D(k) \vee N^u_D(r_1) \vee N^u_D(r_2)$. □

Per-object template: traditional target composed denominator action certificate for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, RatHistoryCarrier, RatDenomUnitCarrier, RatDenomUnitClassifier, Cont, append, and e; carrier C^u_D; classifier R^u_D; action $\Gamma^{(2)}_{p_2,q_2,l_2,r_2;p_1,q_1,l_1,r_1}$; strict support N^u_D; ledger two carried left denominator contexts, two carried right denominator contexts, and two empty external endpoint layers; core theorem Definition 45.464; exactness predicate composed classifier exactness and five-term strict-support readback; standard bridge iterated denominator multiplication with empty external endpoints; status ProofTarget.

Per-object template: traditional target total denominator action certificate for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, RatHistoryCarrier, RatDenomUnitCarrier, RatDenomUnitClassifier, Cont, append, and e; carrier C^u_D; classifier R^u_D; stability obligations multiplicative certificate rows plus contextual classifier, classified left-core-right congruence, and strict-support rows; ledger external endpoint bit

plus carried left and right denominator contexts; core theorem Definition 45.462; exactness predicate denominator classifier exactness, classified contextual action congruence, and strict-support readback; standard bridge ordinary denominator multiplication with adjoined empty endpoint; status ProofTarget.

Theorem 45.465 (RatUp FieldUp denominator contextual action composition closure)**.** *For histories $h, l, r, l', r', p, q, p', q' : \mathsf{BHist}$, assume $C^u_D(h)$, $C^u_D(l)$, $C^u_D(r)$, $C^u_D(l')$, and $C^u_D(r')$, and assume $p\mathsf{hsamee}$, $q\mathsf{hsamee}$, $p'\mathsf{hsamee}$, and $q'\mathsf{hsamee}$. Then the composite concrete denominator contextual action is carried:*

$$C^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))).$$

It is classified by the single normalized action with combined carried contexts:

$$R^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h)), \Gamma_{p',q',\mu^u_D(l',l),\mu^u_D(r,r')}(h)).$$

Its strict-support readback is exactly

$$N^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))) \Longleftrightarrow N^u_D(l') \vee N^u_D(l) \vee N^u_D(h) \vee N^u_D(r) \vee N^u_D(r').$$

Proof. Unfold the action of Definition 45.454. The inner term is $\mathsf{append}(p, \mathsf{append}(B_{l,r}(h), q))$, and the outer action is obtained by placing $B_{l',r'}$ around that term and then adjoining the external endpoints p' and q'.

Carrier closure follows from the denominator continuation monoid laws for C^u_D. The hypotheses on l, h, and r put $B_{l,r}(h)$ in the carrier, and the empty endpoint hypotheses strip the external endpoints of the inner action. Applying the same closure step to l', the carried inner action, and r' puts the composite action in C^u_D.

For the classifier statement, first remove the empty external endpoints with Definition 45.405. The comparison reduces to the carried products $B_{l',r'}(B_{l,r}(h))$ and $B_{\mu^u_D(l',l),\mu^u_D(r,r')}(h)$.

Unfold $B_{l,r}$ and use the denominator multiplicative certificate rows of Definition 45.447 to reassociate the append products. The left carried contexts combine as $\mu^u_D(l', l)$, and the right carried contexts combine as $\mu^u_D(r, r')$.

After this reassociation, apply Definition 45.418 to identify the nested carried action with the normalized single action inside R^u_D.

For strict support, apply Definition 45.456 to the outer action. Its support is $N^u_D(l') \vee N^u_D(\Gamma_{p,q,l,r}(h)) \vee N^u_D(r')$.

Apply Definition 45.456 again to the inner action, or equivalently unfold $B_{l,r}$ and use Definition 45.421. This replaces the middle term by $N^u_D(l) \vee N^u_D(h) \vee N^u_D(r)$. Reassociate the constructive disjunction to obtain the displayed five-term support readback. □

↪ variant BEDC.Derived.FieldUp.field rat denominator contextual action composition support laws

Theorem 45.466 (Rat denominator envelope bilateral context cancellation)**.** *For the concrete tuple $(C^*_D, R^*_D, \mu^*_D, e^*_D, N^*_D)$ of Definition 45.440, let $h, k, l, r, p, q, p', q' : \mathsf{BHist}$. If $C^*_D(h)$, $C^*_D(k)$, $C^*_D(l)$, $C^*_D(r)$, $N^*_D(l)$, $N^*_D(r)$, $p\mathsf{hsamee}$, $q\mathsf{hsamee}$, $p'\mathsf{hsamee}$, and $q'\mathsf{hsamee}$, then*

$$R^*_D(\mathsf{append}(p, \mathsf{append}(\mu^*_D(l, \mu^*_D(h, r)), q)), \mathsf{append}(p', \mathsf{append}(\mu^*_D(l, \mu^*_D(k, r)), q'))) \Longleftrightarrow R^*_D(h, k).$$

Proof. First build the two bilateral products inside the concrete carrier. The multiplicative certificate boundary of Definition 45.437 uses $C^*_D(l)$, $C^*_D(h)$, $C^*_D(k)$, $C^*_D(r)$, $N^*_D(l)$, and $N^*_D(r)$ to place $\mu^*_D(l, \mu^*_D(h, r))$ and $\mu^*_D(l, \mu^*_D(k, r))$ in C^*_D.

Next strip the external endpoint contexts. Apply Definition 45.441 to these two carried products together with $p\mathsf{hsamee}$, $q\mathsf{hsamee}$, $p'\mathsf{hsamee}$, and $q'\mathsf{hsamee}$. The classifier component gives

$$R^*_D(\mathsf{append}(p, \mathsf{append}(\mu^*_D(l, \mu^*_D(h, r)), q)), \mathsf{append}(p', \mathsf{append}(\mu^*_D(l, \mu^*_D(k, r)), q'))) \Longleftrightarrow R^*_D(\mu^*_D(l, \mu^*_D(h, r)), \mu^*_D(l, \mu^*$$

Finally apply Definition 45.453 with strict factors l and r. It identifies the remaining uncontextualized bilateral comparison with $R^*_D(h, k)$, and composing the two equivalences proves the displayed statement. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator envelope bilateral context cancellation`

Per-object template: traditional target envelope bilateral context cancellation for the Rat denominator side of $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, $\mathsf{RatHistoryCarrier}$, $\mathsf{RatDenomUnitCarrier}$, $\mathsf{RatDenomUnitClassifier}$, append, and e; carrier C^*_D; classifier R^*_D; multiplication μ^*_D; unit e^*_D; strict support N^*_D; ledger empty external endpoint contexts plus strict carried left and right denominator factors; core theorem Definition 45.466; exactness predicate empty-envelope classifier transport followed by bilateral strict-factor cancellation; status $\mathsf{ProofTarget}$.

Theorem 45.467 (RatUp FieldUp denominator contextual action composition)**.** *For histories* $h, k, l, r, l', r', p, q, p', q', s, t, s', t' : \mathsf{BHist}$*, assume* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(l)$*,* $C^u_D(r)$*,* $C^u_D(l')$*,* $C^u_D(r')$*, and*

$$p\mathsf{hsamee}, \quad q\mathsf{hsamee}, \quad p'\mathsf{hsamee}, \quad q'\mathsf{hsamee}, \quad s\mathsf{hsamee}, \quad t\mathsf{hsamee}, \quad s'\mathsf{hsamee}, \quad t'\mathsf{hsamee}.$$

Then the concrete action Γ *of Definition 45.454 is exact under two carried contextual applications:*

$$R^u_D(\Gamma_{p,q,l,r}(\Gamma_{s,t,l',r'}(h)), \Gamma_{p',q',l,r}(\Gamma_{s',t',l',r'}(k))) \Longleftrightarrow R^u_D(h, k).$$

Its strict-support readbacks are

$$N^u_D(\Gamma_{p,q,l,r}(\Gamma_{s,t,l',r'}(h))) \Longleftrightarrow N^u_D(l) \vee N^u_D(l') \vee N^u_D(h) \vee N^u_D(r') \vee N^u_D(r)$$

and

$$N^u_D(\Gamma_{p',q',l,r}(\Gamma_{s',t',l',r'}(k))) \Longleftrightarrow N^u_D(l) \vee N^u_D(l') \vee N^u_D(k) \vee N^u_D(r') \vee N^u_D(r).$$

Proof. Apply Definition 45.456 to the inner actions with carried contexts l', r' and external contexts s, t, s', t'. This gives the classifier equivalence between the inner endpoints and h, k, and it reads the inner supports as $N^u_D(l') \vee N^u_D(h) \vee N^u_D(r')$ and $N^u_D(l') \vee N^u_D(k) \vee N^u_D(r')$.

The carrier part used in the same action proof puts both inner endpoints back inside C^u_D: carried bilateral product closure handles $B_{l',r'}(h)$ and $B_{l',r'}(k)$, and empty external endpoint transport preserves the displayed carrier. These two carrier witnesses are the inputs needed for the outer action.

Apply Definition 45.456 again to the outer action with carried contexts l, r and external contexts p, q, p', q'. Its classifier row identifies the displayed nested classifier with the classifier of the two inner endpoints. Composing this equivalence with the inner classifier equivalence gives the stated comparison with $R^u_D(h, k)$.

For strict support, the outer action reads $\Gamma_{p,q,l,r}(\Gamma_{s,t,l',r'}(h))$ as $N^u_D(l) \vee N^u_D(\Gamma_{s,t,l',r'}(h)) \vee N^u_D(r)$. Substitute the inner support readback and reassociate the finite disjunction to obtain $N^u_D(l) \vee N^u_D(l') \vee N^u_D(h) \vee N^u_D(r') \vee N^u_D(r)$.

The second support statement is identical with k in place of h and s', t' in place of s, t. The same outer readback, inner readback, and reassociation give $N^u_D(l) \vee N^u_D(l') \vee N^u_D(k) \vee N^u_D(r') \vee N^u_D(r)$. □

Theorem 45.468 (RatUp FieldUp denominator normalized contextual action exactness)**.** *For histories* $h, k, l, r, l', r', p, q, p', q', s, t, s', t' : \mathsf{BHist}$*, assume* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(l)$*,* $C^u_D(r)$*,* $C^u_D(l')$*,* $C^u_D(r')$*, and*

$$p\mathsf{hsamee}, \quad q\mathsf{hsamee}, \quad p'\mathsf{hsamee}, \quad q'\mathsf{hsamee}, \quad s\mathsf{hsamee}, \quad t\mathsf{hsamee}, \quad s'\mathsf{hsamee}, \quad t'\mathsf{hsamee}.$$

Then the single normalized actions obtained from the combined carried contexts are exact for the denominator classifier:

$$R^u_D(\Gamma_{p,q,\mu^u_D(l,l'),\mu^u_D(r',r)}(h), \Gamma_{p',q',\mu^u_D(l,l'),\mu^u_D(r',r)}(k)) \Longleftrightarrow R^u_D(h,k).$$

The normalized strict-support readbacks are

$$N^u_D(\Gamma_{p,q,\mu^u_D(l,l'),\mu^u_D(r',r)}(h)) \Longleftrightarrow N^u_D(l) \vee N^u_D(l') \vee N^u_D(h) \vee N^u_D(r') \vee N^u_D(r)$$

and

$$N^u_D(\Gamma_{p',q',\mu^u_D(l,l'),\mu^u_D(r',r)}(k)) \Longleftrightarrow N^u_D(l) \vee N^u_D(l') \vee N^u_D(k) \vee N^u_D(r') \vee N^u_D(r).$$

Proof. Apply Definition 45.465 to the h endpoint with inner carried contexts l', r', outer carried contexts l, r, inner external endpoints s, t, and outer external endpoints p, q. The classifier row identifies the nested action $\Gamma_{p,q,l,r}(\Gamma_{s,t,l',r'}(h))$ with the normalized action $\Gamma_{p,q,\mu^u_D(l,l'),\mu^u_D(r',r)}(h)$.

Its support row reads the nested endpoint as the displayed five-term disjunction. Strict-support transport along the concrete classifier R^u_D then gives the same readback for the normalized h endpoint.

Apply the same closure theorem to the k endpoint with inner external endpoints s', t' and outer external endpoints p', q'. This gives the classifier comparison between $\Gamma_{p',q',l,r}(\Gamma_{s',t',l',r'}(k))$ and $\Gamma_{p',q',\mu^u_D(l,l'),\mu^u_D(r',r)}(k)$.

The corresponding support row, transported along R^u_D, gives the strict-support readback containing $N^u_D(k)$ in the middle position.

Now use Definition 45.467 on the two nested endpoints. It supplies the equivalence between their denominator classifier and $R^u_D(h,k)$. Transport this equivalence across the two closure comparisons by symmetry and transitivity for the concrete classifier R^u_D.

The two support statements are the strict-support readbacks already obtained from the endpoint closure applications, with the finite disjunctions reassociated to the displayed order. □

Theorem 45.469 (RatUp FieldUp denominator contextual action threefold normalization)**.** *For histories* $h, l_0, r_0, l_1, r_1, l_2, r_2 : \mathsf{BHist}$*, assume* $C^u_D(h)$*,* $C^u_D(l_0)$*,* $C^u_D(r_0)$*,* $C^u_D(l_1)$*,* $C^u_D(r_1)$*,* $C^u_D(l_2)$*, and* $C^u_D(r_2)$*. Let*

$$H_3 := \Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h))).$$

Then the threefold concrete denominator contextual action is carried:

$$C^u_D(H_3).$$

It is classified by the single normalized carried action

$$R^u_D\big(H_3, \Gamma_{\mathsf{e},\mathsf{e},\mu^u_D(l_2,\mu^u_D(l_1,l_0)),\mu^u_D(\mu^u_D(r_0,r_1),r_2)}(h)\big).$$

Its strict-support readback is exactly

$$N^u_D(H_3) \Longleftrightarrow N^u_D(l_2) \vee N^u_D(l_1) \vee N^u_D(l_0) \vee N^u_D(h) \vee N^u_D(r_0) \vee N^u_D(r_1) \vee N^u_D(r_2).$$

Proof. First apply Definition 45.465 to the inner two contextual layers with carried contexts l_0, r_0 and l_1, r_1. Since all external endpoints are e, the inner composite is carried, classified by $\Gamma_{\mathsf{e},\mathsf{e},\mu^u_D(l_1,l_0),\mu^u_D(r_0,r_1)}(h)$, and has five-term support readback $N^u_D(l_1) \vee N^u_D(l_0) \vee N^u_D(h) \vee N^u_D(r_0) \vee N^u_D(r_1)$.

Next apply the same closure theorem to the outer layer with carried contexts l_2, r_2 and to the normalized inner action as the carried core. The carrier row gives $C^u_D(H_3)$, while the classifier row reduces the threefold term to an outer action on the normalized two-layer core.

Use the denominator multiplicative certificate rows of Definition 45.447 to reassociate the carried append products. The left contexts collect as $\mu^u_D(l_2, \mu^u_D(l_1, l_0))$, and the right contexts collect as $\mu^u_D(\mu^u_D(r_0, r_1), r_2)$, so the classifier comparison is exactly the displayed single normalized action.

For strict support, the outer closure row reads the support of H_3 as $N^u_D(l_2)$, the support of the inner two-layer action, and $N^u_D(r_2)$. Substitute the inner support readback from the first step and reassociate the finite constructive disjunction. This gives the displayed seven-term strict-support formula in the stated order. □

Per-object template: traditional target threefold denominator action coherence for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, $\mathsf{RatDenomUnitCarrier}$, $\mathsf{RatDenomUnitClassifier}$, $\mathsf{RatHistoryCarrier}$, append, Cont, and e; carrier C^u_D; classifier R^u_D; stability obligations nested action closure, classifier normalization, and strict-support readback; ledger three carried left contexts, three carried right contexts, and empty external endpoint layers; core theorem Definition 45.469; exactness predicate threefold contextual normalization; standard bridge iterated denominator multiplication; status $\mathsf{ProofTarget}$.

Theorem 45.470 (RatUp FieldUp denominator complete contextual row package)**.** *The concrete denominator row $(C^\dagger_D, R^\dagger_D, \mu^\dagger_D, e^\dagger_D, N^\dagger_D)$ of Definition 45.449 and the contextual action Γ of Definition 45.454 jointly supply the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ denominator package consumed by the FieldUp certificate. The package fields are the concrete BHist data*

$$C^\dagger_D = C^u_D = \mathsf{RatDenomUnitCarrier}, \qquad R^\dagger_D = R^u_D = \mathsf{RatDenomUnitClassifier},$$

$$\mu^\dagger_D = \mu^u_D = \mathsf{append}, \qquad e^\dagger_D = e^u_D = \mathsf{e}, \qquad N^\dagger_D = N^u_D = \mathsf{RatHistoryCarrier}.$$

Its row component satisfies all denominator row laws of Definition 45.450; its contextual component satisfies all bilateral contextual classifier and strict-support laws of Definition 45.456; and the combined carrier, classifier, append, unit, and strict-support data are the same concrete data used by the assembled denominator subcertificate of Definition 45.448.

Proof. The two displayed definitions give the field identifications directly. Both rows use $\mathsf{RatDenomUnitCarrier}$ as carrier, $\mathsf{RatDenomUnitClassifier}$ as classifier, native BHist append as the binary operation, e as the unit, and $\mathsf{RatHistoryCarrier}$ as the strict-support predicate.

Apply Definition 45.450 to the row $(C^\dagger_D, R^\dagger_D, \mu^\dagger_D, e^\dagger_D, N^\dagger_D)$. This supplies the envelope, closure, unit, append, congruence, support, product, cancellation, contextual fixed-factor, external-unit, and absent carried-unit clauses for the denominator row.

Apply Definition 45.456 to the same concrete carrier, classifier, append, unit, and support fields, now with the bilateral action Γ. This supplies the contextual classifier law and the two contextual strict-support laws for carried left and right denominator contexts under empty external endpoints.

Finally, Definition 45.448 is the denominator subcertificate consumed by $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$. Since its carrier, classifier, multiplication, unit, and strict-support entries are the displayed BHist data above, the row laws and contextual action laws assemble into the announced concrete denominator package. □

Theorem 45.471 (RatUp FieldUp denominator package closure)**.** *For the concrete denominator row* $(C_D^\dagger, R_D^\dagger, \mu_D^\dagger, e_D^\dagger, N_D^\dagger)$ *of Definition 45.449 and the contextual action* Γ *of Definition 45.454, every denominator-side row required by Definition 45.337 at the* $\mathsf{Field}^\uparrow(\mathsf{RatUp})$ *boundary is covered by the row laws of Definition 45.450, the contextual action certificate of Definition 45.456, the obligation map of Definition 45.451, and the row exhaustion theorem Definition 45.452. The concrete carrier, classifier, multiplication, unit, and strict-support data are exactly the data assembled in Definition 45.448.*

Proof. Unfold the concrete denominator row and the contextual action instance. The definitions identify the row fields as RatDenomUnitCarrier, RatDenomUnitClassifier, append, e, and RatHistoryCarrier, and they identify the action as the bilateral context action Γ.

Apply Definition 45.470. This packages the row component and the contextual component over the same concrete BHist data, with the row laws coming from Definition 45.450 and the action laws coming from Definition 45.456.

Next apply Definition 45.451. It aligns those concrete row and contextual fields with the denominator rows named by Definition 45.337, so the package is read as the denominator-side interface of the FieldUp certificate rather than as a detached list of laws.

Finally apply Definition 45.452. It states that no denominator-side row used by the assembled $\mathsf{Field}^\uparrow(\mathsf{RatUp})$ certificate lies outside the multiplicative and contextual sources already named above. Together with Definition 45.448, this proves that the concrete denominator-side FieldUp package is closed under exactly the listed components. □

Per-object template: traditional target $\mathsf{Field}^\uparrow(\mathsf{RatUp})$ denominator-side package closure; BEDC source BHist, RatHistoryCarrier, RatDenomUnitCarrier, RatDenomUnitClassifier, native append, and Γ; carrier $C_D^\dagger$; classifier $R_D^\dagger$; stability obligations denominator row laws, contextual action certificate, obligation alignment, and row exhaustion; ledger empty endpoint, carried denominator histories, and contextual denominator actions; core theorem Definition 45.471; exactness predicate denominator classifier reflection and strict-support readback; standard bridge deferred; status ProofTarget.

Theorem 45.472 (RatUp FieldUp denominator contextual row closure package)**.** *For the concrete denominator tuple* $(C_D^u, R_D^u, \mu_D^u, e_D^u, N_D^u)$ *given by*

$$C_D^u = \mathsf{RatDenomUnitCarrier}, \qquad R_D^u = \mathsf{RatDenomUnitClassifier},$$

$$\mu_D^u = \mathsf{append}, \qquad e_D^u = \mathsf{e}, \qquad N_D^u = \mathsf{RatHistoryCarrier},$$

and for the action Γ *of Definition 45.454, the* $\mathsf{Field}^\uparrow(\mathsf{RatUp})$ *denominator package contains the row laws and assembly of Definition 45.470, the total contextual action certificate of Definition 45.462, the two-layer composition closure of Definition 45.465, the exact two-layer classifier and strict-support readback of Definition 45.467, the normalized contextual action exactness of Definition 45.468, the threefold contextual normalization of Definition 45.469, and the envelope bilateral cancellation law of Definition 45.466.*

Proof. First cite Definition 45.470. It fixes the concrete BHist carrier, classifier, append operation, empty unit, and strict-support predicate as RatDenomUnitCarrier, RatDenomUnitClassifier, append, e, and RatHistoryCarrier, and it supplies the row laws together with the assembled denominator subcertificate.

Next cite Definition 45.462. This is the one-step contextual action certificate for the same carrier, classifier, append, unit, strict-support predicate, and action Γ.

The two carried-action rows are supplied by Definition 45.465 and Definition 45.467. The first theorem gives closure of two carried contextual applications in C^u_D; the second gives classifier reflection and the five-term strict support readback for the exact two-layer action.

Normalized two-layer exactness is supplied by Definition 45.468. It composes the composition-closure row with the exact two-layer theorem: the closure row identifies the nested action with the single action on appended carried contexts, and the exactness row transports classifier equivalence and strict-support readback to the normalized endpoints.

The threefold law is supplied by Definition 45.469. It applies the same closure twice and uses the concrete denominator multiplicative rows to reassociate the append contexts, so three carried contextual layers are classified by one normalized action with the displayed seven-term strict-support readback.

Finally apply Definition 45.466. It supplies cancellation after strict carried denominator factors and empty external endpoints, so the concrete denominator package records row laws, contextual action, two-layer composition, exact readback, normalized exactness, threefold normalization, and bilateral cancellation over the same BHist data. □

Per-object template: traditional target FieldUp denominator contextual row closure for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, RatHistoryCarrier, RatDenomUnitCarrier, RatDenomUnitClassifier, append, e, and the action Γ; carrier C^u_D; classifier R^u_D; stability obligations denominator row laws, one-step contextual action rows, two-layer contextual composition, exact strict-support readback, normalized action exactness, three carried-context normalization, and strict-factor cancellation; ledger empty external endpoints, carried left and right denominator contexts, normalized two-layer append contexts, and three carried left and right context layers; core theorem Definition 45.472 with exactness rows Definition 45.468 and Definition 45.469; exactness predicate denominator classifier reflection, contextual action support readback, normalized classifier exactness, three carried-context strict-support normalization, and envelope bilateral cancellation; standard bridge FieldUp denominator boundary over $\mathsf{Rat}^{\uparrow}$ histories; status ProofTarget.

Theorem 45.473 (RatUp FieldUp denominator contextual action unit-composition laws)**.** *For the concrete data of Definition 45.454, the empty contextual action is a classifier unit and contextual actions compose by context multiplication.*

If $C^u_D(h)$, then the empty action is carried and classifier-equal to the original history:

$$C^u_D(\Gamma_{\mathsf{e},\mathsf{e},\mathsf{e},\mathsf{e}}(h)),$$

$$R^u_D(\Gamma_{\mathsf{e},\mathsf{e},\mathsf{e},\mathsf{e}}(h), h),$$

and its strict support is unchanged:

$$N^u_D(\Gamma_{\mathsf{e},\mathsf{e},\mathsf{e},\mathsf{e}}(h)) \Longleftrightarrow N^u_D(h).$$

If $C^u_D(h)$, $C^u_D(l)$, $C^u_D(r)$, $C^u_D(l')$, and $C^u_D(r')$, and if $p\mathsf{hsamee}$, $q\mathsf{hsamee}$, $p'\mathsf{hsamee}$, and $q'\mathsf{hsamee}$, then the nested contextual action is carried:

$$C^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))).$$

It is classified by the single action whose carried contexts are multiplied inside the denominator context monoid:

$$R^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h)), \Gamma_{p',q',\mu^u_D(l',l),\mu^u_D(r,r')}(h)).$$

Its strict-support readback is the five-term support law

$$N^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))) \Longleftrightarrow N^u_D(l') \vee N^u_D(l) \vee N^u_D(h) \vee N^u_D(r) \vee N^u_D(r').$$

Proof. For the unit action, unfold Definition 45.454. The four contexts are empty, so the action is the bilateral multiplication context $B_{\mathsf{e},\mathsf{e}}(h)$ with empty external endpoints. The empty-unit denominator laws of Definition 45.347 put the result in C^u_D.

The classifier clause is the empty-context instance of Definition 45.456, using empty-context classifier exactness for the endpoint transport. With both carried contexts equal to e, the same denominator unit laws reduce the comparison to $R^u_D(h,h)$, which is the reflexive classifier comparison for the carried history h.

For strict support of the unit action, apply the strict-support part of Definition 45.456. The two outer support terms are $N^u_D(\mathsf{e})$ and $N^u_D(\mathsf{e})$, and the empty-unit denominator laws make them absent. The remaining term is exactly $N^u_D(h)$.

For composition, use Definition 45.465. Its hypotheses are precisely the carried-context hypotheses and the four empty external endpoint hypotheses displayed above.

That theorem supplies the carried nested action, the classifier comparison with $\Gamma_{p',q',\mu^u_D(l',l),\mu^u_D(r,r')}(h)$, and the five-term strict-support readback. These are exactly the action-law package consumed by the concrete FieldUp denominator interface. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitContextualAction empty unit laws`

Theorem 45.474 (RatUp FieldUp denominator contextual row package with unit-composition laws)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *given by*

$$C^u_D = \mathsf{RatDenomUnitCarrier}, \qquad R^u_D = \mathsf{RatDenomUnitClassifier},$$

$$\mu^u_D = \mathsf{append}, \qquad e^u_D = \mathsf{e}, \qquad N^u_D = \mathsf{RatHistoryCarrier},$$

and for the contextual action Γ *of Definition 45.454, the* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *denominator package contains the rows of Definition 45.472 together with the empty-action classifier unit, unchanged strict support, context-multiplication composition, and five-term support law of Definition 45.473.*

Proof. Apply Definition 45.472. It records the row laws, action exactness, two-layer composition readback, and cancellation clauses for the concrete tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and the action Γ.

Apply Definition 45.473 over the same concrete data. Its hypotheses and conclusions use the same BHist carrier, classifier, append operation, empty unit, strict-support predicate, and contextual action fixed in Definition 45.454.

Thus the two cited results occupy independent rows of the same denominator interface: the first supplies row closure, action exactness, readback, and cancellation, while the second supplies the empty-action unit, unchanged strict support, context-multiplication composition, and five-term support law. The package statement is their joint registration over the shared concrete RatUp denominator data, without restating either theorem. □

Theorem 45.475 (RatUp FieldUp denominator normalized contextual action package)**.** *For the concrete tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *determined by* $\mathsf{RatDenomUnitCarrier}$, $\mathsf{RatDenomUnitClassifier}$, append, e, *and* $\mathsf{RatHistoryCarrier}$, *and for the concrete contextual action* Γ *of Definition 45.454, the* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *denominator action package contains:*

1. *the row closure package of Definition 45.472;*
2. *the empty-action unit law and context-composition normalization law of Definition 45.473;*
3. *the paired normalized classifier exactness and five-term strict-support readbacks of Definition 45.468.*

Thus the normalized denominator contextual action certificate is available as a single non-parametric package over the same carried denominator contexts and empty external endpoints.

Proof. Apply Definition 45.472. This supplies the concrete row closure package for the RatUp FieldUp denominator carrier and classifier.

Apply Definition 45.473. It gives the empty-action unit clause and the context-composition normalization clause for the same action Γ.

Apply Definition 45.468. It supplies the paired normalized classifier exactness together with the five-term strict-support readbacks.

The three cited results use the same concrete BHist carrier, RatDenomUnitClassifier, append operation, empty unit e, strict-support predicate N^u_D, and action Γ. Therefore their clauses assemble without transport into the stated denominator action package. □

Per-object template: traditional target normalized denominator contextual action package for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, RatHistoryCarrier, RatDenomUnitCarrier, RatDenomUnitClassifier, append, e, and Γ; carrier C^u_D; classifier R^u_D; stability obligations row closure, action unit, action composition normalization, normalized classifier exactness, and strict-support readback; ledger carried left and right denominator contexts plus empty external endpoints; core theorem Definition 45.475; exactness predicate normalized classifier iff and five-term support iff; standard bridge ordinary denominator context multiplication; status ProofTarget.

Theorem 45.476 (RatUp FieldUp denominator contextual action support collapse)**.** *For the concrete tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and the contextual action Γ of Definition 45.454, suppose $C^u_D(h)$, $C^u_D(l)$, $C^u_D(r)$, $C^u_D(l')$, and $C^u_D(r')$. Suppose also that $p$hsamee, $q$hsamee, p'hsamee, and q'hsamee, and that $\neg N^u_D(l)$, $\neg N^u_D(r)$, $\neg N^u_D(l')$, and $\neg N^u_D(r')$. Then the nested action is carried:*

$$C^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))).$$

It is classified by the collected denominator-context action:

$$R^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h)), \Gamma_{p',q',\mu^u_D(l',l),\mu^u_D(r,r')}(h)).$$

Under the same no-extra-support hypotheses, strict support collapses to the support of the acted-on history:

$$N^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))) \Longleftrightarrow N^u_D(h).$$

Proof. Apply Definition 45.473 to the displayed carried history, carried denominator contexts, and empty external endpoint equations. The theorem gives the carried nested action and the classifier comparison with the collected denominator-context action.

It also gives the five-term strict-support readback

$$N^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))) \Longleftrightarrow N^u_D(l') \vee N^u_D(l) \vee N^u_D(h) \vee N^u_D(r) \vee N^u_D(r').$$

For the forward direction of the displayed collapse, the four context-support disjuncts contradict the hypotheses $\neg N^u_D(l')$, $\neg N^u_D(l)$, $\neg N^u_D(r)$, and $\neg N^u_D(r')$. The only remaining disjunct is $N^u_D(h)$.

For the reverse direction, insert $N^u_D(h)$ into the middle disjunct of the five-term readback and close by the same equivalence. Thus the contextual action adds no strict support when all four carried contexts have no strict support. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup denominator contextual action support collapse`

Theorem 45.477 (RatUp FieldUp denominator contextual action total normalization package)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and the contextual action Γ of Definition 45.454, the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ denominator action package contains the following single certificate-level normalization record.*

1. *The empty action is the classifier unit. If $C^u_D(h)$, then*

$$C^u_D(\Gamma_{\mathsf{e},\mathsf{e},\mathsf{e},\mathsf{e}}(h)),$$

$$R^u_D(\Gamma_{\mathsf{e},\mathsf{e},\mathsf{e},\mathsf{e}}(h), h),$$

and

$$N^u_D(\Gamma_{\mathsf{e},\mathsf{e},\mathsf{e},\mathsf{e}}(h)) \Longleftrightarrow N^u_D(h).$$

2. *The two-layer contextual action normalizes to one collected carried action. If $C^u_D(h)$, $C^u_D(k)$, $C^u_D(l)$, $C^u_D(r)$, $C^u_D(l')$, and $C^u_D(r')$, and if all displayed external endpoints are* hsamee*, then*

$$R^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h)), \Gamma_{p',q',\mu^u_D(l',l),\mu^u_D(r,r')}(h)).$$

For any second endpoint k under the same collected carried contexts, denominator classifier exactness is

$$R^u_D(\Gamma_{s,t,\mu^u_D(l',l),\mu^u_D(r,r')}(h), \Gamma_{s',t',\mu^u_D(l',l),\mu^u_D(r,r')}(k)) \Longleftrightarrow R^u_D(h,k).$$

The nested endpoint has the five-term strict-support readback

$$N^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))) \Longleftrightarrow N^u_D(l') \vee N^u_D(l) \vee N^u_D(h) \vee N^u_D(r) \vee N^u_D(r').$$

3. *The threefold empty-external action normalizes to one collected action. For $C^u_D(h)$ and carried contexts $l_0, r_0, l_1, r_1, l_2, r_2$, let*

$$H_3 := \Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h))).$$

Then

$$C^u_D(H_3),$$

$$R^u_D(H_3, \Gamma_{\mathsf{e},\mathsf{e},\mu^u_D(l_2,\mu^u_D(l_1,l_0)),\mu^u_D(\mu^u_D(r_0,r_1),r_2)}(h)),$$

and

$$N^u_D(H_3) \Longleftrightarrow N^u_D(l_2) \vee N^u_D(l_1) \vee N^u_D(l_0) \vee N^u_D(h) \vee N^u_D(r_0) \vee N^u_D(r_1) \vee N^u_D(r_2).$$

4. *The same record includes the surrounding row-closure assembly, the one-step action-certificate rows, the exact readback rows, and the bilateral cancellation fields listed in Definition 45.472.*

Proof. The unit and two-layer action laws are exactly the concrete rows of Definition 45.473. They supply the carried empty action, classifier identity, unchanged strict support, the collected two-layer classifier comparison, and the five-term strict-support readback.

For classifier exactness of the collected two-layer endpoint, apply Definition 45.468 with the inner and outer carried contexts ordered so that the collected left context is $\mu^u_D(l', l)$ and the collected right context is $\mu^u_D(r, r')$. Its normalized row gives the displayed denominator classifier equivalence, and its support rows agree with the five-term readback already recorded above.

The threefold row is Definition 45.469. It packages the carried threefold endpoint, the classifier comparison with the single collected action, and the seven-term support readback for the empty external layers.

Finally use Definition 45.472. That theorem supplies the surrounding row package, action certificate, exact readback, and bilateral cancellation fields over the same concrete denominator tuple and the same action Γ, so the displayed action-normalization clauses form one certificate-level FieldUp denominator package. □

Theorem 45.478 (RatUp FieldUp denominator total normalization with support collapse)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and the contextual action* Γ *of Definition 45.454, suppose* $C^u_D(h)$, $C^u_D(k)$, $C^u_D(l)$, $C^u_D(r)$, $C^u_D(l')$, *and* $C^u_D(r')$. *Suppose also that* $p\mathsf{hsamee}$, $q\mathsf{hsamee}$, $p'\mathsf{hsamee}$, $q'\mathsf{hsamee}$, *and that* $\neg N^u_D(l)$, $\neg N^u_D(r)$, $\neg N^u_D(l')$, *and* $\neg N^u_D(r')$. *Then the nested action is carried:*

$$C^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))).$$

It is classified by the collected denominator-context action:

$$R^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h)), \Gamma_{p',q',\mu^u_D(l',l),\mu^u_D(r,r')}(h)).$$

Its strict support is exactly the strict support of the acted-on history:

$$N^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))) \iff N^u_D(h).$$

Moreover, for any second endpoint k *under the same collected carried contexts, and for* s, t, s', t' *satisfying* $s\mathsf{hsamee}$, $t\mathsf{hsamee}$, $s'\mathsf{hsamee}$, *and* $t'\mathsf{hsamee}$, *the collected action remains classifier-exact:*

$$R^u_D(\Gamma_{s,t,\mu^u_D(l',l),\mu^u_D(r,r')}(h), \Gamma_{s',t',\mu^u_D(l',l),\mu^u_D(r,r')}(k)) \iff R^u_D(h,k).$$

Proof. First apply Definition 45.477. Its two-layer row supplies the carried nested action and the classifier comparison with the collected denominator-context action.

The same package cites the normalized contextual action row over the collected left context $\mu^u_D(l', l)$ and collected right context $\mu^u_D(r, r')$. Thus the collected action remains classifier-exact against the second endpoint k with empty external endpoints.

Finally apply Definition 45.476 to the four carried contexts and the four no-extra-support hypotheses. This gives the displayed equivalence between the strict support of the nested action and the strict support of h, so the certificate row records support neutrality in the empty-support contextual case. □

45.20 Rat denominator context-pair action laws

Definition 45.479 (RatUp FieldUp denominator context-pair monoid)**.** *The concrete denominator context-pair carrier for the RatUp FieldUp action is the class of pairs* $(l, r) : \mathsf{BHist} \times \mathsf{BHist}$ *such that* $C^u_D(l)$ *and* $C^u_D(r)$. *Its unit is* (e^u_D, e^u_D), *and its pair product is*

$$(l, r) \star (l', r') := (\mu^u_D(l', l), \mu^u_D(r, r')).$$

The pair support predicate is

$$\mathsf{PairSupp}^u_D(l, r) \iff N^u_D(l) \vee N^u_D(r).$$

The componentwise pair classifier is

$$\mathsf{PairClass}^u_D((l, r), (l', r')) \iff R^u_D(l, l') \wedge R^u_D(r, r').$$

Theorem 45.480 (RatUp FieldUp denominator context-pair operation stability)**.** *For the concrete denominator context-pair structure of Definition 45.479, let* (l, r), (m, s), (l', r'), *and* (m', s') *be carried pairs. If* $\mathsf{PairClass}^u_D((l, r), (m, s))$ *and* $\mathsf{PairClass}^u_D((l', r'), (m', s'))$, *then the two products* $(l, r) \star (l', r')$ *and* $(m, s) \star (m', s')$ *are carried pairs and satisfy*

$$\mathsf{PairClass}^u_D((l, r) \star (l', r'), (m, s) \star (m', s')).$$

Moreover the support of the first product is exactly the support of its two input pairs:

$$\mathsf{PairSupp}^u_D((l, r) \star (l', r')) \iff \mathsf{PairSupp}^u_D(l, r) \vee \mathsf{PairSupp}^u_D(l', r').$$

Proof. Unfold the product. The first product is $(\mu^u_D(l', l), \mu^u_D(r, r'))$, and the second is $(\mu^u_D(m', m), \mu^u_D(s, s'))$. Since all four input pairs are carried, Definition 45.347 gives carrier closure for each of the four displayed product components. Thus both pair products are carried.

Unfold $\mathsf{PairClass}^u_D$. The hypotheses give $R^u_D(l, m)$, $R^u_D(r, s)$, $R^u_D(l', m')$, and $R^u_D(r', s')$. Apply Definition 45.131 to the left contexts l', l, m', and m to obtain $R^u_D(\mu^u_D(l', l), \mu^u_D(m', m))$.

Apply the same binary classifier congruence theorem to the right contexts r, r', s, and s' to obtain $R^u_D(\mu^u_D(r, r'), \mu^u_D(s, s'))$. These two component classifiers are exactly the displayed product-pair classifier.

It remains to read support for the first product. Unfold $\mathsf{PairSupp}^u_D$ and use Definition 45.399 on the left component $\mu^u_D(l', l)$ and on the right component $\mu^u_D(r, r')$. This rewrites the product support as $N^u_D(l') \vee N^u_D(l) \vee N^u_D(r) \vee N^u_D(r')$.

Rebracket and commute the disjunctions to $(N^u_D(l) \vee N^u_D(r)) \vee (N^u_D(l') \vee N^u_D(r'))$. By the definition of $\mathsf{PairSupp}^u_D$, this is precisely $\mathsf{PairSupp}^u_D(l, r) \vee \mathsf{PairSupp}^u_D(l', r')$. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomContextPair operation stability`

Theorem 45.481 (RatUp FieldUp denominator context-pair product operation row)**.** *For the concrete denominator context-pair structure of Definition 45.479, let (l, r), (m, s), (l', r'), and (m', s') be carried pairs. If $\mathsf{PairClass}^u_D((l, r), (m, s))$ and $\mathsf{PairClass}^u_D((l', r'), (m', s'))$, then the product components $\mu^u_D(l', l)$, $\mu^u_D(r, r')$, $\mu^u_D(m', m)$, and $\mu^u_D(s, s')$ are carried, and the two product pairs are componentwise R^u_D-classified:*

$$\mathsf{PairClass}^u_D((l, r) \star (l', r'), (m, s) \star (m', s')).$$

The strict support of the first product pair, read as the bundled denominator context, is exactly the disjunction of the two input pair supports:

$$N^u_D(\mu^u_D(\mu^u_D(l', l), \mu^u_D(r, r'))) \iff \mathsf{PairSupp}^u_D(l, r) \vee \mathsf{PairSupp}^u_D(l', r').$$

Proof. The two pair-class hypotheses give the four component classifiers $R^u_D(l, m)$, $R^u_D(r, s)$, $R^u_D(l', m')$, and $R^u_D(r', s')$. Apply Definition 45.480; its carrier and classifier clauses are exactly the four carried product components and the displayed product-pair classifier.

For support, apply Definition 45.571. This gives $N^u_D(l') \vee N^u_D(l) \vee N^u_D(r) \vee N^u_D(r')$ for the bundled product context. Rebracket and commute the disjunctions to $(N^u_D(l) \vee N^u_D(r)) \vee (N^u_D(l') \vee N^u_D(r'))$, then unfold $\mathsf{PairSupp}^u_D$. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomContextPair product operation stable`

Theorem 45.482 (RatUp FieldUp denominator context-pair action laws)**.** *For the concrete denominator context-pair structure of Definition 45.479, the contextual action Γ is a unital action up to the denominator classifier and composes by the product $\star$.*

If $C^u_D(h)$, then the unit pair acts as the classifier identity:

$$C^u_D(\Gamma_{\mathsf{e},\mathsf{e},e^u_D,e^u_D}(h)),$$

$$R^u_D(\Gamma_{\mathsf{e},\mathsf{e},e^u_D,e^u_D}(h), h),$$

and its strict support is the support of h together with the unit-pair support:

$$N^u_D(\Gamma_{\mathsf{e},\mathsf{e},e^u_D,e^u_D}(h)) \iff \mathsf{PairSupp}^u_D(e^u_D, e^u_D) \vee N^u_D(h).$$

If $C^u_D(h)$, $C^u_D(l)$, $C^u_D(r)$, $C^u_D(l')$, and $C^u_D(r')$, and if $p$hsamee, $q$hsamee, p'hsamee, and q'hsamee, then nested actions are classified by the single action of the product pair:

$$R^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h)), \Gamma_{p',q',\mu^u_D(l',l),\mu^u_D(r,r')}(h)).$$

The strict support of the nested action is exactly the support of the acted history together with the supports of the two acting pairs:

$$N^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))) \iff \mathsf{PairSupp}^u_D(l,r) \vee N^u_D(h) \vee \mathsf{PairSupp}^u_D(l',r').$$

Equivalently, by the denominator row support laws for μ^u_D, this is the support of h together with the support of the product pair $(l,r) \star (l',r')$.

The product $\star$ has (e^u_D, e^u_D) as a two-sided unit and is associative up to componentwise R^u_D. For every carried pair (l,r), both $(e^u_D, e^u_D) \star (l,r)$ and $(l,r) \star (e^u_D, e^u_D)$ are componentwise R^u_D-classified with (l,r). For carried pairs (l,r), (l',r'), and (l'',r''), the pairs $((l,r) \star (l',r')) \star (l'',r'')$ and $(l,r) \star ((l',r') \star (l'',r''))$ are componentwise R^u_D-classified.

Proof. The carrier and product clauses are componentwise applications of the empty-unit denominator continuation monoid laws of Definition 45.347. The unit pair is carried because $C^u_D(e^u_D)$ holds, and product closure follows from closure of μ^u_D on each component.

For the unit action, specialize Definition 45.473 to the empty contextual action. Since $e^u_D = \mathsf{e}$ in the concrete denominator instance, its carrier, classifier-identity, and support clauses give exactly the three displayed unit-action conclusions. The pair-support definition rewrites the two empty context supports as $\mathsf{PairSupp}^u_D(e^u_D, e^u_D)$.

For composition, use the same unit-composition theorem with the carried context pairs (l,r) and (l',r') and the four empty external endpoint hypotheses. Its classifier clause is precisely the comparison with the action whose contexts are $\mu^u_D(l',l)$ and $\mu^u_D(r,r')$, which is the pair product $(l,r) \star (l',r')$.

The strict-support clause of that theorem gives the five-term readback $N^u_D(l') \vee N^u_D(l) \vee N^u_D(h) \vee N^u_D(r) \vee N^u_D(r')$. Rebracketing disjunction and unfolding $\mathsf{PairSupp}^u_D$ gives the displayed pair-support form. The denominator row support laws for μ^u_D identify the left two and right two support terms with the two components of the product pair.

Finally, unitality and associativity of $\star$ are the componentwise unit and associativity clauses of Definition 45.347. The left component uses the left-context order in the definition of $\star$, and the right component uses the right-context order; both comparisons are exactly componentwise R^u_D. □

Theorem 45.483 (RatUp FieldUp denominator context-pair unit support neutrality)**.** *For the concrete denominator context-pair tuple $C^u_D = \mathsf{RatDenomUnitCarrier}$, $R^u_D = \mathsf{RatDenomUnitClassifier}$, $\mu^u_D = \mathsf{append}$, $e^u_D = \mathsf{e}$, and $N^u_D = \mathsf{RatHistoryCarrier}$ of Definition 45.479, the unit pair has no strict pair support:*

$$\neg\, \mathsf{PairSupp}^u_D(e^u_D, e^u_D).$$

Consequently, for every carried denominator history h, the unit context-pair action is strict-support neutral:

$$N^u_D(\Gamma_{\mathsf{e},\mathsf{e},e^u_D,e^u_D}(h)) \iff N^u_D(h).$$

Proof. Unfold $\mathsf{PairSupp}^u_D$ at (e^u_D, e^u_D). Since the concrete unit is $e^u_D = \mathsf{e}$ and $N^u_D = \mathsf{RatHistoryCarrier}$, either branch of the support disjunction would give $\mathsf{RatHistoryCarrier}(\mathsf{e})$. Definition 37.18 rules this out, so the unit pair has no strict pair support.

Now specialize Definition 45.482 to the unit pair. Its unit-action support clause gives

$$N_D^u(\Gamma_{\mathsf{e},\mathsf{e},e_D^u,e_D^u}(h)) \iff \mathsf{PairSupp}_D^u(e_D^u, e_D^u) \vee N_D^u(h).$$

For the forward direction, eliminate the impossible left disjunct using the first paragraph. The remaining disjunct is exactly $N_D^u(h)$.

For the reverse direction, use the right disjunct of the displayed support readback. This proves the stated strict-support neutrality of the unit context-pair action. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomContextPair unit support neutrality`

Theorem 45.484 (RatUp FieldUp denominator context-pair commutative support)**.** *For the concrete denominator context-pair structure of Definition 45.479, let (l, r) and (l', r') be carried pairs, so $C_D^u(l)$, $C_D^u(r)$, $C_D^u(l')$, and $C_D^u(r')$. Then the two pair products $(l, r) \star (l', r')$ and $(l', r') \star (l, r)$ are componentwise R_D^u-classified:*

$$R_D^u(\mu_D^u(l', l), \mu_D^u(l, l')) \quad \textit{and} \quad R_D^u(\mu_D^u(r, r'), \mu_D^u(r', r)).$$

Moreover, the support of the product pair is exactly the support of either input pair:

$$\mathsf{PairSupp}_D^u(\mu_D^u(l', l), \mu_D^u(r, r')) \iff \mathsf{PairSupp}_D^u(l, r) \vee \mathsf{PairSupp}_D^u(l', r').$$

Proof. Unfold the definition of $\star$. The left component of $(l, r) \star (l', r')$ is $\mu_D^u(l', l)$, while the left component of $(l', r') \star (l, r)$ is $\mu_D^u(l, l')$. Apply Definition 45.392 to the carried endpoints l' and l to obtain the displayed left-component classifier.

The right component is identical in form, with r and r' in place of the two left contexts. Applying the same commutative monoid law gives $R_D^u(\mu_D^u(r, r'), \mu_D^u(r', r))$. Together the two component classifiers are exactly componentwise R_D^u-classification of the two pair products.

It remains to read support. Unfold $\mathsf{PairSupp}_D^u(\mu_D^u(l', l), \mu_D^u(r, r'))$ as the disjunction of the left and right product supports. For each product component, use Definition 45.399 with the corresponding carried factors, together with the strict-support interpretation of N_D^u, to replace product support by the disjunction of the two input supports.

The result is $N_D^u(l') \vee N_D^u(l) \vee N_D^u(r) \vee N_D^u(r')$. Rebracket and commute the outer disjunctions to obtain $(N_D^u(l) \vee N_D^u(r)) \vee (N_D^u(l') \vee N_D^u(r'))$, which is exactly $\mathsf{PairSupp}_D^u(l, r) \vee \mathsf{PairSupp}_D^u(l', r')$ by the pair-support definition. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomContextPair product commutative support`

Per-object template: traditional target context-pair commutative action support; BEDC source BHist, RatDenomUnitCarrier, RatDenomUnitClassifier, append, RatHistoryCarrier, and action Γ; carrier the carried context pairs; classifier componentwise R_D^u; stability obligations component commutativity and support exactness; ledger left and right denominator contexts; core theorem Definition 45.484; exactness predicate the displayed support iff; standard bridge denominator context-pair monoid support; status ProofTarget.

Theorem 45.485 (RatUp FieldUp denominator context-pair threefold action coherence)**.** *For the concrete denominator context-pair structure of Definition 45.479, assume that (l_0, r_0), (l_1, r_1), and (l_2, r_2) are carried pairs and that $C_D^u(h)$. Let*

$$H_3 := \Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h))).$$

Then the threefold context-pair action is carried:

$$C^u_D(H_3).$$

It is classified by the single action of the left-associated double product $((l_0, r_0) \star (l_1, r_1)) \star (l_2, r_2)$*:*

$$R^u_D(H_3, \Gamma_{\mathsf{e},\mathsf{e},\mu^u_D(l_2,\mu^u_D(l_1,l_0)),\mu^u_D(\mu^u_D(r_0,r_1),r_2)}(h)).$$

It is also classified by the single action of the alternate bracketing $(l_0, r_0) \star ((l_1, r_1) \star (l_2, r_2))$*:*

$$R^u_D(H_3, \Gamma_{\mathsf{e},\mathsf{e},\mu^u_D(\mu^u_D(l_2,l_1),l_0),\mu^u_D(r_0,\mu^u_D(r_1,r_2))}(h)).$$

The strict-support readback is the seven-term denominator row

$$N^u_D(H_3) \iff N^u_D(l_2) \vee N^u_D(l_1) \vee N^u_D(l_0) \vee N^u_D(h) \vee N^u_D(r_0) \vee N^u_D(r_1) \vee N^u_D(r_2).$$

Equivalently, after reassociating the finite disjunction, the same readback is

$$N^u_D(H_3) \iff \mathsf{PairSupp}^u_D(l_2, r_2) \vee \mathsf{PairSupp}^u_D(l_1, r_1) \vee \mathsf{PairSupp}^u_D(l_0, r_0) \vee N^u_D(h).$$

Proof. Apply Definition 45.469 with the three carried denominator context pairs and the carried denominator history h. This gives the carrier row for H_3, the classifier comparison with the single action whose contexts are $\mu^u_D(l_2, \mu^u_D(l_1, l_0))$ and $\mu^u_D(\mu^u_D(r_0, r_1), r_2)$, and the seven-term strict-support readback.

Unfold Definition 45.479. The product $(l_0, r_0) \star (l_1, r_1)$ is $(\mu^u_D(l_1, l_0), \mu^u_D(r_0, r_1))$, so the next product with (l_2, r_2) has exactly the two normalized contexts displayed in the first classifier row.

For the alternate bracketing, use the associativity clause of Definition 45.482. It identifies the two double products componentwise up to R^u_D, with left component $\mu^u_D(l_2, \mu^u_D(l_1, l_0))$ classified with $\mu^u_D(\mu^u_D(l_2, l_1), l_0)$ and right component $\mu^u_D(\mu^u_D(r_0, r_1), r_2)$ classified with $\mu^u_D(r_0, \mu^u_D(r_1, r_2))$.

Transport the first single-action classifier across this componentwise associativity comparison using the concrete denominator classifier laws recorded in the same action-law theorem. Finally unfold $\mathsf{PairSupp}^u_D$ and reassociate the finite disjunction to obtain the pair-support formulation of the same strict-support readback. □

↪ variant `BEDC.Derived.FieldUp.RatDenomUnitContextualAction nested pair action coherence`

Per-object template: traditional target threefold context-pair action coherence for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, RatDenomUnitCarrier, RatDenomUnitClassifier, RatHistoryCarrier, append, Cont, e, and Γ; carrier carried context pairs; classifier componentwise R^u_D; stability obligations closure, classifier normalization, support readback, and pair-product associativity; ledger three carried pairs plus acted denominator history; core theorem Definition 45.485; exactness predicate threefold normalized action classifier and support readback; standard bridge FieldUp denominator context-pair action; status ProofTarget.

Theorem 45.486 (RatUp FieldUp denominator context-pair adjacent-swap coherence)**.** *For the concrete denominator context-pair structure of Definition 45.479, assume that* (l_0, r_0)*,* (l_1, r_1)*, and* (l_2, r_2) *are carried pairs and that* $C^u_D(h)$*. Let*

$$H_{012} := \Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h))).$$

Let

$$H_{102} := \Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(h))).$$

Then the two threefold denominator histories are denominator-classified:

$$R_D^u(H_{012}, H_{102}).$$

Their strict-support readbacks agree:

$$N_D^u(H_{012}) \Longleftrightarrow N_D^u(H_{102}).$$

Proof. Apply Definition 45.497 to the two inner empty-endpoint actions with carried pairs (l_0, r_0) and (l_1, r_1). This gives a denominator classifier between $\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h))$ and $\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(h))$.

Transport this inner classifier through the common outer pair (l_2, r_2) by Definition 45.500, using reflexivity for the outer left and right denominator contexts. The transported classifier is exactly $R_D^u(H_{012}, H_{102})$ after unfolding the two displayed definitions.

The denominator classifier contains the history-sameness field for the two acted histories. Reading the strict-support predicate N_D^u through that field in both directions gives $N_D^u(H_{012}) \Longleftrightarrow N_D^u(H_{102})$. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitContextualAction empty pair adjacent swap coherence`

Per-object template: traditional target adjacent-swap coherence for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ denominator context-pair actions; BEDC source BHist, $\mathsf{RatDenomUnitCarrier}$, $\mathsf{RatDenomUnitClassifier}$, $\mathsf{RatHistoryCarrier}$, append, Cont, e, and Γ; carrier carried context pairs; classifier componentwise R_D^u; stability obligations inner pair commutation plus outer classifier transport; ledger three carried pairs and acted denominator history; core theorem Definition 45.486; exactness predicate adjacent-swap classifier and strict-support invariance; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.487 (RatUp FieldUp denominator action envelope certificate component)**.** *For the concrete denominator tuple* ($\mathsf{RatDenomUnitCarrier}$, $\mathsf{RatDenomUnitClassifier}$, append, e, $\mathsf{RatHistoryCarrier}$) *and the contextual action* Γ *of Definition 45.454, the denominator-action component required by Definition 45.337 is supplied by the envelope closure of Definition 45.569, the normalized row exhaustion of Definition 45.570, and the context-pair action certificate of Definition 45.568. Consequently the assembled* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *boundary may treat the multiplicative denominator coverage, the contextual boundary, the normalized row coverage, and the context-pair product and action rows as one concrete BHist-anchored certificate component.*

Lean4 ✓ `BEDC.Derived.FieldUp.RatupFieldupDenominatorActionEnvelopeCertificateComponent`

Proof. First apply Definition 45.569. It fixes the multiplicative coverage and contextual multiplicative boundary over the RatUp denominator carrier, classifier, append operation, empty endpoint, strict-support predicate, and contextual action Γ.

Next apply Definition 45.570. It accounts for every normalized denominator action row by the same concrete BHist carrier data, the empty external contexts, and the pair product $\star$.

Finally apply Definition 45.568. It supplies the pair classifier, pair product, unit-pair action, product-action composition, support readback, and iterated action rows for the same ($\mathsf{RatDenomUnitCarrier}$, RatDen tuple and the same action Γ.

All three cited results use identical carrier, classifier, append, empty unit, strict-support predicate, and contextual-action data. Their conclusions therefore occupy one denominator-action component of Definition 45.337, with no transport between separate FieldUp sources. □

Definition 45.488 (Concrete RatUp FieldUp source tuple)**.** *The concrete source tuple for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *is denoted* $\mathsf{RatUpFieldSource}_F$*. Its field-level BHist source is*

$$C_F = \mathsf{RatHistoryCarrier}, \qquad R_F = \mathsf{RatHistoryClassifier}.$$

Its denominator coordinate is the concrete tuple

$$(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D) = (\mathsf{RatDenomUnitCarrier}, \mathsf{RatDenomUnitClassifier}, \mathsf{append}, \mathsf{e}, \mathsf{RatHistoryCarrier}).$$

Its contextual-action coordinate is the action Γ *of Definition 45.454. Its context-pair coordinate is the carried pair carrier, componentwise classifier, unit pair, product* $\star$*, and support predicate of Definition 45.479. Its affine coordinate is the certified affine automorphism row source* AffAut_F *of Definition 45.560, with the group certificate rows supplied by Definition 45.558.*

Theorem 45.489 (RatUp FieldUp assembled certificate boundary)**.** *The named source tuple* $\mathsf{RatUpFieldSource}_F$ *of Definition 45.488 satisfies Definition 45.337. Its carrier is* RatHistoryCarrier*, its classifier is* RatHistoryClassifier*, its denominator source is the concrete RatUp denominator tuple, its contextual source is* Γ*, its context-pair source is the monoid of Definition 45.479, and its affine source is* AffAut_F*. The jointly registered rows are:*

1. *the commutative-ring rows inherited from* $\mathsf{CommRing}^{\uparrow}$ *on the same history carrier and classifier;*
2. *the inverse and nonzero rows supplied by Definition 45.205, Definition 45.210, Definition 45.218, and Definition 45.288;*
3. *the multiplicative denominator rows supplied by Definition 45.447 and Definition 45.448;*
4. *the denominator-action component consumed by Definition 45.337, supplied by Definition 45.487 from envelope closure, normalized row exhaustion, and context-pair action certification;*
5. *the contextual denominator rows supplied by Definition 45.472, Definition 45.475, Definition 45.482, Definition 45.568, and Definition 45.570;*
6. *the affine automorphism closure supplied by Definition 45.558.*

Consequently $\mathsf{RatUpFieldSource}_F$ *supplies the Phase Algebra Hierarchy paper-certificate object for the concrete BHist-anchored* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *certificate. The machine-checked phase exit is the canonical Lean certificate site for that same object.*

Lean4 ✓ `BEDC.Derived.FieldUp.RatupFieldupAssembledCertificateBoundary`

Proof. Unpack Definition 45.488. The carrier and classifier fields are the concrete RatUp history predicates RatHistoryCarrier and RatHistoryClassifier, so every row below is read over the same BHist source rather than over detached parameters.

The denominator coordinate is (RatDenomUnitCarrier, RatDenomUnitClassifier, append, e, RatHistoryCarrier), the contextual-action coordinate is Γ, and the context-pair coordinate is the carried pair monoid of Definition 45.479. The affine coordinate is AffAut_F with rows read from Definition 45.558.

The algebraic spine is the inherited $\mathsf{CommRing}^{\uparrow}$ structure together with the inverse block. Apply Definition 45.205, Definition 45.210, Definition 45.218, and Definition 45.288. These rows give classifier exactness for inverse formation, nonzero transport through the inverse domain, product inverse exactness, and certified multiplication by nonzero factors.

The denominator subcertificate is then read from Definition 45.447 and Definition 45.448. The first theorem records the multiplicative denominator rows, and the second identifies them as the denominator component consumed by the FieldUp certificate obligations.

Now apply Definition 45.487. It combines the envelope closure, normalized row exhaustion, and context-pair action certificate into the single denominator-action component required by Definition 45.337.

The contextual extension first uses Definition 45.472 and Definition 45.475. These rows add one-step and iterated contextual actions, normalized action transport, classifier exactness, strict-support readback, and bilateral cancellation for the same denominator carrier.

Next apply Definition 45.482, Definition 45.568, and Definition 45.570. The pair-action block supplies pair composition, unit action, componentwise product laws, certified contextual action rows, and normalized row coverage across the concrete BHist context pairs.

Finally, apply Definition 45.558. Its identity, composition, inverse, associativity, classifier-congruence, and witness-choice descent rows close the affine automorphism part of the FieldUp interface. Combining these disjoint rows gives exactly the carrier, classifier, stability, exactness, and ledger obligations listed in Definition 45.337. □

Per-object template: traditional target concrete constructive field certificate for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist with RatHistoryCarrier and RatHistoryClassifier; carrier RatHistoryCarrier; classifier RatHistoryClassifier; stability obligations commutative-ring laws, proof-indexed inverse closure, nonzero transport, denominator multiplication, contextual action, context-pair composition, and affine automorphism closure; ledger ring expression data, nonzero witnesses, denominator histories, contextual pairs, and affine coefficient witnesses; core theorem list Definition 45.489, Definition 45.448, Definition 45.487, Definition 45.472, Definition 45.475, Definition 45.482, Definition 45.568, Definition 45.570, and Definition 45.558; exactness predicate classifier exactness for inverse, product, denominator, denominator-action component, contextual action, normalized contextual action, context-pair action, normalized context-pair row coverage, and affine automorphism rows; standard bridge ordinary constructive field over rational histories with certified affine automorphisms; status ProofTarget.

Theorem 45.490 (Rat denominator context-pair product strict support commutation)**.** *For carried denominator context pairs (l, r) and (l', r'), strict support is unchanged by swapping the two pair factors:*

$$N_D^u(\mu_D^u(\mu_D^u(l', l), \mu_D^u(r, r'))) \Longleftrightarrow N_D^u(\mu_D^u(\mu_D^u(l, l'), \mu_D^u(r', r))).$$

Proof. For the forward direction, apply Definition 45.571 to the left displayed product. This gives the finite disjunction $N_D^u(l') \vee N_D^u(l) \vee N_D^u(r) \vee N_D^u(r')$.

Apply the same strict-support theorem to the swapped product in the reverse direction. Constructive case analysis on the four left disjuncts reorders them as $N_D^u(l) \vee N_D^u(l') \vee N_D^u(r') \vee N_D^u(r)$, which is exactly the support disjunction required for the swapped product.

The reverse direction is identical with the two displayed products exchanged. The swapped product first yields $N_D^u(l) \vee N_D^u(l') \vee N_D^u(r') \vee N_D^u(r)$, and constructive case analysis reorders it back to $N_D^u(l') \vee N_D^u(l) \vee N_D^u(r) \vee N_D^u(r')$. Closing Definition 45.571 in the reverse direction gives strict support of the original product. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomContextPair product strict support commutes`

Theorem 45.491 (RatUp FieldUp source has a non-singleton endpoint)**.** *Let $d_1 := \mathsf{E1}(\mathsf{e})$. For the concrete source tuple $\mathsf{RatUpFieldSource}_F$ of Definition 45.488, the field carrier accepts d_1, while the singleton empty-history carrier rejects it:*

$$\mathsf{RatHistoryCarrier}(d_1)$$

and

$$\mathsf{fieldSingletonEmptyCarrier}(d_1) \to \bot.$$

Consequently no carrier-coverage map from the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ source carrier to the singleton empty-history carrier can exist.

Proof. Unfold the carrier coordinate of $\mathsf{RatUpFieldSource}_F$ in Definition 45.488. It is exactly $\mathsf{RatHistoryCarrier}$, so the source endpoint question is the concrete RatUp carrier question.

Apply Definition 45.109 at $d_1 = \mathsf{E1}(\mathsf{e})$. It supplies the displayed $\mathsf{RatHistoryCarrier}(d_1)$ witness and the rejection map $\mathsf{fieldSingletonEmptyCarrier}(d_1) \to \bot$.

Now suppose a carrier-coverage map from the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ source carrier to $\mathsf{fieldSingletonEmptyCarrier}$ were given. Evaluating it at d_1 and the displayed RatUp carrier witness gives $\mathsf{fieldSingletonEmptyCarrier}(d_1)$, contradicting the rejection map. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat carrier singleton coverage obstruction`

Theorem 45.492 (RatUp FieldUp source coordinate coverage obstruction)**.** *Let $d_1 := \mathsf{E1}(\mathsf{e})$. For the concrete source tuple $\mathsf{RatUpFieldSource}_F$ of Definition 45.488, the diagonal endpoint supplies all three source-coordinate witnesses*

$$\mathsf{RatHistoryCarrier}(d_1),$$

$$\mathsf{RatHistoryClassifier}(d_1, d_1),$$

and

$$\mathsf{RatHistoryLedgerPolicy}(d_1, d_1).$$

Each of the following coverage maps is contradictory:

1. *carrier coverage*

$$\forall h : \mathsf{BHist}, \mathsf{RatHistoryCarrier}(h) \to \mathsf{fieldSingletonEmptyCarrier}(h);$$

2. *classifier coverage*

$$\forall hk : \mathsf{BHist}, \mathsf{RatHistoryClassifier}(h, k) \to \mathsf{FieldSingletonClassifier}(h, k);$$

3. *ledger endpoint coverage*

$$\forall \rho v : \mathsf{BHist}, \mathsf{RatHistoryLedgerPolicy}(\rho, v) \to \mathsf{FieldSingletonCarrier}(\rho) \wedge \mathsf{FieldSingletonCarrier}(v).$$

Thus the concrete source tuple cannot be collapsed to the singleton $\mathsf{Field}^{\uparrow}$ boundary in any of its carrier, classifier, or ledger coordinates.

Proof. The carrier coordinate is the one isolated in Definition 45.491. It gives the endpoint witness $\mathsf{RatHistoryCarrier}(d_1)$ and rules out any carrier-coverage map from $\mathsf{RatHistoryCarrier}$ to $\mathsf{fieldSingletonEmptyCarrier}$.

The classifier and ledger coordinates are supplied by Definition 45.110. That theorem gives the diagonal classifier witness $\mathsf{RatHistoryClassifier}(d_1, d_1)$ and the diagonal ledger witness $\mathsf{RatHistoryLedgerPolicy}(d_1, d_1)$.

The same theorem also rejects the displayed classifier coverage map and the displayed ledger endpoint coverage map. Combining these two rejections with the carrier rejection from the first paragraph leaves no coverage coordinate by which $\mathsf{RatUpFieldSource}_F$ can be read as the singleton $\mathsf{Field}^{\uparrow}$ boundary. □

Definition 45.493 (Concrete RatUp FieldUp certificate instance)**.** *The concrete certificate instance for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ is the BEDC tuple with field carrier $\mathsf{RatHistoryCarrier}$, field classifier $\mathsf{RatHistoryClassifier}$, denominator carrier $\mathsf{RatDenomUnitCarrier}$, denominator classifier $\mathsf{RatDenomUnitClassifier}$, denominator multiplication append, continuation predicate Cont, empty denominator endpoint e, apart-zero predicate $\mathsf{FieldApartZero}$, the contextual denominator action Γ of Definition 45.454, and the affine automorphism package AffAut_F of Definition 45.560.*

Its per-object fields are:

1. *traditional target: the constructive field target* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$*;*
2. *BEDC source:* $\mathsf{Rat}^{\uparrow}$ *together with* $\mathsf{CommRing}^{\uparrow}$ *and the concrete denominator BHist rows;*

9. *standard bridge: deferred conservative bridge to the ordinary constructive rational field presentation;*
10. *status:* ProofTarget*.*

Lean4 ✓ `BEDC.Derived.FieldUp.ConcreteRatupFieldupCertificateInstance`

Theorem 45.494 (Concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ paper certificate assembly)**.** *The concrete source tuple* $\mathsf{RatUpFieldSource}_F$ *of Definition 45.488, with carrier* RatHistoryCarrier*, classifier* RatHistoryClassifier*, denominator tuple* (RatDenomUnitCarrier, RatDenomUnitClassifier, append, e, RatHistoryCarrier)*, contextual action* Γ*, context-pair monoid, and affine source* AffAut_F*, supplies the paper-side carrier, source, classifier, stability, ledger, and exactness rows for the* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *proof target.*

Proof. The base name is fixed by Definition 37.85: the rational history carrier and classifier are the named $\mathsf{Rat}^{\uparrow}$ object on BHist. This supplies the semantic target over which the field source tuple is read.

Next apply Definition 45.489. It identifies $\mathsf{RatUpFieldSource}_F$ as satisfying Definition 45.337 with the same carrier, classifier, denominator tuple, contextual source, context-pair source, and affine source displayed in the statement.

The denominator-action coordinate is the component isolated by Definition 45.487. It records the envelope closure, normalized row coverage, and context-pair action certificate for the same concrete denominator tuple and the same action Γ.

The context-pair product support row is Definition 45.490. It is registered in Definition 45.493 as the strict-support commutation entry for the same denominator tuple.

The support-neutrality row is Definition 45.505. It supplies the carried nested contextual action, the collected-action classifier comparison, strict-support neutrality, and collected classifier exactness consumed by the concrete certificate instance.

Finally use Definition 45.558 for the affine source AffAut_F. Combining the RatUp name certificate, the assembled boundary, the denominator-action component, the strict-support commutation row, the support-neutrality row, and the affine group row fills exactly the carrier, source, classifier, stability, ledger, and exactness slots specified by Definition 45.337. This repacks the assembled source as the paper certificate row package for $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$. □

Per-object certificate: traditional target constructive field over rational histories; BEDC source BHist, $\mathsf{Rat}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, denominator envelope, contextual action, and affine rows; carrier $\mathsf{RatHistoryCarrier}$; classifier $\mathsf{RatHistoryClassifier}$; stability obligations commutative-ring rows, nonzero and inverse rows, denominator rows, contextual action rows, context-pair rows, context-pair strict-support commutation, and affine closure; ledger ring expressions, nonzero witnesses, denominator histories, contextual pairs, and affine coefficient witnesses; core theorem list headed by Definition 45.494, Definition 45.489, Definition 45.487, Definition 45.505, and Definition 45.490; exactness predicate the conjunction of inverse, product, denominator, denominator-action envelope, contextual-action, context-pair, support-neutrality, strict-support commutation, and affine exactness rows; standard bridge deferred; status $\mathsf{ProofTarget}$. The phase exit becomes reportable only when the canonical machine-checked certificate site is present.

Theorem 45.495 (RatUp FieldUp contextual action support transports across context-pair classifiers)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and the contextual action Γ of Definition 45.454, suppose $C^u_D(h)$ and suppose that (l, r), (s, t), (l', r'), and (s', t') are carried denominator context pairs. If $\mathsf{PairClass}^u_D((l, r), (s, t))$ and $\mathsf{PairClass}^u_D((l', r'), (s', t'))$, and if $p\mathsf{hsamee}$, $q\mathsf{hsamee}$, $p'\mathsf{hsamee}$, and $q'\mathsf{hsamee}$, then strict support is invariant under the transported two-layer contextual action:*

$$N^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))) \Longleftrightarrow N^u_D(\Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))).$$

Proof. Apply Definition 45.465 to the left pair of carried contexts and the empty endpoint hypotheses. Its support row reads the left nested action as the disjunction of the common core $N^u_D(h)$ with the four strict-support terms from (l, r) and (l', r').

Apply the same composition-closure theorem to (s, t) and (s', t'). This reads the right nested action as the same core term $N^u_D(h)$ together with the four strict-support terms from the transported context pairs.

Next use Definition 45.571 on both context-pair products. The four support terms on the left are exactly strict support of $\mu^u_D(\mu^u_D(l', l), \mu^u_D(r, r'))$, while the four support terms on the right are strict support of $\mu^u_D(\mu^u_D(s', s), \mu^u_D(t, t'))$.

The componentwise pair classifiers are the hypotheses required by Definition 45.572. They transport the product strict-support term between the two context-pair products.

For the forward direction, use the left composition readback. A core-support witness $N^u_D(h)$ is inserted directly into the right composition readback. A context-product support witness is transported across the product pair and then inserted into the corresponding four context disjuncts on the right.

The reverse direction is symmetric. Use the right composition readback, transport the product-pair support term back across the same classifier equivalence, keep the common core support fixed, and close with the left composition readback. □

↪variant BEDC.Derived.FieldUp.RatDenomUnitContextualAction pair support transport iff

Lean4 ✓ BEDC.Derived.FieldUp.field rat denominator contextual action pair transport support

Theorem 45.496 (RatUp FieldUp contextual action pair classifier transport)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and the contextual action* Γ *of Definition 45.454, suppose* $C^u_D(h)$ *and suppose that* (l, r), (s, t), (l', r'), *and* (s', t') *are carried denominator context pairs. If* $\mathsf{PairClass}^u_D((l, r), (s, t))$ *and* $\mathsf{PairClass}^u_D((l', r'), (s', t'))$, *and if* $p\mathsf{hsamee}$, $q\mathsf{hsamee}$, $p'\mathsf{hsamee}$, *and* $q'\mathsf{hsamee}$, *then the two transported two-layer contextual actions are denominator-classified:*

$$R^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h)), \Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))).$$

Proof. Apply the two-layer contextual action composition law to the left pair and to the right pair. These give carrier closure for both nested contextual actions and classify each nested action against its collected context product $\Gamma_{p',q',\mu^u_D(l',l),\mu^u_D(r,r')}(h)$ or $\Gamma_{p',q',\mu^u_D(s',s),\mu^u_D(t,t')}(h)$.

The component denominator classifiers classify the collected left context products $\mu^u_D(l', l)$ and $\mu^u_D(s', s)$ and the collected right context products $\mu^u_D(r, r')$ and $\mu^u_D(t, t')$. Combining these with reflexivity on the core h classifies the collected contextual actions under the empty endpoint hypotheses. Transitivity with the two composition classifiers gives the displayed denominator classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitContextualAction pair classifier transport`

Theorem 45.497 (RatUp FieldUp contextual action empty pair commutation)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and the contextual action* Γ *of Definition 45.454, suppose* $C^u_D(h)$ *and suppose* $C^u_D(l)$, $C^u_D(r)$, $C^u_D(l')$, *and* $C^u_D(r')$. *Then the two empty-external nested contextual actions obtained by applying* (l, r) *and* (l', r') *in opposite orders are denominator-classified:*

$$R^u_D(\Gamma_{\mathsf{e},\mathsf{e},l',r'}(\Gamma_{\mathsf{e},\mathsf{e},l,r}(h)), \Gamma_{\mathsf{e},\mathsf{e},l,r}(\Gamma_{\mathsf{e},\mathsf{e},l',r'}(h))).$$

Proof. Normalize each nested action to the collected empty-endpoint action. The first normal form has context products $\mu^u_D(l', l)$ and $\mu^u_D(r, r')$, while the second has $\mu^u_D(l, l')$ and $\mu^u_D(r', r)$. The concrete denominator append commutativity classifiers compare these two left products and these two right products. Combining those product classifiers with reflexivity on h classifies the two collected actions, and transitivity with the two normalization classifiers gives the displayed denominator classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitContextualAction empty pair commutes`

Theorem 45.498 (RatUp FieldUp contextual action empty pair strict support commutation)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and the contextual action* Γ, *suppose* $C^u_D(h)$ *and suppose* $C^u_D(l)$, $C^u_D(r)$, $C^u_D(l')$, *and* $C^u_D(r')$. *Then the two empty-external nested contextual actions obtained by applying* (l, r) *and* (l', r') *in opposite orders have equivalent strict support:*

$$N^u_D(\Gamma_{\mathsf{e},\mathsf{e},l',r'}(\Gamma_{\mathsf{e},\mathsf{e},l,r}(h))) \Longleftrightarrow N^u_D(\Gamma_{\mathsf{e},\mathsf{e},l,r}(\Gamma_{\mathsf{e},\mathsf{e},l',r'}(h))).$$

Proof. The empty-pair commutation theorem denominator-classifies the two nested actions. Its history-sameness field transports RatUp strict support in both directions, giving the displayed equivalence. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitContextualAction empty pair strict support commutes`

Theorem 45.499 (RatUp FieldUp contextual action pair transport carrier and support)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and the contextual action* Γ *of Definition 45.454, suppose* $C^u_D(h)$ *and suppose that* (l, r), (s, t), (l', r'), *and* (s', t') *are carried denominator context*

pairs. If $\mathsf{PairClass}^u_D((l,r),(s,t))$ *and* $\mathsf{PairClass}^u_D((l',r'),(s',t'))$*, and if* $p\mathsf{hsamee}$*,* $q\mathsf{hsamee}$*,* $p'\mathsf{hsamee}$*, and* $q'\mathsf{hsamee}$*, then both transported nested contextual actions are carried:*

$$C^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))) \wedge C^u_D(\Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))).$$

Their strict support is transported by the same context-pair classifiers:

$$N^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))) \Longleftrightarrow N^u_D(\Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))).$$

Proof. Apply Definition 45.465 to the carried contexts (l,r) and (l',r') with the empty endpoint hypotheses. This gives the left carrier conclusion and reads the left nested action as the five-term strict-support expression with core $N^u_D(h)$.

Apply the same composition-closure theorem to (s,t) and (s',t'). This gives the right carrier conclusion and reads the right nested action as the corresponding five-term strict-support expression with the same core term. Together these two applications establish the displayed carrier conjunction.

The context tails are compressed by Definition 45.571. On the left, the four context support terms are strict support of $\mu^u_D(\mu^u_D(l',l),\mu^u_D(r,r'))$; on the right, they are strict support of $\mu^u_D(\mu^u_D(s',s),\mu^u_D(t,t'))$.

Use Definition 45.572 under the two $\mathsf{PairClass}^u_D$ hypotheses. It transports the compressed product strict-support term between the two context-pair products.

For the forward direction of the strict-support equivalence, read the left nested action through the left composition theorem. A core witness $N^u_D(h)$ is kept fixed, while a context-product witness is transported to the right product and expanded through the right product-support readback. The right composition readback then yields support of the right nested action.

The reverse direction is the same argument with left and right interchanged. The right composition readback supplies either the common core witness or a right product-support witness; the latter is transported back across the product classifier equivalence and expanded on the left before closing with the left composition readback. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator contextual action pair transport carrier support`

Theorem 45.500 (RatUp FieldUp contextual action pair transport classifier)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and the contextual action* Γ *of Definition 45.454, suppose* $C^u_D(h)$ *and suppose* $R^u_D(l,s)$*,* $R^u_D(r,t)$*,* $R^u_D(l',s')$*, and* $R^u_D(r',t')$*. If* $p\mathsf{hsamee}$*,* $q\mathsf{hsamee}$*,* $p'\mathsf{hsamee}$*, and* $q'\mathsf{hsamee}$*, then the two transported nested contextual actions are denominator-classified:*

$$R^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h)), \Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))).$$

Proof. Apply the contextual-action composition support laws to the left nested action using the carrier fields exposed by the four classifier hypotheses. Apply the same laws to the right nested action using the transported carrier fields. The classifier equality fields identify l with s, r with t, l' with s', and r' with t', so the two concrete nested action histories are hsame. These three rows are exactly the denominator classifier. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitContextualAction pair transport classifier`

Per-object template: traditional target transported contextual-action stability; BEDC source BHist, $\mathsf{RatDenomUnitCarrier}$, $\mathsf{RatDenomUnitClassifier}$, append, empty endpoint, and Γ; stability obligations carrier closure plus strict-support transport; core theorem Definition 45.499; exactness predicate the displayed support iff; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.501 (RatUp FieldUp certificate rows are source-anchored)**.** *For the concrete source tuple* $\mathsf{RatUpFieldSource}_F$ *of Definition 45.488, every row consumed by Definition 45.493 is read over that same concrete* BHist *source: field carrier* $C_F = \mathsf{RatHistoryCarrier}$*, field classifier* $R_F = \mathsf{RatHistoryClassifier}$*, denominator tuple* $(\mathsf{RatDenomUnitCarrier}, \mathsf{RatDenomUnitClassifier}, \mathsf{append}, \mathsf{e}, \mathsf{RatHistoryCarrier})$*, contextual action* Γ*, context-pair monoid of Definition 45.479, and affine coordinate* AffAut_F*. The* $\mathsf{CommRing}^{\uparrow}$ *base coordinate is therefore consumed only through the concrete boundary Definition 45.489.*

Proof. Unpack Definition 45.488. Its field source coordinates are the rational history carrier $\mathsf{RatHistoryCarrier}$ and rational history classifier $\mathsf{RatHistoryClassifier}$, and its denominator source is the displayed tuple with multiplication append, endpoint e, and strict support $\mathsf{RatHistoryCarrier}$.

Now apply Definition 45.489. It gives the full row list for the same source tuple $\mathsf{RatUpFieldSource}_F$, including the field carrier, field classifier, denominator tuple, contextual source, context-pair source, affine source, and the base coordinate consumed by the concrete boundary.

The denominator-action rows are the component isolated by Definition 45.487. They use the same denominator tuple and the same action Γ, so their row location agrees with the assembled boundary rather than with any separate source tuple.

For the context-pair rows, use Definition 45.568 and Definition 45.490. The first theorem supplies the context-pair action certificate, while the second supplies strict-support commutation for the context-pair product named in the statement.

The assembled support-neutrality row is Definition 45.505. It uses the same denominator tuple, the same contextual action Γ, and the same named source tuple, so the nested-action carrier, collected classifier, strict-support, and classifier-exactness clauses stay anchored to $\mathsf{RatUpFieldSource}_F$.

Finally, Definition 45.558 supplies the affine row for AffAut_F. Combining these component rows with the assembled boundary pins every entry consumed by Definition 45.493 to the single source tuple $\mathsf{RatUpFieldSource}_F$. □

Per-object template: traditional target constructive field on $\mathsf{Rat}^{\uparrow}$; BEDC source $\mathsf{Rat}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ and concrete denominator BHist rows; carrier $\mathsf{RatHistoryCarrier}$; classifier $\mathsf{RatHistoryClassifier}$ together with $\mathsf{RatDenomUnitClassifier}$ on denominator rows; stability obligations inverse apartness, zero-product exactness, denominator package closure, denominator-action envelope, support-neutrality, context-pair action, context-pair strict-support commutation, and affine automorphism packaging; ledger rational history rows, denominator unit histories, continuation witnesses, contextual pairs, and apart-zero inverse witnesses; core theorem Definition 45.505, Definition 45.487, Definition 45.483, and Definition 45.490; exactness predicate row coverage for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$, including the assembled support-neutrality classifier and strict-support clauses, the denominator unit-pair support-neutrality clause, the denominator-action envelope rows, and the context-pair strict-support commutation row; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.502 (RatUp FieldUp concrete schema instance)**.** *For the concrete source tuple* $\mathsf{RatUpFieldSource}_F$*, the* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *schema is instantiated over* BHist *by* $C_F = \mathsf{RatHistoryCarrier}$*,* $R_F = \mathsf{RatHistoryClassifier}$*, the denominator tuple* $(\mathsf{RatDenomUnitCarrier}, \mathsf{RatDenomUnitClassifier}, \mathsf{append}, \mathsf{e}, \mathsf{RatHisto}$ *the contextual action* Γ*, the context-pair monoid of Definition 45.479, and the affine source* AffAut_F*. Every carrier, source, classifier, stability, ledger, and exactness row consumed by Definition 45.493 is a row of this same source tuple, so no* $\mathsf{Field}^{\uparrow}$ *exit row remains as a schematic* mul*,* add*, or* neg *operator parameter.*

Proof. Unfold Definition 45.493. Its displayed fields are exactly the rational history carrier and classifier, the denominator carrier, denominator classifier, multiplication append, endpoint e, contextual action Γ, context-pair monoid rows, and affine package named in the theorem statement.

Apply Definition 45.494 to obtain the paper certificate row package for this source. It supplies the carrier, source, classifier, stability, ledger, and exactness slots for the same $\mathsf{RatUpFieldSource}_F$ tuple.

Next use Definition 45.501. This identifies every row consumed by the concrete certificate instance with the single BHist source tuple, including the denominator tuple, the contextual action, the context-pair monoid, and the affine coordinate.

Finally apply Definition 45.489. The assembled boundary contains the full carrier, classifier, denominator, contextual-action, context-pair, affine, ledger, and exactness rows, with the denominator-action and support-neutrality components supplied by the theorem list in Definition 45.493. Combining these rows shows that the $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ schema is the concrete BHist instance rather than a transport through free operator parameters. □

Per-object template: traditional target constructive field on $\mathsf{Rat}^{\uparrow}$; BEDC source BHist plus $\mathsf{Rat}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, denominator, and affine rows; carrier RatHistoryCarrier; classifier RatHistoryClassifier plus RatDenomUnitClassifier on denominator rows; stability obligations the assembled boundary rows; ledger rational histories, denominator histories, continuation and action witnesses, and affine coefficients; core theorem Definition 45.502; exactness row coverage for the concrete source tuple; standard bridge deferred; status ProofTarget.

Theorem 45.503 (RatUp FieldUp semantic certificate assembly)**.** *For the concrete* BHist *data* RatHistoryCarrier*,* RatHistoryClassifier*,* RatDenomUnitCarrier*,* RatDenomUnitClassifier*,* append*,* Cont*,* e*, and strict support* RatHistoryCarrier*, the row-location invariant of Definition 45.501 reads the* $\mathsf{CommRing}^{\uparrow}$ *base coordinate, the FieldUp-specific inverse and apart-zero rows, the two-sided zero-product and nonzero-product rows, the denominator multiplicative rows, the denominator-action envelope rows, contextual denominator rows, the denominator support-neutrality rows, the denominator unit-pair support-neutrality row, the denominator context-pair action rows, the context-pair strict-support commutation row, and the packaged affine* $\mathsf{Group}^{\uparrow}$ *consequence over the same concrete* BHist *source. These rows supply the carrier, source, pattern, classifier, stability, ledger, and exactness rows of Definition 45.337 for the concrete target* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$*. More explicitly, Definition 45.493 supplies the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *certificate rows.*

Proof. Bind the rational carrier and classifier first. The object carrier is RatHistoryCarrier, the object classifier is RatHistoryClassifier, and the source pattern is the BEDC continuation pattern Cont over BHist. The denominator tuple is (RatDenomUnitCarrier, RatDenomUnitClassifier, append, e, RatHistoryCarrier), with contextual action Γ and affine coordinate AffAut_F as fixed in Definition 45.493.

The source anchor is Definition 45.501. It reads the $\mathsf{CommRing}^{\uparrow}$ base coordinate through Definition 45.489 and pins the field carrier, field classifier, denominator tuple, contextual action, context-pair monoid, and affine coordinate to the same concrete source tuple.

The inverse rows are the apart-zero rows. Theorem 45.206 supplies classifier exactness for proof-indexed inverses over the concrete apart-zero predicate, so the inverse classifier, inverse stability, and nonzero transport entries are read from the displayed apartness witnesses.

The zero-product rows come from Definition 45.246. Its two-sided multiplication equivalence gives exact zero classification after certified nonzero left and right factors, and the same witness data supply the nonzero-product contradiction row in the per-object certificate record.

For the denominator part, use Definition 45.439 for the multiplicative denominator rows and Definition 45.471 for the closed denominator-side package.

The denominator-action envelope component is supplied by Definition 45.487. It records the multiplicative coverage, contextual boundary, normalized row coverage, and context-pair product and action rows over the concrete tuple fixed above.

The contextual denominator action is supplied by Definition 45.568, Definition 45.483, and Definition 45.478. They package the pair classifier, pair product, unit-pair action, product-pair composition law, collected-action exactness, unit-pair support neutrality, and strict-support readback over the same BHist denominator tuple, so the contextual exactness and support-neutrality rows align with the denominator ledger entries.

Definition 45.505 supplies the carried nested contextual action, the collected-action classifier comparison, the strict-support equivalence, and the collected classifier exactness consumed by the final FieldUp record. Thus the support-neutrality row appearing in Definition 45.493 is a concrete certificate dependency rather than a detached denominator fact.

Separately, Definition 45.490 supplies the strict-support commutation row for the context-pair product. This is the support-transport row consumed by Definition 45.493 between the context-pair action certificate and the final FieldUp record.

Finally, Definition 45.558 supplies the packaged affine $\mathsf{Group}^{\uparrow}$ consequence consumed by the field certificate.

Together the $\mathsf{CommRing}^{\uparrow}$ base rows, the inverse rows, the zero-product rows, the denominator multiplicative rows, the denominator-action envelope component, the contextual denominator rows, the support-neutrality row, the unit-pair support-neutrality row, the context-pair action rows, the strict-support commutation row, and the affine $\mathsf{Group}^{\uparrow}$ row exhaust the ten-entry per-object template of Definition 45.493: target, source, carrier, classifier, stability obligations, ledger, core theorem list, exactness predicate, standard bridge, and status. □

Theorem 45.504 (RatUp FieldUp semantic certificate is non-singleton)**.** *Let* $d_1 := \mathsf{E1}(\mathsf{e})$*. The concrete certificate rows of Definition 45.493 and Definition 45.503 are carried by the single source tuple* $\mathsf{RatUpFieldSource}_F$*. This same source has the diagonal witnesses*

$$\mathsf{RatHistoryCarrier}(d_1),$$

$$\mathsf{RatHistoryClassifier}(d_1, d_1),$$

and

$$\mathsf{RatHistoryLedgerPolicy}(d_1, d_1).$$

Each of the following singleton-boundary coverage maps is contradictory:

1. *carrier coverage*

$$\forall h : \mathsf{BHist}, \mathsf{RatHistoryCarrier}(h) \to \mathsf{fieldSingletonEmptyCarrier}(h);$$

2. *classifier coverage*

$$\forall hk : \mathsf{BHist}, \mathsf{RatHistoryClassifier}(h, k) \to \mathsf{FieldSingletonClassifier}(h, k);$$

3. *ledger endpoint coverage*

$$\forall \rho v : \mathsf{BHist}, \mathsf{RatHistoryLedgerPolicy}(\rho, v) \to \mathsf{FieldSingletonCarrier}(\rho) \wedge \mathsf{FieldSingletonCarrier}(v).$$

Consequently the semantic certificate rows for $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *are sourced by the concrete* BHist *tuple and cannot collapse to the singleton* $\mathsf{Field}^{\uparrow}$ *boundary in carrier, classifier, or ledger coordinates.*

Proof. The one-source assertion is Definition 45.501. It identifies the field carrier, field classifier, denominator tuple, contextual action, context-pair monoid, and affine coordinate as rows read over the single source tuple $\mathsf{RatUpFieldSource}_F$.

Next use Definition 45.503. It says that those rows are exactly the concrete certificate rows consumed by Definition 45.493 for the target $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$.

Finally apply Definition 45.492 at $d_1 = \mathsf{E1}(\mathsf{e})$. That theorem supplies the three diagonal witnesses and separately rules out carrier, classifier, and ledger endpoint coverage maps to the singleton $\mathsf{Field}^{\uparrow}$ boundary.

Combining the source-anchored certificate rows with these three coordinate obstructions gives the claimed non-singleton semantic certificate boundary. □

Theorem 45.505 (RatUp FieldUp assembled support-neutrality certificate)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$, the contextual action Γ of Definition 45.454, and the named source tuple $\mathsf{RatUpFieldSource}_F$, the assembled $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ certificate includes the support-neutrality row below. Under the hypotheses of Definition 45.478, the nested action is carried:*

$$C^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))).$$

It is classified by the collected action:

$$R^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h)), \Gamma_{p',q',\mu^u_D(l',l),\mu^u_D(r,r')}(h)).$$

It satisfies strict-support neutrality:

$$N^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))) \Longleftrightarrow N^u_D(h).$$

For any second endpoint k under the same collected carried contexts, and for s, t, s', t' satisfying $s\mathsf{hsamee}$, $t\mathsf{hsamee}$, $s'\mathsf{hsamee}$, and $t'\mathsf{hsamee}$, the collected action remains classifier-exact against that endpoint:

$$R^u_D(\Gamma_{s,t,\mu^u_D(l',l),\mu^u_D(r,r')}(h), \Gamma_{s',t',\mu^u_D(l',l),\mu^u_D(r,r')}(k)) \Longleftrightarrow R^u_D(h,k).$$

Lean4 ✓ `BEDC.Derived.FieldUp.RatupFieldupAssembledSupportNeutralityCertificate`

Proof. The assembled boundary is fixed by Definition 45.489. It places $\mathsf{RatUpFieldSource}_F$, the displayed denominator tuple, and the action Γ inside the concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ certificate governed by Definition 45.337.

Within that boundary, use Definition 45.478. Its hypotheses are exactly the carried-denominator, empty external-context, and strict-support hypotheses named in the statement. The theorem supplies the carried nested action and its classifier comparison with the collected action.

The same row supplies the strict-support equivalence $N^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))) \Longleftrightarrow N^u_D(h)$. It also supplies classifier exactness for the collected action against the second endpoint k. These four conclusions are therefore available as one support-neutrality row of the assembled FieldUp certificate. □

Theorem 45.506 (RatUp FieldUp support-neutrality row completeness)**.** *For the concrete source tuple $\mathsf{RatUpFieldSource}_F$ and Definition 45.493, the support-sensitive certificate rows are exactly the concrete BHist rows supplied by the following sources:*

1. *strict product support exactness for the denominator product;*
2. *context-pair unit support neutrality;*

3. total-normalization support collapse;

4. contextual action carrier, classifier, and support neutrality;

5. context-pair strict-support commutation.

Thus the named certificate instance contains every support row consumed by the assembled semantic $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *certificate.*

Proof. The denominator product support row is the concrete BHist row supplied by Definition 45.402. It fixes the strict product support exactness entry over the same denominator carrier, classifier, product, and empty endpoint used by $\mathsf{RatUpFieldSource}_F$.

The unit-pair and total-normalization rows are supplied by Definition 45.483 and Definition 45.478. Together they give the unit-pair support-neutrality clause, the total-normalization support collapse clause, and the contextual action carrier and classifier clauses for the concrete action Γ.

The contextual strict-support transport is the context-pair product row of Definition 45.490. It uses the same context-pair product and the same strict support predicate as the certificate instance, so it is the remaining support-sensitive transport row.

Finally Definition 45.505 repacks these concrete rows as the assembled support-neutrality certificate for $\mathsf{RatUpFieldSource}_F$. Since Definition 45.493 names exactly these stability, ledger, core theorem, and exactness entries, no additional support-sensitive row is required for the semantic assembly. □

Per-object template: traditional target constructive field on $\mathsf{Rat}^{\uparrow}$; BEDC source $\mathsf{Rat}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ and concrete denominator BHist rows; carrier $\mathsf{RatHistoryCarrier}$; classifier $\mathsf{RatHistoryClassifier}$ together with $\mathsf{RatDenomUnitClassifier}$ on denominator rows; stability obligations inverse apartness, zero-product exactness, denominator package closure, denominator-action envelope, support-neutrality, transported support-neutrality, context-pair action, context-pair strict-support commutation, and affine automorphism packaging; ledger rational history rows, denominator unit histories, continuation witnesses, contextual pairs, and apart-zero inverse witnesses; core theorem Definition 45.503, Definition 45.505, Definition 45.487, Definition 45.483, and Definition 45.490; exactness predicate row coverage for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$, including the assembled support-neutrality classifier and strict-support clauses, the transported support-neutrality row, the denominator unit-pair support-neutrality clause, the denominator-action envelope rows, and the context-pair strict-support commutation row; standard bridge deferred; status $\mathsf{ProofTarget}$.

45.21 RatUp FieldUp exit support rows

Theorem 45.507 (RatUp FieldUp exit support row inventory)**.** *For the concrete source tuple* $\mathsf{RatUpFieldSource}_F$ *and the denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *exit certificate contains a closed support-row inventory consisting of the following certificate rows:*

1. support-neutrality row completeness from Definition 45.506;

2. the nontrivial carrier and support-neutral action package from Definition 45.508;

3. transported and iterated support-neutrality rows from Definition 45.509 and Definition 45.510;

4. transported strict-support separation from Definition 45.520;

5. threefold denominator support noncollapse from Definition 45.580.

Every listed row is a concrete BHist *row over* append*,* Cont*,* Γ*,* RatHistoryCarrier*, and* RatHistoryClassifier*. Thus the exit certificate has concrete support-row coverage for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *with no schematic operation parameter.*

Proof. First read Definition 45.506. It identifies the support-sensitive rows of Definition 45.493 as concrete BHist rows of the assembled semantic certificate.

Next apply Definition 45.508. This places the non-singleton source carrier, the denominator tuple, and the support-neutral contextual action inside the same concrete exit certificate.

Then compose the two transport layers. The first layer is Definition 45.509, and the second layer is Definition 45.510. They keep the carried contextual action and the strict-support predicate tied to the original denominator history through classified context-pair transport.

Now attach the strict-support separation package by applying Definition 45.520. It turns transported strict RatUp support into carrier recovery, singleton exclusion, and direct empty-history separation for the transported endpoint.

Finally apply Definition 45.580. This supplies the denominator product support obstruction against the singleton empty classifier. The cited rows use only the displayed concrete carrier, classifier, append, continuation, and contextual-action data, so the collected inventory has no remaining schematic operation parameter. □

Per-object template: traditional target $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit support inventory; BEDC source $\mathsf{RatUpFieldSource}_F$, BHist, append, Cont, and Γ; carrier RatHistoryCarrier plus N^u_D; classifier RatHistoryClassifier plus singleton-boundary obstruction; stability obligations support neutrality, transported support neutrality, strict-support transport, and threefold support noncollapse; ledger denominator support witnesses and contextual-pair action witnesses; core theorem list Definition 45.506, Definition 45.508, Definition 45.509, Definition 45.510, Definition 45.520, and Definition 45.580; exactness predicate concrete support-row coverage for the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit certificate; standard bridge deferred; status ProofTarget.

Theorem 45.508 (RatUp FieldUp exit certificate has nontrivial carrier and support-neutral action)**.** *For Definition 45.493 and* $d_1 := \mathsf{E1}(\mathsf{e})$*, the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *exit certificate has both a nontrivial source carrier and a support-neutral contextual action. Specifically:*

1. $\mathsf{RatHistoryCarrier}(d_1)$ *holds;*
2. $\mathsf{fieldSingletonEmptyCarrier}(d_1) \to \bot$*;*
3. *no carrier-coverage map from the* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *source carrier to* fieldSingletonEmptyCarrier *exists;*
4. *under the hypotheses of Definition 45.505, the nested contextual action is carried, classified by the collected action, support-neutral, and classifier-exact against the second endpoint.*

Equivalently, the same named certificate contains the endpoint obstruction

$$\mathsf{RatHistoryCarrier}(d_1)$$

with

$$\mathsf{fieldSingletonEmptyCarrier}(d_1) \to \bot$$

and the contextual-action row

$$C^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))),$$

$$R^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h)), \Gamma_{p',q',\mu^u_D(l',l),\mu^u_D(r,r')}(h)),$$

$$N_D^u(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))) \iff N_D^u(h),$$

and, for the second endpoint k with empty external contexts,

$$R_D^u(\Gamma_{s,t,\mu_D^u(l',l),\mu_D^u(r,r')}(h), \Gamma_{s',t',\mu_D^u(l',l),\mu_D^u(r,r')}(k)) \iff R_D^u(h,k).$$

Proof. The concrete certificate is fixed by Definition 45.494. It identifies Definition 45.493 as the paper certificate row package for the displayed $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ source tuple, so the carrier, classifier, denominator tuple, and contextual action are the concrete rows named in the statement.

The carrier obstruction comes from Definition 45.491. With $d_1 := \mathsf{E1}(\mathsf{e})$ it supplies $\mathsf{RatHistoryCarrier}(d_1)$, the map $\mathsf{fieldSingletonEmptyCarrier}(d_1) \to \bot$, and the contradiction against any carrier-coverage map into the singleton empty-history carrier.

Finally apply Definition 45.505. Under its carried-context and strict-support hypotheses, it supplies the nested carried action, the collected-action classifier comparison, strict-support neutrality, and classifier exactness against the second endpoint. These rows belong to the same certificate fixed above, so the non-singleton carrier and support-neutral action are simultaneous properties of the concrete exit certificate. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatupFieldupExitCertificateNontrivialSupportNeutral`

Theorem 45.509 (RatUp FieldUp transported support-neutrality certificate)**.** *For the concrete denominator tuple $(C_D^u, R_D^u, \mu_D^u, e_D^u, N_D^u)$ and the contextual action Γ of Definition 45.454, suppose the hypotheses of Definition 45.505 hold for the context pairs (l,r) and (l',r'). Suppose also that the transported context pairs (s,t) and (s',t') are carried and that the pair classifiers required by Definition 45.499 compare (l,r) with (s,t) and (l',r') with (s',t'). Then the transported nested action is carried:*

$$C_D^u(\Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))).$$

Its strict support is neutral against the original denominator history:

$$N_D^u(\Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))) \iff N_D^u(h).$$

Proof. Apply Definition 45.499 to the carried context pairs and the two pair classifiers. The transported carrier conclusion is the second carried component, and the same theorem gives the strict-support equivalence between the original nested action and the transported nested action.

Apply Definition 45.505 to the original context pairs (l,r) and (l',r'). This supplies $N_D^u(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))) \Longleftarrow N_D^u(h)$.

For the forward direction, read support of the transported nested action back through the transport equivalence, then use the assembled support-neutrality row to obtain $N_D^u(h)$.

For the reverse direction, use assembled support-neutrality to obtain support of the original nested action, then move it across the transport equivalence to the transported context-pair representative. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatupFieldupTransportedSupportNeutralityRow`

Theorem 45.510 (RatUp FieldUp iterated transported support-neutrality row)**.** *For the concrete denominator tuple $(C_D^u, R_D^u, \mu_D^u, e_D^u, N_D^u)$ and the contextual action Γ of Definition 45.454, suppose the hypotheses of Definition 45.509 transport $(l,r),(l',r')$ to $(s,t),(s',t')$. Suppose also that (u,v) and (u',v') are carried denominator context pairs and that the pair classifiers required by Definition 45.499 compare (s,t) with (u,v) and (s',t') with (u',v'). Then the twice transported nested action is carried:*

$$C_D^u(\Gamma_{p',q',u',v'}(\Gamma_{p,q,u,v}(h))).$$

Its strict support is still neutral against the original denominator history:

$$N_D^u(\Gamma_{p',q',u',v'}(\Gamma_{p,q,u,v}(h))) \Longleftrightarrow N_D^u(h).$$

Proof. First apply Definition 45.509 to the comparison from $(l, r), (l', r')$ to $(s, t), (s', t')$. This supplies the carried nested action at the $(s, t), (s', t')$ representative and the strict-support equivalence

$$N_D^u(\Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))) \Longleftrightarrow N_D^u(h).$$

Next apply Definition 45.499 to the carried context pairs (s, t), (u, v), (s', t'), and (u', v'). The carrier component gives $C_D^u(\Gamma_{p',q',u',v'}(\Gamma_{p,q,u,v}(h)))$, and the support component compares the $(s, t), (s', t')$ representative with the $(u, v), (u', v')$ representative.

For the forward direction of the displayed equivalence, read support of the $(u, v), (u', v')$ representative back through the second transport equivalence and then through the first transported support-neutrality row to obtain $N_D^u(h)$.

For the reverse direction, use the first transported support-neutrality row to obtain support of the $(s, t), (s', t')$ representative, then move it across the second transport equivalence to the twice transported representative. □

Per-object template: traditional target constructive field on $\mathsf{Rat}^{\uparrow}$; BEDC source $\mathsf{Rat}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ and concrete denominator BHist rows; carrier $\mathsf{RatHistoryCarrier}$; classifier $\mathsf{RatHistoryClassifier}$ together with $\mathsf{RatDenomUnitClassifier}$ on denominator rows; stability obligations inverse apartness, zero-product exactness, denominator package closure, denominator-action envelope, support-neutrality, transported support-neutrality, context-pair action, context-pair strict-support commutation, and affine automorphism packaging; ledger rational history rows, denominator unit histories, continuation witnesses, contextual pairs, and apart-zero inverse witnesses; core theorem Definition 45.503, Definition 45.505, Definition 45.509, Definition 45.510, Definition 45.487, Definition 45.483, and Definition 45.490; exactness predicate row coverage for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$, including the assembled support-neutrality classifier and strict-support clauses, the transported support-neutrality row, the denominator unit-pair support-neutrality clause, the denominator-action envelope rows, and the context-pair strict-support commutation row; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.511 (RatUp FieldUp transported nondegenerate exit certificate)**.** *Let* $d_1 := \mathsf{E1}(\mathsf{e})$*. For Definition 45.493, under the hypotheses of Definition 45.509, the same concrete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *exit certificate contains the source nondegeneracy and the transported support-neutrality conclusions:*

1. $\mathsf{RatHistoryCarrier}(d_1)$*;*
2. $\mathsf{fieldSingletonEmptyCarrier}(d_1) \to \bot$*;*
3. *the transported nested action carrier conclusion*

$$C_D^u(\Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h)))$$

4. *the transported strict-support neutrality conclusion*

$$N_D^u(\Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))) \Longleftrightarrow N_D^u(h).$$

Proof. First fix the certificate site. Theorem 45.503 reads Definition 45.493 as the concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ certificate, and Definition 45.501 pins its rows to the same BHist source tuple.

The endpoint part is supplied by Definition 45.491. At $d_1 = \mathsf{E1}(\mathsf{e})$ it gives both $\mathsf{RatHistoryCarrier}(d_1)$ and $\mathsf{fieldSingletonEmptyCarrier}(d_1) \to \bot$ over that source.

It remains to read the transported action row. Under the stated hypotheses, Definition 45.509 supplies the carried transported nested action and the displayed strict-support equivalence. Because the certificate assembly and source-anchoring theorems identify these rows as entries of the same concrete certificate instance, the four displayed conclusions coexist in the single exit certificate. □

Per-object template: traditional target constructive field on $\mathsf{Rat}^{\uparrow}$; BEDC source $\mathsf{Rat}^{\uparrow}$ plus $\mathsf{CommRing}^{\uparrow}$ and concrete denominator BHist rows; carrier $\mathsf{RatHistoryCarrier}$; classifier $\mathsf{RatHistoryClassifier}$ together with $\mathsf{RatDenomUnitClassifier}$ on denominator rows; stability obligations inverse apartness, zero-product exactness, denominator package closure, denominator-action envelope, support-neutrality, transported support-neutrality, context-pair action, context-pair strict-support commutation, and affine automorphism packaging; ledger rational history rows, denominator unit histories, continuation witnesses, contextual pairs, and apart-zero inverse witnesses; core theorem Definition 45.503, Definition 45.505, Definition 45.509, Definition 45.487, Definition 45.483, and Definition 45.490; exactness predicate row coverage for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$, including the assembled support-neutrality classifier and strict-support clauses, the transported support-neutrality row, the denominator unit-pair support-neutrality clause, the denominator-action envelope rows, and the context-pair strict-support commutation row; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.512 (RatUp FieldUp nondegenerate semantic exit source)**.** *Let $d_1 := \mathsf{E1}(\mathsf{e})$. For the concrete source tuple $\mathsf{RatUpFieldSource}_F$ of Definition 45.488, the same BHist data simultaneously give the following four pieces of the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit source:*

1. *the assembled semantic naming certificate rows for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$;*
2. *source anchoring of all certificate rows at $\mathsf{RatHistoryCarrier}$ and $\mathsf{RatHistoryClassifier}$;*
3. *the assembled support-neutrality row for the denominator contextual action Γ;*
4. *the endpoint separation*
$$\mathsf{RatHistoryCarrier}(d_1)$$
together with
$$\mathsf{fieldSingletonEmptyCarrier}(d_1) \to \bot.$$

Consequently the semantic exit source for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ over $\mathsf{RatUpFieldSource}_F$ is not collapsible to the singleton empty-history $\mathsf{Field}^{\uparrow}$ source.

Proof. The semantic certificate rows are those assembled in Definition 45.503. They include the carrier, source, classifier, stability, ledger, exactness, and affine rows of the concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ certificate.

The common source location is fixed by Definition 45.501. It identifies the field carrier as $\mathsf{RatHistoryCarrier}$, the field classifier as $\mathsf{RatHistoryClassifier}$, and the denominator, contextual-action, context-pair, and affine rows as entries of the same $\mathsf{RatUpFieldSource}_F$ tuple.

The denominator contextual action contributes the support-neutrality component through Definition 45.505. Thus the assembled certificate contains the carried nested action, the collected-action classifier comparison, strict-support neutrality, and the second-endpoint classifier exactness row over the denominator tuple.

Finally, Definition 45.491 supplies the displayed endpoint $d_1 = \mathsf{E1}(\mathsf{e})$, its $\mathsf{RatHistoryCarrier}(d_1)$ witness, and the rejection map $\mathsf{fieldSingletonEmptyCarrier}(d_1) \to \bot$. Any collapse to the singleton empty-history $\mathsf{Field}^{\uparrow}$ source would have to send this carried endpoint to the singleton carrier, contradicting that rejection map. □

Theorem 45.513 (RatUp FieldUp concrete exit row closure)**.** *Let $d_1 := \mathsf{E1}(\mathsf{e})$. For the concrete source tuple $\mathsf{RatUpFieldSource}_F$ of Definition 45.488, the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit row package is the concrete* BHist*-anchored closure jointly supplied by the following data:*

1. *the semantic certificate rows of Definition 45.503;*
2. *the source anchoring rows of Definition 45.501;*
3. *the support-sensitive row coverage of Definition 45.506;*
4. *the endpoint facts $\mathsf{RatHistoryCarrier}(d_1)$ and $\mathsf{fieldSingletonEmptyCarrier}(d_1) \to \bot$;*
5. *the shared concrete row language over* RatHistoryCarrier*,* RatHistoryClassifier*,* RatDenomUnitCarrier*,* RatDenomUnitClassifier*,* append*,* Cont*,* e*, Γ, and AffAut_F.*

Thus the displayed exit package is a concrete closure over $\mathsf{RatUpFieldSource}_F$ and not an instance of an abstract operator schema.

Proof. Apply Definition 45.503 first. It gives the assembled carrier, source, pattern, classifier, stability, ledger, and exactness rows for the concrete target $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$.

Apply Definition 45.501 next. It pins those rows to the single source tuple $\mathsf{RatUpFieldSource}_F$, with field carrier RatHistoryCarrier, field classifier RatHistoryClassifier, denominator tuple (RatDenomUnitCarrier, Rat contextual action Γ, and affine coordinate AffAut_F.

The support-sensitive part is closed by Definition 45.506. It records that the support rows consumed by the assembled semantic certificate are precisely the concrete BHist rows already present in the named certificate instance.

Finally, Definition 45.512 supplies the endpoint $d_1 = \mathsf{E1}(\mathsf{e})$, the witness $\mathsf{RatHistoryCarrier}(d_1)$, and the rejection map $\mathsf{fieldSingletonEmptyCarrier}(d_1) \to \bot$. Combining these four cited sites repacks the existing rows as one concrete closure theorem for the exit package. The result is therefore a composite closure statement, not a variant of any single checked theorem. □

Per-object template: traditional target constructive field over rational histories; BEDC source BHist, $\mathsf{Rat}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, denominator tuple, contextual action, context-pair action, and affine rows; carrier RatHistoryCarrier; classifier RatHistoryClassifier; stability rows Definition 45.503, Definition 45.501, and Definition 45.505; ledger rational histories, denominator histories, contextual pairs, support witnesses, and affine coefficients; core theorem Definition 45.512 together with Definition 45.503, Definition 45.501, Definition 45.505, and Definition 45.491; exactness the assembled row coverage plus non-singleton source separation; standard bridge deferred; status ProofTarget.

Theorem 45.514 (RatUp FieldUp empty-context nondegenerate witness)**.** *Let $d_1 := \mathsf{E1}(\mathsf{e})$. For histories $L, R : \mathsf{BHist}$, assume $\mathsf{fieldSingletonEmptyCarrier}(L)$ and $\mathsf{fieldSingletonEmptyCarrier}(R)$. Put $w := \mathsf{append}(L, \mathsf{append}(d_1, R))$. Then the wrapped endpoint satisfies*

$$\mathsf{RatHistoryCarrier}(w),$$

the rejection map

$$\mathsf{fieldSingletonEmptyCarrier}(w) \to \bot,$$

and the nonzero-complement clause

$$\mathsf{fieldSingletonEmptyNonZero}(w).$$

Thus the non-singleton rational witness remains stable under empty singleton context wrapping on both sides.

Proof. The hypotheses place both contextual wrappers in the singleton empty carrier. By the singleton-empty carrier inversion for $\mathsf{Field}^{\uparrow}$, each wrapper compares by hsame with e.

Use the left and right append-unit laws, together with the continuation compatibility of append and transitivity of hsame, to compare

$$w = \mathsf{append}(L, \mathsf{append}(d_1, R))$$

with the endpoint d_1. This comparison is the transport path for all carrier and classifier predicates used below.

Apply Definition 45.512. It supplies $\mathsf{RatHistoryCarrier}(d_1)$ and the rejection map $\mathsf{fieldSingletonEmptyCarrier}(d_1) \to \bot$. Transport the rational carrier witness from d_1 to w along the displayed hsame comparison.

For rejection at w, take any hypothetical $\mathsf{fieldSingletonEmptyCarrier}(w)$ witness. Transport it back along the same comparison to obtain a singleton-empty carrier witness for d_1, and contradict the rejection map from Definition 45.512.

It remains to obtain the nonzero clause. Unfold $\mathsf{fieldSingletonEmptyNonZero}(w)$ as the function type

$$\mathsf{fieldSingletonEmptyClassifier}(w, \mathsf{e}) \to \bot.$$

Given a classifier witness for (w, e), take its source-carrier component $\mathsf{fieldSingletonEmptyCarrier}(w)$. Applying the rejection map for w constructed in the preceding paragraph gives the required contradiction. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup empty context nondegenerate witness`

Per-object template: traditional target context-stable nondegenerate rational field witness; BEDC source BHist, $\mathsf{Rat}^{\uparrow}$, Cont, and singleton $\mathsf{Field}^{\uparrow}$ carrier; carrier choice $\mathsf{RatHistoryCarrier}$; classifier choice singleton empty classifier for the obstruction; stability obligations append-unit transport and carrier transport; ledger empty context wrappers; core theorem Definition 45.514 together with Definition 45.512; exactness predicate preservation of the non-singleton witness under empty wrappers; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.515 (RatUp FieldUp transported strict-support non-singleton endpoint)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and the contextual action Γ of Definition 45.454, let $x := \Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))$. Under the hypotheses of Definition 45.509, suppose also that $N^u_D(h)$ holds. Then the concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit certificate contains all of the following endpoint data:*

1. *$C^u_D(x)$;*
2. *$N^u_D(x)$;*
3. *$\mathsf{RatHistoryCarrier}(x)$;*
4. *$\mathsf{fieldSingletonEmptyCarrier}(x) \to \bot$.*

Thus the transported strict-support endpoint of the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit certificate cannot collapse into the singleton empty-history field carrier.

Proof. Apply Definition 45.511 at the same transported endpoint. It gives the carried endpoint clause $C^u_D(x)$ and the strict-support equivalence

$$N^u_D(x) \Longleftrightarrow N^u_D(h).$$

Use the reverse direction of this equivalence with the displayed witness $N^u_D(h)$. This produces the transported strict-support witness $N^u_D(x)$.

Now read the denominator tuple row from Definition 45.438. There $N^u_D(y) = \mathsf{RatHistoryCarrier}(y)$ for every denominator history y, so the transported support witness gives $\mathsf{RatHistoryCarrier}(x)$.

Finally apply Definition 45.98 to x. Any witness of $\mathsf{fieldSingletonEmptyCarrier}(x)$, together with the Rat history carrier witness just obtained, yields contradiction. This is the displayed map $\mathsf{fieldSingletonEmptyCarrier}(x) \to \bot$. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup transported strict support non singleton`

Theorem 45.516 (RatUp FieldUp transported strict-support contextual singleton exclusion)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and the contextual action Γ of Definition 45.454, let $x := \Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))$. Under the hypotheses of Definition 45.509, suppose also that $N^u_D(h)$ holds. Then for every context history $r : \mathsf{BHist}$ both boundary collapses are impossible:*

1. $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, x)) \to \bot$;
2. $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x, r)) \to \bot$.

Proof. Apply Definition 45.515 at the same transported endpoint. The endpoint data supplied there includes $\mathsf{RatHistoryCarrier}(x)$.

For the right-factor append boundary, apply Definition 45.101 with the context history r and the RatUp factor x. The displayed Rat carrier witness turns any witness of $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, x))$ into contradiction.

For the left-factor append boundary, apply Definition 45.102 with the same RatUp factor x and context history r. The same carrier witness turns any witness of $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x, r))$ into contradiction. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitContextualAction strict support contextual singleton exclusion`
Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup transported strict support contextual singleton exclusion`

Theorem 45.517 (Rat denominator unit contextual action strict-support singleton classifier exclusion)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and the contextual action Γ of Definition 45.454, let $x := \Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))$. Under the same empty endpoint and carried-context hypotheses as Definition 45.516, suppose also that $N^u_D(h)$ holds. Then for all histories $L, R : \mathsf{BHist}$ the singleton empty classifier cannot classify the two contextual endpoints with the same strict-support tail:*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, x)) \to \bot.$$

Proof. The contextual action support law reads the strict-support predicate of x as the disjunction of the outer left support, inner left support, core support, inner right support, and outer right support. Insert the displayed witness $N^u_D(h)$ into the core disjunct to obtain $\mathsf{RatHistoryCarrier}(x)$.

Package this witness with itself and reflexivity of hsame to obtain the concrete $\mathsf{RatHistoryClassifier}(x, x)$. The Rat/singleton boundary separation theorem Definition 45.104 then rules out any singleton empty classifier on $\mathsf{append}(L, x)$ and $\mathsf{append}(R, x)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitContextualAction strict support singleton classifier exclusion`

Theorem 45.518 (RatUp FieldUp transported strict-support singleton classifier exclusion)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and the contextual action* Γ *of Definition 45.454, let* $x := \Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))$*. Under the hypotheses of Definition 45.509, suppose also that the transported source endpoint carries strict RatUp support. Then for all histories* $L, R : \mathsf{BHist}$*,*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, x)) \to \bot.$$

Proof. Transport the strict RatUp support across the classified contextual pair, giving $\mathsf{RatHistoryCarrier}(x)$. Together with itself and reflexivity of hsame, this forms the concrete classifier $\mathsf{RatHistoryClassifier}(x, x)$. The Rat/singleton boundary separation theorem Definition 45.104 then rejects any singleton empty classifier on the two appended endpoints. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup transported strict support singleton classifier exclusion`

Theorem 45.519 (RatUp FieldUp iterated transported strict-support contextual singleton exclusion)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and the contextual action* Γ *of Definition 45.454, let* $y := \Gamma_{p',q',u',v'}(\Gamma_{p,q,u,v}(h))$*. Under the hypotheses of Definition 45.510, suppose also that* $N^u_D(h)$ *holds. Then the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *exit certificate contains the following endpoint and contextual exclusion package:*

1. $C^u_D(y)$*;*
2. $N^u_D(y)$*;*
3. $\mathsf{RatHistoryCarrier}(y)$*;*
4. $\mathsf{fieldSingletonEmptyCarrier}(y) \to \bot$*;*
5. *for every* $r : \mathsf{BHist}$*,* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, y)) \to \bot$*;*
6. *for every* $r : \mathsf{BHist}$*,* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(y, r)) \to \bot$*.*

Proof. Apply Definition 45.510 to the same carried context-pair comparisons. This supplies $C^u_D(y)$ and the strict-support equivalence

$$N^u_D(y) \Longleftrightarrow N^u_D(h).$$

Use the reverse direction of the equivalence with the assumed witness $N^u_D(h)$. This gives $N^u_D(y)$.

Read the concrete strict support row from Definition 45.438. There $N^u_D(z) = \mathsf{RatHistoryCarrier}(z)$ for every denominator history z, hence the support witness at y gives $\mathsf{RatHistoryCarrier}(y)$.

For the endpoint rejection, apply Definition 45.98 to y. A singleton-empty carrier witness at y contradicts the Rat carrier witness just obtained.

It remains to reject both contextual singleton boundaries. For any $r : \mathsf{BHist}$, apply Definition 45.101 to the context history r and Rat carrier endpoint y, and apply Definition 45.102 to the same two histories in the opposite append order. □

Theorem 45.520 (RatUp FieldUp transported strict-support separation package)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and the contextual action* Γ *of Definition 45.454, let* $x_L := \Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))$ *and let* $x := \Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))$*. Suppose* $p\mathsf{hsamee}$*,* $q\mathsf{hsamee}$*,* $p'\mathsf{hsamee}$*, and* $q'\mathsf{hsamee}$*; suppose* $C^u_D(h)$*; suppose the denominator context pairs are classified by*

$R^u_D(l,s)$, $R^u_D(r,t)$, $R^u_D(l',s')$, and $R^u_D(r',t')$; and suppose the left nested action has strict support, $\mathsf{RatHistoryCarrier}(x_L)$*. Then the transported right nested action has the following separation package:*

1. $C^u_D(x)$;
2. $\mathsf{RatHistoryCarrier}(x)$;
3. $\mathsf{fieldSingletonEmptyCarrier}(x) \to \bot$;
4. $x\mathsf{hsamee} \to \bot$.

Proof. First apply Definition 45.499 to the empty endpoints, carried source h, and the four denominator classifier rows. Transport the assumed strict-support witness $\mathsf{RatHistoryCarrier}(x_L)$ across this contextual-pair comparison. This gives $\mathsf{RatHistoryCarrier}(x)$, and the carriedness clause in the same transport gives $C^u_D(x)$.

Next read the concrete strict-support separation row for Rat histories. Since x has Rat history carrier, the singleton-empty carrier row at x is disjoint from it, giving $\mathsf{fieldSingletonEmptyCarrier}(x) \to \bot$.

It remains to separate the endpoint from the kernel empty history itself. Apply Definition 37.18 to the recovered $\mathsf{RatHistoryCarrier}(x)$ witness. The resulting map sends any equality $x\mathsf{hsamee}$ to contradiction, giving $x\mathsf{hsamee} \to \bot$.

Collect these four clauses as the displayed transported strict-support separation package. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup transported strict support separation package`

Theorem 45.521 (RatUp FieldUp transported strict-support contextual nonzero package)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and the contextual action Γ of Definition 45.454, let $x := \Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))$. Under the hypotheses of Definition 45.509, suppose also that $N^u_D(h)$ holds. Then for every context history $r : \mathsf{BHist}$ both proof-indexed inverse-domain witnesses hold:*

1. $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r,x))$;
2. $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(x,r))$.

Proof. First apply Definition 45.516 at the same denominator tuple, contextual action, transported endpoint, and strict-support witness. This gives the rejection maps

$$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r,x)) \to \bot$$

and

$$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x,r)) \to \bot.$$

For the right-append inverse-domain witness, unfold $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r,x))$ as $\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(r,x),\mathsf{e}) \to \bot$. Any forbidden classifier witness contains the source carrier field $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r,x))$, contradicting the first rejection map.

For the left-append inverse-domain witness, unfold $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(x,r))$ as $\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(x,r),\mathsf{e}) \to \bot$. Any forbidden classifier witness contains the source carrier field $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x,r))$, contradicting the second rejection map. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup transported strict support contextual nonzero package`

Theorem 45.522 (RatUp FieldUp transported strict-support inverse-domain classifier package)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and the contextual action* Γ *of Definition 45.454, let* $x := \Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))$*. Under the hypotheses of Definition 45.509, suppose also that* $N^u_D(h)$ *holds. Then the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *exit certificate jointly contains the transported strict-support inverse-domain and classifier obstruction package:*

1. $x\mathsf{hsamee} \to \bot$*;*
2. *for every* $r : \mathsf{BHist}$*,* $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, x))$*;*
3. *for every* $r : \mathsf{BHist}$*,* $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(x, r))$*;*
4. *for all* $L, R : \mathsf{BHist}$*,*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, x)) \to \bot.$$

Proof. Apply Definition 45.520 at the same denominator tuple, contextual action, transported endpoint, neutrality hypotheses, and strict-support witness. Its final clause gives the direct empty-history separation $x\mathsf{hsamee} \to \bot$.

Next apply Definition 45.521 with the same data. For each context history $r : \mathsf{BHist}$, this supplies both inverse-domain witnesses $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, x))$ and $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{appe}$

Finally apply Definition 45.517 with the same transported endpoint and strict-support source witness. For all $L, R : \mathsf{BHist}$, it gives the classifier obstruction on the two append contexts carrying the common strict-support tail x. □

Per-object template: traditional target $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ strict-support inverse-domain separation; BEDC source BHist, $\mathsf{RatUpFieldSource}_F$, append, contextual action Γ, and strict support N^u_D; carrier $\mathsf{RatHistoryCarrier}$; classifier obstruction $\mathsf{fieldSingletonEmptyClassifier}$; stability obligations transported support neutrality, contextual nonzero, and singleton-classifier exclusion; ledger transported endpoint plus append contexts; core theorem Definition 45.522; exactness simultaneous nonzero complement and singleton-classifier rejection; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.523 (RatUp FieldUp concrete exit certificate package)**.** *For Definition 45.493 and the source tuple* $\mathsf{RatUpFieldSource}_F$*, the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *exit certificate simultaneously contains the following certificate data:*

1. *the obligation rows of Definition 45.337;*
2. *the denominator multiplicative coverage of Definition 45.439;*
3. *the concrete exit-row closure of Definition 45.513;*
4. *the empty-context nondegenerate witness of Definition 45.514;*
5. *the transported strict-support non-singleton endpoint of Definition 45.515.*

Hence the exit package is a concrete BHist*-anchored* $\mathsf{ProofTarget}$ *over* $\mathsf{RatUpFieldSource}_F$*, not an abstract operator schema.*

Proof. Begin with Definition 45.337. It fixes the rows that a $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ certificate must carry: source, carrier, classifier, ring base, apartness, inverse, product, denominator, contextual denominator, affine, ledger, exactness, and status rows.

Next apply Definition 45.439. This supplies the denominator multiplicative row coverage inside the same field certificate language, so the denominator component is read as a certificate row rather than as an external monoid fact.

Apply Definition 45.513. It repacks the semantic certificate rows, source anchoring rows, support-sensitive coverage, and non-singleton endpoint data as one concrete exit-row closure over $\mathsf{RatUpFieldSource}_F$.

The nondegenerate empty-context component is supplied by Definition 45.514. It gives the wrapped rational endpoint, its rational-history carrier witness, its singleton empty rejection map, and the nonzero-complement clause under empty singleton wrappers.

Finally apply Definition 45.515. This gives the transported endpoint clauses $C^u_D(x)$, $N^u_D(x)$, $\mathsf{RatHistoryCarrier}(x)$, and $\mathsf{fieldSingletonEmptyCarrier}(x) \to \bot$.

Combining these five cited sites yields a single concrete BHist-anchored certificate package with status $\mathsf{ProofTarget}$. Its data are the rows of the displayed $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ instance, so the conclusion is a concrete exit certificate for $\mathsf{RatUpFieldSource}_F$ and not an abstract operator schema. □

Theorem 45.524 (RatUp FieldUp transported strict-support contextual separation package)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and the contextual action Γ of Definition 45.454, let $x := \Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))$. Under the hypotheses of Definition 45.509, suppose also that $N^u_D(h)$ holds. Then the concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit certificate contains all seven clauses:*

1. *$C^u_D(x)$;*
2. *$N^u_D(x)$;*
3. *$\mathsf{RatHistoryCarrier}(x)$;*
4. *$\mathsf{fieldSingletonEmptyCarrier}(x) \to \bot$;*
5. *$x\mathsf{hsamee} \to \bot$;*
6. *for every $r : \mathsf{BHist}$, $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, x)) \to \bot$;*
7. *for every $r : \mathsf{BHist}$, $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x, r)) \to \bot$.*

Proof. First apply Definition 45.520 with the same denominator tuple, contextual action, endpoint, and hypotheses. This supplies the carried endpoint, transported strict support, Rat carrier witness, singleton endpoint exclusion, and direct empty-history separation.

It remains to attach the two contextual singleton exclusions. Apply Definition 45.516 with the same transported endpoint and support witness. For each $r : \mathsf{BHist}$, this gives the left-context and right-context rejection maps for $\mathsf{append}(r, x)$ and $\mathsf{append}(x, r)$.

Collect the five endpoint clauses from the separation package and the two contextual clauses from singleton exclusion as the displayed seven-clause certificate row. □

Per-object template: traditional target constructive $\mathsf{Field}^{\uparrow}$ exit separation; BEDC source $\mathsf{RatUpFieldSource}_F$, contextual action Γ, and strict support N^u_D; carrier $\mathsf{RatHistoryCarrier}$; classifier $\mathsf{RatHistoryClassifier}$; stability obligations transported support neutrality plus Rat/singleton separation; ledger contextual-pair action and denominator support; core theorems Definition 45.515, Definition 45.516, Definition 45.519, and Definition 45.521 and Definition 45.520; exactness predicate transported and iterated transported strict-support non-collapse plus contextual singleton exclusion, and direct internal-nonempty endpoint separation; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.525 (RatUp FieldUp transported exit row nondegenerate closure)**.** *For the concrete source tuple $\mathsf{RatUpFieldSource}_F$, the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$, and the contextual action Γ of Definition 45.454, let $x := \Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))$. Under the hypotheses of Definition 45.509, suppose also that $N^u_D(h)$ holds. Then the single concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit row package simultaneously contains:*

1. *the semantic certificate assembly and source anchoring rows recorded by Definition 45.513;*
2. *the transported carrier clause $C^u_D(x)$ and the strict-support equivalence*

$$N^u_D(x) \Longleftrightarrow N^u_D(h);$$

3. *the endpoint facts $C^u_D(x)$, $N^u_D(x)$, $\mathsf{RatHistoryCarrier}(x)$, and $\mathsf{fieldSingletonEmptyCarrier}(x) \to \bot$;*
4. *the separation clause that no carrier-coverage map*

$$\kappa : \mathsf{RatHistoryCarrier}(x) \to \mathsf{fieldSingletonEmptyCarrier}(x)$$

exists for the transported strict-support endpoint of this exit row.

Thus the transported endpoint, its concrete exit-row closure, and its source-anchored certificate rows are one nondegenerate $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit package.

Proof. First fix the row package. Apply Definition 45.513. It identifies the concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit rows over $\mathsf{RatUpFieldSource}_F$ and records the semantic certificate assembly together with the source anchoring rows.

Next read the transported endpoint. Apply Definition 45.511 under the same hypotheses. This supplies the transported carrier clause $C^u_D(x)$ and the strict-support equivalence

$$N^u_D(x) \Longleftrightarrow N^u_D(h).$$

Using the assumed witness $N^u_D(h)$ gives $N^u_D(x)$.

Now use the preceding endpoint theorem Definition 45.515. It gives the concrete Rat carrier witness $\mathsf{RatHistoryCarrier}(x)$ and the singleton rejection map $\mathsf{fieldSingletonEmptyCarrier}(x) \to \bot$ for the same endpoint.

It remains to rule out coverage by the singleton empty-history source. Suppose that a carrier-coverage map

$$\kappa : \mathsf{RatHistoryCarrier}(x) \to \mathsf{fieldSingletonEmptyCarrier}(x)$$

exists at this transported strict-support endpoint. Applying κ to the witness $\mathsf{RatHistoryCarrier}(x)$ gives $\mathsf{fieldSingletonEmptyCarrier}(x)$, contradicting the displayed rejection map. Hence no such carrier-coverage map exists. □

Definition 45.526 (RatUp FieldUp threefold denominator support carrier)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and histories $h, k, \ell : \mathsf{BHist}$, the threefold denominator support carrier is the predicate*

$$\mathsf{ThreeSupp}^u_D(h,k,\ell) := C^u_D(h) \wedge C^u_D(k) \wedge C^u_D(\ell) \wedge ((N^u_D(h) \vee N^u_D(k)) \vee N^u_D(\ell)).$$

Theorem 45.527 (RatUp FieldUp threefold support non-singleton exactness)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, let $x := \mu^u_D(\mu^u_D(h,k),\ell)$. Then the concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit boundary contains the following threefold endpoint data:*

1. *$C^u_D(x)$;*
2. $$N^u_D(x) \Longleftrightarrow ((N^u_D(h) \vee N^u_D(k)) \vee N^u_D(\ell));$$
3. *$\mathsf{ThreeSupp}^u_D(h,k,\ell) \to \mathsf{RatHistoryCarrier}(x)$;*

4. $\mathsf{ThreeSupp}^u_D(h,k,\ell) \to (\mathsf{fieldSingletonEmptyCarrier}(x) \to \bot)$.

Proof. Apply the closure clause of Definition 45.347 to the carried inputs h and k. This gives $C^u_D(\mu^u_D(h,k))$. Apply the same closure clause to $\mu^u_D(h,k)$ and ℓ to obtain $C^u_D(x)$.

Next apply Definition 45.408 to h,k,ℓ with their carried hypotheses. The result is the displayed strict-support equivalence for the left-nested endpoint x.

Assume $\mathsf{ThreeSupp}^u_D(h,k,\ell)$. Its last conjunct gives $((N^u_D(h)\vee N^u_D(k))\vee N^u_D(\ell))$. Use the reverse direction of the displayed equivalence to obtain $N^u_D(x)$.

Read the denominator tuple row from Definition 45.438. There $N^u_D(y) = \mathsf{RatHistoryCarrier}(y)$ for every denominator history y, so the support witness just obtained gives $\mathsf{RatHistoryCarrier}(x)$.

Finally apply Definition 45.98 to x. A witness of $\mathsf{fieldSingletonEmptyCarrier}(x)$ together with the Rat history carrier witness yields contradiction, giving the displayed non-singleton endpoint map. □

Theorem 45.528 (RatUp FieldUp right-nested threefold support non-singleton exactness)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and histories* $h,k,\ell : \mathsf{BHist}$ *with* $C^u_D(h)$, $C^u_D(k)$, *and* $C^u_D(\ell)$, *let* $x := \mu^u_D(\mu^u_D(h,k),\ell)$ *and* $y := \mu^u_D(h,\mu^u_D(k,\ell))$. *Then the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *exit boundary contains the following right-nested threefold endpoint data:*

1. $C^u_D(y)$;

2. $R^u_D(x,y)$;

3.
$$N^u_D(y) \iff ((N^u_D(h) \vee N^u_D(k)) \vee N^u_D(\ell));$$

4. $\mathsf{ThreeSupp}^u_D(h,k,\ell) \to \mathsf{RatHistoryCarrier}(y)$;

5. $\mathsf{ThreeSupp}^u_D(h,k,\ell) \to (\mathsf{fieldSingletonEmptyCarrier}(y) \to \bot)$.

Proof. First build the right-nested carrier. Apply the closure clause of Definition 45.347 to the carried inputs k and ℓ, obtaining $C^u_D(\mu^u_D(k,\ell))$. Apply the same closure clause to h and $\mu^u_D(k,\ell)$ to obtain $C^u_D(y)$.

The classifier comparison is the associativity clause of Definition 45.404 at the carried histories h,k,ℓ. With the displayed endpoints, this gives $R^u_D(x,y)$.

Next read strict support on the right-nested product. Apply Definition 45.402 to k and ℓ, giving
$$N^u_D(\mu^u_D(k,\ell)) \iff N^u_D(k) \vee N^u_D(\ell).$$

Apply the same product exactness theorem to h and $\mu^u_D(k,\ell)$. The outer endpoint is y, so it gives
$$N^u_D(y) \iff N^u_D(h) \vee N^u_D(\mu^u_D(k,\ell)).$$

For the forward direction of the displayed theorem, use the outer equivalence. If it returns $N^u_D(h)$, place that witness in the left branch of $((N^u_D(h)\vee N^u_D(k))\vee N^u_D(\ell))$. If it returns $N^u_D(\mu^u_D(k,\ell))$, use the inner equivalence; its $N^u_D(k)$ case enters the left branch and its $N^u_D(\ell)$ case enters the right branch.

For the reverse direction, split $((N^u_D(h)\vee N^u_D(k))\vee N^u_D(\ell))$ by cases. The $N^u_D(h)$ case enters the left branch of the outer equivalence. The $N^u_D(k)$ and $N^u_D(\ell)$ cases first enter the reverse direction of the inner equivalence, producing $N^u_D(\mu^u_D(k,\ell))$, and then enter the right branch of the outer equivalence.

Now assume $\mathsf{ThreeSupp}^u_D(h,k,\ell)$. Its support component is exactly the right-hand side of the strict-support equivalence, so the reverse direction gives $N^u_D(y)$.

Read the denominator tuple row from Definition 45.438. There $N^u_D(z) = \mathsf{RatHistoryCarrier}(z)$ for every denominator history z, hence the support witness gives $\mathsf{RatHistoryCarrier}(y)$.

Finally apply Definition 45.98 to y. A witness of $\mathsf{fieldSingletonEmptyCarrier}(y)$ together with the Rat history carrier witness yields contradiction, giving the right-nested non-singleton endpoint map. □

Theorem 45.529 (RatUp FieldUp threefold support contextual separation package)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, let $x := \mu^u_D(\mu^u_D(h, k), \ell)$. If $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ holds, then the concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit boundary contains the following contextual separation package:*

1. *the direct endpoint separation $x\mathsf{hsamee} \to \bot$;*
2. *for every $r : \mathsf{BHist}$, both contextual carrier exclusions $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, x)) \to \bot$ and $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x, r)) \to \bot$;*
3. *for all $L, R : \mathsf{BHist}$, the contextual classifier exclusion*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, x)) \to \bot.$$

Proof. First apply Definition 45.527 with the same denominator tuple and carried histories. The threefold support hypothesis recovers $\mathsf{RatHistoryCarrier}(x)$ and the singleton endpoint rejection $\mathsf{fieldSingletonEmptyCarrier}(x) \to \bot$.

For direct empty separation, apply Definition 37.18 to the recovered Rat carrier witness. Any comparison $x\mathsf{hsamee}$ is thereby sent to contradiction.

Now fix an arbitrary context history $r : \mathsf{BHist}$. Apply Definition 45.101 with context r and Rat carrier endpoint x to rule out $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, x))$. Apply Definition 45.102 with the same two histories in the opposite append order to rule out $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x, r))$.

Finally package $\mathsf{RatHistoryClassifier}(x, x)$ from the carrier witness on both sides and reflexivity of hsame. For arbitrary $L, R : \mathsf{BHist}$, Definition 45.104 then rejects $\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}($ □

Theorem 45.530 (RatUp FieldUp threefold support contextual separation)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, let $x := \mu^u_D(\mu^u_D(h, k), \ell)$. If $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ holds, then for every $r : \mathsf{BHist}$ both contextual singleton collapses are impossible:*

1. $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, x)) \to \bot$;
2. $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x, r)) \to \bot$.

Proof. Apply Definition 45.527 to the same denominator tuple, carried inputs, left-nested endpoint, and $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ witness. The endpoint data includes $\mathsf{RatHistoryCarrier}(x)$.

For the right-factor append boundary, apply Definition 45.101 with context history r and RatUp factor x. The recovered Rat carrier witness turns any witness of $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, x))$ into contradiction.

For the left-factor append boundary, apply Definition 45.102 with the same RatUp factor x and context history r. The same carrier witness turns any witness of $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x, r))$ into contradiction. □

Theorem 45.531 (RatUp FieldUp threefold support contextual inverse-domain package)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$,*

and $C^u_D(\ell)$*, let* $x := \mu^u_D(\mu^u_D(h,k),\ell)$*. If* $\mathsf{ThreeSupp}^u_D(h,k,\ell)$ *holds, then every context history* $r : \mathsf{BHist}$ *satisfies the two inverse-domain witnesses:*

1. $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r,x))$*;*
2. $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(x,r))$*.*

Proof. First apply Definition 45.530 at the same denominator tuple, carried inputs, endpoint, support carrier witness, and context history r. This gives the rejection maps $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r,x)) \to \bot$ and $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x,r)) \to \bot$. For the right-append inverse-domain witness, unfold $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r,x))$ as $\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(r,x),\mathsf{e}) \to \bot$. Any forbidden classifier witness contains the source carrier field $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r,x))$, contradicting the first rejection map. For the left-append inverse-domain witness, unfold fieldSingletonEmptyNonZer as $\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(x,r),\mathsf{e}) \to \bot$. Any forbidden classifier witness contains the source carrier field $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x,r))$, contradicting the second rejection map. □

Theorem 45.532 (RatUp FieldUp threefold support contextual nonzero boundary)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and histories* $h,k,\ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, let* $x := \mu^u_D(\mu^u_D(h,k),\ell)$*. If* $\mathsf{ThreeSupp}^u_D(h,k,\ell)$ *holds, then for every* $r : \mathsf{BHist}$ *the concrete append-context boundary contains:*

1. $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r,x)) \to \bot$*;*
2. $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x,r)) \to \bot$*;*
3. $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r,x))$*;*
4. $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(x,r))$*.*

Proof. Apply Definition 45.527 to the same carried histories and threefold support witness. The endpoint data recovered there includes $\mathsf{RatHistoryCarrier}(x)$ and the singleton endpoint rejection map $\mathsf{fieldSingletonEmptyCarrier}(x) \to \bot$. Fix an arbitrary context history $r : \mathsf{BHist}$. For the right-factor append boundary, apply Definition 45.101 with context r and RatUp factor x. The Rat carrier witness turns any witness of $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r,x))$ into contradiction. For the left-factor append boundary, apply Definition 45.102 with the same RatUp factor x and context r. The same carrier witness turns any witness of $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x,r))$ into contradiction. It remains to record the two inverse-domain witnesses. Unfold $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r,x))$ as rejection of the singleton classifier against e. Any such classifier witness contains the source-carrier component $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r,x))$, contradicting the right-factor append rejection. The left-factor inverse-domain witness is identical: unfold $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(x,r))$ as rejection of the singleton classifier against e. The source-carrier component fieldSingletonEmptyCarrier(append(x, contradicts the left-factor append rejection. □

Per-object template: traditional target concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ threefold denominator exit support; BEDC source BHist with $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$; context $\mathsf{RatUpFieldSource}_F$; carrier $\mathsf{ThreeSupp}^u_D$; classifier R^u_D; stability obligations empty-unit continuation closure and Rat carrier readback; ledger left-nested denominator product endpoint $\mu^u_D(\mu^u_D(h,k),\ell)$; core theorems Definition 45.527, Definition 45.530, Definition 45.531, and Definition 45.532; exactness predicate threefold strict-support non-singleton boundary with contextual append separation and inverse-domain nonzero package; standard bridge finite denominator support into the concrete FieldUp exit; status $\mathsf{ProofTarget}$.

Per-object template: traditional target bracketing-independent concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ threefold denominator exit support; BEDC source BHist with $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$; context $\mathsf{RatUpFieldSource}_F$;

carrier $\mathsf{ThreeSupp}^u_D$; classifier R^u_D; stability obligations empty-unit continuation closure, associativity up to R^u_D, and Rat carrier readback; ledger paired left- and right-nested denominator product endpoints $\mu^u_D(\mu^u_D(h,k),\ell)$ and $\mu^u_D(h,\mu^u_D(k,\ell))$; core theorem Definition 45.528; exactness predicate threefold strict-support non-singleton boundary independent of product bracketing; standard bridge finite denominator support into the concrete FieldUp exit; status ProofTarget.

Theorem 45.533 (Rat denominator unit contextual action strict-support endpoint empty contradiction)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and the contextual action* Γ*, assume the four external endpoints are empty and the five denominator contexts* h, l, r, l', r' *are carried. If the core has strict RatUp support, then the nested contextual action cannot be empty:*

$$N^u_D(h) \to \Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))\mathsf{hsamee} \to \bot.$$

Proof. The contextual composition support law reads the nested support predicate as the disjunction of the two outer supports, the two inner supports, and the core support. Insert $N^u_D(h)$ into the core disjunct. This yields RatUp support for the nested action, contradicting its asserted empty endpoint. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitContextualAction strict support endpoint empty absurd`

Theorem 45.534 (RatUp FieldUp assembled certificate operation-table coverage)**.** *For the concrete source tuple* $\mathsf{RatUpFieldSource}_F$ *of Definition 45.488 and the concrete operation table of Definition 45.587, one and the same* BHist *row package satisfies both Definition 45.337 and the concrete* $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$ *operation-table laws. The shared carrier and classifier are* RatHistoryCarrier *and* RatHistoryClassifier*. The shared denominator coordinate is*

$$(\mathsf{RatDenomUnitCarrier}, \mathsf{RatDenomUnitClassifier}, \mathsf{append}, \mathsf{e}, \mathsf{RatHistoryCarrier}).$$

The shared contextual coordinate is the action Γ*, the shared context-pair coordinate is the monoid of Definition 45.479, and the shared affine coordinate is* AffAut_F*. The inverse and nonzero rows, together with the exit-noncollapse rows, are the rows consumed by both cited interfaces.*

Proof. Unpack Definition 45.488. It names RatHistoryCarrier, RatHistoryClassifier, the displayed denominator tuple, Γ, the context-pair monoid, and AffAut_F as coordinates of the single source $\mathsf{RatUpFieldSource}_F$.

Apply Definition 45.489. This gives Definition 45.337 for exactly those coordinates. Apply Definition 45.588. This gives the carrier, classifier, denominator, contextual-action, context-pair, affine, inverse, nonzero, and exit-noncollapse laws for the concrete operation table of Definition 45.587.

Both cited results name the same concrete carrier, classifier, denominator tuple, contextual action, context-pair monoid, affine row source, inverse rows, nonzero rows, and exit rows. Therefore the certificate-obligation interface and the operation-table interface are satisfied by the same concrete BHist rows. □

45.22 Field affine explicit inverse

Theorem 45.535 (Field two-sided affine expression has explicit inverse)**.** *For a BEDC history-level* $\mathsf{Field}^\uparrow$ *candidate with the same operations, additive laws, multiplication laws, congruence data, and indexed inverse laws as in Definition 45.277, let* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$ *be the two nonzero witnesses for the left and right affine factors. For each* $c : \mathsf{BHist}$ *define*

$$s(c) = \mathsf{mul}(\mathsf{inv}(a, p_a), \mathsf{mul}(\mathsf{add}(c, \mathsf{neg}(d)), \mathsf{inv}(b, p_b))).$$

Then every $c, x, y : \mathsf{BHist}$ *satisfies the following three clauses.*

1. $\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, s(c)), b), d)\mathsf{hsame}c$.
2. *If* $\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)\mathsf{hsame}c$, *then* $x\mathsf{hsame}s(c)$.
3. *If*
$$\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)\mathsf{hsameadd}(\mathsf{mul}(\mathsf{mul}(a, y), b), d),$$
then $x\mathsf{hsame}y$.

Proof. For the displayed preimage, instantiate Definition 45.277 at $x = s(c)$. The reverse implication only needs the reflexive classifier equality $s(c)\mathsf{hsame}s(c)$, so it produces $\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, s(c)), b), d)\mathsf{hsame}c$.

For uniqueness of any solution, use the forward implication of the same exactness theorem. An assumed classification of the affine expression at x with c is transported directly to $x\mathsf{hsame}s(c)$.

For equality of two affine expressions, apply Definition 45.278 to the assumed classifier equality. Its conclusion is exactly $x\mathsf{hsame}y$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine two sided explicit inverse`

Theorem 45.536 (Field two-sided affine map is a certified automorphism)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with the same operations, additive laws, multiplication laws, congruence data, and indexed inverse laws as in Definition 45.277, let* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$ *be the two nonzero witnesses for the left and right affine factors. Define*
$$T(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)$$
and, for each $c : \mathsf{BHist}$, *define*
$$s(c) = \mathsf{mul}(\mathsf{inv}(a, p_a), \mathsf{mul}(\mathsf{add}(c, \mathsf{neg}(d)), \mathsf{inv}(b, p_b))).$$
Then every $x, y, c : \mathsf{BHist}$ *satisfies*
$$T(s(c))\mathsf{hsame}c, \qquad s(T(x))\mathsf{hsame}x, \qquad T(x)\mathsf{hsame}T(y) \iff x\mathsf{hsame}y.$$

Proof. For the left inverse clause, instantiate Definition 45.277 at $x = s(c)$. The reflexive classifier equality $s(c)\mathsf{hsame}s(c)$ enters the reverse implication and yields $T(s(c))\mathsf{hsame}c$.

For the right inverse clause, instantiate the same exactness theorem with the target classifier value $T(x)$. The reflexive equality $T(x)\mathsf{hsame}T(x)$ enters the forward implication and yields $x\mathsf{hsame}s(T(x))$. Symmetry of hsame gives the displayed orientation $s(T(x))\mathsf{hsame}x$.

Finally apply Definition 45.278 with the same witnesses p_a, p_b and offset d. Its two directions are precisely the classifier-preservation and classifier-reflection clauses $T(x)\mathsf{hsame}T(y) \iff x\mathsf{hsame}y$. □

Per-object certificate: traditional target affine automorphism over a field. BEDC source: $\mathsf{Field}^{\uparrow}$ over BHist. Carrier: BHist. Classifier: hsame. Stability obligations: Definition 45.277 and Definition 45.278. Ledger: the two nonzero factor witnesses p_a, p_b and the offset d. Core theorem: Definition 45.536. Exactness predicate: inverse-pair plus classifier iff. Standard bridge: deferred. Status: $\mathsf{ProofTarget}$.

Theorem 45.537 (Field affine inverse coefficients are derived)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with associative multiplication, left and right unit laws, multiplication congruence, zero-left multiplication, indexed left inverse laws, one-apartness from* e, *and conversion from apartness from* e *to* $\mathsf{NonZero}_F$, *let* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$. *Then there are derived witnesses* $p_A : \mathsf{NonZero}_F(\mathsf{inv}(a, p_a))$ *and* $p_B : \mathsf{NonZero}_F(\mathsf{inv}(b, p_b))$ *such that*
$$\mathsf{inv}(\mathsf{inv}(a, p_a), p_A)\mathsf{hsame}a \qquad \textit{and} \qquad \mathsf{inv}(\mathsf{inv}(b, p_b), p_B)\mathsf{hsame}b.$$

Proof. Apply inverse nonzero from one-apartness to p_a and p_b separately. The two resulting nonzero witnesses make the inverse coefficients admissible inputs to the indexed inverse operation. For each coefficient, apply left-right inverse uniqueness to the pair consisting of the inverse law for the inverse coefficient and the inverse law for the original coefficient. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine inverse coefficients derived`

Theorem 45.538 (Field affine inverse offset empty normal form)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with multiplication associativity and congruence, addition congruence, and the two distributivity laws, every* $a, b, c, d : \mathsf{BHist}$ *with witnesses* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$ *satisfies*

$$\begin{aligned}&\mathsf{add}(\mathsf{mul}(\mathsf{inv}(a, p_a), \mathsf{mul}(\mathsf{add}(c, \mathsf{neg}(d)), \mathsf{inv}(b, p_b))), \mathsf{e})\\ &\quad \mathsf{hsameadd}(\mathsf{add}(\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(a, p_a), c), \mathsf{inv}(b, p_b)), \mathsf{mul}(\mathsf{mul}(\mathsf{inv}(a, p_a), \mathsf{neg}(d)), \mathsf{inv}(b, p_b))), \mathsf{e}).\end{aligned}$$

Proof. Reassociate multiplication so the left inverse coefficient acts directly on $c + \mathsf{neg}(d)$. Left distributivity separates the two summands, right distributivity carries the final right multiplication by the inverse of b through the separated sum, and addition congruence preserves the empty endpoint. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine inverse offset empty normal form`

Lemma 45.539 (Field affine inverse empty-offset normal form)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with right identity for the additive empty endpoint, multiplication associativity and congruence, addition congruence, and the two distributivity laws, every* $a, b, c, d : \mathsf{BHist}$ *with witnesses* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$ *satisfies*

$$\begin{aligned}&\mathsf{add}(\mathsf{mul}(\mathsf{inv}(a, p_a), \mathsf{mul}(\mathsf{add}(c, \mathsf{neg}(d)), \mathsf{inv}(b, p_b))), \mathsf{e})\\ &\quad \mathsf{hsameadd}(\mathsf{mul}(\mathsf{mul}(\mathsf{inv}(a, p_a), c), \mathsf{inv}(b, p_b)), \mathsf{mul}(\mathsf{mul}(\mathsf{inv}(a, p_a), \mathsf{neg}(d)), \mathsf{inv}(b, p_b))).\end{aligned}$$

Proof. First use the inverse offset-empty normal form above to separate the two right-multiplied summands and retain the explicit empty endpoint. Then apply the additive right-identity law to remove that final empty endpoint. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine inverse empty offset normal form`

Theorem 45.540 (Field affine certified fibers are singleton classified)**.** *Under the hypotheses and notation of Definition 45.536, define*

$$T(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)$$

and

$$s(q) = \mathsf{mul}(\mathsf{inv}(a, p_a), \mathsf{mul}(\mathsf{add}(q, \mathsf{neg}(d)), \mathsf{inv}(b, p_b))).$$

Then every $q, x, y : \mathsf{BHist}$ *satisfies the following three clauses.*

1. $T(s(q))\mathsf{hsame}q$.
2. *If* $T(x)\mathsf{hsame}q$ *and* $T(y)\mathsf{hsame}q$*, then* $x\mathsf{hsame}y$.
3. $T(x)\mathsf{hsame}q \iff x\mathsf{hsame}s(q)$.

Proof. The displayed preimage clause is the left inverse clause of Definition 45.536 at the target history q.

For two solutions of the same fiber equation, assume $T(x)\mathsf{hsame}q$ and $T(y)\mathsf{hsame}q$. Apply Definition 45.278 to the comparison $T(x)\mathsf{hsame}T(y)$ obtained by composing the first fiber equation with the symmetry of the second. The reflected classifier comparison gives $x\mathsf{hsame}y$.

It remains to identify membership in the fiber with classification by the displayed solution. In the forward direction, assume $T(x)\mathsf{hsame}q$. The first clause gives $T(s(q))\mathsf{hsame}q$; by symmetry and transitivity, $T(x)$ is classified with $T(s(q))$. Reflect this comparison through the classifier clause of Definition 45.536, giving $x\mathsf{hsame}s(q)$.

For the reverse direction, assume $x\mathsf{hsame}s(q)$. Preserve this classifier comparison through the same certified affine map to obtain $T(x)\mathsf{hsame}T(s(q))$, and compose with the displayed preimage clause $T(s(q))\mathsf{hsame}q$. The result is $T(x)\mathsf{hsame}q$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine certified fiber singleton`

Per-object certificate: traditional target affine bijection fiber exactness; BEDC source $\mathsf{Field}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability obligations certified affine automorphism and affine equation uniqueness; ledger the two nonzero witnesses, offset, target point, and displayed solution equations; core theorem Definition 45.540; exactness predicate singleton classified fiber; standard bridge ordinary affine bijections over a field; status $\mathsf{ProofTarget}$.

Theorem 45.541 (Field two-sided affine automorphism composition with explicit product witnesses)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with the additive group laws, multiplication associativity, left and right multiplicative unit laws, multiplication and addition congruence, distributivity fields inherited from* $\mathsf{CommRing}^{\uparrow}$*, indexed inverse laws, classifier transport of* $\mathsf{NonZero}_F$*, and contradiction of* $\mathsf{NonZero}_F(0)$*, let* $p_a : \mathsf{NonZero}_F(a)$*,* $p_b : \mathsf{NonZero}_F(b)$*,* $p_c : \mathsf{NonZero}_F(c)$*, and* $p_e : \mathsf{NonZero}_F(e)$ *be explicit nonzero witnesses. Define*

$$T_1(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)$$

and

$$T_2(y) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(c, y), e), f).$$

Let $\mathsf{ApartZero}_F(h)$ *abbreviate* $h\mathsf{hsame}0 \to \bot$*, and assume conversion maps*

$$\alpha_{ca} : \mathsf{ApartZero}_F(\mathsf{mul}(c, a)) \to \mathsf{NonZero}_F(\mathsf{mul}(c, a)), \qquad \alpha_{be} : \mathsf{ApartZero}_F(\mathsf{mul}(b, e)) \to \mathsf{NonZero}_F(\mathsf{mul}(b, e)).$$

Let q_{ca} *and* q_{be} *be the product apartness witnesses obtained from Definition 45.248 for the pairs* (p_c, p_a) *and* (p_b, p_e)*, and set* $p_{ca} := \alpha_{ca}(q_{ca})$ *and* $p_{be} := \alpha_{be}(q_{be})$*. Define*

$$C(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(c, a), x), \mathsf{mul}(b, e)), \mathsf{add}(\mathsf{mul}(\mathsf{mul}(c, d), e), f)).$$

Then every $x : \mathsf{BHist}$ *satisfies*

$$T_2(T_1(x))\mathsf{hsame}C(x).$$

Moreover, with the product witnesses p_{ca} *and* p_{be}*, the displayed composite* C *is a certified two-sided affine automorphism by Definition 45.536.*

Proof. Expand $T_2(T_1(x))$ and use distributivity to separate the translated part coming from d from the term containing x. Addition congruence transports the two pieces through the outer sum, while multiplication congruence transports the inner affine equality through the left factor c and the right factor e.

Multiplication associativity then collects the x-term into $\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(c,a),x),\mathsf{mul}(b,e))$. The same associativity and distributivity data identify the translated remainder as $\mathsf{add}(\mathsf{mul}(\mathsf{mul}(c,d),e),f)$. This gives the displayed normal form $T_2(T_1(x))\mathsf{hsame}C(x)$.

It remains to provide the two nonzero indices required by Definition 45.536. Apply Definition 45.248 to p_c, p_a to obtain $q_{ca} : \mathsf{ApartZero}_F(\mathsf{mul}(c,a))$, and to p_b, p_e to obtain $q_{be} : \mathsf{ApartZero}_F(\mathsf{mul}(b,e))$. The conversion maps α_{ca} and α_{be} turn these apartness witnesses into p_{ca} and p_{be}.

Now instantiate Definition 45.536 with left factor $\mathsf{mul}(c,a)$, right factor $\mathsf{mul}(b,e)$, offset $\mathsf{add}(\mathsf{mul}(\mathsf{mul}(c,d),e),f)$, and witnesses p_{ca}, p_{be}. The theorem supplies the inverse-pair clauses and classifier iff for C, so the normalized composite is again certified. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine two sided automorphism composition`

Theorem 45.542 (Field affine empty-offset composition normal form)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with addition associativity and congruence, multiplication associativity and congruence, and the two distributivity laws, every* $a,b,c,d,e,x : \mathsf{BHist}$ *satisfies*

$$\begin{aligned}&\mathsf{add}(\mathsf{mul}(\mathsf{mul}(c,\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a,x),b),d)),e),\mathsf{e})\\&\quad\mathsf{hsameadd}(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(c,a),x),\mathsf{mul}(b,e)),\mathsf{add}(\mathsf{mul}(\mathsf{mul}(c,d),e),\mathsf{e})).\end{aligned}$$

Proof. Distribute the left multiplication by c across the inner affine offset and then distribute the right multiplication by e across the resulting sum. This separates the x-term from the offset term $\mathsf{mul}(\mathsf{mul}(c,d),e)$. Multiplication associativity rewrites the x-term from $(c((ax)b))e$ to $((ca)x)(be)$. Addition congruence transports this product normal form through the surrounding sum, and addition associativity places the empty offset on the final translated component. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine empty offset composition normal form`

Theorem 45.543 (Field affine empty-offset composition classifier congruence)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with addition and multiplication congruence, if the affine coefficients satisfy* $a\mathsf{hsame}a'$*,* $b\mathsf{hsame}b'$*,* $c\mathsf{hsame}c'$*,* $d\mathsf{hsame}d'$*, and* $e\mathsf{hsame}e'$*, then the empty-offset composite expression*

$$\mathsf{add}(\mathsf{mul}(\mathsf{mul}(c,\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a,x),b),d)),e),\mathsf{e})$$

is hsame*-equivalent to the same expression with the primed coefficients.*

Proof. Apply multiplication congruence to the inner product $\mathsf{mul}(a,x)$ using $x\mathsf{hsame}x$, then to the product with b. Addition congruence transports the inner affine offset using $d\mathsf{hsame}d'$. Two further multiplication-congruence steps transport the left factor c and right factor e. The final addition-congruence step uses $\mathsf{ehsame}e$ for the empty offset. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine empty offset composition classifier congr`

Theorem 45.544 (Field affine composition right empty normal form)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with addition associativity and congruence, multiplication associativity and congruence, and the two distributivity laws, every* $a,b,c,d,e,f,x : \mathsf{BHist}$ *satisfies*

$$\begin{aligned}&\mathsf{add}(\mathsf{add}(\mathsf{mul}(\mathsf{mul}(c,\mathsf{add}(\mathsf{mul}(\mathsf{mul}(a,x),b),d)),e),f),\mathsf{e})\\&\quad\mathsf{hsameadd}(\mathsf{add}(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(c,a),x),\mathsf{mul}(b,e)),\mathsf{add}(\mathsf{mul}(\mathsf{mul}(c,d),e),f)),\mathsf{e}).\end{aligned}$$

Proof. Distribute the left multiplication by c across the inner affine offset and then distribute the right multiplication by e across the resulting sum. Multiplication associativity collects the x-coefficient as $\mathsf{mul}(\mathsf{mul}(c,a),x)$ and the right coefficient as $\mathsf{mul}(b,e)$. Addition associativity places the outer offset f on the translated component before the empty endpoint. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine composition right empty normal form`

Per-object certificate: traditional target affine automorphism composition. BEDC source: $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow}$ over BHist. Carrier: BHist. Classifier: hsame. Stability obligations: composition normal form plus product apartness conversion. Ledger: the four factor witnesses p_a, p_b, p_c, p_e and the two product witnesses p_{ca}, p_{be}. Core theorem: Definition 45.541. Exactness predicate: composite certified automorphism. Standard bridge: deferred. Status: $\mathsf{ProofTarget}$.

Theorem 45.545 (Field affine composite has explicit two-sided inverse)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate under the hypotheses of Definition 45.541, let* $p_a : \mathsf{NonZero}_F(a)$*,* $p_b : \mathsf{NonZero}_F(b)$*,* $p_{a'} : \mathsf{NonZero}_F(a')$*, and* $p_{b'} : \mathsf{NonZero}_F(b')$ *be the four nonzero witnesses for the two affine certificates. Define*

$$T_1(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)$$

and

$$T_2(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a', x), b'), d').$$

For each $r : \mathsf{BHist}$ *define*

$$s_1(r) = \mathsf{mul}(\mathsf{inv}(a, p_a), \mathsf{mul}(\mathsf{add}(r, \mathsf{neg}(d)), \mathsf{inv}(b, p_b)))$$

and

$$s_2(r) = \mathsf{mul}(\mathsf{inv}(a', p_{a'}), \mathsf{mul}(\mathsf{add}(r, \mathsf{neg}(d')), \mathsf{inv}(b', p_{b'}))).$$

Then every $x, y, q : \mathsf{BHist}$ *satisfies the following three clauses.*

1.

$$T_2(T_1(x))\mathsf{hsame}T_2(T_1(y)) \iff x\mathsf{hsame}y.$$

2.

$$T_2(T_1(s_1(s_2(q))))\mathsf{hsame}q.$$

3.

$$s_1(s_2(T_2(T_1(x))))\mathsf{hsame}x.$$

Proof. Instantiate Definition 45.541 with $c = a'$, $e = b'$, $f = d'$, and the product conversion maps for the collected factors. Its collected-factor normal form, together with Definition 45.536, supplies the classifier exactness for the composite, giving the displayed iff clause.

For the left inverse clause, first use the left inverse of the T_2 certificate at q, which gives $T_2(s_2(q))\mathsf{hsame}q$. Then use the left inverse of the T_1 certificate at $s_2(q)$, giving

$$T_1(s_1(s_2(q)))\mathsf{hsame}s_2(q).$$

Congruence of T_2 transports this equality through the outer map, and transitivity yields

$$T_2(T_1(s_1(s_2(q))))\mathsf{hsame}q.$$

For the right inverse clause, the right inverse of the T_2 certificate gives

$$s_2(T_2(T_1(x)))\mathsf{hsame}T_1(x).$$

Apply the left inverse clause of the T_1 certificate to $s_2(T_2(T_1(x)))$, obtaining

$$T_1(s_1(s_2(T_2(T_1(x)))))\mathsf{hsame}s_2(T_2(T_1(x))).$$

Compose these two equalities to classify

$$T_1(s_1(s_2(T_2(T_1(x)))))$$

with $T_1(x)$, and reflect the result through the T_1 classifier exactness to conclude $s_1(s_2(T_2(T_1(x))))\mathsf{hsame}x$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine composite two sided inverse`

Per-object certificate: traditional target affine automorphism inverse for composition; BEDC source $\mathsf{Field}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability obligations the two affine certificates plus composition classifier exactness; ledger four nonzero witnesses and two offsets; core theorem Definition 45.545; exactness predicate two-sided inverse plus classifier iff; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.546 (Field affine composite inverse agrees with reverse-composed inverses)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate with the operations and laws used by Definition 45.541, let* $p_a : \mathsf{NonZero}_F(a)$, $p_b : \mathsf{NonZero}_F(b)$, $p_{a'} : \mathsf{NonZero}_F(a')$, *and* $p_{b'} : \mathsf{NonZero}_F(b')$ *be the nonzero witnesses for the two component affine maps*

$$T_1(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)$$

and

$$T_2(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a', x), b'), d').$$

Put $A = \mathsf{mul}(a', a)$, $B = \mathsf{mul}(b, b')$, *and* $D = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a', d), b'), d')$. *Let* $\mathsf{ApartZero}_F(h)$ *abbreviate* $h\mathsf{hsame}0 \to \bot$, *and assume conversion maps*

$$\alpha_A : \mathsf{ApartZero}_F(A) \to \mathsf{NonZero}_F(A), \qquad \alpha_B : \mathsf{ApartZero}_F(B) \to \mathsf{NonZero}_F(B).$$

Let q_A *and* q_B *be the product apartness witnesses obtained from Definition 45.248 for the pairs* $(p_{a'}, p_a)$ *and* $(p_b, p_{b'})$, *and set* $p_A := \alpha_A(q_A)$ *and* $p_B := \alpha_B(q_B)$. *Assume the collected-coefficient presentation is pointwise classified with the displayed composite action:*

$$\mathsf{add}(\mathsf{mul}(\mathsf{mul}(A, x), B), D)\mathsf{hsame}T_2(T_1(x)).$$

For each $c : \mathsf{BHist}$ *define*

$$s_1(c) = \mathsf{mul}(\mathsf{inv}(a, p_a), \mathsf{mul}(\mathsf{add}(c, \mathsf{neg}(d)), \mathsf{inv}(b, p_b)))$$

and

$$s_2(c) = \mathsf{mul}(\mathsf{inv}(a', p_{a'}), \mathsf{mul}(\mathsf{add}(c, \mathsf{neg}(d')), \mathsf{inv}(b', p_{b'}))).$$

For each $q : \mathsf{BHist}$ *define the composite explicit inverse*

$$s_{21}(q) = \mathsf{mul}(\mathsf{inv}(A, p_A), \mathsf{mul}(\mathsf{add}(q, \mathsf{neg}(D)), \mathsf{inv}(B, p_B))).$$

Then every $q : \mathsf{BHist}$ *satisfies*

$$s_{21}(q)\mathsf{hsame}s_1(s_2(q)).$$

Lean4 ✓ `BEDC.Derived.FieldUp.field affine composite inverse reverse coherence`

Proof. Let

$$C(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(A, x), B), D).$$

Apply Definition 45.535 to the composite coefficients A, B, D with witnesses p_A, p_B. Its left inverse clause gives $C(s_{21}(q))\mathsf{hsame}q$.

Next instantiate Definition 45.536 for the first component with witnesses p_a, p_b and offset d, and again for the second component with witnesses $p_{a'}, p_{b'}$ and offset d'. The first certificate gives $T_1(s_1(s_2(q)))\mathsf{hsame}s_2(q)$, and the second gives $T_2(s_2(q))\mathsf{hsame}q$.

Use the classifier-preservation direction of the second certificate to transport the first displayed equality through T_2. Transitivity with $T_2(s_2(q))\mathsf{hsame}q$ yields $T_2(T_1(s_1(s_2(q))))\mathsf{hsame}q$.

By Definition 45.541 with the substitution $c = a'$, $e = b'$, and $f = d'$, the left side of this equation is classified by $C(s_1(s_2(q)))$ with the collected coefficients A, B, D, and the certified automorphism status uses the converted witnesses p_A, p_B. Hence $s_1(s_2(q))$ also solves the same composite affine equation $C(x)\mathsf{hsame}q$.

Finally apply Definition 45.298 to the two solutions $s_{21}(q)$ and $s_1(s_2(q))$ of $C(x)\mathsf{hsame}q$. The unique-solution conclusion is exactly $s_{21}(q)\mathsf{hsame}s_1(s_2(q))$. □

Per-object certificate: traditional target affine composite inverse coherence; BEDC source $\mathsf{Field}^{\uparrow}$ over BHist with RingUp distributivity; carrier BHist; classifier hsame; stability obligations explicit inverse exactness, certified component automorphisms, composite coefficient collection, product apartness, and affine equation uniqueness; ledger the four component factor witnesses, the two product witnesses, and the two offsets; core theorem Definition 45.546; exactness predicate reverse-composed explicit inverse equals the collected-coefficient explicit inverse; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.547 (Field affine composite has reverse explicit inverse)**.** *Under the hypotheses and notation of Definition 45.536 and Definition 45.541, define*

$$T(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)$$

and

$$U(z) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(c, z), e), f).$$

Let s_T and s_U be the displayed explicit inverse maps associated to T and U. Then every $x, y, q :$ BHist satisfies

$$U(T(s_T(s_U(q))))\mathsf{hsame}q, \qquad s_T(s_U(U(T(x))))\mathsf{hsame}x, \qquad U(T(x))\mathsf{hsame}U(T(y)) \Longleftrightarrow x\mathsf{hsame}y.$$

Proof. First instantiate Definition 45.541 with the factors and offsets defining T and U. The composition theorem identifies $U \circ T$ as the certified affine composite, and Definition 45.536 supplies the classifier-iff clause for that certified composite.

For the displayed left preimage, apply the left-inverse clause for T at $s_U(q)$, then apply the left-inverse clause for U at q. Congruence of U and transitivity of hsame identify the transported composite with $U(T(s_T(s_U(q))))\mathsf{hsame}q$.

For the right inverse, apply the right-inverse clause of Definition 45.536 to U at the point $T(x)$. This gives

$$s_U(U(T(x)))\mathsf{hsame}T(x).$$

Use the solution-uniqueness clause of Definition 45.535 for T at the target $T(x)$, with the reflexive classification of $T(x)$ as its input. This gives $x\mathsf{hsame}s_T(T(x))$, hence $s_T(T(x))\mathsf{hsame}x$ by symmetry. Transport the displayed equality through the explicit formula for s_T, and finish by transitivity of hsame to obtain $s_T(s_U(U(T(x))))\mathsf{hsame}x$. □

Per-object certificate: traditional target affine automorphism group law; BEDC source $\mathsf{Field}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability obligations two certified affine automorphisms, explicit inverse, and classifier iff; ledger four nonzero factor witnesses and two offsets; core theorem Definition 45.547; exactness predicate two-sided inverse plus composite classifier iff; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.548 (Field affine composite inverse product-witness independence)**.** *Under the notation of Definition 45.546, fix the collected coefficients*

$$A = \mathsf{mul}(a', a), \qquad B = \mathsf{mul}(b, b'), \qquad D = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a', d), b'), d').$$

Let $p_A, p'_A : \mathsf{NonZero}_F(A)$ and $p_B, p'_B : \mathsf{NonZero}_F(B)$ be two choices of product nonzero witnesses. For each $q : \mathsf{BHist}$ define

$$s_{21}^{p_A,p_B}(q) = \mathsf{mul}(\mathsf{inv}(A, p_A), \mathsf{mul}(\mathsf{add}(q, \mathsf{neg}(D)), \mathsf{inv}(B, p_B)))$$

and define $s_{21}^{p'_A,p'_B}(q)$ by the same displayed formula with p'_A, p'_B in place of p_A, p_B. Then every $q : \mathsf{BHist}$ satisfies the three comparisons

1.

$$s_{21}^{p_A,p_B}(q)\mathsf{hsame}s_{21}^{p'_A,p'_B}(q).$$

2.

$$s_{21}^{p_A,p_B}(q)\mathsf{hsame}s_1(s_2(q)).$$

3.

$$s_{21}^{p'_A,p'_B}(q)\mathsf{hsame}s_1(s_2(q)).$$

Proof. We first compare the two collected inverse terms. Apply Definition 45.557 to the two composite affine members with common coefficients A, B, D and witness pairs (p_A, p_B) and (p'_A, p'_B). Its inverse-formula field gives the first displayed comparison pointwise in q.

For agreement with the reverse-composed inverse, apply Definition 45.546 with the witness pair (p_A, p_B) to obtain the second displayed comparison. Apply the same theorem with (p'_A, p'_B) to obtain the third displayed comparison.

The classifier hsame is transitive and symmetric, so these three comparisons form a single certificate: changing product witnesses does not change the collected explicit inverse, and each collected representative agrees with the reverse-composed inverse $s_1(s_2(q))$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine composite inverse product witness independence`

Per-object certificate: traditional target affine composite inverse ledger determinacy; BEDC source $\mathsf{Field}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability obligations Definition 45.557, Definition 45.546, and hsame transitivity; ledger the component witnesses, product witnesses, and offsets; core theorem Definition 45.548; exactness predicate witness-independent collected inverse agreeing with the reverse-composed inverse; downstream consumer affine automorphism group composition certificate; status $\mathsf{ProofTarget}$.

Theorem 45.549 (Field affine inverse is a certified affine map)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow}$ *candidate under the hypotheses of Definition 45.541, let $p_a : \mathsf{NonZero}_F(a)$ and $p_b : \mathsf{NonZero}_F(b)$ be the two nonzero witnesses for*

$$T(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d).$$

For each $c : \mathsf{BHist}$ *put*

$$s(c) = \mathsf{mul}(\mathsf{inv}(a, p_a), \mathsf{mul}(\mathsf{add}(c, \mathsf{neg}(d)), \mathsf{inv}(b, p_b))).$$

Let $A := \mathsf{inv}(a, p_a)$ *and* $B := \mathsf{inv}(b, p_b)$*, and suppose* $p_A : \mathsf{NonZero}_F(A)$ *and* $p_B : \mathsf{NonZero}_F(B)$ *are explicit nonzero witnesses for the inverse coefficients. Define*

$$D := \mathsf{mul}(\mathsf{mul}(A, \mathsf{neg}(d)), B)$$

and

$$S(c) := \mathsf{add}(\mathsf{mul}(\mathsf{mul}(A, c), B), D).$$

Then every $c : \mathsf{BHist}$ *satisfies* $s(c)\mathsf{hsame}S(c)$*, and with witnesses* p_A, p_B *the map* S *is a certified two-sided affine automorphism by Definition 45.536.*

Proof. Expand $s(c)$ and apply the distributivity field from $\mathsf{CommRing}^{\uparrow}$ to the inner sum $c + \mathsf{neg}(d)$ after left multiplication by A. This separates the term containing c from the translated term containing $\mathsf{neg}(d)$.

Next reassociate the right multiplication by B. Multiplication associativity identifies the c-term with $\mathsf{mul}(\mathsf{mul}(A, c), B)$ and identifies the translated term with

$$\mathsf{mul}(\mathsf{mul}(A, \mathsf{neg}(d)), B).$$

The definition of D then gives $s(c)\mathsf{hsame}S(c)$ for every $c : \mathsf{BHist}$.

It remains to certify the displayed normal form. Apply Definition 45.536 with left factor A, right factor B, offset D, and the explicit inverse-coefficient witnesses p_A, p_B. The resulting inverse-pair and classifier-iff clauses are exactly the certified affine automorphism structure for S. □

Theorem 45.550 (Field affine inverse has derived inverse-coefficient witnesses)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow}$ *candidate under the hypotheses of Definition 45.549 before the inverse-coefficient witnesses are supplied, also assume zero-left multiplication* $\mathsf{mul}(0, x)\mathsf{hsame}0$*, one-apartness* $\omega : (1\mathsf{hsame}0) \to \mathsf{False}$*, and conversion maps* $\alpha_x : ((x\mathsf{hsame}0) \to \mathsf{False}) \to \mathsf{NonZero}_F(x)$*. Let* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$ *be the nonzero witnesses for*

$$T(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d).$$

For each $c : \mathsf{BHist}$ *put*

$$s(c) = \mathsf{mul}(\mathsf{inv}(a, p_a), \mathsf{mul}(\mathsf{add}(c, \mathsf{neg}(d)), \mathsf{inv}(b, p_b))).$$

Let $A := \mathsf{inv}(a, p_a)$ *and* $B := \mathsf{inv}(b, p_b)$*. Then there are derived witnesses* $p_A : \mathsf{NonZero}_F(A)$ *and* $p_B : \mathsf{NonZero}_F(B)$ *such that, for*

$$D := \mathsf{mul}(\mathsf{mul}(A, \mathsf{neg}(d)), B)$$

and

$$S(c) := \mathsf{add}(\mathsf{mul}(\mathsf{mul}(A, c), B), D),$$

every $c : \mathsf{BHist}$ *satisfies* $s(c)\mathsf{hsame}S(c)$*, and* S *is a certified two-sided affine automorphism.*

Proof. Apply Definition 45.207 to p_a with the displayed zero-left multiplication law, one-apartness witness ω, and conversion map α_A. This produces $p_A : \mathsf{NonZero}_F(\mathsf{inv}(a, p_a))$, which is $\mathsf{NonZero}_F(A)$ by the definition of A.

Apply the same theorem to p_b with the same structural data and conversion map α_B. This gives $p_B : \mathsf{NonZero}_F(\mathsf{inv}(b, p_b))$, hence $\mathsf{NonZero}_F(B)$.

With p_A and p_B now available, invoke Definition 45.549. Its normal-form clause gives $s(c)\mathsf{hsame}S(c)$ for every $c : \mathsf{BHist}$, and its certification clause is exactly the certified two-sided affine automorphism structure for S. □

Per-object certificate: traditional target $\mathsf{Field}^{\uparrow}$ affine inverse witness derivation; BEDC source $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability obligations zero-left multiplication, one-apartness, inverse laws, and affine normal-form certification; ledger the original coefficient witnesses and the derived inverse-coefficient witnesses; core theorem Definition 45.550; exactness predicate inverse affine normal form with derived witnesses; standard bridge ordinary affine automorphism group; status $\mathsf{ProofTarget}$.

Per-object certificate: traditional target inverse closure for affine automorphisms; BEDC source $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability obligations affine equation exactness, distributivity, associativity, inverse laws, and nonzero witnesses for inverse coefficients; ledger the original and inverse coefficient witnesses plus offset; core theorem Definition 45.549; exactness predicate inverse affine normal form; standard bridge ordinary affine automorphism group; status $\mathsf{ProofTarget}$.

Theorem 45.551 (Field affine explicit inverse is a certified automorphism)**.** *Under the hypotheses and notation of Definition 45.536, define*

$$T(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)$$

and, for each $r : \mathsf{BHist}$*, define*

$$s(r) = \mathsf{mul}(\mathsf{inv}(a, p_a), \mathsf{mul}(\mathsf{add}(r, \mathsf{neg}(d)), \mathsf{inv}(b, p_b))).$$

Then every $c, e, x : \mathsf{BHist}$ *satisfies*

$$s(T(x))\mathsf{hsame}x, \qquad T(s(c))\mathsf{hsame}c, \qquad s(c)\mathsf{hsame}s(e) \iff c\mathsf{hsame}e.$$

Proof. Apply Definition 45.536 with witnesses p_a, p_b and offset d. Its inverse-pair clauses give $s(T(x))\mathsf{hsame}x$ and $T(s(c))\mathsf{hsame}c$ directly.

For the forward direction of the inverse-map classifier iff, assume $c\mathsf{hsame}e$. Compose $T(s(c))\mathsf{hsame}c$, the assumed equality, and the symmetry of $T(s(e))\mathsf{hsame}e$ to obtain

$$T(s(c))\mathsf{hsame}T(s(e)).$$

Reflect this equality through the certified classifier iff for T to conclude $s(c)\mathsf{hsame}s(e)$.

For the reverse direction, assume $s(c)\mathsf{hsame}s(e)$. The classifier-preservation direction for T gives

$$T(s(c))\mathsf{hsame}T(s(e)).$$

Compose the symmetry of $T(s(c))\mathsf{hsame}c$, the displayed equality, and $T(s(e))\mathsf{hsame}e$ to obtain $c\mathsf{hsame}e$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine explicit inverse certified automorphism`

Per-object certificate: traditional target inverse affine automorphism; BEDC source $\mathsf{Field}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability obligations certified affine automorphism, inverse-pair clauses, and classifier iff; ledger the two nonzero witnesses and offset; core theorem Definition 45.551; exactness predicate inverse-map classifier iff; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.552 (Field affine explicit inverse is classifier-congruent)**.** *Under the hypotheses and notation of Definition 45.536, define*

$$T(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)$$

and

$$s(c) = \mathsf{mul}(\mathsf{inv}(a, p_a), \mathsf{mul}(\mathsf{add}(c, \mathsf{neg}(d)), \mathsf{inv}(b, p_b))).$$

If $c\mathsf{hsame}c'$*, then*

$$s(c)\mathsf{hsame}s(c').$$

Proof. The left inverse clauses of Definition 45.536 give $T(s(c))\mathsf{hsame}c$ and $T(s(c'))\mathsf{hsame}c'$. Compose the first equality with $c\mathsf{hsame}c'$ and with the symmetry of the second equality. This produces

$$T(s(c))\mathsf{hsame}T(s(c')).$$

The classifier iff in Definition 45.536 reflects equality of T-images back to equality of inputs. Applying that reflection direction to the displayed classification yields $s(c)\mathsf{hsame}s(c')$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine explicit inverse classifier congruence`

Theorem 45.553 (Field affine pointwise classifier gives operation congruence)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow}$ *candidate under the hypotheses of Definition 45.536, Definition 45.541, and Definition 45.549, let* T, T', U, U' *be certified displayed affine maps over* BHist*. Write* T^{-1}_{exp} *for the displayed explicit inverse formula supplied by Definition 45.536, and similarly for the other certified maps. Suppose* $\equiv_{\mathrm{aff}}$ *is the pointwise classifier of Definition 45.560. Then the following clauses hold.*

1. *If* $T \equiv_{\mathrm{aff}} T'$ *and* $U \equiv_{\mathrm{aff}} U'$*, then*
$$U \circ T \equiv_{\mathrm{aff}} U' \circ T'.$$
2. *If* $T \equiv_{\mathrm{aff}} U$*, then*
$$T^{-1}_{\mathrm{exp}} \equiv_{\mathrm{aff}} U^{-1}_{\mathrm{exp}}.$$

Proof. For composition, fix $x : \mathsf{BHist}$. The assumption $T \equiv_{\mathrm{aff}} T'$ gives $T(x)\mathsf{hsame}T'(x)$. The classifier-preservation direction of the certified affine automorphism structure for U transports this to

$$U(T(x))\mathsf{hsame}U(T'(x)).$$

The assumption $U \equiv_{\mathrm{aff}} U'$ at the point $T'(x)$ gives

$$U(T'(x))\mathsf{hsame}U'(T'(x)).$$

Transitivity of hsame gives $U(T(x))\mathsf{hsame}U'(T'(x))$ for every x, which is exactly $U \circ T \equiv_{\mathrm{aff}} U' \circ T'$.

For inverse congruence, fix $q : \mathsf{BHist}$. The explicit inverse clauses give $T(T^{-1}_{\exp}(q))\mathsf{hsame}q$ and $U(U^{-1}_{\exp}(q))\mathsf{hsame}q$. The pointwise comparison $T \equiv_{\mathrm{aff}} U$ at $U^{-1}_{\exp}(q)$ gives

$$T(U^{-1}_{\exp}(q))\mathsf{hsame}U(U^{-1}_{\exp}(q)).$$

Thus $T(U^{-1}_{\exp}(q))\mathsf{hsame}q$. The two-sided affine equation uniqueness theorem Definition 45.298, applied to the two displayed preimages of q under T, gives $T^{-1}_{\exp}(q)\mathsf{hsame}U^{-1}_{\exp}(q)$. Since q was arbitrary, the explicit inverse formulas are related by $\equiv_{\mathrm{aff}}$. □

Per-object certificate: traditional target affine inverse stability; BEDC source $\mathsf{Field}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability obligations certified affine automorphism, left inverse, and classifier reflection; ledger the two nonzero witnesses and offset; core theorem Definition 45.552; exactness predicate inverse-map classifier congruence; standard bridge ordinary affine inverse congruence; status $\mathsf{ProofTarget}$.

Theorem 45.554 (Field affine automorphism composition is associative)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}+\mathsf{CommRing}^{\uparrow}$ *candidate under the hypotheses of Definition 45.541, let* $p_a, p_b, p_c, p_e, p_g, p_i$ *be nonzero witnesses for the six displayed factors in the certified affine maps*

$$T_1(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d),$$

$$T_2(y) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(c, y), e), f),$$

and

$$T_3(z) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(g, z), i), j).$$

Let $\mathsf{ApartZero}_F(h)$ *abbreviate* $h\mathsf{hsame}0 \to \bot$. *Assume the product-apartness conversion maps required to certify the two binary composites and the two outer composites:*

$\alpha^L_{21} : \mathsf{ApartZero}_F(\mathsf{mul}(c, a)) \to \mathsf{NonZero}_F(\mathsf{mul}(c, a))$, $\alpha^R_{21} : \mathsf{ApartZero}_F(\mathsf{mul}(b, e)) \to \mathsf{NonZero}_F(\mathsf{mul}(b, e))$,

$\alpha^L_{32} : \mathsf{ApartZero}_F(\mathsf{mul}(g, c)) \to \mathsf{NonZero}_F(\mathsf{mul}(g, c))$, $\alpha^R_{32} : \mathsf{ApartZero}_F(\mathsf{mul}(e, i)) \to \mathsf{NonZero}_F(\mathsf{mul}(e, i))$,

$\alpha^L_{3(21)} : \mathsf{ApartZero}_F(\mathsf{mul}(g, \mathsf{mul}(c, a))) \to \mathsf{NonZero}_F(\mathsf{mul}(g, \mathsf{mul}(c, a)))$, $\alpha^R_{3(21)} : \mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(b, e), i)) \to$

and

$\alpha^L_{(32)1} : \mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(g, c), a)) \to \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(g, c), a))$, $\alpha^R_{(32)1} : \mathsf{ApartZero}_F(\mathsf{mul}(b, \mathsf{mul}(e, i))) \to$

Put

$$A_{21} = \mathsf{mul}(c, a), \quad B_{21} = \mathsf{mul}(b, e), \quad D_{21} = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(c, d), e), f),$$
$$A_{32} = \mathsf{mul}(g, c), \quad B_{32} = \mathsf{mul}(e, i), \quad D_{32} = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(g, f), i), j).$$

The bracketing $T_3 \circ (T_2 \circ T_1)$ *supplies*

$$C_L(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(g, A_{21}), x), \mathsf{mul}(B_{21}, i)), \mathsf{add}(\mathsf{mul}(\mathsf{mul}(g, D_{21}), i), j)),$$

and the bracketing $(T_3 \circ T_2) \circ T_1$ *supplies*

$$C_R(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(A_{32}, a), x), \mathsf{mul}(b, B_{32})), \mathsf{add}(\mathsf{mul}(\mathsf{mul}(A_{32}, d), B_{32}), D_{32})).$$

Then every $x, q : \mathsf{BHist}$ *satisfies*

$$C_L(x)\mathsf{hsame}C_R(x).$$

Moreover, if s_1, s_2, s_3 *are the reverse explicit inverse formulas attached to* T_1, T_2, T_3*, if* s_{21} *is the reverse explicit inverse for the certified composite* $T_2 \circ T_1$*, and if* s_{32} *is the reverse explicit inverse for* $T_3 \circ T_2$*, then the two bracketed reverse inverse formulas classify together:*

$$s_{21}(s_3(q))\mathsf{hsame}s_1(s_{32}(q)).$$

Proof. First certify the inner composites. Apply Definition 45.541 to $T_2 \circ T_1$ using $\alpha^L_{21}, \alpha^R_{21}$, and apply the same theorem to $T_3 \circ T_2$ using $\alpha^L_{32}, \alpha^R_{32}$. The collected data are respectively A_{21}, B_{21}, D_{21} and A_{32}, B_{32}, D_{32}.

Next certify the two outer composites. Apply Definition 45.541 to $T_3 \circ (T_2 \circ T_1)$ using $\alpha^L_{3(21)}, \alpha^R_{3(21)}$, and apply it to $(T_3 \circ T_2) \circ T_1$ using $\alpha^L_{(32)1}, \alpha^R_{(32)1}$. Both certified maps classify the same term $T_3(T_2(T_1(x)))$.

The collected left factors are $\mathsf{mul}(g, \mathsf{mul}(c, a))$ and $\mathsf{mul}(\mathsf{mul}(g, c), a)$, the collected right factors are $\mathsf{mul}(\mathsf{mul}(b, e), i)$ and $\mathsf{mul}(b, \mathsf{mul}(e, i))$. Multiplication associativity identifies each pair.

It remains to compare the offsets. Expand D_{21} and D_{32}. Distributivity moves the middle offset f through the final affine map, and multiplication associativity collects the factors multiplying d. The two displayed offsets therefore classify together, so the normal forms $C_L(x)$ and $C_R(x)$ classify together for every x.

For the inverse formulas, apply Definition 45.546 to $T_2 \circ T_1$ and then compose the resulting equality with $s_3(q)$. Apply the same coherence theorem to $T_3 \circ T_2$ at q, then transport through s_1. Transitivity gives $s_{21}(s_3(q))\mathsf{hsame}s_1(s_2(s_3(q)))\mathsf{hsame}s_1(s_{32}(q))$, which is the displayed equality. □

Per-object certificate: traditional target affine automorphism associativity; BEDC source $\mathsf{Field}^{\uparrow}+\mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability obligations binary affine composition, product apartness, distributivity, inverse coherence; ledger the six factor witnesses, product witnesses, and three offsets; core theorem Definition 45.554; exactness predicate associativity of certified affine composition; standard bridge ordinary affine group law; status $\mathsf{ProofTarget}$.

Theorem 45.555 (Field affine automorphism identity and inverse package)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *under the hypotheses used by Definition 45.536 and Definition 45.541, bind the unit witness* $p_1 : \mathsf{NonZero}_F(1)$ *and define*

$$I(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(1, x), 1), 0).$$

For every certified two-sided affine map

$$T(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d)$$

with witnesses $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$*, every* $x : \mathsf{BHist}$ *satisfies*

$$I(x)\mathsf{hsame}x, \qquad I(T(x))\mathsf{hsame}T(x), \qquad T(I(x))\mathsf{hsame}T(x).$$

For every second certified two-sided affine map

$$U(z) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(c, z), e), f)$$

with witnesses $p_c : \mathsf{NonZero}_F(c)$ *and* $p_e : \mathsf{NonZero}_F(e)$*, let* $\mathsf{ApartZero}_F(h)$ *abbreviate* $h\mathsf{hsame}0 \to \bot$*. Assume conversion maps*

$$\alpha_{ca} : \mathsf{ApartZero}_F(\mathsf{mul}(c,a)) \to \mathsf{NonZero}_F(\mathsf{mul}(c,a)), \qquad \alpha_{be} : \mathsf{ApartZero}_F(\mathsf{mul}(b,e)) \to \mathsf{NonZero}_F(\mathsf{mul}(b,e)).$$

Let q_{ca} *and* q_{be} *be the product-apartness witnesses supplied by Definition 45.248 for the pairs* (p_c, p_a) *and* (p_b, p_e)*, and set* $p_{ca} := \alpha_{ca}(q_{ca})$ *and* $p_{be} := \alpha_{be}(q_{be})$*. Then the composite* $U(T(x))$ *is certified by the collected coefficients*

$$A = \mathsf{mul}(c,a), \qquad B = \mathsf{mul}(b,e), \qquad D = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(c,d),e),f)$$

together with the product witnesses p_{ca} *and* p_{be}*. Moreover, if* s_T *and* s_U *are the displayed inverse maps for* T *and* U*, then* $s_T(s_U(q))$ *is a two-sided inverse of* $U(T(x))$ *and agrees with the collected-coefficient inverse of the composite indexed by* p_{ca} *and* p_{be}*. Hence the identity affine map, composition, inverse closure, and classifier iff clauses form the affine automorphism package over* BHist*.*

Proof. The identity clauses use the same $\mathsf{Field}^{\uparrow}$ operations as the certified affine maps. The multiplicative unit laws reduce $\mathsf{mul}(\mathsf{mul}(1,x),1)$ to x, and the additive zero law reduces the outer addition to x; substituting $T(x)$ for x gives $I(T(x))\mathsf{hsame}T(x)$. Classifier preservation for T from Definition 45.536 transports $I(x)\mathsf{hsame}x$ through T, giving $T(I(x))\mathsf{hsame}T(x)$.

For composition, apply Definition 45.541 to the two certified affine maps using the displayed α_{ca} and α_{be} data. The product-apartness witnesses q_{ca} and q_{be} supplied by Definition 45.248 are converted into p_{ca} and p_{be}, so the composition theorem supplies the collected coefficients A, B, D, the certified composite indexed by those product witnesses, and the classifier iff for $U \circ T$. The certified-automorphism clauses are then read through Definition 45.536.

For inverse closure, use Definition 45.547. It states that the reverse composite $s_T(s_U(q))$ is both a left preimage and a right inverse for $U(T(x))$, while preserving the classifier iff. Finally, Definition 45.546 identifies this reverse composite with the inverse obtained directly from the collected coefficients, so the inverse operation is closed under the same ledger data. □

Per-object certificate: traditional target affine automorphism group interface; BEDC source $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability obligations identity, composition, inverse, and classifier iff; ledger factor witnesses, product witnesses, inverse witnesses, and offsets; core theorem Definition 45.555; exactness predicate identity plus inverse-closed composition; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.556 (Field affine automorphisms form a GroupUp-compatible package)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow}$ *candidate over* BHist *under the hypotheses used by Definition 45.536 and Definition 45.541, let* AffAut_F *be the carrier of certified two-sided affine maps. A member is a tuple* (a, b, d, p_a, p_b) *with* $a, b, d : \mathsf{BHist}$*,* $p_a : \mathsf{NonZero}_F(a)$*, and* $p_b : \mathsf{NonZero}_F(b)$*, displaying*

$$T_{a,b,d}(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a,x),b),d).$$

The affine classifier relates two members when their displayed maps are pointwise hsame*, exactly as in Definition 45.560. The identity member has coefficients* $(1,1,0)$ *with the unit nonzero witnesses. The product of* $U = (c, e, f, p_c, p_e)$ *after* $T = (a, b, d, p_a, p_b)$ *has collected coefficients*

$$A = \mathsf{mul}(c,a), \qquad B = \mathsf{mul}(b,e), \qquad D = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(c,d),e),f).$$

The inverse operation is represented by the explicit inverse formula certified in Definition 45.549. With these data, AffAut_F *satisfies the* $\mathsf{Group}^{\uparrow}$ *source fields: carrier inhabitance, closure under*

composition and inverse, associativity under the affine classifier, left and right identity laws, left and right inverse laws, and classifier congruence for both composition and inverse.

Proof. Carrier inhabitance is supplied by the identity coefficients. The unit nonzero witnesses and the identity clauses of Definition 45.555 show that this member acts as the identity map on every $x : \mathsf{BHist}$, and hence is the distinguished AffAut_F element.

Composition closure is the collected-coefficient construction of Definition 45.541. It supplies the product nonzero witnesses for A and B, the displayed affine normal form for $U(T(x))$, and the classifier iff clauses for the composite. The certified two-sided behavior of each displayed map is read through Definition 45.536.

Associativity is exactly the pointwise comparison from Definition 45.554. For three certified affine members, the two parenthesized compositions collect to classifier-equal displayed maps, so the pointwise affine classifier identifies the two products.

The inverse operation uses Definition 45.555 for the single-map identity and inverse clauses, together with Definition 45.549 for inverse closure. These clauses give left and right inverse laws under the affine classifier.

Classifier congruence for composition and inverse is exactly Definition 45.553. Hence the pointwise classifier supplies the operation fields required by the $\mathsf{Group}^{\uparrow}$ package. □

Per-object certificate: traditional target affine automorphism $\mathsf{Group}^{\uparrow}$ interface; BEDC source $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow}$ over BHist; carrier AffAut_F; classifier pointwise hsame on displayed affine maps; stability obligations inhabitance, composition, inverse, associativity, identity, inverse laws, and classifier congruence; ledger identity witnesses, side-factor witnesses, product witnesses, reverse inverse formulas, and offsets; core theorem Definition 45.556; exactness predicate $\mathsf{Group}^{\uparrow}$ source-field satisfaction for certified affine automorphisms; standard bridge ordinary affine automorphism group law; status $\mathsf{ProofTarget}$.

Theorem 45.557 (Field affine product is independent of product witnesses)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow}$ *candidate over* BHist *under the hypotheses of Definition 45.541, let* $T = (a, b, d, p_a, p_b)$ *and* $U = (c, e, f, p_c, p_e)$ *be certified affine members of* AffAut_F*. Set*

$$A = \mathsf{mul}(c, a), \qquad B = \mathsf{mul}(b, e), \qquad D = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(c, d), e), f).$$

Let two choices of apartness-to-nonzero conversion data produce witnesses

$$p_{ca}, p'_{ca} : \mathsf{NonZero}_F(A), \qquad p_{be}, p'_{be} : \mathsf{NonZero}_F(B).$$

Form the two composite affine members with the same collected coefficients (A, B, D) *and with witness pairs* (p_{ca}, p_{be}) *and* (p'_{ca}, p'_{be})*. Then the affine classifier on* AffAut_F *relates these two composites: their displayed maps are pointwise* hsame*, and their reverse explicit inverse formulas are pointwise* hsame*.*

Lean4 ✓ `BEDC.Derived.FieldUp.field affine product witness independence`

Proof. The displayed composite maps have identical coefficients A and B and the same offset D. For each $x : \mathsf{BHist}$, both displays reduce to $\mathsf{add}(\mathsf{mul}(\mathsf{mul}(A, x), B), D)$, so pointwise classification is reflexive.

It remains to compare the proof-indexed inverse factors occurring in the reverse explicit inverse formulas. Apply Definition 45.202 to the reflexive coefficient comparison $A\mathsf{hsame}A$ with witnesses p_{ca} and p'_{ca}, giving $\mathsf{inv}(A, p_{ca})\mathsf{hsameinv}(A, p'_{ca})$. Apply the same theorem to $B\mathsf{hsame}B$ with witnesses p_{be} and p'_{be}, giving $\mathsf{inv}(B, p_{be})\mathsf{hsameinv}(B, p'_{be})$.

Multiplication congruence transports the first inverse comparison through the left affine factor, multiplication congruence transports the second comparison through the right affine factor, and addition congruence transports the shared offset term. Therefore the two reverse explicit inverse formulas are pointwise hsame, which is exactly the second field of the affine classifier. □

Per-object certificate: traditional target affine composition well-definedness; BEDC source $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow}$ over BHist; carrier AffAut_F; classifier the affine classifier; stability obligation proof-index independence for product witnesses; ledger the two witness pairs (p_{ca}, p_{be}) and (p'_{ca}, p'_{be}); core theorem Definition 45.557; exactness predicate product operation descends to the affine classifier; standard bridge ordinary affine automorphism composition; status ProofTarget.

Capstone.

Theorem 45.558 (Field affine automorphism group certificate)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}+\mathsf{CommRing}^{\uparrow}$ *candidate over* BHist*, let* $\mathsf{AffAut}_F(T)$ *mean that* T *carries displayed parameters* $a, b, d :$ BHist*, witnesses* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$*, and the certified two-sided affine automorphism clauses for*

$$T(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d).$$

Equip the affine classifier with pointwise hsame *on all carried histories. Then the identity affine map, the collected-coefficient composition law, and the explicit inverse operation satisfy the* $\mathsf{Group}^{\uparrow}$ *stability fields: left and right identity, associativity of composition, inverse closure, left and right inverse laws, and classifier congruence. Moreover, for certified members* $T = (a, b, d, p_a, p_b)$ *and* $U = (c, e, f, p_c, p_e)$ *with fixed collected coefficients*

$$A = \mathsf{mul}(c, a), \qquad B = \mathsf{mul}(b, e), \qquad D = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(c, d), e), f),$$

any two product-witness choices p_{ca}, p_{be} *and* p'_{ca}, p'_{be} *produce composite affine members related by the affine pointwise classifier, including their reverse explicit inverse formulas. Equivalently, the displayed affine automorphism package determines the concrete* $\mathsf{Group}^{\uparrow}$ *certificate for* AffAut_F *over* BHist*.*

Proof. The identity and inverse data are exactly the package isolated in Definition 45.555. The identity affine map supplies both unit laws pointwise, and Definition 45.535 supplies the displayed inverse operation with its left and right inverse clauses.

Composition uses the collected coefficients from the same package, with the two-sided certification read through Definition 45.536.

For proof-relevant product witnesses, fix collected coefficients A, B, and D and compare the two composites built from witness pairs (p_{ca}, p_{be}) and (p'_{ca}, p'_{be}). Apply Definition 45.557: it gives pointwise hsame for the displayed composite maps and for their reverse explicit inverse formulas, which discharges the witness-choice descent field of the certificate.

The classifier is pointwise hsame, so classifier congruence for composition and inverse is obtained from Definition 45.553.

Associativity is the normal-form statement of Definition 45.554. It identifies the two parenthesized collected composites by the BEDC ring and field laws, and therefore gives the associativity field of the $\mathsf{Group}^{\uparrow}$ certificate.

The theorem BEDC.Derived.GroupUp.group_stability_certificate_fields is the packaging result consumed by Lean: once the identity, composition, associativity, inverse closure, inverse laws, and classifier congruence fields are supplied, it repacks them as the public $\mathsf{Group}^{\uparrow}$ stability certificate. The preceding paragraphs provide precisely those fields for AffAut_F. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldAffineAutomorphismGroupCertificate`

Theorem 45.559 (Field affine automorphism inverse uniqueness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow}$ *candidate over* BHist *satisfying Definition 45.558, let* $T : \mathsf{AffAut}_F$ *be a certified affine automorphism history. Let* $I : \mathsf{AffAut}_F$ *be the identity affine automorphism, let* $\circ_{\mathrm{aff}}$ *be the collected-coefficient affine composition operation, and let* $S : \mathsf{AffAut}_F$ *be the explicit inverse certificate for* T *supplied by Definition 45.555. If* $U : \mathsf{AffAut}_F$ *is any certified affine automorphism history satisfying both inverse equations*

$$(U \circ_{\mathrm{aff}} T) \equiv_{\mathrm{aff}} I$$

and

$$(T \circ_{\mathrm{aff}} U) \equiv_{\mathrm{aff}} I$$

under the affine composition classifier, then U *and* S *are related by the affine pointwise classifier:*

$$U \equiv_{\mathrm{aff}} S.$$

Proof. Read Definition 45.558 as the concrete $\mathsf{Group}^{\uparrow}$ package on the carrier AffAut_F. Its operation is $\circ_{\mathrm{aff}}$, its identity is I, and its classifier is the affine pointwise classifier.

The explicit inverse package Definition 45.555 gives the two inverse equations for S against T. The hypotheses give the corresponding left and right inverse equations for U against the same element T in the same classifier.

Apply the checked group inverse uniqueness principle $\mathsf{BEDC.Derived.GroupUp.group_left_right_inverse_uniquer}$ to this affine $\mathsf{Group}^{\uparrow}$ package, with middle element T, left inverse candidate U, and right inverse candidate S. The resulting group-classifier relation is exactly $U \equiv_{\mathrm{aff}} S$, because the group certificate was built from the affine pointwise classifier. □

Definition 45.560 (Field affine automorphism package)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist*, a field affine certificate is data* (a, b, d, p_a, p_b) *with* $a, b, d : \mathsf{BHist}$*,* $p_a : \mathsf{NonZero}_F(a)$*, and* $p_b : \mathsf{NonZero}_F(b)$*. Its displayed map is*

$$T_{a,b,d}(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a, x), b), d).$$

For two displayed affine maps T *and* U*, the affine pointwise classifier is defined by*

$$T \equiv_{\mathrm{aff}} U \quad \Longleftrightarrow \quad \textit{every } x : \mathsf{BHist} \textit{ satisfies } T(x)\mathsf{hsame}U(x).$$

Theorem 45.561 (Field affine automorphism package laws)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow}$ *candidate over* BHist*, assume the explicit nonzero witness* $p_1 : \mathsf{NonZero}_F(\mathsf{one})$ *and the inverse-coefficient nonzero witnesses required by Definition 45.549. Then the affine certificates of Definition 45.560 satisfy the* $\mathsf{Group}^{\uparrow}$*-style law package under* $\equiv_{\mathrm{aff}}$*: the identity certificate is* $(\mathsf{one}, \mathsf{one}, \mathsf{zero}, p_1, p_1)$*, the coefficient-collected composition is the composite supplied by Definition 45.541, and the inverse of* (a, b, d, p_a, p_b) *is the normal form supplied by Definition 45.549. These operations are closed on certified affine automorphisms, composition is associative under the pointwise classifier, and every certificate satisfies the left and right identity laws and the left and right inverse laws under* $\equiv_{\mathrm{aff}}$*.*

Proof. The identity certificate uses the unit and zero laws already carried by the $\mathsf{Field}^{\uparrow}+\mathsf{CommRing}^{\uparrow}$ setup. For every $x : \mathsf{BHist}$, the displayed map with coefficients $(\mathsf{one}, \mathsf{one}, \mathsf{zero})$ reduces by the left and right multiplicative unit laws and the additive zero law to x, so it is the identity under $\equiv_{\mathrm{aff}}$.

Composition closure is exactly Definition 45.541. Given two certified affine automorphisms, that theorem collects the factors and offset into the displayed affine normal form and returns the product nonzero witnesses needed to certify the composite. The resulting certified map is also covered by Definition 45.536.

Associativity is checked pointwise. For three certificates, compare the two parenthesized triple composites by expanding both through the same displayed coefficient collection classifier from Definition 45.541; associativity of the $\mathsf{CommRing}^{\uparrow}$ multiplication and addition data identifies the collected left factor, right factor, and offset. Hence the two triple composites are related by $\equiv_{\mathrm{aff}}$.

Inverse closure is Definition 45.549: the explicit inverse map is classifier-equal to a certified affine normal form whose coefficients use the supplied inverse-coefficient witnesses. The two-sided inverse laws then follow from Definition 45.536 for a single certificate and from Definition 45.547 for a composite, which identifies the reverse explicit inverse with the collected composite inverse. Together these clauses give the stated $\mathsf{Group}^{\uparrow}$-style law package. □

Theorem 45.562 (Field affine automorphism sibling lattice)**.** *For the affine automorphism package of Definition 45.560, the* $\mathsf{Field}^{\uparrow}$ *exit reads the* $\mathsf{Rat}^{\uparrow}$ *concrete arithmetic surface through chapter 37 and the group-law consumer surface through chapter 41. The package has no independent affine automorphism route that bypasses those two sibling certificates: every accepted read of the affine carrier, pointwise classifier, coefficient ledger, nonzero ledger, inverse ledger, identity law, composition law, associativity law, and inverse law is routed through the displayed rational arithmetic source and the displayed group-law consumer.*

Proof. The carrier and classifier are the ones fixed in Definition 45.560: a certificate is the finite tuple (a, b, d, p_a, p_b) over BHist, and equality of displayed maps is the pointwise relation $\equiv_{\mathrm{aff}}$. The coefficient rows are not new ambient automorphism data; they are the rationally readable arithmetic rows of the $\mathsf{Field}^{\uparrow}$ candidate, so the concrete arithmetic exit is the $\mathsf{Rat}^{\uparrow}$ surface named by chapter 37.

The law package is supplied by Definition 45.561. Its closure, identity, associativity, and inverse clauses are precisely the group-law shape consumed through chapter 41. The certified affine composition row is Definition 45.541; the certified inverse row is Definition 45.549; and the pointwise classifier boundary is the displayed $\equiv_{\mathrm{aff}}$ classifier from the package definition.

Thus the package factors through the two sibling certificates before it reaches any downstream affine action. In ten fields, the public dependency record is: BEDC source $\mathsf{Field}^{\uparrow}$ over $\mathsf{Rat}^{\uparrow}$ plus $\mathsf{Group}^{\uparrow}$; carrier AffAut_F; classifier $\equiv_{\mathrm{aff}}$; coefficient ledger row; nonzero ledger row; inverse ledger row; composition ledger row; identity ledger row; sibling certificate pair chapter 37 and chapter 41; and downstream consumer affine normalizer action. □

Theorem 45.563 (Field threefold certified affine automorphisms compose)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with the operations, congruence laws, distributivity laws, indexed inverse laws, classifier transport of* $\mathsf{NonZero}_F$*, and product-apartness conversion maps used in Definition 45.541, let* $p_{a_1} : \mathsf{NonZero}_F(a_1)$*,* $p_{b_1} : \mathsf{NonZero}_F(b_1)$*,* $p_{a_2} : \mathsf{NonZero}_F(a_2)$*,* $p_{b_2} : \mathsf{NonZero}_F(b_2)$*,* $p_{a_3} : \mathsf{NonZero}_F(a_3)$*, and* $p_{b_3} : \mathsf{NonZero}_F(b_3)$ *be the six side-factor witnesses. Define the component maps*

$$T_1(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a_1, x), b_1), d_1), \qquad T_2(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a_2, x), b_2), d_2), \qquad T_3(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a_3, x), b_3),$$

First collect the factors for $T_2 \circ T_1$ *by*

$$A_{21} = \mathsf{mul}(a_2, a_1), \qquad B_{21} = \mathsf{mul}(b_1, b_2), \qquad D_{21} = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a_2, d_1), b_2), d_2).$$

Then collect the factors for $T_3 \circ T_2 \circ T_1$ by

$$A_{321} = \mathsf{mul}(a_3, A_{21}), \qquad B_{321} = \mathsf{mul}(B_{21}, b_3), \qquad D_{321} = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(a_3, D_{21}), b_3), d_3).$$

Let $p_{A_{21}}, p_{B_{21}}, p_{A_{321}}, p_{B_{321}}$ be the collected nonzero witnesses obtained from the six side-factor witnesses by the product-apartness theorem Definition 45.271 and the available product-apartness conversion maps. Define the collected normal form

$$C_{321}(x) = \mathsf{add}(\mathsf{mul}(\mathsf{mul}(A_{321}, x), B_{321}), D_{321}).$$

For each $q : \mathsf{BHist}$ define the component inverse maps

$$s_1(q) = \mathsf{mul}(\mathsf{inv}(a_1, p_{a_1}), \mathsf{mul}(\mathsf{add}(q, \mathsf{neg}(d_1)), \mathsf{inv}(b_1, p_{b_1}))),$$

$$s_2(q) = \mathsf{mul}(\mathsf{inv}(a_2, p_{a_2}), \mathsf{mul}(\mathsf{add}(q, \mathsf{neg}(d_2)), \mathsf{inv}(b_2, p_{b_2}))),$$

and

$$s_3(q) = \mathsf{mul}(\mathsf{inv}(a_3, p_{a_3}), \mathsf{mul}(\mathsf{add}(q, \mathsf{neg}(d_3)), \mathsf{inv}(b_3, p_{b_3}))).$$

Then every $x, y, q : \mathsf{BHist}$ satisfies the following clauses.

1.

$$T_3(T_2(T_1(x)))\mathsf{hsame}C_{321}(x).$$

2. The collected normal form C_{321} is a certified two-sided affine automorphism by Definition 45.536 with witnesses $p_{A_{321}}$ and $p_{B_{321}}$.

3.

$$C_{321}(x)\mathsf{hsame}C_{321}(y) \iff x\mathsf{hsame}y.$$

4.

$$C_{321}(s_1(s_2(s_3(q))))\mathsf{hsame}q, \qquad s_1(s_2(s_3(C_{321}(x))))\mathsf{hsame}x.$$

Proof. First apply Definition 45.541 to T_1 and T_2. This gives the collected map with coefficients A_{21}, B_{21}, D_{21} and the intermediate certificate supplied by Definition 45.536.

Next apply the same composition theorem to the certified map for $T_2 \circ T_1$ and the component T_3. The product-apartness theorem Definition 45.271 supplies the collected nonzero witnesses in the two factor positions, so the resulting coefficients are $A_{321}, B_{321}, D_{321}$.

The displayed normal-form equality follows by transitivity from the two binary normal-form equalities. The certificate for C_{321} is then exactly Definition 45.536 instantiated with $p_{A_{321}}$ and $p_{B_{321}}$, and its classifier clause gives the displayed iff.

For the inverse, use Definition 45.545 first for $T_2 \circ T_1$, then for T_3 composed with that intermediate certified map. The explicit inverse order is therefore the reverse component order $q \mapsto s_1(s_2(s_3(q)))$.

Finally, Definition 45.546 identifies that reverse component inverse with the collected-coefficient inverse, while Definition 45.547 supplies the two-sided inverse equations for the displayed composite normal form. □

Per-object certificate: traditional target affine automorphism threefold composition; BEDC source $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow}$ over BHist; carrier BHist; classifier hsame; stability obligations binary affine composition, certified affine automorphism exactness, explicit composite inverse, reverse inverse coherence, and product apartness for collected factors; ledger six side-factor nonzero witnesses, two intermediate product witnesses, two collected product witnesses, and three offsets; core theorem Definition 45.563; exactness predicate collected threefold normal form with reverse component inverse; standard bridge deferred; status ProofTarget.

Theorem 45.564 (Field affine automorphism inverse is involutive)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow}$ *candidate over* BHist *satisfying the hypotheses of Definition 45.558, let* $T = (a, b, d, p_a, p_b)$ *be a certified affine automorphism and let* T_{aff}^{-1} *be the explicit inverse certificate supplied by Definition 45.549. Then applying the same inverse construction again returns the original affine certificate under the affine pointwise classifier:*

$$(T_{\mathrm{aff}}^{-1})_{\mathrm{aff}}^{-1} \equiv_{\mathrm{aff}} T.$$

Proof. The inverse certificate T_{aff}^{-1} is closed among certified affine automorphisms by Definition 45.549. The identity and inverse operations of the affine package are the ones recorded in Definition 45.555, so both T and T_{aff}^{-1} inhabit the same $\mathsf{Group}^{\uparrow}$ carrier of certified affine automorphism histories.

The two inverse equations for T are interpreted through the affine pointwise classifier. Operation congruence from Definition 45.553 transports those equations across classifier-equivalent representatives, so the candidate obtained by inverting T_{aff}^{-1} is a left inverse of T_{aff}^{-1} in the same group package.

Now apply the $\mathsf{Group}^{\uparrow}$ inverse involutivity law from Definition 41.57; equivalently, use the left-right inverse uniqueness principle of Definition 41.59 to identify the second inverse with the original certificate. Re-reading that identity through the affine classifier gives the displayed conclusion. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine explicit inverse double cancel at`

Per-object template: traditional target affine automorphism group inverse involutivity; BEDC source $\mathsf{Field}^{\uparrow}+\mathsf{CommRing}^{\uparrow}$, affine package, and $\mathsf{Group}^{\uparrow}$ inverse laws; carrier certified affine automorphism histories; classifier $\equiv_{\mathrm{aff}}$; stability obligation inverse closure and inverse uniqueness; ledger nonzero coefficient witnesses and inverse-certificate provenance; core theorem Definition 45.564; exactness predicate double-inverse pointwise classifier; standard bridge ordinary affine automorphism group; status $\mathsf{ProofTarget}$.

Theorem 45.565 (Field affine automorphism cancellation)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow}$ *candidate over* BHist *satisfying Definition 45.558, let* S, T, U *be certified affine automorphism histories in* AffAut_F*, and let* $\circ_{\mathrm{aff}}$ *be the coefficient-collected composition operation from the affine package. Then the affine classifier is cancellative on both sides: if*

$$(S \circ_{\mathrm{aff}} T) \equiv_{\mathrm{aff}} (U \circ_{\mathrm{aff}} T),$$

then $S \equiv_{\mathrm{aff}} U$*; and if*

$$(T \circ_{\mathrm{aff}} S) \equiv_{\mathrm{aff}} (T \circ_{\mathrm{aff}} U),$$

then $S \equiv_{\mathrm{aff}} U$*.*

Proof. Instantiate the affine automorphism group law package supplied by Definition 45.558. Its carrier is the class of certified affine automorphism histories, its operation is $\circ_{\mathrm{aff}}$, and its classifier is the affine pointwise relation $\equiv_{\mathrm{aff}}$.

For the common right factor, read $(S \circ_{\mathrm{aff}} T) \equiv_{\mathrm{aff}} (U \circ_{\mathrm{aff}} T)$ as the group classifier equality of the two products with the same right component. Apply Definition 41.116 in this instantiated $\mathsf{Group}^{\uparrow}$ package. The conclusion is the group classifier relation between S and U, which is exactly $S \equiv_{\mathrm{aff}} U$ under the pointwise classifier interpretation.

For the common left factor, read $(T \circ_{\mathrm{aff}} S) \equiv_{\mathrm{aff}} (T \circ_{\mathrm{aff}} U)$ as the group classifier equality of the two products with the same left component. Apply Definition 41.66 in the same instantiated package. Translating the resulting group classifier back through the affine pointwise classifier gives $S \equiv_{\mathrm{aff}} U$. □

Per-object template: traditional target affine automorphism cancellativity; BEDC source $\mathsf{Field}^{\uparrow}+\mathsf{CommRing}^{\uparrow}$, the affine package, and $\mathsf{Group}^{\uparrow}$ cancellation; carrier certified affine automorphism histories; classifier $\equiv_{\text{aff}}$; stability associativity, identity, inverse, and operation congruence; ledger nonzero coefficient witnesses and composition provenance; core theorem Definition 45.565; exactness predicate left and right cancellation under the affine classifier; standard bridge ordinary affine automorphism group; status ProofTarget.

Theorem 45.566 (Field affine automorphism cancellation exactness)**.** *Under the same hypotheses and notation as Definition 45.565, for certified affine automorphism histories S, T, U in AffAut_F, cancellation by the common affine factor is exact on both sides:*

$$(S \circ_{\text{aff}} T) \equiv_{\text{aff}} (U \circ_{\text{aff}} T) \Longleftrightarrow S \equiv_{\text{aff}} U,$$

and

$$(T \circ_{\text{aff}} S) \equiv_{\text{aff}} (T \circ_{\text{aff}} U) \Longleftrightarrow S \equiv_{\text{aff}} U.$$

Proof. For the forward directions, apply Definition 45.565. Its first clause cancels the common right factor T, and its second clause cancels the common left factor T. In both cases the resulting classifier is precisely $S \equiv_{\text{aff}} U$.

For the reverse directions, assume $S \equiv_{\text{aff}} U$. The common factor T is reflexively related to itself by the affine pointwise classifier. Apply Definition 45.553 to the classifier between S and U together with reflexivity of T. With the common factor placed on the right this gives $(S \circ_{\text{aff}} T) \equiv_{\text{aff}} (U \circ_{\text{aff}} T)$; with the common factor placed on the left it gives $(T \circ_{\text{aff}} S) \equiv_{\text{aff}} (T \circ_{\text{aff}} U)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field affine automorphism cancellation exact from empty unit group laws iff`

Per-object template: traditional target affine automorphism cancellative action exactness; BEDC source $\mathsf{Field}^{\uparrow} + \mathsf{CommRing}^{\uparrow}$, the affine package, and $\mathsf{Group}^{\uparrow}$ cancellation; carrier certified affine automorphism histories; classifier affine pointwise equivalence; core theorem Definition 45.566; status ProofTarget.

Theorem 45.567 (Field singleton nonzero append context cancellation)**.** *For histories L, R, Q : BHist, if L and R lie in the singleton carrier A_{e}, then surrounding Q by those append contexts preserves and reflects the singleton nonzero endpoint predicate:*

$$\mathsf{FieldSingletonCarrier}(L) \Rightarrow \mathsf{FieldSingletonCarrier}(R) \Rightarrow (\mathsf{FieldSingletonNonZero}(\mathsf{append}(L, \mathsf{append}(Q, R))) \Longleftrightarrow \mathsf{Field}$$

Proof. The two context carrier witnesses identify L and R with e. Thus $\mathsf{append}(L, \mathsf{append}(Q, R))$ is history-same to Q by the left and right empty append laws. In the forward direction, empty-result inversion for append extracts the singleton carrier witness for Q, and the history comparison transports the displayed $\mathsf{E0}(\mathsf{e})$ endpoint witness back to Q.

Conversely, combine the singleton carrier witness for Q with the two context carrier witnesses to rebuild the nested append carrier by empty-result inversion. The same empty-context comparison transports the nonzero endpoint witness from Q to the nested append endpoint. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonNonZero append context cancel iff`

Theorem 45.568 (RatUp FieldUp denominator context-pair action certificate)**.** *For the concrete tuple $(C_D^u, R_D^u, \mu_D^u, e_D^u, N_D^u)$ with*

$$C_D^u = \mathsf{RatDenomUnitCarrier}, \qquad R_D^u = \mathsf{RatDenomUnitClassifier},$$

$$\mu_D^u = \mathsf{append}, \qquad e_D^u = \mathsf{e}, \qquad N_D^u = \mathsf{RatHistoryCarrier},$$

and for the context-pair structure of Definition 45.479 and the contextual action Γ *of Definition 45.454, the denominator context-pair action certificate for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *consists of the following concrete rows:*

1. $\mathsf{PairClass}_D^u$ *is reflexive, symmetric, and transitive on carried pairs, and it transports the carried pair predicate* $C_D^u(l) \wedge C_D^u(r)$.
2. *The product* $\star$ *of Definition 45.479 is closed on carried pairs and congruent for* $\mathsf{PairClass}_D^u$*, with exact* $\mathsf{PairSupp}_D^u$ *readback as in Definition 45.480.*
3. *The unit-pair action, product-pair composition law, and product strict-support readback are exactly the laws of Definition 45.482.*
4. *The three-layer empty-endpoint contextual action has the normalized single-action form*

$$\Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h))) \sim_{R_D^u} \Gamma_{\mathsf{e},\mathsf{e},\mu_D^u(l_2,\mu_D^u(l_1,l_0)),\mu_D^u(\mu_D^u(r_0,r_1),r_2)}(h)$$

   and the seven-term strict-support readback of Definition 45.469.
5. *These rows, together with Definition 45.474, form the concrete denominator context-pair action certificate for* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$.

Equivalently, the certificate records exactly the pair-action interface of Definition 45.480, Definition 45.482, and the contextual row assembly of Definition 45.472 over the same BHist carrier-classifier-operation tuple $(\mathsf{RatDenomUnitCarrier}, \mathsf{RatDenomUnitClassifier}, \mathsf{append}, \mathsf{e}, \mathsf{RatHistoryCarrier})$.

Proof. First build the classifier rows. The concrete denominator classifier R_D^u is an equivalence on carried histories and transports the carried history predicate by the denominator row package. Applying those rows to the left and right coordinates gives reflexivity, symmetry, transitivity, and carrier transport for $\mathsf{PairClass}_D^u$ on carried pairs.

Next establish product stability. Closure of $\star$ is componentwise closure of μ_D^u. Congruence follows by applying the denominator append congruence rows to the left components and to the right components, preserving the product orders $\mu_D^u(l', l)$ and $\mu_D^u(r, r')$ from Definition 45.479. The exact $\mathsf{PairSupp}_D^u$ readback is Definition 45.480.

Now apply Definition 45.482. It supplies the unit-pair action, the product-pair composition law, the product strict-support readback, and the two-sided unit and associativity clauses for the same product $\star$ and componentwise classifier.

Apply Definition 45.460 to the same carried left context, acted history, and carried right context whenever the pair classifier transports an acting pair. This gives contextual action stability under $\mathsf{PairClass}_D^u$ and keeps the external endpoint contexts empty.

For the iterated action row, apply Definition 45.469. It gives the carried three-layer action, its normalized single-action classifier comparison, and the seven-term strict-support readback for the same Γ, μ_D^u, e_D^u, and N_D^u.

Finally apply Definition 45.474. Its row closure, exactness, unit-composition, and support clauses occupy the one-layer and two-layer rows of the same concrete denominator interface. The pair classifier rows, product congruence, pair-action laws, and threefold normalization therefore assemble as the stated FieldUp denominator context-pair action certificate over BHist. □

Theorem 45.569 (RatUp FieldUp denominator action envelope closure)**.** *For* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$*, the concrete RatUp denominator data*

$$C_D^* = \mathsf{RatDenomUnitCarrier}, \qquad R_D^* = \mathsf{RatDenomUnitClassifier},$$

$$\mu_D^* = \mathsf{append}, \qquad e_D^* = \mathsf{e}, \qquad N_D^* = \mathsf{RatHistoryCarrier},$$

together with the empty-unit tuple

$$(C_D^u, R_D^u, \mu_D^u, e_D^u, N_D^u) = (\mathsf{RatDenomUnitCarrier}, \mathsf{RatDenomUnitClassifier}, \mathsf{append}, \mathsf{e}, \mathsf{RatHistoryCarrier})$$

supply one denominator action envelope. The envelope consists of multiplicative obligation coverage, the contextual multiplicative boundary, the unit-composition row package, and the context-pair action certificate over the same BHist histories, append operation, empty endpoint, and denominator carrier-classifier pair.

Proof. First use Definition 45.439 and Definition 45.438. They supply the multiplicative obligation coverage and the contextual multiplicative boundary for the concrete RatUp denominator data $(C_D^*, R_D^*, \mu_D^*, e_D^*, N_D^*)$.

Next use Definition 45.474. It records the same denominator carrier, classifier, append operation, empty unit, strict-support predicate, and contextual action Γ, and it adds the empty-action unit row, unchanged support row, context-multiplication composition row, and five-term support row.

Finally use Definition 45.568. It packages the carried context-pair predicate, pair unit, product $\star$, componentwise classifier, support readbacks, and star unit and associativity laws for the identical empty-unit tuple $(C_D^u, R_D^u, \mu_D^u, e_D^u, N_D^u)$.

The four cited certificates are all stated over concrete BHist carriers and the concrete operation append. Hence the envelope is a single assembly of denominator action data for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$, not a carrier or classifier transport from another instance. □

Per-object template: traditional target FieldUp(RatUp) denominator action envelope; BEDC source BHist, $\mathsf{RatHistoryCarrier}$, $\mathsf{RatDenomUnitCarrier}$, $\mathsf{RatDenomUnitClassifier}$, append, e, and Γ; carrier $\mathsf{RatDenomUnitCarrier}$; classifier $\mathsf{RatDenomUnitClassifier}$; stability obligations multiplicative coverage, contextual multiplicative boundary, unit-composition rows, and context-pair action laws; ledger denominator histories, empty endpoint, carried context pairs, and strict-support rows; core theorem Definition 45.569; exactness predicate denominator classifier readback and strict-support readback; standard bridge $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ denominator action envelope; status $\mathsf{ProofTarget}$.

Per-object template: traditional target denominator context-pair action certificate for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, $\mathsf{RatDenomUnitCarrier}$, $\mathsf{RatDenomUnitClassifier}$, $\mathsf{RatHistoryCarrier}$, append, Cont, e, and Γ; carrier carried denominator context pairs; classifier $\mathsf{PairClass}_D^u$; stability obligations pair classifier equivalence, carrier transport, $\star$ congruence, unit action, product composition, and threefold normalization; ledger left and right carried denominator contexts plus empty external endpoints; core theorem Definition 45.568; exactness predicate support readback and row closure; standard bridge FieldUp denominator action; status $\mathsf{ProofTarget}$.

Theorem 45.570 (RatUp FieldUp denominator context-pair normalized row exhaustion)**.** *For the concrete denominator context-pair monoid of Definition 45.479 and the concrete contextual action Γ of Definition 45.454, every denominator action row used by* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *is supplied by the concrete BHist data*

$$\mathsf{RatDenomUnitCarrier}, \quad \mathsf{RatDenomUnitClassifier}, \quad \mathsf{append}, \quad \mathsf{e}, \quad \mathsf{RatHistoryCarrier},$$

the empty external contexts, and the pair product $\star$. More precisely, the action interface is exhausted by the row closure package of Definition 45.472, the unit-composition laws of Definition 45.474, the normalized contextual action package of Definition 45.475, the context-pair action laws of Definition 45.482, and the context-pair action certificate of Definition 45.568.

Proof. First invoke Definition 45.472 and Definition 45.474. These two rows provide the carried contextual row package, the unit action, and the composition clauses over (RatDenomUnitCarrier, RatDenomUnitClas

Next invoke Definition 45.475. This identifies the normalized contextual rows with the same concrete denominator tuple and the same empty external endpoints, so no abstract carrier or classifier transport is introduced.

Then invoke Definition 45.482. Its clauses give the unit pair, composition by $\star$, support readback, and associativity for the concrete pair product of Definition 45.479.

Finally invoke Definition 45.568. It identifies the preceding row, unit-composition, normalized, and pair-action clauses as the concrete denominator action certificate consumed by $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$. Hence the displayed BHist objects, empty external contexts, and $\star$ account for the whole denominator action interface. □

Per-object template: traditional target FieldUp(RatUp) denominator context-pair normalized row exhaustion; BEDC source BHist, RatHistoryCarrier, RatDenomUnitCarrier, RatDenomUnitClassifier, append, e, and Γ; carrier denominator context pairs of Definition 45.479; classifier componentwise R^u_D; stability obligations row closure, unit composition, normalized exactness, pair-action unit, pair-action composition, support readback, and $\star$ associativity; ledger normalized contextual rows and pair-action rows with empty external endpoints; core theorem Definition 45.570; exactness predicate denominator action row coverage by the concrete BHist data; standard bridge FieldUp denominator action interface; status ProofTarget.

Theorem 45.571 (Rat denominator context-pair product strict support)**.** *For carried denominator context pairs (l, r) and (l', r'), strict support of their product is exactly the disjunction of the four component supports:*

$$N^u_D(\mu^u_D(\mu^u_D(l', l), \mu^u_D(r, r'))) \iff N^u_D(l') \vee N^u_D(l) \vee N^u_D(r) \vee N^u_D(r').$$

Proof. Apply bilateral strict-support exactness to the left product $\mu^u_D(l', l)$ and the carried right product $\mu^u_D(r, r')$. The remaining right-product support term is then opened by denominator product support exactness for r and r'. Reassociating the resulting disjunction yields the four displayed component supports, and the reverse implication closes the same two product-support equivalences in the opposite order. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomContextPair product strict support iff`

Theorem 45.572 (Rat denominator context-pair product strict support transport)**.** *If (l, r) and (s, t) are componentwise R^u_D-classified, and (l', r') and (s', t') are componentwise R^u_D-classified, then strict support is invariant across the two product endpoints:*

$$N^u_D(\mu^u_D(\mu^u_D(l', l), \mu^u_D(r, r'))) \iff N^u_D(\mu^u_D(\mu^u_D(s', s), \mu^u_D(t, t'))).$$

Proof. The component classifiers expose $\mathsf{hsame}(l, s)$, $\mathsf{hsame}(r, t)$, $\mathsf{hsame}(l', s')$, and $\mathsf{hsame}(r', t')$. Continuation congruence composes these through the two product layers, giving an hsame witness between the two displayed product endpoints. Rat denominator support transports across that endpoint witness in both directions. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomContextPair product strict support transport`

Theorem 45.573 (RatUp FieldUp denominator context-pair product certificate row)**.** *For the concrete denominator context-pair structure of Definition 45.479, let (l, r) and (l', r') be carried denominator context pairs. Let (m, s) and (m', s') be carried comparison pairs with* $\mathsf{PairClass}^u_D((l, r), (m, s))$

and $\mathsf{PairClass}^u_D((l', r'), (m', s'))$. *Then the concrete product* $(l, r) \star (l', r')$ *preserves carried membership, respects the componentwise* R^u_D *classifiers against* $(m, s) \star (m', s')$, *and has bundled strict support exactly*

$$N^u_D(\mu^u_D(\mu^u_D(l', l), \mu^u_D(r, r'))) \Longleftrightarrow \mathsf{PairSupp}^u_D(l, r) \vee \mathsf{PairSupp}^u_D(l', r').$$

The transported product endpoint has the same bundled strict support:

$$N^u_D(\mu^u_D(\mu^u_D(l', l), \mu^u_D(r, r'))) \Longleftrightarrow N^u_D(\mu^u_D(\mu^u_D(m', m), \mu^u_D(s, s'))).$$

Reversing the two acting pairs preserves the component classifiers,

$$R^u_D(\mu^u_D(l', l), \mu^u_D(l, l')) \quad \textit{and} \quad R^u_D(\mu^u_D(r, r'), \mu^u_D(r', r)),$$

and the reversed bundled support has the same readback:

$$N^u_D(\mu^u_D(\mu^u_D(l, l'), \mu^u_D(r', r))) \Longleftrightarrow \mathsf{PairSupp}^u_D(l, r) \vee \mathsf{PairSupp}^u_D(l', r').$$

Proof. Apply Definition 45.481. Its carrier clause gives carried membership for the two components of $(l, r) \star (l', r')$, and its classifier clause gives componentwise R^u_D respect against $(m, s) \star (m', s')$.

The strict support of the concrete product is the support clause of the same operation row. Equivalently, apply Definition 45.571 and regroup the four component supports into $\mathsf{PairSupp}^u_D(l, r) \vee \mathsf{PairSupp}^u_D(l', r')$.

The comparison endpoint has the same strict support by Definition 45.572, using the four component classifiers supplied by the two pair-class hypotheses.

For the reversed product, apply Definition 45.484. It gives the displayed left and right component classifiers. Applying the same commutative-support theorem with the acting pairs exchanged gives the reversed support readback, and commutativity of disjunction identifies it with the displayed pair-support disjunction. □

45.23 Five-factor inverse reversal

Theorem 45.574 (Field inverse five-factor product reversal from apartness-indexed inverses)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *with multiplication associativity, multiplication congruence, left and right identity laws, proof-indexed inverse laws, product nonzero exclusion, and conversion maps from* $\mathsf{ApartZero}_F$ *to* $\mathsf{NonZero}_F$ *for all needed factors and left-nested prefixes*

$$\alpha_a : \mathsf{ApartZero}_F(a) \to \mathsf{NonZero}_F(a), \quad \alpha_b : \mathsf{ApartZero}_F(b) \to \mathsf{NonZero}_F(b),$$

$$\alpha_c : \mathsf{ApartZero}_F(c) \to \mathsf{NonZero}_F(c), \quad \alpha_d : \mathsf{ApartZero}_F(d) \to \mathsf{NonZero}_F(d),$$

$$\alpha_e : \mathsf{ApartZero}_F(e) \to \mathsf{NonZero}_F(e),$$

$$\alpha_{ab} : \mathsf{ApartZero}_F(\mathsf{mul}(a, b)) \to \mathsf{NonZero}_F(\mathsf{mul}(a, b)),$$

$$\alpha_{abc} : \mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(a, b), c)) \to \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(a, b), c)),$$

$$\alpha_{abcd} : \mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a, b), c), d)) \to \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a, b), c), d)),$$

where $\mathsf{ApartZero}_F(h) := (h\mathsf{hsame}0 \to \bot)$, *any witness*

$$p_{abcde} : \mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a, b), c), d), e))$$

induces witnesses p_a, p_b, p_c, p_d, *and* p_e *such that*

$$\mathsf{inv}(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a, b), c), d), e), p_{abcde})\mathsf{hsamemul}(\mathsf{inv}(e, p_e), \mathsf{mul}(\mathsf{inv}(d, p_d), \mathsf{mul}(\mathsf{inv}(c, p_c), \mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a$$

Proof. Apply Definition 45.303 to p_{abcde} for the binary product $(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a,b),c),d),e)$. This gives $q_{abcd} : \mathsf{ApartZero}_F(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a,b),c),d))$ and $q_e : \mathsf{ApartZero}_F(e)$; set $p_{abcd} := \alpha_{abcd}(q_{abcd})$ and $p_e := \alpha_e(q_e)$.

Next apply Definition 45.213 to the same outer binary product with witnesses p_{abcde}, p_{abcd}, and p_e. It identifies the inverse of the fivefold product with $\mathsf{mul}(\mathsf{inv}(e,p_e),\mathsf{inv}(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a,b),c),d),p_{abcd}))$.

Apply Definition 45.221 to the left fourfold prefix, using p_{abcd} and the conversion maps α_{ab}, α_{abc}, α_a, α_b, α_c, and α_d. This produces the factor witnesses p_a, p_b, p_c, and p_d and the reversed fourfold inverse spine.

Multiplication congruence transports the fourfold equality into the right factor of the outer equality. Associativity and transitivity of hsame then rebracket the product into the displayed e,d,c,b,a reversed inverse spine, with all witnesses induced from the original ledger entry p_{abcde}. □

Per-object certificate: Traditional target: finite product inverse reversal. BEDC source: $\mathsf{Field}^{\uparrow}$ over BHist plus zero-product exclusion. Carrier choice: BHist. Classifier choice: hsame. Stability obligations: product apartness extraction, inverse reversal, associativity, and multiplication congruence. Ledger: p_{abcde} plus induced prefix and factor witnesses. Core theorem list: Theorem 45.574. Exactness predicate: the displayed reversed equality. Standard bridge: deferred. Status: $\mathsf{ProofTarget}$.

Theorem 45.575 (RatUp FieldUp transported exit row contextual separation package)**.** *For the concrete source tuple* $\mathsf{RatUpFieldSource}_F$*, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, and the contextual action* Γ *of Definition 45.454, let* $x := \Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))$*. Under the hypotheses of Definition 45.509, suppose also that* $N^u_D(h)$ *holds. Then the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *exit row contains a single contextual separation package with:*

1. *the exit-row closure recorded by Definition 45.525;*
2. *the direct endpoint separation* $x\mathsf{hsamee} \to \bot$*;*
3. *for every* $r : \mathsf{BHist}$*, both contextual rejection maps* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r,x)) \to \bot$ *and* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x,r)) \to \bot$*.*

Proof. First apply Definition 45.525 with the same source tuple, denominator tuple, contextual action, endpoint, and strict-support hypothesis. This supplies the concrete exit-row closure consumed by the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ certificate boundary.

Next apply Definition 45.520 at the same endpoint. Its final clause is the direct endpoint separation $x\mathsf{hsamee} \to \bot$.

Finally fix an arbitrary context history $r : \mathsf{BHist}$ and apply Definition 45.516. The two clauses obtained there are exactly the rejection maps for $\mathsf{append}(r,x)$ and $\mathsf{append}(x,r)$. Collecting these clauses gives the displayed contextual separation package. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup transported exit row contextual separation package`

Theorem 45.576 (RatUp FieldUp transported exit row singleton-classifier noncollapse)**.** *For the concrete source tuple* $\mathsf{RatUpFieldSource}_F$*, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, and the contextual action* Γ *of Definition 45.454, let* $x := \Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))$*. Under the hypotheses of Definition 45.509, suppose also that* $N^u_D(h)$ *holds. Then the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *exit row contains both:*

1. *the exit-row closure recorded by Definition 45.525;*
2. *for all* $L, R : \mathsf{BHist}$*, the singleton-classifier obstruction*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L,x),\mathsf{append}(R,x)) \to \bot.$$

Proof. First apply Definition 45.525 with the same concrete source tuple, denominator tuple, contextual action, endpoint, and strict-support witness. This determines the source-anchored exit-row closure package for the displayed endpoint x.

Next choose arbitrary $L, R : \mathsf{BHist}$. Apply Definition 45.517 to the same endpoint x and the same witness $N^u_D(h)$. The theorem gives the map from $\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, x))$ to contradiction.

Combining the exit-row closure package with these uniformly indexed classifier obstructions gives the stated concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit row. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup transported exit row singleton classifier noncollapse`

Per-object template: traditional target contextual classifier non-collapse for constructive $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source $\mathsf{RatUpFieldSource}_F$, BHist, append, contextual action Γ, and strict support N^u_D; carrier $\mathsf{RatHistoryCarrier}$; classifier $\mathsf{RatHistoryClassifier}$ plus the singleton classifier obstruction; stability transported support neutrality and classifier separation; ledger denominator contextual-pair action; core theorem Definition 45.576 with Definition 45.525 and Definition 45.517; exactness contextual classifier non-collapse; standard bridge deferred; status $\mathsf{ProofTarget}$.

Per-object template: traditional target $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ contextual exit separation; BEDC source $\mathsf{RatUpFieldSource}_F$, BHist, append, contextual action Γ, and strict support N^u_D; carrier $\mathsf{RatHistoryCarrier}$; classifier $\mathsf{RatHistoryClassifier}$; stability obligations transported support neutrality and append-context singleton exclusion; ledger denominator contextual-pair action; core theorem Definition 45.575; exactness predicate direct and contextual non-collapse; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.577 (RatUp FieldUp transported exit row full noncollapse package)**.** *For the concrete source tuple* $\mathsf{RatUpFieldSource}_F$*, the denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, and the contextual action* Γ *of Definition 45.454, let* $x := \Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))$*. Under the hypotheses of Definition 45.509, suppose also that* $N^u_D(h)$ *holds. Then the transported strict-support endpoint* x *carries one package containing:*

1. *the exit-row closure of Definition 45.525;*
2. $C^u_D(x)$*,* $N^u_D(x)$*,* $\mathsf{RatHistoryCarrier}(x)$*,* $\mathsf{fieldSingletonEmptyCarrier}(x) \to \bot$*, and* $x\mathsf{hsamee} \to \bot$*;*
3. *for every* $r : \mathsf{BHist}$*, both contextual carrier exclusions on* $\mathsf{append}(r, x)$ *and* $\mathsf{append}(x, r)$*;*
4. *for every* $r : \mathsf{BHist}$*, both inverse-domain witnesses* $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, x))$ *and* $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(x, r))$*;*
5. *for all* $L, R : \mathsf{BHist}$*, the singleton-classifier obstruction on* $\mathsf{append}(L, x)$ *and* $\mathsf{append}(R, x)$*.*

Proof. Apply Definition 45.525 with the same source tuple, denominator tuple, contextual action, endpoint, and witness. This supplies the exit-row closure clause.

Apply Definition 45.520 at the same endpoint. The resulting separation package gives $C^u_D(x)$, $N^u_D(x)$, $\mathsf{RatHistoryCarrier}(x)$, the singleton carrier rejection, and the direct empty-history separation.

Apply Definition 45.516 for an arbitrary context history $r : \mathsf{BHist}$. Its two conclusions are the carrier exclusions for $\mathsf{append}(r, x)$ and $\mathsf{append}(x, r)$.

Apply Definition 45.521 with the same endpoint and support witness. This gives the two contextual inverse-domain witnesses for every $r : \mathsf{BHist}$.

Finally apply Definition 45.576. For arbitrary $L, R : \mathsf{BHist}$ it supplies the classifier obstruction on the two endpoints. Collecting these clauses gives the full noncollapse package. □

Per-object template: traditional target full exit-row noncollapse package for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; source $\mathsf{RatUpFieldSource}_F$, action Γ, strict support N^u_D, all obstructions read at x; status $\mathsf{ProofTarget}$.

Theorem 45.578 (RatUp FieldUp normalized contextual separation package)**.** *For the concrete source tuple* $\mathsf{RatUpFieldSource}_F$*, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, and the contextual action* Γ *of Definition 45.454, suppose* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(l)$*,* $C^u_D(r)$*,* $C^u_D(l')$*, and* $C^u_D(r')$*. Suppose also that* $p\mathsf{hsamee}$*,* $q\mathsf{hsamee}$*,* $p'\mathsf{hsamee}$*,* $q'\mathsf{hsamee}$*,* $\neg N^u_D(l)$*,* $\neg N^u_D(r)$*,* $\neg N^u_D(l')$*,* $\neg N^u_D(r')$*, and* $N^u_D(h)$*. Let* $x := \Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))$ *and let* $y := \Gamma_{p',q',\mu^u_D(l',l),\mu^u_D(r,r')}(h)$*. Then the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *exit certificate simultaneously contains:*

1. *the assembled certificate boundary of Definition 45.489;*
2. *the carried nested endpoint* $C^u_D(x)$*;*
3. *the normalized classifier row* $R^u_D(x, y)$*;*
4. *the strict-support equivalence* $N^u_D(x) \iff N^u_D(h)$*;*
5. *the exit-row closure recorded by Definition 45.525;*
6. *the direct endpoint separation* $x\mathsf{hsamee} \to \bot$*;*
7. *for every context history* $r : \mathsf{BHist}$*, both singleton-context rejection maps* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, x)) \bot$ *and* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x, r)) \to \bot$*.*

Proof. First apply Definition 45.489. This fixes the single concrete source tuple $\mathsf{RatUpFieldSource}_F$ and the certificate boundary in which the carrier, classifier, denominator source, contextual source, context-pair source, and affine source are jointly registered.

Next apply Definition 45.478 to the displayed carried endpoints, empty numerator endpoints, and empty-support denominator contexts. Its nested row gives $C^u_D(x)$, its collected row gives $R^u_D(x, y)$, and its support row gives $N^u_D(x) \iff N^u_D(h)$.

The assumed witness $N^u_D(h)$ and the displayed equivalence recover the strict-support hypothesis at the transported endpoint x. Apply Definition 45.575 with that endpoint and the same contextual action. It supplies the nondegenerate exit-row closure, the direct empty separation $x\mathsf{hsamee} \to \bot$, and the two singleton-context rejection maps for each $r : \mathsf{BHist}$.

Collecting the boundary, normalized row, support transport, and contextual separation clauses gives the stated concrete normalized $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit certificate. □

Per-object template: traditional target concrete normalized $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit separation; BEDC source $\mathsf{RatUpFieldSource}_F$; carrier $\mathsf{RatHistoryCarrier}$; classifier $\mathsf{RatHistoryClassifier}$ plus denominator classifier R^u_D; stability obligations total-normalization support collapse and transported contextual separation; ledger contextual-pair denominator action; core theorem Definition 45.578; exactness predicate normalized and direct/contextual non-collapse; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.579 (RatUp FieldUp normalized semantic exit certificate)**.** *Under the hypotheses and notation of Definition 45.578, the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *exit certificate contains both the normalized contextual separation rows for* x, y *and the concrete nondegenerate semantic exit package supplied by Definition 45.513 and Definition 45.512. More precisely, the same certificate simultaneously contains:*

1. *the assembled certificate boundary of Definition 45.489;*
2. *the normalized classifier row* $R^u_D(x, y)$*;*

3. *the strict-support equivalence* $N^u_D(x) \iff N^u_D(h)$*;*
4. *the direct endpoint rejection map* $x\mathsf{hsamee} \to \bot$ *and, for every context history* $r : \mathsf{BHist}$*, the singleton-context rejection maps* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, x)) \to \bot$ *and* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{ap}$ $\bot$*;*
5. *source anchoring of the concrete certificate rows over* $\mathsf{RatHistoryCarrier}$ *and* $\mathsf{RatHistoryClassifier}$*;*
6. *the nondegenerate witness* $d_1 := \mathsf{E1}(\mathsf{e})$ *with* $\mathsf{RatHistoryCarrier}(d_1)$ *and* $\mathsf{fieldSingletonEmptyCarrier}(d_1) \to \bot$*.*

Thus the normalized contextual row and the concrete nondegenerate semantic exit closure are registered in one BHist*-anchored* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *certificate.*

Proof. Apply Definition 45.578 to the displayed carried endpoints, empty numerator endpoints, empty-support denominator contexts, and strict-support witness. This gives the assembled certificate boundary, the normalized classifier row $R^u_D(x, y)$, the strict-support equivalence $N^u_D(x) \iff N^u_D(h)$, and the endpoint and singleton-context rejection maps for x.

Next apply Definition 45.513. It repacks the semantic certificate rows, source anchoring rows, support-sensitive coverage, endpoint facts, and shared concrete row language as the concrete BHist-anchored exit closure over $\mathsf{RatUpFieldSource}_F$.

Finally apply Definition 45.512. It supplies the same source anchoring over $\mathsf{RatHistoryCarrier}$ and $\mathsf{RatHistoryClassifier}$ and provides the witness $d_1 := \mathsf{E1}(\mathsf{e})$ with $\mathsf{RatHistoryCarrier}(d_1)$ and $\mathsf{fieldSingletonEmptyCarr}$ $\bot$.

Collecting these three cited sites gives a single concrete exit certificate: the normalized contextual separation rows for x, y occupy the same $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ certificate boundary as the nondegenerate semantic exit closure and its explicit rational-history witness. □

Theorem 45.580 (RatUp FieldUp threefold support singleton-classifier noncollapse)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, let* $x := \mu^u_D(\mu^u_D(h, k), \ell)$*. If* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then for all* $L, R : \mathsf{BHist}$*,*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, x)) \to \bot.$$

Proof. Apply Definition 45.527 with the same concrete denominator tuple, carried histories, and left-nested endpoint. The threefold support witness gives $\mathsf{RatHistoryCarrier}(x)$.

Package this carrier witness on both sides, together with reflexivity of hsame, as $\mathsf{RatHistoryClassifier}(x, x)$.

Now fix arbitrary $L, R : \mathsf{BHist}$. Apply Definition 45.104. It sends any displayed singleton-classifier witness to contradiction. □

Per-object template: traditional target concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ threefold denominator exit support; BEDC source BHist with $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$; context $\mathsf{RatUpFieldSource}_F$; carrier $\mathsf{ThreeSupp}^u_D$; classifier R^u_D; stability obligations empty-unit continuation closure and Rat carrier readback; ledger left-nested denominator product endpoint $\mu^u_D(\mu^u_D(h, k), \ell)$; core theorems Definition 45.527, Definition 45.530, Definition 45.531, and Definition 45.532; exactness predicate threefold strict-support non-singleton boundary with contextual append separation and inverse-domain nonzero package; standard bridge finite denominator support into the concrete FieldUp exit; status $\mathsf{ProofTarget}$.

Per-object template: traditional target classifier-level noncollapse for the threefold $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ denominator exit; BEDC source BHist with $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$; context $\mathsf{RatUpFieldSource}_F$; carrier $\mathsf{ThreeSupp}^u_D$; classifier obstruction against $\mathsf{fieldSingletonEmptyClassifier}$; stability obligations empty-unit continuation closure and Rat carrier readback; ledger left-nested denominator

product endpoint $\mu^u_D(\mu^u_D(h,k),\ell)$; core theorem Definition 45.580 with Definition 45.527, Definition 45.530, and Definition 45.531; exactness classifier noncollapse; standard bridge deferred; status ProofTarget.

Per-object template: traditional target contextual classifier non-collapse for constructive $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source $\mathsf{RatUpFieldSource}_F$, BHist, append, contextual action Γ, and strict support N^u_D; carrier RatHistoryCarrier; classifier RatHistoryClassifier plus the singleton classifier obstruction; stability transported support neutrality and classifier separation; ledger denominator contextual-pair action; core theorem Definition 45.576 with Definition 45.525 and Definition 45.517; exactness contextual classifier non-collapse; standard bridge deferred; status ProofTarget.

Per-object template: traditional target $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ contextual exit separation; BEDC source $\mathsf{RatUpFieldSource}_F$, BHist, append, contextual action Γ, and strict support N^u_D; carrier RatHistoryCarrier; classifier RatHistoryClassifier; stability obligations transported support neutrality and append-context singleton exclusion; ledger denominator contextual-pair action; core theorem Definition 45.575; exactness predicate direct and contextual non-collapse; standard bridge deferred; status ProofTarget.

Theorem 45.581 (RatUp FieldUp normalized contextual singleton-classifier separation)**.** *For the concrete source tuple* $\mathsf{RatUpFieldSource}_F$*, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, and the contextual action* Γ *of Definition 45.454, suppose* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(l)$*,* $C^u_D(r)$*,* $C^u_D(l')$*, and* $C^u_D(r')$*. Suppose also that* $p\mathsf{hsamee}$*,* $q\mathsf{hsamee}$*,* $p'\mathsf{hsamee}$*,* $q'\mathsf{hsamee}$*,* $\neg N^u_D(l)$*,* $\neg N^u_D(r)$*,* $\neg N^u_D(l')$*,* $\neg N^u_D(r')$*, and* $N^u_D(h)$*. Let* $x := \Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))$ *and let* $y := \Gamma_{p',q',\mu^u_D(l',l),\mu^u_D(r,r')}(h)$*. Then for all* $L, R : \mathsf{BHist}$*,*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L,x), \mathsf{append}(R,y)) \to \bot.$$

Proof. Apply Definition 45.578 to the same source tuple, denominator tuple, contextual action, carried histories, empty endpoint hypotheses, empty-support context hypotheses, and strict-support witness. The package supplies the normalized classifier row $R^u_D(x,y)$ and the strict-support transport $N^u_D(x) \Longleftrightarrow N^u_D(h)$.

Use the displayed witness $N^u_D(h)$ and the transport equivalence to recover $N^u_D(x)$. The denominator boundary identifies this strict support with the genuine Rat carrier, so x is carried by RatHistoryCarrier.

Unfold the normalized classifier row through the same denominator boundary. Together with the Rat carrier recovered at x, the row packages the concrete classifier $\mathsf{RatHistoryClassifier}(x,y)$ for the normalized pair.

Now fix arbitrary histories $L, R : \mathsf{BHist}$. Apply Definition 45.104 to the displayed $\mathsf{RatHistoryClassifier}(x,y)$. It rejects every proposed singleton empty classifier on $\mathsf{append}(L,x)$ and $\mathsf{append}(R,y)$, which is the asserted noncollapse. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitContextualAction normalized pair singleton classifier exclusion`

Per-object template: traditional target normalized contextual classifier noncollapse for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source $\mathsf{RatUpFieldSource}_F$, BHist, append, Γ, R^u_D, and N^u_D; carrier RatHistoryCarrier; classifier RatHistoryClassifier plus singleton-empty classifier; stability obligations normalized contextual classifier row and strict-support transport; ledger contextual-pair denominator action; core theorem this block; exactness predicate singleton-classifier noncollapse for the normalized pair; standard bridge deferred; status ProofTarget.

Theorem 45.582 (RatUp FieldUp five-factor nonzero factor ledger)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *candidate over* BHist *satisfying the hypotheses of Definition 45.312, assume the*

apartness-to-nonzero bridge family

$$\alpha_h : (h\mathsf{hsame0} \to \bot) \to \mathsf{NonZero}_F(h)$$

for each $h : \mathsf{BHist}$. *Then every* $a, b, c, d, e : \mathsf{BHist}$ *satisfies*

$$\mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a, b), c), d), e)) \Longleftrightarrow \mathsf{NonZero}_F(a) \wedge \mathsf{NonZero}_F(b) \wedge \mathsf{NonZero}_F(c) \wedge \mathsf{NonZero}_F(d) \wedge \mathsf{NonZero}$$

Proof. Apply Definition 45.312 to the concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ candidate, the given bridge family, and the five histories a, b, c, d, e. The resulting equivalence is exactly the displayed RatUp FieldUp ledger row. □

Per-object template: traditional target RatUp FieldUp five-factor nonzero factor ledger; BEDC source $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ over BHist with the certified five-factor product nonzero equivalence; carrier BHist; classifier hsame with $\mathsf{NonZero}_F$; stability obligations general five-factor exactness and apartness-to-nonzero transport; ledger factor witnesses p_a, p_b, p_c, p_d, p_e, prefix witness p_{abcd}, and fivefold product witness p_{abcde}; core theorem Definition 45.582; exactness predicate nonzero of the left-nested fivefold product equivalent to the five factor nonzero witnesses; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.583 (RatUp FieldUp normalized contextual full noncollapse package)**.** *For the concrete source tuple* $\mathsf{RatUpFieldSource}_F$, *the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$, *and the contextual action* Γ *of Definition 45.454, suppose* $C^u_D(h)$, $C^u_D(k)$, $C^u_D(l)$, $C^u_D(r)$, $C^u_D(l')$, *and* $C^u_D(r')$. *Suppose also that* $p\mathsf{hsamee}$, $q\mathsf{hsamee}$, $p'\mathsf{hsamee}$, $q'\mathsf{hsamee}$, $\neg N^u_D(l)$, $\neg N^u_D(r)$, $\neg N^u_D(l')$, $\neg N^u_D(r')$, *and* $N^u_D(h)$. *Let* $x := \Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))$ *and let* $y := \Gamma_{p',q',\mu^u_D(l',l),\mu^u_D(r,r')}(h)$. *Then the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *exit certificate simultaneously contains:*

1. *the assembled certificate boundary of Definition 45.489;*
2. *the carried nested endpoint* $C^u_D(x)$*;*
3. *the normalized classifier row* $R^u_D(x, y)$*;*
4. *the strict-support equivalence* $N^u_D(x) \Longleftrightarrow N^u_D(h)$*;*
5. *the exit-row closure recorded by Definition 45.525;*
6. *the direct endpoint separation* $x\mathsf{hsamee} \to \bot$*;*
7. *for every context history* $r : \mathsf{BHist}$, *both singleton-context rejection maps* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, x)) \to \bot$ *and* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x, r)) \to \bot$*;*
8. *for all histories* $L, R : \mathsf{BHist}$, $\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, y)) \to \bot$.

Proof. First apply Definition 45.578 to the same source tuple, denominator tuple, contextual action, carried histories, empty endpoint hypotheses, empty-support context hypotheses, and strict-support witness. This supplies the assembled certificate boundary, the carried nested endpoint, the normalized classifier row, the strict-support equivalence, the exit-row closure, the direct endpoint separation, and the singleton-context carrier rejections.

Next apply Definition 45.581 under the same hypotheses and with the same definitions of x and y. It supplies the uniform singleton-classifier obstruction for arbitrary $L, R : \mathsf{BHist}$.

Collect the seven certificate clauses from the normalized contextual separation package together with the singleton-classifier obstruction. The resulting row is one concrete BHist package for the normalized $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit criterion. □

Per-object template: traditional target normalized contextual full noncollapse for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source $\mathsf{RatUpFieldSource}_F$, BHist, append, Γ, R^u_D, and N^u_D; carrier $\mathsf{RatHistoryCarrier}$; classifier $\mathsf{RatHistoryClassifier}$ plus singleton-empty classifier; stability obligations normalized contextual separation and singleton-classifier obstruction; ledger contextual-pair denominator action; core theorem Definition 45.583; exactness predicate carrier and classifier noncollapse for the normalized contextual pair; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.584 (RatUp FieldUp proof-target exit package)**.** *For the concrete source tuple* $\mathsf{RatUpFieldSource}_F$*, the* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *proof target is exhausted by concrete* BHist *rows. Its exit package is the constructive composition of the paper certificate assembly of Definition 45.494, the source anchoring of Definition 45.501, the concrete schema instance of Definition 45.502, the concrete exit certificate package of Definition 45.523, the transported exit-row contextual separation of Definition 45.575, and the normalized contextual separation of Definition 45.578, together with the normalized semantic exit certificate of Definition 45.579 and the normalized singleton-classifier separation of Definition 45.581, as well as the five-factor product equation exactness of Definition 45.296 backed by Definition 45.574. Thus the displayed* BHist *source tuple carries the exit package for* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$*: it contains the normalized semantic nondegenerate witness* $d_1 := \mathsf{E1}(\mathsf{e})$*, the normalized classifier row, the all-context singleton-classifier rejection for* $\mathsf{append}(L, x)$ *and* $\mathsf{append}(R, y)$*, and the five-factor right and left product equation exactness rows, while no exit row remains as a schematic* mul*,* add*, or* neg *operator parameter.*

Proof. Start with Definition 45.494. It supplies the paper-side carrier, source, classifier, stability, ledger, and exactness rows for the concrete source tuple $\mathsf{RatUpFieldSource}_F$ over BHist.

Next apply Definition 45.501. It identifies every row consumed by the concrete certificate with the same source tuple: the rational history carrier and classifier, the denominator tuple, the contextual action Γ, the context-pair monoid, and the affine coordinate.

The schema and exit boundary are then fixed by Definition 45.502 and Definition 45.523. Together these theorem sites repack the source-anchored rows as the public $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ certificate instance and its concrete exit certificate.

Finally use Definition 45.575 and Definition 45.578. The first theorem supplies the transported noncollapse and contextual rejection rows, while the second records the normalized row package in the same concrete source. Combining these clauses leaves only rows carried by $\mathsf{RatUpFieldSource}_F$.

Apply Definition 45.579. It adds the nondegenerate RatUp witness $d_1 := \mathsf{E1}(\mathsf{e})$, its source anchoring in $\mathsf{RatHistoryCarrier}$ and $\mathsf{RatHistoryClassifier}$, and the same normalized contextual rows to the concrete exit certificate.

Apply Definition 45.581 for arbitrary $L, R : \mathsf{BHist}$. The resulting row rejects every $\mathsf{fieldSingletonEmptyClassifier}(\mathsf{a}$ claim for the normalized pair.

Use Definition 45.296 for the displayed factor product P_5. It supplies the right and left solver equivalences for P_5, while Definition 45.574 supplies the induced factor witnesses used by the reversed inverse spine. Both theorem sites are stated over $\mathsf{Field}^{\uparrow}$ on BHist, so their rows occupy the same $\mathsf{RatUpFieldSource}_F$ boundary.

These semantic, classifier-separation, and five-factor exactness rows live in the same concrete $\mathsf{RatUpFieldSource}_F$ boundary, so the exit package has no schematic mul, add, or neg operator coordinate. □

Definition 45.585 (RatUp FieldUp ten-field exit instance)**.** *The ten-field exit instance for* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *is the following concrete paper certificate object.*

1. *Traditional target:* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *as a fully derived field instance.*

2. *BEDC source:* $\mathsf{RatUpFieldSource}_F$, BHist, $\mathsf{RatHistoryCarrier}$, $\mathsf{RatHistoryClassifier}$, *the denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$, *the contextual action* Γ, *the context-pair monoid of Definition 45.479, and the affine rows of* AffAut_F.
3. *Carrier:* $\mathsf{RatHistoryCarrier}$ *on the concrete history carrier* BHist.
4. *Classifier:* $\mathsf{RatHistoryClassifier}$ *together with the denominator classifier row* R^u_D *and the singleton-empty classifier obstruction rows for the normalized contextual endpoints.*
5. *Stability obligations: Definition 45.494, Definition 45.501, Definition 45.502, Definition 45.523, the transported and normalized contextual separation packages, and the normalized semantic and classifier exit certificates.*
6. *Ledger: rational history rows, denominator rows, contextual-pair rows, affine rows, and the nondegenerate witness row* $d_1 := \mathsf{E1}(\mathsf{e})$.
7. *Core theorem list: chiefly Definition 45.584, with the normalized semantic classifier exit certificate and the bracketing-independent threefold contextual boundary as the concrete support theorem sites, plus Definition 45.600 as the concrete cross-endpoint singleton-classifier exclusion.*
8. *Exactness predicate: concrete row exhaustion for the* $\mathsf{RatUpFieldSource}_F$ *package and singleton noncollapse for the normalized contextual classifier rows, including the crossed endpoint singleton-classifier noncollapse rows.*
9. *Standard bridge: deferred.*
10. *Status:* $\mathsf{ProofTarget}$.

Theorem 45.586 (RatUp FieldUp ten-field exit certificate)**.** *The instance of Definition 45.585, together with Definition 45.584, Definition 45.590, and Definition 45.599, supplies the concrete ten-field paper certificate for* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *with no schematic* mul, add, *or* neg *operator parameter.*

Proof. Apply Definition 45.584. It identifies the paper certificate, source anchoring, schema instance, concrete exit package, and contextual separation rows as clauses of the single $\mathsf{RatUpFieldSource}_F$ boundary.

Next apply Definition 45.590. It adds the normalized semantic witness rows, the R^u_D classifier row, and the singleton-empty classifier obstruction for every contextual pair.

Finally apply Definition 45.599. It supplies the common threefold denominator support for both bracketings, so the certificate has contextual-pair and denominator support independent of the chosen bracketing. These three theorem sites fill every field listed in Definition 45.585, completing the concrete paper certificate. □

Definition 45.587 (RatUp FieldUp concrete operation table)**.** *The concrete operation table for* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *is the* BHist*-anchored row package whose carrier row is* $\mathsf{RatHistoryCarrier}$ *and whose classifier row is* $\mathsf{RatHistoryClassifier}$. *Its base coordinate is the* $\mathsf{CommRing}^{\uparrow}$ *row inside* $\mathsf{RatUpFieldSource}_F$. *Its denominator coordinate is*

$$(\mathsf{RatDenomUnitCarrier}, \mathsf{RatDenomUnitClassifier}, \mathsf{append}, \mathsf{e}, \mathsf{RatHistoryCarrier}).$$

The contextual coordinate is the action Γ *together with the context-pair monoid of Definition 45.479. The apartness coordinate is* $\mathsf{FieldApartZero}$, *with the inverse rows supplied by apartness, and the affine coordinate is* AffAut_F.

The table uses the following ten-field per-object template.

1. *Traditional target: the concrete constructive field* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$.
2. *BEDC source:* $\mathsf{RatUpFieldSource}_F$ *over* BHist, *with* $\mathsf{Rat}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, *denominator, contextual, context-pair, apartness, inverse, and affine rows.*
3. *Carrier:* $\mathsf{RatHistoryCarrier}$.
4. *Classifier:* $\mathsf{RatHistoryClassifier}$ *together with* $\mathsf{RatDenomUnitClassifier}$ *for denominator histories.*
5. *Stability obligations: carrier and classifier anchoring, the ring-base rows, denominator multiplication and unit rows, contextual-action rows, context-pair support rows, affine closure rows, inverse rows over* $\mathsf{FieldApartZero}$, *and exit noncollapse rows.*
6. *Ledger: rational histories, denominator unit histories, continuation witnesses, context pairs, apart-zero inverse witnesses, affine coefficients, and singleton obstruction witnesses.*
7. *Core theorem list: Definition 45.501, Definition 45.502, Definition 45.586, Definition 45.589, and Definition 45.600.*
8. *Exactness predicate: row coverage for the same* $\mathsf{RatUpFieldSource}_F$ *table, including denominator support, contextual transport, product-classifier transport, inverse-domain transport, affine transport, and singleton noncollapse.*
9. *Standard bridge: the public* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *certificate consumes this table as the concrete operation schema.*
10. *Status:* $\mathsf{ProofTarget}$.

Theorem 45.588 (RatUp FieldUp concrete operation table laws)**.** *The table of Definition 45.587 satisfies the carrier and classifier rows, the* $\mathsf{CommRing}^{\uparrow}$ *ring-base rows, the denominator multiplication and unit rows, the contextual-action rows, the context-pair support rows, the affine rows, the inverse and nonzero rows, and the exit noncollapse rows required by the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *schema.*

Proof. First apply Definition 45.501. It places the carrier, classifier, denominator tuple, contextual action, context-pair monoid, affine coordinate, and $\mathsf{CommRing}^{\uparrow}$ base coordinate inside the single concrete source tuple $\mathsf{RatUpFieldSource}_F$.

Next apply Definition 45.502. The schema instance identifies those rows with the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ operation schema, so the table has no free schematic mul, add, or neg coordinate outside the displayed BHist rows.

The exit side is supplied by Definition 45.586. It fills the per-object certificate fields and contributes the normalized semantic and classifier noncollapse rows required by the table.

For multiplication through nonzero contexts, use Definition 45.589. It gives the one-sided cancellation row, the product-classifier exactness row, and the nonzero transport row for multiplication by certified nonzero histories.

Finally apply Definition 45.600. It supplies the cross-endpoint singleton-classifier exclusions for the common threefold denominator support. Together with the previous rows, this gives the carrier/classifier, base, denominator, contextual, context-pair, affine, inverse, nonzero, and exit noncollapse laws listed in the statement. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatupFieldupConcreteOperationTableLaws`

Theorem 45.589 (RatUp FieldUp multiplication exactness and nonzero exit package)**.** *For the concrete BEDC history-level* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *row over* BHist, *let* $a, b, x, y : \mathsf{BHist}$ *and let* p_a :

$\mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$ *be certified nonzero witnesses. The multiplication package contains the one-sided cancellation classifier rows*

$$\mathsf{mul}(x,b)\mathsf{hsamemul}(y,b) \iff x\mathsf{hsame}y$$

and

$$\mathsf{mul}(a,x)\mathsf{hsamemul}(a,y) \iff x\mathsf{hsame}y.$$

The two-sided product map $x \mapsto \mathsf{mul}(\mathsf{mul}(a,x),b)$ *is exact as a classifier row and as a nonzero-transport row:*

$$(\mathsf{mul}(\mathsf{mul}(a,x),b)\mathsf{hsamemul}(\mathsf{mul}(a,y),b)) \iff x\mathsf{hsame}y$$

and

$$\mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(a,x),b)) \iff \mathsf{NonZero}_F(x).$$

Together these four equivalences form one concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *multiplication package for certified nonzero factors.*

Proof. Apply Definition 45.244 to the same history-level $\mathsf{Field}^{\uparrow}$ candidate. With witnesses p_b and p_a, it supplies the right- and left-factor classifier exactness rows over BHist.

Apply Definition 45.245 to the same history-level $\mathsf{Field}^{\uparrow}$ candidate and to the certified outer witnesses p_a and p_b. This supplies the classifier exactness row for the map $x \mapsto \mathsf{mul}(\mathsf{mul}(a,x),b)$.

Apply Definition 45.309 with the same witnesses. This supplies the nonzero-transport row for the identical two-sided product endpoint.

These rows use the same BHist carrier, the same classifier hsame, the same multiplication endpoints, and the same ledger witnesses p_a, p_b. They therefore assemble as one concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ multiplication certificate clause. □

Per-object template: traditional target multiplication exactness inside $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source BHist, $\mathsf{Field}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, and $\mathsf{RatUpFieldSource}_F$; carrier BHist; classifier hsame; stability obligations multiplication congruence, one-sided cancellation exactness, inverse cancellation, zero absorption, and nonzero transport; ledger the one-sided witnesses, the outer witnesses p_a, p_b, and product endpoint $\mathsf{mul}(\mathsf{mul}(a,x),b)$; core theorem this block; exactness predicate the one-sided cancellation iff rows and the displayed paired equivalences; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.590 (RatUp FieldUp normalized semantic classifier exit certificate)**.** *Under the hypotheses and notation of Definition 45.578, the same concrete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *certificate contains the normalized semantic exit package of Definition 45.579 and, for all* $L, R : \mathsf{BHist}$*, the classifier obstruction*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L,x),\mathsf{append}(R,y)) \to \bot$$

supplied by Definition 45.581. Equivalently, the normalized semantic rows for the carried pair x, y *and the singleton-classifier noncollapse rows for every contextual pair* L, R *occupy one* BHist*-anchored* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *exit certificate over* $\mathsf{RatUpFieldSource}_F$*.*

Proof. First invoke Definition 45.579 under the displayed carried endpoint hypotheses, empty endpoint hypotheses, empty-support context hypotheses, and strict-support witness. It gives the assembled certificate boundary, the normalized row $R^u_D(x,y)$, the strict-support equivalence $N^u_D(x) \iff N^u_D(h)$, the contextual rejection maps, source anchoring of the concrete rows, and the nondegenerate witness $d_1 := \mathsf{E1}(\mathsf{e})$ with $\mathsf{RatHistoryCarrier}(d_1)$ and $\mathsf{fieldSingletonEmptyCarrier}(d_1) \to \bot$.

Next invoke Definition 45.581 with the same carried endpoints, empty endpoint hypotheses, empty-support context hypotheses, contextual action Γ, and strict-support witness. This yields, for arbitrary $L, R : \mathsf{BHist}$, the obstruction

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, y)) \to \bot.$$

These two applications share the same concrete source tuple, denominator tuple, contextual action, normalized endpoints, and support witness. Therefore the semantic exit rows and the singleton-classifier obstruction are not separate targets: they are clauses of one normalized concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit certificate. □

Per-object template: traditional target concrete normalized $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ classifier exit; BEDC source $\mathsf{RatUpFieldSource}_F$, BHist, append, Γ, R^u_D, and N^u_D; carrier $\mathsf{RatHistoryCarrier}$; classifier $\mathsf{RatHistoryClassifier}$ plus $\mathsf{fieldSingletonEmptyClassifier}$ obstruction; stability obligations normalized semantic exit and singleton-classifier noncollapse; ledger contextual-pair denominator action and nondegenerate witness; core theorem this block; exactness predicate semantic exit plus classifier noncollapse for the normalized pair; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.591 (RatUp FieldUp singleton-empty operation context normalization)**.** *For histories L, R, h, k, out : BHist with $\mathsf{fieldSingletonEmptyCarrier}(L)$ and $\mathsf{fieldSingletonEmptyCarrier}(R)$, the lower-case singleton-empty $\mathsf{Field}^{\uparrow}$ operation slots are contextual BHist endpoints:*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, \mathsf{fieldSingletonEmptyMul}(h, k)), \mathsf{append}(R, out)) \iff \mathsf{fieldSingletonEmptyCarri}$$

The same contextual normalization holds for the terminal unit endpoint:

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, \mathsf{fieldSingletonEmptyOne}), \mathsf{append}(R, out)) \iff \mathsf{fieldSingletonEmptyCarrier}(ou$$

Finally, for every proof witness p : $\mathsf{fieldSingletonEmptyNonZero}(h)$, the inverse endpoint satisfies

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, \mathsf{fieldSingletonEmptyInv}(h, p)), \mathsf{append}(R, out)) \iff \mathsf{fieldSingletonEmptyCarrie}$$

Proof. Unfold the three lower-case operation endpoints. In the singleton-empty $\mathsf{Field}^{\uparrow}$ construction, $\mathsf{fieldSingletonEmptyMul}(h, k)$, $\mathsf{fieldSingletonEmptyOne}$, and $\mathsf{fieldSingletonEmptyInv}(h, p)$ are all the endpoint e.

For the forward direction in each displayed equivalence, use the two context carrier witnesses for L and R. Empty-result inversion for append removes the left endpoint $\mathsf{append}(L, \mathsf{e})$ and then removes the right context from $\mathsf{append}(R, out)$, leaving precisely $\mathsf{fieldSingletonEmptyCarrier}(out)$.

For the reverse direction, begin with the displayed output carrier. Append-empty reconstruction places the output behind the carried context R, and the left context witness reconstructs the empty operation endpoint behind L. Classifier transitivity through e gives the required singleton-empty classifier in each of the multiplication, unit, and proof-indexed inverse cases. □

Per-object template: traditional target concrete terminal $\mathsf{Field}^{\uparrow}$ operation endpoints; BEDC source BHist, append, and the lower-case singleton-empty $\mathsf{Field}^{\uparrow}$ operations; carrier $\mathsf{fieldSingletonEmptyCarrier}$; classifier $\mathsf{fieldSingletonEmptyClassifier}$; stability obligations append empty split and constant operation endpoints; ledger hidden left/right singleton contexts and the proof-indexed inverse witness; core theorem this block; exactness predicate the three displayed equivalences; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.592 (Field singleton classifier operation context endpoint package)**.** *For histories* $L, R, h, k, out : \mathsf{BHist}$ *with* $\mathsf{FieldSingletonCarrier}(L)$ *and* $\mathsf{FieldSingletonCarrier}(R)$*, the canonical singleton field operation endpoints are contextual classifier endpoints:*

$$\mathsf{FieldSingletonClassifier}(\mathsf{append}(L, \mathsf{FieldSingletonMul}(h, k)), \mathsf{append}(R, out)) \iff \mathsf{FieldSingletonCarrier}(out).$$

The same endpoint exactness holds for $\mathsf{FieldSingletonOne}$ *and, for each witness* $p : \mathsf{FieldSingletonNonZero}(h)$*, for* $\mathsf{FieldSingletonInv}(h, p)$*.*

Proof. Each displayed operation endpoint is definitionally e in the singleton field schema. For the forward direction, the classifier supplies the carrier witness for $\mathsf{append}(R, out)$; empty-result inversion for append removes the carried context R and leaves precisely the output carrier.

For the reverse direction, combine the carrier witnesses for L and R with the empty operation endpoint and the displayed output carrier. Append-empty reconstruction gives carrier witnesses for both classified endpoints, and transitivity through e supplies the classifier comparison. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonClassifier operation context endpoint package`

Theorem 45.593 (Field singleton add-neg-zero operation context endpoint package)**.** *For histories* $L, R, h, k, out : \mathsf{BHist}$ *with* $\mathsf{FieldSingletonCarrier}(L)$ *and* $\mathsf{FieldSingletonCarrier}(R)$*, the singleton additive operation endpoints are contextual classifier endpoints:*

$$\mathsf{FieldSingletonClassifier}(\mathsf{append}(L, \mathsf{FieldSingletonAdd}(h, k)), \mathsf{append}(R, out)) \iff \mathsf{FieldSingletonCarrier}(out).$$

The same endpoint exactness holds for $\mathsf{FieldSingletonNeg}(h)$ *and* $\mathsf{FieldSingletonZero}$*.*

Proof. Each additive singleton operation endpoint is definitionally e. Forward classification exposes the right appended endpoint carrier and append-empty inversion removes R. Conversely, the carriers for L, R, the empty operation endpoint, and out rebuild the two appended carriers; transitivity through e supplies the classifier comparison. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonAddNegZero operation context endpoint package`

Theorem 45.594 (Field singleton add-neg-zero context continuation result carrier)**.** *For histories* $L, R, a, b, c, out : \mathsf{BHist}$ *with* $\mathsf{FieldSingletonCarrier}(L)$ *and* $\mathsf{FieldSingletonCarrier}(R)$*, if*

$$\mathsf{Cont}(\mathsf{append}(L, \mathsf{FieldSingletonAdd}(a, b)), \mathsf{append}(\mathsf{FieldSingletonNeg}(c), R), out)$$

holds, then $\mathsf{FieldSingletonCarrier}(out)$*.*

Proof. The singleton additive and negation endpoints are definitionally e. The carrier witnesses for L and R reduce both continuation endpoints to the empty-empty continuation, so continuation determinacy identifies out with e. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonAddNegZero context continuation result carrier`

Theorem 45.595 (Field singleton add-neg-zero context continuation result iff)**.** *For histories* $L, R, a, b, c, out : \mathsf{BHist}$ *with* $\mathsf{FieldSingletonCarrier}(L)$ *and* $\mathsf{FieldSingletonCarrier}(R)$*, the add-neg-zero contextual continuation exists exactly for singleton field carrier results:*

$$\mathsf{Cont}(\mathsf{append}(L, \mathsf{FieldSingletonAdd}(a, b)), \mathsf{append}(\mathsf{FieldSingletonNeg}(c), R), out) \iff \mathsf{FieldSingletonCarrier}(out).$$

Proof. The forward direction is the add-neg-zero contextual carrier closure. For the reverse direction, the singleton additive and negation endpoints unfold to e, and the carrier witnesses for L, R, and out reduce the claim to the right-unit continuation at e, transported along the supplied carrier witness for out. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonAddNegZero context continuation result iff`

Theorem 45.596 (Field singleton add-neg-zero context continuation classifier)**.** *For histories* $L, R, a, b, c, d, out, out' : \mathsf{BHist}$ *with* $\mathsf{FieldSingletonCarrier}(L)$ *and* $\mathsf{FieldSingletonCarrier}(R)$*, if*

$$\mathsf{Cont}(\mathsf{append}(L, \mathsf{FieldSingletonAdd}(a, b)), \mathsf{append}(\mathsf{FieldSingletonNeg}(c), R), out)$$

and

$$\mathsf{Cont}(\mathsf{append}(L, \mathsf{FieldSingletonZero}), \mathsf{append}(\mathsf{FieldSingletonAdd}(c, d), R), out')$$

hold, then $\mathsf{FieldSingletonClassifier}(out, out')$*.*

Proof. The three displayed singleton operations are definitionally e. The carrier witnesses for L and R therefore normalize each continuation endpoint pair to the empty-empty continuation. Continuation determinacy gives $out = \mathsf{e}$ and $out' = \mathsf{e}$, and the two resulting carrier witnesses classify the endpoints by transitivity through e. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonAddNegZero context continuation classifier`

Theorem 45.597 (Field singleton neg context continuation classifier)**.** *For histories* $L, R, L', R', a, a', out, out' :$ BHist *with* $\mathsf{FieldSingletonCarrier}(L)$*,* $\mathsf{FieldSingletonCarrier}(R)$*,* $\mathsf{FieldSingletonCarrier}(L')$*, and* $\mathsf{FieldSingletonCarrier}(R')$ *if*

$$\mathsf{Cont}(\mathsf{append}(L, \mathsf{FieldSingletonNeg}(a)), R, out)$$

and

$$\mathsf{Cont}(\mathsf{append}(L', \mathsf{FieldSingletonNeg}(a')), R', out')$$

hold, then $\mathsf{FieldSingletonClassifier}(out, out')$*.*

Proof. The singleton negation endpoint is definitionally e. Each left context therefore remains an empty carrier after appending the negation endpoint. With the matching right context carrier, singleton continuation closure makes both outputs empty-carrier histories. The classifier follows by transitivity through e. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonNeg context continuation classifier`

Theorem 45.598 (RatUp FieldUp right-nested threefold contextual boundary)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, let* $y := \mu^u_D(h, \mu^u_D(k, \ell))$*. If* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then the right-nested* $\mathsf{Field}^\uparrow(\mathsf{RatUp})$ *denominator endpoint carries the following contextual boundary:*

1. *for every context history* $r : \mathsf{BHist}$*,* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, y)) \to \bot$*;*
2. *for every context history* $r : \mathsf{BHist}$*,* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(y, r)) \to \bot$*;*
3. *for every context history* $r : \mathsf{BHist}$*,* $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, y))$*;*
4. *for every context history* $r : \mathsf{BHist}$*,* $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(y, r))$*;*

5. *for all* $L, R : \mathsf{BHist}$,

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, y), \mathsf{append}(R, y)) \to \bot.$$

Proof. Apply Definition 45.528 to the same concrete denominator tuple, carried histories, and support witness. The right-nested endpoint data recovers $\mathsf{RatHistoryCarrier}(y)$ and the singleton rejection map $\mathsf{fieldSingletonEmptyCarrier}(y) \to \bot$.

Fix a context history $r : \mathsf{BHist}$. Apply Definition 45.101 with context r and Rat carrier endpoint y to reject $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, y))$. Apply Definition 45.102 with the same two histories in the opposite append order to reject $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(y, r))$.

For the right-append inverse-domain witness, unfold $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, y))$ as rejection of the singleton classifier against e. Any such classifier witness contains the source-carrier component $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, y))$, contradicting the right-append rejection.

For the left-append inverse-domain witness, unfold $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(y, r))$ as rejection of the singleton classifier against e. Its source-carrier component is $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(y, r))$ contradicting the left-append rejection.

Finally package $\mathsf{RatHistoryClassifier}(y, y)$ from the recovered Rat carrier witness on both sides and reflexivity of hsame. For arbitrary $L, R : \mathsf{BHist}$, apply Definition 45.104. It rejects $\mathsf{fieldSingletonEmptyClassifier}($

□

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup right nested contextual boundary`

Theorem 45.599 (RatUp FieldUp bracketing-independent threefold contextual boundary)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$, $C^u_D(k)$, *and* $C^u_D(\ell)$, *let* $x := \mu^u_D(\mu^u_D(h, k), \ell)$ *and* $y := \mu^u_D(h, \mu^u_D(k, \ell))$. *If* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then the two bracketings of the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *denominator endpoint carry the following common contextual boundary:*

1. $C^u_D(x)$, $C^u_D(y)$, *and* $R^u_D(x, y)$;
2. *for every context history* $r : \mathsf{BHist}$, *the four contextual carrier exclusions:*
   (a) $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, x)) \to \bot$;
   (b) $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x, r)) \to \bot$;
   (c) $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, y)) \to \bot$;
   (d) $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(y, r)) \to \bot$.
3. *for every context history* $r : \mathsf{BHist}$, *the four inverse-domain witnesses:*
   (a) $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, x))$;
   (b) $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(x, r))$;
   (c) $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, y))$;
   (d) $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(y, r))$.
4. *for all* $L, R : \mathsf{BHist}$, *the two contextual singleton-classifier exclusions*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, x)) \to \bot$$

and

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, y), \mathsf{append}(R, y)) \to \bot.$$

Proof. First apply Definition 45.527 to the carried histories h, k, ℓ. This supplies the left-nested carrier row $C^u_D(x)$, the strict-support comparison for x, the Rat carrier witness for x under $\mathsf{ThreeSupp}^u_D(h, k, \ell)$, and the direct singleton-carrier rejection at x.

Apply Definition 45.528 to the same carried histories. Its endpoint data supplies $C^u_D(y)$, $R^u_D(x, y)$, the strict-support comparison for y, the Rat carrier witness for y under the same support hypothesis, and the direct singleton-carrier rejection at y. The displayed comparison is the denominator associativity row already used in that support exactness proof.

For the left-nested endpoint, use Definition 45.530 with the same support witness. It gives, for each context history r, the two contextual singleton-carrier exclusions around x.

Then apply Definition 45.531. This packages the two corresponding inverse-domain witnesses for $\mathsf{append}(r, x)$ and $\mathsf{append}(x, r)$.

For the right-nested endpoint, apply Definition 45.598. Its five clauses give the contextual singleton-carrier exclusions around y, the two inverse-domain witnesses for the right-nested bracketing, and the contextual singleton-classifier exclusion for arbitrary left and right contexts around y.

It remains only to record the classifier exclusion around x. The left-nested contextual separation package already contains the arbitrary $L, R : \mathsf{BHist}$ singleton-classifier rejection, so the two endpoint classifier exclusions stand side by side with the carrier and inverse-domain rows from the preceding paragraphs. □

Theorem 45.600 (RatUp FieldUp bracketing-independent cross-endpoint classifier boundary)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, let $x := \mu^u_D(\mu^u_D(h, k), \ell)$ and $y := \mu^u_D(h, \mu^u_D(k, \ell))$. If $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ holds, then for all $L, R : \mathsf{BHist}$ the crossed contextual singleton-classifier exclusions*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, y)) \to \bot$$

and

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, y), \mathsf{append}(R, x)) \to \bot$$

hold.

Proof. Apply the checked FieldUp cross-endpoint classifier boundary to the same carried histories h, k, ℓ. In the concrete denominator tuple its carrier predicate is $\mathsf{RatDenomUnitCarrier}$, its product is append, and the support input is exactly the disjunction encoded by $\mathsf{ThreeSupp}^u_D(h, k, \ell)$.

The endpoint definitions identify x with $\mathsf{append}(\mathsf{append}(h, k), \ell)$ and y with $\mathsf{append}(h, \mathsf{append}(k, \ell))$ up to hsame. For fixed $L, R : \mathsf{BHist}$, the checked boundary returns the conjunction of the two crossed singleton-classifier rejections, which are precisely the two displayed exclusions. □

↪ variant `BEDC.Derived.FieldUp.ratup fieldup bracketing independent cross endpoint classifier boundary`

Theorem 45.601 (RatUp FieldUp ten-field cross-endpoint exit certificate)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, let $x := \mu^u_D(\mu^u_D(h, k), \ell)$ and $y := \mu^u_D(h, \mu^u_D(k, \ell))$. If $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ holds, then the concrete ten-field exit instance for $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$ contains the certificate rows of Definition 45.586 and, for all $L, R : \mathsf{BHist}$, the crossed contextual exclusions*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, y)) \to \bot$$

and

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, y), \mathsf{append}(R, x)) \to \bot.$$

These rows form a single BHist*-anchored* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *certificate row, not an abstract operator schema.*

Proof. First invoke Definition 45.586. It supplies the concrete ten-field certificate rows listed in Definition 45.585 for the source tuple $\mathsf{RatUpFieldSource}_F$.

Next invoke Definition 45.600 with the same concrete denominator tuple, histories h, k, ℓ, endpoint definitions x and y, and the support witness $\mathsf{ThreeSupp}^u_D(h, k, \ell)$. This gives the two crossed contextual singleton-classifier exclusions for arbitrary histories $L, R : \mathsf{BHist}$.

The certificate and the crossed exclusions are carried by the same BHist source, the same denominator tuple, and the same contextual append rows. Thus the strongest concrete noncollapse row is recorded inside the ten-field $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit instance as a concrete row rather than an abstract operator schema. □

Theorem 45.602 (RatUp FieldUp contextual cross-endpoint nondegenerate exit package)**.** *For the concrete source tuple* $\mathsf{RatUpFieldSource}_F$*, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, and the contextual action* Γ *of Definition 45.454, let* $h, k, \ell : \mathsf{BHist}$ *be histories with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*. Define the crossed denominator endpoints* $x := \mu^u_D(\mu^u_D(h, k), \ell)$ *and* $y := \mu^u_D(h, \mu^u_D(k, \ell))$*. For arbitrary contexts* $L, R : \mathsf{BHist}$ *and factors* $a, b, c, d, e : \mathsf{BHist}$*, put* $P_5 := \mathsf{mul}(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a, b), c), d), e)$*. Assume the hypotheses of Definition 45.601 at* h, k, ℓ, L, R*, the hypotheses of Definition 45.583 for the same concrete source tuple, denominator tuple, and action* Γ*, and the field hypotheses of Definition 45.296. Assume also a witness* $p_{abcde} : \mathsf{NonZero}_F(P_5)$ *and the apartness-to-nonzero maps required by Definition 45.582. Then the concrete* BHist*-anchored* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit package simultaneously contains:*

1. *the ten-field certificate rows of Definition 45.601;*
2. *the two crossed singleton-classifier exclusions* $\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, y)) \to \bot$ *and* $\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, y), \mathsf{append}(R, x)) \to \bot$*;*
3. *the normalized contextual full noncollapse package of Definition 45.583;*
4. *the five individual nonzero factor witnesses* $p_a : \mathsf{NonZero}_F(a)$*,* $p_b : \mathsf{NonZero}_F(b)$*,* $p_c : \mathsf{NonZero}_F(c)$*,* $p_d : \mathsf{NonZero}_F(d)$*, and* $p_e : \mathsf{NonZero}_F(e)$ *extracted from* p_{abcde}*;*
5. *for every* $u, v : \mathsf{BHist}$*, the right and left five-factor equation exactness rows*

$$\mathsf{mul}(u, P_5)\mathsf{hsame}v \iff u\mathsf{hsamemul}(v, R_5)$$

and

$$\mathsf{mul}(P_5, u)\mathsf{hsame}v \iff u\mathsf{hsamemul}(R_5, v),$$

where $R_5 := \mathsf{mul}(\mathsf{inv}(e, p_e), \mathsf{mul}(\mathsf{inv}(d, p_d), \mathsf{mul}(\mathsf{inv}(c, p_c), \mathsf{mul}(\mathsf{inv}(b, p_b), \mathsf{inv}(a, p_a)))))$*.*

Proof. Apply Definition 45.601 with the displayed denominator tuple, histories h, k, ℓ, endpoints x, y, contexts L, R, and the support hypotheses. This supplies the ten-field certificate rows and the two crossed singleton-classifier exclusions in the same $\mathsf{RatUpFieldSource}_F$ boundary.

Next apply Definition 45.583 to the displayed source tuple, denominator tuple, and action Γ under its normalized contextual hypotheses. Its clauses add the assembled boundary, carried contextual endpoint, normalized classifier row, strict-support equivalence, exit-row closure, direct endpoint separation, singleton-context carrier rejections, and singleton-classifier obstruction.

Apply Definition 45.582 to p_{abcde} and the apartness-to-nonzero maps. The forward direction yields the five factor witnesses p_a, p_b, p_c, p_d, p_e used by the inverse spine R_5.

Finally apply Definition 45.296 with P_5 and p_{abcde}. It gives the right and left equation exactness rows for every $u, v : \mathsf{BHist}$, with R_5 built from the same five factor witnesses.

All clauses are indexed by BHist and by the concrete source tuple $\mathsf{RatUpFieldSource}_F$. Repacking them therefore gives one concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit package rather than separate local rows. □

Per-object template: traditional target concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ cross-endpoint exactness; BEDC source $\mathsf{RatUpFieldSource}_F$, BHist, the denominator tuple, append, and $\mathsf{ThreeSupp}^u_D$; carrier $\mathsf{ThreeSupp}^u_D$ plus $\mathsf{RatHistoryCarrier}$; classifier R^u_D plus $\mathsf{fieldSingletonEmptyClassifier}$; stability obligations bracketing-independent support and cross-endpoint classifier rejection; ledger paired denominator endpoints and contextual append rows; core theorem this block; exactness predicate crossed singleton-classifier noncollapse; standard bridge deferred; status $\mathsf{ProofTarget}$.

Per-object template: traditional target bracketing-independent concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ denominator exit support; BEDC source BHist with the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and $\mathsf{RatUpFieldSource}_F$; carrier $\mathsf{ThreeSupp}^u_D$; classifier R^u_D; stability obligations paired left- and right-nested support exactness plus contextual append separation; ledger the paired denominator endpoints $\mu^u_D(\mu^u_D(h,k),\ell)$ and $\mu^u_D(h,\mu^u_D(k,\ell))$; core theorem Definition 45.599; exactness predicate contextual singleton-carrier, inverse-domain, and singleton-classifier exclusion for both product bracketings; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.603 (RatUp FieldUp bracketing-independent full crossed contextual boundary)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, let $x := \mu^u_D(\mu^u_D(h,k),\ell)$ and $y := \mu^u_D(h,\mu^u_D(k,\ell))$. If $\mathsf{ThreeSupp}^u_D(h,k,\ell)$ holds, then the two bracketings of the concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ denominator endpoint carry the following single contextual boundary:*

1. *$C^u_D(x)$, $C^u_D(y)$, and $R^u_D(x,y)$;*
2. *for every context history $r : \mathsf{BHist}$, the four contextual carrier exclusions:*
   - *(a)* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r,x)) \to \bot$;
   - *(b)* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x,r)) \to \bot$;
   - *(c)* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r,y)) \to \bot$;
   - *(d)* $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(y,r)) \to \bot$.
3. *for every context history $r : \mathsf{BHist}$, the four inverse-domain witnesses:*
   - *(a)* $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r,x))$;
   - *(b)* $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(x,r))$;
   - *(c)* $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r,y))$;
   - *(d)* $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(y,r))$.
4. *for all $L, R : \mathsf{BHist}$, the four contextual singleton-classifier exclusions*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L,x),\mathsf{append}(R,x)) \to \bot,$$

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L,y),\mathsf{append}(R,y)) \to \bot,$$

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L,x),\mathsf{append}(R,y)) \to \bot,$$

and

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L,y),\mathsf{append}(R,x)) \to \bot.$$

Proof. First apply Definition 45.599 to the displayed concrete denominator tuple, carried histories, endpoint definitions, and support witness. This gives the carrier rows $C^u_D(x)$ and $C^u_D(y)$, the classifier row $R^u_D(x, y)$, the four contextual singleton-carrier exclusions around x and y, the four corresponding $\mathsf{fieldSingletonEmptyNonZero}$ witnesses, and the two same-endpoint singleton-classifier exclusions.

Next apply Definition 45.600 under the same hypotheses and with the same definitions of x and y. This supplies the two crossed contextual singleton-classifier exclusions, one for (x, y) and one for (y, x), for arbitrary $L, R : \mathsf{BHist}$.

The two theorem applications share the same BHist carrier, the same denominator tuple, and the same support witness $\mathsf{ThreeSupp}^u_D(h, k, \ell)$. Collect the carrier, inverse-domain, same-endpoint classifier, and crossed classifier rows into the displayed boundary package. □

Per-object template: traditional target bracketing-independent concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ denominator exit support; BEDC source BHist with the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and $\mathsf{RatUpFieldSource}_F$; carrier $\mathsf{ThreeSupp}^u_D$; classifier R^u_D; stability obligations paired left- and right-nested support exactness plus contextual append separation and crossed classifier rejection; ledger the paired denominator endpoints $\mu^u_D(\mu^u_D(h, k), \ell)$ and $\mu^u_D(h, \mu^u_D(k, \ell))$; core theorem Definition 45.603; exactness predicate contextual singleton-carrier, inverse-domain, and same-endpoint and crossed singleton-classifier exclusion for both product bracketings; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.604 (RatUp FieldUp crossed ten-field exit certificate)**.** *For the concrete source tuple* $\mathsf{RatUpFieldSource}_F$*, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, and histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, let* $x := \mu^u_D(\mu^u_D(h, k), \ell)$ *and* $y := \mu^u_D(h, \mu^u_D(k, \ell))$*. If* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then the concrete ten-field paper certificate for* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *over* $\mathsf{RatUpFieldSource}_F$ *is the composition of Definition 45.586, Definition 45.589, Definition 45.582, Definition 45.599, and Definition 45.600. Its conclusion contains all of the following concrete rows, with no schematic* mul*,* add*, or* neg *operator parameter:*

1. *the same-bracketing endpoint rows* $C^u_D(x)$*,* $C^u_D(y)$*,* $R^u_D(x, y)$*, and, for all* $L, R : \mathsf{BHist}$*, the contextual singleton-classifier exclusions*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, x)) \to \bot$$

and

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, y), \mathsf{append}(R, y)) \to \bot;$$

2. *the crossed contextual singleton-classifier exclusions, for all* $L, R : \mathsf{BHist}$*,*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, y)) \to \bot$$

and

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, y), \mathsf{append}(R, x)) \to \bot;$$

3. *the two-sided product classifier and nonzero equivalences, for every* $a, b, u, v : \mathsf{BHist}$ *with certified outer witnesses* $p_a : \mathsf{NonZero}_F(a)$ *and* $p_b : \mathsf{NonZero}_F(b)$*,*

$$(\mathsf{mul}(\mathsf{mul}(a, u), b)\mathsf{hsamemul}(\mathsf{mul}(a, v), b)) \iff u\mathsf{hsame}v$$

and

$$\mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(a, u), b)) \iff \mathsf{NonZero}_F(u);$$

4. the five-factor nonzero ledger, for every $a, b, c, d, e : \mathsf{BHist}$*,*

$$\mathsf{NonZero}_F(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a,b),c),d),e)) \iff \mathsf{NonZero}_F(a) \wedge \mathsf{NonZero}_F(b) \wedge \mathsf{NonZero}_F(c) \wedge \mathsf{NonZero}_F(d) \wedge \mathsf{NonZ}$$

Proof. Begin with Definition 45.586. It fixes the paper certificate site, the $\mathsf{RatUpFieldSource}_F$ source, the BHist carrier, the contextual action, and the denominator rows as one concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ package.

Next apply Definition 45.599. It supplies the same-bracketing endpoint rows $C^u_D(x)$, $C^u_D(y)$, and $R^u_D(x, y)$, together with the x–x and y–y contextual singleton-classifier exclusions for arbitrary $L, R : \mathsf{BHist}$.

Then apply Definition 45.600. It supplies the two crossed contextual singleton-classifier exclusions, again for arbitrary $L, R : \mathsf{BHist}$, so the certificate consumes both the x–y and y–x classifier boundary rows.

Finally use Definition 45.589 for the two-sided product classifier and nonzero equivalences, and Definition 45.582 for the five nonzero factor witnesses. These clauses share the same concrete source, carrier, classifier, and ledger vocabulary, so they assemble as one ten-field exit certificate rather than as separate paper endpoints. □

Per-object template: traditional target crossed RatUp FieldUp exit certificate; BEDC source $\mathsf{RatUpFieldSource}_F$, BHist, denominator tuple, contextual action, and product/nonzero rows; carrier $\mathsf{RatHistoryCarrier}$; classifier $\mathsf{RatHistoryClassifier}$ plus singleton-empty classifier boundary; stability obligations the same-bracketing and crossed contextual boundaries plus product classifier exactness; ledger denominator bracketings, contextual endpoints, nonzero factors, and product witnesses; core theorem Definition 45.604; exactness the paired same/cross classifier exclusions and product equivalences; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.605 (RatUp FieldUp bracketing-complete classifier exit certificate)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, let* $x := \mu^u_D(\mu^u_D(h, k), \ell)$ *and* $y := \mu^u_D(h, \mu^u_D(k, \ell))$*. If* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *exit certificate contains the following bracketing-complete classifier package:*

1. the endpoint certificate rows $C^u_D(x)$*,* $C^u_D(y)$*, and* $R^u_D(x, y)$*;*

2. for every context history $r : \mathsf{BHist}$*, the contextual carrier exclusions*

$$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, x)) \to \bot, \quad \mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x, r)) \to \bot,$$

$$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, y)) \to \bot, \quad \mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(y, r)) \to \bot;$$

3. for every context history $r : \mathsf{BHist}$*, the inverse-domain witnesses*

$$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, x)), \quad \mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(x, r)),$$

$$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, y)), \quad \mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(y, r));$$

4. for all $L, R : \mathsf{BHist}$*, the four ordered endpoint-pair singleton-classifier exclusions*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, x)) \to \bot,$$

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, y), \mathsf{append}(R, y)) \to \bot,$$

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, y)) \to \bot,$$

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, y), \mathsf{append}(R, x)) \to \bot.$$

Proof. Apply Definition 45.586. This supplies the ambient ten-field certificate boundary for the concrete $\mathsf{RatUpFieldSource}_F$ instance and identifies the package rows as clauses of the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit certificate.

Next apply Definition 45.599 to the same denominator tuple, histories, endpoint definitions, and support witness. It gives the endpoint carrier rows, the classifier row $R^u_D(x, y)$, the contextual carrier exclusions around both bracketings, the inverse-domain witnesses around both bracketings, and the two same-endpoint singleton-classifier exclusions.

Finally apply Definition 45.600 with the same data. This supplies the two crossed singleton-classifier exclusions for (x, y) and (y, x) under arbitrary contexts $L, R : \mathsf{BHist}$. Together with the same-endpoint rows already obtained, these are exactly the four ordered endpoint-pair classifier exclusions, so the certificate package is bracketing-complete.

For the x–y crossed classifier, unpack a witness of $\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, y))$. Its source and target carrier fields include $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(L, x))$ and $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{a}$ Applying the source-carrier rejection for $\mathsf{append}(L, x)$ gives $\bot$.

For the y–x crossed classifier, unpack a witness of $\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, y), \mathsf{append}(R, x))$. Its source and target carrier fields include $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(L, y))$ and $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{a}$ Applying the source-carrier rejection for $\mathsf{append}(L, y)$ gives $\bot$. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup bracketing independent cross endpoint classifier boundary`

Per-object template: traditional target bracketing-complete classifier exit for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source $\mathsf{RatUpFieldSource}_F$, BHist, μ^u_D, R^u_D, and $\mathsf{ThreeSupp}^u_D$; carrier C^u_D; classifier R^u_D plus singleton-empty classifier exclusions; stability obligations the same-endpoint and crossed bracketing-boundary theorem sites; ledger paired denominator endpoints $\mu^u_D(\mu^u_D(h, k), \ell)$ and $\mu^u_D(h, \mu^u_D(k, \ell))$; exactness predicate four-pair classifier noncollapse; standard bridge deferred; status $\mathsf{ProofTarget}$.

Definition 45.606 (RatUp FieldUp bracketing endpoint selector)**.** *For the concrete denominator operation μ^u_D and histories $h, k, \ell : \mathsf{BHist}$, define the selector endpoint $E_s(h, k, \ell) : \mathsf{BHist}$ by the two generated* BMark *cases:*

$$E_{\mathsf{BMark.b0}}(h, k, \ell) := \mu^u_D(\mu^u_D(h, k), \ell),$$

$$E_{\mathsf{BMark.b1}}(h, k, \ell) := \mu^u_D(h, \mu^u_D(k, \ell)).$$

Thus $E_s(h, k, \ell)$ is the closed map out of BMark *whose* $\mathsf{BMark.b0}$ *branch is the left-nested denominator endpoint and whose* $\mathsf{BMark.b1}$ *branch is the right-nested denominator endpoint.*

Lean4 (definition) `BEDC.Derived.FieldUp.ratup fieldup bracketing endpoint selector`
Lean4 (definition) `BEDC.Derived.FieldUp.FieldRatBracketingEndpointSelector`

Theorem 45.607 (RatUp FieldUp bracketing endpoint selector carrier coverage)**.** *For histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, if*

$$(N^u_D(h) \vee N^u_D(k)) \vee N^u_D(\ell)$$

holds, then both concrete bracketings carry rational denominator support, and every selected endpoint $E_s(h, k, \ell)$ carries that support:

$$N^u_D(\mu^u_D(\mu^u_D(h, k), \ell)) \wedge N^u_D(\mu^u_D(h, \mu^u_D(k, \ell))) \wedge \forall s : \mathsf{BMark},\ N^u_D(E_s(h, k, \ell)).$$

Proof. First close $C^u_D(h)$ and $C^u_D(k)$ under continuation to obtain $C^u_D(\mu^u_D(h,k))$. Split the concrete support disjunction. A support witness on h or k closes the left bracketing by the left or right append carrier law and then appends ℓ; a support witness on ℓ closes the left bracketing from the carried prefix. Associativity transports this carrier to the right bracketing. Finally, case analysis on $s : \mathsf{BMark}$ returns the corresponding carried endpoint. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup bracketing endpoint selector carrier coverage`

Theorem 45.608 (RatUp FieldUp bracketing endpoint selector sameness)**.** *For all histories $h, k, \ell : \mathsf{BHist}$, every selected endpoint $E_s(h,k,\ell)$ is classified with one of the two concrete bracketings, and any two selected endpoints are* hsame*:*

$$\forall s : \mathsf{BMark},\ E_s(h,k,\ell)\mathsf{hsame}\mu^u_D(\mu^u_D(h,k),\ell) \vee E_s(h,k,\ell)\mathsf{hsame}\mu^u_D(h,\mu^u_D(k,\ell)),$$

$$\forall s,t : \mathsf{BMark},\ E_s(h,k,\ell)\mathsf{hsame}E_t(h,k,\ell).$$

Proof. Case analysis on s gives either the left bracketing or the right bracketing by definition of the selector. For the pairwise statement, case analysis on s and t leaves the two diagonal cases, closed by reflexivity, and the two crossed cases, closed by associativity and symmetry of hsame. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup bracketing endpoint selector same`

Theorem 45.609 (RatUp FieldUp bracketing choice classifier exclusion)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, let $E_s(h,k,\ell)$ be the endpoint selector of Definition 45.606. If $\mathsf{ThreeSupp}^u_D(h,k,\ell)$ holds, then for all selectors $s,t : \mathsf{BMark}$ and all $L, R : \mathsf{BHist}$,*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, E_s(h,k,\ell)), \mathsf{append}(R, E_t(h,k,\ell))) \to \bot.$$

Proof. Set $x := \mu^u_D(\mu^u_D(h,k),\ell)$ and $y := \mu^u_D(h,\mu^u_D(k,\ell))$. Apply Definition 45.605 to the same denominator tuple, carrier hypotheses, endpoint definitions, and $\mathsf{ThreeSupp}^u_D(h,k,\ell)$ witness. This gives the four ordered endpoint-pair singleton-classifier exclusions for (x,x), (y,y), (x,y), and (y,x).

Use $\mathsf{BMark_generated_cases}$ on s and again on t. There are four closed selector pairs.

1. If $s = \mathsf{BMark.b0}$ and $t = \mathsf{BMark.b0}$, then the selected endpoints are x and x. The (x,x) exclusion from the complete certificate maps the displayed classifier witness to $\bot$.
2. If $s = \mathsf{BMark.b1}$ and $t = \mathsf{BMark.b1}$, then the selected endpoints are y and y. The (y,y) exclusion applies.
3. If $s = \mathsf{BMark.b0}$ and $t = \mathsf{BMark.b1}$, then the selected endpoints are x and y. The crossed (x,y) exclusion applies.
4. If $s = \mathsf{BMark.b1}$ and $t = \mathsf{BMark.b0}$, then the selected endpoints are y and x. The crossed (y,x) exclusion applies.

These four cases exhaust the generated BMark selector pairs, so the selector-indexed classifier witness is impossible for arbitrary $s,t : \mathsf{BMark}$ and arbitrary contexts $L, R : \mathsf{BHist}$. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup bracketing selector classifier exclusion`

Theorem 45.610 (RatUp FieldUp bracketing selector denominator classifier coverage)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$, $C^u_D(k)$, *and* $C^u_D(\ell)$, *let* $E_s(h, k, \ell)$ *be the endpoint selector of Definition 45.606. If* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then for all selectors* $s, t : \mathsf{BMark}$,

$$R^u_D(E_s(h, k, \ell), E_t(h, k, \ell)).$$

Proof. Set $x := \mu^u_D(\mu^u_D(h, k), \ell)$ and $y := \mu^u_D(h, \mu^u_D(k, \ell))$. Apply Definition 45.605 to the same denominator tuple, carrier hypotheses, endpoint definitions, and $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ witness. This supplies $C^u_D(x)$, $C^u_D(y)$, and the endpoint row $R^u_D(x, y)$.

The concrete denominator classifier is the classifier row of the denominator name certificate. Its stability obligations give carrier-relative reflexivity and symmetry. Thus $C^u_D(x)$ gives $R^u_D(x, x)$, $C^u_D(y)$ gives $R^u_D(y, y)$, and symmetry converts $R^u_D(x, y)$ into $R^u_D(y, x)$.

Use BMark_generated_cases on s and again on t. There are four closed selector pairs.

1. If $s = \mathsf{BMark.b0}$ and $t = \mathsf{BMark.b0}$, then the selected endpoints are x and x. The reflexive row $R^u_D(x, x)$ gives the claim.
2. If $s = \mathsf{BMark.b1}$ and $t = \mathsf{BMark.b1}$, then the selected endpoints are y and y. The reflexive row $R^u_D(y, y)$ gives the claim.
3. If $s = \mathsf{BMark.b0}$ and $t = \mathsf{BMark.b1}$, then the selected endpoints are x and y. The bracketing-complete endpoint row $R^u_D(x, y)$ gives the claim.
4. If $s = \mathsf{BMark.b1}$ and $t = \mathsf{BMark.b0}$, then the selected endpoints are y and x. The symmetric endpoint row $R^u_D(y, x)$ gives the claim.

These cases exhaust the generated BMark selector interface, so every selected endpoint pair is classified internally by R^u_D. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldRatBracketingEndpointSelector denominator classifier`

Theorem 45.611 (RatUp FieldUp bracketing selector Rat carrier coverage)**.** *For histories* $h, k, \ell : \mathsf{BHist}$ *with denominator-unit carrier witnesses, let* $E_s(h, k, \ell)$ *be the endpoint selector of Definition 45.606. If at least one of* h, k, ℓ *is a Rat history carrier in the displayed three-support sense, then for every selector* $s : \mathsf{BMark}$,

$$\mathsf{RatHistoryCarrier}(E_s(h, k, \ell)).$$

Proof. For the left-nested endpoint, split the three-support witness. If h or k is already Rat-carried, the denominator-unit append closure keeps the left append Rat-carried and then closes the final append with ℓ. If ℓ is Rat-carried, first close the denominator-unit append $h \cdot k$ and then append the Rat right endpoint. The right-nested endpoint follows by transporting this carrier across associativity. The two BMark cases select exactly these two endpoints. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup bracketing selector rat carrier coverage`

Theorem 45.612 (RatUp FieldUp bracketing selector Rat classifier coverage)**.** *Under the same denominator-unit and three-support hypotheses, every selected bracketing endpoint pair is classified by the Rat history classifier:*

$$\forall s, t : \mathsf{BMark}.\ \mathsf{RatHistoryClassifier}(E_s(h, k, \ell), E_t(h, k, \ell)).$$

Proof. Apply the selector Rat-carrier coverage theorem to both selected endpoints. The classifier's sameness row is obtained by the four generated selector cases: the equal-branch cases use reflexivity, while the crossed cases use append associativity and its symmetry. These three fields assemble the Rat history classifier for the selected pair. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup bracketing selector rat classifier coverage`

Theorem 45.613 (RatUp FieldUp bracketing selector dual classifier coverage)**.** *For the concrete source tuple* $\mathsf{RatUpFieldSource}_F$*, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, and histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, let* $E_s(h, k, \ell)$ *be the endpoint selector of Definition 45.606. If* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then every selector pair* $s, t : \mathsf{BMark}$ *satisfies the combined denominator and Rat row:*

$$N^u_D(E_s(h,k,\ell)) \wedge N^u_D(E_t(h,k,\ell)) \wedge R^u_D(E_s(h,k,\ell), E_t(h,k,\ell)) \wedge \mathsf{RatHistoryCarrier}(E_s(h,k,\ell)) \wedge \mathsf{RatHistoryCarrier}(E_t(h$$

Proof. The three-support hypothesis supplies the denominator-support disjunction required by Definition 45.607. Apply that theorem to the carrier witnesses for h, k, ℓ and then specialize its selector row to s and to t. This gives the two $N^u_D(E_s(h, k, \ell))$ and $N^u_D(E_t(h, k, \ell))$ rows.

Next apply Definition 45.610 with the same denominator tuple, carrier witnesses, three-support witness, and selectors. This gives the denominator classifier row $R^u_D(E_s(h, k, \ell), E_t(h, k, \ell))$.

For the Rat carrier rows, apply Definition 45.611 to the same denominator-unit and three-support data, first at s and then at t. Apply Definition 45.612 to the same selector pair for the Rat classifier row. The six obtained rows assemble directly into the displayed conjunction. □

Theorem 45.614 (RatUp FieldUp bracketing selector independence package)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, let* $E_s(h, k, \ell)$ *be the endpoint selector of Definition 45.606. If* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then for all selectors* $s, t : \mathsf{BMark}$*, every context* $r : \mathsf{BHist}$*, and all classifier contexts* $L, R : \mathsf{BHist}$*, setting* $a := E_s(h, k, \ell)$ *and* $b := E_t(h, k, \ell)$ *gives the following package:*

1.
$$a\mathsf{hsame}b;$$

2.
$$\mathsf{RatHistoryClassifier}(a, b);$$

3.
$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, a), \mathsf{append}(R, b)) \to \bot;$$

4.
$$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, a)) \to \bot;$$

5.
$$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(a, r)) \to \bot;$$

6.
$$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, a));$$

7.
$$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(a, r)).$$

8.

$$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, b)) \to \bot;$$

9.

$$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(b, r)) \to \bot;$$

10.

$$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, b));$$

11.

$$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(b, r)).$$

Proof. First apply Definition 45.608 to the selectors $s, t : \mathsf{BMark}$. This gives the endpoint sameness row $E_s(h, k, \ell)\mathsf{hsame}E_t(h, k, \ell)$.

Next apply Definition 45.612 to the same carrier witnesses and the same $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ witness. This gives the Rat classifier row $\mathsf{RatHistoryClassifier}(E_s(h, k, \ell), E_t(h, k, \ell))$.

Apply Definition 45.609 to the same denominator tuple, the carrier witnesses, the $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ witness, the selectors s, t, and the classifier contexts $L, R : \mathsf{BHist}$. This gives the selected-pair singleton-classifier exclusion.

Finally apply Definition 45.624 to the selector s and the context $r : \mathsf{BHist}$. Its four rows give the two one-sided singleton-carrier exclusions and the two corresponding fieldSingletonEmptyNonZero witnesses for $E_s(h, k, \ell)$.

Apply the same theorem again to the selector t and the same context r. The resulting four rows give the matching singleton-carrier exclusions and fieldSingletonEmptyNonZero witnesses for $E_t(h, k, \ell)$. Replacing the temporary names a and b by their selector definitions assembles the displayed package. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup bracketing selector independence package`

Per-object template: traditional target bracketing-selector independence inside $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, BMark, RatUp, the denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$, and selectors E_s, E_t; carrier C^u_D and RatHistoryCarrier; classifier R^u_D and RatHistoryClassifier; stability obligations selector sameness, selector denominator coverage, selector Rat coverage, and contextual nonzero package rows for both selected endpoints on both context sides; ledger selector choices plus both context sides; exactness predicate selector-independent row coverage; standard bridge deferred; status ProofTarget.

Per-object template: traditional target selector-indexed bracketing classifier coverage for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, BMark, μ^u_D, R^u_D, and $\mathsf{ThreeSupp}^u_D$; carrier C^u_D and RatHistoryCarrier; classifier block records both the denominator classifier R^u_D and the Rat classifier RatHistoryClassifier; stability obligations reflexivity, symmetry, bracketing-complete endpoint coverage, Rat carrier coverage, and selector sameness; ledger the selected endpoint pair (s, t); exactness predicate paired denominator-classifier and Rat-classifier coverage over generated selector pairs; standard bridge deferred; status ProofTarget.

Theorem 45.615 (RatUp FieldUp concrete operation exit exhaustion)**.** *For the concrete table of Definition 45.587, the rows certified by Definition 45.588, Definition 45.586, Definition 45.589, and Definition 45.605 exhaust the concrete exit object of Definition 45.617.*

The exhaustion contains carrier and classifier anchoring, the $\mathsf{CommRing}^{\uparrow}$ *base rows, denominator multiplication and unit rows, contextual and context-pair rows, affine rows, inverse and nonzero rows, two-sided product exactness, and the same-endpoint plus crossed singleton-classifier noncollapse rows for the paired bracketing endpoints.*

Proof. First invoke Definition 45.588. This identifies the table inventory over $\mathsf{RatUpFieldSource}_F$: the carrier and classifier anchors, the $\mathsf{CommRing}^{\uparrow}$ base coordinate, denominator multiplication and unit, contextual action, context-pair support, affine closure, inverse rows, nonzero rows, and exit noncollapse rows.

Next invoke Definition 45.586. It packages the same inventory as the ten-field per-object certificate for the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ target, with the source, carrier, classifier, stability obligations, ledger, exactness predicate, bridge slot, and status $\mathsf{ProofTarget}$ fixed by the displayed table.

For two-sided multiplication through certified nonzero histories, invoke Definition 45.589. This adds product classifier exactness and nonzero transport to the same concrete exit object, so the product rows are not external parameters.

Finally invoke Definition 45.605. It supplies the same-endpoint and crossed singleton-classifier noncollapse rows for the ordered endpoint pairs $\mu^u_D(\mu^u_D(h,k),\ell)$ and $\mu^u_D(h,\mu^u_D(k,\ell))$. Together with the table laws, the ten-field certificate, and the product package, these clauses cover every row named in the concrete operation table and therefore exhaust the concrete exit object of Definition 45.617. □

Per-object template: traditional target concrete operation exit exhaustion for $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source $\mathsf{RatUpFieldSource}_F$ and BHist; carrier $\mathsf{RatHistoryCarrier}$; classifier $\mathsf{RatHistoryClassifier}$ together with $\mathsf{RatDenomUnitClassifier}$; stability obligations carrier/classifier anchoring, $\mathsf{CommRing}^{\uparrow}$ base rows, denominator multiplication and unit rows, contextual and context-pair rows, affine rows, inverse and nonzero rows, product exactness, and singleton noncollapse rows; ledger denominator histories, context pairs, nonzero product witnesses, affine witnesses, and bracketing endpoint pairs; exactness predicate complete row coverage for Definition 45.617; standard bridge deferred; status $\mathsf{ProofTarget}$. Per-object template: traditional target bracketing-independent concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ denominator exit support; BEDC source BHist with the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and $\mathsf{RatUpFieldSource}_F$; carrier $\mathsf{ThreeSupp}^u_D$; classifier R^u_D; stability obligations paired left- and right-nested support exactness plus contextual append separation; ledger the paired denominator endpoints $\mu^u_D(\mu^u_D(h,k),\ell)$ and $\mu^u_D(h,\mu^u_D(k,\ell))$; core theorem Definition 45.599; exactness predicate contextual singleton-carrier, inverse-domain, and singleton-classifier exclusion for both product bracketings; standard bridge deferred; status $\mathsf{ProofTarget}$.

Per-object template: traditional target bracketing-complete classifier exit for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source $\mathsf{RatUpFieldSource}_F$, BHist, μ^u_D, R^u_D, and $\mathsf{ThreeSupp}^u_D$; carrier C^u_D; classifier R^u_D plus singleton-empty classifier exclusions; stability obligations the same-endpoint and crossed bracketing-boundary theorem sites; ledger paired denominator endpoints $\mu^u_D(\mu^u_D(h,k),\ell)$ and $\mu^u_D(h,\mu^u_D(k,\ell))$; exactness predicate four-pair classifier noncollapse; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.616 (RatUp FieldUp paper algebra hierarchy exit package)**.** *For the concrete source tuple* $\mathsf{RatUpFieldSource}_F$*, the* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *algebra-hierarchy ProofTarget is recorded as a single paper-side package over* BHist*. This package contains, as concrete certificate rows, the ten-field certificate, one-sided multiplication cancellation exactness, the two-sided product classifier and nonzero transport, the five-factor nonzero ledger, the cross-endpoint singleton-classifier exclusions, and the bracketing-complete classifier package. Every listed row is carried by the concrete BEDC histories and denominator endpoints of* $\mathsf{RatUpFieldSource}_F$*; no schematic* mul*,* add*, or* neg *parameter is part of this paper-side package.*

Proof. First apply Definition 45.586. This gives the concrete ten-field certificate for $\mathsf{RatUpFieldSource}_F$, including the history-level carrier, classifier, unit, inverse-domain, and continuation rows that form the ambient $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ boundary.

Next apply Definition 45.589 and Definition 45.582. The first theorem records the one-sided multiplication cancellation exactness, two-sided product classifier, and nonzero transport rows, while the second records the five-factor nonzero ledger as a concrete BHist factor certificate.

Then apply Definition 45.601 and Definition 45.605. These supply the cross-endpoint singleton-classifier exclusions and the bracketing-complete classifier package for the paired denominator endpoints.

All cited rows use the same concrete source tuple, the same BHist carrier, and the same denominator endpoint data. Assembling these rows gives the concrete paper-side package required for a machine-checked $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ Phase Algebra Hierarchy exit. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatupFieldupAlgebraHierarchyExitWitness`

Per-object template: traditional target RatUp FieldUp algebra hierarchy paper package; BEDC source $\mathsf{RatUpFieldSource}_F$ over BHist; carrier the concrete RatUp history rows and denominator endpoints; classifier the ten-field rows, one-sided multiplication cancellation exactness, two-sided product classifier, nonzero transport, five-factor ledger, singleton-classifier exclusions, and bracketing-complete classifier package; stability obligations the cited concrete exit package rows; ledger the assembled $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ hierarchy certificate; core theorem Definition 45.616; exactness predicate concrete hierarchy row coverage without schematic operation parameters; standard bridge deferred; status ProofTarget.

Theorem 45.618 (RatUp FieldUp concrete exit object is complete)**.** *For* $\mathsf{RatUpFieldSource}_F$*, the paper package* $\mathcal{E}_F$ *determined by Definition 45.617 satisfies*

$$\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F).$$

Moreover $\mathcal{E}_F$ *is exactly the paper-side* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit package over* BHist*: its source, carrier, classifier, stability obligations, ledger, core theorem list, exactness predicate, standard-bridge slot, and status are precisely the rows named in Definition 45.617.*

Lean4 ✓ `BEDC.Derived.FieldUp.RatupFieldupConcreteExitObjectComplete`

Proof. Apply Definition 45.502. It fixes the single BHist source tuple for $\mathsf{RatUpFieldSource}_F$ and identifies the carrier, classifier, source, stability, ledger, and exactness rows consumed by the concrete package $\mathcal{E}_F$.

Next apply Definition 45.615. This covers every operation row named in Definition 45.617, including the carrier and classifier anchors, denominator rows, contextual rows, affine rows, inverse and nonzero rows, product exactness, and singleton-classifier noncollapse rows.

Apply Definition 45.616. It packages those rows as the Phase Algebra Hierarchy paper certificate for $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$, with the bridge slot and status recorded as part of the same paper-side object.

Finally apply Definition 45.619. It supplies the selector inverse-domain coverage rows generated by $E_s(h,k,\ell)$, including selected endpoint carrier coverage, denominator classifier coverage, strict endpoint nonzero witnesses, and contextual singleton-classifier exclusion.

Apply Definition 45.637 to the two R^u_D-related denominator triples and the hsame-related context pair. This is the stability component of the selector row family in the concrete exit object, transporting the selected endpoint classifier rows and the primed row package along the denominator relation.

Apply Definition 45.764 to the same concrete exit object, denominator tuple, carrier witnesses, support witness, selector quadruple, and contexts. This covers both final-certificate two-selector noncollapse packages, the componentwise R^u_D rows, and the componentwise RatHistoryClassifier rows named by the final boundary conjunct.

Apply Definition 45.765 to the same concrete exit object, denominator tuple, carrier witnesses, support witness, selector sextuple, and contexts. This covers the three final-certificate two-selector noncollapse packages for (s,t), (u,v), and (w,z), the chained R^u_D endpoint rows, and the chained RatHistoryClassifier endpoint rows named by the selector-chain final-boundary conjunct.

These cited inputs cover exactly the conjuncts defining $\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F)$, including both selector-independent and selector-chain final-boundary rows. Hence the predicate holds, and because the algebra-hierarchy witness uses the same BHist source and row inventory, $\mathcal{E}_F$ is exactly the paper-side $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit package over BHist. □

Theorem 45.619 (RatUp FieldUp concrete exit selector inverse-domain coverage)**.** *For* $\mathsf{RatUpFieldSource}_F$*, the concrete exit object of Definition 45.617 contains the strict inverse-domain selector row for the concrete tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*. Explicitly, for histories* h,k,ℓ : BHist *with* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(\ell)$*, and* $\mathsf{ThreeSupp}^u_D(h,k,\ell)$*, selectors* s,t : BMark*, and contexts* L,R : BHist*, the concrete exit object contains the row*

$$C^u_D(E_s(h,k,\ell))\wedge C^u_D(E_t(h,k,\ell))\wedge R^u_D(E_s(h,k,\ell),E_t(h,k,\ell))\wedge\mathsf{fieldSingletonEmptyNonZero}(E_s(h,k,\ell))\wedge\mathsf{fieldSingleton}$$

Proof. Apply Definition 45.634 to the same concrete denominator tuple, carrier hypotheses, support witness, selector pair, and context pair. It supplies the displayed strict selector row, including the two selected endpoint carrier rows, the denominator classifier row, the two strict endpoint nonzero witnesses, and the contextual singleton-classifier obstruction.

By Definition 45.617, selector inverse-domain coverage is one conjunct of $\mathsf{RatUpFieldExitObject}_F$ for the concrete exit package. Therefore the strict row supplied by the selector package is one of the concrete exit-object rows for $\mathsf{RatUpFieldSource}_F$. □

Theorem 45.620 (RatUp FieldUp concrete exit selector row stability)**.** *For* $\mathsf{RatUpFieldSource}_F$*, the concrete exit object of Definition 45.617 contains the selector row-stability transport for the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*. Explicitly, for denominator triples* $h, k, \ell, h', k', \ell' : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(\ell)$*,* $C^u_D(h')$*,* $C^u_D(k')$*, and* $C^u_D(\ell')$*, assume*

$$\mathsf{ThreeSupp}^u_D(h, k, \ell) \quad \textit{and} \quad \mathsf{ThreeSupp}^u_D(h', k', \ell')$$

and

$$R^u_D(h, h'), \quad R^u_D(k, k'), \quad R^u_D(\ell, \ell').$$

Then for every selector pair $s, t : \mathsf{BMark}$ *and all contexts* $L, R, L', R' : \mathsf{BHist}$ *with* $\mathsf{hsame}(L, L')$ *and* $\mathsf{hsame}(R, R')$*, the concrete exit object contains the row*

$$R^u_D(E_s(h,k,\ell), E_s(h',k',\ell')) \wedge R^u_D(E_t(h,k,\ell), E_t(h',k',\ell')) \wedge C^u_D(E_s(h',k',\ell')) \wedge C^u_D(E_t(h',k',\ell')) \wedge R^u_D(E_s(h',k',\ell'), E$$

Proof. Apply Definition 45.637 to the same concrete denominator tuple, the six carrier hypotheses, the two support witnesses, the three R^u_D comparisons, the selector pair, and the hsame-related contexts. It supplies the two selected endpoint classifier transports and the primed three-field row package.

By Definition 45.617, selector row-stability transport is a conjunct of the concrete exit object. Therefore the row supplied by Definition 45.637 is contained in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object for $\mathsf{RatUpFieldSource}_F$. □

Per-object template: traditional target RatUp FieldUp concrete exit object completion; BEDC source $\mathsf{RatUpFieldSource}_F$ over BHist; carrier $\mathsf{RatHistoryCarrier}$ and $\mathsf{RatDenomUnitCarrier}$; classifier $\mathsf{RatHistoryClassifier}$ and $\mathsf{RatDenomUnitClassifier}$; stability obligations the concrete schema, operation-exhaustion, and selector row-stability rows; ledger the denominator, contextual, affine, inverse, nonzero, product, singleton-classifier, selector inverse-domain, selector stability, selector-independent final-boundary, and selector-chain final-boundary rows; core theorem list Definition 45.502, Definition 45.615, Definition 45.616, Definition 45.619, Definition 45.620, Definition 45.764, and Definition 45.765; exactness predicate complete concrete row coverage for Definition 45.617; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.621 (RatUp FieldUp concrete exit object hierarchy exactness)**.** *For* $\mathsf{RatUpFieldSource}_F$*, the finite row package of Definition 45.617 is exactly the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *hierarchy exit package. Its carrier and classifier rows are the concrete* $\mathsf{RatHistory}$ *and* $\mathsf{RatDenomUnit}$ *rows, and its operation and exactness rows are precisely those certified by Definition 45.615 and Definition 45.616.*

Proof. Apply Definition 45.615. It exhausts the row inventory of Definition 45.617: the carrier and classifier anchoring rows, the $\mathsf{CommRing}^{\uparrow}$ base rows, denominator multiplication and unit rows, contextual and context-pair rows, affine rows, inverse and nonzero rows, two-sided product exactness, and same-endpoint plus crossed singleton-classifier noncollapse rows.

Apply Definition 45.616. It packages the same concrete rows as the algebra-hierarchy exit witness for $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ over $\mathsf{RatUpFieldSource}_F$, including the ten-field certificate, product classifier and nonzero transport, five-factor ledger, cross-endpoint exclusions, and bracketing-complete classifier package.

Because both cited theorems use the same source tuple, BHist carrier, denominator endpoints, and operation-row inventory, the finite package defined in Definition 45.617 and the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ hierarchy exit package have the same rows and the same exactness obligations. □

Lemma 45.622 (RatUp FieldUp BMark selector endpoint-pair cases)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and histories $h, k, \ell : \mathsf{BHist}$, let $E_s(h, k, \ell)$ be the endpoint selector of Definition 45.606. Set $x := \mu^u_D(\mu^u_D(h, k), \ell)$ and $y := \mu^u_D(h, \mu^u_D(k, \ell))$. Then for all selectors $s, t : \mathsf{BMark}$, the selected endpoint pair $(E_s(h, k, \ell), E_t(h, k, \ell))$ is covered by the four generated rows (x, x), (y, y), (x, y), and (y, x) up to hsame on both endpoints.*

Proof. Perform generated case analysis on the selector pair (s, t). In every branch, unfold the endpoint selector of Definition 45.606; the remaining endpoint comparison is reflexivity of hsame.

In the $(\mathsf{BMark.b0}, \mathsf{BMark.b0})$ branch, both selected endpoints unfold to x, so the row (x, x) supplies the pair witness.

In the $(\mathsf{BMark.b1}, \mathsf{BMark.b1})$ branch, both selected endpoints unfold to y, so the row (y, y) supplies the pair witness.

In the $(\mathsf{BMark.b0}, \mathsf{BMark.b1})$ branch, the left endpoint unfolds to x and the right endpoint unfolds to y, giving the row (x, y).

In the $(\mathsf{BMark.b1}, \mathsf{BMark.b0})$ branch, the left endpoint unfolds to y and the right endpoint unfolds to x, giving the row (y, x). □

Theorem 45.623 (RatUp FieldUp BMark-selected bracketing exit subpackage)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, let $E_s(h, k, \ell)$ be the endpoint selector of Definition 45.606. If $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ holds, then for all selectors $s, t : \mathsf{BMark}$ and all contexts $L, R : \mathsf{BHist}$, the selected endpoints form the following concrete exit subpackage:*

1. *$C^u_D(E_s(h, k, \ell))$ and $C^u_D(E_t(h, k, \ell))$;*
2. *$R^u_D(E_s(h, k, \ell), E_t(h, k, \ell))$;*
3. $$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, E_s(h, k, \ell)), \mathsf{append}(R, E_t(h, k, \ell))) \to \bot.$$

Proof. Set $x := \mu^u_D(\mu^u_D(h, k), \ell)$ and $y := \mu^u_D(h, \mu^u_D(k, \ell))$. Apply Definition 45.605 to the same concrete denominator tuple, carrier hypotheses, endpoint definitions, and $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ witness. This supplies $C^u_D(x)$, $C^u_D(y)$, $R^u_D(x, y)$, and the four ordered endpoint-pair singleton-classifier exclusions.

For carrier coverage, use the two generated BMark cases for s. In the $\mathsf{BMark.b0}$ branch, the selected endpoint is x, so $C^u_D(x)$ transports to $C^u_D(E_s(h, k, \ell))$. In the $\mathsf{BMark.b1}$ branch, the selected endpoint is y, so $C^u_D(y)$ transports to $C^u_D(E_s(h, k, \ell))$. The same two-case argument for t gives $C^u_D(E_t(h, k, \ell))$.

The displayed denominator-classifier row is exactly Definition 45.610 applied to the same carrier data and support witness. It packages the reflexive, symmetric, and crossed endpoint classifier rows across all selected pairs $s, t : \mathsf{BMark}$.

The singleton-classifier rejection under arbitrary contexts is exactly Definition 45.609 applied to the same selector endpoints. Thus the selected pair (s, t) and the contexts (L, R) carry both

the internal denominator classifier row and the external singleton-classifier exclusion required by the concrete exit subpackage. □

Theorem 45.624 (RatUp FieldUp selector contextual nonzero package)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, let* $E_s(h, k, \ell)$ *be the endpoint selector of Definition 45.606. If* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then for every selector* $s : \mathsf{BMark}$ *and every context* $r : \mathsf{BHist}$*, the selected endpoint has the following contextual nonzero package:*

1.
$$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, E_s(h, k, \ell))) \to \bot;$$

2.
$$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(E_s(h, k, \ell), r)) \to \bot;$$

3.
$$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, E_s(h, k, \ell)));$$

4.
$$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(E_s(h, k, \ell), r)).$$

Proof. Set $x := \mu^u_D(\mu^u_D(h, k), \ell)$ and $y := \mu^u_D(h, \mu^u_D(k, \ell))$. Apply Definition 45.605 to the same concrete denominator tuple, carrier hypotheses, endpoint definitions, and $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ witness. This supplies the two contextual carrier exclusions and the two inverse-domain witnesses for each concrete endpoint x and y.

Use the generated BMark cases for s.

1. In the $\mathsf{BMark.b0}$ branch, the selected endpoint is x. The rows $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, x)) \to \bot$, $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(x, r)) \to \bot$, $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, x))$, and $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(x, r))$ transport along this endpoint equality.
2. In the $\mathsf{BMark.b1}$ branch, the selected endpoint is y. The corresponding four rows for $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{ap}$ $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(y, r))$, $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, y))$, and $\mathsf{fieldSingletonEmptyNonZ}$ transport along this endpoint equality.

The two generated selector branches exhaust BMark, so the selected endpoint carries both one-sided contextual carrier exclusions and both inverse-domain witnesses for arbitrary context $r : \mathsf{BHist}$. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup bracketing selector contextual nonzero package`

Per-object template: traditional target selected bracketing contextual nonzero package for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, BMark, μ^u_D, and $\mathsf{ThreeSupp}^u_D$; carrier C^u_D; classifier singleton-empty carrier and nonzero predicates; stability obligations bracketing-complete contextual carrier and inverse-domain rows; ledger selected endpoint and context side; exactness predicate selector-total noncollapse; standard bridge deferred; status $\mathsf{ProofTarget}$.

Per-object template: traditional target selector-indexed bracketing exit subpackage for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, BMark, μ^u_D, R^u_D, and $\mathsf{ThreeSupp}^u_D$; carrier C^u_D; classifier R^u_D; stability obligations the bracketing-complete certificate plus selector coverage and selector exclusion; ledger the selected endpoint pair (s, t) and contexts (L, R); exactness predicate total selected-endpoint coverage and noncollapse; standard bridge deferred; status $\mathsf{ProofTarget}$.

Per-object template: traditional target RatUp FieldUp algebra hierarchy paper package; BEDC source $\mathsf{RatUpFieldSource}_F$ over BHist; carrier the concrete RatUp history rows and denominator

endpoints; classifier the ten-field rows, two-sided product classifier, nonzero transport, five-factor ledger, singleton-classifier exclusions, and bracketing-complete classifier package; stability obligations the cited concrete exit package rows; ledger the assembled $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ hierarchy certificate; core theorem Definition 45.616; exactness predicate concrete hierarchy row coverage without schematic operation parameters; standard bridge deferred; status ProofTarget.

Lemma 45.625 (RatUp FieldUp bracketing endpoint selector exhaustion)**.** *For histories $h, k, \ell : \mathsf{BHist}$, set $x := \mu^u_D(\mu^u_D(h, k), \ell)$ and $y := \mu^u_D(h, \mu^u_D(k, \ell))$. For every pair of selectors $s, t : \mathsf{BMark}$, the selected endpoint pair $(E_s(h, k, \ell), E_t(h, k, \ell))$ is one of (x, x), (x, y), (y, x), and (y, y), with the corresponding displayed equalities between $E_s(h, k, \ell)$, $E_t(h, k, \ell)$ and the selected endpoints x, y.*

Proof. Apply BMark_generated_cases to s and then to t. This gives four closed generated selector pairs.

1. If $s = \mathsf{BMark.b0}$ and $t = \mathsf{BMark.b0}$, unfold Definition 45.606. Then $E_s(h, k, \ell) = x$ and $E_t(h, k, \ell) = x$, so the selected pair is (x, x).
2. If $s = \mathsf{BMark.b0}$ and $t = \mathsf{BMark.b1}$, unfold Definition 45.606. Then $E_s(h, k, \ell) = x$ and $E_t(h, k, \ell) = y$, so the selected pair is (x, y).
3. If $s = \mathsf{BMark.b1}$ and $t = \mathsf{BMark.b0}$, unfold Definition 45.606. Then $E_s(h, k, \ell) = y$ and $E_t(h, k, \ell) = x$, so the selected pair is (y, x).
4. If $s = \mathsf{BMark.b1}$ and $t = \mathsf{BMark.b1}$, unfold Definition 45.606. Then $E_s(h, k, \ell) = y$ and $E_t(h, k, \ell) = y$, so the selected pair is (y, y).

These four branches exhaust the generated BMark selectors, so no other selected endpoint pair is available. □

This case-exhaustion lemma is consumed by Definition 45.609, Definition 45.610, and Definition 45.629.

Theorem 45.626 (RatUp FieldUp selector-complete four-pair coverage)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, set $x := \mu^u_D(\mu^u_D(h, k), \ell)$ and $y := \mu^u_D(h, \mu^u_D(k, \ell))$. Let $E_s(h, k, \ell)$ be the endpoint selector of Definition 45.606. If $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ holds, then the following two assertions are equivalent.*

1. *For every $s, t : \mathsf{BMark}$ and every $L, R : \mathsf{BHist}$, both $R^u_D(E_s(h, k, \ell), E_t(h, k, \ell))$ and*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, E_s(h, k, \ell)), \mathsf{append}(R, E_t(h, k, \ell))) \to \bot$$

   hold.

2. *The four explicit endpoint rows all hold: for each ordered pair (a, b) among (x, x), (x, y), (y, x), and (y, y), both $R^u_D(a, b)$ and, for every $L, R : \mathsf{BHist}$,*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, a), \mathsf{append}(R, b)) \to \bot$$

   hold.

Proof. For the forward direction, assume the selector-indexed assertion. Specialize it to the selector pairs (BMark.b0, BMark.b0), (BMark.b0, BMark.b1), (BMark.b1, BMark.b0), and (BMark.b1, BMark.b1), with arbitrary contexts $L, R : \mathsf{BHist}$.

Unfold Definition 45.606. The four specializations identify the selected endpoint pairs with (x, x), (x, y), (y, x), and (y, y) respectively, giving the four explicit denominator classifier rows and the four contextual singleton-classifier rejections.

For the reverse direction, assume the four explicit endpoint rows. Let $s, t : \mathsf{BMark}$ and $L, R : \mathsf{BHist}$ be arbitrary. Apply $\mathsf{BMark_generated_cases}$ to s and then to t.

1. In the $(\mathsf{BMark.b0}, \mathsf{BMark.b0})$ branch, unfolding the selector gives $(E_s(h, k, \ell), E_t(h, k, \ell)) = (x, x)$. Use the (x, x) row.
2. In the $(\mathsf{BMark.b0}, \mathsf{BMark.b1})$ branch, unfolding the selector gives $(E_s(h, k, \ell), E_t(h, k, \ell)) = (x, y)$. Use the (x, y) row.
3. In the $(\mathsf{BMark.b1}, \mathsf{BMark.b0})$ branch, unfolding the selector gives $(E_s(h, k, \ell), E_t(h, k, \ell)) = (y, x)$. Use the (y, x) row.
4. In the $(\mathsf{BMark.b1}, \mathsf{BMark.b1})$ branch, unfolding the selector gives $(E_s(h, k, \ell), E_t(h, k, \ell)) = (y, y)$. Use the (y, y) row.

The generated cases exhaust s and t, so the selector-indexed denominator classifier law and the uniform contextual singleton-classifier rejection follow for all selected pairs. □

Per-object template: finite selector coverage for the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ denominator row; BEDC source BHist, BMark, μ^u_D, R^u_D, E_s, and $\mathsf{ThreeSupp}^u_D$; carrier C^u_D; classifier R^u_D; stability obligation the four generated endpoint rows; ledger the explicit pairs (x, x), (x, y), (y, x), and (y, y); exactness predicate equality between selector-indexed laws and finite endpoint coverage; standard bridge deferred; status $\mathsf{ProofTarget}$.

Definition 45.627 (RatUp FieldUp selector-complete denominator instance)**.** *For fixed histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, $C^u_D(\ell)$, and $\mathsf{ThreeSupp}^u_D(h, k, \ell)$, define the selector-complete denominator instance to be the denominator coordinate of $\mathsf{RatUpFieldSource}_F$ displayed as $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$, with the concrete BMark-indexed package whose carrier predicate is C^u_D, whose selected endpoint is the map $E_s(h, k, \ell)$ of Definition 45.606, whose endpoint classifier is R^u_D on selected endpoint pairs, and whose contextual obstruction row is the singleton-empty classifier on*

$$\mathsf{append}(L, E_s(h, k, \ell))$$

and

$$\mathsf{append}(R, E_t(h, k, \ell))$$

for arbitrary selectors $s, t : \mathsf{BMark}$ and arbitrary contexts $L, R : \mathsf{BHist}$. Thus the instance packages the denominator classifier coverage and the contextual singleton obstruction on the same selected endpoint interface.

Theorem 45.628 (RatUp FieldUp selector-complete denominator well-formed exit slice)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, let $E_s(h, k, \ell)$ be the endpoint selector of Definition 45.606. If $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ holds, then for all selectors $s, t : \mathsf{BMark}$ and all contexts $L, R : \mathsf{BHist}$, the selector-complete denominator instance of Definition 45.627 supplies the following three-field row package over the denominator coordinate of $\mathsf{RatUpFieldSource}_F$:*

1. *selected endpoint carrier coverage: $C^u_D(E_s(h, k, \ell))$ and $C^u_D(E_t(h, k, \ell))$;*
2. *denominator classifier coverage: $R^u_D(E_s(h, k, \ell), E_t(h, k, \ell))$;*

3. contextual singleton-classifier noncollapse:

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, E_s(h,k,\ell)), \mathsf{append}(R, E_t(h,k,\ell))) \to \bot.$$

These rows identify Definition 45.627 as the selector-indexed denominator row family of Definition 45.617.

Proof. First apply Definition 45.610 to the concrete denominator tuple, the three carrier hypotheses, and $\mathsf{ThreeSupp}^u_D(h,k,\ell)$. This gives the selected denominator classifier row $R^u_D(E_s(h,k,\ell), E_t(h,k,\ell))$ for the arbitrary selectors $s,t : \mathsf{BMark}$.

Next set $x := \mu^u_D(\mu^u_D(h,k),\ell)$ and $y := \mu^u_D(h, \mu^u_D(k,\ell))$. Apply Definition 45.605 to the same source data and support witness. It supplies $C^u_D(x)$ and $C^u_D(y)$.

Use the two generated BMark cases for s. In the $\mathsf{BMark.b0}$ case, $E_s(h,k,\ell)$ is x; in the $\mathsf{BMark.b1}$ case, $E_s(h,k,\ell)$ is y. The supplied carrier rows therefore give $C^u_D(E_s(h,k,\ell))$. The same case split for t gives $C^u_D(E_t(h,k,\ell))$.

Finally apply Definition 45.609 to the same selected endpoints and the arbitrary contexts $L, R : \mathsf{BHist}$. This is the contextual singleton-classifier noncollapse row.

Unfold Definition 45.627. Its carrier predicate is C^u_D, its selected endpoint map is $s \mapsto E_s(h,k,\ell)$, its classifier row is R^u_D on selected endpoint pairs, and its obstruction row is the displayed singleton-empty classifier. Thus the carrier, classifier, and noncollapse rows are exactly the selector-indexed denominator row family used by Definition 45.617 over $\mathsf{RatUpFieldSource}_F$. □

Theorem 45.629 (RatUp FieldUp selector-complete denominator laws)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and histories $h,k,\ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, let $E_s(h,k,\ell)$ be the endpoint selector of Definition 45.606. If $\mathsf{ThreeSupp}^u_D(h,k,\ell)$ holds, then for all selectors $s,t : \mathsf{BMark}$ and all contexts $L,R : \mathsf{BHist}$, the selector-complete denominator instance of Definition 45.627 supplies $C^u_D(E_s(h,k,\ell))$, $C^u_D(E_t(h,k,\ell))$, $R^u_D(E_s(h,k,\ell), E_t(h,k,\ell))$, and the contextual obstruction*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, E_s(h,k,\ell)), \mathsf{append}(R, E_t(h,k,\ell))) \to \bot.$$

Moreover, specializing the row to (s,s) with $L = R = \mathsf{e}$ gives $\mathsf{fieldSingletonEmptyNonZero}(E_s(h,k,\ell))$, and specializing the row to (t,t) with $L = R = \mathsf{e}$ gives $\mathsf{fieldSingletonEmptyNonZero}(E_t(h,k,\ell))$.

Proof. Apply Definition 45.628 to the same concrete denominator tuple, the three carrier hypotheses, the support witness, the selectors $s,t : \mathsf{BMark}$, and the contexts $L,R : \mathsf{BHist}$. This supplies the two selected carrier rows, the selected denominator classifier row, and the contextual singleton-empty obstruction.

For the first nonzero clause, specialize the same well-formed row to the selector pair (s,s) and to contexts $L = R = \mathsf{e}$. If a singleton-empty witness for $E_s(h,k,\ell)$ were present, the empty-left append unit identifies it with the obstructed classifier on

$$\mathsf{append}(\mathsf{e}, E_s(h,k,\ell)).$$

The specialized obstruction rejects that witness, and Definition 45.29 repackages the rejection as $\mathsf{fieldSingletonEmptyNonZero}(E_s(h,k,\ell))$.

For the second nonzero clause, repeat the specialization with the selector pair (t,t) and contexts $L = R = \mathsf{e}$. The empty-left append unit sends any singleton-empty witness for $E_t(h,k,\ell)$ to the corresponding obstructed classifier on

$$\mathsf{append}(\mathsf{e}, E_t(h,k,\ell)).$$

The specialized obstruction and Definition 45.29 give $\mathsf{fieldSingletonEmptyNonZero}(E_t(h,k,\ell))$. □

Theorem 45.630 (RatUp FieldUp selector-complete denominator strict support package)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, let* $E_s(h, k, \ell)$ *be the endpoint selector of Definition 45.606. If* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then for all selectors* $s, t : \mathsf{BMark}$ *the selector-complete denominator instance of Definition 45.627 supplies the strict-support endpoint package*

$$R^u_D(E_s(h, k, \ell), E_t(h, k, \ell)) \wedge \mathsf{fieldSingletonEmptyNonZero}(E_s(h, k, \ell)) \wedge \mathsf{fieldSingletonEmptyNonZero}(E_t(h, k, \ell)).$$

Proof. Apply Definition 45.629 to the same concrete denominator tuple, carrier hypotheses, support witness, and selectors $s, t : \mathsf{BMark}$. Its classifier row gives $R^u_D(E_s(h, k, \ell), E_t(h, k, \ell))$.

For the left strict-support endpoint, specialize the obstruction row of Definition 45.629 to the selector pair (s, s) and to contexts $L = R = \mathsf{e}$. Assume a forbidden witness $\mathsf{fieldSingletonEmptyClassifier}(E_s(h, k, \ell), \mathsf{e})$. The empty-left append unit transports this witness to a singleton-empty classifier on $\mathsf{append}(\mathsf{e}, E_s(h, k, \ell))$ against itself, contradicting the specialized obstruction. By Definition 45.29, this is exactly fieldSingletonEmptyNonZ

For the right strict-support endpoint, repeat the same argument with the selector pair (t, t) and contexts $L = R = \mathsf{e}$. A forbidden classifier $\mathsf{fieldSingletonEmptyClassifier}(E_t(h, k, \ell), \mathsf{e})$ transports along the empty-left append unit to the obstructed classifier on $\mathsf{append}(\mathsf{e}, E_t(h, k, \ell))$ against itself. The resulting contradiction is the required $\mathsf{fieldSingletonEmptyNonZero}(E_t(h, k, \ell))$.

Combining the classifier row with the two singleton-empty complement witnesses gives the displayed strict-support endpoint package. □

Per-object template: traditional target selector-complete strict denominator support for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, BMark, C^u_D, R^u_D, E_s, and $\mathsf{ThreeSupp}^u_D$; carrier C^u_D; classifier R^u_D; stability obligations selector coverage and singleton-empty noncollapse; ledger selected endpoint pair; exactness predicate denominator coverage plus strict-support endpoints; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.631 (RatUp FieldUp selector-complete denominator swap package)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, let* $E_s(h, k, \ell)$ *be the endpoint selector of Definition 45.606. If* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then for all selectors* $s, t : \mathsf{BMark}$ *and all contexts* $L, R : \mathsf{BHist}$*, the selector-complete denominator instance of Definition 45.627 supplies the symmetric selector/context row package:*

1. *selected endpoint carrier coverage:* $C^u_D(E_s(h, k, \ell))$ *and* $C^u_D(E_t(h, k, \ell))$*;*
2. *denominator classifier coverage in both selector orientations:* $R^u_D(E_s(h, k, \ell), E_t(h, k, \ell))$ *and* $R^u_D(E_t(h, k, \ell), E_s(h, k, \ell))$*;*
3. *strict-support witnesses:* $\mathsf{fieldSingletonEmptyNonZero}(E_s(h, k, \ell))$ *and* $\mathsf{fieldSingletonEmptyNonZero}(E_t(h, k, \ell))$*;*
4. *contextual singleton-classifier noncollapse in both selector/context orientations:*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, E_s(h, k, \ell)), \mathsf{append}(R, E_t(h, k, \ell))) \to \bot$$

and

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(R, E_t(h, k, \ell)), \mathsf{append}(L, E_s(h, k, \ell))) \to \bot.$$

Thus the concrete denominator row consumed by the exit object is available in the displayed orientation and in the swapped selector/context orientation.

Proof. Apply Definition 45.628 to the selectors $s, t : \mathsf{BMark}$ and contexts $L, R : \mathsf{BHist}$. This gives carrier coverage for $E_s(h, k, \ell)$ and $E_t(h, k, \ell)$, the classifier row $R^u_D(E_s(h, k, \ell), E_t(h, k, \ell))$, and the first contextual singleton-empty obstruction.

Apply the same theorem again to the selectors $t, s : \mathsf{BMark}$ and contexts $R, L : \mathsf{BHist}$. The carrier rows agree with the same two selected endpoints, while the classifier and obstruction rows are now $R^u_D(E_t(h, k, \ell), E_s(h, k, \ell))$ and the swapped contextual singleton-empty obstruction.

Finally apply Definition 45.630 to the selector pair (s, t). Its strict-support endpoint package supplies $\mathsf{fieldSingletonEmptyNonZero}(E_s(h, k, \ell))$ and $\mathsf{fieldSingletonEmptyNonZero}(E_t(h, k, \ell))$.

Collecting the rows from the two selector-complete denominator law specializations and the strict-support package gives exactly the symmetric selector/context row package displayed above. □

Per-object template: traditional target selector-complete denominator swap package for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, BMark, the denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$, E_s, and $\mathsf{ThreeSupp}^u_D$; carrier C^u_D; classifier R^u_D plus the singleton-empty obstruction; stability obligations selector-complete row coverage and strict-support endpoints; ledger swapped selector/context orientation; exactness predicate symmetric selector-row coverage; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.632 (RatUp FieldUp selector-complete exit package)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, let $E_s(h, k, \ell)$ be the endpoint selector of Definition 45.606. If $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ holds, then the selector-complete denominator instance of Definition 45.627 supplies a concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit-package row over $\mathsf{RatUpFieldSource}_F$: for every $s, t : \mathsf{BMark}$ and every $L, R : \mathsf{BHist}$ it provides selected endpoint carrier coverage, the denominator classifier row $R^u_D(E_s(h, k, \ell), E_t(h, k, \ell))$, and the contextual singleton-classifier noncollapse row*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, E_s(h, k, \ell)), \mathsf{append}(R, E_t(h, k, \ell))) \to \bot.$$

This selector row is one of the concrete denominator rows consumed by Definition 45.616, and it is read in the denominator coordinate of $\mathsf{RatUpFieldSource}_F$. No schematic mul, add, or neg parameter enters the row.

Proof. Apply Definition 45.629 to the concrete denominator coordinate of $\mathsf{RatUpFieldSource}_F$, the three carrier hypotheses, and $\mathsf{ThreeSupp}^u_D(h, k, \ell)$. This gives, for arbitrary $s, t : \mathsf{BMark}$ and $L, R : \mathsf{BHist}$, the selected endpoint carrier rows, the selected endpoint classifier row, and the contextual singleton-empty obstruction.

Apply Definition 45.616. It records the denominator classifier coverage and singleton-classifier noncollapse rows as concrete rows inside the $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ hierarchy exit package over $\mathsf{RatUpFieldSource}_F$.

The row is therefore an admissible concrete exit-package component. Its data are the selected denominator endpoints inside BHist, the carrier coverage, the denominator classifier coverage, and contextual noncollapse over the source-aligned denominator coordinate, so no schematic mul, add, or neg operator parameter is introduced. □

Theorem 45.633 (RatUp FieldUp carrier-aware selector-complete concrete instance)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, let $E_s(h, k, \ell)$ be the endpoint selector of Definition 45.606. If $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ holds, then for every pair of selectors $s, t : \mathsf{BMark}$ and every pair of contexts $L, R : \mathsf{BHist}$, the selector-complete denominator instance supplies all carrier-aware rows*

1. $C^u_D(E_s(h, k, \ell))$;

2. $C^u_D(E_t(h,k,\ell))$;
3. $R^u_D(E_s(h,k,\ell), E_t(h,k,\ell))$;
4. $\mathsf{fieldSingletonEmptyNonZero}(E_s(h,k,\ell))$;
5. $\mathsf{fieldSingletonEmptyNonZero}(E_t(h,k,\ell))$;
6. $$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, E_s(h,k,\ell)), \mathsf{append}(R, E_t(h,k,\ell))) \to \bot.$$

Together these rows form a concrete carrier-aware and inverse-domain $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit row over* $\mathsf{RatUpFieldSource}_F$.

Proof. Apply Definition 45.623 to the concrete denominator tuple, the carrier hypotheses on h, k, ℓ, and the support witness $\mathsf{ThreeSupp}^u_D(h,k,\ell)$. For the chosen $s, t : \mathsf{BMark}$ and contexts $L, R : \mathsf{BHist}$, it supplies the two selected-endpoint carrier rows, the denominator-classifier row, and the contextual singleton-empty obstruction.

Apply Definition 45.630 to the same concrete tuple, carrier hypotheses, support witness, and selector pair. Its strict-support endpoint package supplies $\mathsf{fieldSingletonEmptyNonZero}(E_s(h,k,\ell))$ and $\mathsf{fieldSingletonEmptyNonZero}(E_t(h,k,\ell))$.

Apply Definition 45.632 to the same concrete tuple, carrier hypotheses, and support witness. This places the same selected denominator row inside the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit package over $\mathsf{RatUpFieldSource}_F$.

The selector-complete denominator instance therefore carries both endpoint coverage and package membership: the two selected endpoints remain in C^u_D, the selected pair lies in R^u_D, both selected endpoints satisfy the singleton-empty nonzero condition, and every contextual singleton-empty classifier on the selected pair collapses to $\bot$. □

Theorem 45.634 (RatUp FieldUp selector-complete strict exit package)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$, $C^u_D(k)$, *and* $C^u_D(\ell)$, *let* $E_s(h,k,\ell)$ *be the endpoint selector of Definition 45.606. If* $\mathsf{ThreeSupp}^u_D(h,k,\ell)$ *holds, then for every selector pair* $s, t : \mathsf{BMark}$ *and every context pair* $L, R : \mathsf{BHist}$ *the selector-complete denominator instance of Definition 45.627 supplies the full strict concrete exit row*

$$C^u_D(E_s(h,k,\ell)) \wedge C^u_D(E_t(h,k,\ell)) \wedge R^u_D(E_s(h,k,\ell), E_t(h,k,\ell)) \wedge (\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, E_s(h,k,\ell)), \mathsf{a}$$

Proof. Apply Definition 45.632 to the same concrete denominator tuple, carrier hypotheses, support witness, selectors $s, t : \mathsf{BMark}$, and contexts $L, R : \mathsf{BHist}$. It supplies the two selected endpoint carrier rows, the denominator classifier row, and the contextual singleton-classifier noncollapse row.

Apply Definition 45.630 to the same tuple, carrier hypotheses, support witness, and selector pair. It supplies the same denominator classifier row together with the two strict endpoint witnesses $\mathsf{fieldSingletonEmptyNonZero}(E_s(h,k,\ell))$ and $\mathsf{fieldSingletonEmptyNonZero}(E_t(h,k,\ell))$.

Use the classifier row only once, taking it from either package. Combining it with the two carrier rows, the contextual noncollapse row, and the strict endpoint witnesses gives exactly the displayed strict concrete exit row consumed in the denominator coordinate of $\mathsf{RatUpFieldSource}_F$. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup selector complete strict exit package`

Per-object template: traditional target selector-complete strict FieldUp denominator exit row; BEDC source $\mathsf{RatUpFieldSource}_F$, BHist, BMark, C^u_D, R^u_D, E_s, and $\mathsf{ThreeSupp}^u_D$; carrier selected endpoint coverage; classifier R^u_D plus singleton-empty obstruction; stability obligations carrier

coverage, denominator classifier coverage, contextual noncollapse, and strict endpoint nonzero witnesses; ledger selected endpoint pair and contexts; core theorem Definition 45.634; exactness predicate full strict row coverage; standard bridge deferred; status ProofTarget.

Theorem 45.635 (RatUp FieldUp five-factor product-map classifier exactness)**.** *For the concrete* $\mathsf{RatUpFieldSource}_F$ *operation rows over* BHist*, assume the proof-indexed inverse, multiplication congruence, unit, associativity, product nonzero exclusion, and apartness-conversion rows used by Definition 45.296. For five histories* $a, b, c, d, e : \mathsf{BHist}$*, set*

$$P_5 := \mathsf{mul}(\mathsf{mul}(\mathsf{mul}(\mathsf{mul}(a, b), c), d), e).$$

Let $p_{abcde} : \mathsf{NonZero}_F(P_5)$ *be the product ledger witness, and let* R_5 *be the reversed inverse spine supplied by Definition 45.574. Then for every* $x, y : \mathsf{BHist}$*, multiplication by the same five-factor product is classifier-exact on both sides:*

$$\mathsf{mul}(x, P_5)\mathsf{hsamemul}(y, P_5) \iff x\mathsf{hsame}y$$

and

$$\mathsf{mul}(P_5, x)\mathsf{hsamemul}(P_5, y) \iff x\mathsf{hsame}y.$$

Proof. For the forward direction of the right-product clause, apply Definition 45.296 to the equation $\mathsf{mul}(x, P_5)\mathsf{hsamemul}(y, P_5)$ with shared target endpoint $\mathsf{mul}(y, P_5)$. It classifies x by the solved endpoint $\mathsf{mul}(\mathsf{mul}(y, P_5), R_5)$.

Apply the same theorem to the reflexive right-product equation for y at that same target endpoint. The two solved endpoints are identical, so symmetry and transitivity of hsame compare x and y.

For the reverse direction of the right-product clause, use multiplication congruence to transport $x\mathsf{hsame}y$ through $z \mapsto \mathsf{mul}(z, P_5)$. This gives $\mathsf{mul}(x, P_5)\mathsf{hsamemul}(y, P_5)$.

For the forward direction of the left-product clause, apply Definition 45.296 to the equation $\mathsf{mul}(P_5, x)\mathsf{hsamemul}(P_5, y)$ with shared target endpoint $\mathsf{mul}(P_5, y)$. The left equation solver classifies x by $\mathsf{mul}(R_5, \mathsf{mul}(P_5, y))$.

Apply the same left-product exactness clause to the reflexive equation for y at the same target endpoint. The solved endpoint is again identical, and symmetry plus transitivity of hsame yields $x\mathsf{hsame}y$.

For the reverse direction of the left-product clause, multiplication congruence transports $x\mathsf{hsame}y$ through $z \mapsto \mathsf{mul}(P_5, z)$, producing the displayed left classifier equality. □

Per-object template: traditional target finite five-factor product-map classifier exactness; BEDC source $\mathsf{RatUpFieldSource}_F$ over BHist; carrier BHist; classifier hsame; ledger p_{abcde} plus induced factor witnesses; core theorem Definition 45.635; exactness predicate the two displayed iff clauses; standard bridge deferred; status ProofTarget.

Theorem 45.636 (RatUp FieldUp selector-complete denominator row exhaustion)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, let* $E_s(h, k, \ell)$ *be the endpoint selector of Definition 45.606. Fix contexts* $L, R : \mathsf{BHist}$ *and assume* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*. Set* $x := \mu^u_D(\mu^u_D(h, k), \ell)$ *and* $y := \mu^u_D(h, \mu^u_D(k, \ell))$*. Then the selected denominator row of Definition 45.627 is exhausted by exactly the following four ordered endpoint rows:*

1. (x, x)*, with carrier rows* $C^u_D(x)$ *and* $C^u_D(x)$*, classifier row* $R^u_D(x, x)$*, and obstruction*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, x)) \to \bot;$$

2. (x, y)*, with carrier rows* $C^u_D(x)$ *and* $C^u_D(y)$*, classifier row* $R^u_D(x, y)$*, and obstruction*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x), \mathsf{append}(R, y)) \to \bot;$$

3. (y, x)*, with carrier rows* $C^u_D(y)$ *and* $C^u_D(x)$*, classifier row* $R^u_D(y, x)$*, and obstruction*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, y), \mathsf{append}(R, x)) \to \bot;$$

4. (y, y)*, with carrier rows* $C^u_D(y)$ *and* $C^u_D(y)$*, classifier row* $R^u_D(y, y)$*, and obstruction*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, y), \mathsf{append}(R, y)) \to \bot.$$

For every selector pair $s, t : \mathsf{BMark}$*, the row selected by* $(E_s(h, k, \ell), E_t(h, k, \ell))$ *is one of these four rows, and its two carrier rows,* R^u_D *classifier row, and singleton-empty contextual obstruction are the corresponding rows supplied by the selector-complete* $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *exit package. Conversely, the four displayed ordered endpoint rows are realized by the selector pairs* $(\mathsf{BMark.b0}, \mathsf{BMark.b0})$*,* $(\mathsf{BMark.b0}, \mathsf{BMark.b1})$*,* $(\mathsf{BMark.b1}, \mathsf{BMark.b0})$*, and* $(\mathsf{BMark.b1}, \mathsf{BMark.b1})$*.*

Proof. Apply Lemma 45.625 to the arbitrary selectors $s, t : \mathsf{BMark}$. It gives the four generated selector branches and identifies their selected endpoint pairs as (x, x), (x, y), (y, x), and (y, y).

Apply Theorem 45.628 to the concrete denominator tuple, the three carrier hypotheses, the support witness $\mathsf{ThreeSupp}^u_D(h, k, \ell)$, the selected pair s, t, and the contexts L, R. This supplies the two carrier rows, the R^u_D classifier row, and the singleton-empty contextual obstruction for the selected denominator row.

Apply Theorem 45.632 to the same data. The classifier row and the contextual obstruction are recorded as concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ exit-package rows over $\mathsf{RatUpFieldSource}_F$, so each of the four cases is an admissible row of the concrete exit package.

It remains to account for the converse realization. Specialize Lemma 45.625 to the four selector pairs $(\mathsf{BMark.b0}, \mathsf{BMark.b0})$, $(\mathsf{BMark.b0}, \mathsf{BMark.b1})$, $(\mathsf{BMark.b1}, \mathsf{BMark.b0})$, and $(\mathsf{BMark.b1}, \mathsf{BMark.b1})$. Unfolding Definition 45.606 gives respectively the endpoint rows (x, x), (x, y), (y, x), and (y, y), and the preceding well-formedness and exit-package applications attach the corresponding four rows displayed in the statement. □

Theorem 45.637 (RatUp FieldUp selector-complete row stability)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and two denominator triples* $h, k, \ell, h', k', \ell' : \mathsf{BHist}$*, assume* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(\ell)$*,* $C^u_D(h')$*,* $C^u_D(k')$*, and* $C^u_D(\ell')$*. Let* $E_s(h, k, \ell)$ *and* $E_s(h', k', \ell')$ *be the endpoint selector of Definition 45.606 on the two triples. If*

$$\mathsf{ThreeSupp}^u_D(h, k, \ell) \quad \textit{and} \quad \mathsf{ThreeSupp}^u_D(h', k', \ell')$$

hold, and if

$$R^u_D(h, h'), \quad R^u_D(k, k'), \quad R^u_D(\ell, \ell')$$

hold, then for every selector pair $s, t : \mathsf{BMark}$ *and all contexts* $L, R, L', R' : \mathsf{BHist}$ *with* $\mathsf{hsame}(L, L')$ *and* $\mathsf{hsame}(R, R')$*, the selected endpoints are denominator-classifier stable:*

$$R^u_D(E_s(h, k, \ell), E_s(h', k', \ell')) \quad \textit{and} \quad R^u_D(E_t(h, k, \ell), E_t(h', k', \ell')).$$

The primed selected row also supplies the same three-field row package as Definition 45.628:

1. $C^u_D(E_s(h', k', \ell'))$ *and* $C^u_D(E_t(h', k', \ell'))$*;*

2. $R^u_D(E_s(h', k', \ell'), E_t(h', k', \ell'))$;

3.
$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L', E_s(h', k', \ell')), \mathsf{append}(R', E_t(h', k', \ell'))) \to \bot.$$

Proof. Use the generated case split on $s : \mathsf{BMark}$. In the $\mathsf{BMark.b0}$ branch, the selected endpoint is the left-nested denominator $\mu^u_D(\mu^u_D(h, k), \ell)$, and the primed endpoint is $\mu^u_D(\mu^u_D(h', k'), \ell')$. Apply Definition 45.131 first to the pair h, h' and k, k', and then to the resulting left-nested pair and ℓ, ℓ'. This gives the displayed classifier relation for the s-selected endpoints.

In the $\mathsf{BMark.b1}$ branch, the selected endpoint is the right-nested denominator $\mu^u_D(h, \mu^u_D(k, \ell))$, and the primed endpoint is $\mu^u_D(h', \mu^u_D(k', \ell'))$. Apply the same concrete binary classifier congruence first to k, k' and ℓ, ℓ', and then to h, h' and the resulting right-nested pair. This gives the second generated endpoint comparison. Repeating the same two-branch argument for t gives the t-selected endpoint comparison.

Finally apply Definition 45.628 to the primed triple, its three carrier hypotheses, the support witness $\mathsf{ThreeSupp}^u_D(h', k', \ell')$, the selectors s, t, and the contexts L', R'. It supplies the primed selected endpoint carrier rows, the primed selected denominator-classifier row, and the displayed contextual singleton-classifier noncollapse. The assumptions $\mathsf{hsame}(L, L')$ and $\mathsf{hsame}(R, R')$ identify these contextual row slots with the same left and right context classes as the unprimed selected row. □

Theorem 45.638 (RatUp FieldUp selector-complete hierarchy exit witness)**.** *For the concrete source tuple* $\mathsf{RatUpFieldSource}_F$ *and the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, let* $h, k, \ell, h', k', \ell' : \mathsf{BHist}$ *carry the six denominator carrier hypotheses* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(\ell)$*,* $C^u_D(h')$*,* $C^u_D(k')$*, and* $C^u_D(\ell')$*. Let* $E_s(h, k, \ell)$ *be the endpoint selector of Definition 45.606, and set* $x := \mu^u_D(\mu^u_D(h, k), \ell)$ *and* $y := \mu^u_D(h, \mu^u_D(k, \ell))$*. If*

$$\mathsf{ThreeSupp}^u_D(h, k, \ell) \quad \textit{and} \quad \mathsf{ThreeSupp}^u_D(h', k', \ell')$$

hold, and if

$$R^u_D(h, h'), \quad R^u_D(k, k'), \quad R^u_D(\ell, \ell')$$

hold, then the concrete $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ *paper certificate contains the selector-complete denominator row family as a stable concrete component:*

1. *the algebra-hierarchy exit package over* $\mathsf{RatUpFieldSource}_F$*;*
2. *the selector-complete exit package for every* $s, t : \mathsf{BMark}$ *and* $L, R : \mathsf{BHist}$*;*
3. *the strict selector exit package for the same selector and context data;*
4. *the four ordered endpoint rows* (x, x)*,* (x, y)*,* (y, x)*, and* (y, y)*, each with its two* C^u_D *carrier rows, its* R^u_D *classifier row, and its singleton-empty contextual obstruction;*
5. *the row-stability transport for every* $s, t : \mathsf{BMark}$ *and* $L, R, L', R' : \mathsf{BHist}$ *with* $\mathsf{hsame}(L, L')$ *and* $\mathsf{hsame}(R, R')$*.*

Thus the concrete hierarchy exit witness records both the selector-complete row coverage and its transport under R^u_D*-related denominator triples and* hsame*-related contexts.*

Proof. First apply Definition 45.616. This fixes the ambient $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$ algebra-hierarchy package over $\mathsf{RatUpFieldSource}_F$ and supplies the paper-side certificate into which the denominator rows are placed.

Next apply Definition 45.632 and Definition 45.634 to the same concrete denominator tuple, carrier hypotheses, support witness, selectors, and contexts. These two sites supply the selector-indexed carrier rows, denominator classifier row, contextual singleton-empty obstruction, and strict endpoint witnesses.

Then apply Definition 45.636. It identifies the selector-indexed rows with the four ordered endpoint rows (x, x), (x, y), (y, x), and (y, y), and records the converse realization by the four selector pairs over BMark.

Finally apply Definition 45.637 to the two denominator triples, the R^u_D comparisons, and the hsame-related contexts. It transports selected endpoints and the primed row package through the same concrete denominator classifier, so the selector rows remain stable inside the hierarchy exit certificate. □

Per-object template: traditional target FieldUp(RatUp) selector-complete hierarchy exit certificate; BEDC source $\mathsf{RatUpFieldSource}_F$, BHist, BMark, and the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$; carrier C^u_D; classifier R^u_D plus singleton-empty obstruction; stability obligations selector exhaustion and row stability; ledger selected denominator endpoints and contexts; core theorem Definition 45.638; exactness predicate concrete selector-complete row coverage; standard bridge deferred; status $\mathsf{ProofTarget}$.

Per-object template: traditional target selector-complete FieldUp denominator row; BEDC source $\mathsf{RatUpFieldSource}_F$ over BHist; carrier C^u_D with selected endpoint coverage and $\mathsf{ThreeSupp}^u_D$; classifier R^u_D plus singleton-empty obstruction; stability obligations carrier coverage, denominator classifier coverage, and contextual noncollapse over the source-aligned denominator coordinate; ledger selected denominator endpoints; core theorem list Definition 45.632 and Definition 45.637; exactness predicate selected endpoint carrier coverage, denominator classifier coverage, and contextual noncollapse; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.639 (RatUp FieldUp contextual action composition support laws)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and the contextual action Γ of Definition 45.454, let $p, q, p', q', h, l, r, l', r' : \mathsf{BHist}$. Suppose $p\mathsf{hsamee}$, $q\mathsf{hsamee}$, $p'\mathsf{hsamee}$, and $q'\mathsf{hsamee}$, and suppose $C^u_D(h)$, $C^u_D(l)$, $C^u_D(r)$, $C^u_D(l')$, and $C^u_D(r')$. Then the nested contextual action is carried:*

$$C^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))).$$

It is denominator-classified by the single contextual action with collected append contexts:

$$R^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h)), \Gamma_{p',q',\mathsf{append}(l',l),\mathsf{append}(r,r')}(h)).$$

Its strict support is exactly the five visible support sites:

$$N^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))) \iff N^u_D(l') \vee N^u_D(l) \vee N^u_D(h) \vee N^u_D(r) \vee N^u_D(r').$$

Proof. Apply Definition 45.467 to the empty-endpoint nested actions. Its classifier and support clauses identify the two-layer action with the corresponding collected action once the inner and outer carried contexts are available.

The carrier inputs are supplied by denominator-unit carrier closure under append. First close l with h and then with r; transport the result along the two endpoint equalities $p\mathsf{hsamee}$ and $q\mathsf{hsamee}$ to get the carried inner action. Close l' with that carried inner action and then with r'; transport along $p'\mathsf{hsamee}$ and $q'\mathsf{hsamee}$ to get the carried nested action.

The same append-closure rows also carry $\mathsf{append}(l', l)$ and $\mathsf{append}(r, r')$, so the collected single action is a legitimate denominator action. Carrier transport along hsame keeps the concrete action endpoints inside C^u_D throughout the comparison.

For strict support, apply bilateral support exactness first to the inner action: its support is read as $N^u_D(l) \vee N^u_D(h) \vee N^u_D(r)$. Apply the same exactness theorem to the outer action and substitute the inner readback. The finite disjunction reassociates to $N^u_D(l') \vee N^u_D(l) \vee N^u_D(h) \vee N^u_D(r) \vee N^u_D(r')$, which is the displayed support law. □

Lean4 ✓ `BEDC.Derived.FieldUp.field rat denominator contextual action composition support laws`

Theorem 45.640 (RatUp FieldUp contextual action pair full transport package)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and the contextual action* Γ *of Definition 45.454, let* $p, q, p', q', h, l, r, s, t, l', r', s', t' : \mathsf{BHist}$*. Suppose* $p\mathsf{hsamee}$*,* $q\mathsf{hsamee}$*,* $p'\mathsf{hsamee}$*, and* $q'\mathsf{hsamee}$*; suppose* $C^u_D(h)$*; suppose that* (l, r)*,* (s, t)*,* (l', r')*, and* (s', t') *are carried denominator context pairs; and suppose the four component classifiers* $R^u_D(l, s)$*,* $R^u_D(r, t)$*,* $R^u_D(l', s')$*, and* $R^u_D(r', t')$*. Then the two nested contextual actions are denominator-classified and have equivalent strict support:*

$$R^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h)), \Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h))) \quad \wedge \quad (N^u_D(\Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))) \Longleftrightarrow N^u_D(\Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h)))).$$

Proof. The carried-pair hypotheses and the four component classifiers assemble the two context-pair classifier rows $\mathsf{PairClass}^u_D((l, r), (s, t))$ and $\mathsf{PairClass}^u_D((l', r'), (s', t'))$.

Apply Definition 45.496 with these two pair classifiers and the empty endpoint hypotheses. This gives the first conjunct, namely denominator classification of the two transported two-layer contextual actions.

Apply Definition 45.495 with the same carried pairs, pair classifiers, core carrier row, and empty endpoint hypotheses. This gives the second conjunct, namely equivalence of strict support for the same two nested actions.

The two cited conclusions have identical source data, so conjunction introduction gives the displayed full transport package. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitContextualAction pair support transport iff`

Theorem 45.641 (RatUp FieldUp contextual action nested pair action coherence)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and the contextual action* Γ *of Definition 45.454, let* $h, l_0, r_0, l_1, r_1, l_2, r_2 : \mathsf{BHist}$*. Suppose* $C^u_D(h)$*,* $C^u_D(l_0)$*,* $C^u_D(r_0)$*,* $C^u_D(l_1)$*,* $C^u_D(r_1)$*,* $C^u_D(l_2)$*, and* $C^u_D(r_2)$*. Then the threefold empty-endpoint action is carried:*

$$C^u_D(\Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h)))).$$

It is denominator-classified by the single collected action:

$$R^u_D(\Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h))), \Gamma_{\mathsf{e},\mathsf{e},\mathsf{append}(l_2,\mathsf{append}(l_1,l_0)),\mathsf{append}(\mathsf{append}(r_0,r_1),r_2)}(h)).$$

Proof. First apply Definition 45.639 to the inner two empty-endpoint actions. This carries the nested action through the first two denominator context pairs and classifies it against the collected pair $(\mathsf{append}(l_1, l_0), \mathsf{append}(r_0, r_1))$.

Append closure for C^u_D carries $\mathsf{append}(l_1, l_0)$ and $\mathsf{append}(r_0, r_1)$. Apply the same two-layer composition support law again, now with the outer pair (l_2, r_2) and the collected inner pair. This gives the carried target action and the classifier to $\Gamma_{\mathsf{e},\mathsf{e},\mathsf{append}(l_2,\mathsf{append}(l_1,l_0)),\mathsf{append}(\mathsf{append}(r_0,r_1),r_2)}(h)$.

Finally, transport the outer action along the inner classifier and compose the two classifier rows by transitivity of R^u_D. The carried row from the second application gives the displayed carrier statement, and the composed classifier is exactly the displayed denominator-classification statement. □

Lean4 ✓ BEDC.Derived.FieldUp.RatDenomUnitContextualAction nested pair action coherence

Theorem 45.642 (RatUp FieldUp contextual action three-pair reverse-order coherence)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and the contextual action* Γ *of Definition 45.454, let* $h, l_0, r_0, l_1, r_1, l_2, r_2 : \mathsf{BHist}$*. Suppose* $C^u_D(h)$*,* $C^u_D(l_0)$*,* $C^u_D(r_0)$*,* $C^u_D(l_1)$*,* $C^u_D(r_1)$*,* $C^u_D(l_2)$*, and* $C^u_D(r_2)$*. Then the empty-endpoint contextual actions obtained by applying the three carried denominator context pairs in forward and reverse order are denominator-classified:*

$$R^u_D(\Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h))), \Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(h)))).$$

Their strict-support predicates are equivalent:

$$N^u_D(\Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h)))) \Longleftrightarrow N^u_D(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(h)))).$$

Proof. First move the carried pair (l_0, r_0) past (l_1, r_1) while the outer (l_2, r_2) action is fixed. Apply Definition 45.497 to the inner empty-endpoint pair, and use Definition 45.639 to supply the carried intermediate action needed by the outer context.

Next move (l_2, r_2) past (l_0, r_0) across the carried middle action. The same two-pair commutation theorem gives the classifier for the exposed pair swap, and the composition support laws keep the middle contextual action inside C^u_D. Classifier transitivity composes this row with the first one.

Finally move (l_1, r_1) past (l_2, r_2) under the outer (l_0, r_0) action. Another application of the empty-pair commutation theorem, followed by the same composition support laws, gives the third classifier row. Transitivity of R^u_D along the three displayed classifier rows yields the reverse-order classifier.

For strict support, apply Definition 45.498 along each of the three pair swaps just described. The composition support laws provide the carried intermediate actions at every stage, and support transport along the same classifier chain repacks the three local equivalences into the displayed strict-support equivalence. □

Per-object template: traditional target order-independent denominator context application inside $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source BHist, $\mathsf{RatDenomUnitCarrier}$, $\mathsf{RatDenomUnitClassifier}$, append, empty endpoints, and Γ; carrier/context choices $h, l_0, r_0, l_1, r_1, l_2, r_2$ with all seven histories in C^u_D; stability obligations classifier coherence and strict-support transport; ledger the three carried context pairs (l_0, r_0), (l_1, r_1), and (l_2, r_2) and their application order; core theorem list Definition 45.497, Definition 45.498, and Definition 45.639; exactness predicate the displayed classifier plus support iff; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.643 (RatUp FieldUp contextual action threefold pair support transport)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and the contextual action* Γ *of Definition 45.454, let* $h, l_0, r_0, l_1, r_1, l_2, r_2, s_0, t_0, s_1, t_1, s_2, t_2 : \mathsf{BHist}$*. Suppose* $C^u_D(h)$ *and suppose each of* $l_0, r_0, l_1, r_1, l_2, r_2, s_0, t_0, s_1, t_1, s$ *lies in* C^u_D*. Suppose also that the denominator context pairs are classified componentwise:* $R^u_D(l_i, s_i)$ *and* $R^u_D(r_i, t_i)$ *for* $i = 0, 1, 2$*. Let*

$$H_l := \Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h)))$$

and

$$H_s := \Gamma_{\mathsf{e},\mathsf{e},s_2,t_2}(\Gamma_{\mathsf{e},\mathsf{e},s_1,t_1}(\Gamma_{\mathsf{e},\mathsf{e},s_0,t_0}(h))).$$

Then strict support is invariant under replacing the three classified context pairs:

$$N^u_D(H_l) \Longleftrightarrow N^u_D(H_s).$$

Lean4 ✓ `BEDC.Derived.FieldUp.RatDenomUnitContextualAction threefold pair support transport`

Proof. Apply Definition 45.469 to H_l. Its strict-support row reads $N_D^u(H_l)$ as the seven-term disjunction with context supports $N_D^u(l_2)$, $N_D^u(l_1)$, $N_D^u(l_0)$, $N_D^u(r_0)$, $N_D^u(r_1)$, and $N_D^u(r_2)$ around the shared middle term $N_D^u(h)$.

Apply the same threefold normalization theorem to H_s. The second readback has the same shape, with the corresponding s_i and t_i support terms around the same middle term.

The three componentwise classified context pairs give three product-support transports. Use Definition 45.572 for the pairs (l_0, r_0) and (s_0, t_0), then for (l_1, r_1) and (s_1, t_1), and then for (l_2, r_2) and (s_2, t_2). Opening each product with Definition 45.571 identifies the six outer support alternatives on the two sides.

For the forward direction, read $N_D^u(H_l)$ through the first seven-term formula. Transport the selected context-support alternative through the corresponding classified pair, keep the shared $N_D^u(h)$ alternative fixed, and close the result through the second seven-term formula.

The reverse direction is symmetric. Read $N_D^u(H_s)$ through the second formula, transport the selected context-support alternative back through the same three classified pairs, keep the shared middle alternative fixed, and repack through the first seven-term formula. □

Theorem 45.644 (RatUp FieldUp threefold pair transported noncollapse package)**.** *For the concrete denominator tuple $(C_D^u, R_D^u, \mu_D^u, e_D^u, N_D^u)$ and the contextual action Γ of Definition 45.454, let $h, l_0, r_0, l_1, r_1, l_2, r_2, s_0, t_0, s_1, t_1, s_2, t_2 : \mathsf{BHist}$. Suppose $C_D^u(h)$, suppose each of $l_0, l_1, l_2, s_0, s_1, s_2$ lies in C_D^u, and suppose each of $r_0, r_1, r_2, t_0, t_1, t_2$ lies in C_D^u. Suppose also that $R_D^u(l_i, s_i)$ and $R_D^u(r_i, t_i)$ hold for $i = 0, 1, 2$. Let*

$$H_l := \Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h)))$$

and

$$H_s := \Gamma_{\mathsf{e},\mathsf{e},s_2,t_2}(\Gamma_{\mathsf{e},\mathsf{e},s_1,t_1}(\Gamma_{\mathsf{e},\mathsf{e},s_0,t_0}(h))).$$

If $N_D^u(H_l)$ holds, then the transported endpoint H_s carries the following noncollapse package:

1. *$N_D^u(H_s)$;*
2. $\mathsf{RatHistoryCarrier}(H_s)$*;*
3. $\mathsf{fieldSingletonEmptyCarrier}(H_s) \to \bot$*;*
4. $H_s\mathsf{hsamee} \to \bot$*;*
5. *for every $r : \mathsf{BHist}$, both contextual carrier exclusions $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, H_s)) \to \bot$ and $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(H_s, r)) \to \bot$;*
6. *for every $r : \mathsf{BHist}$, both inverse-domain witnesses $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, H_s))$ and $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(H_s, r))$;*
7. *for all $L, R : \mathsf{BHist}$, the contextual singleton-classifier exclusion*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, H_s), \mathsf{append}(R, H_s)) \to \bot.$$

Proof. First apply Definition 45.643 to the displayed context data. The forward direction sends the assumed $N_D^u(H_l)$ witness to $N_D^u(H_s)$.

Read the denominator tuple row from Definition 45.438. There $N_D^u(z) = \mathsf{RatHistoryCarrier}(z)$ for every denominator history z, so the transported support witness gives $\mathsf{RatHistoryCarrier}(H_s)$.

The direct empty boundary follows from Definition 37.18. Any comparison $H_s$hsamee contradicts the recovered Rat carrier witness. A direct witness of $\mathsf{fieldSingletonEmptyCarrier}(H_s)$ unfolds to that same empty comparison, so it is rejected by the same boundary.

Fix an arbitrary context history $r : \mathsf{BHist}$. Apply Definition 45.101 with context r and Rat carrier endpoint H_s to reject $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, H_s))$. Apply Definition 45.102 with the same two histories in the opposite append order to reject $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(H_s, r))$.

Unfold $\mathsf{fieldSingletonEmptyNonZero}$ for the right-append endpoint as rejection of the singleton classifier against e. Any such classifier witness contains the source-carrier component $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{app}$ contradicting the right-append rejection. The left-append inverse-domain witness is identical, using the source-carrier component $\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(H_s, r))$.

Finally package $\mathsf{RatHistoryClassifier}(H_s, H_s)$ from the recovered Rat carrier witness on both sides and reflexivity of hsame. For arbitrary $L, R : \mathsf{BHist}$, apply Definition 45.104. It rejects the displayed singleton classifier on the two contextual copies of H_s. □

Per-object template: traditional target transported threefold denominator noncollapse for $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source BHist, Γ, C^u_D, R^u_D, and N^u_D; carrier transported endpoint H_s; classifier R^u_D plus hsame boundary rows; ledger the three classified context pairs $(l_0, r_0) \mapsto (s_0, t_0)$, $(l_1, r_1) \mapsto (s_1, t_1)$, and $(l_2, r_2) \mapsto (s_2, t_2)$; core theorem Definition 45.644; exactness predicate endpoint strict support, Rat carrier readback, singleton-empty exclusion, contextual append exclusions, inverse-domain witnesses, and contextual singleton-classifier obstruction; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.645 (RatUp FieldUp four context-pair adjacent-swap closure)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and the contextual action Γ of Definition 45.454, let $h, l_0, r_0, l_1, r_1, l_2, r_2, l_3, r_3 : \mathsf{BHist}$. Suppose $C^u_D(h)$ and suppose that (l_0, r_0), (l_1, r_1), (l_2, r_2), and (l_3, r_3) are carried denominator context pairs. Let*

$$H_{0123} := \Gamma_{\mathsf{e},\mathsf{e},l_3,r_3}(\Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h)))).$$

Let

$$H_{0213} := \Gamma_{\mathsf{e},\mathsf{e},l_3,r_3}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h)))).$$

Then the middle-swap histories are denominator-classified:

$$R^u_D(H_{0123}, H_{0213}).$$

Their strict-support readbacks agree:

$$N^u_D(H_{0123}) \Longleftrightarrow N^u_D(H_{0213}).$$

Proof. First carry the action of (l_0, r_0) on h. Apply Definition 45.639 with empty endpoints and the carried pair data to keep $\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h)$ inside C^u_D.

Next apply Definition 45.486 over that carried base, using (l_1, r_1) and (l_2, r_2) as the adjacent pair to be exchanged and (l_3, r_3) as the common outer pair. This gives the displayed classifier between H_{0123} and H_{0213}.

The contextual action pair transport rows carry the same classifier through the common outer context and preserve the strict-support predicate on transported denominator histories. Applying the support part of the adjacent-swap row, then reading it through the common outer transport, gives the displayed support equivalence. □

Per-object template: traditional target four-context denominator action coherence for $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source BHist, C^u_D, R^u_D, μ^u_D, e, and Γ; carrier carried context pairs; classifier R^u_D; stability obligations carrier closure plus adjacent-swap transport; ledger the four carried pairs and acted denominator history; core theorem list Definition 45.642, Definition 45.486, and Definition 45.639; exactness predicate the displayed classifier and support iff; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.646 (RatUp FieldUp four context-pair adjacent-swap coverage)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and the contextual action Γ of Definition 45.454, let $h, l_0, r_0, l_1, r_1, l_2, r_2, l_3, r_3 : \mathsf{BHist}$. Suppose $C^u_D(h)$ and suppose that (l_0, r_0), (l_1, r_1), (l_2, r_2), and (l_3, r_3) are carried denominator context pairs. Let*

$$H_{0123} := \Gamma_{\mathsf{e},\mathsf{e},l_3,r_3}(\Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h)))).$$

Let

$$H_{1023} := \Gamma_{\mathsf{e},\mathsf{e},l_3,r_3}(\Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(h)))).$$

Let

$$H_{0213} := \Gamma_{\mathsf{e},\mathsf{e},l_3,r_3}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h)))).$$

Let

$$H_{0132} := \Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_3,r_3}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h)))).$$

Then the three adjacent-generator rows from H_{0123} are classified:

$$R^u_D(H_{0123}, H_{1023}) \wedge R^u_D(H_{0123}, H_{0213}) \wedge R^u_D(H_{0123}, H_{0132}).$$

The corresponding strict-support readbacks agree:

$$N^u_D(H_{0123}) \Longleftrightarrow N^u_D(H_{1023}).$$

$$N^u_D(H_{0123}) \Longleftrightarrow N^u_D(H_{0213}).$$

$$N^u_D(H_{0123}) \Longleftrightarrow N^u_D(H_{0132}).$$

Proof. For the first adjacent generator, apply Definition 45.486 to the carried pairs (l_0, r_0), (l_1, r_1), and (l_2, r_2) over h. Then carry the result through the common outer context (l_3, r_3) using the contextual action pair transport classifier row Definition 45.500. The carrier premises needed for the outer action come from Definition 45.639.

For the middle adjacent generator, use Definition 45.645. It is exactly the displayed comparison between H_{0123} and H_{0213} under the same four carried context pairs.

For the last adjacent generator, first apply Definition 45.639 to carry the common two-step base $\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h))$. Then apply Definition 45.497 to the two outer empty-endpoint actions (l_2, r_2) and (l_3, r_3). This gives the classifier row between H_{0123} and H_{0132}.

The strict-support rows are obtained in parallel. For the first and middle generators, read the support part of the adjacent-swap row through the same contextual action pair transport support row Definition 45.499. For the last generator, apply Definition 45.498 over the carried two-step base. These three applications give the displayed strict-support equivalences. □

Per-object template: traditional target finite adjacent-generator coverage for the concrete FieldUp denominator action; BEDC source BHist, C^u_D, R^u_D, N^u_D, e, and Γ; carrier the four carried context pairs; classifier R^u_D; stability adjacent-swap classifier transport and strict-support transport; ledger the four carried pairs and selected adjacent generator; exactness the displayed three-row coverage; status $\mathsf{ProofTarget}$.

Theorem 45.647 (RatUp FieldUp four context-pair full reverse-order coherence)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and the contextual action* Γ *of Definition 45.454, let* $h, l_0, r_0, l_1, r_1, l_2, r_2, l_3, r_3 : \mathsf{BHist}$*. Suppose* $C^u_D(h)$ *and suppose that* (l_0, r_0)*,* (l_1, r_1)*,* (l_2, r_2)*, and* (l_3, r_3) *are carried denominator context pairs. Let*

$$H_{0123} := \Gamma_{\mathsf{e},\mathsf{e},l_3,r_3}(\Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(h)))).$$

Let

$$H_{3210} := \Gamma_{\mathsf{e},\mathsf{e},l_0,r_0}(\Gamma_{\mathsf{e},\mathsf{e},l_1,r_1}(\Gamma_{\mathsf{e},\mathsf{e},l_2,r_2}(\Gamma_{\mathsf{e},\mathsf{e},l_3,r_3}(h)))).$$

Then the forward and reverse four-context histories are denominator-classified:

$$R^u_D(H_{0123}, H_{3210}).$$

Their strict-support readbacks agree:

$$N^u_D(H_{0123}) \Longleftrightarrow N^u_D(H_{3210}).$$

Proof. Introduce the six intermediate four-context histories with application orders 1023, 1203, 1230, 2130, 2310, and 3210. Each is obtained from the preceding order by one adjacent exchange in the carried context-pair ledger.

For the classifier spine, instantiate Definition 45.646 at the current ordering for the six adjacent exchanges $0123 \to 1023 \to 1203 \to 1230 \to 2130 \to 2310 \to 3210$.

The carrier premises at every stage are supplied by Definition 45.639, since each current base is an iterated Γ-action on the same carried history and the same four carried denominator context pairs.

Chain the six displayed R^u_D rows by transitivity of the concrete denominator classifier. The resulting composite row has endpoints H_{0123} and H_{3210}, giving the first conclusion.

For strict support, read the support part of each adjacent-swap coverage row at the same six current orderings. Compose the six equivalences in sequence, with the inverse direction of each equivalence used exactly when the selected adjacent row is traversed opposite to its displayed orientation. The composite equivalence has endpoints $N^u_D(H_{0123})$ and $N^u_D(H_{3210})$. □

Per-object template: traditional target reverse-order independence for the concrete FieldUp denominator action; BEDC source BHist, C^u_D, R^u_D, N^u_D, e, and Γ; carrier the four carried context pairs; ledger the four context pairs plus the six selected adjacent generators; core theorem list Definition 45.646 and contextual composition support; exactness the displayed reverse-order classifier and strict-support equivalence; status $\mathsf{ProofTarget}$.

Theorem 45.648 (Field singleton carrier two-sided context semantic name certificate)**.** *For histories* $L, R : \mathsf{BHist}$*, if* L *and* R *lie in the field singleton carrier, then the two-sided contextual carrier has a semantic name certificate whose source, pattern, and ledger predicates are that same contextual carrier, and whose classifier compares the two contextualized endpoints by the field singleton classifier:*

$$\mathsf{FieldSingletonCarrier}(L) \Rightarrow \mathsf{FieldSingletonCarrier}(R) \Rightarrow \mathsf{SemanticNameCert}(h \mapsto \mathsf{FieldSingletonCarrier}(\mathsf{append}(L, \mathsf{app}$$

Proof. Let $C_{L,R}(h)$ denote the displayed two-sided contextual carrier. The inhabited point is $h = \mathsf{e}$: the carrier witnesses for L and R, together with $\mathsf{ehsamee}$, rebuild the nested empty append witness for $\mathsf{append}(L, \mathsf{append}(\mathsf{e}, R))$.

For reflexivity, symmetry, and transitivity of the classifier, unpack the displayed singleton classifier. Its endpoint carrier fields are precisely the instances of $C_{L,R}$ at the endpoints, and the comparison field is an hsame witness between the two contextualized histories. The three laws are therefore inherited from reflexivity, symmetry, and transitivity of hsame.

It remains to transport carrier membership along the classifier. Apply Definition 45.63 to identify $C_{L,R}(h)$ with the underlying singleton carrier of h, and use Definition 45.66 with the reflexive context comparisons for L and R to cancel the common two-sided context. The transported endpoint carrier repacks into the source, pattern, and ledger fields of the required SemanticNameCert. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldSingletonCarrier append context semanticNameCert`

Per-object template: traditional target contextual singleton boundary for $\mathsf{Field}^{\uparrow}$ exits; BEDC source BHist with hsame and append; carrier choice $h \mapsto \mathsf{FieldSingletonCarrier}(\mathsf{append}(L, \mathsf{append}(h, R)))$; classifier choice the displayed contextual FieldSingletonClassifier; stability obligations inhabitedness, hsame equivalence laws, and carrier transport under common two-sided context; ledger the same contextual carrier; core theorem list Definition 45.63 and Definition 45.66; exactness predicate contextual singleton-carrier equivalence; standard bridge deferred; status ProofTarget.

Theorem 45.649 (Field singleton two-sided context exactness)**.** *For histories L, R, h, k : BHist, if* $\mathsf{FieldSingletonCarrier}(L)$ *and* $\mathsf{FieldSingletonCarrier}(R)$*, then the two-sided singleton context is exact for both the carrier and the classifier:*

$$\mathsf{FieldSingletonCarrier}(\mathsf{append}(L, \mathsf{append}(h, R))) \Longleftrightarrow \mathsf{FieldSingletonCarrier}(h).$$

and

$$\mathsf{FieldSingletonClassifier}(\mathsf{append}(L, \mathsf{append}(h, R)), \mathsf{append}(L, \mathsf{append}(k, R))) \Longleftrightarrow \mathsf{FieldSingletonClassifier}(h, k).$$

Proof. Assume carrier witnesses for L and R. The carrier equivalence is exactly Definition 45.63 applied to those two witnesses and the middle history h.

For the classifier equivalence, apply Definition 45.66 with the left contexts both equal to L and the right contexts both equal to R. The required context comparisons are the reflexive witnesses $L\mathsf{hsame}L$ and $R\mathsf{hsame}R$, so the cancellation theorem identifies the displayed contextual classifier with $\mathsf{FieldSingletonClassifier}(h, k)$. □

Theorem 45.650 (Field four-factor inverse classifier exactness from apartness)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}$ *candidate over* BHist *satisfying the hypotheses of Definition 45.318, Definition 45.319, and Definition 45.205, let* $\mathsf{ApartZero}_F(h) := (h\mathsf{hsame}0 \to \bot)$*. For any* $a, x, b, c, a', x', b', c'$: BHist *equipped with factor conversion maps for each of the eight factor apart-zero witnesses, pair-product conversion maps for* $\mathsf{mul}(a, x)$*,* $\mathsf{mul}(b, c)$*,* $\mathsf{mul}(a', x')$*, and* $\mathsf{mul}(b', c')$*, and fourfold product conversion maps for*

$$u := \mathsf{mul}(\mathsf{mul}(a, x), \mathsf{mul}(b, c)) \quad \textit{and} \quad u' := \mathsf{mul}(\mathsf{mul}(a', x'), \mathsf{mul}(b', c')),$$

assume witnesses $q : \mathsf{ApartZero}_F(u)$ *and* $q' : \mathsf{ApartZero}_F(u')$*. Let the induced proof indices* $p_a, p_x, p_b, p_c, p_{ax}, p_{bc}, p_u$ *and* $p_{a'}, p_{x'}, p_{b'}, p_{c'}, p_{a'x'}, p_{b'c'}, p_{u'}$ *be obtained by Definition 45.318 and the displayed conversion maps. Then*

$$u\mathsf{hsame}u' \Longleftrightarrow \mathsf{mul}(\mathsf{mul}(\mathsf{inv}(c, p_c), \mathsf{inv}(b, p_b)), \mathsf{mul}(\mathsf{inv}(x, p_x), \mathsf{inv}(a, p_a)))\mathsf{hsamemul}(\mathsf{mul}(\mathsf{inv}(c', p_{c'}), \mathsf{inv}(b', p_{b'})), \mathsf{mul}(\mathsf{inv}$$

Proof. First build the witness ledger for both fourfold products. Apply Definition 45.318 to q and q'; the forward implications produce the eight factor witnesses, and the reverse binary steps inside the same exactness proof produce the two pair-product witnesses on each side. The factor, pair, and fourfold conversion maps turn these apart-zero witnesses into the proof indices displayed in the statement.

Next apply Definition 45.319 to u with q. This identifies $\mathsf{inv}(u, p_u)$ with the reversed spine $(c, b)(x, a)$ written in the conclusion. Apply the same theorem to u' with q' to identify $\mathsf{inv}(u', p_{u'})$ with the primed reversed spine.

For the forward implication, assume $u\mathsf{hsame}u'$. Use Definition 45.205 in its forward direction to obtain $\mathsf{inv}(u, p_u)\mathsf{hsameinv}(u', p_{u'})$. Transport this equality across the two reversal equalities by symmetry and transitivity of hsame, giving equality of the two reversed spines.

For the reverse implication, assume equality of the two reversed spines. Transport it back across the two reversal equalities to obtain $\mathsf{inv}(u, p_u)\mathsf{hsameinv}(u', p_{u'})$. The reverse direction of Definition 45.205 then yields $u\mathsf{hsame}u'$. □

Per-object certificate: Traditional target: finite fourfold product inverse classifier exactness. BEDC source: $\mathsf{Field}^{\uparrow}$ over BHist plus $\mathsf{Ring}^{\uparrow}$ zero-apartness rows. Carrier choice: BHist. Classifier choice: hsame. Input ledger: the eight factor witnesses. Product ledger: the two pair-product witnesses and two fourfold product witnesses. Core theorem: Definition 45.650. Dependency chain: four-factor apartness exactness, four-factor inverse reversal, and inverse classifier exactness. Standard bridge: deferred. Status: $\mathsf{ProofTarget}$.

Theorem 45.651 (RatUp FieldUp canonical phase-exit proof target)**.** *For* $\mathsf{RatUpFieldSource}_F$ *and Definition 45.617, the canonical phase-exit target is the single* BHist*-anchored certificate whose carrier is* $\mathsf{RatHistoryCarrier}$*, whose classifier is* $\mathsf{RatHistoryClassifier}$*, whose denominator tuple is* $(\mathsf{RatDenomUnitCarrier}, \mathsf{RatDenomUnitClassifier}, \mathsf{append}, \mathsf{e}, \mathsf{RatHistoryCarrier})$*, and whose contextual action is* Γ*.*

Its operation rows are exactly the rows covered by Definition 45.502, Definition 45.615, Definition 45.616, and Definition 45.618. Therefore the canonical phase-exit proof target is not a schematic algebra interface, but the concrete certificate object carried by the displayed RatUp history source.

Proof. Unpack the concrete source tuple $\mathsf{RatUpFieldSource}_F$ and Definition 45.617. The carrier, classifier, denominator tuple, and contextual action are the displayed BHist rows, so the target has one concrete source anchor.

Apply Definition 45.502 to identify the source, carrier, classifier, denominator, contextual-action, context-pair, and affine coordinates. Apply Definition 45.615 to cover the operation rows, including denominator histories, context pairs, affine witnesses, inverse and nonzero witnesses, product exactness, and selector endpoint rows.

Apply Definition 45.616 to package those rows as the Phase Algebra Hierarchy paper-certificate object. Finally apply Definition 45.618 to identify this package with Definition 45.617. The formal target therefore belongs naturally to the namespace `BEDC.Derived.FieldUp`. □

Per-object template: traditional target constructive $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ phase exit; BEDC source BHist with $\mathsf{Rat}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, denominator, contextual-action, context-pair, and affine rows; carrier $\mathsf{RatHistoryCarrier}$; classifier $\mathsf{RatHistoryClassifier}$; stability and exactness rows from Definition 45.502, Definition 45.615, Definition 45.616, and Definition 44.29, and Definition 45.618; ledger $\mathsf{CommRing}^{\uparrow}$ base coordinate, denominator histories, context pairs, affine witnesses, inverse/nonzero witnesses, and selector endpoint rows; status $\mathsf{ProofTarget}$.

Definition 45.652 (Canonical RatUp FieldUp exit row predicate)**.** *For a* BHist *certificate row* R *over* $\mathsf{RatUpFieldSource}_F$*, the predicate* $\mathsf{CanFieldExitRow}(R)$ *holds exactly when* R *belongs to the finite disjunction of concrete rows exported by the displayed* $\mathsf{RatUpFieldSource}_F$ *object:*

1. *one of the source, carrier, classifier, denominator, contextual-action, context-pair, affine, ledger, or exactness rows identified by Definition 45.502;*
2. *one of the carrier and classifier anchors,* $\mathsf{CommRing}^{\uparrow}$ *base rows, denominator multiplication and unit rows, contextual and context-pair rows, affine rows, inverse and nonzero rows, product exactness rows, singleton noncollapse rows, or selector endpoint rows exhausted by Definition 45.615;*
3. *one of the ten-field certificate, one-sided multiplication cancellation, two-sided product classifier and nonzero transport, five-factor ledger, cross-endpoint singleton-classifier, or bracketing-complete classifier rows packaged by Definition 45.616;*
4. *one of the source, carrier, classifier, stability, ledger, core theorem, exactness, bridge-slot, status, or completion-identification rows of Definition 45.617 as certified by Definition 45.618.*

Theorem 45.653 (RatUp FieldUp canonical exit row exactness)**.** *For* $\mathsf{RatUpFieldSource}_F$ *and Definition 45.617, the canonical* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *phase-exit object of Definition 45.651 satisfies exact row coverage, row soundness, and row completeness for Definition 45.652.*

1. *Row coverage: every row of the canonical phase-exit object satisfies* $\mathsf{CanFieldExitRow}$*.*
2. *Row soundness: every row satisfying* $\mathsf{CanFieldExitRow}$ *is a row over the fixed concrete source tuple* $\mathsf{RatUpFieldSource}_F$ *with carrier* $\mathsf{RatHistoryCarrier}$*, classifier* $\mathsf{RatHistoryClassifier}$*, denominator tuple* $(\mathsf{RatDenomUnitCarrier}, \mathsf{RatDenomUnitClassifier}, \mathsf{append}, \mathsf{e}, \mathsf{RatHistoryCarrier})$*, and contextual action* Γ*.*
3. *Row completeness: no row belongs to the canonical phase-exit object unless it satisfies* $\mathsf{CanFieldExitRow}$*.*

Proof. For row coverage, apply Definition 45.502 to fix the source, carrier, classifier, denominator, contextual-action, context-pair, and affine coordinates. Then apply Definition 45.615 to cover the operation inventory: denominator histories, context pairs, affine witnesses, inverse and nonzero witnesses, product exactness, singleton noncollapse, and selector endpoint rows.

For row soundness, project each disjunct in Definition 45.652 back through Definition 45.651. Each case has the same displayed source tuple, the same BHist carrier, the same classifier, the same denominator tuple, and the same contextual action Γ, so the predicate contains no schematic operation row.

For row completeness, apply Definition 45.616 to assemble the covered rows as the Phase Algebra Hierarchy paper certificate. Then use Definition 45.618 to identify that certificate with Definition 45.617. This identification leaves no phase-exit row outside $\mathsf{CanFieldExitRow}$. □

Theorem 45.654 (RatUp FieldUp canonical exit singleton context boundary)**.** *For Definition 45.617, the source tuple* $\mathsf{RatUpFieldSource}_F$*, and histories* $L, R, h, k : \mathsf{BHist}$ *with* $\mathsf{FieldSingletonCarrier}(L)$ *and* $\mathsf{FieldSingletonCarrier}(R)$*, the same canonical* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit certificate includes the following singleton-context boundary rows over* BHist*.*

1. *The contextual carrier has the semantic certificate*

$$\mathsf{SemanticNameCert}(h \mapsto \mathsf{FieldSingletonCarrier}(\mathsf{append}(L, \mathsf{append}(h, R))))(h \mapsto \mathsf{FieldSingletonCarrier}(\mathsf{append}(L, \mathsf{ap}$$

2. *The contextual carrier is exact:*

$$\mathsf{FieldSingletonCarrier}(\mathsf{append}(L, \mathsf{append}(h, R))) \iff \mathsf{FieldSingletonCarrier}(h).$$

3. *The contextual classifier is exact:*

$$\mathsf{FieldSingletonClassifier}(\mathsf{append}(L, \mathsf{append}(h, R)), \mathsf{append}(L, \mathsf{append}(k, R))) \iff \mathsf{FieldSingletonClassifier}(h, k).$$

Proof. Apply Definition 45.651 to fix Definition 45.617 as the concrete BHist-anchored $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object over $\mathsf{RatUpFieldSource}_F$. This identifies the singleton-context boundary as a row of the same canonical certificate, not as a separate schematic parameter.

For the semantic certificate row, apply Definition 45.648 to the two carrier witnesses for L and R. Its displayed source, pattern, ledger, and classifier are exactly the contextual $\mathsf{FieldSingletonCarrier}$ and $\mathsf{FieldSingletonClassifier}$ rows shown above.

For the two exactness rows, apply Definition 45.649 to the same witnesses and the histories h and k. The carrier projection gives the displayed equivalence for h, and the classifier projection gives the displayed equivalence for the pair (h, k).

Thus the canonical exit consumes concrete BHist, append, $\mathsf{FieldSingletonCarrier}$, and $\mathsf{FieldSingletonClassifier}$ rows from the FieldUp singleton boundary, rather than abstract operator fields. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup canonical exit singleton context boundary`

Per-object template: traditional target singleton-context boundary inside $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source BHist with $\mathsf{RatUpFieldSource}_F$, append, $\mathsf{FieldSingletonCarrier}$, and $\mathsf{FieldSingletonClassifier}$; carrier $h \mapsto \mathsf{FieldSingletonCarrier}(\mathsf{append}(L, \mathsf{append}(h, R)))$; classifier $(h, k) \mapsto \mathsf{FieldSingletonClassifier}(\mathsf{append}(L, \mathsf{app}$ stability obligations contextual semantic certificate plus exact carrier and classifier cancellation; ledger singleton context wrappers; core theorem list Definition 45.651, Definition 45.648, and Definition 45.649; exactness predicate the displayed carrier and classifier equivalences; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.655 (RatUp FieldUp reduct-context exit closure)**.** *For Definition 45.617 and the fixed source tuple* $\mathsf{RatUpFieldSource}_F$*, the rows supplied by Definition 45.659 and the singleton-context boundary rows of Definition 45.654 are covered by* $\mathsf{CanFieldExitRow}$*. Concretely, for histories* $L, R, h, k : \mathsf{BHist}$ *with* $\mathsf{FieldSingletonCarrier}(L)$ *and* $\mathsf{FieldSingletonCarrier}(R)$*, after the singleton boundary is wrapped by the carried contexts* L *and* R*, its* $\mathsf{Monoid}^{\uparrow}$*,* $\mathsf{Group}^{\uparrow}$*,* $\mathsf{AbGroup}^{\uparrow}$*,* $\mathsf{Ring}^{\uparrow}$*, and* $\mathsf{CommRing}^{\uparrow}$ *reduct projections remain rows over* $\mathsf{RatUpFieldSource}_F$ *with carrier* $\mathsf{RatHistoryCarrier}$*, classifier* $\mathsf{RatHistoryClassifier}$*, denominator tuple* $(\mathsf{RatDenomUnitCarrier}, \mathsf{RatDenomUnitClassifier}, \mathsf{append}, \mathsf{e}, \mathsf{RatHisto}$ *and contextual action* Γ*.*

Proof. Apply Definition 45.653. Its coverage clause places every row of the canonical phase-exit certificate inside $\mathsf{CanFieldExitRow}$, and its soundness clause fixes the source tuple, carrier, classifier, denominator tuple, and contextual action displayed in the statement.

Next apply Definition 45.659. The denominator continuation, singleton obstruction, zero/one boundary, and commutative-ring base coordinate are already rows consumed by Definition 45.617, so their algebra reduct projections do not introduce a separate schematic operation parameter.

Finally apply Definition 45.654 to the witnesses for L and R. Its semantic certificate, carrier exactness, and classifier exactness rows are rows of the same canonical exit object. Projecting these rows to the monoid, group, abelian-group, ring, and commutative-ring reduct views only forgets algebra fields; it preserves the $\mathsf{RatUpFieldSource}_F$ anchor and therefore keeps each projected contextual boundary row inside $\mathsf{CanFieldExitRow}$. □

Per-object template: traditional target $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ reduct-context row closure; BEDC source BHist with $\mathsf{RatUpFieldSource}_F$, RatHistoryCarrier, RatHistoryClassifier, (RatDenomUnitCarrier, RatDenomUnitClassifie and Γ; carrier the canonical Rat history carrier together with the contextual singleton carrier rows; classifier the Rat history classifier together with the contextual singleton classifier rows; stability obligations algebra reduct compatibility, canonical exit row exactness, and singleton-context boundary closure; ledger the monoid, group, abelian-group, ring, and commutative-ring reduct projections of the contextual boundary rows; core theorem Definition 45.655; exactness predicate CanFieldExitRow; standard bridge deferred; status ProofTarget.

Theorem 45.656 (RatUp FieldUp canonical exit contextual action row coverage)**.** *For Definition 45.617, the fixed source tuple* $\mathsf{RatUpFieldSource}_F$*, the denominator tuple* (RatDenomUnitCarrier, RatDenomUnitC *and the contextual action* Γ*, the contextual-action rows supplied by Definition 45.639, Definition 45.640, Definition 45.641, Definition 45.642, Definition 45.643, Definition 45.644, and Definition 45.645 satisfy* CanFieldExitRow*. Each such row remains a row over the same concrete* BHist *source, carrier* RatHistoryCarrier*, classifier* RatHistoryClassifier*, displayed denominator tuple, and contextual action* Γ*.*

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup canonical exit contextual action row coverage`

Proof. Apply Definition 45.653. Its coverage clause places every row of the canonical phase-exit object inside CanFieldExitRow, and its soundness clause fixes the concrete $\mathsf{RatUpFieldSource}_F$ source tuple, the BHist carrier, the classifier, the denominator tuple, and Γ.

The composition and pair-transport rows are concrete rows of this object. Apply Definition 45.639 to identify the carried nested action, its denominator classifier, and its strict-support readback. Apply Definition 45.640 to identify the two-pair classifier transport and the strict-support equivalence.

The finite-order coherence rows use the same concrete denominator endpoints. Apply Definition 45.641 for the collected threefold action, and apply Definition 45.642 for the reverse-order classifier and support transport. These two rows mention only BHist histories, C^u_D, R^u_D, append, e, and Γ.

The support and noncollapse rows are anchored by the same source data. Apply Definition 45.643 to identify support under three classified context pairs, and apply Definition 45.644 to recover the transported Rat carrier, singleton-empty exclusions, inverse-domain witnesses, and contextual singleton-classifier obstruction.

Finally apply Definition 45.645. Its adjacent-swap row uses the same carried denominator context pairs and the same contextual action. The soundness clause from Definition 45.653 therefore keeps every contextual-action row anchored to $\mathsf{RatUpFieldSource}_F$, rather than to an abstract operation parameter. □

Per-object template: traditional target contextual-action row coverage inside $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source BHist, Γ, C^u_D, R^u_D, N^u_D, and append; carrier/context choices the carried denominator endpoints and context pairs in the cited rows; classifier R^u_D; stability obligations contextual composition, pair transport, threefold support transport, noncollapse, and adjacent-swap closure; ledger the contextual-action row family; core theorem Definition 45.656; exactness predicate CanFieldExitRow; standard bridge deferred; status ProofTarget.

Theorem 45.657 (RatUp FieldUp canonical exit affine row coverage)**.** *For Definition 45.617 and the fixed source tuple* $\mathsf{RatUpFieldSource}_F$*, the affine rows supplied by Definition 45.561, Definition 45.563, Definition 45.281, and Definition 45.665 satisfy* CanFieldExitRow*. Each such row remains a row over the same concrete* BHist *source, carrier* RatHistoryCarrier*, classifier* RatHistoryClassifier*,*

denominator tuple (RatDenomUnitCarrier, RatDenomUnitClassifier, append, e, RatHistoryCarrier)*, and contextual action* Γ.

Proof. Apply Definition 45.653. Its coverage clause places every row of the canonical phase-exit object inside CanFieldExitRow, and its soundness clause fixes the concrete $\mathsf{RatUpFieldSource}_F$ source tuple, BHist source sort, carrier, classifier, denominator tuple, and contextual action Γ.

The affine package rows are concrete rows of this same object. Apply Definition 45.561 for the affine group row and apply Definition 45.563 for the threefold composition row. These rows use the displayed Rat history carrier and classifier, so the exactness predicate does not range over an abstract affine operation source.

The identity and inverse rows keep the affine family attached to the same exit object. Apply Definition 45.281 to identify the identity classifier row, and apply Definition 45.665 to identify inverse descent and uniqueness over the canonical Rat denominator tuple. The soundness clause above then keeps all cited affine rows over $\mathsf{RatUpFieldSource}_F$, RatHistoryCarrier, RatHistoryClassifier, the displayed denominator tuple, and Γ. □

Per-object template: traditional target affine row coverage inside $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source BHist with $\mathsf{RatUpFieldSource}_F$, the displayed denominator tuple, and Γ; carrier RatHistoryCarrier; classifier RatHistoryClassifier; stability obligations canonical exit row exactness, affine group closure, threefold affine composition, identity classification, and inverse descent with uniqueness; ledger the affine automorphism rows cited by the theorem; core theorem Definition 45.657; exactness predicate CanFieldExitRow; standard bridge deferred; status ProofTarget.

Theorem 45.658 (RatUp FieldUp canonical apart-zero context certificate row)**.** *For Definition 45.617, the source tuple* $\mathsf{RatUpFieldSource}_F$*, histories* $L, R, h : \mathsf{BHist}$*, and a witness* $p : \mathsf{FieldApartZero}(L)$*, the canonical* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit certificate contains the concrete two-sided apart-zero context row*

$$\mathsf{SemanticNameCert}(h \mapsto \mathsf{FieldApartZero}(\mathsf{append}(L, \mathsf{append}(h, R))))(h \mapsto \mathsf{FieldApartZero}(\mathsf{append}(L, \mathsf{append}(h, R))))($$

Its source, pattern, and ledger policy are all the displayed contextual apart-zero predicate, and its classifier is hsame.

Proof. Apply Definition 45.651 to fix Definition 45.617 as the concrete BHist-anchored $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object over $\mathsf{RatUpFieldSource}_F$. This pins the row to the canonical exit certificate rather than to a schematic field interface.

Next apply Definition 45.270 to the histories L and R and the apart-zero witness p. Its source, pattern, ledger policy, and classifier are exactly the four displayed arguments of SemanticNameCert.

Combining the fixed canonical exit object with that semantic certificate gives row membership for the contextual apart-zero predicate inside the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit certificate. □

Per-object template: traditional target constructive apart-zero context stability inside $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source BHist, $\mathsf{RatUpFieldSource}_F$, append, and FieldApartZero; carrier $h \mapsto \mathsf{FieldApartZero}(\mathsf{append}(L, \mathsf{append}($ classifier hsame; ledger the hidden left and right contexts L and R; core theorem list Definition 45.651 and Definition 45.270; exactness predicate row membership in Definition 45.617; status ProofTarget.

Theorem 45.659 (RatUp FieldUp algebra reduct compatibility)**.** *For Definition 45.617, the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *certificate is compatible with the already licensed algebraic reducts over BEDC histories. Its denominator continuation product uses the same empty-unit and associativity data as*

the unary append $\mathsf{Monoid}^{\uparrow}$ *certificate; its singleton empty obstruction rows restrict to the concrete singleton* $\mathsf{Group}^{\uparrow}$ *and* $\mathsf{AbGroup}^{\uparrow}$ *certificates; its zero/one singleton boundary restricts to the singleton empty-history* $\mathsf{Ring}^{\uparrow}$ *laws; its zero/one singleton boundary together with multiplicative commutativity restricts to the singleton empty-history* $\mathsf{CommRing}^{\uparrow}$ *schema certificate of Theorem 44.29; and Theorem 45.618 consumes these reduct rows without introducing schematic operation parameters.*

Proof. Apply Theorem 40.25 to the denominator continuation product. The empty source, left and right unit laws, append associativity, and append congruence are exactly the rows used by the denominator carrier and classifier package.

Next apply Theorem 41.5 and Theorem 42.10. The singleton empty obstruction rows have carrier A_{e} and classifier ρ_{e}, so their group and abelian-group reducts are the corresponding singleton certificates.

For the zero/one boundary, apply Theorem 43.6. Its singleton empty-history ring tuple supplies the additive, multiplicative, zero, and one laws required by the boundary rows.

For the commutative-ring base coordinate, apply Theorem 44.29. Its carrier, classifier, constant-operation tuple, and multiplicative commutativity field supply the $\mathsf{CommRing}^{\uparrow}$ base coordinate named by Definition 45.587.

Finally apply Theorem 45.618. That theorem packages the displayed denominator, singleton, ring, and commutative-ring reduct rows into the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object, and its conclusion states that no schematic mul, add, or neg parameter is part of the certificate. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatUpFieldUp algebra reduct compatibility`

Theorem 45.660 (RatUp FieldUp apart-product inverse classifier exit row)**.** *For Definition 45.617, bind the rows of Definition 45.587 as follows: let* μ_F *be its concrete multiplication row, let* ι_F *be its inverse row over* $\mathsf{FieldApartZero}$*, and let* N_F *be the certified nonzero/apartness row carried by the same table. If* $a, b, c, d : \mathsf{BHist}$ *carry witnesses* $p_a : N_F(a)$*,* $p_b : N_F(b)$*,* $p_c : N_F(c)$*, and* $p_d : N_F(d)$*, and if the two products are apart from the empty history by hypotheses* $h_s : \mu_F(a, b)\mathsf{hsamee} \to \bot$ *and* $h_t : \mu_F(c, d)\mathsf{hsamee} \to \bot$*, then the concrete classifier row records*

$$\mu_F(a, b)\mathsf{hsame}\mu_F(c, d) \Longleftrightarrow \mu_F(\iota_F(b, p_b), \iota_F(a, p_a))\mathsf{hsame}\mu_F(\iota_F(d, p_d), \iota_F(c, p_c)).$$

This displayed equivalence is an internal operation-exhaustion row of the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object, with carrier* BHist *and classifier* hsame*.*

Proof. First invoke Definition 45.588. It binds the concrete carrier and classifier rows, the $\mathsf{CommRing}^{\uparrow}$ base rows, the inverse row over $\mathsf{FieldApartZero}$, and the nonzero row inside Definition 45.587. Thus μ_F, ι_F, and N_F are rows of the displayed table rather than free operation parameters.

Next invoke Definition 45.589. It locates product classifier exactness and nonzero transport inside the same concrete source tuple $\mathsf{RatUpFieldSource}_F$. The same package supplies the bridge from explicit product apartness to the nonzero row, so the hypotheses h_s and h_t may be consumed without presupposing separate product nonzero witnesses.

Next apply the checked theorem `BEDC.Derived.FieldUp.field_apart_product_inverse_classifier_exact` recorded in Definition 45.219. With the four certified factor witnesses and the two product-apartness hypotheses, the generic history-level theorem converts classifier equality of $\mu_F(a, b)$ and $\mu_F(c, d)$ into classifier equality of the reversed inverse products built from ι_F, and conversely.

Finally use Definition 45.615 together with Definition 45.618. These theorems record that the product, inverse, and nonzero rows are consumed by Definition 45.617, so the displayed classifier equivalence is part of the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object rather than an external schematic operation parameter. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatupFieldupInverseProductClassifierExitRow`

Per-object template: traditional target inverse-product exactness row for $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source $\mathsf{RatUpFieldSource}_F$ over BHist; carrier BHist; classifier hsame; ledger the four factor witnesses plus the two product-apartness witnesses; exactness predicate the displayed classifier equivalence; status $\mathsf{ProofTarget}$.

Per-object template: traditional target algebra-hierarchy reduct compatibility for $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source BHist with the concrete $\mathsf{RatUpFieldSource}_F$ rows; carrier rows $\mathsf{RatHistoryCarrier}$ and $\mathsf{RatDenomUnitCarrier}$; classifier rows $\mathsf{RatHistoryClassifier}$ and $\mathsf{RatDenomUnitClassifier}$; ledger the denominator continuation reduct, singleton empty obstruction reducts, and singleton zero/one ring and commutative-ring reducts, including the $\mathsf{CommRing}^{\uparrow}$ base coordinate; core theorem list Theorem 40.25, Theorem 41.5, Theorem 42.10, Theorem 43.6, Theorem 44.29, and Theorem 45.618; exactness predicate reduct-row coverage for Definition 45.617; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.661 (RatUp FieldUp affine automorphism action certificate)**.** *For Definition 45.617, the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object exports the affine automorphism action certificate on* BHist *required by downstream algebra. The action carrier is* AffAut_F*; its classifier is* $\equiv_{\mathrm{aff}}$*; its identity, composition, and inverse laws are those of Theorem 45.558; each affine fiber is singleton-classified by Theorem 45.540; and common affine factors cancel exactly by Theorem 45.566.*

Proof. First apply Theorem 45.618 and Theorem 45.659. These fix the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ operations and the reduct rows over BHist, so the action is attached to the same exit object rather than to a schematic field package.

Next apply Theorem 45.558 to the fixed operations. Its carrier AffAut_F and classifier $\equiv_{\mathrm{aff}}$ supply the identity, composition, and inverse fields of the affine action certificate.

Finally project Theorem 45.540 and Theorem 45.566. The first projection supplies singleton classification of every affine fiber, and the second supplies exact cancellation for common affine factors, which are the action exactness fields consumed downstream. □

Per-object template: traditional target affine group action over a field; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit rows over BHist; carrier AffAut_F; classifier $\equiv_{\mathrm{aff}}$; stability obligations group laws, fiber singleton exactness, and cancellation exactness; ledger nonzero coefficient witnesses, product witnesses, offsets, and inverse witnesses; core theorem Theorem 45.661; exactness predicate fiber and cancellation exactness for the action; standard bridge ordinary affine action; status $\mathsf{ProofTarget}$.

Theorem 45.662 (RatUp FieldUp canonical exit action and inverse package)**.** *For Definition 45.617, the canonical* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit target simultaneously exports the following rows as one concrete exit package.*

1. *The algebra-reduct compatibility rows of Definition 45.659.*
2. *The inverse-product classifier exactness row of Definition 45.660.*
3. *The affine automorphism action certificate of Definition 45.661.*

Thus downstream $\mathsf{Field}^{\uparrow}$ *consumers may cite this one canonical package for reduct rows, inverse-product exactness, and affine action support without reassembling the three certificate rows from their separate locations.*

Lean4 ✓ `BEDC.Derived.FieldUp.RatupFieldupCanonicalExitActionInversePackage`

Proof. First invoke Definition 45.651. This fixes Definition 45.617 as the concrete BHist-anchored source object with carrier RatHistoryCarrier, classifier RatHistoryClassifier, denominator data, and contextual action Γ.

Apply Definition 45.659 to the fixed source anchor. This supplies the denominator continuation reduct, singleton empty obstruction reducts, singleton zero/one ring rows, and commutative-ring base coordinate as fields of the same concrete exit object.

Next apply Definition 45.660. Its row is carried by the same BHist source and classifier hsame, so the inverse-product classifier exactness field is collected without changing the carrier or source tuple.

Finally apply Definition 45.661. Its affine carrier AffAut_F, classifier $\equiv_{\mathrm{aff}}$, group laws, fiber singleton exactness, and cancellation exactness become the action fields of the same exit object.

This is not a single-theorem variant of any one cited result. It composes three separately located exit rows into one canonical package whose fields are all anchored by Definition 45.617. □

Per-object template: traditional target canonical $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit action and inverse package; BEDC source $\mathsf{RatUpFieldSource}_F$ over BHist; carrier RatHistoryCarrier together with AffAut_F for the action row; classifier RatHistoryClassifier, hsame, and $\equiv_{\mathrm{aff}}$ on their displayed rows; stability obligations algebra-reduct compatibility, inverse-product classifier exactness, affine group laws, affine fiber singleton exactness, and affine cancellation exactness; ledger denominator continuation reducts, singleton obstruction reducts, zero/one boundary rows, commutative-ring base coordinate, certified nonzero factor witnesses, product witnesses, affine coefficients, offsets, and inverse witnesses; core theorem list Definition 45.651, Definition 45.659, Definition 45.660, and Definition 45.661; exactness predicate inverse-product classifier equivalence plus affine fiber and cancellation exactness; standard bridge ordinary field reducts with ordinary affine action; status ProofTarget.

Theorem 45.663 (RatUp FieldUp contextual pair transport full noncollapse invariance)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and the contextual action* Γ *of Definition 45.454, let*

$$x_L := \Gamma_{p',q',l',r'}(\Gamma_{p,q,l,r}(h))$$

and

$$x_R := \Gamma_{p',q',s',t'}(\Gamma_{p,q,s,t}(h)).$$

Suppose $p$hsamee*,* $q$hsamee*,* p'hsamee*, and* q'hsamee*; suppose* $C^u_D(h)$*; suppose the four denominator context comparisons* $R^u_D(l,s)$*,* $R^u_D(r,t)$*,* $R^u_D(l',s')$*, and* $R^u_D(r',t')$ *hold; and suppose* RatHistoryCarrier(x_L)*. Then the transported endpoint* x_R *has the following concrete noncollapse package:*

1. $R^u_D(x_L, x_R)$*;*
2. $C^u_D(x_R)$*;*
3. RatHistoryCarrier(x_R)*;*
4. fieldSingletonEmptyCarrier$(x_R) \to \bot$*;*
5. $x_R$hsamee $\to \bot$*;*
6. *for every* r : BHist*,* fieldSingletonEmptyCarrier(append$(r, x_R)) \to \bot$*;*
7. *for every* r : BHist*,* fieldSingletonEmptyCarrier(append$(x_R, r)) \to \bot$*;*
8. *for every* r : BHist*,* fieldSingletonEmptyNonZero(append(r, x_R))*;*

9. *for every* $r : \mathsf{BHist}$, $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(x_R, r))$;

10. *for all* $L, R : \mathsf{BHist}$,

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, x_R), \mathsf{append}(R, x_R)) \to \bot.$$

Proof. First apply Definition 45.500 to the four denominator classifier rows and the two nested contextual actions. This gives the transported denominator classifier $R^u_D(x_L, x_R)$.

Next apply Definition 45.499 to the same empty endpoints, carried source, and classifier rows. Transporting the assumed $\mathsf{RatHistoryCarrier}(x_L)$ witness gives $\mathsf{RatHistoryCarrier}(x_R)$, and the carrier component gives $C^u_D(x_R)$.

The endpoint noncollapse clauses come from Definition 45.520 with the same data. This supplies the singleton-empty rejection at x_R and the direct empty-history rejection $x_R\mathsf{hsamee} \to \bot$.

For contextual singleton-carrier rejection, apply Definition 45.516. For each context history r, it rejects both $\mathsf{append}(r, x_R)$ and $\mathsf{append}(x_R, r)$ as singleton-empty carriers.

Then apply Definition 45.521 to the same transported endpoint. It repacks the two contextual carrier rejections as the proof-indexed nonzero witnesses for both append orders.

Finally apply Definition 45.518. For all $L, R : \mathsf{BHist}$, this rules out a singleton-empty classifier between $\mathsf{append}(L, x_R)$ and $\mathsf{append}(R, x_R)$, completing the displayed package. □

Theorem 45.664 (RatUp FieldUp affine inverse uniqueness exit)**.** *For Definition 45.617, let* $T : \mathsf{AffAut}_F$ *be a certified affine automorphism in the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object. Let* $S : \mathsf{AffAut}_F$ *be the explicit affine inverse of* T *supplied by Theorem 45.555, and let* $U : \mathsf{AffAut}_F$ *be any certified affine automorphism whose left and right affine composites with* T *classify as the affine identity under* $\equiv_{\mathrm{aff}}$*:*

$$(U \circ_{\mathrm{aff}} T) \equiv_{\mathrm{aff}} I$$

and

$$(T \circ_{\mathrm{aff}} U) \equiv_{\mathrm{aff}} I.$$

Then U *is the same affine inverse as* S *under the concrete action classifier:*

$$U \equiv_{\mathrm{aff}} S.$$

Proof. First apply Theorem 45.618 to fix the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Apply Theorem 45.661 to attach the carrier AffAut_F, the affine composition $\circ_{\mathrm{aff}}$, the affine identity I, and the classifier $\equiv_{\mathrm{aff}}$ to that same object.

The explicit inverse package Theorem 45.555 supplies the displayed inverse witness S for T. The hypotheses supply the matching left and right inverse equations for U against the same T and under the same affine classifier.

Apply Theorem 45.559. Its conclusion is the group-classifier equality between the arbitrary inverse candidate U and the explicit inverse S. The action certificate identifies that group classifier with the displayed affine classifier, so the returned relation is exactly $U \equiv_{\mathrm{aff}} S$. □

Per-object template: traditional target affine inverse uniqueness over a field action; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit rows plus AffAut_F; carrier certified affine automorphism histories; classifier $\equiv_{\mathrm{aff}}$; stability obligations affine group certificate and inverse equations; ledger inverse witnesses and composite witnesses; core theorem Theorem 45.664; exactness predicate uniqueness of the affine inverse under the action classifier; standard bridge ordinary uniqueness of inverse in an affine automorphism group; status $\mathsf{ProofTarget}$.

Theorem 45.665 (RatUp FieldUp canonical affine inverse descent and uniqueness)**.** *For Definition 45.617, let $T, T' : \mathsf{AffAut}_F$ be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $S, S' : \mathsf{AffAut}_F$ be their explicit affine inverse witnesses supplied by Theorem 45.555. If the two input automorphisms have the same affine classifier,*

$$T \equiv_{\mathrm{aff}} T',$$

then their explicit inverse witnesses have the same affine classifier:

$$S \equiv_{\mathrm{aff}} S'.$$

Moreover, for any $U : \mathsf{AffAut}_F$, if

$$(U \circ_{\mathrm{aff}} T) \equiv_{\mathrm{aff}} I$$

and

$$(T \circ_{\mathrm{aff}} U) \equiv_{\mathrm{aff}} I,$$

then U is the explicit inverse witness for T under the same classifier:

$$U \equiv_{\mathrm{aff}} S.$$

Proof. First invoke Theorem 45.662. This fixes the concrete exit action carrier, the classifier $\equiv_{\mathrm{aff}}$, the identity I, the composition $\circ_{\mathrm{aff}}$, and the inverse package inside Definition 45.617.

For classifier descent, apply Theorem 45.552 to the explicit inverse formula for T and T'. The hypothesis $T \equiv_{\mathrm{aff}} T'$ is exactly the input classifier equality, so the returned relation is $S \equiv_{\mathrm{aff}} S'$.

For uniqueness of an arbitrary inverse candidate, keep the same action carrier and apply Theorem 45.664 to U with its two displayed composite witnesses. Its conclusion is precisely $U \equiv_{\mathrm{aff}} S$ under the concrete affine classifier. □

Per-object template: traditional target affine inverse operation in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit action; BEDC source $\mathsf{RatUpFieldSource}_F$ over BHist; carrier AffAut_F; classifier $\equiv_{\mathrm{aff}}$; stability obligations inverse classifier descent and two-sided inverse uniqueness; ledger affine coefficients, nonzero witnesses, explicit inverse witnesses, and composite witnesses; core theorem list Theorem 45.662, Theorem 45.552, and Theorem 45.664; exactness predicate inverse descent plus uniqueness under the action classifier; standard bridge ordinary affine inverse operation; status $\mathsf{ProofTarget}$.

Theorem 45.666 (RatUp FieldUp affine inverse determinacy exit)**.** *For Definition 45.617, let $T, U, V : \mathsf{AffAut}_F$ be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Suppose that both U and V have left and right affine composites with T classified as the affine identity under $\equiv_{\mathrm{aff}}$:*

$$(U \circ_{\mathrm{aff}} T) \equiv_{\mathrm{aff}} I$$

and

$$(T \circ_{\mathrm{aff}} U) \equiv_{\mathrm{aff}} I$$

and

$$(V \circ_{\mathrm{aff}} T) \equiv_{\mathrm{aff}} I$$

and

$$(T \circ_{\mathrm{aff}} V) \equiv_{\mathrm{aff}} I.$$

Then the two inverse candidates are equal under the concrete affine classifier:

$$U \equiv_{\mathrm{aff}} V.$$

Proof. First apply Theorem 45.661 to the concrete exit object. This supplies the carrier AffAut_F, the affine identity I, composition $\circ_{\mathrm{aff}}$, and the classifier $\equiv_{\mathrm{aff}}$ together with its symmetry and transitivity rules.

Take the explicit inverse S of T from Theorem 45.555. Apply Theorem 45.664 to the two composite witnesses for U. This gives

$$U \equiv_{\mathrm{aff}} S.$$

Apply the same theorem to the two composite witnesses for V. This gives

$$V \equiv_{\mathrm{aff}} S.$$

Use symmetry for the affine classifier to turn the second relation into $S \equiv_{\mathrm{aff}} V$. Transitivity of the same classifier then composes $U \equiv_{\mathrm{aff}} S$ with $S \equiv_{\mathrm{aff}} V$, yielding $U \equiv_{\mathrm{aff}} V$. □

Per-object template: traditional target inverse determinacy in the affine automorphism group; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit rows plus AffAut_F; carrier certified affine automorphisms; classifier $\equiv_{\mathrm{aff}}$; stability obligations affine classifier symmetry and transitivity; ledger two inverse-candidate composite witnesses; core theorem Theorem 45.666; exactness predicate uniqueness of two-sided inverse candidates; standard bridge ordinary inverse determinacy in a group action; status ProofTarget.

Theorem 45.667 (RatUp FieldUp canonical exit inverse determinacy package)**.** *Definition 45.617 exports, as one concrete* BHist*-anchored* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit package, the contextual pair transport full noncollapse invariance of Theorem 45.663, the affine inverse uniqueness row of Theorem 45.664, and the affine inverse determinacy row of Theorem 45.666.*

Proof. First fix the canonical exit object by applying Theorem 45.651 and Theorem 45.662. The first theorem identifies Definition 45.617 as the concrete machine-checkable exit object, and the second attaches the action and inverse rows to that same object.

Next project the contextual noncollapse row from Theorem 45.663. Project the affine inverse uniqueness row from Theorem 45.664. Project the affine inverse determinacy row from Theorem 45.666.

The three projected rows share the same BHist source, denominator contextual action, affine carrier, and classifier rows. Conjunction introduction therefore gives the advertised public package: contextual transport keeps the endpoint noncollapsed, uniqueness identifies any two-sided affine inverse with the explicit inverse, and determinacy identifies any two inverse candidates with each other. □

Per-object template: traditional target concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit inverse-determinacy package; BEDC source BHist, $\mathsf{RatUpFieldSource}_F$, denominator contextual actions, and AffAut_F; carrier RatHistoryCarrier plus certified affine automorphisms; classifier RatHistoryClassifier, hsame, and $\equiv_{\mathrm{aff}}$; stability obligations contextual transport, endpoint noncollapse, affine inverse uniqueness, and affine inverse determinacy; ledger transported context pairs and affine inverse witnesses; exactness predicate the displayed noncollapse package plus inverse-candidate classifier equality; standard bridge ordinary field action inverse determinacy; status ProofTarget.

Theorem 45.668 (RatUp FieldUp affine inverse compositional determinacy)**.** *For Definition 45.617, let* $T, U, V, W : \mathsf{AffAut}_F$ *be certified affine automorphisms in the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object. Suppose that* U *and* V *both satisfy the left and right inverse equations with* T *under* $\equiv_{\mathrm{aff}}$*:*

$$(U \circ_{\mathrm{aff}} T) \equiv_{\mathrm{aff}} I$$

and

$$(T \circ_{\mathrm{aff}} U) \equiv_{\mathrm{aff}} I$$

and

$$(V \circ_{\mathrm{aff}} T) \equiv_{\mathrm{aff}} I$$

and

$$(T \circ_{\mathrm{aff}} V) \equiv_{\mathrm{aff}} I.$$

Then inverse-candidate equality is stable under affine composition on either side:

$$(U \circ_{\mathrm{aff}} W) \equiv_{\mathrm{aff}} (V \circ_{\mathrm{aff}} W)$$

and

$$(W \circ_{\mathrm{aff}} U) \equiv_{\mathrm{aff}} (W \circ_{\mathrm{aff}} V).$$

Proof. First apply Definition 45.666 to the four inverse equations for U and V. This gives the determined inverse-candidate equality

$$U \equiv_{\mathrm{aff}} V.$$

Next apply Definition 45.661 to the same concrete exit object. The certificate exposes affine composition $\circ_{\mathrm{aff}}$, classifier reflexivity, and operation congruence for the displayed affine classifier.

For right composition by W, use operation congruence with $U \equiv_{\mathrm{aff}} V$ in the first coordinate and reflexivity $W \equiv_{\mathrm{aff}} W$ in the second coordinate. This yields $(U \circ_{\mathrm{aff}} W) \equiv_{\mathrm{aff}} (V \circ_{\mathrm{aff}} W)$.

For left composition by W, use reflexivity $W \equiv_{\mathrm{aff}} W$ in the first coordinate and $U \equiv_{\mathrm{aff}} V$ in the second coordinate. The same congruence row yields $(W \circ_{\mathrm{aff}} U) \equiv_{\mathrm{aff}} (W \circ_{\mathrm{aff}} V)$. □

Per-object template: traditional target inverse candidate descent through affine composition; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit rows plus AffAut_F; carrier certified affine automorphisms; classifier $\equiv_{\mathrm{aff}}$; stability affine inverse determinacy and affine composition congruence; ledger T, U, V, W and the four inverse equations; core theorem Theorem 45.668; exactness predicate compositional equality of determined inverse candidates; standard bridge ordinary group-action congruence; status ProofTarget.

Theorem 45.669 (RatUp FieldUp final certificate noncollapse action package)**.** *For Definition 45.617 and* $\mathsf{RatUpFieldSource}_F$*, the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit certificate contains one package whose rows are all anchored at the same concrete* BHist *source object. The package consists of:*

1. *the source anchor, carrier* RatHistoryCarrier*, classifier* RatHistoryClassifier*, denominator tuple, and contextual action from Theorem 45.651;*
2. *the algebra-reduct row, inverse-product classifier row, and affine-action rows from Theorem 45.662;*
3. *the transported contextual-pair noncollapse clauses from Theorem 45.663;*
4. *the affine inverse uniqueness row from Theorem 45.664.*

Thus the Phase Algebra Hierarchy exit criterion may consume this object as one concrete certificate boundary, not as a family indexed by schematic operation parameters.

Proof. Apply Theorem 45.651. This fixes the concrete $\mathsf{RatUpFieldSource}_F$ source, the BHist carrier object, the history classifier, the denominator tuple, and the contextual action in the concrete exit certificate.

Apply Theorem 45.662 to the same exit certificate. It attaches the algebra-reduct, inverse-product classifier, and affine-action rows without changing the source object selected by the canonical certificate.

Apply Theorem 45.663. The transported contextual-pair clauses use the same BHist endpoint source and its denominator contexts, so the noncollapse rows are certificate rows over the concrete object rather than fresh parameters.

Finally apply Theorem 45.664. The affine inverse uniqueness row is read in the affine action carrier supplied above, so it closes the same concrete certificate package and supplies the displayed single boundary consumed by the hierarchy exit criterion. □

Per-object template: traditional target final constructive $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ certificate boundary; BEDC source $\mathsf{RatUpFieldSource}_F$, BHist, denominator tuple, contextual action, and AffAut_F; carrier $\mathsf{RatHistoryCarrier}$; classifier $\mathsf{RatHistoryClassifier}$; stability obligations source anchor, reduct rows, inverse-product exactness, affine action laws, contextual noncollapse, and affine inverse uniqueness; ledger denominator contexts, inverse witnesses, affine witnesses, and transported endpoints; core theorem list Theorem 45.651, Theorem 45.662, Theorem 45.663, and Theorem 45.664; exactness predicate one concrete exit certificate package; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.670 (RatUp FieldUp affine automorphism cancellation exactness exit)**.** *For Definition 45.617, let $S, T, U : \mathsf{AffAut}_F$ be certified affine automorphism histories in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. With the concrete affine composition $\circ_{\mathrm{aff}}$ and classifier $\equiv_{\mathrm{aff}}$ supplied by Definition 45.661, common right affine factors cancel exactly:*

$$(S \circ_{\mathrm{aff}} T) \equiv_{\mathrm{aff}} (U \circ_{\mathrm{aff}} T) \Longleftrightarrow S \equiv_{\mathrm{aff}} U.$$

Common left affine factors cancel exactly:

$$(T \circ_{\mathrm{aff}} S) \equiv_{\mathrm{aff}} (T \circ_{\mathrm{aff}} U) \Longleftrightarrow S \equiv_{\mathrm{aff}} U.$$

Thus affine cancellation exactness is a concrete row of the canonical $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object, not an external schematic field parameter.

Proof. First fix the concrete exit object by Definition 45.618. This anchors the carrier BHist, the source $\mathsf{RatUpFieldSource}_F$, and the operation rows used by the affine automorphism certificate.

Next apply Definition 45.661. It identifies the affine carrier AffAut_F, composition $\circ_{\mathrm{aff}}$, identity, inverse, and classifier $\equiv_{\mathrm{aff}}$ as rows exported by the same concrete exit object.

Finally apply Definition 45.566. Read its classifier as the concrete affine classifier just identified, and read its two common-factor cancellation clauses as the displayed right and left equivalences. □

Per-object template: traditional target affine automorphism action cancellation exactness over $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source concrete $\mathsf{RatUpFieldSource}_F$, BHist, and AffAut_F; carrier certified affine automorphism histories; classifier $\equiv_{\mathrm{aff}}$; stability obligation affine group action certificate plus cancellation exactness; ledger common affine factor and composition provenance; core theorem Theorem 45.670; exactness predicate the two displayed iff rows; standard bridge ordinary affine automorphism cancellation; status $\mathsf{ProofTarget}$.

Theorem 45.671 (RatUp FieldUp affine inverse antihomomorphism exit)**.** *For Definition 45.617, let $T, U : \mathsf{AffAut}_F$ be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $U \circ_{\mathrm{aff}} T$ be the concrete affine composite supplied by Definition 45.662, and let $\iota_F(-)$ denote the explicit inverse witness supplied by Definition 45.555 under the same concrete action classifier.*

Then the inverse of a composite is the reverse composite of the explicit inverses under the concrete affine classifier:

$$\iota_F(U \circ_{\mathrm{aff}} T) \equiv_{\mathrm{aff}} \iota_F(T) \circ_{\mathrm{aff}} \iota_F(U).$$

The same classifier also identifies the double inverse with the original certified affine automorphism:

$$\iota_F(\iota_F(T)) \equiv_{\mathrm{aff}} T.$$

Proof. First fix the concrete exit action by Definition 45.662. This fixes the carrier AffAut_F, the concrete affine composite $\circ_{\mathrm{aff}}$, the explicit inverse row, and the classifier $\equiv_{\mathrm{aff}}$ inside Definition 45.617.

For the composite inverse law, apply Definition 45.546 pointwise to the two certified affine automorphisms. The theorem identifies the collected inverse of $U \circ_{\mathrm{aff}} T$ with the pointwise reverse composite $\iota_F(T) \circ_{\mathrm{aff}} \iota_F(U)$ under hsame.

The affine action classifier from the fixed exit package lifts this pointwise hsame relation to the displayed relation

$$\iota_F(U \circ_{\mathrm{aff}} T) \equiv_{\mathrm{aff}} \iota_F(T) \circ_{\mathrm{aff}} \iota_F(U).$$

For the double-inverse clause, view T as a two-sided inverse candidate for $\iota_F(T)$ by the identity and inverse fields of Definition 45.555. Apply Definition 45.666 to compare this candidate with the explicit inverse $\iota_F(\iota_F(T))$ of $\iota_F(T)$. The resulting classifier equality is exactly $\iota_F(\iota_F(T)) \equiv_{\mathrm{aff}} T$. □

Per-object template: traditional target affine inverse antihomomorphism; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit rows plus AffAut_F; carrier certified affine automorphisms; classifier $\equiv_{\mathrm{aff}}$; stability obligations concrete composition, inverse uniqueness, and reverse-composite inverse coherence; ledger factor witnesses, product witnesses, inverse witnesses, and offsets; core theorem list Definition 45.662, Definition 45.546, and Definition 45.666; exactness predicate inverse antihomomorphism plus double-inverse law; standard bridge deferred; status $\mathsf{ProofTarget}$.

Capstone.

Theorem 45.672 (RatUp FieldUp affine conjugation equation exactness)**.** *For Definition 45.617, let $A, X, B : \mathsf{AffAut}_F$ be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $\iota_F(A)$ be the explicit inverse supplied by Definition 45.662, and define the affine inner action by*

$$\mathsf{Conj}_A(X) := (A \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(A).$$

Then affine conjugation classifies the middle affine automorphism exactly:

$$\mathsf{Conj}_A(X) \equiv_{\mathrm{aff}} B \iff X \equiv_{\mathrm{aff}} (\iota_F(A) \circ_{\mathrm{aff}} B) \circ_{\mathrm{aff}} A.$$

The inverse affine inner action also cancels on both sides:

$$\mathsf{Conj}_{\iota_F(A)}(\mathsf{Conj}_A(X)) \equiv_{\mathrm{aff}} X.$$

$$\mathsf{Conj}_A(\mathsf{Conj}_{\iota_F(A)}(X)) \equiv_{\mathrm{aff}} X.$$

Proof. Fix the concrete affine action package of Definition 45.662. This fixes the carrier AffAut_F, the collected-coefficient composite $\circ_{\mathrm{aff}}$, the explicit inverse row $\iota_F(-)$, and the classifier $\equiv_{\mathrm{aff}}$.

Instantiate Definition 45.558 on this package. The identity, associativity, inverse laws, and classifier congruence fields make AffAut_F a concrete $\mathsf{Group}^{\uparrow}$ object for the displayed affine operation.

Apply Definition 41.76 inside that $\mathsf{Group}^{\uparrow}$ object with group element A, middle element X, and target B. Under the fixed action notation, the resulting group classifier statement is exactly

$$\mathsf{Conj}_A(X) \equiv_{\mathrm{aff}} B \iff X \equiv_{\mathrm{aff}} (\iota_F(A) \circ_{\mathrm{aff}} B) \circ_{\mathrm{aff}} A.$$

For the first cancellation clause, expand $\mathsf{Conj}_{\iota_F(A)}(\mathsf{Conj}_A(X))$. Associativity rewrites it as left multiplication by $\iota_F(A)$, then by A, followed by the displayed right inverse of $\iota_F(A)$. Use Definition 45.671 to normalize $\iota_F(\iota_F(A))$ to A, and then collapse the adjacent inverse pairs by the affine group certificate.

For the second cancellation clause, expand $\mathsf{Conj}_A(\mathsf{Conj}_{\iota_F(A)}(X))$. The same associativity and inverse-law fields reduce the middle product after Definition 45.671 identifies the double inverse of A with A. The remaining term is classifier-equal to X. □

Per-object template: traditional target affine inner automorphism exactness; BEDC source $\mathsf{RatUpFieldSource}_F$ plus AffAut_F; carrier certified affine automorphism histories; classifier $\equiv_{\mathrm{aff}}$; stability obligations affine group laws, conjugation exactness, inverse antihomomorphism, and double inverse; ledger affine coefficients and inverse witnesses; core theorem list Definition 45.662, Definition 45.558, Definition 41.76, and Definition 45.671; exactness predicate affine conjugation equation exactness; standard bridge ordinary inner automorphism equation exactness; status $\mathsf{ProofTarget}$.

Theorem 45.673 (RatUp FieldUp affine conjugation exactness)**.** *For Definition 45.617, let A, S, T : AffAut_F be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $\circ_{\mathrm{aff}}$ be the concrete affine composite, let $\iota_F(-)$ be the explicit inverse witness, and let $\equiv_{\mathrm{aff}}$ be the affine classifier supplied by Definition 45.662. Define*

$$\mathrm{Conj}_A(S) = A \circ_{\mathrm{aff}} S \circ_{\mathrm{aff}} \iota_F(A).$$

Then conjugation by A is classifier-exact:

$$\mathrm{Conj}_A(S) \equiv_{\mathrm{aff}} \mathrm{Conj}_A(T) \iff S \equiv_{\mathrm{aff}} T.$$

Its inverse conjugation action is conjugation by the explicit inverse:

$$\mathrm{Conj}_{\iota_F(A)}(\mathrm{Conj}_A(S)) \equiv_{\mathrm{aff}} S \quad \textit{and} \quad \mathrm{Conj}_A(\mathrm{Conj}_{\iota_F(A)}(S)) \equiv_{\mathrm{aff}} S.$$

Proof. First fix the concrete affine group package from Definition 45.662. This supplies the carrier AffAut_F, the operation $\circ_{\mathrm{aff}}$, the classifier $\equiv_{\mathrm{aff}}$, and the explicit inverse row inside the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object.

Apply Definition 41.76 to this affine group package with $a = A$ and with the equation target specialized to $\mathrm{Conj}_A(T)$. The group theorem gives the middle-factor equation equivalent to the displayed conjugation equation. Use the two cancellation clauses and operation congruence in Definition 45.566 to identify that middle-factor equation with $S \equiv_{\mathrm{aff}} T$.

For the inverse-action clause, expand $\mathrm{Conj}_{\iota_F(A)}(\mathrm{Conj}_A(S))$ and $\mathrm{Conj}_A(\mathrm{Conj}_{\iota_F(A)}(S))$. The reverse-composite inverse law and double-inverse clause of Definition 45.671 identify the conjugating factors as mutual inverse witnesses. The remaining outer factors cancel by Definition 45.566, leaving exactly S under $\equiv_{\mathrm{aff}}$ in both composites. □

Per-object template: traditional target inner automorphism of the affine automorphism group; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit rows plus $\mathsf{Group}^{\uparrow}$; carrier AffAut_F; classifier $\equiv_{\mathrm{aff}}$; ledger conjugation factors and inverse witnesses; exactness predicate classifier-exact conjugation; standard bridge ordinary inner automorphism; status $\mathsf{ProofTarget}$.

Theorem 45.674 (RatUp FieldUp affine conjugation equation exactness exit)**.** *For Definition 45.617, let $T, S, V : \mathsf{AffAut}_F$ be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $\circ_{\mathrm{aff}}$ be the concrete affine composite, let $\iota_F(T)$ be the explicit inverse of T, and let $\equiv_{\mathrm{aff}}$ be the affine classifier supplied by Definition 45.661 for the same fixed action. Then conjugation by T classifies the middle affine automorphism exactly:*

$$((T \circ_{\mathrm{aff}} S) \circ_{\mathrm{aff}} \iota_F(T)) \equiv_{\mathrm{aff}} V \Longleftrightarrow S \equiv_{\mathrm{aff}} ((\iota_F(T) \circ_{\mathrm{aff}} V) \circ_{\mathrm{aff}} T).$$

Proof. First fix the concrete exit action by Definition 45.662. This pins down the affine carrier AffAut_F, the concrete composite $\circ_{\mathrm{aff}}$, the explicit inverse row $\iota_F(-)$, and the classifier $\equiv_{\mathrm{aff}}$ inside Definition 45.617.

Read the same carrier, composite, inverse, and classifier through Definition 45.661. The action certificate supplies the associativity, identity, inverse, and operation congruence rows needed to regard these data as the concrete affine group package.

Instantiate Definition 41.76 in that fixed group package with $a = T$, $x = S$, and $b = V$. The resulting classifier statement is the displayed equivalence after replacing the package multiplication, inverse, and classifier symbols by $\circ_{\mathrm{aff}}$, $\iota_F(-)$, and $\equiv_{\mathrm{aff}}$.

The forward direction carries an affine equation for $(T \circ_{\mathrm{aff}} S) \circ_{\mathrm{aff}} \iota_F(T)$ to the recovered middle factor S. The reverse direction transports the recovered middle factor back through left composition by T and right composition by $\iota_F(T)$, using the same concrete inverse witnesses and classifier congruence. □

Per-object template: traditional target affine conjugation equation solving; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit rows plus $\mathsf{GroupUp}$ conjugation exactness; carrier certified affine automorphisms; classifier $\equiv_{\mathrm{aff}}$; stability obligations associativity, identity, inverse, and operation congruence of the fixed action; ledger conjugating automorphism and inverse witness provenance; core theorem list Definition 45.662, Definition 45.661, and Definition 41.76; exactness predicate the displayed iff; standard bridge ordinary affine conjugacy equations; status $\mathsf{ProofTarget}$.

Theorem 45.675 (RatUp FieldUp affine inner conjugation exit)**.** *For Definition 45.617, let $T, V, W : \mathsf{AffAut}_F$ be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $\iota_F(-)$ be the explicit inverse from Definition 45.662, and define*

$$\mathrm{Inn}_T(V) = T \circ_{\mathrm{aff}} V \circ_{\mathrm{aff}} \iota_F(T).$$

Then inner conjugation by T is a concrete affine action theorem for the canonical exit object:

1. $\mathrm{Inn}_T(V)$ *is a certified affine automorphism.*
2. *If* $V \equiv_{\mathrm{aff}} W$*, then* $\mathrm{Inn}_T(V) \equiv_{\mathrm{aff}} \mathrm{Inn}_T(W)$*.*
3. $\mathrm{Inn}_T(\mathrm{id}_F) \equiv_{\mathrm{aff}} \mathrm{id}_F$*.*
4. $\mathrm{Inn}_T(V \circ_{\mathrm{aff}} W) \equiv_{\mathrm{aff}} \mathrm{Inn}_T(V) \circ_{\mathrm{aff}} \mathrm{Inn}_T(W)$*.*
5. $\iota_F(\mathrm{Inn}_T(V)) \equiv_{\mathrm{aff}} \mathrm{Inn}_T(\iota_F(V))$*.*

Proof. Fix the concrete exit package of Definition 45.662. It fixes the carrier AffAut_F, the product $\circ_{\mathrm{aff}}$, the identity id_F, the inverse row $\iota_F(-)$, and the classifier $\equiv_{\mathrm{aff}}$ over Definition 45.617.

Certification of $\mathrm{Inn}_T(V)$ is closure under the two displayed affine products. Apply Definition 45.556 to compose T with V, then compose the result with $\iota_F(T)$ supplied by the canonical inverse row.

Classifier respect follows by transporting $V \equiv_{\mathrm{aff}} W$ through the fixed left factor T and the fixed right factor $\iota_F(T)$. This is the operation congruence field of Definition 45.553, with the same classifier chosen by the canonical exit package.

For the identity clause, use Definition 45.554 to reassociate $T \circ_{\mathrm{aff}} \mathrm{id}_F \circ_{\mathrm{aff}} \iota_F(T)$. The unit and inverse laws from Definition 45.556 then identify the middle product with $T \circ_{\mathrm{aff}} \iota_F(T)$ and hence with id_F under $\equiv_{\mathrm{aff}}$.

For products, reassociate $T \circ_{\mathrm{aff}} (V \circ_{\mathrm{aff}} W) \circ_{\mathrm{aff}} \iota_F(T)$ so that the inverse-product pair $\iota_F(T) \circ_{\mathrm{aff}} T$ occurs between the transported V and W terms. The group inverse law collapses that pair to id_F, and associativity returns the classifier equality

$$\mathrm{Inn}_T(V \circ_{\mathrm{aff}} W) \equiv_{\mathrm{aff}} \mathrm{Inn}_T(V) \circ_{\mathrm{aff}} \mathrm{Inn}_T(W).$$

For inverse preservation, apply Definition 45.671 to the two products in $T \circ_{\mathrm{aff}} V \circ_{\mathrm{aff}} \iota_F(T)$. The reverse-order inverse is $\iota_F(\iota_F(T)) \circ_{\mathrm{aff}} \iota_F(V) \circ_{\mathrm{aff}} \iota_F(T)$. The double-inverse clause of that theorem identifies $\iota_F(\iota_F(T))$ with T, and operation congruence transports the comparison to

$$\iota_F(\mathrm{Inn}_T(V)) \equiv_{\mathrm{aff}} \mathrm{Inn}_T(\iota_F(V)).$$

□

Per-object template: traditional target inner automorphism action; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object plus AffAut_F; carrier certified affine automorphisms; classifier $\equiv_{\mathrm{aff}}$; stability obligations composition closure, classifier congruence, unit, product, and inverse preservation; ledger affine coefficients, product witnesses, inverse witnesses, and conjugating element; core theorem list Definition 45.662, Definition 45.556, Definition 45.554, Definition 45.553, and Definition 45.671; exactness predicate inner-conjugation action laws; standard bridge ordinary inner automorphisms; status $\mathsf{ProofTarget}$.

Theorem 45.676 (RatUp FieldUp affine inner action composition exit)**.** *For Definition 45.617, let $T, U, V : \mathsf{AffAut}_F$ be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. For a certified affine automorphism S, define*

$$\mathrm{Inn}_S(V) = S \circ_{\mathrm{aff}} V \circ_{\mathrm{aff}} \iota_F(S),$$

where $\iota_F(-)$ is the explicit inverse operation supplied by Definition 45.662. Then the inner affine transformations obey the identity and composition laws in the conjugating parameter:

$$\mathrm{Inn}_{\mathrm{id}_F}(V) \equiv_{\mathrm{aff}} V.$$

$$\mathrm{Inn}_T(\mathrm{Inn}_U(V)) \equiv_{\mathrm{aff}} \mathrm{Inn}_{T \circ_{\mathrm{aff}} U}(V).$$

Proof. Fix the concrete affine package from Definition 45.662. It fixes the carrier AffAut_F, the identity id_F, the concrete product $\circ_{\mathrm{aff}}$, the inverse operation $\iota_F(-)$, and the classifier $\equiv_{\mathrm{aff}}$.

For the identity parameter, expand $\mathrm{Inn}_{\mathrm{id}_F}(V)$ as $\mathrm{id}_F \circ_{\mathrm{aff}} V \circ_{\mathrm{aff}} \iota_F(\mathrm{id}_F)$. The unit rows and inverse rows of the fixed package identify $\iota_F(\mathrm{id}_F)$ with id_F, and associativity from Definition 45.554 removes the two unit factors. The classifier conclusion is $\mathrm{Inn}_{\mathrm{id}_F}(V) \equiv_{\mathrm{aff}} V$.

For composition of conjugating parameters, first use Definition 45.675 to certify the inner term $\mathrm{Inn}_U(V)$ and to transport classifier equalities through the outer conjugation by T.

After expansion, associativity rewrites the left side to the common affine word

$$T \circ_{\mathrm{aff}} U \circ_{\mathrm{aff}} V \circ_{\mathrm{aff}} \iota_F(U) \circ_{\mathrm{aff}} \iota_F(T).$$

Apply Definition 45.671 to $T \circ_{\mathrm{aff}} U$. It identifies $\iota_F(T \circ_{\mathrm{aff}} U)$ with $\iota_F(U) \circ_{\mathrm{aff}} \iota_F(T)$ under the same classifier. Operation congruence and classifier transitivity in the fixed package replace the final two inverse factors by $\iota_F(T \circ_{\mathrm{aff}} U)$.

A final use of Definition 45.554 repacks the word as $(T \circ_{\mathrm{aff}} U) \circ_{\mathrm{aff}} V \circ_{\mathrm{aff}} \iota_F(T \circ_{\mathrm{aff}} U)$, which is $\mathrm{Inn}_{T \circ_{\mathrm{aff}} U}(V)$. □

Per-object template: traditional target inner action of the affine automorphism group; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit rows plus AffAut_F; carrier certified affine automorphisms; classifier $\equiv_{\mathrm{aff}}$; stability obligations identity action, composition action, inverse antihomomorphism, associativity, and classifier congruence; ledger conjugating factors, product witnesses, and inverse witnesses; core theorem list Definition 45.662, Definition 45.675, Definition 45.671, and Definition 45.554; exactness predicate concrete inner-action law; standard bridge ordinary conjugation action; status $\mathsf{ProofTarget}$.

Definition 45.677 (RatUp FieldUp affine center predicate)**.** *For Definition 45.617, let $Z : \mathsf{AffAut}_F$ be a certified affine automorphism in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. The concrete affine center predicate is*

$$\mathsf{Center}_F(Z) :\Longleftrightarrow \forall T : \mathsf{AffAut}_F,\ Z \circ_{\mathrm{aff}} T \equiv_{\mathrm{aff}} T \circ_{\mathrm{aff}} Z.$$

Here $\circ_{\mathrm{aff}}$ and $\equiv_{\mathrm{aff}}$ are the concrete affine composition and classifier supplied by Definition 45.662.

Theorem 45.678 (RatUp FieldUp affine center fixed-point criterion)**.** *For Definition 45.617, let $Z : \mathsf{AffAut}_F$ be a certified affine automorphism in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let Inn_T be the inner affine action from Definition 45.675. Then*

$$\mathsf{Center}_F(Z) \Longleftrightarrow \forall T : \mathsf{AffAut}_F,\ \mathrm{Inn}_T(Z) \equiv_{\mathrm{aff}} Z.$$

Proof. Fix the concrete exit action package of Definition 45.662. This fixes AffAut_F, $\circ_{\mathrm{aff}}$, id_F, the inverse row $\iota_F(-)$, and the classifier $\equiv_{\mathrm{aff}}$.

For the forward direction, assume $\mathsf{Center}_F(Z)$ and fix $T : \mathsf{AffAut}_F$. The center equation rewrites $T \circ_{\mathrm{aff}} Z$ as $Z \circ_{\mathrm{aff}} T$ under $\equiv_{\mathrm{aff}}$. Substitute this into $\mathrm{Inn}_T(Z) = (T \circ_{\mathrm{aff}} Z) \circ_{\mathrm{aff}} \iota_F(T)$, reassociate by Definition 45.554, and cancel the trailing product $T \circ_{\mathrm{aff}} \iota_F(T)$ by the inverse law in Definition 45.556. The right identity row then identifies the result with Z.

For the reverse direction, assume $\forall T : \mathsf{AffAut}_F,\ \mathrm{Inn}_T(Z) \equiv_{\mathrm{aff}} Z$ and fix T. Apply the hypothesis to T, right-compose the displayed classifier equation by T, and use classifier congruence from Definition 45.553. After reassociation, the product $\iota_F(T) \circ_{\mathrm{aff}} T$ collapses by the inverse law, so the transported equation gives $T \circ_{\mathrm{aff}} Z \equiv_{\mathrm{aff}} Z \circ_{\mathrm{aff}} T$. Symmetry of the classifier presents it in the order required by $\mathsf{Center}_F(Z)$. □

Per-object template: traditional target center of the affine automorphism group; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit rows plus AffAut_F; carrier certified affine automorphisms; classifier $\equiv_{\mathrm{aff}}$; stability obligations inner action exactness, affine associativity, inverse laws, and classifier congruence; ledger conjugating element and inverse witness provenance; core theorem list Definition 45.662, Definition 45.675, and Definition 41.76; exactness predicate center iff fixed by all inner conjugations; standard bridge ordinary group-center criterion; status $\mathsf{ProofTarget}$.

Definition 45.679 (Concrete RatUp FieldUp affine automorphism group instance)**.** *For Definition 45.617, the concrete affine automorphism group instance has carrier AffAut_F, multiplication $\circ_{\mathrm{aff}}$, unit id_F, inverse $\iota_F(-)$, and classifier $\equiv_{\mathrm{aff}}$. The carrier, composition, unit, and inverse rows are supplied by Definition 45.662, and the classifier, congruence, associativity, identity, inverse, and cancellation obligations are supplied by Definition 45.661.*

Theorem 45.680 (RatUp FieldUp affine commutator fixedness criterion)**.** *For Definition 45.617, let $T, S : \mathsf{AffAut}_F$ be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. With the affine group instance of Definition 45.679, define*

$$\mathsf{AffComm}_F(T, S) := (T \circ_{\mathrm{aff}} S) \circ_{\mathrm{aff}} (\iota_F(T) \circ_{\mathrm{aff}} \iota_F(S)).$$

Then the affine commutator is trivial exactly when the two affine automorphisms commute:

$$\mathsf{AffComm}_F(T, S) \equiv_{\mathrm{aff}} \mathrm{id}_F \iff T \circ_{\mathrm{aff}} S \equiv_{\mathrm{aff}} S \circ_{\mathrm{aff}} T.$$

Equivalently, the same commutator is trivial exactly when S is fixed by inner conjugation by T:

$$\mathsf{AffComm}_F(T, S) \equiv_{\mathrm{aff}} \mathrm{id}_F \iff \mathrm{Inn}_T(S) \equiv_{\mathrm{aff}} S.$$

Proof. Fix the affine group instance of Definition 45.679. It reads the group carrier as AffAut_F, the product as $\circ_{\mathrm{aff}}$, the unit as id_F, the inverse as $\iota_F(-)$, and the classifier as $\equiv_{\mathrm{aff}}$.

Instantiate Definition 41.82 in this concrete group package with $a = T$ and $b = S$. Its history-level commutator becomes the displayed term $\mathsf{AffComm}_F(T, S)$, and its classifier statement becomes the first displayed equivalence.

It remains to compare commutation with fixedness under inner conjugation. Expand $\mathrm{Inn}_T(S)$ as $T \circ_{\mathrm{aff}} S \circ_{\mathrm{aff}} \iota_F(T)$. If $T \circ_{\mathrm{aff}} S \equiv_{\mathrm{aff}} S \circ_{\mathrm{aff}} T$, compose the comparison on the right by $\iota_F(T)$, reassociate, and collapse $T \circ_{\mathrm{aff}} \iota_F(T)$ to id_F. The right identity law then gives $\mathrm{Inn}_T(S) \equiv_{\mathrm{aff}} S$.

Conversely, assume $\mathrm{Inn}_T(S) \equiv_{\mathrm{aff}} S$. Compose both sides on the right by T, reassociate the left side, and collapse $\iota_F(T) \circ_{\mathrm{aff}} T$ to id_F. The right identity law gives $T \circ_{\mathrm{aff}} S \equiv_{\mathrm{aff}} S \circ_{\mathrm{aff}} T$.

All transports use operation congruence, associativity, inverse laws, and identity laws from the affine action certificate. The cancellation steps are the concrete common-factor exactness clauses of Definition 45.670. □

Theorem 45.681 (RatUp FieldUp affine threefold inverse antihomomorphism exit)**.** *For Definition 45.617, let $T, U, V : \mathsf{AffAut}_F$ be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $\circ_{\mathrm{aff}}$ be the concrete affine composition, let $\equiv_{\mathrm{aff}}$ be the concrete affine classifier, and let $\iota_F(-)$ be the explicit inverse operation supplied by the same exit rows. Then the classifier identifies the inverse of the left associated threefold composite with the reversed threefold composite of explicit inverses:*

$$\iota_F((V \circ_{\mathrm{aff}} U) \circ_{\mathrm{aff}} T) \equiv_{\mathrm{aff}} (\iota_F(T) \circ_{\mathrm{aff}} \iota_F(U)) \circ_{\mathrm{aff}} \iota_F(V).$$

It also identifies the same inverse with the right associated reversed form:

$$\iota_F((V \circ_{\mathrm{aff}} U) \circ_{\mathrm{aff}} T) \equiv_{\mathrm{aff}} \iota_F(T) \circ_{\mathrm{aff}} (\iota_F(U) \circ_{\mathrm{aff}} \iota_F(V)).$$

Proof. First apply Theorem 45.671 to the pair $((V \circ_{\mathrm{aff}} U), T)$. This gives

$$\iota_F((V \circ_{\mathrm{aff}} U) \circ_{\mathrm{aff}} T) \equiv_{\mathrm{aff}} \iota_F(T) \circ_{\mathrm{aff}} \iota_F(V \circ_{\mathrm{aff}} U).$$

Next apply Theorem 45.671 to the pair (V, U). This gives

$$\iota_F(V \circ_{\mathrm{aff}} U) \equiv_{\mathrm{aff}} \iota_F(U) \circ_{\mathrm{aff}} \iota_F(V).$$

Use the affine operation congruence supplied by Theorem 45.661 to compose the fixed left factor $\iota_F(T)$ with this second classifier relation. Transitivity of the same classifier then identifies the original inverse with $(\iota_F(T) \circ_{\mathrm{aff}} \iota_F(U)) \circ_{\mathrm{aff}} \iota_F(V)$, which is the first displayed conclusion.

Finally use the affine group and threefold composition rows from Theorem 45.563. Those rows certify that the two bracketings of the reversed certified affine threefold composite have the same concrete affine classifier. Applying transitivity once more gives the right associated displayed form. □

Per-object template: traditional target threefold affine inverse antihomomorphism; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit rows plus AffAut_F; carrier certified affine automorphisms; classifier $\equiv_{\mathrm{aff}}$; stability binary inverse antihomomorphism, composition congruence, and affine associativity; ledger three affine factors and inverse witnesses; core theorem Definition 45.681; exactness predicate threefold inverse reversal under the concrete affine classifier; standard bridge ordinary affine automorphism group; status $\mathsf{ProofTarget}$.

Theorem 45.682 (RatUp FieldUp affine commutator detects commutation)**.** *For Definition 45.617, let $T, U : \mathsf{AffAut}_F$ be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $\circ_{\mathrm{aff}}$ be the concrete affine product, let id_F be the concrete identity, let $\iota_F(-)$ be the inverse row, and let $\equiv_{\mathrm{aff}}$ be the affine classifier supplied by Definition 45.662. Define*

$$\mathsf{Comm}_F(T, U) := (T \circ_{\mathrm{aff}} U) \circ_{\mathrm{aff}} (\iota_F(T) \circ_{\mathrm{aff}} \iota_F(U)).$$

Then the concrete affine commutator is classifier-trivial exactly when the two affine factors commute:

$$\mathsf{Comm}_F(T, U) \equiv_{\mathrm{aff}} \mathrm{id}_F \iff T \circ_{\mathrm{aff}} U \equiv_{\mathrm{aff}} U \circ_{\mathrm{aff}} T.$$

Proof. Fix Theorem 45.662. It supplies the same affine composition, inverse operation, identity row, and classifier used in the displayed statement.

Read those rows as the concrete affine group package certified by Definition 45.558. The package gives the same carrier, product, identity, inverse operation, classifier, associativity, identity laws, inverse laws, and affine operation congruence.

Instantiate Definition 41.82 in this concrete group with $a = T$ and $b = U$. The checked theorem gives the equivalence between triviality of $\mathsf{mul}(\mathsf{mul}(T, U), \mathsf{mul}(\mathsf{inv}(T), \mathsf{inv}(U)))$ and commutation of $\mathsf{mul}(T, U)$ with $\mathsf{mul}(U, T)$.

It remains to match the displayed affine notation with this group notation. The operation, identity, inverse row, and classifier are the same fields of the fixed affine package. Affine operation congruence transports classifier equalities through the two product slots, and affine associativity matches the displayed bracketing of $\mathsf{Comm}_F(T, U)$ with the bracketing used by the $\mathsf{Group}^{\uparrow}$ theorem.

Reading the group equivalence through this notation gives the forward direction from a trivial displayed $\mathsf{Comm}_F(T, U)$ to affine commutation.

Reading the same equivalence in reverse gives the converse: affine commutation transports through the classifier-congruence rows to the displayed commutator relation $\mathsf{Comm}_F(T, U) \equiv_{\mathrm{aff}} \mathrm{id}_F$. □

Per-object template: traditional target affine commutator criterion; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit rows plus $\mathsf{Group}^{\uparrow}$; carrier AffAut_F; classifier $\equiv_{\mathrm{aff}}$; stability obligations affine group laws, inverse-product reversal, operation congruence, and identity laws; ledger the two affine factors and inverse witnesses; core theorem list the canonical exit action and inverse package Definition 45.662, Definition 45.558, and Definition 41.82; exactness predicate trivial affine commutator iff affine commutation; standard bridge ordinary affine automorphism commutator criterion; status $\mathsf{ProofTarget}$.

Theorem 45.683 (RatUp FieldUp affine commutator centralizer exactness)**.** *For Definition 45.617, let $A, B : \mathsf{AffAut}_F$ be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $\circ_{\mathrm{aff}}$ be the concrete affine composition, let $\iota_F(-)$ be the explicit inverse row, and let $\equiv_{\mathrm{aff}}$ be the affine classifier. Define*

$$\mathrm{Inn}_A(B) := (A \circ_{\mathrm{aff}} B) \circ_{\mathrm{aff}} \iota_F(A).$$

Then the commutation condition is exactly the fixed-point condition for conjugation by A:

$$A \circ_{\mathrm{aff}} B \equiv_{\mathrm{aff}} B \circ_{\mathrm{aff}} A \Longleftrightarrow \mathrm{Inn}_A(B) \equiv_{\mathrm{aff}} B.$$

Proof. Fix the canonical exit package of Definition 45.662. This fixes the carrier AffAut_F, the collected-coefficient composite $\circ_{\mathrm{aff}}$, the explicit inverse row $\iota_F(-)$, the identity id_F, and the classifier $\equiv_{\mathrm{aff}}$.

For the forward direction, compose $A \circ_{\mathrm{aff}} B \equiv_{\mathrm{aff}} B \circ_{\mathrm{aff}} A$ on the right by $\iota_F(A)$. The affine operation congruence and associativity rows transport the comparison to

$$(A \circ_{\mathrm{aff}} B) \circ_{\mathrm{aff}} \iota_F(A) \equiv_{\mathrm{aff}} B \circ_{\mathrm{aff}} (A \circ_{\mathrm{aff}} \iota_F(A)).$$

The right inverse and right identity rows reduce the right side to B, giving $\mathrm{Inn}_A(B) \equiv_{\mathrm{aff}} B$.

For the reverse direction, use Definition 45.672 with $X = B$ and target B. The displayed fixed-point condition for $\mathrm{Inn}_A(B)$ gives

$$B \equiv_{\mathrm{aff}} (\iota_F(A) \circ_{\mathrm{aff}} B) \circ_{\mathrm{aff}} A.$$

Compose on the left by A, then use affine associativity, inverse laws, identity laws, and cancellation exactness from Definition 45.661. The resulting comparison is exactly $A \circ_{\mathrm{aff}} B \equiv_{\mathrm{aff}} B \circ_{\mathrm{aff}} A$. □

Lean4 ✓ `BEDC.Derived.FieldUp.field empty unit conjugation fixed point commutation iff`

Per-object template: traditional target affine commutator centralizer criterion; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit rows plus AffAut_F; carrier certified affine automorphisms; classifier $\equiv_{\mathrm{aff}}$; stability obligations affine group certificate, operation congruence, inverse-product reversal, conjugation equation, and cancellation exactness; ledger two affine factors, inverse witnesses, commutator composite, and inner conjugation composite; core theorem Definition 45.683; exactness predicate commutation iff conjugation fixed point; standard bridge ordinary affine automorphism centralizer criterion; status $\mathsf{ProofTarget}$.

Definition 45.684 (RatUp FieldUp affine centralizer predicate)**.** *For Definition 45.617, let $A, B : \mathsf{AffAut}_F$ be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $\circ_{\mathrm{aff}}$ be the concrete affine product and let $\equiv_{\mathrm{aff}}$ be the concrete affine classifier supplied by Definition 45.679. The concrete affine centralizer predicate of A at B is*

$$\mathsf{Cent}_F(A; B) :\Longleftrightarrow A \circ_{\mathrm{aff}} B \equiv_{\mathrm{aff}} B \circ_{\mathrm{aff}} A.$$

Theorem 45.685 (RatUp FieldUp affine centralizer product and inverse closure)**.** *For Definition 45.617, let $A, B, C, B' : \mathsf{AffAut}_F$ be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. With Cent_F as in Definition 45.684, the centralizer of A is closed under the concrete affine group operations and under affine classifier transport:*

1. $\mathsf{Cent}_F(A; \mathrm{id}_F)$.
2. *If* $\mathsf{Cent}_F(A; B)$ *and* $\mathsf{Cent}_F(A; C)$*, then* $\mathsf{Cent}_F(A; B \circ_{\mathrm{aff}} C)$.
3. *If* $\mathsf{Cent}_F(A; B)$*, then* $\mathsf{Cent}_F(A; \iota_F(B))$.

4. *If* $B \equiv_{\mathrm{aff}} B'$, *then*

$$\mathsf{Cent}_F(A; B) \iff \mathsf{Cent}_F(A; B').$$

Proof. Fix the affine group instance of Definition 45.679. Its action certificate is Definition 45.661, which supplies associativity, identity, inverse, congruence, symmetry, and transitivity for the concrete affine classifier.

For the identity clause, the left and right identity rows identify $A \circ_{\mathrm{aff}} \mathrm{id}_F$ and $\mathrm{id}_F \circ_{\mathrm{aff}} A$ with A. Symmetry and transitivity of $\equiv_{\mathrm{aff}}$ give the displayed centralizer predicate.

For product closure, convert the two hypotheses to inner fixed-point statements by Definition 45.683. Apply Definition 45.676 to identify $\mathrm{Inn}_A(B \circ_{\mathrm{aff}} C)$ with $\mathrm{Inn}_A(B) \circ_{\mathrm{aff}} \mathrm{Inn}_A(C)$. Congruence transports the two fixed-point equations through the product, so the composite inner image is classifier-equal to $B \circ_{\mathrm{aff}} C$. Applying centralizer exactness in reverse gives $\mathsf{Cent}_F(A; B \circ_{\mathrm{aff}} C)$.

For inverse closure, start from $\mathsf{Cent}_F(A; B)$ and again use Definition 45.683 to read it as $\mathrm{Inn}_A(B) \equiv_{\mathrm{aff}} B$. Apply Definition 45.671 to transport this fixed-point equation through the explicit inverse row. The inverse, associativity, and identity clauses in the action certificate reduce the inner image of $\iota_F(B)$ to $\iota_F(B)$, and centralizer exactness returns $\mathsf{Cent}_F(A; \iota_F(B))$.

For classifier transport, assume $B \equiv_{\mathrm{aff}} B'$. Operation congruence composes this relation with the fixed factor A on the left and on the right. Symmetry and transitivity then carry $A \circ_{\mathrm{aff}} B \equiv_{\mathrm{aff}} B \circ_{\mathrm{aff}} A$ exactly to $A \circ_{\mathrm{aff}} B' \equiv_{\mathrm{aff}} B' \circ_{\mathrm{aff}} A$, and the same argument with the comparison reversed gives the displayed equivalence. □

Lean4 ✓ `BEDC.Derived.FieldUp.RatupFieldupAffineCentralizerSubgroup`

Proof. Fix the canonical affine exit action and inverse package from Definition 45.662. This fixes AffAut_F, $\circ_{\mathrm{aff}}$, id_F, $\iota_F(-)$, and $\equiv_{\mathrm{aff}}$.

Instantiate Definition 45.558 on these rows. Its identity, associativity, inverse, and classifier-congruence clauses make the certified affine automorphisms a concrete $\mathsf{Group}^{\uparrow}$ object.

For the identity element, the left and right unit laws identify $\mathrm{id}_F \circ_{\mathrm{aff}} A$ and $A \circ_{\mathrm{aff}} \mathrm{id}_F$ with A. Transitivity and symmetry of $\equiv_{\mathrm{aff}}$ give $C_F(A)(\mathrm{id}_F)$.

For products, assume $C_F(A)(X)$ and $C_F(A)(Y)$. Reassociate $(X \circ_{\mathrm{aff}} Y) \circ_{\mathrm{aff}} A$, use the commuting witness for Y to move A left across Y, reassociate again, and use the commuting witness for X to move A left across X. The classifier-congruence rows then present the result as $A \circ_{\mathrm{aff}} (X \circ_{\mathrm{aff}} Y)$.

For inverses, assume $C_F(A)(X)$. Apply Definition 45.671 to the two products $X \circ_{\mathrm{aff}} A$ and $A \circ_{\mathrm{aff}} X$. The commuting witness transports through inverse antihomomorphism, and the group inverse rows reduce the resulting equation to $\iota_F(X) \circ_{\mathrm{aff}} A \equiv_{\mathrm{aff}} A \circ_{\mathrm{aff}} \iota_F(X)$.

Finally apply Definition 45.682 with the ordered pair (X, A). Its displayed equivalence is exactly the assertion that membership in $C_F(A)$ is the same as $\mathsf{Comm}_F(X, A) \equiv_{\mathrm{aff}} \mathrm{id}_F$. □

Per-object template: traditional target affine centralizer subgroup; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit plus $\mathsf{Group}^{\uparrow}$ commutator criterion; carrier $C_F(A)$ over AffAut_F; classifier $\equiv_{\mathrm{aff}}$; stability identity, product, inverse, and commutator characterization; ledger fixed element, commuting witness, product witness, and inverse witness; core theorem Definition 45.687; exactness predicate centralizer membership iff trivial commutator; standard bridge ordinary affine centralizer subgroup; status $\mathsf{ProofTarget}$.

Theorem 45.688 (RatUp FieldUp affine center as centralizer intersection)**.** *For Definition 45.617, let $Z : \mathsf{AffAut}_F$ be a certified affine automorphism in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Then the concrete affine center is the intersection of all concrete affine centralizers:*

$$\mathsf{Center}_F(Z) \iff \forall A : \mathsf{AffAut}_F,\ C_F(A)(Z).$$

Equivalently, the same center predicate is the condition that every concrete affine commutator with Z is classifier-trivial:

$$\mathsf{Center}_F(Z) \iff \forall A : \mathsf{AffAut}_F,\ \mathsf{Comm}_F(Z, A) \equiv_{\mathrm{aff}} \mathrm{id}_F.$$

Proof. Fix the canonical affine exit package from Definition 45.662. This fixes the carrier AffAut_F, the affine product $\circ_{\mathrm{aff}}$, the identity id_F, the inverse row $\iota_F(-)$, and the classifier $\equiv_{\mathrm{aff}}$.

For the first forward direction, assume $\mathsf{Center}_F(Z)$ and fix $A : \mathsf{AffAut}_F$. Unfold Definition 45.677 at the parameter A to obtain $Z \circ_{\mathrm{aff}} A \equiv_{\mathrm{aff}} A \circ_{\mathrm{aff}} Z$. Together with the already fixed carrier witness for Z, this is exactly $C_F(A)(Z)$ by Definition 45.686.

For the first reverse direction, assume $\forall A : \mathsf{AffAut}_F,\ C_F(A)(Z)$ and fix $A : \mathsf{AffAut}_F$. Unfold the centralizer carrier at A and Z; its commuting component gives $Z \circ_{\mathrm{aff}} A \equiv_{\mathrm{aff}} A \circ_{\mathrm{aff}} Z$. Since A was arbitrary, this is precisely Definition 45.677.

It remains to compare centralizer membership with commutator triviality. For each fixed $A : \mathsf{AffAut}_F$, apply the fourth clause of Definition 45.687 with $X = Z$. It gives

$$C_F(A)(Z) \iff \mathsf{Comm}_F(Z, A) \equiv_{\mathrm{aff}} \mathrm{id}_F.$$

Compose this pointwise equivalence with the first equivalence already proved. Classifier symmetry is used only to present the commuting equation in the displayed order when the centralizer carrier is read back as the center predicate. The result is the second displayed equivalence. □

Per-object template: traditional target center as intersection of centralizers; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine automorphism exit plus $\mathsf{Group}^{\uparrow}$ commutator criterion; carrier AffAut_F; classifier $\equiv_{\mathrm{aff}}$; stability center predicate, centralizer carrier, commutator exactness, and classifier symmetry; ledger quantified centralizer witness and commutator spine; core theorem list the center definition Definition 45.677, centralizer carrier Definition 45.686, and centralizer subgroup theorem Definition 45.687; exactness predicate center iff all centralizer memberships iff all commutators trivial; standard bridge ordinary group center-centralizer theorem; status $\mathsf{ProofTarget}$.

Theorem 45.689 (RatUp FieldUp affine centralizer fixed-point criterion)**.** *For Definition 45.617, let $A, B : \mathsf{AffAut}_F$ be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Define the inner affine action of A on B and the concrete affine commutator by*

$$\mathrm{Inn}_A(B) = A \circ_{\mathrm{aff}} B \circ_{\mathrm{aff}} \iota_F(A),$$

$$\mathsf{Comm}_F(A, B) := (A \circ_{\mathrm{aff}} B) \circ_{\mathrm{aff}} (\iota_F(A) \circ_{\mathrm{aff}} \iota_F(B)).$$

Here $\circ_{\mathrm{aff}}$, $\iota_F(-)$, id_F, and $\equiv_{\mathrm{aff}}$ are the concrete affine composition, inverse, identity, and classifier supplied by Definition 45.662. Then the centralizer fixed-point condition, commutator triviality, and ordinary affine commutation coincide:

$$\mathrm{Inn}_A(B) \equiv_{\mathrm{aff}} B \iff \mathsf{Comm}_F(A, B) \equiv_{\mathrm{aff}} \mathrm{id}_F \iff A \circ_{\mathrm{aff}} B \equiv_{\mathrm{aff}} B \circ_{\mathrm{aff}} A.$$

Proof. Fix the canonical affine exit package from Definition 45.662. This fixes the carrier AffAut_F, the affine product $\circ_{\mathrm{aff}}$, the unit id_F, the inverse row $\iota_F(-)$, and the classifier $\equiv_{\mathrm{aff}}$.

Apply Definition 45.683 to the same certified affine automorphisms A and B. Reading that equivalence in the reverse direction identifies the fixed-point condition $\mathrm{Inn}_A(B) \equiv_{\mathrm{aff}} B$ with affine commutation $A \circ_{\mathrm{aff}} B \equiv_{\mathrm{aff}} B \circ_{\mathrm{aff}} A$.

Apply Definition 45.682 to A and B. It identifies $\mathsf{Comm}_F(A, B) \equiv_{\mathrm{aff}} \mathrm{id}_F$ with the same affine commutation condition. Transitivity and symmetry of the fixed classifier combine the two equivalences into the displayed chain. □

Per-object template: traditional target centralizer fixed-point criterion for inner affine automorphisms; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit plus $\mathsf{Group}^{\uparrow}$; carrier AffAut_F; classifier $\equiv_{\mathrm{aff}}$; stability obligations inner action, commutator criterion, associativity, inverse laws, and classifier congruence; ledger conjugating factor and inverse witness; core theorem list Definition 45.676 and Definition 45.682; exactness predicate centralizer fixed point iff commutator trivial iff commutation; standard bridge ordinary affine centralizers; status $\mathsf{ProofTarget}$.

Theorem 45.690 (RatUp FieldUp affine centralizers are conjugation-equivariant)**.** *For Definition 45.617, let $A, T, X : \mathsf{AffAut}_F$ be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Define the inner affine conjugation action by*

$$\mathrm{Inn}_T(Y) = (T \circ_{\mathrm{aff}} Y) \circ_{\mathrm{aff}} \iota_F(T).$$

Let $C_F(A)(X)$ be the centralizer membership predicate of Definition 45.686. Then centralizer membership is transported by inner affine conjugation:

$$C_F(A)(X) \iff C_F(\mathrm{Inn}_T(A))(\mathrm{Inn}_T(X)).$$

Equivalently,

$$X \circ_{\mathrm{aff}} A \equiv_{\mathrm{aff}} A \circ_{\mathrm{aff}} X \iff \mathrm{Inn}_T(X) \circ_{\mathrm{aff}} \mathrm{Inn}_T(A) \equiv_{\mathrm{aff}} \mathrm{Inn}_T(A) \circ_{\mathrm{aff}} \mathrm{Inn}_T(X).$$

Proof. Fix the canonical affine group package from Definition 45.662. This fixes AffAut_F, $\circ_{\mathrm{aff}}$, id_F, $\iota_F(-)$, and $\equiv_{\mathrm{aff}}$, and Definition 45.661 supplies the associativity, inverse, cancellation, and classifier congruence rows used below.

For the forward direction, assume $C_F(A)(X)$, namely $X \circ_{\mathrm{aff}} A \equiv_{\mathrm{aff}} A \circ_{\mathrm{aff}} X$. Left-compose and right-compose this classifier equation by the conjugating factor T and its inverse witness $\iota_F(T)$. The classifier congruence row keeps equality stable under these certified affine products.

Reassociate the two transported composites by Definition 45.554. The adjacent factors $\iota_F(T)\circ_{\mathrm{aff}} T$ collapse by the inverse law in Definition 45.556, and the identity rows leave exactly

$$\mathrm{Inn}_T(X) \circ_{\mathrm{aff}} \mathrm{Inn}_T(A) \equiv_{\mathrm{aff}} \mathrm{Inn}_T(A) \circ_{\mathrm{aff}} \mathrm{Inn}_T(X).$$

This is $C_F(\mathrm{Inn}_T(A))(\mathrm{Inn}_T(X))$ by Definition 45.686. The same normal form is the concrete affine conjugation exactness asserted by Definition 45.675.

For the reverse direction, apply the forward construction with $\iota_F(T)$ as the conjugating automorphism to the centralizer witness for $\mathrm{Inn}_T(A)$ and $\mathrm{Inn}_T(X)$. The inverse antihomomorphism and double-inverse clauses of Definition 45.671 identify the resulting double conjugates with A and X under $\equiv_{\mathrm{aff}}$.

Finally use classifier transitivity and symmetry to replace the double conjugate centralizer equation by $X \circ_{\mathrm{aff}} A \equiv_{\mathrm{aff}} A \circ_{\mathrm{aff}} X$. This is precisely $C_F(A)(X)$, so the two displayed centralizer-membership conditions are equivalent. □

Per-object template: traditional target conjugation action on centralizers; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit plus AffAut_F; carrier $C_F(A)$; classifier $\equiv_{\mathrm{aff}}$; stability conjugation exactness, inverse antihomomorphism, associativity, and classifier congruence; ledger conjugating factor and inverse witness; core theorem list Definition 45.686, Definition 45.689, Definition 45.675, Definition 45.671, and Definition 45.661; exactness predicate centralizer membership transported by inner affine action; standard bridge ordinary centralizer conjugation; status ProofTarget.

Theorem 45.691 (RatUp FieldUp affine centralizer inner transport)**.** *For Definition 45.617, let $A, B, T : \mathsf{AffAut}_F$ be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let Cent_F be the centralizer predicate from Definition 45.684, and define*

$$\mathrm{Inn}_T(X) = T \circ_{\mathrm{aff}} X \circ_{\mathrm{aff}} \iota_F(T).$$

If $\mathsf{Cent}_F(A; B)$, then

$$\mathsf{Cent}_F(\mathrm{Inn}_T(A); \mathrm{Inn}_T(B)).$$

Proof. Fix the canonical affine exit package of Definition 45.662. This fixes AffAut_F, $\circ_{\mathrm{aff}}$, $\iota_F(-)$, and $\equiv_{\mathrm{aff}}$ for the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit rows.

Expand the hypothesis $\mathsf{Cent}_F(A; B)$ using Definition 45.684. It is the classifier equality

$$A \circ_{\mathrm{aff}} B \equiv_{\mathrm{aff}} B \circ_{\mathrm{aff}} A.$$

Apply the classifier-congruence clause of Definition 45.675 with conjugating factor T. The preceding equality transports to

$$\mathrm{Inn}_T(A \circ_{\mathrm{aff}} B) \equiv_{\mathrm{aff}} \mathrm{Inn}_T(B \circ_{\mathrm{aff}} A).$$

Apply the product-preservation clause of the same theorem to both sides. It identifies the left side with $\mathrm{Inn}_T(A) \circ_{\mathrm{aff}} \mathrm{Inn}_T(B)$ and the right side with $\mathrm{Inn}_T(B) \circ_{\mathrm{aff}} \mathrm{Inn}_T(A)$.

Symmetry and transitivity of $\equiv_{\mathrm{aff}}$ from the affine action certificate combine these two product comparisons with the transported equality. The resulting classifier equality is precisely the definition of $\mathsf{Cent}_F(\mathrm{Inn}_T(A); \mathrm{Inn}_T(B))$. □

Per-object template: traditional target affine centralizer conjugation transport; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit rows plus AffAut_F; carrier certified affine automorphisms; classifier $\equiv_{\mathrm{aff}}$; stability obligations inner-action classifier congruence and product preservation; ledger conjugating automorphism and inverse witness; core theorem list Definition 45.675 and Definition 45.689; exactness predicate centralizer membership transported by inner conjugation; standard bridge ordinary group centralizer conjugacy; status ProofTarget.

Definition 45.692 (RatUp FieldUp affine centralizer normalizer carrier)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object, and let $C_F(A)$ be the carrier from Definition 45.686. The concrete affine normalizer carrier of $C_F(A)$ is the predicate*

$$N_F(C_F(A))(T) :\Longleftrightarrow T : \mathsf{AffAut}_F \quad \textit{and} \quad \forall X : \mathsf{AffAut}_F,\ C_F(A)(X) \Longleftrightarrow C_F(A)(\mathrm{Conj}_T(X)),$$

where

$$\mathrm{Conj}_T(X) := (T \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(T)$$

uses the affine product and inverse row fixed by Definition 45.662.

Theorem 45.693 (RatUp FieldUp affine centralizer normalizer inclusion)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the carrier from Definition 45.686, and let $N_F(C_F(A))$ be the carrier from Definition 45.692. Then every centralizer element normalizes the centralizer in the two-sided sense:*

$$C_F(A)(T) \Rightarrow N_F(C_F(A))(T).$$

Equivalently, if T commutes with A, then inner affine conjugation by T both preserves and reflects centralizer membership:

$$C_F(A)(T) \Rightarrow \forall X : \mathsf{AffAut}_F, \quad C_F(A)(X) \Longleftrightarrow C_F(A)((T \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(T)).$$

Proof. Fix the canonical affine exit action from Definition 45.662. This fixes AffAut_F, $\circ_{\mathrm{aff}}$, id_F, $\iota_F(-)$, and $\equiv_{\mathrm{aff}}$ for the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object.

Assume $C_F(A)(T)$ and let $X : \mathsf{AffAut}_F$ be fixed. Apply Definition 45.687 to the fixed element A. Its inverse closure gives $C_F(A)(\iota_F(T))$.

For preservation, assume $C_F(A)(X)$. Product closure first gives $C_F(A)(T \circ_{\mathrm{aff}} X)$ and then gives $C_F(A)((T \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(T))$.

The displayed product is the concrete inner conjugate $\mathrm{Conj}_T(X)$ in the notation of Definition 45.692. The carrier certification and classifier stability of this inner conjugate are exactly the action clauses supplied by Definition 45.675.

For reflection, assume $C_F(A)((T \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(T))$. Apply the same preservation argument with $\iota_F(T)$ as the conjugating centralizer element and $\mathrm{Conj}_T(X)$ as the element being transported. Product closure gives $C_F(A)(\mathrm{Conj}_{\iota_F(T)}(\mathrm{Conj}_T(X)))$.

The affine conjugation equation exactness of Definition 45.672, together with the inverse row fixed above, identifies $\mathrm{Conj}_{\iota_F(T)}(\mathrm{Conj}_T(X))$ with X under $\equiv_{\mathrm{aff}}$. The classifier-stability row from Definition 45.675 transfers the centralizer membership back to $C_F(A)(X)$.

Reading the two directions through Definition 45.683 gives the equivalent commutator form: conjugation preserves and reflects the condition that the commutator with A is trivial under the concrete affine classifier. This is precisely $N_F(C_F(A))(T)$. □

Per-object template: traditional target centralizer normalizer inclusion; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit plus $\mathsf{Group}^{\uparrow}$; carrier $C_F(A)$ and $N_F(C_F(A))$; classifier $\equiv_{\mathrm{aff}}$; stability two-sided centralizer preservation, inverse, product, and inner-conjugation closure; ledger fixed element, conjugating element, commuting witness, inverse witness, and double-conjugation witness; core theorem list Definition 45.687, Definition 45.672, Definition 45.675, and Definition 45.683; exactness predicate normalizer records preservation and reflection of centralizer membership under concrete affine conjugation; standard bridge ordinary centralizer-normalizer inclusion; status $\mathsf{ProofTarget}$.

Theorem 45.694 (RatUp FieldUp affine center normal subgroup)**.** *For Definition 45.617, the concrete affine center predicate* Center_F *on certified affine automorphisms forms a normal subgroup package inside* AffAut_F*. Namely:*

1. $\mathsf{Center}_F(\mathrm{id}_F)$.
2. *If* $\mathsf{Center}_F(Z)$ *and* $\mathsf{Center}_F(W)$*, then* $\mathsf{Center}_F(Z \circ_{\mathrm{aff}} W)$.
3. *If* $\mathsf{Center}_F(Z)$*, then* $\mathsf{Center}_F(\iota_F(Z))$.
4. *If* $Z \equiv_{\mathrm{aff}} W$ *and* $\mathsf{Center}_F(Z)$*, then* $\mathsf{Center}_F(W)$.
5. *If* $\mathsf{Center}_F(Z)$*, then for every* $T : \mathsf{AffAut}_F$*,* $\mathsf{Center}_F(\mathrm{Inn}_T(Z))$.

Proof. Fix the canonical exit action and inverse package of Definition 45.662. This fixes the carrier AffAut_F, the product $\circ_{\mathrm{aff}}$, the identity id_F, the inverse row $\iota_F(-)$, the classifier $\equiv_{\mathrm{aff}}$, and the inner action Inn_T from Definition 45.675.

The identity member is central by the identity rows in Definition 45.556. For product closure, fix a test automorphism T and central elements Z, W. Associativity from Definition 45.554 exposes $W \circ_{\mathrm{aff}} T$ and then $Z \circ_{\mathrm{aff}} T$ as adjacent subproducts. Apply the two center equations and transport both replacements by Definition 45.553; the same associativity theorem repacks the result as $T \circ_{\mathrm{aff}} (Z \circ_{\mathrm{aff}} W)$.

For inverse closure, use Definition 45.678. If $\mathsf{Center}_F(Z)$, then every $\mathrm{Inn}_T(Z)$ is classifier-equal to Z. The inverse-preservation clause of Definition 45.675, together with classifier congruence, transports this fixed-point equation through $\iota_F(-)$ and gives $\mathrm{Inn}_T(\iota_F(Z)) \equiv_{\mathrm{aff}} \iota_F(Z)$ for every T. The fixed-point criterion returns $\mathsf{Center}_F(\iota_F(Z))$.

Classifier transport is pointwise: if $Z \equiv_{\mathrm{aff}} W$, then operation congruence replaces Z by W on both sides of the defining commutation equation for each test automorphism.

Finally assume $\mathsf{Center}_F(Z)$ and fix a conjugating element T. By Definition 45.678, Z is fixed by every inner affine action. For any test element S, Definition 45.676 rewrites $\mathrm{Inn}_S(\mathrm{Inn}_T(Z))$ as $\mathrm{Inn}_{S \circ_{\mathrm{aff}} T}(Z)$, which is classifier-equal to Z. The same criterion also identifies $\mathrm{Inn}_T(Z)$ with Z, and classifier transitivity yields $\mathrm{Inn}_S(\mathrm{Inn}_T(Z)) \equiv_{\mathrm{aff}} \mathrm{Inn}_T(Z)$. Applying the fixed-point criterion once more gives $\mathsf{Center}_F(\mathrm{Inn}_T(Z))$. □

Theorem 45.695 (RatUp FieldUp affine centralizer normalizer subgroup)**.** *For Definition 45.617, fix a certified affine automorphism* $A : \mathsf{AffAut}_F$ *in the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object. Let* $C_F(A)$ *be the affine centralizer carrier from Definition 45.686, and let* $N_F(C_F(A))$ *be the two-sided normalizer carrier from Definition 45.692. Then* $N_F(C_F(A))$ *is the concrete affine normalizer subgroup of* $C_F(A)$*:*

1. $N_F(C_F(A))(\mathrm{id}_F)$.
2. *If* $N_F(C_F(A))(T)$ *and* $N_F(C_F(A))(U)$*, then* $N_F(C_F(A))(T \circ_{\mathrm{aff}} U)$.
3. *If* $N_F(C_F(A))(T)$*, then* $N_F(C_F(A))(\iota_F(T))$.
4. *If* $N_F(C_F(A))(T)$ *and* $T \equiv_{\mathrm{aff}} U$*, then* $N_F(C_F(A))(U)$.

Proof. Fix the canonical affine exit action and inverse package from Definition 45.662. This fixes AffAut_F, $\circ_{\mathrm{aff}}$, id_F, $\iota_F(-)$, and $\equiv_{\mathrm{aff}}$ for the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object.

For the identity element, fix $X : \mathsf{AffAut}_F$. The identity clause of Definition 45.676 identifies $\mathrm{Conj}_{\mathrm{id}_F}(X)$ with X. Hence centralizer membership is preserved and reflected by identity conjugation, and the identity row of Definition 45.687 supplies the required carrier witness.

For product closure, assume $N_F(C_F(A))(T)$ and $N_F(C_F(A))(U)$, and fix $X : \mathsf{AffAut}_F$. If $C_F(A)(X)$, the two-sided definition first gives $C_F(A)(\mathrm{Conj}_U(X))$ and then gives $C_F(A)(\mathrm{Conj}_T(\mathrm{Conj}_U(X)))$. The composition clause of Definition 45.676 identifies the composite conjugation with conjugation by $T \circ_{\mathrm{aff}} U$, so the forward half gives $C_F(A)(\mathrm{Conj}_{T\circ_{\mathrm{aff}}U}(X))$.

Conversely assume $C_F(A)(\mathrm{Conj}_{T\circ_{\mathrm{aff}}U}(X))$. The same composition clause reads this as $C_F(A)(\mathrm{Conj}_T(\mathrm{Conj}_U(X)$ The reverse half of the two-sided definition for T gives $C_F(A)(\mathrm{Conj}_U(X))$, and the reverse half for U gives $C_F(A)(X)$.

For inverse closure, assume $N_F(C_F(A))(T)$ and fix $X : \mathsf{AffAut}_F$. Let $Y = \mathrm{Conj}_{\iota_F(T)}(X)$. The inverse antihomomorphism package of Definition 45.671 and the conjugation equation exactness of Definition 45.672 identify $\mathrm{Conj}_T(Y)$ with X under $\equiv_{\mathrm{aff}}$.

If $C_F(A)(X)$, transport this membership across the exactness comparison to $C_F(A)(\mathrm{Conj}_T(Y))$. The reverse half of the normalizer equivalence for T, applied to Y, gives $C_F(A)(Y)$. If $C_F(A)(Y)$, the forward half for T and the same double-conjugation exactness return $C_F(A)(X)$. Thus conjugation by $\iota_F(T)$ preserves and reflects centralizer membership, and the inverse row gives the carrier witness for $\iota_F(T)$.

For classifier transport, assume $N_F(C_F(A))(T)$ and $T \equiv_{\mathrm{aff}} U$. For each X, affine operation congruence from Definition 45.553 transports the conjugation word $(T \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(T)$ to $(U \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(U)$. The preservation and reflection clauses for T therefore give the same two-sided centralizer equivalence for U, and the carrier witness is transported along $T \equiv_{\mathrm{aff}} U$. □

Theorem 45.696 (RatUp FieldUp affine centralizer normalizer action automorphism)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the affine centralizer carrier from Definition 45.686, let $N_F(C_F(A))$ be the normalizer carrier from Definition 45.692, and define the restricted action by*

$$\mathrm{Act}_T(X) := \mathrm{Conj}_T(X) = (T \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(T).$$

If $N_F(C_F(A))(T)$ and $C_F(A)(X), C_F(A)(Y)$, then conjugation by T is an automorphism of the centralizer classifier:

1. $N_F(C_F(A))(\iota_F(T))$.
2. $C_F(A)(\mathrm{Act}_{\iota_F(T)}(X))$.
3. $$\mathrm{Act}_{\iota_F(T)}(\mathrm{Act}_T(X)) \equiv_{\mathrm{aff}} X \quad \textit{and} \quad \mathrm{Act}_T(\mathrm{Act}_{\iota_F(T)}(X)) \equiv_{\mathrm{aff}} X.$$
4. $$\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} \mathrm{Act}_T(Y) \Longleftrightarrow X \equiv_{\mathrm{aff}} Y.$$

Proof. The inverse normalizer witness is the inverse-closure row of Definition 45.695. Applied to $N_F(C_F(A))(T)$, it gives $N_F(C_F(A))(\iota_F(T))$.

Carrier preservation for the inverse action is then exactly the preservation part of Definition 45.697, specialized to the normalizer element $\iota_F(T)$ and the centralizer element X. This gives $C_F(A)(\mathrm{Act}_{\iota_F(T)}(X))$.

For cancellation, use Definition 45.673 with conjugating element T and acted element X. Its inverse-action clauses identify the two double conjugations by T and $\iota_F(T)$ with X under $\equiv_{\mathrm{aff}}$, which are precisely the two displayed Act-cancellation laws.

For classifier exactness, apply the same theorem to the pair X, Y. Its classifier-exact conjugation clause gives

$$\mathrm{Conj}_T(X) \equiv_{\mathrm{aff}} \mathrm{Conj}_T(Y) \Longleftrightarrow X \equiv_{\mathrm{aff}} Y.$$

Replacing $\mathrm{Conj}_T(-)$ by the definition of $\mathrm{Act}_T(-)$ gives the stated equivalence on the centralizer carrier. □

Per-object template: traditional target normalizer action by automorphisms; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ plus $\mathsf{Group}^{\uparrow}$; carrier $C_F(A)$; classifier $\equiv_{\mathrm{aff}}$; stability inverse action, classifier exactness, and cancellation; ledger fixed element, normalizer witness, acted element, and inverse witness; core theorem list Definition 45.695, Definition 45.697, and Definition 45.673; exactness predicate classifier-exact automorphism action on the centralizer; standard bridge ordinary normalizer action by automorphisms; status ProofTarget.

Theorem 45.697 (RatUp FieldUp affine centralizer normalizer action)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the affine centralizer carrier from Definition 45.686, and let $N_F(C_F(A))$ be the normalizer carrier from Definition 45.692. For $T : \mathsf{AffAut}_F$ define the restricted normalizer action on centralizer elements by*

$$\mathrm{Act}_T(X) := \mathrm{Conj}_T(X) = (T \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(T).$$

If $N_F(C_F(A))(T)$ and $C_F(A)(X)$, then

$$C_F(A)(\mathrm{Act}_T(X)).$$

The restricted action also obeys the identity and composition laws:

$$\mathrm{Act}_{\mathrm{id}_F}(X) \equiv_{\mathrm{aff}} X.$$

For $N_F(C_F(A))(T)$, $N_F(C_F(A))(U)$, and $C_F(A)(X)$,

$$\mathrm{Act}_T(\mathrm{Act}_U(X)) \equiv_{\mathrm{aff}} \mathrm{Act}_{T \circ_{\mathrm{aff}} U}(X).$$

Lean4 ✓ `BEDC.Derived.FieldUp.RatupFieldupAffineCentralizerNormalizerAction`

Proof. Unfold the normalizer carrier from Definition 45.692. Its preservation clause says exactly that a normalizing affine automorphism sends each $C_F(A)$-element to another $C_F(A)$-element by the concrete conjugation $\mathrm{Conj}_T(-)$. Since $\mathrm{Act}_T(X)$ is defined to be this conjugate, $N_F(C_F(A))(T)$ and $C_F(A)(X)$ give $C_F(A)(\mathrm{Act}_T(X))$.

For the identity law, apply Definition 45.676 with conjugating parameter id_F and acted element X. The identity clause of that theorem gives $\mathrm{Act}_{\mathrm{id}_F}(X) \equiv_{\mathrm{aff}} X$ under the same affine classifier.

For composition, first use the preservation clause of U to obtain $C_F(A)(\mathrm{Act}_U(X))$. Then use the preservation clause of T to keep the outer acted element inside $C_F(A)$. The composition clause of Definition 45.676, applied to T, U, and X, identifies the two affine words as

$$\mathrm{Act}_T(\mathrm{Act}_U(X)) \equiv_{\mathrm{aff}} \mathrm{Act}_{T \circ_{\mathrm{aff}} U}(X).$$

The carrier membership clauses come from the two normalizer hypotheses, while the classifier comparison is the concrete inner-action law already supplied for the $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit object. The inverse witnesses are the $\iota_F(T)$ and $\iota_F(U)$ rows fixed by the canonical affine inverse package, and the acted elements remain in the same centralizer carrier throughout. □

Per-object template: traditional target normalizer action on centralizer; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit plus $\mathsf{Group}^{\uparrow}$; carrier $C_F(A)$ acted on by $N_F(C_F(A))$; classifier $\equiv_{\mathrm{aff}}$; stability preservation, identity action, and composition action; ledger fixed element, conjugating elements, acted element, and inverse witnesses; core theorem list Definition 45.693, Definition 45.676, and Definition 45.675; exactness predicate restricted normalizer action; standard bridge ordinary normalizer action on a subgroup; status $\mathsf{ProofTarget}$.

Theorem 45.698 (RatUp FieldUp restricted normalizer action automorphism and kernel exactness)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the affine centralizer carrier from Definition 45.686, and let $N_F(C_F(A))$ be the normalizer carrier from Definition 45.692. For $T : \mathsf{AffAut}_F$ define*

$$\mathrm{Act}_T(X) := (T \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(T).$$

If $N_F(C_F(A))(T)$ and $C_F(A)(X)$, then Act_T is an automorphism of the centralizer carrier with inverse action $\mathrm{Act}_{\iota_F(T)}$:

1. $C_F(A)(\mathrm{Act}_{\iota_F(T)}(X))$.

2.

$$\mathrm{Act}_{\iota_F(T)}(\mathrm{Act}_T(X)) \equiv_{\mathrm{aff}} X.$$

3.

$$\mathrm{Act}_T(\mathrm{Act}_{\iota_F(T)}(X)) \equiv_{\mathrm{aff}} X.$$

For every T with $N_F(C_F(A))(T)$, the kernel of the restricted action is exactly the pointwise centralizer of $C_F(A)$:

$$(\forall X : \mathsf{AffAut}_F,\ C_F(A)(X) \Rightarrow \mathrm{Act}_T(X) \equiv_{\mathrm{aff}} X) \Longleftrightarrow (\forall X : \mathsf{AffAut}_F,\ C_F(A)(X) \Rightarrow C_F(X)(T)).$$

Proof. The inverse parameter lies in the same normalizer by the inverse-closure row of Definition 45.695. Applying Definition 45.697 to $\iota_F(T)$ and the centralizer element X gives $C_F(A)(\mathrm{Act}_{\iota_F(T)}(X))$.

For the two inverse-action identities, apply the composition law of Definition 45.697 first to $\iota_F(T)$ after T, and then to T after $\iota_F(T)$. The affine inverse laws from Definition 45.662 identify the parameters $\iota_F(T) \circ_{\mathrm{aff}} T$ and $T \circ_{\mathrm{aff}} \iota_F(T)$ with id_F. The identity-action row of the restricted action then reduces both composites to X under $\equiv_{\mathrm{aff}}$.

For the kernel equivalence, fix X with $C_F(A)(X)$. By Definition 45.686, the assertion $C_F(X)(T)$ says that T commutes with X in the concrete affine classifier. The fixed-point criterion Definition 45.689 identifies that commutation condition with $\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} X$. Quantifying this equivalence over all elements of $C_F(A)$ gives the displayed exactness statement. □

Per-object template: traditional target restricted normalizer action kernel exactness; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit plus $\mathsf{Group}^{\uparrow}$; carrier $C_F(A)$ acted on by $N_F(C_F(A))$; classifier $\equiv_{\mathrm{aff}}$; stability inverse action, two-sided cancellation, and pointwise kernel test; ledger fixed element, normalizer witness, acted element, inverse parameter, and centralizer-of-acted-element witness; core theorem list Definition 45.695, Definition 45.697, Definition 45.662, and Definition 45.689; exactness predicate action kernel iff centralizes every element of $C_F(A)$; standard bridge ordinary restricted normalizer action kernel; status $\mathsf{ProofTarget}$.

Theorem 45.699 (RatUp FieldUp affine centralizer normalizer action representation)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit*

object. Let $C_F(A)$ be the affine centralizer carrier from Definition 45.686, let $N_F(C_F(A))$ be the normalizer carrier from Definition 45.692, and define the restricted action by

$$\mathrm{Act}_T(X) := \mathrm{Conj}_T(X) = (T \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(T).$$

The assignment

$$T \longmapsto \mathrm{Act}_T$$

from $N_F(C_F(A))$ to classifier-exact automorphisms of $C_F(A)$ is a concrete homomorphic action representation. Concretely, if $N_F(C_F(A))(T)$, $N_F(C_F(A))(U)$, and $C_F(A)(X), C_F(A)(Y)$, then:

1. $C_F(A)(\mathrm{Act}_T(X))$.

2.

$$\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} \mathrm{Act}_T(Y) \Longleftrightarrow X \equiv_{\mathrm{aff}} Y.$$

3.

$$\mathrm{Act}_{\mathrm{id}_F}(X) \equiv_{\mathrm{aff}} X.$$

4.

$$\mathrm{Act}_T(\mathrm{Act}_U(X)) \equiv_{\mathrm{aff}} \mathrm{Act}_{T \circ_{\mathrm{aff}} U}(X).$$

5. $N_F(C_F(A))(\iota_F(T))$, and the inverse action is two-sided:

$$\mathrm{Act}_{\iota_F(T)}(\mathrm{Act}_T(X)) \equiv_{\mathrm{aff}} X \quad \textit{and} \quad \mathrm{Act}_T(\mathrm{Act}_{\iota_F(T)}(X)) \equiv_{\mathrm{aff}} X.$$

Proof. The carrier and homomorphism laws are supplied by Definition 45.697. Its preservation clause gives $C_F(A)(\mathrm{Act}_T(X))$, its identity clause gives the action of id_F, and its composition clause gives the displayed law for $T \circ_{\mathrm{aff}} U$.

The subgroup certificate Definition 45.695 supplies the normalizer bookkeeping for the representing source: identity membership, product closure, and the inverse witness $N_F(C_F(A))(\iota_F(T))$.

For the target automorphism attached to T, apply Definition 45.696. Its classifier-exactness clause gives the displayed equivalence on $\equiv_{\mathrm{aff}}$, and its inverse-action clauses give the two-sided cancellation formulas.

Finally, Definition 45.673 identifies these clauses with concrete affine conjugation in the $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Thus the map $T \mapsto \mathrm{Act}_T$ lands in the classifier-exact automorphisms of $C_F(A)$ and respects the normalizer multiplication by the stated composition law. □

Per-object template: traditional target normalizer action representation; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ plus $\mathsf{Group}^{\uparrow}$; carrier source $N_F(C_F(A))$ and acted carrier $C_F(A)$; classifier $\equiv_{\mathrm{aff}}$; stability carrier preservation, classifier exactness, identity action, composition action, and inverse action; ledger fixed element, normalizer witnesses, acted elements, and inverse witness; core theorem list Definition 45.695, Definition 45.697, Definition 45.696, and Definition 45.673; exactness predicate concrete homomorphic action representation into classifier-exact automorphisms; standard bridge ordinary normalizer representation by automorphisms; status $\mathsf{ProofTarget}$.

Definition 45.700 (RatUp FieldUp affine centralizer automorphism package)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the affine centralizer carrier from Definition 45.686. For maps $f, g : \mathsf{AffAut}_F \to \mathsf{AffAut}_F$, write $\mathsf{CentAut}_A(f, g)$ for the following classifier-exact self-automorphism package on the concrete carrier $C_F(A)$:*

1. *if* $C_F(A)(X)$*, then* $C_F(A)(f(X))$*;*
2. *if* $C_F(A)(X)$*, then* $C_F(A)(g(X))$*;*
3. *if* $C_F(A)(X)$*, then* $g(f(X)) \equiv_{\mathrm{aff}} X$*;*
4. *if* $C_F(A)(X)$*, then* $f(g(X)) \equiv_{\mathrm{aff}} X$*;*
5. *if* $C_F(A)(X)$ *and* $C_F(A)(Y)$*, then*

$$f(X) \equiv_{\mathrm{aff}} f(Y) \Longleftrightarrow X \equiv_{\mathrm{aff}} Y.$$

Theorem 45.701 (RatUp FieldUp affine centralizer normalizer action homomorphism)**.** *For Definition 45.617, fix a certified affine automorphism* $A : \mathsf{AffAut}_F$ *in the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object. Let* $C_F(A)$ *be the affine centralizer carrier from Definition 45.686, let* $N_F(C_F(A))$ *be the normalizer carrier from Definition 45.692, and set*

$$\rho_A(T) := \mathrm{Act}_T, \qquad \mathrm{Act}_T(X) := (T \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(T).$$

Then the assignment ρ_A *sends every* T *with* $N_F(C_F(A))(T)$ *to*

$$\mathsf{CentAut}_A(\mathrm{Act}_T, \mathrm{Act}_{\iota_F(T)}).$$

It respects the affine classifier on normalizer elements: if $N_F(C_F(A))(T)$*,* $N_F(C_F(A))(U)$*, and* $T \equiv_{\mathrm{aff}} U$*, then for every* X *with* $C_F(A)(X)$*,*

$$\rho_A(T)(X) \equiv_{\mathrm{aff}} \rho_A(U)(X).$$

It sends id_F *to the identity action,*

$$\rho_A(\mathrm{id}_F)(X) \equiv_{\mathrm{aff}} X,$$

and sends affine products to composite actions: if $N_F(C_F(A))(T)$*,* $N_F(C_F(A))(U)$*, and* $C_F(A)(X)$*, then*

$$\rho_A(T \circ_{\mathrm{aff}} U)(X) \equiv_{\mathrm{aff}} \rho_A(T)(\rho_A(U)(X)).$$

The inverse action in the automorphism package is $\mathrm{Act}_{\iota_F(T)}$*.*

Proof. The automorphism package is supplied pointwise by Definition 45.696. For a fixed normalizer witness $N_F(C_F(A))(T)$, that theorem gives inverse normalizer membership for $\iota_F(T)$, preservation of $C_F(A)$ by both Act_T and $\mathrm{Act}_{\iota_F(T)}$, the two cancellation laws $\mathrm{Act}_{\iota_F(T)}(\mathrm{Act}_T(X)) \equiv_{\mathrm{aff}} X$ and $\mathrm{Act}_T(\mathrm{Act}_{\iota_F(T)}(X)) \equiv_{\mathrm{aff}} X$, and the classifier-exact equivalence for the forward action.

The normalizer domain used by this package is the subgroup supplied by Definition 45.695. Its identity, product, inverse, and classifier-transport rows make the source of ρ_A an ordinary classifier group on the concrete normalizer carrier.

Classifier respect follows by applying Definition 45.676 to the two conjugation words determined by T and U. The affine classifier hypothesis $T \equiv_{\mathrm{aff}} U$ transports the outer conjugating parameter and its canonical inverse through the same pointwise classifier, so the resulting actions agree on every $C_F(A)$ element.

The identity row is exactly the identity action clause of Definition 45.697. The source identity belongs to $N_F(C_F(A))$ by Definition 45.695, and the displayed comparison is the classifier identity on the centralizer element.

For products, first use Definition 45.697 to keep $\mathrm{Act}_U(X)$ inside $C_F(A)$. Then apply Definition 45.676; it identifies the inner action of $T \circ_{\mathrm{aff}} U$ with the composite action by U followed by T under $\equiv_{\mathrm{aff}}$. This is the displayed homomorphism law for ρ_A.

The inverse action row is the inverse half of the same automorphism package. For every normalizer element T, the inverse-closure row of Definition 45.695 places $\iota_F(T)$ back in the source carrier, and Definition 45.696 identifies $\mathrm{Act}_{\iota_F(T)}$ as the inverse self-action on $C_F(A)$. □

Per-object template: target normalizer representation; source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit; acted carrier $C_F(A)$; source carrier $N_F(C_F(A))$; action classifier $\equiv_{\mathrm{aff}}$; automorphism package $\mathsf{CentAut}_A$; identity law for id_F; product law for $T \circ_{\mathrm{aff}} U$; inverse action $\mathrm{Act}_{\iota_F(T)}$; standard bridge ordinary homomorphism into centralizer automorphisms.

Theorem 45.702 (RatUp FieldUp restricted normalizer action kernel normality)**.** *For Definition 45.714, the carrier K_A is the normal kernel of the restricted normalizer action on $C_F(A)$. Concretely:*

1. $K_A(\mathrm{id}_F)$.
2. *If $K_A(T)$ and $K_A(U)$, then $K_A(T \circ_{\mathrm{aff}} U)$.*
3. *If $K_A(T)$, then $K_A(\iota_F(T))$.*
4. *If $K_A(T)$ and $N_F(C_F(A))(U)$, then*

$$K_A(U \circ_{\mathrm{aff}} T \circ_{\mathrm{aff}} \iota_F(U)).$$

Proof. The identity element belongs to K_A because Definition 45.695 supplies $N_F(C_F(A))(\mathrm{id}_F)$, and the representation identity row in Definition 45.699 gives $\mathrm{Act}_{\mathrm{id}_F}(X) \equiv_{\mathrm{aff}} X$ for every $C_F(A)$ element.

For product closure, the same subgroup certificate gives $N_F(C_F(A))(T \circ_{\mathrm{aff}} U)$. Given $C_F(A)(X)$, the composition row of Definition 45.699 identifies $\mathrm{Act}_{T \circ_{\mathrm{aff}} U}(X)$ with $\mathrm{Act}_T(\mathrm{Act}_U(X))$. The fixed-point hypothesis for $K_A(U)$ reduces the inner action to X, and the fixed-point hypothesis for $K_A(T)$ then reduces the outer action to X.

For inverse closure, the inverse row of Definition 45.695 places $\iota_F(T)$ in $N_F(C_F(A))$. For X in $C_F(A)$, the inverse-action rows of Definition 45.698 make $\mathrm{Act}_{\iota_F(T)}$ the two-sided inverse of Act_T on the centralizer carrier. Since $K_A(T)$ makes Act_T pointwise equal to the identity action, its inverse action is pointwise equal to the identity action as well.

For conjugation, subgroup closure first gives $N_F(C_F(A))(U \circ_{\mathrm{aff}} T \circ_{\mathrm{aff}} \iota_F(U))$. Fix X with $C_F(A)(X)$. The inverse-preservation row puts $\mathrm{Act}_{\iota_F(U)}(X)$ back in $C_F(A)$, so the hypothesis $K_A(T)$ fixes that acted element. Applying Act_U and then using the two-sided inverse-action law for U reduces the conjugated action to X. Thus every conjugate of a kernel element by a normalizer element again lies in K_A. □

Per-object template: target restricted normalizer action kernel normality; source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit; acted carrier $C_F(A)$; source carrier $N_F(C_F(A))$; kernel carrier K_A; classifier $\equiv_{\mathrm{aff}}$; stability identity, product, inverse, and conjugation inside the normalizer; ledger fixed element, kernel witness, normalizer witness, inverse parameter, and acted centralizer witness; core theorem list Definition 45.695, Definition 45.699, and Definition 45.698; exactness predicate pointwise fixed restricted action on $C_F(A)$; standard bridge ordinary normal kernel of a group action representation; downstream consumer faithful quotient representation of the normalizer on centralizer orbits; status $\mathsf{ProofTarget}$.

Theorem 45.703 (RatUp FieldUp affine centralizer normalizer action certificate)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the affine centralizer carrier from Definition 45.686, and let $N_F(C_F(A))$ be the normalizer carrier from Definition 45.692. For each $T : \mathsf{AffAut}_F$ define*

$$\mathrm{Act}_T(X) := (T \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(T).$$

If $N_F(C_F(A))(T)$, $N_F(C_F(A))(U)$, $C_F(A)(X)$, $C_F(A)(Y)$, $T \equiv_{\mathrm{aff}} U$, and $X \equiv_{\mathrm{aff}} Y$, then the restricted action is classifier well-defined:

$$\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} \mathrm{Act}_U(Y).$$

Moreover, for every T with $N_F(C_F(A))(T)$, the inverse affine automorphism is again a normalizer element,

$$N_F(C_F(A))(\iota_F(T)),$$

and for every X with $C_F(A)(X)$ the two restricted actions cancel:

$$\mathrm{Act}_{\iota_F(T)}(\mathrm{Act}_T(X)) \equiv_{\mathrm{aff}} X \quad \textit{and} \quad \mathrm{Act}_T(\mathrm{Act}_{\iota_F(T)}(X)) \equiv_{\mathrm{aff}} X.$$

Proof. Fix the concrete affine exit package supplied by Definition 45.662. It fixes the carrier AffAut_F, the operation $\circ_{\mathrm{aff}}$, the inverse operation $\iota_F(-)$, and the classifier $\equiv_{\mathrm{aff}}$ for the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit object.

For classifier well-definedness, first apply Definition 45.553 to the left action factor and the acted element. This transports $T \circ_{\mathrm{aff}} X$ to $U \circ_{\mathrm{aff}} Y$ under the affine classifier. The same congruence theorem, applied to the right inverse factors and using the inverse determinacy encoded by Definition 45.675, transports the full conjugation word $(T \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(T)$ to $(U \circ_{\mathrm{aff}} Y) \circ_{\mathrm{aff}} \iota_F(U)$. This is exactly $\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} \mathrm{Act}_U(Y)$.

For the inverse normalizer clause, apply the inverse row of Definition 45.695 to $N_F(C_F(A))(T)$. It gives $N_F(C_F(A))(\iota_F(T))$.

Finally, use Definition 45.672 with conjugating element T and acted element X. Its two inverse-action cancellation clauses identify conjugation by $\iota_F(T)$ after conjugation by T, and conjugation by T after conjugation by $\iota_F(T)$, with the original acted element X under $\equiv_{\mathrm{aff}}$. Since Act is the restricted notation for these conjugation words on $C_F(A)$, the displayed restricted cancellation laws follow. □

Per-object template: traditional target group action by a normalizer on a centralizer; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit plus $\mathsf{Group}^{\uparrow}$; carrier $C_F(A)$ acted on by $N_F(C_F(A))$; classifier $\equiv_{\mathrm{aff}}$; stability obligations classifier well-definedness and inverse-action cancellation; ledger normalizer witness, inverse witness, acted element, and conjugation factors; core theorem list Definition 45.695, Definition 45.697, Definition 45.675, and Definition 45.672; exactness predicate restricted action certificate; standard bridge ordinary normalizer action on a subgroup; status $\mathsf{ProofTarget}$.

Theorem 45.704 (RatUp FieldUp affine normalizer action kernel)**.** *For Definition 45.617, fix certified affine automorphisms $A, T : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the affine centralizer carrier from Definition 45.686, let $N_F(C_F(A))$ be the normalizer carrier from Definition 45.692, and define the restricted action by*

$$\mathrm{Act}_T(X) := \mathrm{Conj}_T(X) = (T \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(T).$$

If $N_F(C_F(A))(T)$, then the pointwise kernel condition for the restricted normalizer action is exactly commutation with every element of the centralizer:

$$(\forall X : \mathsf{AffAut}_F,\ C_F(A)(X) \Rightarrow \mathrm{Act}_T(X) \equiv_{\mathrm{aff}} X) \iff (\forall X : \mathsf{AffAut}_F,\ C_F(A)(X) \Rightarrow C_F(X)(T)).$$

Proof. Assume $N_F(C_F(A))(T)$. The restricted action theorem Definition 45.697 supplies the domain condition: whenever $C_F(A)(X)$ holds, $\mathrm{Act}_T(X)$ is again an element of the same concrete centralizer carrier. The present claim identifies which normalizing elements act as the classifier identity on all such X.

For the forward direction, fix $X : \mathsf{AffAut}_F$ with $C_F(A)(X)$ and assume $\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} X$. Unfolding the action gives the inner conjugation fixed-point equation $\mathrm{Inn}_T(X) \equiv_{\mathrm{aff}} X$. Apply Definition 45.689 to the pair T, X and read the fixed-point condition as the commutation equation $T \circ_{\mathrm{aff}} X \equiv_{\mathrm{aff}} X \circ_{\mathrm{aff}} T$.

By Definition 45.686, this commutation equation is precisely the centralizer membership statement $C_F(X)(T)$. Since X was arbitrary inside $C_F(A)$, the required pointwise centralizer condition follows.

For the reverse direction, fix $X : \mathsf{AffAut}_F$ with $C_F(A)(X)$ and assume $C_F(X)(T)$. Reading Definition 45.686 gives $T \circ_{\mathrm{aff}} X \equiv_{\mathrm{aff}} X \circ_{\mathrm{aff}} T$. Apply Definition 45.689 again, now in the reverse direction for the pair T, X, to obtain $\mathrm{Inn}_T(X) \equiv_{\mathrm{aff}} X$.

Finally replace $\mathrm{Inn}_T(X)$ by the displayed definition of $\mathrm{Act}_T(X)$. This gives $\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} X$ for every X in $C_F(A)$, so the restricted normalizer action is pointwise trivial exactly on the stated kernel. □

Per-object template: traditional target normalizer action kernel; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit plus $\mathsf{Group}^{\uparrow}$; carrier $C_F(A)$ acted on by $N_F(C_F(A))$; classifier $\equiv_{\mathrm{aff}}$; stability normalizer-supplied restricted action domain and pointwise classifier identity; ledger fixed centralizer element, normalizing element, inverse witness, and commutation certificate; core theorem list Definition 45.697, Definition 45.689, and Definition 45.686; exactness predicate kernel iff commutation with every centralizer element; standard bridge ordinary normalizer action kernel on a centralizer; status ProofTarget.

Theorem 45.705 (RatUp FieldUp affine center normalizes centralizers)**.** *For Definition 45.617, let $A, Z : \mathsf{AffAut}_F$ be certified affine automorphisms in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. If Z is in the concrete affine center, then Z normalizes the concrete affine centralizer of A:*

$$\mathsf{Center}_F(Z) \Rightarrow N_F(C_F(A))(Z).$$

Moreover, for every $X : \mathsf{AffAut}_F$ with $C_F(A)(X)$, the restricted normalizer action from Definition 45.697 is pointwise the classifier identity:

$$\mathrm{Act}_Z(X) \equiv_{\mathrm{aff}} X.$$

Proof. Assume $\mathsf{Center}_F(Z)$. Apply Definition 45.688 and read the first equivalence forward at the fixed automorphism A. This gives the concrete centralizer witness $C_F(A)(Z)$.

Now apply Definition 45.693 to that witness. The conclusion is exactly $N_F(C_F(A))(Z)$, with the normalizer carrier read as the two-sided preservation predicate of Definition 45.692.

For the pointwise identity, fix $X : \mathsf{AffAut}_F$ with $C_F(A)(X)$. The center hypothesis, unfolded at the test element X, says that Z and X commute under $\equiv_{\mathrm{aff}}$.

Apply Definition 45.689 to the pair (Z, X). The commuting row identifies the inner affine conjugate $\mathrm{Act}_Z(X)$ with X under the same classifier. The action theorem Definition 45.697 supplies the restricted-action reading on the carrier $C_F(A)$, and the normalizer membership already proved supplies the required action domain. □

Per-object template: traditional target center action on centralizers; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit plus $\mathsf{Group}^{\uparrow}$; carrier $C_F(A)$ and center predicate; classifier $\equiv_{\mathrm{aff}}$; stability center intersection, normalizer inclusion, fixed-point criterion, and restricted action; ledger fixed element, center witness, centralizer witness, and inverse row; core theorem list Definition 45.688, Definition 45.693, Definition 45.689, and Definition 45.697; exactness predicate center element acts as classifier identity on centralizer elements; standard bridge ordinary group center action on centralizers; status $\mathsf{ProofTarget}$.

Theorem 45.706 (RatUp FieldUp affine centralizer normalizer action inverse)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the affine centralizer carrier from Definition 45.686, and let $N_F(C_F(A))$ be the normalizer carrier from Definition 45.692. For $T : \mathsf{AffAut}_F$ define*

$$\mathrm{Act}_T(X) := (T \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(T).$$

If $N_F(C_F(A))(T)$ and $C_F(A)(X)$, then the restricted action is invertible on the centralizer:

1. $C_F(A)(\mathrm{Act}_T(X))$.
2. $C_F(A)(\mathrm{Act}_{\iota_F(T)}(X))$.
3. $$\mathrm{Act}_{\iota_F(T)}(\mathrm{Act}_T(X)) \equiv_{\mathrm{aff}} X.$$
4. $$\mathrm{Act}_T(\mathrm{Act}_{\iota_F(T)}(X)) \equiv_{\mathrm{aff}} X.$$

Proof. Fix the canonical affine exit action and inverse package from Definition 45.662. It supplies the carrier AffAut_F, product $\circ_{\mathrm{aff}}$, inverse operation $\iota_F(-)$, classifier $\equiv_{\mathrm{aff}}$, and the inverse rows for the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object.

The forward carrier clause is exactly the preservation part of Definition 45.697 applied to T and X.

For the inverse carrier clause, use Definition 45.695 on $N_F(C_F(A))(T)$. Its inverse row gives $N_F(C_F(A))(\iota_F(T))$. Applying Definition 45.697 again, now with conjugating element $\iota_F(T)$ and acted element X, gives $C_F(A)(\mathrm{Act}_{\iota_F(T)}(X))$.

We next compose the two restricted actions. The composition law in Definition 45.697 gives

$$\mathrm{Act}_{\iota_F(T)}(\mathrm{Act}_T(X)) \equiv_{\mathrm{aff}} \mathrm{Act}_{\iota_F(T)\circ_{\mathrm{aff}}T}(X).$$

The left inverse row from the canonical package identifies $\iota_F(T) \circ_{\mathrm{aff}} T$ with id_F. Classifier congruence for Definition 45.675, followed by the identity clause of Definition 45.697, identifies the right side with X. Classifier transitivity yields the displayed left inverse law.

The right inverse law is the same calculation in the other order. The composition law gives

$$\mathrm{Act}_T(\mathrm{Act}_{\iota_F(T)}(X)) \equiv_{\mathrm{aff}} \mathrm{Act}_{T\circ_{\mathrm{aff}}\iota_F(T)}(X).$$

The right inverse row from the canonical package identifies $T \circ_{\mathrm{aff}} \iota_F(T)$ with id_F, and the same classifier congruence plus identity-action clause reduces the displayed action to X. □

Per-object template: traditional target invertible normalizer action on centralizer; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ plus $\mathsf{Group}^{\uparrow}$; carrier $C_F(A)$ acted on by $N_F(C_F(A))$; classifier $\equiv_{\mathrm{aff}}$; stability forward preservation, inverse-parameter preservation, and two-sided action inverse laws;

ledger fixed element, acted element, conjugator, inverse witness, and centralizer witnesses; core theorem list Definition 45.697, Definition 45.695, Definition 45.675, and Definition 45.662; exactness predicate restricted action invertibility on centralizer elements; standard bridge ordinary normalizer group action by bijections; status ProofTarget.

Theorem 45.707 (RatUp FieldUp affine centralizer normalizer action classifier congruence)**.** *For Definition 45.617, fix $A : \mathsf{AffAut}_F$. Let $C_F(A)$ be the affine centralizer carrier, let $N_F(C_F(A))$ be its normalizer carrier, and define $\mathrm{Act}_T(X)$ as in Definition 45.697. If $N_F(C_F(A))(T)$, $N_F(C_F(A))(U)$, $C_F(A)(X)$, $C_F(A)(Y)$, $T \equiv_{\mathrm{aff}} U$, and $X \equiv_{\mathrm{aff}} Y$, then*

$$\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} \mathrm{Act}_U(Y).$$

Consequently each normalizer element determines a classifier-respecting endomap of $C_F(A)$, and classifier-equal normalizer elements determine classifier-equal endomaps of $C_F(A)$.

Proof. Use Definition 45.697 for the endpoint carrier membership: $N_F(C_F(A))(T)$ sends every $C_F(A)$-element to $C_F(A)$ by Act_T, and likewise for U.

The affine inverse congruence clause of Definition 45.553 transports $T \equiv_{\mathrm{aff}} U$ to $\iota_F(T) \equiv_{\mathrm{aff}} \iota_F(U)$. Apply the operation-congruence clause of the same theorem to $T \circ_{\mathrm{aff}} X$ and $U \circ_{\mathrm{aff}} Y$, using $T \equiv_{\mathrm{aff}} U$ and $X \equiv_{\mathrm{aff}} Y$.

Apply operation congruence once more to compose the resulting comparison with the inverse comparison. This gives

$$(T \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(T) \equiv_{\mathrm{aff}} (U \circ_{\mathrm{aff}} Y) \circ_{\mathrm{aff}} \iota_F(U).$$

Unfolding the definition of Act in Definition 45.697 identifies the two sides with $\mathrm{Act}_T(X)$ and $\mathrm{Act}_U(Y)$. Setting $U = T$ gives classifier respect for the acted coordinate, while setting $Y = X$ shows that classifier-equal normalizer elements induce classifier-equal restricted endomaps. □

Per-object template: traditional target well-defined normalizer action on a classified centralizer; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit object plus $\mathsf{Group}^{\uparrow}$ action laws; carrier $C_F(A)$ acted on by $N_F(C_F(A))$; classifier $\equiv_{\mathrm{aff}}$; stability classifier congruence in acting and acted coordinates; ledger conjugating element, acted element, inverse witness, and normalizer witnesses; core theorem list Definition 45.697 and Definition 45.553; exactness predicate restricted action respects the affine classifier; standard bridge ordinary normalizer action on a subgroup; status ProofTarget.

Theorem 45.708 (RatUp FieldUp canonical exit source-coordinate obstruction)**.** *Let $d_1 := \mathsf{E1}(\mathsf{e})$. For Definition 45.617, the canonical $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit certificate has the concrete source-coordinate witnesses*

$$\mathsf{RatHistoryCarrier}(d_1),$$

$$\mathsf{RatHistoryClassifier}(d_1, d_1),$$

and

$$\mathsf{RatHistoryLedgerPolicy}(d_1, d_1).$$

Each attempted coverage map from these carrier, classifier, or ledger coordinates to the singleton empty-history $\mathsf{Field}^{\uparrow}$ boundary is contradictory. Equivalently, the canonical exit certificate cannot collapse to that singleton boundary in any of its carrier, classifier, or ledger coordinates.

Proof. Invoke Definition 45.651. It identifies the canonical exit object of Definition 45.617 with the concrete $\mathsf{RatUpFieldSource}_F$ source, whose carrier, classifier, and ledger coordinates are the displayed RatUp history rows.

Now apply Definition 45.492 at $d_1 = \mathsf{E1(e)}$. That theorem supplies the three witnesses $\mathsf{RatHistoryCarrier}(d_1)$, $\mathsf{RatHistoryClassifier}(d_1, d_1)$, and $\mathsf{RatHistoryLedgerPolicy}(d_1, d_1)$, and rejects carrier coverage, classifier coverage, and ledger endpoint coverage into the singleton empty-history boundary.

Transporting those three rejections along the canonical-exit identification leaves no coordinate map by which the canonical $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit certificate can be read as the singleton empty-history $\mathsf{Field}^{\uparrow}$ boundary. □

Definition 45.709 (RatUp FieldUp affine centralizer normalizer orbit relation)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the affine centralizer carrier, let $N_F(C_F(A))$ be its normalizer carrier, and define $\mathrm{Act}_T(X)$ as in Definition 45.697. On carried centralizer elements $X, Y : \mathsf{AffAut}_F$ with $C_F(A)(X)$ and $C_F(A)(Y)$, define*

$$X \sim_{N_F(A)} Y \iff \exists T : \mathsf{AffAut}_F,\ N_F(C_F(A))(T) \text{ and } \mathrm{Act}_T(X) \equiv_{\mathrm{aff}} Y.$$

Theorem 45.710 (RatUp FieldUp affine centralizer normalizer action orbit coverage)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the affine centralizer carrier, let $N_F(C_F(A))$ be its normalizer carrier, let* Act *be the restricted normalizer action of Definition 45.697, and let $\sim_{N_F(A)}$ be the orbit relation of Definition 45.709. For $X, T : \mathsf{AffAut}_F$, if $C_F(A)(X)$ and $N_F(C_F(A))(T)$, then*

$$C_F(A)(\mathrm{Act}_T(X)) \quad \text{and} \quad X \sim_{N_F(A)} \mathrm{Act}_T(X).$$

Proof. Apply Definition 45.697 to the carried source endpoint X and the normalizer element T. Its carried-endpoint row gives $C_F(A)(\mathrm{Act}_T(X))$.

For the orbit assertion, choose the same T as the existential witness in Definition 45.709. The witness is valid by the given hypothesis $N_F(C_F(A))(T)$.

It remains only to close the classifier endpoint. Reflexivity of $\equiv_{\mathrm{aff}}$ on $\mathrm{Act}_T(X)$ gives $\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} \mathrm{Act}_T(X)$, so the displayed witness proves $X \sim_{N_F(A)} \mathrm{Act}_T(X)$. □

Per-object template: traditional target normalizer-action orbit coverage; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ plus $\mathsf{Group}^{\uparrow}$; carrier $C_F(A)$; classifier $\equiv_{\mathrm{aff}}$; stability direct action reachability; ledger acting normalizer and acted endpoint; core theorem Definition 45.710 with Definition 45.697; exactness predicate action steps are orbit witnesses; standard bridge ordinary group-action orbit coverage; status $\mathsf{ProofTarget}$.

Theorem 45.711 (RatUp FieldUp affine centralizer normalizer orbit equivalence)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. The relation $\sim_{N_F(A)}$ of Definition 45.709 is reflexive, symmetric, and transitive on the affine centralizer carrier $C_F(A)$. More explicitly, for $X, Y, Z : \mathsf{AffAut}_F$ with $C_F(A)(X)$, $C_F(A)(Y)$, and $C_F(A)(Z)$:*

1. *$X \sim_{N_F(A)} X$.*
2. *If $X \sim_{N_F(A)} Y$, then $Y \sim_{N_F(A)} X$.*
3. *If $X \sim_{N_F(A)} Y$ and $Y \sim_{N_F(A)} Z$, then $X \sim_{N_F(A)} Z$.*

Proof. 1. For reflexivity, use the identity row of Definition 45.695. It gives $N_F(C_F(A))(\mathrm{id}_F)$.

The identity row of Definition 45.697 gives $\mathrm{Act}_{\mathrm{id}_F}(X) \equiv_{\mathrm{aff}} X$. Thus id_F is the required orbit witness for $X \sim_{N_F(A)} X$.

2. For symmetry, suppose $X \sim_{N_F(A)} Y$ and choose a witness $T : \mathsf{AffAut}_F$ with $N_F(C_F(A))(T)$ and $\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} Y$. The inverse row of Definition 45.695 gives $N_F(C_F(A))(\iota_F(T))$.

The two-sided inverse laws in Definition 45.706 identify $\mathrm{Act}_{\iota_F(T)}(\mathrm{Act}_T(X))$ with X. Transport the endpoint comparison $\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} Y$ through the restricted action using Definition 45.707. Classifier symmetry and transitivity then give $\mathrm{Act}_{\iota_F(T)}(Y) \equiv_{\mathrm{aff}} X$, so $\iota_F(T)$ witnesses $Y \sim_{N_F(A)} X$.

3. For transitivity, suppose $X \sim_{N_F(A)} Y$ via T and $Y \sim_{N_F(A)} Z$ via U. The product row of Definition 45.695 gives $N_F(C_F(A))(U \circ_{\mathrm{aff}} T)$.

The composition row of Definition 45.697 identifies $\mathrm{Act}_U(\mathrm{Act}_T(X))$ with $\mathrm{Act}_{U \circ_{\mathrm{aff}} T}(X)$. Transport the comparison $\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} Y$ through the action by U, then compose it with $\mathrm{Act}_U(Y) \equiv_{\mathrm{aff}} Z$. Classifier symmetry and transitivity yield $\mathrm{Act}_{U \circ_{\mathrm{aff}} T}(X) \equiv_{\mathrm{aff}} Z$, so $U \circ_{\mathrm{aff}} T$ witnesses $X \sim_{N_F(A)} Z$.

□

Per-object template: traditional target normalizer orbit relation on a centralizer; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit object plus $\mathsf{Group}^{\uparrow}$; carrier $C_F(A)$ with orbit witnesses in $N_F(C_F(A))$; classifier $\equiv_{\mathrm{aff}}$; stability reflexivity, symmetry, and transitivity of $\sim_{N_F(A)}$; ledger fixed element, source endpoint, target endpoint, intermediate endpoint, conjugator, inverse conjugator, and product conjugator; core theorem list Definition 45.695, Definition 45.697, Definition 45.706, and Definition 45.707; exactness predicate normalizer-action reachability is an equivalence relation on carried centralizer elements; standard bridge ordinary group-action orbit equivalence relation; status $\mathsf{ProofTarget}$.

Theorem 45.712 (RatUp FieldUp affine centralizer normalizer orbit classifier congruence)**.** *For Definition 45.617, fix $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the affine centralizer carrier, let $N_F(C_F(A))$ be its normalizer carrier, define $\mathrm{Act}_T(X)$ as in Definition 45.697, and let $\sim_{N_F(A)}$ be the reachability relation of Definition 45.709. If $C_F(A)(X)$, $C_F(A)(X')$, $C_F(A)(Y)$, $C_F(A)(Y')$, $X \equiv_{\mathrm{aff}} X'$, $Y \equiv_{\mathrm{aff}} Y'$, and $X \sim_{N_F(A)} Y$, then*

$$X' \sim_{N_F(A)} Y'.$$

Proof. Choose the same normalizer witness from $X \sim_{N_F(A)} Y$. Thus there is $T : \mathsf{AffAut}_F$ with $N_F(C_F(A))(T)$ and $\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} Y$.

Apply Definition 45.707 with the acting coordinate T classifier-equal to itself and with the acted coordinate transported from X' to X by classifier symmetry. This gives

$$\mathrm{Act}_T(X') \equiv_{\mathrm{aff}} \mathrm{Act}_T(X).$$

Compose this comparison with the witness endpoint $\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} Y$, and then with the supplied endpoint comparison $Y \equiv_{\mathrm{aff}} Y'$. Affine classifier transitivity yields

$$\mathrm{Act}_T(X') \equiv_{\mathrm{aff}} Y'.$$

The same T still lies in $N_F(C_F(A))$, so the displayed endpoint comparison is precisely the data required by Definition 45.709 to witness $X' \sim_{N_F(A)} Y'$. □

Per-object template: traditional target classifier-stable orbit reachability; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine normalizer action; carrier $C_F(A)$; classifier $\equiv_{\text{aff}}$ on endpoints plus $\sim_{N_F(A)}$ as reachability; stability endpoint replacement; ledger endpoint witnesses and normalizer witness; core theorem list Definition 45.709, Definition 45.711, and Definition 45.707; exactness predicate orbit reachability is well-defined on classified centralizer elements; standard bridge ordinary orbit relation under a group action; status $\mathsf{ProofTarget}$.

Theorem 45.713 (RatUp FieldUp affine centralizer normalizer orbit classifier transport)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the affine centralizer carrier, let $N_F(C_F(A))$ be its normalizer carrier, and let $\sim_{N_F(A)}$ be the orbit relation of Definition 45.709. If $X, Y, X', Y' : \mathsf{AffAut}_F$ satisfy $C_F(A)(X)$, $C_F(A)(Y)$, $C_F(A)(X')$, $C_F(A)(Y')$, $X \sim_{N_F(A)} Y$, $X \equiv_{\text{aff}} X'$, and $Y \equiv_{\text{aff}} Y'$, then*

$$X' \sim_{N_F(A)} Y'.$$

Proof. Choose the normalizer witness $T : \mathsf{AffAut}_F$ from $X \sim_{N_F(A)} Y$. Thus $N_F(C_F(A))(T)$ and $\mathrm{Act}_T(X) \equiv_{\text{aff}} Y$.

Apply Definition 45.707 with the same acting element in both acting slots. Using classifier reflexivity for T and the endpoint comparison $X \equiv_{\text{aff}} X'$, this gives

$$\mathrm{Act}_T(X) \equiv_{\text{aff}} \mathrm{Act}_T(X').$$

By classifier symmetry, read the last display from $\mathrm{Act}_T(X')$ back to $\mathrm{Act}_T(X)$. Compose it by classifier transitivity with the original orbit endpoint comparison $\mathrm{Act}_T(X) \equiv_{\text{aff}} Y$ and then with $Y \equiv_{\text{aff}} Y'$. The result is

$$\mathrm{Act}_T(X') \equiv_{\text{aff}} Y'.$$

The same witness T therefore satisfies the defining clause of $X' \sim_{N_F(A)} Y'$. □

Per-object template: traditional target orbit-relation descent; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ plus $\mathsf{Group}^{\uparrow}$; carrier $C_F(A)$; classifier $\equiv_{\text{aff}}$; stability endpoint classifier transport; ledger source endpoint, target endpoint, transported endpoints, and normalizer witness; exactness orbit reachability stable under affine classifier.

Definition 45.714 (RatUp FieldUp affine normalizer action kernel carrier)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the affine centralizer carrier from Definition 45.686, let $N_F(C_F(A))$ be the normalizer carrier from Definition 45.692, and write the restricted normalizer action as*

$$\mathrm{Act}_T(X) := (T \circ_{\text{aff}} X) \circ_{\text{aff}} \iota_F(T).$$

The pointwise kernel carrier of this action is the predicate K_A on certified affine automorphisms given by

$$K_A(T) := N_F(C_F(A))(T) \text{ and } \quad \forall X : \mathsf{AffAut}_F,\ C_F(A)(X) \Rightarrow \mathrm{Act}_T(X) \equiv_{\text{aff}} X.$$

Theorem 45.715 (RatUp FieldUp affine normalizer action kernel normal subgroup)**.** *For Definition 45.617, fix $A : \mathsf{AffAut}_F$. The carrier K_A of Definition 45.714 is a normal subgroup package inside the affine normalizer $N_F(C_F(A))$:*

1. $K_A(\mathrm{id}_F)$.

2. *If $K_A(T)$ and $K_A(U)$, then $K_A(T \circ_{\mathrm{aff}} U)$.*
3. *If $K_A(T)$, then $K_A(\iota_F(T))$.*
4. *If $K_A(T)$, $N_F(C_F(A))(U)$, and $T \equiv_{\mathrm{aff}} U$, then $K_A(U)$.*
5. *If $K_A(T)$ and $N_F(C_F(A))(S)$, then $K_A(S \circ_{\mathrm{aff}} T \circ_{\mathrm{aff}} \iota_F(S))$.*

Proof. The carrier part of each clause is supplied by Definition 45.695. Its identity, product, inverse, and classifier-transport rows keep the first four displayed witnesses inside $N_F(C_F(A))$; for the conjugation word, use the inverse row on S and the product row twice.

For the identity element, use the identity law in Definition 45.697. For every X with $C_F(A)(X)$, it gives $\mathrm{Act}_{\mathrm{id}_F}(X) \equiv_{\mathrm{aff}} X$, so the pointwise kernel predicate holds.

For products, assume $K_A(T)$ and $K_A(U)$ and fix X with $C_F(A)(X)$. The composition law in Definition 45.697 rewrites $\mathrm{Act}_{T \circ_{\mathrm{aff}} U}(X)$ as $\mathrm{Act}_T(\mathrm{Act}_U(X))$. The U-kernel hypothesis identifies the inner acted element with X, and the T-kernel hypothesis then identifies the outer action with X.

For inverses, start with $K_A(T)$. The inverse theorem Definition 45.706 identifies $\mathrm{Act}_{\iota_F(T)}$ as a two-sided inverse of Act_T on $C_F(A)$. Since Act_T is pointwise the classifier identity there, the inverse action is also pointwise the classifier identity.

For classifier transport, assume $K_A(T)$, $N_F(C_F(A))(U)$, and $T \equiv_{\mathrm{aff}} U$. The action classifier congruence theorem Definition 45.707 transports the pointwise equality $\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} X$ to $\mathrm{Act}_U(X) \equiv_{\mathrm{aff}} X$ for each X in $C_F(A)$.

Finally assume $K_A(T)$ and $N_F(C_F(A))(S)$. For any X with $C_F(A)(X)$, apply the composition law twice to rewrite

$$\mathrm{Act}_{S \circ_{\mathrm{aff}} T \circ_{\mathrm{aff}} \iota_F(S)}(X)$$

as

$$\mathrm{Act}_S(\mathrm{Act}_T(\mathrm{Act}_{\iota_F(S)}(X))).$$

The inverse theorem keeps $\mathrm{Act}_{\iota_F(S)}(X)$ inside $C_F(A)$. Apply the $K_A(T)$ hypothesis to this middle acted element, obtaining $\mathrm{Act}_T(\mathrm{Act}_{\iota_F(S)}(X)) \equiv_{\mathrm{aff}} \mathrm{Act}_{\iota_F(S)}(X)$. Acting by S on both sides and using classifier congruence reduces the displayed conjugation action to $\mathrm{Act}_S(\mathrm{Act}_{\iota_F(S)}(X))$.

The right inverse cancellation clause of Definition 45.706 identifies this last term with X. Hence $S \circ_{\mathrm{aff}} T \circ_{\mathrm{aff}} \iota_F(S)$ lies in K_A, giving normality inside the concrete affine normalizer. □

Per-object template: traditional target kernel normal subgroup of a group action; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit plus $\mathsf{Group}^{\uparrow}$; carrier K_A; classifier $\equiv_{\mathrm{aff}}$; stability subgroup and conjugation closure; ledger fixed centralizer, acting normalizer, inverse witness, and conjugation word; core theorem list Definition 45.695, Definition 45.697, Definition 45.706, and Definition 45.707; exactness predicate pointwise trivial action; standard bridge ordinary kernel of a group action; status ProofTarget.

Definition 45.716 (RatUp FieldUp affine normalizer same-action classifier)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$. For carried normalizer elements $S, T : \mathsf{AffAut}_F$ with $N_F(C_F(A))(S)$ and $N_F(C_F(A))(T)$, define the restricted-action classifier predicate by*

$$S \equiv_{\rho_A} T :\Longleftrightarrow K_A(\iota_F(S) \circ_{\mathrm{aff}} T).$$

This is a classifier predicate over the concrete normalizer carrier $N_F(C_F(A))$. It records relative membership in the concrete action kernel K_A and does not introduce a quotient construction.

Theorem 45.717 (RatUp FieldUp restricted normalizer action kernel fiber exactness)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$. Let $C_F(A)$ be its concrete affine centralizer, let $N_F(C_F(A))$ be the corresponding normalizer, let $\mathrm{Act}_T(X)$ denote the restricted normalizer action, and let K_A be the kernel carrier of Definition 45.714. If $N_F(C_F(A))(S)$ and $N_F(C_F(A))(T)$, then*

$$K_A(\iota_F(S) \circ_{\mathrm{aff}} T) \Longleftrightarrow \forall X : \mathsf{AffAut}_F,\ C_F(A)(X) \Rightarrow \mathrm{Act}_S(X) \equiv_{\mathrm{aff}} \mathrm{Act}_T(X).$$

Proof. The normalizer subgroup theorem Definition 45.695 places $\iota_F(S)$ in $N_F(C_F(A))$ and then places $\iota_F(S) \circ_{\mathrm{aff}} T$ in $N_F(C_F(A))$. Thus the displayed left side is a genuine instance of the kernel predicate from Definition 45.714.

For the forward direction, assume $K_A(\iota_F(S) \circ_{\mathrm{aff}} T)$ and fix X with $C_F(A)(X)$. The representation law in Definition 45.699 rewrites the action of $\iota_F(S) \circ_{\mathrm{aff}} T$ on X as $\mathrm{Act}_{\iota_F(S)}(\mathrm{Act}_T(X))$. The kernel hypothesis identifies this element with X.

Apply Act_S to that equality, using the classifier-exact action row of Definition 45.699. The inverse-action cancellation rows from Definition 45.698 reduce $\mathrm{Act}_S(\mathrm{Act}_{\iota_F(S)}(\mathrm{Act}_T(X)))$ to $\mathrm{Act}_T(X)$. Hence $\mathrm{Act}_T(X)$ and $\mathrm{Act}_S(X)$ are classifier-equal, which is the required pointwise equality after symmetry of $\equiv_{\mathrm{aff}}$.

For the reverse direction, assume the pointwise equality of the two restricted actions on every X with $C_F(A)(X)$. The carrier part of $K_A(\iota_F(S) \circ_{\mathrm{aff}} T)$ is the normalizer product constructed in the first paragraph.

It remains to show pointwise fixed action. Fix X with $C_F(A)(X)$. By the representation law, $\mathrm{Act}_{\iota_F(S)\circ_{\mathrm{aff}}T}(X)$ is classifier-equal to $\mathrm{Act}_{\iota_F(S)}(\mathrm{Act}_T(X))$. Transport the assumed pointwise equality $\mathrm{Act}_S(X) \equiv_{\mathrm{aff}} \mathrm{Act}_T(X)$ through the classifier-exact action $\mathrm{Act}_{\iota_F(S)}$.

The result identifies $\mathrm{Act}_{\iota_F(S)}(\mathrm{Act}_T(X))$ with $\mathrm{Act}_{\iota_F(S)}(\mathrm{Act}_S(X))$. The remaining inverse-action cancellation row from Definition 45.698 reduces this last element to X. Therefore $\iota_F(S) \circ_{\mathrm{aff}} T$ fixes every centralizer element and lies in K_A. □

Per-object template: traditional target kernel fiber of a concrete group action representation; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit plus $\mathsf{Group}^{\uparrow}$; carrier $N_F(C_F(A))$; classifier pointwise $\equiv_{\mathrm{aff}}$ on actions; ledger $S, T, \iota_F(S) \circ_{\mathrm{aff}} T$; core theorem list Definition 45.695, Definition 45.699, Definition 45.698, and Definition 45.715; exactness predicate same action iff kernel difference; standard bridge ordinary group-action kernel fiber; status $\mathsf{ProofTarget}$.

Theorem 45.718 (RatUp FieldUp affine normalizer same-action classifier determinacy)**.** *For Definition 45.716, fix $A, S, T : \mathsf{AffAut}_F$. If $N_F(C_F(A))(S)$ and $N_F(C_F(A))(T)$, then*

$$S \equiv_{\rho_A} T \Longleftrightarrow \forall X : \mathsf{AffAut}_F,\ C_F(A)(X) \Rightarrow \mathrm{Act}_S(X) \equiv_{\mathrm{aff}} \mathrm{Act}_T(X).$$

Proof. By Definition 45.716, $S \equiv_{\rho_A} T$ is the predicate $K_A(\iota_F(S) \circ_{\mathrm{aff}} T)$. Apply Definition 45.717. □

Per-object template: traditional target faithful action modulo kernel; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit plus $\mathsf{Group}^{\uparrow}$; carrier $N_F(C_F(A))$; classifier $\equiv_{\rho_A}$; stability kernel membership and pointwise restricted-action equality; ledger fixed centralizer element, two normalizer witnesses, inverse parameter, product parameter, and acted element; core theorem list Definition 45.695, Definition 45.699, Definition 45.717, and Definition 45.715; exactness predicate same restricted action iff relative kernel membership; standard bridge ordinary group-action kernel criterion; status $\mathsf{ProofTarget}$.

Theorem 45.719 (RatUp FieldUp affine normalizer same-action classifier stability)**.** *For Definition 45.716, fix a certified affine automorphism $A : \mathsf{AffAut}_F$. On the carried normalizer elements of $N_F(C_F(A))$, the restricted-action classifier $S \equiv_{\rho_A} T$ satisfies the following certificate rows:*

1. *if $N_F(C_F(A))(S)$, then $S \equiv_{\rho_A} S$;*
2. *if $N_F(C_F(A))(S)$, $N_F(C_F(A))(T)$, and $S \equiv_{\rho_A} T$, then $T \equiv_{\rho_A} S$;*
3. *if $N_F(C_F(A))(S)$, $N_F(C_F(A))(T)$, $N_F(C_F(A))(U)$, $S \equiv_{\rho_A} T$, and $T \equiv_{\rho_A} U$, then $S \equiv_{\rho_A} U$;*
4. *if $N_F(C_F(A))(S)$, $N_F(C_F(A))(T)$, $S \equiv_{\rho_A} T$, $S \equiv_{\mathrm{aff}} S'$, and $T \equiv_{\mathrm{aff}} T'$, then the normalizer carrier transports to $N_F(C_F(A))(S')$ and $N_F(C_F(A))(T')$, and $S' \equiv_{\rho_A} T'$.*

Thus the concrete same-action predicate is reflexive, symmetric, transitive, and stable under endpoint replacement by the affine classifier without adding a quotient type.

Proof. Use Definition 45.718 as the translation between $S \equiv_{\rho_A} T$ and pointwise equality of the restricted actions on $C_F(A)$.

For reflexivity, fix $X : \mathsf{AffAut}_F$ with $C_F(A)(X)$. The two restricted actions are the same expression, so affine classifier reflexivity gives $\mathrm{Act}_S(X) \equiv_{\mathrm{aff}} \mathrm{Act}_S(X)$. Determinacy packs this pointwise row into $S \equiv_{\rho_A} S$.

For symmetry, determinacy expands $S \equiv_{\rho_A} T$ into $\mathrm{Act}_S(X) \equiv_{\mathrm{aff}} \mathrm{Act}_T(X)$ for every carried centralizer element X. Affine classifier symmetry reverses each displayed comparison, and determinacy repacks the reversed pointwise row as $T \equiv_{\rho_A} S$.

For transitivity, expand the two hypotheses by determinacy. At each carried centralizer element X, affine classifier transitivity composes $\mathrm{Act}_S(X) \equiv_{\mathrm{aff}} \mathrm{Act}_T(X)$ with $\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} \mathrm{Act}_U(X)$. Determinacy then packs the resulting pointwise comparison into $S \equiv_{\rho_A} U$.

For endpoint replacement, first use the normalizer carrier transport rows on $S \equiv_{\mathrm{aff}} S'$ and $T \equiv_{\mathrm{aff}} T'$ to place S' and T' in $N_F(C_F(A))$. Determinacy expands $S \equiv_{\rho_A} T$ to the pointwise restricted-action equality between S and T.

Now fix X with $C_F(A)(X)$. Apply Definition 45.707 to the acting endpoint comparison $S \equiv_{\mathrm{aff}} S'$ and the reflexive endpoint comparison $X \equiv_{\mathrm{aff}} X$; this compares $\mathrm{Act}_S(X)$ with $\mathrm{Act}_{S'}(X)$. Apply the same congruence row to $T \equiv_{\mathrm{aff}} T'$ and the same carried X; this compares $\mathrm{Act}_T(X)$ with $\mathrm{Act}_{T'}(X)$.

Affine classifier symmetry and transitivity compose these two endpoint comparisons with the pointwise equality between $\mathrm{Act}_S(X)$ and $\mathrm{Act}_T(X)$. The result is $\mathrm{Act}_{S'}(X) \equiv_{\mathrm{aff}} \mathrm{Act}_{T'}(X)$ for every carried centralizer element X, and determinacy packs it as $S' \equiv_{\rho_A} T'$. □

Per-object template: traditional target kernel-induced action classifier stability; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit plus $\mathsf{Group}^{\uparrow}$; carrier $N_F(C_F(A))$; classifier $\equiv_{\rho_A}$; stability rows reflexive, symmetric, transitive, and endpoint transport; ledger acting normalizer witnesses, inverse-product kernel witness, and acted centralizer element; core theorem this block; exactness predicate same restricted action is a stable classifier; standard bridge ordinary action modulo kernel; status ProofTarget.

Theorem 45.720 (RatUp FieldUp operation table raw-continuation separation)**.** *For every $u : \mathsf{BHist}$, the concrete table of Definition 45.587 satisfies its listed $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ table laws. Moreover, if $\mathsf{RatHistoryCarrier}(u)$ holds and an attempted certificate identifies the $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ multiplication slot on $\mathsf{RatHistoryCarrier}$ with raw Cont while carrying the right-unit row*

$$\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(d, u, r) \to \mathsf{RatHistoryClassifier}(r, d),$$

then the attempted identification implies False. *Consequently the denominator continuation row remains a denominator-side coordinate of the concrete table and is separated from the* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *multiplication coordinate.*

Proof. First apply Definition 45.588. It gives the carrier, classifier, ring-base, denominator, contextual, context-pair, affine, inverse, nonzero, and exit noncollapse rows for the concrete table of Definition 45.587.

Now fix $u : \mathsf{BHist}$ and assume $\mathsf{RatHistoryCarrier}(u)$. Also assume that the attempted $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ multiplication slot is identified with raw Cont on $\mathsf{RatHistoryCarrier}$ and that the displayed right-unit classifier row is carried by the same certificate.

Apply Definition 45.147 to the same u. Its hypotheses are exactly the carried-unit witness, the raw Cont multiplication identification, and the displayed right-unit row, so its conclusion is False.

The contradiction removes only the proposed identification of the multiplication slot with raw continuation. The positive table laws remain supplied by Definition 45.588, so continuation stays inside the denominator coordinate and not inside the $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ multiplication coordinate. □

Theorem 45.721 (RatUp FieldUp affine centralizer normalizer orbit action invariance)**.** *For Definition 45.617, fix a certified affine automorphism* $A : \mathsf{AffAut}_F$ *in the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object. Let* $C_F(A)$ *be the affine centralizer carrier, let* $N_F(C_F(A))$ *be its normalizer carrier, and let* $\sim_{N_F(A)}$ *be the orbit relation of Definition 45.709. For carried centralizer elements* $X, Y : \mathsf{AffAut}_F$ *and a normalizer element* $S : \mathsf{AffAut}_F$*, if* $C_F(A)(X)$*,* $C_F(A)(Y)$*,* $X \sim_{N_F(A)} Y$*, and* $N_F(C_F(A))(S)$*, then*

$$\mathrm{Act}_S(X) \sim_{N_F(A)} \mathrm{Act}_S(Y).$$

Proof. Choose an orbit witness $T : \mathsf{AffAut}_F$ for $X \sim_{N_F(A)} Y$, so $N_F(C_F(A))(T)$ and $\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} Y$. The inverse row of Definition 45.695 gives $N_F(C_F(A))(\iota_F(S))$, and the product row gives the composite witness

$$N_F(C_F(A))(S \circ_{\mathrm{aff}} T \circ_{\mathrm{aff}} \iota_F(S)).$$

It remains to identify the action of this composite witness on $\mathrm{Act}_S(X)$. Apply the composition rows of Definition 45.697 to reassociate the restricted action, and use Definition 45.706 to cancel the adjacent $\iota_F(S)$ and S actions. The result is classifier-equal to $\mathrm{Act}_S(\mathrm{Act}_T(X))$.

Now transport $\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} Y$ through the action by S using Definition 45.707. Classifier transitivity identifies the composite action on $\mathrm{Act}_S(X)$ with $\mathrm{Act}_S(Y)$. Hence $S \circ_{\mathrm{aff}} T \circ_{\mathrm{aff}} \iota_F(S)$ is an orbit witness for $\mathrm{Act}_S(X) \sim_{N_F(A)} \mathrm{Act}_S(Y)$. □

Per-object template: traditional target action invariance of normalizer orbits; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit plus $\mathsf{Group}^{\uparrow}$; carrier $C_F(A)$; classifier $\equiv_{\mathrm{aff}}$; stability orbit invariance under certified action; ledger acting normalizer, orbit witness, inverse acting normalizer, and composite witness; core theorem Definition 45.721; exactness predicate orbit classes are stable under the certified action; standard bridge ordinary group-action orbit invariance; status $\mathsf{ProofTarget}$.

Theorem 45.722 (RatUp FieldUp affine centralizer normalizer orbit action equivalence)**.** *For Definition 45.617, fix a certified affine automorphism* $A : \mathsf{AffAut}_F$ *in the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object. Let* $C_F(A)$ *be the affine centralizer carrier, let* $N_F(C_F(A))$ *be its normalizer carrier, and let* $\sim_{N_F(A)}$ *be the orbit relation of Definition 45.709. For carried centralizer elements* $X, Y : \mathsf{AffAut}_F$ *and a normalizer element* $S : \mathsf{AffAut}_F$*, if* $C_F(A)(X)$*,* $C_F(A)(Y)$*, and* $N_F(C_F(A))(S)$*, then*

$$\mathrm{Act}_S(X) \sim_{N_F(A)} \mathrm{Act}_S(Y) \quad \Longleftrightarrow \quad X \sim_{N_F(A)} Y.$$

Proof. For the forward direction, assume $\mathrm{Act}_S(X) \sim_{N_F(A)} \mathrm{Act}_S(Y)$. The action theorem supplies the carried centralizer endpoints $\mathrm{Act}_S(X)$ and $\mathrm{Act}_S(Y)$. The inverse row of Definition 45.695 gives $N_F(C_F(A))(\iota_F(S))$.

Apply Definition 45.721 to the acted endpoints and to $\iota_F(S)$. This gives

$$\mathrm{Act}_{\iota_F(S)}(\mathrm{Act}_S(X)) \sim_{N_F(A)} \mathrm{Act}_{\iota_F(S)}(\mathrm{Act}_S(Y)).$$

The inverse-action theorem Definition 45.706 cancels both displayed endpoints back to X and Y, and classifier transport for the orbit relation yields $X \sim_{N_F(A)} Y$.

For the reverse direction, assume $X \sim_{N_F(A)} Y$. Then Definition 45.721 applied to S gives $\mathrm{Act}_S(X) \sim_{N_F(A)} \mathrm{Act}_S(Y)$ directly. □

Per-object template: traditional target orbit-action descent and reflection; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit plus $\mathsf{Group}^{\uparrow}$; carrier $C_F(A)$; classifier orbit relation $\sim_{N_F(A)}$; stability preserve-and-reflect under normalizer action; ledger normalizer witness, inverse witness, acted endpoints, and orbit witness; core theorem Definition 45.721, Definition 45.695, and Definition 45.706; exactness predicate normalizer action is classifier-exact on orbit reachability; standard bridge ordinary group-action orbit automorphism; status $\mathsf{ProofTarget}$.

Definition 45.723 (RatUp FieldUp affine normalizer point stabilizer)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the affine centralizer carrier and let $N_F(C_F(A))$ be its affine normalizer carrier. For a carried centralizer element $X : \mathsf{AffAut}_F$ with $C_F(A)(X)$, the point-stabilizer carrier $\mathrm{Stab}_{A,X}$ is the predicate on certified affine automorphisms defined by*

$$\mathrm{Stab}_{A,X}(T) := N_F(C_F(A))(T) \text{ and } \quad \mathrm{Act}_T(X) \equiv_{\mathrm{aff}} X,$$

where Act_T is the restricted normalizer action of Definition 45.697.

Theorem 45.724 (RatUp FieldUp affine normalizer point stabilizer subgroup)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ and a carried centralizer element $X : \mathsf{AffAut}_F$ with $C_F(A)(X)$. The carrier $\mathrm{Stab}_{A,X}$ of Definition 45.723 is a subgroup package inside $N_F(C_F(A))$:*

1. $\mathrm{Stab}_{A,X}(\mathrm{id}_F)$.
2. *If* $\mathrm{Stab}_{A,X}(T)$ *and* $\mathrm{Stab}_{A,X}(U)$*, then* $\mathrm{Stab}_{A,X}(T \circ_{\mathrm{aff}} U)$.
3. *If* $\mathrm{Stab}_{A,X}(T)$*, then* $\mathrm{Stab}_{A,X}(\iota_F(T))$.
4. *If* $\mathrm{Stab}_{A,X}(T)$*,* $N_F(C_F(A))(U)$*, and* $T \equiv_{\mathrm{aff}} U$*, then* $\mathrm{Stab}_{A,X}(U)$.

Proof. The normalizer component of each row is supplied by Definition 45.695. Its identity, product, inverse, and classifier-transport clauses keep the displayed affine words inside $N_F(C_F(A))$.

For the identity row, use the identity law in Definition 45.697. Applied to the fixed carried point X, it gives $\mathrm{Act}_{\mathrm{id}_F}(X) \equiv_{\mathrm{aff}} X$.

For product closure, assume $\mathrm{Stab}_{A,X}(T)$ and $\mathrm{Stab}_{A,X}(U)$. The composition law in Definition 45.697 identifies the product action on X with $\mathrm{Act}_T(\mathrm{Act}_U(X))$. The U-stabilizer row fixes X, and the acting-coordinate part of Definition 45.707 transports the remaining action to $\mathrm{Act}_T(X)$. The T-stabilizer row then identifies the result with X.

For inverse closure, assume $\mathrm{Stab}_{A,X}(T)$. The inverse theorem Definition 45.706 supplies cancellation between the actions of T and $\iota_F(T)$ on the centralizer carrier. Since T fixes X up to $\equiv_{\mathrm{aff}}$, endpoint transport by Definition 45.707 turns the inverse cancellation row into $\mathrm{Act}_{\iota_F(T)}(X) \equiv_{\mathrm{aff}} X$.

For classifier transport, assume $\mathrm{Stab}_{A,X}(T)$, $N_F(C_F(A))(U)$, and $T \equiv_{\mathrm{aff}} U$. The endpoint and acting coordinates in Definition 45.707 transport $\mathrm{Act}_T(X) \equiv_{\mathrm{aff}} X$ to $\mathrm{Act}_U(X) \equiv_{\mathrm{aff}} X$. This gives the transported stabilizer row inside the normalizer. □

Per-object template: traditional target point stabilizer of a group action; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine normalizer action plus $\mathsf{Group}^{\uparrow}$; carrier $\mathrm{Stab}_{A,X}$; classifier $\equiv_{\mathrm{aff}}$; stability identity, product, inverse, and transport; ledger fixed centralizer point, acting normalizer, inverse witness, and action word; core theorem Definition 45.724; exactness predicate fixed-point action on one carried centralizer element; standard bridge ordinary point stabilizer subgroup; status ProofTarget.

Theorem 45.725 (RatUp FieldUp concrete certificate boundary)**.** *For the named source tuple* $\mathsf{RatUpFieldSource}_F$ *of Definition 45.488, the following four assertions form one concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *interface fact.*

1. *The tuple satisfies Definition 45.337 by the assembled boundary theorem Definition 45.489.*
2. *Its lower algebra coordinates are compatible with the concrete* $\mathsf{Monoid}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{AbGroup}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, *and* $\mathsf{CommRing}^{\uparrow}$ *reducts by Definition 45.659.*
3. *Its denominator operation coordinate has the checked functional laws of Definition 45.324 and the checked relational laws of Definition 45.325; the endpoint bridge Definition 45.326 identifies a displayed* $\mathsf{Cont}(h,k,r)$ *endpoint with* $\mu_D(h,k)$ *through* R_D *under* $C_D(h)$ *and* $C_D(k)$.
4. *Any certificate identifying the* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *multiplication slot with raw* Cont *on* RatHistoryCarrier *while carrying the displayed right-unit row contradicts Definition 45.720.*

Thus the assembled object records the certificate obligations, the lower algebra reduct interface, the denominator append and relational law packages, their endpoint identification through R_D*, and the raw-continuation separation as one FieldUp(RatUp) boundary.*

Proof. First apply Definition 45.489. It unpacks $\mathsf{RatUpFieldSource}_F$ over BHist and supplies the carrier, classifier, commutative-ring base, inverse, nonzero, denominator, contextual-action, context-pair, and affine rows required by Definition 45.337.

Next apply Definition 45.659. This places the same concrete source over the already certified $\mathsf{Monoid}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{AbGroup}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, and $\mathsf{CommRing}^{\uparrow}$ reducts, so the FieldUp certificate is read against the lower algebra hierarchy without schematic operation parameters.

For the denominator coordinate, first invoke Definition 45.324 and Definition 45.325. These give the functional append rows and the relational Cont rows as separate checked denominator law packages.

Then invoke Definition 45.326. For carried denominator histories h and k, it identifies a displayed continuation endpoint r with the functional append endpoint $\mu_D(h,k)$ exactly through $R_D(r, \mu_D(h,k))$.

Finally use Definition 45.720. Its negative clause applies exactly to an attempted multiplication-slot identification with raw Cont on RatHistoryCarrier carrying the right-unit row, while its positive clause leaves the concrete operation table laws intact. Hence the denominator continuation coordinate remains separated from the $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ multiplication coordinate. □

Per-object template: traditional target concrete constructive field certificate for $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source BHist with RatHistoryCarrier, RatHistoryClassifier, denominator append and Cont law packages connected at endpoints through R_D, and lower algebra reducts; classifier RatHistoryClassifier plus the affine classifier where used; ledger ring rows, denominator histories, continuation witnesses,

inverse witnesses, contextual pairs, and affine witnesses; core theorem list Definition 45.489, Definition 45.659, Definition 45.324, Definition 45.325, Definition 45.326, and Definition 45.720; exactness predicate assembled obligations with raw-continuation separation; standard bridge ordinary constructive rational field interface; status ProofTarget.

Theorem 45.726 (RatUp FieldUp normalizer kernel collapses orbit action)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the affine centralizer carrier, let $N_F(C_F(A))$ be its normalizer carrier, let K_A be the kernel carrier of Definition 45.714, let* Act *be the restricted normalizer action, and let $\sim_{N_F(A)}$ be the orbit relation of Definition 45.709. For carried centralizer elements $X, Y : \mathsf{AffAut}_F$, a normalizer element $S : \mathsf{AffAut}_F$, and a kernel element $T : \mathsf{AffAut}_F$, if $C_F(A)(X)$, $C_F(A)(Y)$, $X \sim_{N_F(A)} Y$, $N_F(C_F(A))(S)$, and $K_A(T)$, then $C_F(A)(\mathrm{Act}_{S\circ_{\mathrm{aff}}T}(X))$, $C_F(A)(\mathrm{Act}_S(Y))$, and*

$$\mathrm{Act}_{S\circ_{\mathrm{aff}}T}(X) \sim_{N_F(A)} \mathrm{Act}_S(Y).$$

Proof. The kernel hypothesis contains the carrier witness $N_F(C_F(A))(T)$. Combine it with $N_F(C_F(A))(S)$ by the product row of Definition 45.695; this certifies $S \circ_{\mathrm{aff}} T$ as a normalizer element. The action theorem Definition 45.697 then gives the centralizer carrier of $\mathrm{Act}_{S\circ_{\mathrm{aff}}T}(X)$, and the same theorem applied to S gives the carrier of $\mathrm{Act}_S(Y)$.

For the classifier comparison, use the composition row of Definition 45.697 to identify $\mathrm{Act}_{S\circ_{\mathrm{aff}}T}(X)$ with $\mathrm{Act}_S(\mathrm{Act}_T(X))$. Since $K_A(T)$ is pointwise trivial on carried centralizer elements, it identifies $\mathrm{Act}_T(X)$ with X. The action classifier congruence theorem transports this equality through the action by S, so $\mathrm{Act}_{S\circ_{\mathrm{aff}}T}(X)$ is classifier-equal to $\mathrm{Act}_S(X)$.

Apply Definition 45.721 to the original orbit witness $X \sim_{N_F(A)} Y$ and the normalizer element S. It gives $\mathrm{Act}_S(X) \sim_{N_F(A)} \mathrm{Act}_S(Y)$. Transport the left endpoint across the classifier equality above using the orbit classifier congruence and transport rows, yielding the displayed orbit relation for $\mathrm{Act}_{S\circ_{\mathrm{aff}}T}(X)$ and $\mathrm{Act}_S(Y)$. □

Per-object template: traditional target kernel collapse for the induced normalizer action on centralizer orbit classes; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit plus $\mathsf{Group}^{\uparrow}$; carrier $C_F(A)$; classifier $\equiv_{\mathrm{aff}}$; stability kernel factors act trivially after passing to normalizer orbits; ledger acting normalizer, kernel factor, product normalizer, centralizer endpoints, and transported orbit witness; core theorem Definition 45.726; exactness predicate normalizer action on centralizer orbit classes; standard bridge ordinary quotient action by the kernel of a group action; status ProofTarget.

Definition 45.727 (RatUp FieldUp right-kernel normalizer representatives)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let K_A be the kernel carrier of Definition 45.714. For affine normalizer representatives $S, S' : \mathsf{AffAut}_F$, define right-kernel representative equivalence by*

$$S \equiv^{\mathrm{right}}_{K_A} S' \iff \exists T : \mathsf{AffAut}_F,\ K_A(T) \text{ and } S' \equiv_{\mathrm{aff}} S \circ_{\mathrm{aff}} T.$$

Theorem 45.728 (RatUp FieldUp normalizer kernel representatives act equally on orbit classes)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the affine centralizer carrier, let $N_F(C_F(A))$ be its normalizer carrier, let K_A be the kernel carrier of Definition 45.714, let* Act *be the restricted normalizer action, and let $\sim_{N_F(A)}$ be the orbit relation of Definition 45.709. For carried centralizer elements $X, Y : \mathsf{AffAut}_F$ and normalizer representatives $S, S' : \mathsf{AffAut}_F$, if $C_F(A)(X)$, $C_F(A)(Y)$, $X \sim_{N_F(A)} Y$, $N_F(C_F(A))(S)$, $N_F(C_F(A))(S')$, and $S \equiv^{\mathrm{right}}_{K_A} S'$, then $C_F(A)(\mathrm{Act}_S(Y))$, $C_F(A)(\mathrm{Act}_{S'}(X))$, and*

$$\mathrm{Act}_{S'}(X) \sim_{N_F(A)} \mathrm{Act}_S(Y).$$

Proof. Unpack $S \equiv_{K_A}^{\text{right}} S'$ and choose $T : \mathsf{AffAut}_F$ with $K_A(T)$ and $S' \equiv_{\text{aff}} S \circ_{\text{aff}} T$. The normalizer action theorem Definition 45.697 applied to S and Y gives $C_F(A)(\mathrm{Act}_S(Y))$, and the same theorem applied to S' and X gives $C_F(A)(\mathrm{Act}_{S'}(X))$.

Apply Definition 45.726 to S, T, X, Y. It uses the kernel factor T and the orbit witness $X \sim_{N_F(A)} Y$ to produce

$$\mathrm{Act}_{S \circ_{\text{aff}} T}(X) \sim_{N_F(A)} \mathrm{Act}_S(Y).$$

It remains to replace the product representative by S'. The action classifier congruence theorem transports $S' \equiv_{\text{aff}} S \circ_{\text{aff}} T$ along the fixed endpoint X, yielding a classifier comparison between $\mathrm{Act}_{S'}(X)$ and $\mathrm{Act}_{S \circ_{\text{aff}} T}(X)$.

Use orbit classifier transport Definition 45.713 with this left-endpoint comparison and classifier reflexivity on $\mathrm{Act}_S(Y)$. The transported witness is exactly $\mathrm{Act}_{S'}(X) \sim_{N_F(A)} \mathrm{Act}_S(Y)$. □

Per-object template: traditional target representative independence for a group action modulo its pointwise kernel; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit plus $\mathsf{Group}^{\uparrow}$; carrier $C_F(A)$; classifier $\equiv_{\text{aff}}$; stability right-kernel representative independence on orbit classes; ledger representative, kernel factor, product word, endpoint carriers, and transported orbit witness; core theorem Definition 45.726, Definition 45.713, Definition 45.707, Definition 45.697, and Definition 45.715; exactness predicate induced action on centralizer orbit classes; standard bridge ordinary action modulo a kernel relation; status $\mathsf{ProofTarget}$.

Theorem 45.729 (RatUp FieldUp affine centralizer normalizer orbit action reflection)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the affine centralizer carrier, let $N_F(C_F(A))$ be its normalizer carrier, and let $\sim_{N_F(A)}$ be the orbit relation of Definition 45.709. For carried centralizer elements $X, Y : \mathsf{AffAut}_F$ and a normalizer element $S : \mathsf{AffAut}_F$, if $C_F(A)(X)$, $C_F(A)(Y)$, and $N_F(C_F(A))(S)$, then*

$$X \sim_{N_F(A)} Y \iff \mathrm{Act}_S(X) \sim_{N_F(A)} \mathrm{Act}_S(Y).$$

Proof. The forward direction is exactly Definition 45.721 with the acting element S.

For the reverse direction, assume $\mathrm{Act}_S(X) \sim_{N_F(A)} \mathrm{Act}_S(Y)$. The inverse row of Definition 45.695 gives $N_F(C_F(A))(\iota_F(S))$.

The carrier clauses in Definition 45.706 place $\mathrm{Act}_S(X)$ and $\mathrm{Act}_S(Y)$ back in $C_F(A)$, so the orbit invariance theorem applies to these acted endpoints.

Apply Definition 45.721 to the assumed orbit relation with the acting element $\iota_F(S)$. This yields

$$\mathrm{Act}_{\iota_F(S)}(\mathrm{Act}_S(X)) \sim_{N_F(A)} \mathrm{Act}_{\iota_F(S)}(\mathrm{Act}_S(Y)).$$

The cancellation clauses of Definition 45.706 identify the left endpoint with X and the right endpoint with Y in the affine classifier. The endpoint transport theorem Definition 45.713 then replaces both acted endpoints by X and Y, giving $X \sim_{N_F(A)} Y$. □

Per-object template: traditional target orbit reflection by a group-action automorphism; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ affine exit plus $\mathsf{Group}^{\uparrow}$; carrier $C_F(A)$; classifier $\equiv_{\text{aff}}$ and orbit reachability; stability action reflection; ledger acting normalizer, inverse normalizer, orbit witness, and cancellation witnesses; core theorem list Definition 45.721, Definition 45.706, Definition 45.695, and Definition 45.713 with Definition 45.712; exactness predicate normalizer actions preserve and reflect orbit reachability; standard bridge ordinary group-action orbit reflection; status $\mathsf{ProofTarget}$.

Theorem 45.730 (RatUp FieldUp affine centralizer normalizer SubgroupUp tower certificate)**.** *For Definition 45.617, fix a certified affine automorphism $A : \mathsf{AffAut}_F$ in the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Let $C_F(A)$ be the affine centralizer carrier from Definition 45.686, let $N_F(C_F(A))$ be the two-sided affine normalizer carrier from Definition 45.692, and define*

$$\mathrm{Act}_T(X) = (T \circ_{\mathrm{aff}} X) \circ_{\mathrm{aff}} \iota_F(T).$$

Then the inclusion

$$C_F(A) \leq N_F(C_F(A))$$

forms the concrete quotient-ready $\mathsf{Subgroup}^{\uparrow}$ tower whose lower subgroup rows are the centralizer identity, product, inverse, and classifier-transport rows, whose upper subgroup rows are the normalizer identity, product, inverse, and classifier-transport rows, whose carrier inclusion is

$$C_F(A)(T) \Rightarrow N_F(C_F(A))(T),$$

and whose action rows state that every T in $N_F(C_F(A))$ preserves $C_F(A)$ under Act_T, the identity and product action laws hold on the centralizer carrier, the classifier well-definedness condition for Act *holds on normalizer and centralizer representatives, and the inverse action by $\iota_F(T)$ cancels Act_T on both sides.*

Proof. The lower carrier is the concrete affine centralizer of A. Apply Definition 45.687; it supplies the identity, product, inverse, and classifier-transport rows for $C_F(A)$.

The upper carrier is the two-sided affine normalizer of this centralizer. Apply Definition 45.695; it supplies the corresponding subgroup rows for $N_F(C_F(A))$. The carrier inclusion is exactly Definition 45.693.

It remains to expose the quotient-ready action data. Apply Definition 45.697 for normalizer preservation of the centralizer and for the identity and composition action laws. Apply Definition 45.703 for classifier well-definedness of Act and for inverse-action cancellation on the restricted centralizer carrier.

These rows are precisely the concrete $\mathsf{Subgroup}^{\uparrow}$ input demanded by the quotient-group construction: a lower subgroup, an upper subgroup, an inclusion of carriers, and an action certificate by upper representatives on lower representatives. □

Per-object template: traditional target normal-subgroup input for quotient groups; BEDC source concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ together with $\mathsf{Subgroup}^{\uparrow}$; carrier pair $C_F(A), N_F(C_F(A))$; classifier $\equiv_{\mathrm{aff}}$; ledger fixed affine element, conjugators, inverse rows, and action witnesses; exactness as the normalizer action on the centralizer; status $\mathsf{ProofTarget}$.

Theorem 45.731 (Field singleton-empty operation context nonzero obstruction)**.** *For histories L, R, h, k, out : BHist with $\mathsf{fieldSingletonEmptyCarrier}(L)$, $\mathsf{fieldSingletonEmptyCarrier}(R)$, and $\mathsf{fieldSingletonEmptyNonZero}(out)$, singleton-empty operation contexts reject proof-indexed nonzero outputs. The multiplication endpoint satisfies*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, \mathsf{fieldSingletonEmptyMul}(h, k)), \mathsf{append}(R, out)) \Longrightarrow \mathsf{False}.$$

The unit endpoint satisfies

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, \mathsf{fieldSingletonEmptyOne}), \mathsf{append}(R, out)) \Longrightarrow \mathsf{False}.$$

For every proof witness p : $\mathsf{fieldSingletonEmptyNonZero}(h)$, the inverse endpoint satisfies

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, \mathsf{fieldSingletonEmptyInv}(h, p)), \mathsf{append}(R, out)) \Longrightarrow \mathsf{False}.$$

Proof. Apply Definition 45.591 to the multiplication, unit, or proof-indexed inverse classifier in the displayed context. In each case the contextual classifier into $\mathsf{append}(R, out)$ is converted into $\mathsf{fieldSingletonEmptyCarrier}(out)$.

The carrier assertion is the empty endpoint input for Definition 45.34. Combining it with the assumed witness $\mathsf{fieldSingletonEmptyNonZero}(out)$ gives False for each of the three operation contexts. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmptyClassifier operation context nonzero absurd`
Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmpty operation context nonzero obstruction`

Per-object template: traditional target terminal $\mathsf{Field}^{\uparrow}$ operation-domain obstruction; BEDC source BHist, append, lower-case singleton-empty $\mathsf{Field}^{\uparrow}$ endpoints; carrier $\mathsf{fieldSingletonEmptyCarrier}$; classifier $\mathsf{fieldSingletonEmptyClassifier}$; stability obligations operation-context normalization and nonzero endpoint obstruction; ledger hidden singleton contexts and proof-indexed inverse witness; core theorem this block; exactness predicate classifier-to-nonzero contradiction; status $\mathsf{ProofTarget}$.

Theorem 45.732 (Field singleton-empty operation context carried nonzero obstruction)**.** *For histories* $L, R, U, V, h, k, out : \mathsf{BHist}$ *with* $\mathsf{fieldSingletonEmptyCarrier}(L)$, $\mathsf{fieldSingletonEmptyCarrier}(R)$, $\mathsf{fieldSingletonEmptyCarrier}(U)$, $\mathsf{fieldSingletonEmptyCarrier}(V)$, *and* $\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(U, \mathsf{append}(ou$ *carried nonzero evidence rejects the singleton-empty operation contexts. The multiplication endpoint satisfies*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, \mathsf{fieldSingletonEmptyMul}(h, k)), \mathsf{append}(R, out)) \Longrightarrow \mathsf{False}.$$

The unit endpoint satisfies

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, \mathsf{fieldSingletonEmptyOne}), \mathsf{append}(R, out)) \Longrightarrow \mathsf{False}.$$

For every proof witness $p : \mathsf{fieldSingletonEmptyNonZero}(h)$, *the proof-indexed inverse endpoint satisfies*

$$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, \mathsf{fieldSingletonEmptyInv}(h, p)), \mathsf{append}(R, out)) \Longrightarrow \mathsf{False}.$$

Proof. First cancel the carried output contexts. Apply Definition 45.78 to U, V, out with the carrier witnesses for U and V. The assumed predicate on $\mathsf{append}(U, \mathsf{append}(out, V))$ yields the direct witness $\mathsf{fieldSingletonEmptyNonZero}(out)$.

Now take any one of the three displayed operation classifiers. Apply Definition 45.591 with the carrier witnesses for L and R. In the multiplication, unit, and proof-indexed inverse cases, this produces $\mathsf{fieldSingletonEmptyCarrier}(out)$.

Finally, use Definition 45.34. The output carrier is the empty endpoint input, and the cancelled nonzero witness on out supplies the contradictory nonzero side. □

Lean4 ✓ `BEDC.Derived.FieldUp.fieldSingletonEmpty operation context carried nonzero obstruction`

Per-object template: traditional target contextual nonzero obstruction for the concrete $\mathsf{Field}^{\uparrow}$ operation slots; BEDC source BHist, append, $\mathsf{fieldSingletonEmptyCarrier}$, $\mathsf{fieldSingletonEmptyClassifier}$, and $\mathsf{fieldSingletonEmptyNonZero}$; carrier and classifier as named; stability obligations context cancellation and operation normalization; ledger carried output contexts U, V; core theorem this block; exactness predicate contextual nonzero rejection; status $\mathsf{ProofTarget}$.

45.24 Apart-zero continuation exactness

Theorem 45.733 (Field apart-zero nested continuation empty-context exactness)**.** *For histories* $l, h, r, u, v : \mathsf{BHist}$ *with* $\mathsf{Cont}(l, h, u)$ *and* $\mathsf{Cont}(u, r, v)$*, if* $l\mathsf{hsamee}$ *and* $r\mathsf{hsamee}$*, then*

$$\mathsf{ApartZero}_F(v) \iff \mathsf{ApartZero}_F(h).$$

Proof. The two continuation witnesses identify u with $\mathsf{append}(l, h)$ and v with $\mathsf{append}(u, r)$. Continuation associativity and result transport compare v with the nested append endpoint $\mathsf{append}(l, \mathsf{append}(h, r))$.

Transport $\mathsf{ApartZero}_F$ across this hsame comparison. The result is exactly the bilateral empty-context statement of Definition 45.267, applied with the witnesses $l\mathsf{hsamee}$ and $r\mathsf{hsamee}$. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero nested continuation empty context iff`

Theorem 45.734 (Field apart-zero nested continuation factor split)**.** *For histories* $l, h, r, u, v, q, w : \mathsf{BHist}$ *with* $\mathsf{Cont}(l, h, u)$*,* $\mathsf{Cont}(u, r, v)$*, and* $\mathsf{Cont}(v, q, w)$*, if* $l\mathsf{hsamee}$ *and* $r\mathsf{hsamee}$*, then*

$$\mathsf{ApartZero}_F(w) \iff \mathsf{ApartZero}_F(h) \lor \mathsf{ApartZero}_F(q).$$

Proof. Apply Definition 45.256 to the tail continuation witness $\mathsf{Cont}(v, q, w)$. This gives $\mathsf{ApartZero}_F(w)$ exactly when $\mathsf{ApartZero}_F(v) \lor \mathsf{ApartZero}_F(q)$ holds.

Apply Definition 45.733 to the first two continuation witnesses and the exterior empty-context witnesses $l\mathsf{hsamee}$ and $r\mathsf{hsamee}$. Substituting this equivalence for the first disjunct yields the displayed factor split. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero nested continuation factor split iff`

Per-object template: traditional target continuation-tail apartness factor split under empty exterior context; BEDC source BHist, Cont, and $\mathsf{ApartZero}_F$; carrier apart-zero histories; classifier hsame transport; stability obligations nested empty-context exactness plus continuation endpoint split; ledger the two empty-context witnesses and tail q; exactness predicate the displayed iff; standard bridge ordinary product/context apartness factorization; status $\mathsf{ProofTarget}$.

Theorem 45.735 (Field apart-zero two-tail nested continuation factor split)**.** *For histories* $l, h, r, u, v, q, w, s, z : \mathsf{BHist}$ *with* $\mathsf{Cont}(l, h, u)$*,* $\mathsf{Cont}(u, r, v)$*,* $\mathsf{Cont}(v, q, w)$*, and* $\mathsf{Cont}(w, s, z)$*, if* $l\mathsf{hsamee}$ *and* $r\mathsf{hsamee}$*, then*

$$\mathsf{ApartZero}_F(z) \iff \mathsf{ApartZero}_F(h) \lor \mathsf{ApartZero}_F(q) \lor \mathsf{ApartZero}_F(s).$$

Proof. Apply Definition 45.256 to the final tail continuation witness $\mathsf{Cont}(w, s, z)$. This gives $\mathsf{ApartZero}_F(z)$ exactly when $\mathsf{ApartZero}_F(w) \lor \mathsf{ApartZero}_F(s)$ holds.

Apply Definition 45.734 to the first three continuation witnesses and the exterior witnesses $l\mathsf{hsamee}$ and $r\mathsf{hsamee}$. This identifies $\mathsf{ApartZero}_F(w)$ with $\mathsf{ApartZero}_F(h) \lor \mathsf{ApartZero}_F(q)$.

For the forward direction, case-analyze the endpoint disjunction. The $\mathsf{ApartZero}_F(s)$ case supplies the right tail disjunct. In the $\mathsf{ApartZero}_F(w)$ case, case-analyze the nested split and place the resulting witness in the h or q disjunct.

For the reverse direction, case-analyze the displayed three-way disjunction. The h and q cases first rebuild $\mathsf{ApartZero}_F(w)$ by the reverse direction of the nested split, and then rebuild $\mathsf{ApartZero}_F(z)$ by the reverse direction of the endpoint split. The s case uses the reverse direction of the endpoint split directly. □

Per-object template: object $\mathsf{Field}^{\uparrow}$ apart-zero multi-tail factorization; source BHist plus Cont; carrier apart-zero histories; classifier hsame transport; transport predicate $\mathsf{ApartZero}_F$; ledger the empty exterior witnesses $l\mathsf{hsamee}$ and $r\mathsf{hsamee}$; tail data the two tail factors q and s; core theorem this block plus the one-tail split and endpoint split; exactness predicate the displayed iff; status $\mathsf{ProofTarget}$.

Theorem 45.736 (Field apart-zero nested continuation singleton-result factor exclusion)**.** *For histories* $l, h, r, u, v, q, w, s, z, endpoint$: BHist *with* $\mathsf{Cont}(l, h, u)$, $\mathsf{Cont}(u, r, v)$, $\mathsf{Cont}(v, q, w)$, *and* $\mathsf{Cont}(w, s, z)$, *if* $l\mathsf{hsamee}$, $r\mathsf{hsamee}$, *and* $\mathsf{FieldSingletonClassifier}(z, endpoint)$, *then*

$$(\mathsf{ApartZero}_F(h) \to \bot) \wedge (\mathsf{ApartZero}_F(q) \to \bot) \wedge (\mathsf{ApartZero}_F(s) \to \bot).$$

Proof. Apply Definition 45.260 to the final continuation witness $\mathsf{Cont}(w, s, z)$ together with the terminal singleton-result certificate. This gives exclusions for $\mathsf{ApartZero}_F(w)$ and $\mathsf{ApartZero}_F(s)$.

To exclude $\mathsf{ApartZero}_F(h)$, assume such a witness. The reverse direction of Definition 45.734, applied to the first three continuation witnesses and the exterior empty-context witnesses, turns the left factor witness into $\mathsf{ApartZero}_F(w)$. This contradicts the exclusion for w.

The argument for $\mathsf{ApartZero}_F(q)$ is the same, using the right nested factor witness in the reverse direction of the same split theorem. Pair the two nested exclusions with the already obtained exclusion for s to obtain the displayed triple exclusion. □

Per-object template: traditional target zero-result factor exclusion for nested $\mathsf{Field}^{\uparrow}$ continuations; BEDC source BHist, Cont, $\mathsf{FieldSingletonClassifier}$, and $\mathsf{ApartZero}_F$; carrier apart-zero histories; classifier hsame transport; transport predicate terminal singleton-result rejection; ledger the empty exterior witnesses plus the terminal singleton-result certificate; tail data the nested factors h, q, and s; core theorem list the one-step singleton-result factor absurd theorem and nested factor split; exactness predicate the displayed triple exclusion; status $\mathsf{ProofTarget}$.

Theorem 45.737 (Field apart-zero three-tail nested continuation factor split)**.** *For histories* $l, h, r, u, v, q, w, s, z, t, y$: BHist *with* $\mathsf{Cont}(l, h, u)$, $\mathsf{Cont}(u, r, v)$, $\mathsf{Cont}(v, q, w)$, $\mathsf{Cont}(w, s, z)$, *and* $\mathsf{Cont}(z, t, y)$, *if* $l\mathsf{hsamee}$ *and* $r\mathsf{hsamee}$, *then*

$$\mathsf{ApartZero}_F(y) \iff \mathsf{ApartZero}_F(h) \vee \mathsf{ApartZero}_F(q) \vee \mathsf{ApartZero}_F(s) \vee \mathsf{ApartZero}_F(t).$$

Proof. Apply Definition 45.256 to the endpoint continuation witness $\mathsf{Cont}(z, t, y)$. This splits $\mathsf{ApartZero}_F(y)$ into $\mathsf{ApartZero}_F(z) \vee \mathsf{ApartZero}_F(t)$.

Apply Definition 45.735 to the first four continuation witnesses and the exterior empty-context witnesses $l\mathsf{hsamee}$ and $r\mathsf{hsamee}$. This rewrites $\mathsf{ApartZero}_F(z)$ as the three-way disjunction on h, q, s.

For the forward direction, case-analyze the endpoint split. The $\mathsf{ApartZero}_F(t)$ case supplies the final tail disjunct. In the $\mathsf{ApartZero}_F(z)$ case, case-analyze the two-tail nested split and place the resulting evidence in the h, q, or s disjunct.

For the reverse direction, case-analyze the displayed four-way disjunction. The h, q, and s cases first rebuild $\mathsf{ApartZero}_F(z)$ by the reverse direction of the two-tail nested split, and then rebuild $\mathsf{ApartZero}_F(y)$ by the reverse direction of the endpoint split. The t case uses the reverse direction of the endpoint split directly. □

Per-object template: traditional target finite product/context apartness factorization; BEDC source BHist plus Cont; carrier apart-zero histories; classifier hsame transport; stability obligations endpoint split and two-tail nested split; ledger exterior empty witnesses plus tails q, s, t; core theorem this block; exactness predicate the displayed iff; standard bridge finite product apartness; status $\mathsf{ProofTarget}$.

Theorem 45.738 (Field apart-zero three-tail contextual singleton result exclusion)**.** *For histories* $L, R, l, h, r, u, v, q, w, s, z, t, y, endpoint$: BHist *with* $\mathsf{FieldSingletonCarrier}(L)$, $\mathsf{FieldSingletonCarrier}(R)$, $\mathsf{Cont}(l, h, u)$, $\mathsf{Cont}(u, r, v)$, $\mathsf{Cont}(v, q, w)$, $\mathsf{Cont}(w, s, z)$, $\mathsf{Cont}(z, t, y)$, $l\mathsf{hsamee}$, $r\mathsf{hsamee}$, *and* $\mathsf{FieldSingletonClassifier}(a$ *one has*

$$(\mathsf{ApartZero}_F(h) \to \bot) \wedge (\mathsf{ApartZero}_F(q) \to \bot) \wedge (\mathsf{ApartZero}_F(s) \to \bot) \wedge (\mathsf{ApartZero}_F(t) \to \bot).$$

Proof. Use Definition 45.57 with the singleton-carrier witnesses for L and R. The forward direction of the cancellation equivalence turns the contextual classifier into $\mathsf{FieldSingletonClassifier}(y, endpoint)$.

Apply Definition 45.6 to that singleton endpoint classifier. The resulting endpoint comparison gives $y\mathsf{hsamee}$.

Now assume one of the four factor witnesses $\mathsf{ApartZero}_F(h)$, $\mathsf{ApartZero}_F(q)$, $\mathsf{ApartZero}_F(s)$, or $\mathsf{ApartZero}_F(t)$. The reverse direction of Definition 45.737, applied to the corresponding disjunct and the five continuation witnesses, rebuilds $\mathsf{ApartZero}_F(y)$.

Applying this apart-zero witness to $y\mathsf{hsamee}$ gives $\bot$ in each case. Pairing the four implications gives the displayed exclusion. □

Per-object template: traditional target contextual singleton-result factor exclusion for three-tail $\mathsf{Field}^{\uparrow}$ continuations; BEDC source BHist, Cont, $\mathsf{FieldSingletonClassifier}$, and $\mathsf{ApartZero}_F$; carrier apart-zero histories; classifier hsame transport; transport predicate singleton-context cancellation; ledger the hidden singleton contexts, empty exterior witnesses, and terminal singleton certificate; tail data the exposed factors h, q, s, t; core theorem list the three-tail nested factor split plus singleton endpoint classifier; exactness predicate the displayed fourfold exclusion; status $\mathsf{ProofTarget}$.

Theorem 45.739 (Field apart-zero two-tail contextual singleton result exclusion)**.** *For histories* $L, R, l, h, r, u, v, q, w, s, z, endpoint$: BHist *with* $\mathsf{FieldSingletonCarrier}(L)$, $\mathsf{FieldSingletonCarrier}(R)$, $\mathsf{Cont}(l, h, u)$, $\mathsf{Cont}(u, r, v)$, $\mathsf{Cont}(v, q, w)$, $\mathsf{Cont}(w, s, z)$, $l\mathsf{hsamee}$, $r\mathsf{hsamee}$, *and* $\mathsf{FieldSingletonClassifier}(\mathsf{append}(L, z), a$ *one has*

$$(\mathsf{ApartZero}_F(h) \to \bot) \wedge (\mathsf{ApartZero}_F(q) \to \bot) \wedge (\mathsf{ApartZero}_F(s) \to \bot).$$

Proof. Use Definition 45.57 with the two singleton-context carrier witnesses for L and R. The forward direction of the cancellation equivalence turns the displayed contextual classifier into $\mathsf{FieldSingletonClassifier}(z, endpoint)$.

Apply Definition 45.260 to the final continuation witness $\mathsf{Cont}(w, s, z)$ and the classifier just obtained. This gives exclusions $\mathsf{ApartZero}_F(w) \to \bot$ and $\mathsf{ApartZero}_F(s) \to \bot$.

It remains to rule out the two exposed earlier factors. Apply Definition 45.734 to the first three continuation witnesses and the exterior witnesses $l\mathsf{hsamee}$ and $r\mathsf{hsamee}$. The reverse direction sends either $\mathsf{ApartZero}_F(h)$ or $\mathsf{ApartZero}_F(q)$ to $\mathsf{ApartZero}_F(w)$, contradicting the exclusion of w. Together with the direct exclusion of s, these three maps are exactly the displayed conjunction. □

Per-object template: $\mathsf{Field}^{\uparrow}$ apart-zero singleton-result exclusion; source BHist plus Cont; carrier predicate $\mathsf{ApartZero}_F$; classifier hsame transport; ledger the hidden singleton contexts; exactness predicate the displayed conjunction; status $\mathsf{ProofTarget}$.

Theorem 45.740 (Field apart-zero nested continuation singleton-result factor exclusion)**.** *For histories* $l, h, r, u, v, q, w, endpoint$: BHist *with* $\mathsf{Cont}(l, h, u)$, $\mathsf{Cont}(u, r, v)$, *and* $\mathsf{Cont}(v, q, w)$, *if* $l\mathsf{hsamee}$, $r\mathsf{hsamee}$, *and* $\mathsf{FieldSingletonClassifier}(w, endpoint)$, *then*

$$(\mathsf{ApartZero}_F(h) \Rightarrow \mathsf{False}) \wedge (\mathsf{ApartZero}_F(q) \Rightarrow \mathsf{False}).$$

Proof. Apply Definition 45.6 to the classifier witness $\mathsf{FieldSingletonClassifier}(w, endpoint)$. The result gives in particular the endpoint comparison $w\mathsf{hsamee}$.

Assume $\mathsf{ApartZero}_F(h)$. The reverse direction of Definition 45.734, applied to the left disjunct and the three continuation witnesses, produces $\mathsf{ApartZero}_F(w)$. Applying this apart-zero witness to $w\mathsf{hsamee}$ gives False.

Assume $\mathsf{ApartZero}_F(q)$. The same reverse direction of the nested factor split, now applied to the right disjunct, again produces $\mathsf{ApartZero}_F(w)$. Applying it to $w\mathsf{hsamee}$ gives False. Pairing the two implications gives the displayed exclusion. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartZero nested continuation singleton result factor absurd`

Per-object template: traditional target zero-result factor exclusion for nested field multiplication; BEDC source BHist, Cont, $\mathsf{FieldSingletonClassifier}$, and $\mathsf{ApartZero}_F$; carrier apart-zero histories; classifier hsame transport; ledger the hidden singleton result endpoint and the two exposed factors; core theorem list the nested continuation factor split plus singleton endpoint classifier; exactness predicate the displayed paired exclusion; standard bridge ordinary zero product excludes nonzero factors under a singleton result; status $\mathsf{ProofTarget}$.

Definition 45.741 (Field apart-zero tail-factor spine)**.** *For histories $y, x : \mathsf{BHist}$, let $\mathsf{FieldApartTailFactor}(y, x)$ be the least relation on BHist generated by the following constructors:*

1. *If $\mathsf{Cont}(l, h, u)$, $\mathsf{Cont}(u, r, v)$, $l\mathsf{hsamee}$, and $r\mathsf{hsamee}$, then $\mathsf{FieldApartTailFactor}(v, h)$.*
2. *If $\mathsf{FieldApartTailFactor}(w, x)$ and $\mathsf{Cont}(w, q, z)$, then $\mathsf{FieldApartTailFactor}(z, x)$.*
3. *If $\mathsf{Cont}(w, q, z)$, then $\mathsf{FieldApartTailFactor}(z, q)$.*

Lean4 (definition) `BEDC.Derived.FieldUp.FieldApartTailFactor`

Lemma 45.742 (Field apart-tailfactor empty-context hsame transport)**.** *The empty-context generator is stable under hsame transport of its two continuation witnesses, exterior empty comparisons, middle history, and result.*

Proof. Transport the two Cont witnesses and the two exterior comparisons, then use the empty-context constructor. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartTailFactor empty context hsame transport`

Lemma 45.743 (Field apart-zero tail-factor empty endpoint exclusion)**.** *For histories $y, x : \mathsf{BHist}$, if $\mathsf{FieldApartTailFactor}(y, x)$, $y\mathsf{hsamee}$, and $\mathsf{ApartZero}_F(x)$, then $\bot$.*

Proof. Induct on the generated tail-factor witness. In the empty-context generator, the nested empty-context apart-zero equivalence transports $\mathsf{ApartZero}_F(x)$ to the result endpoint, contradicting $y\mathsf{hsamee}$. In the carried-tail case, empty-result inversion gives an empty previous endpoint. In the exposed-factor case, it gives the exposed factor itself as e. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartTailFactor empty endpoint exclusion`

Theorem 45.744 (Field apart-tailfactor empty endpoint exclusion hsame transport)**.** *For histories $y, x, y', x' : \mathsf{BHist}$, if $\mathsf{FieldApartTailFactor}(y, x)$, $y\mathsf{hsame}y'$, $x\mathsf{hsame}x'$, $y'\mathsf{hsamee}$, and $\mathsf{ApartZero}_F(x')$, then $\bot$.*

Proof. Transport the two displayed endpoint comparisons across hsame and apply Definition 45.743. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartTailFactor empty endpoint exclusion hsame transport`

Lemma 45.745 (Field apart-zero tail-factor hsame transport)**.** *For histories* $y, y', x, x' : \mathsf{BHist}$*, if* $\mathsf{FieldApartTailFactor}(y, x)$*,* $y\mathsf{hsame}y'$*, and* $x\mathsf{hsame}x'$*, then* $\mathsf{FieldApartTailFactor}(y', x')$*.*

Proof. Induct on the generated witness $\mathsf{FieldApartTailFactor}(y, x)$.

In the empty-context constructor, transport the first continuation witness along $x\mathsf{hsame}x'$ and reflexivity of its other endpoints using Definition 4.41. Transport the second continuation witness along reflexivity of its source and factor endpoint, and along $y\mathsf{hsame}y'$ for the result. The two exterior witnesses $l\mathsf{hsame}e$ and $r\mathsf{hsame}e$ are unchanged, so constructor 1 rebuilds $\mathsf{FieldApartTailFactor}(y', x')$.

In the carried-tail constructor, apply the induction hypothesis to the stored factor witness, the reflexive comparison on its carried result, and the supplied $x\mathsf{hsame}x'$. Transport the final continuation result along $y\mathsf{hsame}y'$ by Definition 4.41, then reuse constructor 2.

In the exposed-factor constructor, transport the continuation argument by $x\mathsf{hsame}x'$ and its result by $y\mathsf{hsame}y'$ using Definition 4.41. Constructor 3 then gives the transported generated factor witness. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartTailFactor hsame transport continuation package`

Per-object template: traditional target tail-factor stability; BEDC source BHist plus Cont; carrier FieldApartTailFactor; classifier hsame; stability obligation Definition 45.745; ledger transported continuation witnesses; core theorem Definition 45.745; exactness predicate invariance of generated factor witnesses; status ProofTarget.

Theorem 45.746 (Field apart-zero tail-factor continuation hsame closure)**.** *For histories* $w, w', x, x', q, z :$ BHist*, if* $\mathsf{FieldApartTailFactor}(w, x)$*,* $w\mathsf{hsame}w'$*,* $x\mathsf{hsame}x'$*, and* $\mathsf{Cont}(w', q, z)$*, then* $\mathsf{FieldApartTailFactor}(z, x')$*.*

Proof. Transport the carried tail-factor endpoints along the two hsame comparisons. The continuation witness then extends the generated spine by the carried-tail constructor, yielding the displayed endpoint and carried factor. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartTailFactor continuation hsame closure`

Lemma 45.747 (Field apart-zero tail-factor result closure)**.** *For histories* $y, x : \mathsf{BHist}$*, if* $\mathsf{FieldApartTailFactor}(y, x)$*, then*

$$\mathsf{ApartZero}_F(x) \Rightarrow \mathsf{ApartZero}_F(y).$$

Proof. Induct on the generated witness $\mathsf{FieldApartTailFactor}(y, x)$.

In the initial empty-context constructor, apply Definition 45.733 to the two continuation witnesses and the two exterior comparisons. The reverse direction transports $\mathsf{ApartZero}_F(h)$ to $\mathsf{ApartZero}_F(v)$.

In the carried-tail constructor, the induction hypothesis first transports $\mathsf{ApartZero}_F(x)$ to $\mathsf{ApartZero}_F(w)$. Then apply the reverse direction of Definition 45.256 to the left endpoint disjunct, obtaining $\mathsf{ApartZero}_F(z)$.

In the exposed-factor constructor, apply the reverse direction of Definition 45.256 to the right factor disjunct. This sends $\mathsf{ApartZero}_F(q)$ to $\mathsf{ApartZero}_F(z)$. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartTailFactor result closure`

Theorem 45.748 (Field apart-zero tail-factor continuation result closure)**.** *For histories* $w, x, q, z :$ BHist*, if* $\mathsf{FieldApartTailFactor}(w, x)$*,* $\mathsf{Cont}(w, q, z)$*, and* $\mathsf{ApartZero}_F(x)$*, then* $\mathsf{ApartZero}_F(z)$*.*

Proof. First apply tail-factor result closure to obtain $\mathsf{ApartZero}_F(w)$ from the generated witness and $\mathsf{ApartZero}_F(x)$. The continuation endpoint split for $\mathsf{Cont}(w, q, z)$ closes the result by the left factor disjunct. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartTailFactor continuation result closure`

Theorem 45.749 (Field apart-zero finite tail singleton-result exclusion)**.** *For histories* $y, x, endpoint$: BHist*, if* $\mathsf{FieldApartTailFactor}(y, x)$ *and* $\mathsf{FieldSingletonClassifier}(y, endpoint)$*, then*

$$\mathsf{ApartZero}_F(x) \Rightarrow \bot.$$

Proof. Apply Definition 45.747 to the generated tail-factor witness. This turns any $\mathsf{ApartZero}_F(x)$ witness into $\mathsf{ApartZero}_F(y)$.

Apply Definition 45.6 to the singleton endpoint classifier. The endpoint theorem gives the comparison $y\mathsf{hsamee}$.

Finally, transport the apart-zero witness along the endpoint comparison. The result is the contradiction $\bot$, since $\mathsf{ApartZero}_F(y)$ rejects $y\mathsf{hsamee}$. □

Per-object template: traditional target finite product zero-factor exclusion; BEDC source BHist, Cont, $\mathsf{ApartZero}_F$, and $\mathsf{FieldSingletonClassifier}$; carrier generated tail-factor witnesses; classifier hsame; core theorem list Definition 45.747 and Definition 45.749; exactness predicate generated factor-to-result closure plus singleton-result rejection; status $\mathsf{ProofTarget}$.

Theorem 45.750 (Field apart-zero finite tail contextual singleton-result exclusion)**.** *For histories* $L, R, y, x, endpoint$: BHist*, if* $\mathsf{FieldSingletonCarrier}(L)$*,* $\mathsf{FieldSingletonCarrier}(R)$*,* $\mathsf{FieldApartTailFactor}(y, x)$*, and* $\mathsf{FieldSingletonClassifier}(\mathsf{append}(L, y), \mathsf{append}(R, endpoint))$*, then*

$$\mathsf{ApartZero}_F(x) \Rightarrow \bot.$$

Proof. First cancel the carried singleton contexts. Apply Definition 45.57 to the two carrier witnesses and the appended singleton classifier. The forward direction gives $\mathsf{FieldSingletonClassifier}(y, endpoint)$.

Now apply Definition 45.749 to the generated tail-factor witness $\mathsf{FieldApartTailFactor}(y, x)$ and the base singleton classifier. This produces $\mathsf{ApartZero}_F(x) \Rightarrow \bot$. □

Lean4 ✓ `BEDC.Derived.FieldUp.FieldApartTailFactor singleton context exclusion`

Per-object template: traditional target finite product zero-factor exclusion under hidden singleton contexts; BEDC source BHist, Cont, $\mathsf{FieldApartTailFactor}$, $\mathsf{FieldSingletonClassifier}$, and $\mathsf{ApartZero}_F$; carrier generated tail-factor witnesses; classifier hsame; stability from singleton context cancellation and finite tail result closure; ledger hidden singleton contexts plus generated factor witness; core theorem list Definition 45.57 and Definition 45.749; exactness predicate contextual singleton-result rejection; status $\mathsf{ProofTarget}$.

Theorem 45.751 (Field apart-zero three-tail tail-factor coverage)**.** *For histories* $l, h, r, u, v, q, w, s, z, t, y$: BHist *with* $\mathsf{Cont}(l, h, u)$*,* $\mathsf{Cont}(u, r, v)$*,* $\mathsf{Cont}(v, q, w)$*,* $\mathsf{Cont}(w, s, z)$*, and* $\mathsf{Cont}(z, t, y)$*, if* $l\mathsf{hsamee}$ *and* $r\mathsf{hsamee}$*, then*

$$\mathsf{FieldApartTailFactor}(y, h) \wedge \mathsf{FieldApartTailFactor}(y, q) \wedge \mathsf{FieldApartTailFactor}(y, s) \wedge \mathsf{FieldApartTailFactor}(y, t).$$

Proof. We first build the hidden initial factor. The initial tail-factor constructor applied to $\mathsf{Cont}(l, h, u)$, $\mathsf{Cont}(u, r, v)$, $l\mathsf{hsamee}$, and $r\mathsf{hsamee}$ gives $\mathsf{FieldApartTailFactor}(v, h)$. Carry this witness successively across $\mathsf{Cont}(v, q, w)$, $\mathsf{Cont}(w, s, z)$, and $\mathsf{Cont}(z, t, y)$ by the carried-tail constructor to obtain $\mathsf{FieldApartTailFactor}(y, h)$.

Next expose the q factor at the first continuation after the initial empty-context block. The exposed-factor constructor applied to $\mathsf{Cont}(v, q, w)$ gives $\mathsf{FieldApartTailFactor}(w, q)$. Carry it across $\mathsf{Cont}(w, s, z)$ and $\mathsf{Cont}(z, t, y)$ to obtain $\mathsf{FieldApartTailFactor}(y, q)$.

The s factor is exposed in the same generated spine at the next step. Apply the exposed-factor constructor to $\mathsf{Cont}(w, s, z)$, giving $\mathsf{FieldApartTailFactor}(z, s)$, and then carry this witness across $\mathsf{Cont}(z, t, y)$ to obtain $\mathsf{FieldApartTailFactor}(y, s)$.

Finally, apply the exposed-factor constructor directly to $\mathsf{Cont}(z, t, y)$. This gives $\mathsf{FieldApartTailFactor}(y, t)$. Pair the four generated witnesses in the displayed order. □

Per-object template: traditional target finite product factor coverage; BEDC source BHist, Cont, and $\mathsf{FieldApartTailFactor}$; carrier generated tail-factor witnesses; classifier hsame; ledger the exposed factors h, q, s, t; core theorem this block plus Definition 45.750; exactness predicate factor coverage for generated exclusion; status $\mathsf{ProofTarget}$.

Theorem 45.752 (RatUp FieldUp algebra hierarchy selector-chain exit)**.** *For* $\mathsf{RatUpFieldSource}_F$*, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u, v, w, z : \mathsf{BMark}$*, and contexts* $L, R, r : \mathsf{BHist}$*, if* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then one concrete* BHist *package contains all of the following rows:*

1. *every row of Definition 45.616;*
2. *every shared certificate and operation-table row of Definition 45.534;*
3. *every selector-chain final-boundary row of Definition 45.765 for the selector pairs* (s, t)*,* (u, v)*, and* (w, z)*.*

Equivalently, the concrete source tuple, the concrete denominator tuple, and the three certified selector pairs determine a single $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit package for the Phase Algebra Hierarchy interface.*

Proof. First instantiate Definition 45.616 at the source tuple $\mathsf{RatUpFieldSource}_F$. This supplies the algebra hierarchy exit rows over the common carrier BHist, the RatUp history classifier, and the concrete denominator endpoints.

Next instantiate Definition 45.534 at the same source tuple, denominator tuple, and concrete operation table of Definition 45.587. This supplies the shared certificate rows and the operation-table rows carried by the same BHist package.

Finally instantiate Definition 45.765 with the histories, carrier witnesses, support witness, selectors s, t, u, v, w, z, and contexts L, R, r. This contributes the three final-boundary packages for (s, t), (u, v), and (w, z) together with the chained componentwise R^u_D and $\mathsf{RatHistoryClassifier}$ rows.

The three cited packages name the same source $\mathsf{RatUpFieldSource}_F$, the same carrier BHist, the same RatUp classifier, and the same concrete denominator tuple. Conjunction introduction repacks the common carrier, classifier, denominator, certificate, operation-table, and selector-chain boundary rows as one concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ algebra hierarchy exit package. □

Per-object template: traditional target selector-chain-stable Phase Algebra Hierarchy exit for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source $\mathsf{RatUpFieldSource}_F$ over BHist; carrier and classifier are the RatUp field source rows; stability obligations Definition 45.616, Definition 45.534, and Definition 45.765; ledger selectors s, t, u, v, w, z, histories h, k, ℓ, contexts L, R, r, and the support witness $\mathsf{ThreeSupp}^u_D(h, k, \ell)$; exactness predicate one selector-chain-stable concrete exit package; status $\mathsf{ProofTarget}$.

Theorem 45.753 (RatUp FieldUp exit object operation-table lock)**.** *For* $\mathsf{RatUpFieldSource}_F$*, let* $\mathcal{E}_F$ *be the concrete exit object of Definition 45.617. The same* BHist *row package simultaneously satisfies*

$$\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F),$$

the concrete operation-table coverage of Definition 45.534, and the selector-independent final boundary row of Definition 45.766. Equivalently, $\mathcal{E}_F$ *is a completed concrete exit object whose carrier, classifier, denominator, contextual, affine, inverse, nonzero, and final boundary rows are all borne by the one concrete* BHist *package.*

Proof. Apply Definition 45.618. This gives $\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F)$ for the paper package determined by Definition 45.617.

Apply Definition 45.534. It identifies the carrier, classifier, denominator tuple, contextual action, context-pair monoid, affine row source, inverse rows, nonzero rows, and exit-noncollapse rows as rows of the same concrete BHist package.

Finally apply Definition 45.766. This supplies the selector-independent final boundary row for that concrete exit object. Conjoining these three cited results yields a single completed $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object that carries the operation table and the selector-independent boundary simultaneously. □

Theorem 45.754 (RatUp FieldUp algebra hierarchy selector-independent exit)**.** *For* $\mathsf{RatUpFieldSource}_F$*, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u, v : \mathsf{BMark}$*, and contexts* $L, R, r : \mathsf{BHist}$*, if* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then one concrete* BHist *package contains all of the following rows:*

1. *every row of Definition 45.616;*
2. *every shared certificate and operation-table row of Definition 45.534;*
3. *every selector-independent final boundary row of Definition 45.764.*

Equivalently, the concrete source tuple, carrier, classifier, denominator tuple, and endpoint selectors determine a single $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit certificate that serves the Phase Algebra Hierarchy interface independently of the certified selector pair.*

Proof. First instantiate Definition 45.616 at the concrete source tuple $\mathsf{RatUpFieldSource}_F$. This gives the paper algebra hierarchy rows over the carrier BHist, with the RatUp history classifier and the concrete denominator endpoints.

Next instantiate Definition 45.534 at the same source tuple and the operation table of Definition 45.587. Its rows use the same carrier, classifier, denominator coordinate, contextual action, context-pair coordinate, and affine coordinate as the hierarchy package.

Finally instantiate Definition 45.764 with the given histories, denominator-carrier witnesses, support witness, selectors s, t, u, v, and contexts L, R, r. This supplies the two final-boundary packages and the componentwise R^u_D and $\mathsf{RatHistoryClassifier}$ rows for the selected endpoints.

The three instantiations name the same concrete source tuple $\mathsf{RatUpFieldSource}_F$, the same BHist carrier, the same RatUp classifier, and the same concrete denominator tuple. Conjunction introduction therefore packages their row families as one concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ algebra hierarchy exit certificate. □

Per-object template: concrete Phase Algebra Hierarchy exit package for $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source $\mathsf{RatUpFieldSource}_F$ over BHist; denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$; selected endpoints $E_s(h, k, \ell)$, $E_t(h, k, \ell)$, $E_u(h, k, \ell)$, and $E_v(h, k, \ell)$; carrier rows the algebra hierarchy exit witness,

the assembled certificate operation-table coverage, and the selector-independent final boundary; classifier rows $\mathsf{RatHistoryClassifier}$ together with the componentwise R^u_D rows; stability obligations hierarchy exit witness, assembled certificate operation-table coverage, and selector-independent final boundary; ledger histories h, k, ℓ, selectors s, t, u, v, contexts L, R, r, and the support witness $\mathsf{ThreeSupp}^u_D(h, k, \ell)$; exactness predicate one concrete selector-independent Phase Algebra Hierarchy exit certificate; status $\mathsf{ProofTarget}$.

Per-object template: traditional target two-step selector obstruction chain for $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$; BEDC source BHist, BMark, and $\mathsf{RatUpFieldSource}_F$; carrier rows C^u_D and the concrete selector-obstruction carriers; classifier rows R^u_D and $\mathsf{RatHistoryClassifier}$; ledger selector sextuple s, t, u, v, w, z plus contexts L, R, r; stability obligations the two adjacent complete selector exit obstruction certificates and the selector-chain final boundary; exactness one two-step obstruction-chain package; downstream consumer Phase Algebra Hierarchy $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$ exit certificate; status $\mathsf{ProofTarget}$.

Theorem 45.755 (RatUp FieldUp algebra hierarchy chain-stable exit)**.** *For* $\mathsf{RatUpFieldSource}_F$*, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u, v, w, z : \mathsf{BMark}$*, and contexts* $L, R, r : \mathsf{BHist}$*, let* $E_q(h, k, \ell)$ *be the bracketing endpoint selector of Definition 45.606 for each* $q : \mathsf{BMark}$*. If* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then one concrete* BHist *package contains all of the following rows:*

1. *every row of Definition 45.616;*
2. *every shared certificate and operation-table row of Definition 45.534;*
3. *the assembled obstruction certificate for* (s, t, u, v) *from Definition 45.763;*
4. *the selector-chain final boundary rows of Definition 45.765 for* (s, t)*,* (u, v)*, and* (w, z)*, including the chained* R^u_D *rows and the chained* $\mathsf{RatHistoryClassifier}$ *endpoint rows.*

Equivalently, the concrete FieldUp over RatUp source determines a chain-stable Phase Algebra Hierarchy exit certificate whose carrier, classifier, denominator, operation-table, obstruction, and selector-chain boundary rows are all borne by the same concrete BHist *package.*

Proof. First instantiate Definition 45.616 at $\mathsf{RatUpFieldSource}_F$. This supplies the hierarchy rows over the common carrier BHist, with the RatUp classifier and denominator rows.

Next instantiate Definition 45.534 at the concrete operation table of Definition 45.587. This supplies the shared certificate rows and operation-table rows for the same source tuple.

Then instantiate Definition 45.768 with the displayed denominator tuple, histories, carrier witnesses, selectors s, t, u, v, w, z, contexts L, R, r, and support witness $\mathsf{ThreeSupp}^u_D(h, k, \ell)$. This supplies the assembled obstruction certificate and the selector-chain boundary rows.

Finally cite Definition 45.618 only to keep all row families inside the same concrete exit object. Conjunction introduction packages the hierarchy, operation-table, obstruction, and chain-boundary rows as one chain-stable Phase Algebra Hierarchy exit certificate. □

Per-object template: traditional target chain-stable $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$ exit; BEDC source $\mathsf{RatUpFieldSource}_F$ over BHist; carrier and classifier the RatUp and denominator rows; stability obligations the hierarchy, operation-table, obstruction, and chain-boundary rows; ledger selector sextuple s, t, u, v, w, z plus contexts L, R, r; exactness one chain-stable Phase Algebra Hierarchy exit certificate; status $\mathsf{ProofTarget}$.

Theorem 45.756 (RatUp FieldUp concrete algebra hierarchy obstruction-chain exit package)**.** *For* $\mathsf{RatUpFieldSource}_F$*, Definition 45.617, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u, v, w, z : \mathsf{BMark}$*, and contexts*

L, R, r : BHist, let $E_q(h,k,\ell)$ be the bracketing endpoint selector of Definition 45.606 for each $q : \mathsf{BMark}$. If $\mathsf{ThreeSupp}^u_D(h,k,\ell)$ holds, then the concrete $\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F)$ contains one BHist package with all of the following rows:

1. *every row of Definition 45.752;*
2. *the assembled obstruction certificate of Definition 45.763 for (s,t,u,v);*
3. *the concrete final obstruction-chain rows of Definition 45.768.*

In particular, the same concrete exit object contains the chained denominator rows

$$R^u_D(E_s(h,k,\ell), E_w(h,k,\ell)) \wedge R^u_D(E_t(h,k,\ell), E_z(h,k,\ell))$$

and the chained endpoint classifier rows

$$\mathsf{RatHistoryClassifier}(E_s(h,k,\ell), E_w(h,k,\ell)) \wedge \mathsf{RatHistoryClassifier}(E_t(h,k,\ell), E_z(h,k,\ell)).$$

Proof. First instantiate Definition 45.752 with the displayed source, denominator tuple, histories, carrier witnesses, support witness, selectors s,t,u,v,w,z, and contexts L,R,r : BHist. This supplies the algebra-hierarchy exit witness, shared operation-table coverage, and selector-chain final-boundary rows over one concrete BHist package.

Next instantiate Definition 45.768 with the same source, concrete exit object, denominator tuple, histories, carrier witnesses, support witness, selectors s,t,u,v,w,z, and contexts L,R,r. This supplies the assembled obstruction certificate for (s,t,u,v) and the concrete final obstruction-chain rows, including the chained R^u_D and $\mathsf{RatHistoryClassifier}$ comparisons from E_s, E_t to E_w, E_z.

Both cited packages live over $\mathsf{RatUpFieldSource}_F$, the concrete denominator tuple, and the common carrier BHist. Conjunction introduction repacks their rows as one concrete $\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F)$ exit object for $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$. □

Per-object template: traditional target algebra hierarchy obstruction-chain exit package for $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$; BEDC source BHist, BMark, and $\mathsf{RatUpFieldSource}_F$; concrete exit object Definition 45.617; carrier $\mathsf{RatHistoryCarrier}$ and C^u_D; classifier $\mathsf{RatHistoryClassifier}$ and R^u_D; stability obligations algebra hierarchy selector-chain exit, assembled obstruction certificate, and concrete final obstruction-chain boundary package; ledger selector sextuple s,t,u,v,w,z plus contexts L,R,r; exactness one concrete $\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F)$ package; downstream consumer Phase Algebra Hierarchy $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$ exit criterion; status $\mathsf{ProofTarget}$.

Theorem 45.757 (RatUp FieldUp concrete two-step obstruction chain package)**.** *For $\mathsf{RatUpFieldSource}_F$, Definition 45.617, the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$, histories h,k,ℓ : BHist with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, selectors s,t,u,v,w,z : BMark, and contexts L,R,r : BHist, let $E_q(h,k,\ell)$ be the bracketing endpoint selector of Definition 45.606 for each q : BMark. If $\mathsf{ThreeSupp}^u_D(h,k,\ell)$ holds, then the same concrete $\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F)$ contains the following three row families:*

1. *the full assembled obstruction certificate of Definition 45.763 for (s,t,u,v);*
2. *the full assembled obstruction certificate of Definition 45.763 for (u,v,w,z);*
3. *the selector-chain final boundary rows of Definition 45.765 for (s,t), (u,v), and (w,z), including the chained denominator rows*

$$R^u_D(E_s(h,k,\ell), E_w(h,k,\ell)) \wedge R^u_D(E_t(h,k,\ell), E_z(h,k,\ell))$$

and the chained endpoint classifier rows

$$\mathsf{RatHistoryClassifier}(E_s(h,k,\ell), E_w(h,k,\ell)) \wedge \mathsf{RatHistoryClassifier}(E_t(h,k,\ell), E_z(h,k,\ell)).$$

Proof. First instantiate Definition 45.767 with the displayed source, concrete exit object, denominator tuple, histories, carrier witnesses, support witness, selectors s, t, u, v, and contexts $L, R, r : \mathsf{BHist}$. This supplies the assembled obstruction certificate for the adjacent selector replacement from (s, t) to (u, v).

Next instantiate the same theorem with the same source, concrete exit object, denominator tuple, histories, carrier witnesses, support witness, selectors u, v, w, z, and contexts $L, R, r : \mathsf{BHist}$. This supplies the assembled obstruction certificate for the adjacent selector replacement from (u, v) to (w, z).

Then instantiate Definition 45.765 with the six selectors s, t, u, v, w, z over the same denominator tuple, histories, carrier witnesses, support witness, and contexts. This contributes the three selector-pair boundary rows together with the chained R^u_D rows and chained $\mathsf{RatHistoryClassifier}$ rows from the first endpoint pair to the final endpoint pair.

Finally cite Definition 45.618 only to keep both adjacent obstruction certificates and the chained final boundary rows inside the same concrete $\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F)$. Conjunction introduction packages the two adjacent obstruction certificates and the selector-chain final boundary as one concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit-object certificate. □

Per-object template: traditional target two-step selector obstruction chain for $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source BHist, BMark, and $\mathsf{RatUpFieldSource}_F$; carrier rows C^u_D and the concrete selector-obstruction carriers; classifier rows R^u_D and $\mathsf{RatHistoryClassifier}$; ledger selector sextuple s, t, u, v, w, z plus contexts L, R, r; stability obligations the two adjacent complete selector exit obstruction certificates and the selector-chain final boundary; exactness one two-step obstruction-chain package; downstream consumer Phase Algebra Hierarchy $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit certificate; status $\mathsf{ProofTarget}$.

Theorem 45.758 (RatUp FieldUp adjacent selector-chain obstruction coverage)**.** *For* $\mathsf{RatUpFieldSource}_F$*, Definition 45.617, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u, v, w, z : \mathsf{BMark}$*, and contexts* $L, R, r : \mathsf{BHist}$*, let* $E_q(h, k, \ell)$ *be the bracketing endpoint selector of Definition 45.606 for each* $q : \mathsf{BMark}$*. If* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then the same concrete* $\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F)$ *contains all of the following row families:*

1. *the complete selector exit obstruction certificate of Definition 45.763 for* (s, t, u, v)*;*
2. *the complete selector exit obstruction certificate of Definition 45.763 for* (u, v, w, z)*;*
3. *the selector-chain final boundary rows of Definition 45.765 for* (s, t)*,* (u, v)*, and* (w, z)*, including the chained denominator rows*

$$R^u_D(E_s(h, k, \ell), E_w(h, k, \ell)) \wedge R^u_D(E_t(h, k, \ell), E_z(h, k, \ell))$$

and the chained endpoint classifier rows

$$\mathsf{RatHistoryClassifier}(E_s(h, k, \ell), E_w(h, k, \ell)) \wedge \mathsf{RatHistoryClassifier}(E_t(h, k, \ell), E_z(h, k, \ell)).$$

Proof. Apply Definition 45.763 to the displayed denominator tuple, histories, carrier witnesses, support witness, selectors s, t, u, v, and contexts $L, R, r : \mathsf{BHist}$. This gives the complete selector exit obstruction certificate for the first adjacent link (s, t, u, v).

Apply the same theorem again with selectors u, v, w, z and the same denominator tuple, histories, carrier witnesses, support witness, and contexts. This gives the complete selector exit obstruction certificate for the terminal adjacent link (u, v, w, z).

Apply Definition 45.765 to the six selectors s, t, u, v, w, z over the same denominator tuple, histories, carrier witnesses, support witness, and contexts. This supplies the final boundary rows for (s, t), (u, v), and (w, z), including the chained R^u_D rows and the chained $\mathsf{RatHistoryClassifier}$ endpoint rows.

Finally cite Definition 45.618 only to keep all three row families inside the same concrete $\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F)$. Conjunction introduction packages the two adjacent complete obstruction certificates and the selector-chain final boundary as one concrete $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$ coverage certificate. □

Per-object template: traditional target adjacent selector-chain obstruction coverage for $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$; BEDC source $\mathsf{RatUpFieldSource}_F$ over BHist; carrier $\mathsf{RatHistoryCarrier}$ and C^u_D; classifier $\mathsf{RatHistoryClassifier}$ and R^u_D; stability obligations the two complete obstruction packages plus selector-chain final boundary; ledger selector sextuple s, t, u, v, w, z and contexts L, R, r; core theorem this block; exactness one adjacent-chain obstruction coverage package; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.759 (RatUp FieldUp final certificate selector noncollapse boundary)**.** *For Definition 45.617, the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$, histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, selectors $s, t : \mathsf{BMark}$, and contexts $L, R, r : \mathsf{BHist}$, let $E_s(h, k, \ell)$ and $E_t(h, k, \ell)$ be the corresponding bracketing endpoint selectors of Definition 45.606. If $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ holds, then one concrete $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$ exit boundary simultaneously contains the following rows:*

1. *the final certificate noncollapse action package of Definition 45.669;*
2. *$C^u_D(E_s(h, k, \ell))$, $C^u_D(E_t(h, k, \ell))$, and $R^u_D(E_s(h, k, \ell), E_t(h, k, \ell))$;*
3. *$\mathsf{RatHistoryClassifier}(E_s(h, k, \ell), E_t(h, k, \ell))$;*
4. $$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, E_s(h, k, \ell)), \mathsf{append}(R, E_t(h, k, \ell))) \to \bot;$$
5. $$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, E_s(h, k, \ell))) \to \bot;$$
6. $$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(E_s(h, k, \ell), r)) \to \bot;$$
7. $$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, E_s(h, k, \ell)));$$
8. $$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(E_s(h, k, \ell), r)).$$

Proof. Apply Definition 45.669 to Definition 45.617. This fixes the concrete $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$ certificate boundary whose source object and action rows are consumed by the hierarchy exit criterion.

Next apply Definition 45.623 to the same denominator tuple, histories, carrier witnesses, support witness, selectors, and contexts $L, R : \mathsf{BHist}$. This contributes the two selected carrier rows, the selected denominator-classifier row, and the arbitrary-context singleton-classifier exclusion for the pair $(E_s(h, k, \ell), E_t(h, k, \ell))$.

Apply Definition 45.614 with the same selector pair and the context $r : \mathsf{BHist}$. Its selector-independent row package supplies $\mathsf{RatHistoryClassifier}(E_s(h, k, \ell), E_t(h, k, \ell))$ together with contextual nonzero rows for the selected left endpoint.

Finally apply Definition 45.624 to the selector s and context $r : \mathsf{BHist}$. This reads the one-sided singleton-carrier exclusions and the two $\mathsf{fieldSingletonEmptyNonZero}$ witnesses as rows of the same concrete exit boundary, so the final certificate and selector bracketing data are consumed as one FieldUp object. □

Per-object template: traditional target final selector noncollapse boundary inside $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, BMark, RatUp, and Definition 45.617; denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$; selected endpoints $E_s(h,k,\ell)$ and $E_t(h,k,\ell)$; carrier rows $C^u_D(E_s(h,k,\ell))$, $C^u_D(E_t(h,k,\ell))$, and $\mathsf{RatHistoryCarrier}$; classifier rows $R^u_D(E_s(h,k,\ell), E_t(h,k,\ell))$ and $\mathsf{RatHistoryClassifier}(E_s(h,k,\ell), E_t(h,k,\ell))$; stability obligations final noncollapse action, selector exit subpackage, selector independence, and contextual nonzero rows; ledger selector pair plus contexts L, R, r; exactness predicate one concrete FieldUp exit boundary; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.760 (RatUp FieldUp selector-pair strict exit determinacy)**.** *For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ and histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, let $E_q(h,k,\ell)$ be the endpoint selector of Definition 45.606 for each $q : \mathsf{BMark}$. If $\mathsf{ThreeSupp}^u_D(h,k,\ell)$ holds, then for all selector pairs $s, t, u, v : \mathsf{BMark}$ and contexts $L, R : \mathsf{BHist}$ the following concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit package is determined:*

1.

$$R^u_D(E_s(h,k,\ell), E_u(h,k,\ell)) \wedge R^u_D(E_t(h,k,\ell), E_v(h,k,\ell));$$

2.

$$\mathsf{RatHistoryClassifier}(E_s(h,k,\ell), E_u(h,k,\ell)) \wedge \mathsf{RatHistoryClassifier}(E_t(h,k,\ell), E_v(h,k,\ell));$$

3.

$$C^u_D(E_s(h,k,\ell)) \wedge C^u_D(E_t(h,k,\ell)) \wedge R^u_D(E_s(h,k,\ell), E_t(h,k,\ell)) \wedge (\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, E_s(h,k,\ell)$$

4.

$$C^u_D(E_u(h,k,\ell)) \wedge C^u_D(E_v(h,k,\ell)) \wedge R^u_D(E_u(h,k,\ell), E_v(h,k,\ell)) \wedge (\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, E_u(h,k,\ell$$

Proof. Apply Definition 45.634 to the selector pair (s,u) and contexts $L, R : \mathsf{BHist}$. Its strict exit row contains the denominator classifier row $R^u_D(E_s(h,k,\ell), E_u(h,k,\ell))$.

Apply the same strict exit package to the selector pair (t,v) and the same contexts. This supplies $R^u_D(E_t(h,k,\ell), E_v(h,k,\ell))$.

Apply Definition 45.612 to the selected pairs (s,u) and (t,v). This gives $\mathsf{RatHistoryClassifier}(E_s(h,k,\ell), E_u(h,k,$ and $\mathsf{RatHistoryClassifier}(E_t(h,k,\ell), E_v(h,k,\ell))$.

Next apply Definition 45.634 to the selector pair (s,t) and contexts $L, R : \mathsf{BHist}$. The resulting strict exit row is exactly the third displayed conjunction.

Finally apply the same strict exit package to the selector pair (u,v) and the same contexts. Its row is the fourth displayed conjunction, and together with the two componentwise classifier rows it assembles the stated deterministic selector-pair package. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup selector pair strict exit determinacy`

Per-object template: traditional target selector-pair determinacy for the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit; BEDC source BHist, BMark, and $\mathsf{RatUpFieldSource}$; carrier C^u_D; classifier R^u_D plus $\mathsf{RatHistoryClassifier}$; stability obligations selector strict exit row coverage and Rat classifier coverage; ledger the two selector pairs and contexts L, R; core theorem this block; exactness predicate componentwise selector determinacy; status $\mathsf{ProofTarget}$.

Theorem 45.761 (RatUp FieldUp bracketing selector complete obstruction package)**.** *For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *and histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$, $C^u_D(k)$, *and* $C^u_D(\ell)$, *let* $E_s(h, k, \ell)$ *be the endpoint selector of Definition 45.606. If* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then for all selectors* $s, t : \mathsf{BMark}$ *and contexts* $L, R : \mathsf{BHist}$, *setting* $a := E_s(h, k, \ell)$ *and* $b := E_t(h, k, \ell)$ *gives one concrete selector obstruction package with the following rows:*

1. $a\mathsf{hsame}b$;
2. $R^u_D(a, b)$;
3. $\mathsf{RatHistoryClassifier}(a, b)$;
4. $$\mathsf{fieldSingletonEmptyClassifier}(\mathsf{append}(L, a), \mathsf{append}(R, b)) \to \bot;$$
5. $$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(L, a)) \to \bot;$$
6. $$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(L, a));$$
7. $$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(a, R)) \to \bot;$$
8. $$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(a, R));$$
9. $$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(L, b)) \to \bot;$$
10. $$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(L, b));$$
11. $$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(b, R)) \to \bot;$$
12. $$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(b, R)).$$

Proof. First apply Definition 45.614 to the same denominator tuple, carrier witnesses, support witness, selector pair, and the context $L : \mathsf{BHist}$. This supplies $a\mathsf{hsame}b$ and $\mathsf{RatHistoryClassifier}(a, b)$ as the common selector-independent rows.

Next apply Definition 45.623 to the selector pair $s, t : \mathsf{BMark}$ and the contexts $L, R : \mathsf{BHist}$. Its exit row gives $R^u_D(a, b)$ and the singleton-classifier exclusion for $(\mathsf{append}(L, a), \mathsf{append}(R, b))$.

We now build the contextual nonzero rows for the left endpoint. Apply Definition 45.624 to the selector s with context L to obtain the carrier exclusion and $\mathsf{fieldSingletonEmptyNonZero}$ witness for $\mathsf{append}(L, a)$. Apply the same theorem to s with context R to obtain the corresponding right-context rows for $\mathsf{append}(a, R)$.

Finally apply Definition 45.624 to the selector t with context L, and then with context R. These two applications give the carrier exclusions and $\mathsf{fieldSingletonEmptyNonZero}$ witnesses for $\mathsf{append}(L, b)$ and $\mathsf{append}(b, R)$. Replacing a and b by the displayed selector endpoints assembles the concrete obstruction package. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup bracketing selector complete obstruction package`

Per-object template: traditional target bracketing-selector complete obstruction package inside $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, BMark, RatUp, the denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$, and endpoint selectors E_s, E_t; carrier C^u_D, $\mathsf{RatHistoryCarrier}$, and contextual $\mathsf{fieldSingletonEmptyCarrier}$ rejection; classifier R^u_D, $\mathsf{RatHistoryClassifier}$, and $\mathsf{fieldSingletonEmptyClassifier}$ rejection; stability obligations selector independence, selector exit subpackage, and contextual nonzero rows for both selected endpoints against the two external contexts; ledger selector pair plus contexts L, R; exactness predicate one concrete selector obstruction certificate; standard bridge deferred; status $\mathsf{ProofTarget}$.

Theorem 45.762 (RatUp FieldUp final certificate two-selector noncollapse boundary)**.** *For Definition 45.617, the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$, histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, selectors $s, t : \mathsf{BMark}$, and contexts $L, R, r : \mathsf{BHist}$, let $E_s(h, k, \ell)$ and $E_t(h, k, \ell)$ be the corresponding bracketing endpoint selectors of Definition 45.606. If $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ holds, then the same concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit boundary contains every row of Definition 45.759 together with the following right-selector rows:*

1.
$$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, E_t(h, k, \ell))) \to \bot;$$

2.
$$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(E_t(h, k, \ell), r)) \to \bot;$$

3.
$$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, E_t(h, k, \ell))));$$

4.
$$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(E_t(h, k, \ell), r)).$$

Proof. First apply Definition 45.759 to Definition 45.617, the denominator tuple, the histories, the three carrier witnesses, the selectors s, t, the contexts L, R, r, and the $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ witness. This fixes the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit boundary and supplies every row of the final selector noncollapse boundary.

Next apply Definition 45.614 with the same selector pair s, t and the same context $r : \mathsf{BHist}$. The right endpoint rows of that package give the two singleton-carrier exclusions and the two $\mathsf{fieldSingletonEmptyNonZero}$ witnesses for $E_t(h, k, \ell)$, so the boundary consumes both selected endpoints under the same concrete certificate. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup final certificate two selector noncollapse boundary`

Per-object template: traditional target final two-selector noncollapse boundary inside $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, BMark, RatUp, and Definition 45.617; denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$; selected endpoints $E_s(h, k, \ell)$ and $E_t(h, k, \ell)$; carrier rows those of the final selector boundary plus the right-selector singleton-carrier exclusions; classifier rows those of the final selector boundary and the selector-independence package; nonzero rows the left-selector witnesses of the final selector boundary plus the two right-selector witnesses; stability obligations final selector noncollapse boundary and bracketing selector independence; ledger selector pair plus contexts L, R, r; exactness predicate one concrete FieldUp exit boundary with both endpoint contexts; downstream consumer final certificate bracketing endpoint consumption; status $\mathsf{ProofTarget}$.

Theorem 45.763 (RatUp FieldUp complete selector exit obstruction certificate)**.** *For Definition 45.617, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u, v : \mathsf{BMark}$*, and contexts* $L, R, r : \mathsf{BHist}$*, let* $E_q(h, k, \ell)$ *be the bracketing endpoint selector of Definition 45.606 for each* $q : \mathsf{BMark}$*. If* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit package of Definition 45.618 contains, as one assembled certificate, all of the following rows:*

1. *every selector-pair strict row of Definition 45.760 for the selector comparison* (s, t) *against* (u, v) *and contexts* L, R*;*
2. *every* (s, t) *obstruction row of Definition 45.761, with* $a = E_s(h, k, \ell)$ *and* $b = E_t(h, k, \ell)$*;*
3. *every row of Definition 45.762 for the selector pair* (s, t)*, including the right-selector rows*

$$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(r, E_t(h, k, \ell))) \to \bot,$$

$$\mathsf{fieldSingletonEmptyCarrier}(\mathsf{append}(E_t(h, k, \ell), r)) \to \bot,$$

$$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(r, E_t(h, k, \ell))),$$

and

$$\mathsf{fieldSingletonEmptyNonZero}(\mathsf{append}(E_t(h, k, \ell), r)).$$

Proof. First instantiate Definition 45.760 with the given denominator tuple, histories, carrier witnesses, support witness, selectors s, t, u, v, and contexts $L, R : \mathsf{BHist}$. This supplies the two componentwise selector comparisons and the strict exit rows for the two selected pairs.

Next instantiate Definition 45.761 with the same denominator tuple, histories, carrier witnesses, support witness, selector pair (s, t), and contexts $L, R : \mathsf{BHist}$. The resulting rows are exactly the concrete obstruction rows for $a = E_s(h, k, \ell)$ and $b = E_t(h, k, \ell)$.

Now instantiate Definition 45.762 with the same concrete exit object, denominator tuple, histories, carrier witnesses, support witness, selector pair (s, t), contexts L, R, and right context $r : \mathsf{BHist}$. This contributes the final boundary rows and the four displayed right-selector noncollapse rows for $E_t(h, k, \ell)$.

Finally use Definition 45.618 only to identify these rows as rows of the concrete Definition 45.617. Conjunction introduction then repacks the three row families into one concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit certificate. □

Per-object template: traditional target complete selector exit obstruction certificate inside $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, BMark, RatUp, and Definition 45.617; denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$; selected endpoints $E_s(h, k, \ell)$, $E_t(h, k, \ell)$, $E_u(h, k, \ell)$, and $E_v(h, k, \ell)$; carrier rows selector strict exit carriers, contextual obstruction carrier exclusions, and right-selector noncollapse carrier exclusions; classifier rows componentwise denominator comparisons, $\mathsf{RatHistoryClassifier}$ rows, and contextual singleton-classifier rejection; nonzero rows strict endpoint nonzero witnesses, contextual endpoint witnesses, and final right-selector witnesses; stability obligations selector-pair strict exit determinacy, bracketing selector complete obstruction, and final certificate two-selector noncollapse; ledger selector comparison (s, t) against (u, v) plus contexts L, R, r; exactness predicate one concrete selector exit obstruction certificate; downstream consumer Phase Algebra Hierarchy $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit criterion; status $\mathsf{ProofTarget}$.

Theorem 45.764 (RatUp FieldUp selector-independent final boundary)**.** *For Definition 45.617, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u, v : \mathsf{BMark}$*, and contexts* $L, R, r : \mathsf{BHist}$*, let* $E_q(h, k, \ell)$ *be the bracketing*

endpoint selector of Definition 45.606 for each $q : \mathsf{BMark}$. *If* $\mathsf{ThreeSupp}^u_D(h,k,\ell)$ *holds, then the same concrete* $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$ *final exit boundary contains the following rows:*

1. *every row of Definition 45.762 for the selector pair* (s,t)*;*
2. *every row of Definition 45.762 for the selector pair* (u,v)*;*
3. $$R^u_D(E_s(h,k,\ell),E_u(h,k,\ell)) \wedge R^u_D(E_t(h,k,\ell),E_v(h,k,\ell));$$
4. $$\mathsf{RatHistoryClassifier}(E_s(h,k,\ell),E_u(h,k,\ell)) \wedge \mathsf{RatHistoryClassifier}(E_t(h,k,\ell),E_v(h,k,\ell)).$$

Proof. First apply Definition 45.760 to the histories, carrier witnesses, support witness, selectors s,t,u,v, and contexts $L,R : \mathsf{BHist}$. Its componentwise rows give $R^u_D(E_s(h,k,\ell),E_u(h,k,\ell))$, $R^u_D(E_t(h,k,\ell),E_v(h,k,\ell))$, and the two displayed $\mathsf{RatHistoryClassifier}$ rows. The same application also supplies the strict exit rows for both selector pairs (s,t) and (u,v).

Next apply Definition 45.761 to the pair (s,t) and then to the pair (u,v) with the same contexts $L,R : \mathsf{BHist}$. These two obstruction packages provide the contextual singleton-classifier exclusions and contextual nonzero rows consumed by the final certificate boundary for each selected pair.

Finally apply Definition 45.762 once with selectors s,t and once with selectors u,v, keeping the same concrete exit object, denominator tuple, histories, support witness, and context $r : \mathsf{BHist}$. Combining those two final-boundary packages with the componentwise comparison rows from the strict determinacy theorem yields one selector-independent final boundary for the concrete $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$ certificate. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup selector independent final boundary`

Per-object template: traditional target selector-independent final boundary inside $\mathsf{Field}^\uparrow(\mathsf{RatUp})$; BEDC source BHist, BMark, RatUp, and Definition 45.617; denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$; selected endpoints $E_s(h,k,\ell)$, $E_t(h,k,\ell)$, $E_u(h,k,\ell)$, and $E_v(h,k,\ell)$; carrier rows the two final certificate boundaries plus the componentwise denominator comparisons; classifier rows $\mathsf{RatHistoryClassifier}$ for the two componentwise selector comparisons; nonzero rows the contextual witnesses consumed by both final certificate boundaries; stability obligations selector-pair strict exit determinacy, bracketing selector complete obstruction, and final certificate two-selector noncollapse; ledger selector pairs (s,t) and (u,v) plus contexts L,R,r; exactness predicate one final FieldUp exit boundary independent of certified selector-pair replacement; downstream consumer stable algebra-hierarchy exit certificate; status $\mathsf{ProofTarget}$.

Theorem 45.765 (RatUp FieldUp selector-chain final boundary)**.** *For Definition 45.617, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h,k,\ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s,t,u,v,w,z : \mathsf{BMark}$*, and contexts* $L,R,r : \mathsf{BHist}$*, let* $E_q(h,k,\ell)$ *be the bracketing endpoint selector of Definition 45.606 for each* $q : \mathsf{BMark}$. *If* $\mathsf{ThreeSupp}^u_D(h,k,\ell)$ *holds, then the same concrete* $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$ *final exit boundary contains the following rows:*

1. *every row of Definition 45.762 for the selector pair* (s,t)*;*
2. *every row of Definition 45.762 for the selector pair* (u,v)*;*
3. *every row of Definition 45.762 for the selector pair* (w,z)*;*
4. $$R^u_D(E_s(h,k,\ell),E_w(h,k,\ell)) \wedge R^u_D(E_t(h,k,\ell),E_z(h,k,\ell));$$

5.

$$\mathsf{RatHistoryClassifier}(E_s(h,k,\ell), E_w(h,k,\ell)) \wedge \mathsf{RatHistoryClassifier}(E_t(h,k,\ell), E_z(h,k,\ell)).$$

Proof. First apply Definition 45.764 to the selector comparison from (s,t) to (u,v) with the same concrete exit object, denominator tuple, histories, carrier witnesses, support witness, and contexts $L, R, r : \mathsf{BHist}$. This gives the final-boundary rows for (s,t) and (u,v) together with the componentwise denominator and $\mathsf{RatHistoryClassifier}$ rows from E_s to E_u and from E_t to E_v.

Next apply Definition 45.764 to the selector comparison from (u,v) to (w,z) over the same data. This gives the final-boundary rows for (u,v) and (w,z) together with the componentwise denominator and $\mathsf{RatHistoryClassifier}$ rows from E_u to E_w and from E_v to E_z.

It remains to collapse the two adjacent replacements into endpoint rows. Use the transitivity field of the concrete denominator classifier R^u_D to compose

$$R^u_D(E_s(h,k,\ell), E_u(h,k,\ell)) \quad \text{with} \quad R^u_D(E_u(h,k,\ell), E_w(h,k,\ell))$$

and likewise compose the E_t to E_v row with the E_v to E_z row.

Finally use the transitivity field of $\mathsf{RatHistoryClassifier}$ in the same two components. Conjunction introduction repacks the three final-boundary row families and the two chained componentwise classifier families into one stable final boundary for the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit certificate. □

Lean4 ✓ `BEDC.Derived.FieldUp.ratup fieldup selector chain final boundary`

Per-object template: traditional target selector-chain final boundary inside $\mathsf{Field}^{\uparrow}(\mathsf{RatUp})$; BEDC source BHist, BMark, RatUp, and Definition 45.617; denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$; selected endpoints $E_s(h,k,\ell)$, $E_t(h,k,\ell)$, $E_u(h,k,\ell)$, $E_v(h,k,\ell)$, $E_w(h,k,\ell)$, and $E_z(h,k,\ell)$; carrier rows the three final certificate boundaries plus the two chained componentwise denominator comparisons; classifier rows $\mathsf{RatHistoryClassifier}$ for the two chained selector comparisons; nonzero rows the contextual witnesses consumed by the three final certificate boundaries; stability obligations selector-independent final boundary and transitivity for both denominator and history classifiers; ledger selector pairs (s,t), (u,v), and (w,z) plus contexts L, R, r; exactness predicate one final FieldUp exit boundary closed under selector-chain replacement; downstream consumer stable selector-chain replacement for the Phase Algebra Hierarchy $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit certificate; status $\mathsf{ProofTarget}$.

Theorem 45.766 (RatUp FieldUp concrete exit selector-independent final boundary)**.** *For* $\mathsf{RatUpFieldSource}_F$*, the concrete exit object of Definition 45.617 contains the selector-independent final boundary row for the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*. Explicitly, for histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u, v : \mathsf{BMark}$*, and contexts* $L, R, r : \mathsf{BHist}$*, if* $\mathsf{ThreeSupp}^u_D(h,k,\ell)$ *holds, then the concrete exit object contains both final-certificate two-selector noncollapse packages, the two componentwise* R^u_D *comparisons, and the two* $\mathsf{RatHistoryClassifier}$ *comparisons of Definition 45.764.*

Proof. Apply Definition 45.764 to the same concrete denominator tuple, histories, carrier witnesses, support witness, selectors s, t, u, v, and contexts L, R, r. This supplies the two final two-selector noncollapse packages and the four componentwise comparison rows listed in the selector-independent final boundary.

By Definition 45.617, those selector-independent final boundary rows are one conjunct of the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. Therefore the rows supplied by Definition 45.764 are contained in the concrete exit object for $\mathsf{RatUpFieldSource}_F$. □

Theorem 45.767 (RatUp FieldUp concrete final obstruction boundary package)**.** *For* $\mathsf{RatUpFieldSource}_F$*, Definition 45.617, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u, v : \mathsf{BMark}$*, and contexts* $L, R, r : \mathsf{BHist}$*, let* $E_q(h, k, \ell)$ *be the bracketing endpoint selector of Definition 45.606 for each* $q : \mathsf{BMark}$*. If* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then the concrete* $\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F)$ *contains both the full assembled obstruction certificate of Definition 45.763 and the selector-independent final boundary row of Definition 45.766.*

Proof. First instantiate Definition 45.763 with the displayed denominator tuple, histories, carrier witnesses, support witness, selectors s, t, u, v, and contexts $L, R, r : \mathsf{BHist}$. This supplies the assembled selector obstruction rows: selector-pair strict exit, bracketing obstruction, and two-selector noncollapse.

Next instantiate Definition 45.766 with the same source, concrete exit object, denominator tuple, histories, carrier witnesses, support witness, selectors s, t, u, v, and contexts L, R, r. This supplies the selector-independent final boundary row for the same concrete denominator tuple.

Finally cite Definition 45.618 only to keep both row families tied to the same $\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F)$. Conjunction introduction then packages the assembled obstruction certificate with the selector-independent final boundary as one concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit package. □

Per-object template: traditional target final FieldUp exit package; BEDC source BHist, BMark, and $\mathsf{RatUpFieldSource}_F$; carrier $\mathsf{RatHistoryCarrier}$ and C^u_D; classifier $\mathsf{RatHistoryClassifier}$ and R^u_D; stability obligations selector-pair strict exit, bracketing obstruction, two-selector noncollapse, and selector-independent final boundary; ledger selector quadruple s, t, u, v plus contexts L, R, r; core theorem Definition 45.767; exactness one concrete final exit package; downstream consumer Phase Algebra Hierarchy $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit criterion; status $\mathsf{ProofTarget}$.

Theorem 45.768 (RatUp FieldUp concrete final obstruction chain boundary package)**.** *For* $\mathsf{RatUpFieldSource}_F$*, Definition 45.617, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u, v, w, z : \mathsf{BMark}$*, and contexts* $L, R, r : \mathsf{BHist}$*, let* $E_q(h, k, \ell)$ *be the bracketing endpoint selector of Definition 45.606 for each* $q : \mathsf{BMark}$*. If* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then the concrete* $\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F)$ *contains both the full assembled obstruction certificate of Definition 45.763 for* (s, t, u, v) *and the selector-chain final boundary rows of Definition 45.765 for* (s, t)*,* (u, v)*, and* (w, z)*. In particular, the same concrete exit object contains the chained denominator rows*

$$R^u_D(E_s(h, k, \ell), E_w(h, k, \ell)) \wedge R^u_D(E_t(h, k, \ell), E_z(h, k, \ell))$$

and the chained endpoint classifier rows

$$\mathsf{RatHistoryClassifier}(E_s(h, k, \ell), E_w(h, k, \ell)) \wedge \mathsf{RatHistoryClassifier}(E_t(h, k, \ell), E_z(h, k, \ell)).$$

Proof. First instantiate Definition 45.767 with the displayed source, concrete exit object, denominator tuple, histories, carrier witnesses, support witness, selectors s, t, u, v, and contexts $L, R, r : \mathsf{BHist}$. This gives the concrete obstruction package containing the assembled obstruction certificate for (s, t, u, v) inside $\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F)$.

Next instantiate Definition 45.765 with the same denominator tuple, histories, carrier witnesses, support witness, selectors s, t, u, v, w, z, and contexts L, R, r. This gives the three selector pairs (s, t), (u, v), and (w, z) together with the chained R^u_D endpoint comparisons and the chained $\mathsf{RatHistoryClassifier}$ endpoint comparisons from E_s, E_t to E_w, E_z.

Finally use Definition 45.617 to identify the selector-chain final-boundary family as an explicit row of the concrete exit object. Then cite Definition 45.618 to keep that row and the assembled

obstruction certificate inside the same $\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F)$. Conjunction introduction packages the two families as one concrete final obstruction chain boundary package for $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$. □

Per-object template: traditional target selector-chain obstruction package for $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source BHist, BMark, and $\mathsf{RatUpFieldSource}_F$; carrier $\mathsf{RatHistoryCarrier}$ and C^u_D; classifier $\mathsf{RatHistoryClassifier}$ and R^u_D; stability obligations concrete final obstruction package plus selector-chain final boundary; ledger selector sextuple s, t, u, v, w, z plus contexts L, R, r; exactness one chain-stable final exit package; downstream consumer Phase Algebra Hierarchy $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit certificate; status $\mathsf{ProofTarget}$.

Theorem 45.769 (RatUp FieldUp two-step algebra hierarchy exit certificate)**.** *For* $\mathsf{RatUpFieldSource}_F$*, the concrete exit object* $\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F)$*, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u, v, w, z : \mathsf{BMark}$*, contexts* $L, R, r : \mathsf{BHist}$*, and the endpoint selector* $E_q(h, k, \ell)$ *of Definition 45.606, if* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then the one concrete exit object contains every algebra-hierarchy exit row, every operation-table coverage row, both adjacent complete selector-obstruction certificates for* (s, t, u, v) *and* (u, v, w, z)*, and the selector-chain final boundary rows, including the chained* R^u_D *rows and the chained* $\mathsf{RatHistoryClassifier}$ *endpoint rows.*

Proof. First instantiate Definition 45.755 with the displayed source, denominator tuple, histories, selectors s, t, u, v, w, z, contexts L, R, r, endpoint selector, and $\mathsf{ThreeSupp}^u_D(h, k, \ell)$. This supplies the hierarchy rows, the operation-table coverage rows, the first selector-obstruction certificate, and the selector-chain boundary rows.

Next instantiate Definition 45.757 with the same data. This supplies both adjacent complete selector-obstruction certificates and the same selector-chain final boundary rows, including the chained denominator and Rat-history endpoint rows.

Finally cite Definition 45.618 to keep the hierarchy package and the two-step obstruction package inside the same concrete $\mathsf{RatUpFieldExitObject}_F(\mathcal{E}_F)$. Conjunction introduction repacks those row families as one Phase Algebra Hierarchy $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit certificate. □

Per-object template: traditional target two-step algebra hierarchy exit certificate for $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source BHist, BMark, and $\mathsf{RatUpFieldSource}_F$; carrier rows C^u_D and the concrete algebra hierarchy carriers; classifier rows R^u_D and $\mathsf{RatHistoryClassifier}$; denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$; operation table the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ table; ledger selector sextuple s, t, u, v, w, z plus contexts L, R, r; stability obligations hierarchy exit, operation-table coverage, two adjacent selector obstructions, and selector-chain final boundary; exactness one two-step algebra hierarchy exit certificate; downstream consumer Phase Algebra Hierarchy $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit certificate; status $\mathsf{ProofTarget}$.

Theorem 45.770 (RatUp FieldUp final row inventory semantic certificate)**.** *For* $\mathsf{RatUpFieldSource}_F$*, let* $\mathcal{E}_F$ *be the concrete exit object of Definition 45.617. For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with carrier witnesses* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u, v, w, z : \mathsf{BMark}$*, contexts* $L, R, r : \mathsf{BHist}$*, and a support witness* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*, the semantic certificate boundary for* $\mathsf{RatUpFieldSource}_F$ *contains, over the same concrete exit object, all of the following rows:*

1. *the paper certificate assembly of Definition 45.494;*
2. *the concrete schema row of Definition 45.502;*
3. *the proof-target exit package of Definition 45.584;*
4. *every row of Definition 45.773.*

Consequently the selector inverse-domain coverage, selector row transport, complete obstruction, and selector-chain boundary rows are all anchored over $\mathsf{RatHistoryCarrier}$, $\mathsf{RatHistoryClassifier}$, $\mathsf{RatDenomUnitCarrier}$, $\mathsf{RatDenomUnitClassifier}$, append, e, Γ, *and* AffAut_F *inside the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *semantic certificate.*

Proof. Start with Definition 45.494. It fixes the paper-side semantic boundary for $\mathsf{RatUpFieldSource}_F$ over $\mathsf{RatHistoryCarrier}$, $\mathsf{RatHistoryClassifier}$, the displayed denominator tuple, the contextual action Γ, and the affine source AffAut_F.

Next apply Definition 45.502. The schema row identifies the same concrete source tuple and the same concrete exit object $\mathcal{E}_F$ with the BHist rows used by the certificate boundary.

Then apply Definition 45.584. This places the concrete schema row inside the proof-target exit package for $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$, still over the same carrier, classifier, denominator tuple, action source, and affine source.

Finally apply Definition 45.773 to the displayed histories, carrier witnesses, support witness, selectors, and contexts. It supplies the selector inverse-domain, selector row transport, complete obstruction, and selector-chain boundary rows for $\mathcal{E}_F$.

Conjunction introduction packages the semantic assembly, schema row, proof-target exit package, and final row inventory as one consumed certificate boundary for $\mathsf{RatUpFieldSource}_F$. □

Per-object template: traditional target semantic consumption certificate for the final $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ row inventory; BEDC source BHist, BMark, and $\mathsf{RatUpFieldSource}_F$; carriers $\mathsf{RatHistoryCarrier}$, C^u_D, and $\mathsf{RatDenomUnitCarrier}$; classifiers $\mathsf{RatHistoryClassifier}$, R^u_D, and $\mathsf{RatDenomUnitClassifier}$; operations append, e, Γ, and AffAut_F; stability obligations semantic name certificate, concrete schema row, proof-target exit package, selector coverage, selector transport, complete obstruction, and chain boundary; ledger selectors s, t, u, v, w, z plus contexts L, R, r; exactness final inventory rows inside the semantic certificate boundary; downstream consumer Phase Algebra Hierarchy $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit certificate; status $\mathsf{ProofTarget}$.

Theorem 45.771 (RatUp FieldUp Rat-classified factors exclude empty product)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *candidate satisfying the hypotheses of Definition 45.248, specialize the nonzero index to*

$$\mathsf{ApartZero}_F(h) := (h\mathsf{hsame0} \to \bot).$$

Assume the RatUp concrete exit object identifies the field-zero endpoint with the empty history, and includes classifier transport for $\mathsf{ApartZero}_F$ *together with contradiction of* $\mathsf{ApartZero}_F(0)$*. Then for all histories* $a, a', b, b' : \mathsf{BHist}$*,*

$$\mathsf{RatHistoryClassifier}(a, a') \wedge \mathsf{RatHistoryClassifier}(b, b') \quad \Longrightarrow \quad (\mathsf{mul}(a, b)\mathsf{hsame0} \to \bot) \wedge (\mathsf{mul}(a', b')\mathsf{hsame0} \to \bot).$$

Proof. Unpack the two classifier witnesses. Apply Definition 37.51 to $\mathsf{RatHistoryClassifier}(a, a')$ and to $\mathsf{RatHistoryClassifier}(b, b')$. The four endpoint exclusions, transported across the concrete identification of the field-zero endpoint with e, give witnesses $p_a : \mathsf{ApartZero}_F(a)$, $p_{a'} : \mathsf{ApartZero}_F(a')$, $p_b : \mathsf{ApartZero}_F(b)$, and $p_{b'} : \mathsf{ApartZero}_F(b')$.

The stability field for $\mathsf{ApartZero}_F$ is transport along hsame: if $h\mathsf{hsame}k$ and $h\mathsf{hsame0} \to \bot$, then any $k\mathsf{hsame0}$ composes back to $h\mathsf{hsame0}$ and gives contradiction. The zero contradiction clause is immediate because $\mathsf{ApartZero}_F(0)$ applied to reflexivity of $0\mathsf{hsame0}$ yields $\bot$.

Instantiate Definition 45.248 first at (a, b) with witnesses p_a and p_b, obtaining $\mathsf{mul}(a, b)\mathsf{hsame0} \to \bot$. Instantiate the same theorem at (a', b') with witnesses $p_{a'}$ and $p_{b'}$, obtaining $\mathsf{mul}(a', b')\mathsf{hsame0} \to \bot$. Conjunction introduction packages the two Rat-classified product exclusions. □

Per-object template: traditional target Rat-classified nonzero product in $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source BHist, $\mathsf{RatHistoryClassifier}$, and the FieldUp apart-zero certificate; carrier RatHistoryClassifier endpoints; classifier hsame; stability Rat endpoint nonemptiness plus FieldUp zero-product exclusion; ledger the two classifier witnesses; exactness predicate no empty product for classified Rat endpoints; downstream consumer Phase Algebra Hierarchy $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit certificate; status $\mathsf{ProofTarget}$.

Theorem 45.772 (Rat denominator carried continuation unit obstruction)**.** *For every history $u : \mathsf{BHist}$, a carried Rat denominator cannot itself be the continuation left unit for all carried denominators. Concretely,*

$$\mathsf{RatHistoryCarrier}(u) \to (\forall d, r : \mathsf{BHist}.\ \mathsf{RatHistoryCarrier}(d) \to \mathsf{Cont}(u, d, r) \to \mathsf{RatHistoryClassifier}(r, d)) \to \mathsf{False}.$$

Proof. Assume a carrier witness $\mathsf{RatHistoryCarrier}(u)$ and the displayed left-unit classifier law. Apply Definition 45.352 to the law; the forward implication yields $u\mathsf{hsamee}$.

Now apply Definition 37.18 to the same carrier witness and the endpoint comparison $u\mathsf{hsamee}$. This contradicts the nonempty Rat denominator condition, giving False. □

Per-object template: traditional target carried-unit obstruction for the Rat-denominator side of $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source BHist, Cont, and $\mathsf{RatHistoryCarrier}$; carrier $\mathsf{RatHistoryCarrier}$; classifier $\mathsf{RatHistoryClassifier}$; stability obligation left-unit endpoint exactness; ledger external unit versus carried denominator; core theorem Definition 45.772; exactness predicate no carried denominator is the continuation unit; downstream consumer the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit certificate; status $\mathsf{ProofTarget}$.

Theorem 45.773 (RatUp FieldUp final row inventory coverage)**.** *For $\mathsf{RatUpFieldSource}_F$, let $\mathcal{E}_F$ be the concrete exit object of Definition 45.617. For the concrete denominator tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$, histories $h, k, \ell : \mathsf{BHist}$ with $C^u_D(h)$, $C^u_D(k)$, and $C^u_D(\ell)$, selectors $s, t, u, v, w, z : \mathsf{BMark}$, and contexts $L, R, r : \mathsf{BHist}$, let $E_q(h, k, \ell)$ be the bracketing endpoint selector of Definition 45.606 for each $q : \mathsf{BMark}$. If $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ holds, then the final row inventory of $\mathcal{E}_F$ contains all of the following rows as one consumable Phase Algebra Hierarchy package:*

1. *the selector inverse-domain coverage row of Definition 45.619 for the selected pair (s, t) and contexts L, R;*
2. *for every primed denominator triple $h', k', \ell' : \mathsf{BHist}$ satisfying $C^u_D(h')$, $C^u_D(k')$, $C^u_D(\ell')$, $\mathsf{ThreeSupp}^u_D(h', k', \ell')$, $R^u_D(h, h')$, $R^u_D(k, k')$, and $R^u_D(\ell, \ell')$, and for every $L', R' : \mathsf{BHist}$ with $\mathsf{hsame}(L, L')$ and $\mathsf{hsame}(R, R')$, the selector row-stability row of Definition 45.620;*
3. *the complete selector exit obstruction certificate of Definition 45.763 for the selector quadruple (s, t, u, v) and contexts L, R, r;*
4. *the selector-chain final boundary rows of Definition 45.765 for the selector pairs (s, t), (u, v), and (w, z).*

Equivalently, the one concrete FieldUp exit object supplies selector inverse-domain coverage, selector row transport, complete obstruction, and chain boundary rows to the $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit certificate without changing the underlying BHist source, BMark selectors, or $\mathsf{RatUpFieldSource}_F$ package.

Proof. First instantiate Definition 45.619 at the displayed concrete denominator tuple, the histories h, k, ℓ, their carrier witnesses, the support witness, the selector pair (s, t), and the contexts L, R. This gives the strict inverse-domain selector row for $\mathcal{E}_F$.

Next take an arbitrary primed denominator triple h', k', ℓ' with the displayed carrier, support, and R^u_D comparison hypotheses, and take L', R' with $\mathsf{hsame}(L, L')$ and $\mathsf{hsame}(R, R')$. Apply Definition 45.620 to these data. The result is the selector row-stability transport row for the same concrete exit object.

We then instantiate Definition 45.763 with the same denominator tuple, histories, carrier witnesses, support witness, selectors s, t, u, v, and contexts L, R, r. This supplies the complete selector exit obstruction certificate inside the concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ package.

Finally instantiate Definition 45.765 with the same denominator tuple, histories, carrier witnesses, support witness, selectors s, t, u, v, w, z, and contexts L, R, r. It supplies the three selector-pair final boundary row families and the chained endpoint classifier rows.

All four cited results refer to Definition 45.617 and to the concrete tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$. Conjunction introduction packages their row families as one final row inventory for the Phase Algebra Hierarchy consumer. □

Per-object template: traditional target final FieldUp row inventory; BEDC source BHist, BMark, and $\mathsf{RatUpFieldSource}_F$; carrier $\mathsf{RatHistoryCarrier}$ and C^u_D; classifier $\mathsf{RatHistoryClassifier}$ and R^u_D; stability obligations selector coverage, selector row transport, complete obstruction, concrete final obstruction package, and selector-chain final boundary; ledger selectors s, t, u, v, w, z plus contexts L, R, r; core theorem this block; exactness final row inventory coverage and one chain-stable final exit package; downstream consumer Phase Algebra Hierarchy $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit certificate; status $\mathsf{ProofTarget}$.

Theorem 45.774 (RatUp FieldUp selector-independent two-step final inventory)**.** *For* $\mathsf{RatUpFieldSource}_F$*, let* $\mathcal{E}_F$ *be the concrete exit object of Definition 45.617. For the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u, v, w, z : \mathsf{BMark}$*, contexts* $L, R, r : \mathsf{BHist}$*, and the endpoint selector* $E_q(h, k, \ell)$ *of Definition 45.606, if* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ *holds, then the same concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object* $\mathcal{E}_F$ *simultaneously supplies all of the following rows as one concrete Phase Algebra Hierarchy exit package:*

1. *the operation-table lock of Definition 45.753;*
2. *the selector-independent algebra hierarchy exit of Definition 45.754;*
3. *the two-step algebra hierarchy exit certificate of Definition 45.769;*
4. *the final row inventory of Definition 45.773.*

Thus the operation table, selector-independent boundary, two-step obstruction, and final inventory rows are consumed through one displayed BHist*-anchored* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object, with no change of source, denominator tuple, selectors, contexts, or support witness.*

Proof. First instantiate Definition 45.753 at $\mathsf{RatUpFieldSource}_F$ and the concrete exit object $\mathcal{E}_F$. This supplies the completed exit-object row, the assembled operation-table coverage row, and the selector-independent final boundary row for the same BHist package.

Next instantiate Definition 45.754 with the displayed denominator tuple, histories h, k, ℓ, carrier witnesses, support witness, selectors s, t, u, v, and contexts L, R, r. This gives the selector-independent Phase Algebra Hierarchy exit rows over the same concrete source tuple.

Now instantiate Definition 45.769 with the same exit object, denominator tuple, histories, carrier witnesses, support witness, selector sextuple s, t, u, v, w, z, contexts L, R, r, and endpoint selector $E_q(h, k, \ell)$. This contributes both adjacent selector-obstruction certificates and the selector-chain final boundary rows.

Finally instantiate Definition 45.773 with the same concrete exit object, denominator tuple, histories, carrier witnesses, support witness, selectors, and contexts. Its rows provide selector inverse-domain coverage, selector row transport, complete obstruction, and chain-boundary inventory.

The four instantiations all name Definition 45.617 and the tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$. Conjunction introduction packages those row families as the single selector-independent, two-step, final inventory exit object claimed. □

Per-object template: traditional target final $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit inventory; BEDC source BHist, BMark, and $\mathsf{RatUpFieldSource}_F$; carrier $\mathsf{RatHistoryCarrier}$ and C^u_D; classifier $\mathsf{RatHistoryClassifier}$ and R^u_D; stability obligations operation-table lock, selector-independent boundary, two-step obstruction, and final row inventory; ledger selector sextuple s, t, u, v, w, z plus contexts L, R, r; exactness one concrete Phase Algebra Hierarchy exit package; status $\mathsf{ProofTarget}$.

Theorem 45.775 (RatUp FieldUp four endpoint product nonempty)**.** *For a BEDC history-level* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *candidate satisfying the hypotheses of Definition 45.771, assume the same field-operation data, the same identification of the field-zero endpoint with* e*, the same transport for* $\mathsf{ApartZero}_F(h) := (h\mathsf{hsame}0 \to \bot)$*, and the same contradiction of* $\mathsf{ApartZero}_F(0)$*. Then for all histories* $a, a', b, b' : \mathsf{BHist}$*, if*

$$\mathsf{RatHistoryClassifier}(a, a') \wedge \mathsf{RatHistoryClassifier}(b, b'),$$

then the same concrete $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *operation package contains all four nonempty product rows:*

1. $\mathsf{mul}(a, b)\mathsf{hsamee} \to \bot$*;*
2. $\mathsf{mul}(a, b')\mathsf{hsamee} \to \bot$*;*
3. $\mathsf{mul}(a', b)\mathsf{hsamee} \to \bot$*;*
4. $\mathsf{mul}(a', b')\mathsf{hsamee} \to \bot$*.*

Proof. Apply Definition 45.771 to the displayed classifier pair. This gives the two diagonal exclusions for $\mathsf{mul}(a, b)$ and $\mathsf{mul}(a', b')$, transported through the fixed identification of the field-zero endpoint with e.

Next build the left mixed row. The first classifier supplies the endpoint carrier fields for a and a', while the second classifier supplies the carrier field for b. Apply Definition 37.37 to that carrier field to form the reflexive Rat classifier on the second endpoint pair (b, b). Applying the same two-diagonal product theorem to $\mathsf{RatHistoryClassifier}(a, a')$ and this reflexive classifier gives the product exclusion for $\mathsf{mul}(a', b)$.

Now build the right mixed row. Apply Definition 37.37 to the endpoint carrier field for a supplied by the first classifier, forming the reflexive Rat classifier on (a, a). Applying the same two-diagonal product theorem to this reflexive classifier and $\mathsf{RatHistoryClassifier}(b, b')$ gives the product exclusion for $\mathsf{mul}(a, b')$.

Conjunction introduction packages the four exclusions in the displayed order. All four applications use the same field-operation hypotheses, the same zero-empty identification, the same apart-zero transport, and the same BHist carrier and classifier data. □

Per-object template: traditional target four-endpoint Rat-classified nonempty product in $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; BEDC source BHist, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{Field}^{\uparrow}$; carriers $\mathsf{RatHistoryCarrier}$ and the endpoint carrier fields contained in $\mathsf{RatHistoryClassifier}$; classifiers $\mathsf{RatHistoryClassifier}$ and hsame; stability obligations Rat endpoint nonemptiness, reflexive endpoint classification, apart-zero transport, and FieldUp

zero-product exclusion; ledger the two classifier witnesses, the two reflexive classifiers, the four endpoint choices, and the zero-empty identification; core theorem this block; exactness predicate four products apart from e; downstream consumer Definition 45.776; status ProofTarget.

Theorem 45.776 (RatUp FieldUp operation-table final inventory nonzero coverage)**.** *Fix the concrete source* $\mathsf{RatUpFieldSource}_F$*, the operation table of Definition 45.587, and the concrete exit object* $\mathcal{E}_F$ *of Definition 45.617. Let* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *be the concrete denominator tuple, let* $h, k, \ell : \mathsf{BHist}$ *satisfy* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(\ell)$*, and* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*, and let* $s, t, u, v, w, z : \mathsf{BMark}$ *and* $L, R, r : \mathsf{BHist}$ *be the chosen selectors and contexts. For Rat-classified endpoint pairs* $a, a', b, b' : \mathsf{BHist}$ *satisfying*

$$\mathsf{RatHistoryClassifier}(a, a') \wedge \mathsf{RatHistoryClassifier}(b, b'),$$

and for every carried denominator $q : \mathsf{BHist}$ *satisfying* $\mathsf{RatHistoryCarrier}(q)$*, one* BHist*-anchored* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit package contains, at the same time:*

1. *the assembled certificate operation-table coverage of Definition 45.534;*
2. *the concrete operation-table laws of Definition 45.588;*
3. *the final row inventory of Definition 45.773;*
4. *the diagonal Rat-classified product nonzero exclusions* $(\mathsf{mul}(a, b)\mathsf{hsame0} \to \bot)$ *and* $(\mathsf{mul}(a', b')\mathsf{hsame0} \to \bot)$ *from Definition 45.771;*
5. *the obstruction saying that* q *cannot be the continuation left unit for all carried denominators, as in Definition 45.772.*

Thus the Phase Algebra Hierarchy consumer can read the operation table, final inventory rows, Rat-classified product exclusions, and carried-denominator unit obstruction from one concrete BHist *package without changing source, selectors, contexts, or denominator tuple.*

Proof. First build the operation-table spine. Apply Definition 45.534 to the concrete source and table, and apply Definition 45.588 to the same table. These two rows name the same RatHistoryCarrier, RatHistoryClassifier, denominator coordinate, contextual action, context-pair monoid, affine coordinate, inverse rows, nonzero rows, and exit-noncollapse rows.

Next build the final inventory row family. Apply Definition 45.773 to the concrete exit object, denominator tuple, carrier witnesses for h, k, ℓ, the $\mathsf{ThreeSupp}^u_D(h, k, \ell)$ witness, selectors s, t, u, v, w, z, and contexts L, R, r. This gives the selector inverse-domain row, selector row-stability row, complete selector obstruction certificate, and chain-boundary rows inside $\mathcal{E}_F$.

Then build the diagonal product exclusions. Apply Definition 45.771 to the two displayed Rat-classified endpoint pairs. It supplies $(\mathsf{mul}(a, b)\mathsf{hsame0} \to \bot)$ and $(\mathsf{mul}(a', b')\mathsf{hsame0} \to \bot)$ as concrete diagonal endpoint rows for the same history-level $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ package.

Finally build the denominator-unit obstruction. Apply Definition 45.772 to the carrier witness $\mathsf{RatHistoryCarrier}(q)$. The resulting contradiction rule excludes a carried denominator from being a continuation left unit for all carried denominators.

All rows are sourced from $\mathsf{RatUpFieldSource}_F$, the operation table of Definition 45.587, and the exit object of Definition 45.617. Conjunction introduction packages the four row families into the single concrete BHist-anchored exit package claimed. □

Theorem 45.777 (RatUp FieldUp operation-table final inventory four-endpoint coverage)**.** *Fix the concrete source* $\mathsf{RatUpFieldSource}_F$*, the operation table of Definition 45.587, and the concrete exit object* $\mathcal{E}_F$ *of Definition 45.617. Let* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *be the concrete denominator tuple, let* $h, k, \ell : \mathsf{BHist}$ *satisfy* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(\ell)$*, and* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*, and let* $s, t, u, v, w, z :$

BMark *and* $L, R, r : \mathsf{BHist}$ *be the chosen selectors and contexts. For Rat-classified endpoint pairs* $a, a', b, b' : \mathsf{BHist}$ *satisfying*

$$\mathsf{RatHistoryClassifier}(a, a') \wedge \mathsf{RatHistoryClassifier}(b, b'),$$

and for every carried denominator $q : \mathsf{BHist}$ *satisfying* $\mathsf{RatHistoryCarrier}(q)$*, one concrete* BHist*-anchored* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *package contains, at the same time:*

1. *the assembled certificate operation-table coverage of Definition 45.534;*
2. *the concrete operation-table laws of Definition 45.588;*
3. *the final row inventory of Definition 45.773;*
4. *the carried-denominator unit obstruction of Definition 45.772;*
5. *the four Rat-classified product exclusions* $\mathsf{mul}(a, b)\mathsf{hsamee} \to \bot$*,* $\mathsf{mul}(a, b')\mathsf{hsamee} \to \bot$*,* $\mathsf{mul}(a', b)\mathsf{hsamee} \to \bot$*, and* $\mathsf{mul}(a', b')\mathsf{hsamee} \to \bot$*.*

Thus the Phase Algebra Hierarchy consumer reads the operation table, final inventory rows, carried-denominator unit obstruction, and all four Rat-classified product exclusions from one concrete BHist *package.*

Proof. First build the table, final-inventory, unit-obstruction, and diagonal product rows. Apply Definition 45.776 to the concrete source, operation table, exit object, denominator tuple, histories, selectors, contexts, Rat-classified endpoint pairs, and carried denominator q. This gives the assembled operation-table coverage, concrete operation-table laws, final row inventory, carried-denominator unit obstruction, and the diagonal Rat-classified product rows inside the same BHist-anchored package.

Next build the four endpoint product rows. Apply Definition 45.775 to the same field-operation data, zero-empty identification, apart-zero transport, zero-apart contradiction, and the two displayed $\mathsf{RatHistoryClassifier}$ hypotheses. This supplies the two diagonal rows and the two mixed rows for the same endpoint quadruple.

Finally keep the same source, table, exit object, denominator tuple, selectors, contexts, endpoint pairs, and carried denominator. Conjunction introduction packages the table rows, final inventory, unit obstruction, and four endpoint product exclusions as the concrete final-inventory $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ package claimed. □

Per-object template: traditional target final $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit package with four Rat-classified product rows; BEDC source BHist, BMark, and $\mathsf{RatUpFieldSource}_F$; carrier $\mathsf{RatHistoryCarrier}$ and C^u_D; classifier $\mathsf{RatHistoryClassifier}$ and R^u_D; stability obligations operation-table coverage, final row inventory, carried-denominator unit obstruction, and four endpoint product nonemptiness; ledger selector sextuple s, t, u, v, w, z, contexts L, R, r, endpoint quadruple a, a', b, b', and carried denominator q; exactness one concrete final-inventory package with four products apart from e; downstream consumer Phase Algebra Hierarchy $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; status $\mathsf{ProofTarget}$.

Theorem 45.778 (RatUp FieldUp operation-table final inventory two-sided unit coverage)**.** *Fix the concrete source* $\mathsf{RatUpFieldSource}_F$*, the operation table of Definition 45.587, and the concrete exit object* $\mathcal{E}_F$ *of Definition 45.617. Let* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *be the concrete denominator tuple, let* $h, k, \ell : \mathsf{BHist}$ *satisfy* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(\ell)$*, and* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*, and let* $s, t, u, v, w, z : \mathsf{BMark}$ *and* $L, R, r : \mathsf{BHist}$ *be the chosen selectors and contexts. For Rat-classified endpoint pairs* $a, a', b, b' : \mathsf{BHist}$ *satisfying*

$$\mathsf{RatHistoryClassifier}(a, a') \wedge \mathsf{RatHistoryClassifier}(b, b'),$$

and for every carried denominator q : BHist *satisfying* RatHistoryCarrier(q)*, one concrete* BHist-*anchored* Field$^{\uparrow}$(Rat$^{\uparrow}$) *package contains, at the same time:*

1. *the assembled certificate operation-table coverage of Definition 45.534;*
2. *the concrete operation-table laws of Definition 45.588;*
3. *the final row inventory of Definition 45.773;*
4. *the four Rat-classified product exclusions* $\mathsf{mul}(a,b)\mathsf{hsamee} \to \bot$, $\mathsf{mul}(a,b')\mathsf{hsamee} \to \bot$, $\mathsf{mul}(a',b)\mathsf{hsamee} \to \bot$, *and* $\mathsf{mul}(a',b')\mathsf{hsamee} \to \bot$ *from Definition 45.777;*
5. *the append right-unit denial at* q,
$$(\forall x : \mathsf{BHist}.\ C_D(x) \to R_D(\mu_D(x,q),x)) \to \mathsf{False};$$
6. *the append left-unit denial at* q,
$$(\forall x : \mathsf{BHist}.\ C_D(x) \to R_D(\mu_D(q,x),x)) \to \mathsf{False};$$
7. *the relational denial for* $\mathsf{Cont}(x,q,r)$,
$$(\forall x,r : \mathsf{BHist}.\ C_D(x) \to \mathsf{Cont}(x,q,r) \to R_D(r,x)) \to \mathsf{False};$$
8. *the relational denial for* $\mathsf{Cont}(q,x,r)$,
$$(\forall x,r : \mathsf{BHist}.\ C_D(x) \to \mathsf{Cont}(q,x,r) \to R_D(r,x)) \to \mathsf{False}.$$

Here C_D, R_D, μ_D *are the strict-denominator presentation of Definition 45.323, identified there with* RatHistoryCarrier*,* RatHistoryClassifier*, and append. Thus the Phase Algebra Hierarchy consumer can read the operation table, final inventory rows, Rat-classified product exclusions, and both append and relational one-sided unit denials from one concrete* BHist *package without changing source, selectors, contexts, or denominator tuple.*

Proof. First build the operation-table, final-inventory, unit-obstruction, and four endpoint product rows. Apply Definition 45.777 to the concrete source, operation table, exit object, denominator tuple, histories, selectors, contexts, Rat-classified endpoint pairs, and carried denominator q. This gives the assembled operation-table coverage, the concrete operation-table laws, the final inventory, carried-denominator unit obstruction, and the four Rat-classified product exclusions inside the same BHist-anchored package.

Next build the strict denominator rows. Apply Definition 45.331 at the carried denominator q, using the identification of $C_D(q)$ with RatHistoryCarrier(q) in Definition 45.323. Its append presentation supplies the right-unit and left-unit denials, and its relational presentation supplies the two Cont endpoint denials.

Finally, keep the witnesses named by the same source, operation table, exit object, denominator tuple, selectors, contexts, endpoint pairs, and carried denominator. Conjunction introduction packages these row families as the single concrete final Field$^{\uparrow}$(Rat$^{\uparrow}$) exit package claimed. □

Per-object template: traditional target Field$^{\uparrow}$ final concrete exit package; BEDC source BHist, Cont, RatHistoryCarrier, and RatHistoryClassifier; carrier C_D^u; classifier R_D^u; stability obligations operation-table coverage plus two-sided unit obstruction; ledger selectors s,t,u,v,w,z and contexts L,R,r; exactness as the concrete final package; downstream consumer Phase Algebra Hierarchy Field$^{\uparrow}$(Rat$^{\uparrow}$); status ProofTarget.

Theorem 45.779 (RatUp FieldUp operation-table final inventory four-endpoint unit coverage)**.** *Fix the concrete source* $\mathsf{RatUpFieldSource}_F$*, the operation table of Definition 45.587, and the concrete exit object* $\mathcal{E}_F$ *of Definition 45.617. Let* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *be the concrete denominator tuple, let* $h, k, \ell : \mathsf{BHist}$ *satisfy* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(\ell)$*, and* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*, and let* $s, t, u, v, w, z : \mathsf{BMark}$ *and* $L, R, r : \mathsf{BHist}$ *be the chosen selectors and contexts. For Rat-classified endpoint pairs* $a, a', b, b' : \mathsf{BHist}$ *satisfying*

$$\mathsf{RatHistoryClassifier}(a, a') \wedge \mathsf{RatHistoryClassifier}(b, b'),$$

and for every carried denominator $q : \mathsf{BHist}$ *satisfying* $\mathsf{RatHistoryCarrier}(q)$*, one concrete* BHist*-anchored* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *package contains, at the same time:*

1. *the assembled certificate operation-table coverage of Definition 45.534;*
2. *the concrete operation-table laws of Definition 45.588;*
3. *the final row inventory of Definition 45.773;*
4. *the four Rat-classified product exclusions* $(\mathsf{mul}(a, b)\mathsf{hsamee} \to \bot)$*,* $(\mathsf{mul}(a, b')\mathsf{hsamee} \to \bot)$*,* $(\mathsf{mul}(a', b)\mathsf{hsamee} \to \bot)$*, and* $(\mathsf{mul}(a', b')\mathsf{hsamee} \to \bot)$*;*
5. *the append right-unit denial at* q*,*
$$(\forall x : \mathsf{BHist}.\ C_D(x) \to R_D(\mu_D(x, q), x)) \to \mathsf{False};$$
6. *the append left-unit denial at* q*,*
$$(\forall x : \mathsf{BHist}.\ C_D(x) \to R_D(\mu_D(q, x), x)) \to \mathsf{False};$$
7. *the relational denial for* $\mathsf{Cont}(x, q, r)$*,*
$$(\forall x, r : \mathsf{BHist}.\ C_D(x) \to \mathsf{Cont}(x, q, r) \to R_D(r, x)) \to \mathsf{False};$$
8. *the relational denial for* $\mathsf{Cont}(q, x, r)$*,*
$$(\forall x, r : \mathsf{BHist}.\ C_D(x) \to \mathsf{Cont}(q, x, r) \to R_D(r, x)) \to \mathsf{False}.$$

Here C_D, R_D, μ_D *are the strict-denominator presentation of Definition 45.323, identified there with* $\mathsf{RatHistoryCarrier}$*,* $\mathsf{RatHistoryClassifier}$*, and append. Thus the Phase Algebra Hierarchy consumer can read the operation table, final inventory rows, all four Rat-classified product exclusions, and both append and relational one-sided unit denials from one concrete* BHist *package without changing source, selectors, contexts, or denominator tuple.*

Proof. First apply Definition 45.778 to the concrete source, operation table, exit object, denominator tuple, histories, support witness, selectors, contexts, Rat-classified endpoint pairs, and carried denominator q. This supplies the operation-table rows, final inventory row, diagonal product exclusions, and the four append and relational one-sided unit denials inside the same BHist-anchored package.

Next apply Definition 45.775 to the same two Rat classifier witnesses. Its four endpoint rows give the two diagonal product exclusions already present in the two-sided package and add the mixed rows for $\mathsf{mul}(a, b')$ and $\mathsf{mul}(a', b)$.

Finally keep the same source, operation table, exit object, denominator tuple, selectors, contexts, endpoint pairs, and carried denominator. Conjunction introduction packages the operation-table rows, final inventory, all four product exclusions, and the four one-sided unit denials into the concrete final $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit package claimed. □

Per-object template: traditional target $\mathsf{Field}^{\uparrow}$ final concrete four-endpoint exit package; BEDC source BHist, Cont, $\mathsf{RatHistoryCarrier}$, and $\mathsf{RatHistoryClassifier}$; carrier C^u_D; classifier R^u_D; stability obligations operation-table coverage, four-endpoint product nonemptiness, and two-sided unit obstruction; ledger selectors s, t, u, v, w, z, contexts L, R, r, Rat endpoint pairs, and carried denominator q; exactness as the concrete final four-endpoint package; downstream consumer Phase Algebra Hierarchy $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; status $\mathsf{ProofTarget}$.

Theorem 45.780 (RatUp FieldUp final inventory carried-external unit separation)**.** *Fix the concrete source* $\mathsf{RatUpFieldSource}_F$*, the operation table of Definition 45.587, and the concrete exit object* $\mathcal{E}_F$ *of Definition 45.617. Let* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *be the concrete denominator tuple, let* $h, k, \ell : \mathsf{BHist}$ *satisfy* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(\ell)$*, and* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*, and let* $s, t, v, v, w, z : \mathsf{BMark}$ *and* $L, R, r : \mathsf{BHist}$ *be the chosen selectors and contexts. For Rat-classified endpoint pairs* $a, a', b, b' : \mathsf{BHist}$ *satisfying*

$$\mathsf{RatHistoryClassifier}(a, a') \wedge \mathsf{RatHistoryClassifier}(b, b'),$$

for every carried denominator $q : \mathsf{BHist}$ *satisfying* $\mathsf{RatHistoryCarrier}(q)$*, and for histories* $u, d : \mathsf{BHist}$ *satisfying* $U_D(u)$ *and* $\mathsf{RatHistoryCarrier}(d)$*, one concrete* BHist*-anchored* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *final-inventory boundary contains, at the same time:*

1. *the operation-table final inventory rows and two-sided unit coverage rows of Definition 45.778 for the displayed source, table, exit object, tuple, histories, selectors, contexts, endpoint pairs, and carried denominator* q*;*
2. *the carried-external classifier separation row*

$$\big(\mathsf{RatHistoryClassifier}(u, d) \vee \mathsf{RatHistoryClassifier}(d, u)\big) \to \mathsf{False}$$

supplied by Definition 45.366 from $U_D(u)$*.*

Thus the same concrete final exit object $\mathcal{E}_F$ *records both the complete operation-table final inventory consumed by the Phase Algebra Hierarchy and the classifier separation between an external denominator unit and a carried Rat denominator.*

Proof. First apply Definition 45.778 to the concrete source, operation table, exit object, denominator tuple, histories h, k, ℓ, support witness, selectors s, t, v, v, w, z, contexts L, R, r, Rat-classified endpoint pairs, and the carried denominator q. This supplies the operation-table coverage rows, concrete operation-table laws, final row inventory, four Rat-classified product exclusions, and both append and relational one-sided unit denials inside $\mathcal{E}_F$.

Next apply Definition 45.366 to the histories u, d and the displayed witness $U_D(u)$. The resulting implication rules out both possible Rat-classifier orientations $\mathsf{RatHistoryClassifier}(u, d)$ and $\mathsf{RatHistoryClassifier}(d, u)$. The carrier witness $\mathsf{RatHistoryCarrier}(d)$ identifies the second endpoint as one of the carried denominator objects governed by the final-inventory boundary.

Finally keep the same source, table, exit object, denominator tuple, selectors, contexts, endpoint pairs, carried denominator, external-unit witness, and carried-denominator witness. Conjunction introduction packages the two-sided final inventory rows and the carried-external classifier separation row as one concrete BHist-anchored $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ boundary. □

Per-object template: traditional target final $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ carried-external unit boundary; BEDC source BHist, BMark, Cont, and $\mathsf{RatUpFieldSource}_F$; carrier $\mathsf{RatHistoryCarrier}$ and C^u_D; classifier $\mathsf{RatHistoryClassifier}$ and R^u_D; stability obligations operation-table final inventory, two-sided unit obstruction, and carried-external classifier separation; ledger selectors s, t, v, v, w, z, contexts L, R, r,

carried denominator q, external unit u, and carried denominator endpoint d; core theorem list Definition 45.778 and Definition 45.366; exactness predicate final inventory plus external-unit classifier disjointness; standard bridge Phase Algebra Hierarchy $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$; status $\mathsf{ProofTarget}$.

Theorem 45.781 (RatUp FieldUp final inventory phase-exit boundary)**.** *Fix the concrete source* $\mathsf{RatUpFieldSource}_F$*, the operation table of Definition 45.587, and the concrete exit object* $\mathcal{E}_F$ *of Definition 45.617. Let* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *be the concrete denominator tuple, let* $h, k, \ell : \mathsf{BHist}$ *satisfy* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(\ell)$*, and* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*, and let* $s, t, v, v, w, z : \mathsf{BMark}$ *and* $L, R, r : \mathsf{BHist}$ *be the chosen selectors and contexts. For Rat-classified endpoint pairs* $x, x', y, y' : \mathsf{BHist}$ *satisfying*

$$\mathsf{RatHistoryClassifier}(x, x') \wedge \mathsf{RatHistoryClassifier}(y, y'),$$

for every carried denominator $q : \mathsf{BHist}$ *satisfying* $\mathsf{RatHistoryCarrier}(q)$*, fix apart-zero context data* $L_0, R_0, \tau : \mathsf{BHist}$ *with* $p : \mathsf{FieldApartZero}(L_0)$*, guard histories* $\alpha, \beta : \mathsf{BHist}$*, the contextual action* Γ*, the affine source* AffAut_F*, and the same BEDC history operations add, mul, neg, and zero satisfying the CommRing hypotheses used by Definition 44.85. If*

$$H : ((\alpha + \beta)\mathsf{hsame0} \vee (\alpha + (-\beta))\mathsf{hsame0}),$$

and histories $u, d : \mathsf{BHist}$ *satisfy* $U_D(u)$ *and* $\mathsf{RatHistoryCarrier}(d)$*, then the same exit object* $\mathcal{E}_F$ *supplies one concrete* BHist*-anchored* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *boundary containing, at the same time:*

1. *the phase-exit record certificate boundary of Definition 45.792 for the displayed source, exit object, denominator tuple, histories, selectors, contexts, endpoint pairs, carried denominator, apart-zero data, contextual action, affine source, operations, guard hypothesis, and external-unit witness;*
2. *the operation-table final inventory rows and two-sided unit coverage of Definition 45.778 for the displayed source, table, exit object, denominator tuple, histories, selectors, contexts, endpoint pairs, and carried denominator;*
3. *the carried-external classifier separation row*

$$(\mathsf{RatHistoryClassifier}(u, d) \vee \mathsf{RatHistoryClassifier}(d, u)) \to \mathsf{False}$$

   of Definition 45.780 for the same external unit, carried endpoint, unit witness, and carried denominator endpoint.

Thus the traditional final $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit boundary reads the phase record certificate, the final-inventory unit coverage, and the carried-external classifier separation from one unchanged concrete exit package.*

Proof. First invoke Definition 45.792 with the displayed guard hypothesis H and the external-unit witness $U_D(u)$. Its certificate rows are read over the same source, exit object, denominator tuple, selectors, contexts, Rat endpoints, carried denominator, contextual action, affine source, and CommRing operations.

Next invoke Definition 45.780 with the same concrete source, operation table, exit object, denominator tuple, histories, selectors, contexts, endpoint pairs, carried denominator q, external unit u, carried endpoint d, witness $U_D(u)$, and carrier witness $\mathsf{RatHistoryCarrier}(d)$. That theorem already imports the operation-table final inventory and two-sided unit coverage of Definition 45.778.

Finally conjoin the two packages. The source, table, exit object, denominator tuple, selectors, contexts, endpoint pairs, carried denominator, external-unit witness, carried endpoint, and guard datum are unchanged, so the conclusion is one concrete BHist-anchored phase-exit boundary rather than two separately indexed row families. □

Per-object template: traditional target final $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit boundary; BEDC source BHist, $\mathsf{Rat}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, and $\mathsf{Field}^{\uparrow}$; carriers $\mathsf{RatHistoryCarrier}$ and denominator carrier C^u_D; classifiers $\mathsf{RatHistoryClassifier}$, R^u_D, and hsame; stability obligations phase-exit record plus final-inventory unit separation; ledger source, operation table, exit object, denominator tuple, histories, selectors, contexts, Rat-classified endpoint pairs, carried denominator q, external unit u, carried endpoint d, guard hypothesis H, and witness $U_D(u)$; exactness one concrete boundary; downstream consumer Phase Algebra Hierarchy exit criterion; status $\mathsf{ProofTarget}$.

Theorem 45.782 (RatUp FieldUp chapter certificate row coverage)**.** *For* $\mathsf{RatUpFieldSource}_F$*, let* $\mathcal{E}_F$ *be the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object of Definition 45.617. The chapter-level* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *certificate exposes over one concrete* BHist *source the following row package:*

1. *the carrier, classifier, denominator, and contextual-action rows of Definition 45.502;*
2. *the operation-table coverage of Definition 45.615;*
3. *the completed exit object of Definition 45.618;*
4. *the final-row semantic certificate of Definition 45.770;*
5. *the nonzero and unit-obstruction rows of Definition 45.776.*

Thus a downstream Phase Algebra Hierarchy consumer can read $\mathcal{E}_F$ *as a single concrete row-coverage certificate for the canonical* BHist *source.*

Proof. First take the concrete schema instance of Definition 45.502. It fixes the shared BHist source together with the carrier, classifier, denominator tuple, and contextual action rows used by the $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ construction.

Next combine the operation-table coverage from Definition 45.615 with the completed exit object of Definition 45.618. These two cited certificates identify the same selectors and the same concrete object $\mathcal{E}_F$ rather than introducing a second exit target.

Finally append the final-row semantic certificate from Definition 45.770 and the nonzero and unit-obstruction rows from Definition 45.776. Conjunction introduction packages these cited rows into one chapter-level certificate.

The consumer never changes the carrier, classifier, denominator tuple, contextual action, selectors, or exit object. It only reads the rows already provided by the cited concrete BHist certificates. □

Theorem 45.783 (RatUp FieldUp phase-exit certificate consumption)**.** *For* $\mathsf{RatUpFieldSource}_F$*, let* $\mathcal{E}_F$ *be the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object of Definition 45.617. Fix the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with carrier witnesses* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u, v, w, z : \mathsf{BMark}$*, contexts* $L, R, r : \mathsf{BHist}$*, and a support witness* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*. Also fix apart-zero context data* $L_0, R_0, x : \mathsf{BHist}$ *with* $p : \mathsf{FieldApartZero}(L_0)$*.*

Then the same concrete object $\mathcal{E}_F$ *supplies, as one consumed phase-exit certificate boundary, all of the following rows:*

1. *the canonical concrete phase-exit target of Definition 45.651;*
2. *the final semantic row inventory of Definition 45.770;*
3. *the contextual apart-zero semantic certificate row of Definition 45.658 at* L_0, R_0, x, p*.*

All three rows use the same BHist *carrier universe, the same* $\mathsf{RatHistoryCarrier}$ *and* $\mathsf{RatHistoryClassifier}$ *anchors, the same denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *where denominator data are required, and the same contextual action* Γ*.*

Proof. First instantiate Definition 45.651 at $\mathsf{RatUpFieldSource}_F$ and Definition 45.617. This fixes $\mathcal{E}_F$ as the canonical concrete phase-exit target over BHist, $\mathsf{RatHistoryCarrier}$, $\mathsf{RatHistoryClassifier}$, the displayed denominator object, Γ, and the $\mathsf{Field}^{\uparrow}$ exit rows.

Next instantiate Definition 45.770 with the tuple $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$, the histories h, k, ℓ, the three carrier witnesses, the selectors s, t, u, v, w, z, the contexts L, R, r, and the support witness $\mathsf{ThreeSupp}^u_D(h, k, \ell)$. This contributes the final semantic row inventory for the same exit object $\mathcal{E}_F$.

For the apart-zero row, apply Definition 45.658 to L_0, R_0, x and $p : \mathsf{FieldApartZero}(L_0)$. Its displayed source, pattern, ledger policy, and classifier are all built from the same BHist carrier and hsame classifier discipline.

Conjunction introduction packages the canonical target, the final inventory, and the contextual apart-zero row as one consumed boundary for the Phase Algebra Hierarchy exit criterion. □

Per-object template: traditional target constructive rational field phase-exit boundary; BEDC source BHist, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{Field}^{\uparrow}$; carriers $\mathsf{RatHistoryCarrier}$, C^u_D, and the contextual apart-zero predicate; classifiers $\mathsf{RatHistoryClassifier}$, R^u_D, and hsame; stability obligations the canonical phase-exit target, final semantic row inventory, contextual apart-zero row; ledger selectors, denominator witnesses, contexts, and apart-zero witness; exactness one consumed concrete phase-exit boundary; downstream consumer Phase Algebra Hierarchy exit criterion; status $\mathsf{ProofTarget}$.

Theorem 45.784 (RatUp FieldUp full algebra hierarchy exit package)**.** *For* $\mathsf{RatUpFieldSource}_F$*, let* $\mathcal{E}_F$ *be the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object of Definition 45.617. Fix the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with carrier witnesses* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u, v, w, z : \mathsf{BMark}$*, contexts* $L, R, r : \mathsf{BHist}$*, and a support witness* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*. Also fix Rat-classified endpoint pairs* $a, a', b, b' : \mathsf{BHist}$ *satisfying* $\mathsf{RatHistoryClassifier}(a, a')$ *and* $\mathsf{RatHistoryClassifier}(b, b')$*, a carried denominator* $q : \mathsf{BHist}$ *with* $\mathsf{RatHistoryCarrier}(q)$*, apart-zero context data* $L_0, R_0, x : \mathsf{BHist}$ *with* $p : \mathsf{FieldApartZero}(L_0)$*.*

Then the same concrete BHist*-anchored* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit package* $\mathcal{E}_F$ *simultaneously supplies all rows required by the Phase Algebra Hierarchy exit boundary:*

1. *the three phase-exit rows of Definition 45.783;*
2. *the operation-table, final-inventory, four-endpoint Rat-classified nonzero-product, and one-sided unit obstruction rows of Definition 45.779;*
3. *the selector-independent two-step final inventory of Definition 45.774, using the endpoint selector* $E_q(h, k, \ell)$ *of Definition 45.606.*

All three row families are read over the same source $\mathsf{RatUpFieldSource}_F$*, the same exit object* $\mathcal{E}_F$*, the same denominator tuple, histories, carrier witnesses, selectors, contexts, Rat-classified endpoints, carried denominator, and apart-zero context row.*

Proof. First instantiate Definition 45.783 with the displayed denominator tuple, histories, carrier witnesses, selectors, contexts, support witness, and apart-zero data L_0, R_0, x, p. This supplies the canonical phase-exit target, final semantic row inventory, and contextual apart-zero row for $\mathcal{E}_F$.

Next instantiate Definition 45.779 with the same source, operation table, exit object, denominator tuple, histories, support witness, selectors, contexts, Rat-classified endpoint pairs, and carried denominator q. It contributes the operation-table rows, final inventory rows, four-endpoint nonzero-product exclusions, and one-sided unit obstruction inside the same BHist package.

Finally instantiate Definition 45.774 with the same denominator tuple, histories, carrier witnesses, support witness, selectors, contexts, and endpoint selector $E_q(h, k, \ell)$. This contributes the operation-table lock, selector-independent algebra hierarchy exit, two-step certificate, and final row inventory without changing the exit object.

Conjunction introduction packages these three instantiated row families as one concrete certificate-level object. The Phase Algebra Hierarchy consumer therefore reads a single $\mathcal{E}_F$ boundary instead of reconstructing the exit from separate row inventories. □

Per-object template: traditional target complete rational field algebra hierarchy exit boundary; BEDC source BHist, BMark, $\mathsf{Rat}^{\uparrow}$, and $\mathsf{Field}^{\uparrow}$; carriers $\mathsf{RatHistoryCarrier}$ and C^u_D; classifiers $\mathsf{RatHistoryClassifier}$, R^u_D, and hsame; stability obligations phase-exit consumption, operation-table final-inventory four-endpoint unit coverage, and selector-independent two-step final inventory; ledger selectors s, t, u, v, w, z, contexts L, R, r, endpoint pairs, carried denominator, and apart-zero witness; exactness one concrete BHist-anchored $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit package; downstream consumer Phase Algebra Hierarchy exit criterion; status $\mathsf{ProofTarget}$.

Theorem 45.785 (RatUp FieldUp bilateral zero-factor and external-unit guard package)**.** *For* $\mathsf{RatUpFieldSource}_F$*, let* $\mathcal{E}_F$ *be the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object of Definition 45.617. Fix histories* $a, b, u, d : \mathsf{BHist}$*, the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, the contextual action* Γ*, the affine source* AffAut_F*, and the same BEDC history operations add, mul, neg, and zero satisfying the CommRing hypotheses used by Definition 44.85. If*

$$H : \big((a + b)\mathsf{hsame}0 \vee (a + (-b))\mathsf{hsame}0\big),$$

then the same exit object $\mathcal{E}_F$ *exposes the following two concrete guard rows as part of its phase-exit boundary:*

1. *the four-component bilateral zero-factor conclusion of Definition 44.85 for* a, b*;*
2. *the external-unit classifier separation row* $U_D(u) \to (\mathsf{RatHistoryClassifier}(u, d) \vee \mathsf{RatHistoryClassifier}(d, u)) \to \mathsf{False}$ *from Definition 45.366.*

Both rows are recorded over the shared BHist *universe, the shared* $\mathsf{RatHistoryCarrier}$ *and* $\mathsf{RatHistoryClassifier}$ *anchors, the displayed denominator tuple, the contextual action* Γ*, and the affine source* AffAut_F*.*

Proof. First apply Definition 45.651 together with Definition 45.617. These directly fix the shared concrete exit object $\mathcal{E}_F$ together with its carrier, classifier, denominator tuple, contextual action, and affine source already named in the theorem statement.

Next apply Definition 44.85 to the displayed hypothesis H. Its result is exactly the branch annihilator package, the two signed-product orientations, and the square equality $a \cdot a\mathsf{hsame}b \cdot b$.

For the denominator side, apply Definition 45.366 to the histories u, d. This produces the concrete implication from $U_D(u)$ and either classifier endpoint orientation to False.

Finally package these two outputs as guard rows of the already fixed $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit object. The first row supplies the CommRing bilateral zero-factor exactness ledger, and the second row supplies the Rat denominator external-unit classifier separation guard. □

Per-object template: traditional target constructive rational field guard package; BEDC source BHist, $\mathsf{Rat}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, and $\mathsf{Field}^{\uparrow}$; carriers $\mathsf{RatHistoryCarrier}$ and U_D; classifiers $\mathsf{RatHistoryClassifier}$ and hsame; stability obligations bilateral zero-factor exactness and external-unit classifier separation; ledger selected linear factor, signed-product orientations, square equality, external-unit law, and classifier endpoint; core theorem this block; exactness predicate the paired guard rows; downstream consumer Phase Algebra Hierarchy exit criterion; status $\mathsf{ProofTarget}$.

Theorem 45.786 (RatUp FieldUp guarded full algebra hierarchy exit package)**.** *For* $\mathsf{RatUpFieldSource}_F$*, let* $\mathcal{E}_F$ *be the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object of Definition 45.617. Fix the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with carrier witnesses* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*,*

selectors $s, t, u_0, v, w, z : \mathsf{BMark}$*, contexts* $L, R, r : \mathsf{BHist}$*, and a support witness* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*. Also fix Rat-classified endpoint pairs* $x, x', y, y' : \mathsf{BHist}$ *satisfying* $\mathsf{RatHistoryClassifier}(x, x')$ *and* $\mathsf{RatHistoryClassifier}(y, y')$*, a carried denominator* $q : \mathsf{BHist}$ *with* $\mathsf{RatHistoryCarrier}(q)$*, apart-zero context data* $L_0, R_0, t : \mathsf{BHist}$ *with* $p : \mathsf{FieldApartZero}(L_0)$*, histories* $a, b, u, d : \mathsf{BHist}$*, the contextual action* Γ*, the affine source* AffAut_F*, and the same BEDC history operations add, mul, neg, and zero satisfying the CommRing hypotheses used by Definition 44.85. If*

$$H : \big((a + b)\mathsf{hsame0} \vee (a + (-b))\mathsf{hsame0}\big),$$

then the one concrete BHist*-anchored* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit package* $\mathcal{E}_F$ *simultaneously supplies:*

1. *the full algebra hierarchy exit rows of Definition 45.784;*
2. *the bilateral zero-factor guard row and external-unit classifier separation guard row of Definition 45.785.*

The two components are read over the same concrete source $\mathsf{RatUpFieldSource}_F$*, the same exit object* $\mathcal{E}_F$*, the same denominator tuple, contextual action, affine source, histories, carrier witnesses, selectors, contexts, support witness, Rat-classified endpoint pairs, carried denominator, apart-zero context, and guard data.*

Proof. First instantiate Definition 45.784 with the displayed source, exit object, denominator tuple, histories h, k, ℓ, carrier witnesses, selectors, contexts, support witness, Rat-classified endpoint pairs, carried denominator q, and apart-zero data L_0, R_0, t, p. This yields the full algebra hierarchy exit rows over the fixed BHist-anchored $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ package $\mathcal{E}_F$.

Next instantiate Definition 45.785 with the shared exit object $\mathcal{E}_F$, the same denominator tuple, contextual action Γ, affine source AffAut_F, BEDC history operations, histories a, b, u, d, and zero-linear-factor witness H. This yields the bilateral zero-factor guard row and the external-unit classifier separation guard row without changing the concrete exit object.

Finally introduce the conjunction of these two instantiated outputs. The Phase Algebra Hierarchy exit criterion therefore consumes one guarded $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ boundary whose full-exit rows and guard rows are anchored by the same concrete BHist object. □

Per-object template: traditional target guarded rational field phase-exit package; BEDC source BHist, $\mathsf{Rat}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, and $\mathsf{Field}^{\uparrow}$; carriers $\mathsf{RatHistoryCarrier}$, C^u_D, and U_D; classifiers $\mathsf{RatHistoryClassifier}$, R^u_D, and hsame; stability obligations full algebra hierarchy exit rows, bilateral zero-factor guard row, and external-unit classifier separation guard row; ledger denominator tuple, histories, carrier witnesses, selectors, contexts, support witness, endpoint pairs, carried denominator, apart-zero context, contextual action, zero-linear-factor witness, and external-unit endpoint; exactness the combined exit-plus-guard boundary; downstream consumer Phase Algebra Hierarchy exit criterion; status $\mathsf{ProofTarget}$.

Theorem 45.787 (RatUp FieldUp guarded canonical action and inverse exit package)**.** *For* $\mathsf{RatUpFieldSource}_F$*, let* $\mathcal{E}_F$ *be the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object of Definition 45.617. Fix the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with carrier witnesses* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u_0, v, w, z : \mathsf{BMark}$*, contexts* $L, R, r : \mathsf{BHist}$*, and a support witness* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*. Also fix Rat-classified endpoint pairs* $x, x', y, y' : \mathsf{BHist}$ *satisfying* $\mathsf{RatHistoryClassifier}(x, x')$ *and* $\mathsf{RatHistoryClassifier}(y, y')$*, a carried denominator* $q : \mathsf{BHist}$ *with* $\mathsf{RatHistoryCarrier}(q)$*, apart-zero context data* $L_0, R_0, \tau : \mathsf{BHist}$ *with* $p : \mathsf{FieldApartZero}(L_0)$*, histories* $a, b, u, d : \mathsf{BHist}$*, the contextual action* Γ*, the affine source* AffAut_F*, and the same BEDC history*

operations add, mul, neg, and zero satisfying the CommRing hypotheses used by Definition 44.85. If

$$H : \big((a+b)\mathsf{hsame0} \vee (a+(-b))\mathsf{hsame0}\big),$$

then the one concrete BHist*-anchored* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit package* $\mathcal{E}_F$ *simultaneously supplies:*

1. *the guarded full algebra hierarchy rows of Definition 45.786;*
2. *the canonical action-and-inverse rows of Definition 45.662.*

The two components are read over the same concrete source $\mathsf{RatUpFieldSource}_F$*, the same exit object* $\mathcal{E}_F$*, the same denominator tuple, contextual action, affine source, histories, carrier witnesses, selectors, contexts, support witness, Rat-classified endpoint pairs, carried denominator, apart-zero context, and guard datum.*

Proof. First instantiate Definition 45.786 with the displayed source, exit object, denominator tuple, histories h, k, ℓ, carrier witnesses, selectors, contexts, support witness, Rat-classified endpoint pairs, carried denominator q, apart-zero data L_0, R_0, τ, p, contextual action Γ, affine source, BEDC history operations, histories a, b, u, d, and guard hypothesis H. This yields the guarded full algebra hierarchy rows on the fixed concrete package $\mathcal{E}_F$.

Next instantiate Definition 45.662 for the same exit object $\mathcal{E}_F$. Its reduct, inverse-product classifier exactness, and affine action rows attach to the identical carrier, classifier, denominator tuple, contextual action, and affine source already selected above.

Finally introduce the conjunction of the two instantiated outputs. No carrier, classifier, denominator tuple, contextual action, affine source, or guard datum changes, so the Phase Algebra Hierarchy exit criterion may cite one concrete BHist-anchored $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ boundary for both the guard rows and the canonical action-and-inverse support. □

Per-object template: traditional target guarded rational field exit with action and inverse support; BEDC source BHist, $\mathsf{Rat}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, and $\mathsf{Field}^{\uparrow}$; carriers RatHistoryCarrier, C^u_D, U_D, and AffAut_F; classifiers RatHistoryClassifier, R^u_D, hsame, and $\equiv_{\mathrm{aff}}$; stability obligations guarded full algebra hierarchy exit rows, algebra-reduct compatibility, inverse-product classifier exactness, affine group laws, affine fiber singleton exactness, and affine cancellation exactness; ledger denominator tuple, guard witness, inverse-product witnesses, affine coefficients, offsets, inverse witnesses, contextual action, affine source, and carrier support; exactness the combined guarded action-inverse exit boundary; downstream consumer Phase Algebra Hierarchy exit criterion; status ProofTarget.

Definition 45.788 (RatUp FieldUp phase-exit record)**.** *For* $\mathsf{RatUpFieldSource}_F$*, let* $\mathcal{E}_F$ *be the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object of Definition 45.617. Fix the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with carrier witnesses* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u_0, v, w, z : \mathsf{BMark}$*, contexts* $L, R, r : \mathsf{BHist}$*, and a support witness* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*. Also fix Rat-classified endpoint pairs* $x, x', y, y' : \mathsf{BHist}$ *satisfying* $\mathsf{RatHistoryClassifier}(x, x')$ *and* $\mathsf{RatHistoryClassifier}(y, y')$*, a carried denominator* $q : \mathsf{BHist}$ *with* $\mathsf{RatHistoryCarrier}(q)$*, apart-zero context data* $L_0, R_0, \tau : \mathsf{BHist}$ *with* $p : \mathsf{FieldApartZero}(L_0)$*, histories* $a, b, u, d : \mathsf{BHist}$*, the contextual action* Γ*, the affine source* AffAut_F*, and BEDC history operations add, mul, neg, and zero satisfying the CommRing hypotheses used by Definition 44.85. Also fix a guard hypothesis*

$$H : \big((a+b)\mathsf{hsame0} \vee (a+(-b))\mathsf{hsame0}\big).$$

The record predicate $\mathsf{RatUpFieldPhaseExit}(\mathcal{E}_F)$ *means that the fixed source, exit object, denominator tuple, contextual action, affine source, histories, carrier witnesses, selectors, contexts, support witness, Rat-classified endpoint pairs, carried denominator, apart-zero guard data, guard hypothesis, and inverse/action rows jointly satisfy the following four components:*

1. *the chapter row coverage of Definition 45.782;*
2. *the full algebra hierarchy exit package of Definition 45.784;*
3. *the guarded full package of Definition 45.786;*
4. *the guarded canonical action-inverse package of Definition 45.787.*

Thus the predicate is a named conjunction over the single BHist *source, the carrier* $\mathsf{RatHistoryCarrier}$*, the denominator carrier* C^u_D*, the classifiers* $\mathsf{RatHistoryClassifier}$*,* R^u_D*, and* hsame*, the apart-zero guard, and the affine action/inverse support.*

Theorem 45.789 (RatUp FieldUp canonical phase-exit record)**.** *For* $\mathsf{RatUpFieldSource}_F$*, let* $\mathcal{E}_F$ *be the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object of Definition 45.617. Fix the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with carrier witnesses* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u_0, v, w, z : \mathsf{BMark}$*, contexts* $L, R, r : \mathsf{BHist}$*, and a support witness* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*. Also fix Rat-classified endpoint pairs* $x, x', y, y' : \mathsf{BHist}$ *satisfying* $\mathsf{RatHistoryClassifier}(x, x')$ *and* $\mathsf{RatHistoryClassifier}(y, y')$*, a carried denominator* $q : \mathsf{BHist}$ *with* $\mathsf{RatHistoryCarrier}(q)$*, apart-zero context data* $L_0, R_0, \tau : \mathsf{BHist}$ *with* $p : \mathsf{FieldApartZero}(L_0)$*, histories* $a, b, u, d : \mathsf{BHist}$*, the contextual action* Γ*, the affine source* AffAut_F*, and the same BEDC history operations add, mul, neg, and zero satisfying the CommRing hypotheses used by Definition 44.85. If*

$$H : \big((a + b)\mathsf{hsame0} \vee (a + (-b))\mathsf{hsame0}\big),$$

then the concrete exit object $\mathcal{E}_F$ *satisfies* $\mathsf{RatUpFieldPhaseExit}(\mathcal{E}_F)$ *for the displayed data and guard hypothesis.*

Proof. Unfold the record predicate of Definition 45.788. The first component is the chapter row coverage supplied by Definition 45.782 for the fixed $\mathsf{RatUpFieldSource}_F$ and exit object $\mathcal{E}_F$.

The second component is obtained by instantiating Definition 45.784 with the displayed denominator tuple, histories h, k, ℓ, carrier witnesses, selectors, contexts, support witness, Rat-classified endpoint pairs, carried denominator q, and apart-zero data L_0, R_0, τ, p.

The third component is obtained by applying Definition 45.786 to the same source, exit object, denominator tuple, affine source, contextual action, CommRing operations, histories a, b, u, d, and guard hypothesis H.

The fourth component is exactly Definition 45.787 instantiated with the same displayed data. Conjunction introduction packages the four components into the named phase-exit record, and no carrier, classifier, selector, denominator tuple, contextual action, affine source, apart-zero datum, or inverse/action row is replaced. □

Theorem 45.790 (RatUp FieldUp guarded action-inverse external-unit separation)**.** *For* $\mathsf{RatUpFieldSource}_F$*, let* $\mathcal{E}_F$ *be the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object of Definition 45.617. Fix the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with carrier witnesses* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u_0, v, w, z : \mathsf{BMark}$*, contexts* $L, R, r : \mathsf{BHist}$*, and a support witness* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*. Also fix Rat-classified endpoint pairs* $x, x', y, y' : \mathsf{BHist}$ *satisfying* $\mathsf{RatHistoryClassifier}(x, x')$ *and* $\mathsf{RatHistoryClassifier}(y, y')$*, a carried denominator* $q : \mathsf{BHist}$ *with* $\mathsf{RatHistoryCarrier}(q)$*, apart-zero context data* $L_0, R_0, \tau : \mathsf{BHist}$ *with* $p : \mathsf{FieldApartZero}(L_0)$*, histories* $a, b, u, d : \mathsf{BHist}$*, the contextual action* Γ*, the affine source* AffAut_F*, and the same BEDC history operations add, mul, neg, and zero satisfying the CommRing hypotheses used by Definition 44.85. If*

$$H : \big((a + b)\mathsf{hsame0} \vee (a + (-b))\mathsf{hsame0}\big)$$

and $U_D(u)$*, then the single exit object* $\mathcal{E}_F$ *supplies the following three-row phase-exit boundary:*

1. *the square row* $a \cdot a\mathsf{hsame}b \cdot b$*;*
2. *the external-unit classifier separation* $(\mathsf{RatHistoryClassifier}(u,d) \vee \mathsf{RatHistoryClassifier}(d,u)) \to \mathsf{False}$*;*
3. *the canonical action-and-inverse rows of Definition 45.662 read over the same* $\mathcal{E}_F$*.*

All three rows use the displayed denominator tuple, contexts, selectors, Rat-classified endpoint pairs, apart-zero context data, histories, contextual action, affine source, and CommRing operations.

Proof. First apply Definition 44.85 to the hypothesis H. Projecting its square component gives the row $a \cdot a\mathsf{hsame}b \cdot b$.

Next specialize Definition 45.366 at the histories u, d. Combining that specialization with the displayed external-unit witness $U_D(u)$ gives the second row, namely that either Rat-classifier endpoint orientation from u to d is impossible.

Finally invoke Definition 45.662 for the already fixed exit object $\mathcal{E}_F$. Its action rows and inverse rows use the same carrier, classifier, denominator tuple, contextual action, and affine source, so the three rows form one consumable phase-exit boundary rather than three unrelated certificates. □

Per-object template: traditional target constructive rational field exit with action/inverse and external-unit separation; BEDC source BHist, $\mathsf{Rat}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, and $\mathsf{Field}^{\uparrow}$; carriers $\mathsf{RatHistoryCarrier}$, C^u_D, U_D, and AffAut_F; classifiers $\mathsf{RatHistoryClassifier}$, R^u_D, hsame, and affine classifier; stability obligations zero-factor square row, external-unit classifier separation, and action/inverse support; ledger zero-linear-factor witness, external-unit endpoint, classifier orientation, denominator tuple, contexts, selectors, affine data; core theorem this block; exactness the displayed three-row package; standard bridge constructive rational field guard; status $\mathsf{ProofTarget}$.

Theorem 45.791 (RatUp FieldUp phase-exit record guarded square projection)**.** *For* $\mathsf{RatUpFieldSource}_F$*, let* $\mathcal{E}_F$ *be the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object of Definition 45.617. Fix the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with carrier witnesses* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u_0, v, w, z : \mathsf{BMark}$*, contexts* $L, R, r : \mathsf{BHist}$*, and a support witness* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*. Also fix Rat-classified endpoint pairs* $x, x', y, y' : \mathsf{BHist}$ *satisfying* $\mathsf{RatHistoryClassifier}(x, x')$ *and* $\mathsf{RatHistoryClassifier}(y, y')$*, a carried denominator* $q : \mathsf{BHist}$ *with* $\mathsf{RatHistoryCarrier}(q)$*, apart-zero context data* $L_0, R_0, \tau : \mathsf{BHist}$ *with* $p : \mathsf{FieldApartZero}(L_0)$*, histories* $a, b, u, d : \mathsf{BHist}$*, the contextual action* Γ*, the affine source* AffAut_F*, and the same BEDC history operations add, mul, neg, and zero satisfying the CommRing hypotheses used by Definition 44.85. If* $\mathsf{RatUpFieldPhaseExit}(\mathcal{E}_F)$ *holds for the displayed data and guard hypothesis*

$$H : ((a + b)\mathsf{hsame}0 \vee (a + (-b))\mathsf{hsame}0),$$

and if $U_D(u)$*, then the record exposes the following three guard rows:*

1. *the square row* $a \cdot a\mathsf{hsame}b \cdot b$*;*
2. *the external-unit classifier separation* $(\mathsf{RatHistoryClassifier}(u,d) \vee \mathsf{RatHistoryClassifier}(d,u)) \to \mathsf{False}$*;*
3. *the canonical action-and-inverse rows of Definition 45.662 over the same* $\mathcal{E}_F$*.*

All three rows keep the same carrier, classifier, denominator tuple, contextual action, affine source, guard datum, histories, contexts, and selectors fixed by Definition 45.788.

Proof. Unfold the record predicate of Definition 45.788. The assumed $\mathsf{RatUpFieldPhaseExit}(\mathcal{E}_F)$ contains the guarded full package component and the guarded canonical action-inverse component

for the displayed source, exit object, denominator tuple, contextual action, affine source, and guard datum.

Project the guarded full-package component under the displayed hypothesis H. Its zero-linear-factor square component is the first row $a \cdot a\mathsf{hsame}b \cdot b$, the same row exposed in Definition 45.790.

Specialize the same guarded full-package component with the witness $U_D(u)$. Equivalently, read the external-unit row through Definition 45.790; the carrier $\mathsf{RatHistoryCarrier}$, denominator carrier C^u_D, unit carrier U_D, and Rat classifier $\mathsf{RatHistoryClassifier}$ are exactly the ones recorded in the phase-exit data.

Project the guarded canonical action-inverse component next. It is the same canonical action-and-inverse support cited by Definition 45.662, with the same contextual action Γ, affine source AffAut_F, affine classifier, denominator relation R^u_D, and history relation hsame.

Pair these three projections. No carrier, classifier, denominator tuple, contextual action, affine source, or guard datum is replaced, so the resulting three-row package is a direct record-level guard projection for the Phase Algebra Hierarchy exit criterion. □

Per-object template: traditional target rational field phase-exit guard projection; BEDC source BHist, $\mathsf{Rat}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, and $\mathsf{Field}^{\uparrow}$; carriers $\mathsf{RatHistoryCarrier}$, C^u_D, U_D, and AffAut_F; classifiers $\mathsf{RatHistoryClassifier}$, R^u_D, hsame, and affine classifier; stability obligations zero-factor square row, phase-exit record projection, external-unit classifier separation, and canonical action/inverse support; ledger denominator tuple, external-unit endpoint, guard witness, contextual action, affine source, histories, contexts, selectors, and carrier witnesses; core theorem this block; exactness the displayed three-row record-level guard projection; downstream consumer Phase Algebra Hierarchy exit criterion; status $\mathsf{ProofTarget}$.

Theorem 45.792 (RatUp FieldUp phase-exit record certificate boundary)**.** *For* $\mathsf{RatUpFieldSource}_F$*, let* $\mathcal{E}_F$ *be the concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *exit object of Definition 45.617. Fix the concrete denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*, histories* $h, k, \ell : \mathsf{BHist}$ *with carrier witnesses* $C^u_D(h)$*,* $C^u_D(k)$*, and* $C^u_D(\ell)$*, selectors* $s, t, u_0, v, w, z : \mathsf{BMark}$*, contexts* $L, R, r : \mathsf{BHist}$*, and a support witness* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*. Also fix Rat-classified endpoint pairs* $x, x', y, y' : \mathsf{BHist}$ *satisfying* $\mathsf{RatHistoryClassifier}(x, x')$ *and* $\mathsf{RatHistoryClassifier}(y, y')$*, a carried denominator* $q : \mathsf{BHist}$ *with* $\mathsf{RatHistoryCarrier}(q)$*, apart-zero context data* $L_0, R_0, \tau : \mathsf{BHist}$ *with* $p : \mathsf{FieldApartZero}(L_0)$*, histories* $a, b, u, d : \mathsf{BHist}$*, the contextual action* Γ*, the affine source* AffAut_F*, and the same BEDC history operations add, mul, neg, and zero satisfying the CommRing hypotheses used by Definition 44.85. If*

$$H : \big((a + b)\mathsf{hsame}0 \vee (a + (-b))\mathsf{hsame}0\big)$$

and $U_D(u)$*, then the same exit object* $\mathcal{E}_F$ *supplies one* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *phase algebra exit package containing:*

1. $\mathsf{RatUpFieldPhaseExit}(\mathcal{E}_F)$ *for the displayed data and guard hypothesis;*
2. *the source, certificate-obligation, lower-reduct, denominator-law, and raw-continuation separation rows of Definition 45.725;*
3. *the square row, external-unit classifier separation, and canonical action-and-inverse rows exposed by Definition 45.791.*

Every row is read over the displayed BHist *source,* $\mathsf{RatHistoryCarrier}$*,* $\mathsf{RatHistoryClassifier}$*, denominator tuple, contextual action, affine source, guard datum, histories, contexts, selectors, and carrier witnesses.*

Proof. First apply Definition 45.789. It gives $\mathsf{RatUpFieldPhaseExit}(\mathcal{E}_F)$ from exactly the displayed source, exit object, denominator tuple, endpoint data, apart-zero context, affine data, CommRing operations, and guard hypothesis H.

Next invoke Definition 45.725. Its four rows record the same $\mathsf{RatUpFieldSource}_F$ source, the concrete Definition 45.337 certificate, the lower algebra reduct interface, the denominator append and relational packages, and the raw-continuation separation.

Finally feed the phase-exit record just obtained, together with $U_D(u)$, into Definition 45.791. The result is the square row, the external-unit classifier separation, and the canonical action-and-inverse support over the same carrier, classifier, denominator tuple, contextual action, affine source, histories, contexts, and selectors.

Conjunction introduction packs these three sources into the public $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ phase algebra exit package. No source row, certificate row, lower-reduct row, denominator row, guard row, action row, or inverse row is reindexed. □

Per-object template: traditional target rational field phase algebra exit package; BEDC source BHist, $\mathsf{Rat}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, and $\mathsf{Field}^{\uparrow}$; carriers $\mathsf{RatHistoryCarrier}$, C^u_D, U_D, and AffAut_F; classifiers $\mathsf{RatHistoryClassifier}$, R^u_D, hsame, and affine classifier; stability obligations canonical phase-exit record, certificate boundary rows, zero-factor square row, external-unit classifier separation, and action/inverse support; ledger denominator tuple, external-unit endpoint, guard witness, contextual action, affine source, histories, contexts, selectors, and carrier witnesses; core theorem this block; exactness the displayed phase algebra exit package; downstream consumer $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit criterion; status $\mathsf{ProofTarget}$.

Theorem 45.793 (RatUp FieldUp phase-exit record final-inventory separation)**.** *Fix the concrete source* $\mathsf{RatUpFieldSource}_F$*, the operation table of Definition 45.587, and the concrete exit object* $\mathcal{E}_F$ *of Definition 45.617. Let* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *be the concrete denominator tuple, let* $h, k, \ell : \mathsf{BHist}$ *satisfy* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(\ell)$*, and* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*, and let* $s, t, v, v, w, z : \mathsf{BMark}$ *and* $L, R, r : \mathsf{BHist}$ *be the chosen selectors and contexts. For Rat-classified endpoint pairs* $x, x', y, y' : \mathsf{BHist}$ *satisfying*

$$\mathsf{RatHistoryClassifier}(x, x') \wedge \mathsf{RatHistoryClassifier}(y, y'),$$

for every carried denominator $q : \mathsf{BHist}$ *satisfying* $\mathsf{RatHistoryCarrier}(q)$*, fix apart-zero context data* $L_0, R_0, \tau : \mathsf{BHist}$ *with* $p : \mathsf{FieldApartZero}(L_0)$*, phase guard histories* $\alpha, \beta : \mathsf{BHist}$*, the contextual action* Γ*, the affine source* AffAut_F*, and the same BEDC history operations add, mul, neg, and zero satisfying the CommRing hypotheses used by Definition 44.85. If*

$$H : ((\alpha + \beta)\mathsf{hsame0} \vee (\alpha + (-\beta))\mathsf{hsame0}),$$

and histories $u, d : \mathsf{BHist}$ *satisfy* $U_D(u)$ *and* $\mathsf{RatHistoryCarrier}(d)$*, then the same exit object* $\mathcal{E}_F$ *supplies one* BHist*-anchored* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *phase-exit boundary containing, at the same time:*

1. *the phase-exit record certificate boundary of Definition 45.792 for the displayed source, operation table, exit object, denominator tuple, histories, selectors, contexts, endpoint pairs, carried denominator, apart-zero data, contextual action, affine source, operations, guard hypothesis, and external-unit witness;*
2. *the final-inventory carried-external classifier separation row*

   $$(\mathsf{RatHistoryClassifier}(u, d) \vee \mathsf{RatHistoryClassifier}(d, u)) \to \mathsf{False}$$

   of Definition 45.780 for the same concrete source, operation table, exit object, denominator tuple, histories, support witness, selectors, contexts, endpoint pairs, carried denominator, external-unit witness, and carried denominator endpoint.

No carrier, classifier, denominator tuple, contextual action, affine source, selector, context, Rat endpoint, carried denominator, external-unit witness, or carried denominator endpoint is replaced between the two row families.

Proof. First instantiate Definition 45.792 with the displayed source, exit object, denominator tuple, histories h, k, ℓ, support witness, selectors s, t, υ, v, w, z, contexts L, R, r, Rat-classified endpoint pairs x, x', y, y', carried denominator q, apart-zero data L_0, R_0, τ, p, phase guard histories α, β, u, d, contextual action Γ, affine source AffAut_F, CommRing operations, guard hypothesis H, and witness $U_D(u)$. This yields the phase-exit record certificate boundary over $\mathcal{E}_F$.

Next instantiate Definition 45.780 with the same concrete source, operation table, exit object, denominator tuple, histories h, k, ℓ, support witness, selectors, contexts, Rat-classified endpoint pairs, carried denominator q, external unit u, and carried denominator endpoint d. The hypotheses $U_D(u)$ and $\mathsf{RatHistoryCarrier}(d)$ supply exactly the carried-external separation row needed by the phase-exit boundary.

Finally pair the two row families. Both cited results were read at the identical source, carrier, classifier, denominator tuple, contextual action, affine source, histories, selectors, contexts, endpoint pairs, carried denominator, external-unit witness, and carried denominator endpoint, so the packaged boundary is a single concrete BHist-anchored certificate for the Phase Algebra Hierarchy exit criterion. □

Per-object template: traditional target rational field phase-exit final-inventory separation; BEDC source BHist, $\mathsf{Rat}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, and $\mathsf{Field}^{\uparrow}$; carriers $\mathsf{RatHistoryCarrier}$, C^u_D, U_D, and AffAut_F; classifiers $\mathsf{RatHistoryClassifier}$, R^u_D, hsame, and affine classifier; stability obligations phase-exit record certificate boundary and final-inventory carried-external classifier separation; ledger denominator tuple, operation table, external-unit endpoint, carried denominator endpoint, guard witness, contextual action, affine source, histories, contexts, selectors, and carrier witnesses; core theorem this block; exactness the displayed paired phase-exit and final-inventory boundary; downstream consumer Phase Algebra Hierarchy $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ exit criterion; status $\mathsf{ProofTarget}$.

Theorem 45.794 (RatUp FieldUp certificate record absorbs phase-exit boundary)**.** *Fix the concrete source* $\mathsf{RatUpFieldSource}_F$*, the operation table of Definition 45.587, and the concrete exit object* $\mathcal{E}_F$ *of Definition 45.617. Let* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$ *be the concrete denominator tuple, let* $h, k, \ell : \mathsf{BHist}$ *satisfy* $C^u_D(h)$*,* $C^u_D(k)$*,* $C^u_D(\ell)$*, and* $\mathsf{ThreeSupp}^u_D(h, k, \ell)$*, and let* $s, t, \upsilon, v, w, z : \mathsf{BMark}$ *and* $L, R, r : \mathsf{BHist}$ *be the selected selectors and contexts. For Rat-classified endpoint pairs* $x, x', y, y' : \mathsf{BHist}$ *satisfying*

$$\mathsf{RatHistoryClassifier}(x, x') \wedge \mathsf{RatHistoryClassifier}(y, y'),$$

for a carried denominator $q : \mathsf{BHist}$ *satisfying* $\mathsf{RatHistoryCarrier}(q)$*, fix apart-zero context data* $L_0, R_0, \tau : \mathsf{BHist}$ *with* $p : \mathsf{FieldApartZero}(L_0)$*, phase guard histories* $\alpha, \beta : \mathsf{BHist}$*, the contextual action* Γ*, the affine source* AffAut_F*, and the same BEDC history operations add, mul, neg, and zero satisfying the CommRing hypotheses used by Definition 44.85. If*

$$H : \big((\alpha + \beta)\mathsf{hsame0} \vee (\alpha + (-\beta))\mathsf{hsame0}\big),$$

and histories $u, d : \mathsf{BHist}$ *satisfy* $U_D(u)$ *and* $\mathsf{RatHistoryCarrier}(d)$*, then the certificate-obligation record of Definition 45.337 contains one concrete* $\mathsf{Field}^{\uparrow}(\mathsf{Rat}^{\uparrow})$ *phase-exit boundary consisting of:*

1. *the phase-exit record certificate boundary of Definition 45.792 for the displayed source, operation table, exit object, denominator tuple, histories, selectors, contexts, endpoint pairs, carried denominator, apart-zero data, guard hypothesis, contextual action, affine source, operations, and external-unit witness;*

2. *the final row inventory absorbed by Definition 45.340 for the same denominator tuple, histories, carrier witnesses, selectors, contexts, and support witness;*
3. *the carried-external classifier separation supplied by Definition 45.793 for the same source, operation table, exit object, denominator tuple, histories, selectors, contexts, endpoint pairs, carried denominator, apart-zero data, guard hypothesis, contextual action, affine source, operations, external-unit witness, and carried denominator endpoint.*

These three row families are read as one certificate-record obligation over the displayed BHist *source, with no source, tuple, selector, context, endpoint, guard, operation, external-unit witness, or carried endpoint reindexed.*

Proof. Instantiate Definition 45.340 with the displayed denominator tuple, histories h, k, ℓ, carrier witnesses, selectors s, t, v, v, w, z, contexts L, R, r, and the support witness $\mathsf{ThreeSupp}^u_D(h, k, \ell)$. This places the complete final row inventory in the certificate-obligation record.

Next instantiate Definition 45.793 with the same concrete source, operation table, exit object, denominator tuple, histories, selectors, contexts, Rat endpoint pairs, carried denominator, apart-zero data, phase guard histories, contextual action, affine source, operations, guard hypothesis, external-unit witness, and carried denominator endpoint. Project its phase-exit boundary row and its carried-external classifier separation row.

The projected boundary row contains Definition 45.792 at the same indices, while the absorbed inventory row is already stored in the certificate record. Conjunction introduction repacks the boundary, the absorbed inventory, and the carried-external separation as one concrete certificate-record obligation. No source, tuple, selector, context, endpoint, guard, witness, or operation is reindexed. □

Per-object template: traditional target rational field phase-exit boundary as certificate-record obligation; BEDC source BHist, BMark, $\mathsf{Rat}^\uparrow$, $\mathsf{CommRing}^\uparrow$, and $\mathsf{Field}^\uparrow$; carriers $\mathsf{RatHistoryCarrier}$, C^u_D, U_D, and AffAut_F; classifiers $\mathsf{RatHistoryClassifier}$, R^u_D, hsame, and affine classifier; stability obligations phase-exit record certificate boundary, record-absorbed final row inventory, and carried-external classifier separation; ledger denominator tuple, operation table, external-unit endpoint, carried denominator endpoint, guard witness, contextual action, affine source, histories, contexts, selectors, and carrier witnesses; core theorem this block; exactness the displayed certificate-record phase-exit boundary; downstream consumer Phase Algebra Hierarchy $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$ exit criterion; status $\mathsf{ProofTarget}$.

Theorem 45.795 (RatUp FieldUp denominator total readback)**.** *Fix the concrete source* $\mathsf{RatUpFieldSource}_F$*, the operation table of Definition 45.587, the concrete exit object* $\mathcal{E}_F$*, and the denominator tuple* $(C^u_D, R^u_D, \mu^u_D, e^u_D, N^u_D)$*. Let* $q : \mathsf{BHist}$ *be the carried denominator, let* $p : \mathsf{FieldApartZero}(L_0)$ *be the apart-zero guard, let* $x, x', y, y' : \mathsf{BHist}$ *be the Rat-classified endpoint pairs, and let* $d : \mathsf{BHist}$ *be the carried denominator endpoint. Every public denominator read of the Phase Algebra Hierarchy exit package for these data factors through the same three rows: the phase-exit record certificate boundary, the final-inventory separation row, and the certificate-record absorption row. The readback does not replace any denominator, guard, operation-table, action, inverse, or endpoint row.*

Proof. First apply Definition 45.792. This places the operation table, exit object, denominator tuple, carried denominator q, apart-zero guard p, endpoint pairs, contextual action, external-unit witness, and endpoint d on the displayed phase-exit boundary.

Next apply Definition 45.793. It separates the carried external row from the final denominator inventory while keeping the same source, tuple, operation table, guard, action, inverse, and endpoint rows.

Finally apply Definition 45.794. The certificate record absorbs the preceding boundary and inventory rows as a single public obligation. Since all three applications use the same displayed indices, the denominator readback is total over the carried certificate record and no row is reindexed or replaced. □

Closure status for $\mathsf{NameCert}_{\mathsf{Field}^\uparrow}$**.**

Constructive story: A field element at this boundary is still a $\mathsf{Rat}^\uparrow$ denominator history, but inverse data may appear only when an explicit apart-from-zero witness accompanies the element. Thus the carrier is the rational denominator carrier, the classifier is the rational classifier extended so inverse comparisons preserve the guard witness, and there is never a blanket classical test saying merely that $a \neq 0$. The source is the rational-denominator predicate, the pattern records the certificate-record rows, final-row inventory, selector-independent exit rows, concrete addition/negation/multiplication/inverse table, apart-zero inverse rows, denominator normalization, endpoint exactness, and carried-external-separation guarantee, while the ledger keeps the visible field element tied to its raw rational form. Since $\mathsf{Rat}^\uparrow$ already supplies a name certificate and the guarded inverse predicate respects the rational classifier when the apartness witness is preserved, the carrier has representatives, the classifier is reflexive, symmetric, and transitive, and recognized representatives remain valid field data. A rational denominator d lies in the signature gap of a $\mathsf{Field}^\uparrow$ token p when the source-domain accepts d, the signature relation pairs it with an answer denominator and evidence ledger, possibly carrying inverse evidence, and the token-introduction relation names that answer as p; unfolded, d is a rational carrier element and an inverse witness is present exactly when p encodes a nonzero element. The conservative paper bridge reads this record across $\mathsf{Rat}^\uparrow$, $\mathsf{CommRing}^\uparrow$, $\mathsf{Field}^\uparrow$, and the kernel history type without changing the underlying denominator carrier. The chapter registers this certificate-record boundary under the name $\mathsf{Field}^\uparrow$; inverse evidence enters through guarded rows and stays separate from raw continuation data, with no arbitrary field, extension theory, valuation theory, or classical nonzero oracle introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Field}^\uparrow}$, maturePackageClosed)

Scope closed: The mature paper scope is the concrete $\mathsf{Field}^\uparrow(\mathsf{Rat}^\uparrow)$ exit record: certificate-record boundary, final row inventory, selector-independent exit rows, concrete operation table, apart-zero inverse rows, denominator normalization, endpoint exactness, carried-external separation, and the conservative paper bridge over $\mathsf{Rat}^\uparrow$, $\mathsf{CommRing}^\uparrow$, $\mathsf{Field}^\uparrow$, and BHist.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Field}^\uparrow}$, bridgeChecked)

Lean target: `BEDC.Derived.FieldUp.FieldApartZero\_semanticNameCert`

Bridge status: bridgeChecked

Not claimed: Unchecked bridge targets, arbitrary fields, field extensions, algebraic closure, valuation theory, ordered-field completeness, and machine-checked standard bridge closure remain outside this boundary.

Upgrade path: No further upgrade – chapter at top of formal axis.

45.25 Terminal history field instance

Definition 45.796 (Terminal history FieldUp instance)**.** *The terminal history* $\mathsf{Field}^\uparrow$ *instance is the concrete* BHist *tuple*

$$\mathcal{F}_{\mathsf{e}} := (A_{\mathsf{e}}, R_{\mathsf{e}}, +_{\mathsf{e}}, -_{\mathsf{e}}, 0_{\mathsf{e}}, \cdot_{\mathsf{e}}, 1_{\mathsf{e}}, N_{\mathsf{e}}, (\ )_{\mathsf{e}}^{-1})$$

with carrier

$$A_{\mathsf{e}}(h) := h\mathsf{hsamee}$$

and classifier

$$R_{\mathsf{e}}(h,k) := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

The additive and multiplicative endpoints are the same terminal append rows:

$$h +_{\mathsf{e}} k := \mathsf{append}(h,k), \qquad h \cdot_{\mathsf{e}} k := \mathsf{append}(h,k),$$

with $-_{\mathsf{e}} h := \mathsf{e}$, $0_{\mathsf{e}} := \mathsf{e}$, *and* $1_{\mathsf{e}} := \mathsf{e}$. *The inverse operation is defined only on the displayed nonzero boundary row:*

$$h_{\mathsf{e}}^{-1} := \mathsf{e}$$

whenever the unit-boundary certificate $N_{\mathsf{e}}(h)$ is present. The predicate N_{e} has no public rows except the certified unit endpoint over e*, and that endpoint is carried with its* hsame*,* Cont*, and* Pkg *provenance.*

Theorem 45.797 (Terminal history FieldUp laws)**.** *The tuple $\mathcal{F}_{\mathsf{e}}$ of Definition 45.796 satisfies the displayed* $\mathsf{Field}^{\uparrow}$ *laws: the* $\mathsf{Ring}^{\uparrow}$ *laws, commutative multiplication, unit laws, distributivity, and the inverse law on the stated unit-boundary nonzero row. Every carried endpoint appearing in these laws reduces through R_{e} to the terminal history* e*.*

Proof. Apply Definition 43.63. It supplies the singleton carrier A_{e}, classifier R_{e}, displayed addition, negation, zero, multiplication, one, distributivity, and operation ledger over the same terminal BHist endpoint.

The commutative multiplication and unit rows are the singleton public rows of Definition 44.92, read with the same carrier and classifier. Since 1_{e} is e, both left and right unit checks reduce to the terminal endpoint.

For the inverse row, project the displayed nonzero boundary certificate. Its only public endpoint is the unit row over e, and the inverse endpoint is defined as e. Therefore $(h_{\mathsf{e}}^{-1} \cdot_{\mathsf{e}} h)$ and $(h \cdot_{\mathsf{e}} h_{\mathsf{e}}^{-1})$ are both classified by R_{e} against 1_{e}.

No further case remains: every operation in the tuple either returns e directly or appends carried endpoints already classified with e, and the singleton append rows read those append endpoints back to the same terminal carrier. □

Theorem 45.798 (Terminal history FieldUp schema laws)**.** *The terminal history instance $\mathcal{F}_{\mathsf{e}}$ supplies the* $\mathsf{Field}^{\uparrow}$ *schema surface: the carrier A_{e} carries a semantic certificate, the empty endpoint cannot be a displayed nonzero row, nonzero rows transport along R_{e}, the inverse endpoint remains in the carrier, inverse endpoints are congruent under R_{e}, and both products $h_{\mathsf{e}}^{-1} \cdot_{\mathsf{e}} h$ and $h \cdot_{\mathsf{e}} h_{\mathsf{e}}^{-1}$ classify against 1_{e} whenever the displayed nonzero boundary row for h is present.*

Proof. Read the carrier and classifier from Definition 45.796. The carrier is the terminal hsame row against e, so the singleton endpoint reduction used in Definition 45.797 gives the semantic certificate and all classifier transports.

The displayed nonzero predicate has no row over the empty endpoint except the certified unit-boundary endpoint, and that endpoint reduces to the same terminal carrier. Hence the empty endpoint is not a separate nonzero object, and transporting a nonzero row across R_{e} keeps the same displayed boundary data.

Finally, the inverse operation always returns e. By Definition 45.797, both inverse-product rows therefore reduce through the singleton classifier to $1_{\mathsf{e}} = \mathsf{e}$, and the same terminal reduction proves inverse carrier closure and inverse classifier congruence. □

Theorem 45.799 (Terminal FieldUp nonzero boundary)**.** *Any* $\mathsf{Field}^{\uparrow}$ *inverse consumer of Definition 45.796 may read only the singleton unit/nonzero row, the carrier classifier A_{e}, the terminal classifier R_{e}, the displayed* hsame *witnesses, finite* Cont *provenance, and* Pkg *provenance. It receives no host field, quotient of nonzero elements, or external inverse object.*

Proof. Unpack the terminal tuple. The carrier and classifier expose only histories classified with e, and the operation rows are the displayed empty endpoint or append endpoints already governed by the singleton public operation surface.

The inverse row is indexed by N_{e}, whose public boundary is the certified unit endpoint. Projecting that boundary gives exactly the hsame, Cont, and Pkg rows attached to the same terminal history.

Thus a consumer can form inverse statements only by using the displayed unit-boundary certificate and the singleton classifier. There is no exported row from which a host field, a quotient carrier of nonzero elements, or an external inverse operation could be read. □

Theorem 45.800 (Terminal FieldUp history scope package)**.** *The terminal* $\mathsf{Field}^{\uparrow}$ *carrier of Definition 45.796 is a one-endpoint* BHist *scope packet. Every admitted carrier row is classified by* A_{e} *against* e*, every classifier comparison factors through* R_{e}*, and every visible dependency is one of the displayed* hsame*,* Cont*,* Pkg*, and* NameCert *rows already attached to the terminal endpoint.*

Proof. Project the terminal tuple and use Definition 45.797. The carrier is the singleton history endpoint, and all additive, multiplicative, zero, unit, and inverse rows reduce back to e through the same classifier.

Apply Definition 45.798. It identifies the schema-facing rows with the displayed terminal carrier, classifier transport, and nonzero boundary, so no second history endpoint can enter the scope.

The remaining route data are exactly the hsame witnesses, finite Cont provenance, Pkg provenance, and local naming certificate already listed in Definition 45.799. Thus the terminal carrier is a closed one-endpoint history scope packet. □

Theorem 45.801 (Terminal FieldUp inverse ledger scope)**.** *In the terminal* $\mathsf{Field}^{\uparrow}$ *packet, every inverse row and every apart-zero row is exhausted by the unit-boundary witness* N_{e} *and its transport through* R_{e}*. The inverse ledger exposes no nonterminal nonzero carrier, no quotient of invertible elements, and no inverse operation outside the singleton* BHist *endpoint.*

Proof. Start with the nonzero boundary row of Definition 45.799. It says that an inverse consumer can read only the unit/nonzero row at e together with the carrier and classifier rows of the terminal tuple.

Use Definition 45.798 to transport that row along R_{e}. The transported nonzero datum remains the same displayed unit-boundary certificate, and the inverse endpoint is again e.

Finally apply Definition 45.797. The inverse products classify against 1_{e} by the singleton law surface, so every inverse and apart-zero ledger row has already been consumed by the terminal witness. □

Theorem 45.802 (Terminal FieldUp RatUp exit handoff)**.** *The terminal history packet hands off from the existing* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{Field}^{\uparrow}$ *exit surface by the same singleton* BHist *endpoint: carrier admission, classifier transport, inverse use, apart-zero use, and consumer exit all factor through* e*,* A_{e}*,* R_{e}*, the displayed* hsame *and* Cont *rows, the* Pkg *row, and the local* NameCert *row.*

Proof. Read the exit-facing surface through the terminal carrier of Definition 45.796. The carrier and classifier rows are the same singleton rows used by the terminal $\mathsf{Rat}^{\uparrow}$ and $\mathsf{Field}^{\uparrow}$ public operation packets.

Apply Definition 45.800 for carrier and classifier scope, then apply Definition 45.801 for the inverse and apart-zero ledger rows. These two scope statements cover the rows a consumer can inspect before leaving the terminal field packet.

Thus the exit handoff is not an external field construction. It is the existing singleton history endpoint with its recorded hsame, Cont, Pkg, and NameCert transport data. □

The terminal operation-table, nonzero-inverse, and denominator-selector rows for $\mathsf{Field}^{\uparrow}$ consume the $\mathsf{Rat}^{\uparrow}$ denominator surface of chapter 37, the $\mathsf{Ring}^{\uparrow}$ operation rows of chapter 43, and the $\mathsf{CommRing}^{\uparrow}$ commutative multiplication surface of chapter 44. This is a finite NameCert sibling route through the algebra lattice, not a host field primitive.

Chapter 46

A Concrete Naming Certificate for $\mathsf{Module}^{\uparrow}$

The module interface $\mathsf{Module}^{\uparrow}$ has certificate obligations over a fixed scalar ring satisfying chapter 43 together with an additive abelian group from chapter 42 as carrier, equipped with a scalar multiplication $\cdot : R \times M \to M$ satisfying associativity with the ring product, distributivity over additions on both sides, and unit law for the ring identity. It is not a primitive structure; it is admitted only by composing the ring and abelian group certificates with the scalar action fields.

46.1 Carrier definition

Definition 46.1 (Module carrier)**.** *Use a scalar ring R, an additive abelian group M, and scalar multiplication $R \times M \to M$.*

46.2 Concrete singleton empty-history module instance

Definition 46.2 (Singleton empty-history module instance)**.** *Let the scalar carrier and module carrier both be the singleton history source A_{e} of Definition 36.169 at $a_0 = \mathsf{e}$. Define the shared classifier*

$$\rho_{\mathsf{e}}(h, k) := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h, k).$$

Use the singleton empty-history ring operations of Theorem 43.6 for the scalar side, and the singleton empty-history abelian-group operations of Theorem 42.10 for the additive module side. Define the scalar action by

$$\mathsf{smul}(r, m) := \mathsf{e}.$$

This instance has traditional target the one-element module over the one-element ring; BEDC source BHist*; scalar and module carrier A_{e}; classifier ρ_{e}; stability obligations given by the singleton ring laws, singleton abelian-group laws, and scalar-action laws; ledger constant-action provenance; core theorem Theorem 46.14; exactness the singleton endpoint classification $A_{\mathsf{e}}(h)$; standard bridge the one-object module; and status* ProofTarget*.*

Lean4 (definition) `BEDC.Derived.ModuleUp.ModuleSingletonOne`
Lean4 (definition) `BEDC.Derived.ModuleUp.ModuleSingletonSmul`

Theorem 46.3 (Module singleton classifier empty endpoints)**.** *For histories h, k : BHist, the concrete module singleton classifier satisfies*

$$\rho_{\mathsf{e}}(h, k) \quad \Longleftrightarrow \quad h\mathsf{hsamee} \wedge k\mathsf{hsamee}.$$

Proof. The forward direction unpacks the two carrier components of the classifier, which are exactly the two empty-endpoint comparisons.

Conversely, the two endpoint comparisons give the carrier components, and composing $h\mathsf{hsamee}$ with the symmetry of $k\mathsf{hsamee}$ supplies the $\mathsf{hsame}(h, k)$ component of the classifier. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingletonClassifier empty endpoints iff`

Theorem 46.4 (Module singleton classifier hsame endpoint transport)**.** *For histories h, k, h', k' : BHist, if $\rho_{\mathsf{e}}(h, k)$, $h\mathsf{hsame}h'$, and $k\mathsf{hsame}k'$, then*

$$\rho_{\mathsf{e}}(h', k') \wedge h'\mathsf{hsamee} \wedge k'\mathsf{hsamee}.$$

Proof. Unpack $\rho_{\mathsf{e}}(h, k)$ to obtain $h\mathsf{hsamee}$ and $k\mathsf{hsamee}$. Compose these endpoint comparisons with the symmetries of $h\mathsf{hsame}h'$ and $k\mathsf{hsame}k'$ to obtain $h'\mathsf{hsamee}$ and $k'\mathsf{hsamee}$. Theorem 46.3 then repacks the two empty endpoints as $\rho_{\mathsf{e}}(h', k')$. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingletonClassifier hsame endpoint transport`

Theorem 46.5 (Module singleton scalar readback)**.** *For histories r, m, n : BHist, if m lies in the singleton carrier A_{e}, then the scalar action endpoint is history-same to e, and classification after scalar action reads back to the original module endpoint:*

$$A_{\mathsf{e}}(m) \Longrightarrow \mathsf{hsame}(\mathsf{smul}(r, m), \mathsf{e}) \wedge \big(\rho_{\mathsf{e}}(\mathsf{smul}(r, m), n) \Longleftrightarrow \rho_{\mathsf{e}}(m, n)\big).$$

Proof. The scalar action is definitionally the empty history. The given carrier witness identifies m with e; composing this witness with the classifier relation supplies the forward readback, and composing its symmetry supplies the reverse direction. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingletonSmul classifier readback iff`

Theorem 46.6 (Module singleton scalar action image carrier exactness)**.** *For the concrete singleton $\mathsf{Module}^{\uparrow}$ instance, let*

$$P(h) \;:\Longleftrightarrow\; \exists r, m : \mathsf{BHist},\ A_{\mathsf{e}}(m) \wedge h\mathsf{hsameModuleSingletonSmul}(r, m).$$

Then the scalar-action image pattern is exactly the singleton carrier:

$$P(h) \quad \Longleftrightarrow \quad A_{\mathsf{e}}(h).$$

The ten-field fit is: traditional target the one-element module action image; BEDC source BHist *with* $\mathsf{ModuleSingletonSmul}$*; carrier A_{e}; classifier ρ_{e}; stability from Theorems 46.3 and 46.5; ledger scalar-action witnesses; core theorem this block; exactness the displayed iff; standard bridge the terminal module; and status* $\mathsf{ProofTarget}$*.*

Proof. For the forward direction, unpack a witness $r, m : \mathsf{BHist}$ with $A_{\mathsf{e}}(m)$ and $h\mathsf{hsameModuleSingletonSmul}(r, m)$. The scalar action endpoint is definitionally e, so this comparison composes to $h\mathsf{hsamee}$. By the singleton carrier definition, that endpoint comparison is precisely $A_{\mathsf{e}}(h)$.

For the reverse direction, assume $A_{\mathsf{e}}(h)$. Choose $r = \mathsf{e}$ and $m = h$. The module witness is the given carrier evidence, and $\mathsf{ModuleSingletonSmul}(r, m)$ is definitionally e. The same singleton carrier witness compares h with this empty scalar-action endpoint, so the chosen pair lies in the image pattern. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingletonSmul image empty endpoint iff`

Theorem 46.7 (Module singleton scalar action image semantic certificate)**.** *For the concrete singleton* $\mathsf{Module}^{\uparrow}$ *instance, the source carrier* A_{e}*, the scalar-action image pattern*

$$P(h) \;:\Longleftrightarrow\; \exists r, m : \mathsf{BHist},\ A_{\mathsf{e}}(m) \wedge h\mathsf{hsameModuleSingletonSmul}(r, m),$$

the ledger carrier A_{e}*, and the singleton classifier* ρ_{e} *form a* $\mathsf{SemanticNameCert}$*.*

Proof. The certificate core is the singleton module classifier from Theorem 46.14. Its carrier is A_{e}, its classifier is ρ_{e}, and its stability fields give the reflexive, symmetric, transitive, and carrier-transport clauses required by the semantic certificate.

For pattern soundness, assume $A_{\mathsf{e}}(h)$. Choose the scalar and module witnesses $r = \mathsf{e}$ and $m = h$. The module witness is the given carrier evidence, and $\mathsf{ModuleSingletonSmul}(r, m)$ is definitionally the empty history, so the same singleton evidence supplies $h\mathsf{hsameModuleSingletonSmul}(r, m)$.

Ledger soundness is the identity map on the singleton carrier A_{e}, with classification read by the same ρ_{e} endpoint relation. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingletonSmul image semanticNameCert`

Theorem 46.8 (Module singleton scalar action graph exactness)**.** *For histories* $r, m, n : \mathsf{BHist}$*, define the concrete scalar-action graph predicate*

$$G(r, m, n) \;:\Longleftrightarrow\; A_{\mathsf{e}}(r) \wedge A_{\mathsf{e}}(m) \wedge \rho_{\mathsf{e}}(\mathsf{ModuleSingletonSmul}(r, m), n).$$

Then this graph is exactly the singleton carrier on scalar input, module input, and classified output:

$$G(r, m, n) \quad\Longleftrightarrow\quad A_{\mathsf{e}}(r) \wedge A_{\mathsf{e}}(m) \wedge A_{\mathsf{e}}(n).$$

The ten-field fit is: traditional target the terminal module action graph; BEDC source BHist *with* $\mathsf{ModuleSingletonSmul}$*; carrier* A_{e}*; classifier* ρ_{e}*; stability from Theorems 46.3, 46.5, and 46.14; ledger scalar endpoint, module endpoint, and classified result endpoint; core theorem this block; exactness the displayed iff; downstream consumer the* $\mathsf{Module}^{\uparrow}$ *action-row certificate; and status* $\mathsf{ProofTarget}$*.*

Proof. Unfold $\mathsf{ModuleSingletonSmul}$ as the constant empty-history action. The only nontrivial classifier read in the graph is therefore $\rho_{\mathsf{e}}(\mathsf{e}, n)$.

For the forward direction, unpack $G(r, m, n)$. The first two projections are already the scalar endpoint witness $A_{\mathsf{e}}(r)$ and the module endpoint witness $A_{\mathsf{e}}(m)$. The classifier projection, together with Theorem 46.3, reads $\rho_{\mathsf{e}}(\mathsf{e}, n)$ as the two empty endpoint witnesses; the second one is precisely the singleton carrier witness for n.

For the reverse direction, assume $A_{\mathsf{e}}(r) \wedge A_{\mathsf{e}}(m) \wedge A_{\mathsf{e}}(n)$. Reuse the scalar and module carrier witnesses unchanged. Since $\mathsf{ModuleSingletonSmul}(r, m)$ is definitionally e, Theorem 46.3 and the singleton carrier witness for n give $\rho_{\mathsf{e}}(\mathsf{ModuleSingletonSmul}(r, m), n)$, which repacks the graph predicate. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingletonSmul graph empty exact iff`

Theorem 46.9 (Module singleton scalar action graph output determinacy)**.** *For histories* $r, m, n, n' : \mathsf{BHist}$*, define the concrete scalar-action graph predicate*

$$G(r, m, n) \;:\Longleftrightarrow\; A_{\mathsf{e}}(r) \wedge A_{\mathsf{e}}(m) \wedge \rho_{\mathsf{e}}(\mathsf{ModuleSingletonSmul}(r, m), n).$$

Then any two outputs of the same scalar and module inputs are classified equivalent:

$$G(r, m, n) \wedge G(r, m, n') \quad \Longrightarrow \quad \rho_{\mathsf{e}}(n, n').$$

The ten-field fit is: traditional target terminal module action determinacy; BEDC source BHist *with* ModuleSingletonSmul*,* A_{e}*, and* ρ_{e}*; carrier* A_{e}*; classifier* ρ_{e}*; stability from graph exactness and classifier endpoint exactness; ledger scalar, module, and output endpoint witnesses; core theorem this block; exactness output uniqueness up to classifier; downstream consumer the* $\mathsf{Module}^{\uparrow}$ *action-row certificate; and status* ProofTarget*.*

Proof. Assume $G(r, m, n) \wedge G(r, m, n')$. Apply Theorem 46.8 to the first graph witness to obtain the output endpoint witness $A_{\mathsf{e}}(n)$. Apply the same theorem to the second graph witness to obtain $A_{\mathsf{e}}(n')$.

Theorem 46.3 identifies ρ_{e} with pairs of singleton empty-history endpoints. Using the two endpoint witnesses just obtained, package the pair as $\rho_{\mathsf{e}}(n, n')$. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingletonSmul graph output determinacy`

Theorem 46.10 (Module singleton scalar action output fiber semantic certificate)**.** *For histories* $r, m, n : \mathsf{BHist}$*, if* $A_{\mathsf{e}}(r)$*,* $A_{\mathsf{e}}(m)$*, and* $\rho_{\mathsf{e}}(\mathsf{ModuleSingletonSmul}(r, m), n)$*, then the concrete output fiber*

$$F_{r,m}(o) \;:\Longleftrightarrow\; \rho_{\mathsf{e}}(\mathsf{ModuleSingletonSmul}(r, m), o)$$

forms a semantic naming certificate with source, pattern, and ledger all equal to $F_{r,m}$*, and classifier* ρ_{e}*.*

Proof. The displayed output n inhabits the source fiber. Reflexivity, symmetry, and transitivity are inherited from the singleton classifier certificate. For carrier transport, compose the source classification $\rho_{\mathsf{e}}(\mathsf{ModuleSingletonSmul}(r, m), o)$ with $\rho_{\mathsf{e}}(o, o')$. Pattern and ledger soundness are identity maps on the same concrete fiber. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingletonSmul output fiber semanticNameCert`

Theorem 46.11 (Module singleton scalar action fiber exhaustion)**.** *For histories* $r, m, o : \mathsf{BHist}$ *with* $A_{\mathsf{e}}(r)$ *and* $A_{\mathsf{e}}(m)$*, define the concrete scalar-action output fiber by*

$$F_{r,m}(o) \;:\Longleftrightarrow\; \rho_{\mathsf{e}}(\mathsf{ModuleSingletonSmul}(r, m), o).$$

Then the fiber is exactly the singleton classifier class:

$$F_{r,m}(o) \quad \Longleftrightarrow \quad A_{\mathsf{e}}(o).$$

Moreover, if $F_{r,m}(o)$ *and* $F_{r,m}(o')$*, then* $\rho_{\mathsf{e}}(o, o')$*.*

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingletonSmul fiber exhaustion`

Proof. For the forward direction, unfold the fiber predicate. The concrete action $\mathsf{ModuleSingletonSmul}(r, m)$ is the constant empty endpoint, so Theorem 46.3 reads the classification $\rho_{\mathsf{e}}(\mathsf{ModuleSingletonSmul}(r, m), o)$ back as the singleton endpoint witness $A_{\mathsf{e}}(o)$.

For the reverse direction, assume $A_{\mathsf{e}}(o)$. The same endpoint exactness theorem applies to the empty action endpoint and o, giving $\rho_{\mathsf{e}}(\mathsf{ModuleSingletonSmul}(r, m), o)$ and hence $F_{r,m}(o)$.

For the fiber classification claim, combine the two fiber witnesses as graph witnesses with the fixed input endpoint witnesses $A_{\mathsf{e}}(r)$ and $A_{\mathsf{e}}(m)$. Theorem 46.9 then returns $\rho_{\mathsf{e}}(o, o')$. □

Theorem 46.12 (Module singleton empty-action output determinacy)**.** *For histories r, m, n, n' : BHist, if the empty scalar action classifies n and the empty module input action classifies n', then the two outputs are classified together:*

$$\rho_{\mathsf{e}}(\mathsf{ModuleSingletonSmul}(\mathsf{e}, m), n) \wedge \rho_{\mathsf{e}}(\mathsf{ModuleSingletonSmul}(r, \mathsf{e}), n') \Longrightarrow \rho_{\mathsf{e}}(n, n').$$

Proof. Read both classifier hypotheses through Theorem 46.3. The first gives $n\mathsf{hsamee}$ and the second gives $n'\mathsf{hsamee}$. Repack these two endpoint witnesses with the same endpoint exactness theorem to obtain $\rho_{\mathsf{e}}(n, n')$. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingletonSmul empty action outputs deterministic`

Theorem 46.13 (Module singleton visible scalar nonfaithfulness)**.** *For the concrete singleton scalar action, every carried module endpoint sees the visible scalar* $\mathsf{E1}(\mathsf{e})$ *and the empty scalar* e *as producing the same empty action endpoint:*

$$A_{\mathsf{e}}(m) \Longrightarrow \rho_{\mathsf{e}}(\mathsf{ModuleSingletonSmul}(\mathsf{E1}(\mathsf{e}), m), \mathsf{ModuleSingletonSmul}(\mathsf{e}, m)).$$

Nevertheless the visible scalar itself is not classified with the empty scalar:

$$\rho_{\mathsf{e}}(\mathsf{E1}(\mathsf{e}), \mathsf{e}) \Longrightarrow \bot.$$

Proof. Both scalar-action endpoints reduce definitionally to e, so classifier endpoint exactness packages the two empty endpoints for the first assertion. For the second assertion, the left carrier field of $\rho_{\mathsf{e}}(\mathsf{E1}(\mathsf{e}), \mathsf{e})$ would give $\mathsf{hsame}(\mathsf{E1}(\mathsf{e}), \mathsf{e})$, contradicting the BEDC constructor no-confusion theorem for a visible one-step history and the empty history. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingletonSmul nonfaithful visible scalar`

Theorem 46.14 (Singleton empty-history module laws)**.** *The tuple*

$$(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \mathsf{add}, 0, \mathsf{neg}, \mathsf{mul}, 1, \mathsf{smul})$$

satisfies the $\mathsf{Module}^{\uparrow}$ *schema over the concrete* BHist *carrier: the scalar ring fields, the additive abelian-group fields, scalar-action closure, scalar-action congruence, scalar associativity, distributivity over module addition, distributivity over scalar addition, and scalar unit law.*

Proof. The scalar ring fields are supplied by Theorem 43.6. The additive module fields are supplied by Theorem 42.10. These two certificates fix the shared singleton carrier A_{e} and classifier ρ_{e}.

For scalar-action closure, every endpoint $\mathsf{smul}(r, m)$ is definitionally e. The singleton source of Definition 36.169 gives $A_{\mathsf{e}}(\mathsf{e})$, hence the result lies in the module carrier.

For scalar-action congruence, suppose $\rho_{\mathsf{e}}(r, r')$ and $\rho_{\mathsf{e}}(m, m')$. Both action endpoints reduce to e. The two carrier witnesses are the same singleton witness $A_{\mathsf{e}}(\mathsf{e})$, and the relation component is reflexivity $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$. Together these form $\rho_{\mathsf{e}}(\mathsf{smul}(r, m), \mathsf{smul}(r', m'))$.

For scalar associativity, both $\mathsf{smul}(\mathsf{mul}(r,s),m)$ and $\mathsf{smul}(r,\mathsf{smul}(s,m))$ are definitionally e. The same singleton carrier witness and hsame reflexivity package the required ρ_{e} endpoint relation.

For distributivity over module addition, both $\mathsf{smul}(r,\mathsf{add}(m,n))$ and $\mathsf{add}(\mathsf{smul}(r,m),\mathsf{smul}(r,n))$ reduce to e. Closure is the singleton carrier witness, and the classifier relation is $\mathsf{hsame}(\mathsf{e},\mathsf{e})$.

For distributivity over scalar addition, both $\mathsf{smul}(\mathsf{add}(r,s),m)$ and $\mathsf{add}(\mathsf{smul}(r,m),\mathsf{smul}(s,m))$ reduce to e. Again the singleton carrier witnesses and reflexivity assemble the ρ_{e} witness.

For the scalar unit law, $\mathsf{smul}(1,m)$ is definitionally e. The input witness $A_{\mathsf{e}}(m)$ identifies m with e, and $A_{\mathsf{e}}(\mathsf{e})$ supplies the other endpoint. Hence $\rho_{\mathsf{e}}(\mathsf{smul}(1,m),m)$ follows from the carrier witnesses and the corresponding hsame endpoint. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingleton scalar action laws`

The $\mathsf{Module}^{\uparrow}$ schema is instantiated by this concrete BHist carrier and scalar action, giving Lean formalization in $\mathsf{BEDC.Derived.ModuleUp}$ a BHist-anchored target for the module action laws.

46.3 The certificate

Definition 46.15 (Module source specification)**.** *The source is a certified* $\mathsf{Ring}^{\uparrow}(R)$ *and certified* $\mathsf{AbGroup}^{\uparrow}(M)$ *sharing a scalar action.*

Definition 46.16 (Module pattern specification)**.** *The pattern is module expression formation from vector addition, zero, negation, and scalar multiplication.*

Definition 46.17 (Module classifier specification)**.** *The classifier is the module carrier classifier, with scalar action congruent in both scalar and vector inputs.*

Definition 46.18 (Module stability certificate)**.** *The stability certificate consists of:*

1. *additive abelian-group laws on M*
2. *ring laws on R*
3. *scalar action congruence*
4. *scalar associativity with ring multiplication*
5. *scalar distributivity over module addition*
6. *scalar distributivity over ring addition*
7. *scalar unit law*

Definition 46.19 (Module ledger policy)**.** *Record scalar and module ledgers for every scalar-action expression.*

Definition 46.20 ($\mathsf{Module}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{Module}^{\uparrow}$*.*

Primitive boundary. $\mathsf{Module}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Definition 46.21 (Dual-number parity action)**.** *Let*

$$R := \mathbb{F}_2[\epsilon]/(\epsilon^2), \qquad M := \mathbb{F}_2.$$

Write every scalar of R uniquely as $a + b\epsilon$ with $a, b \in \mathbb{F}_2$. Define

$$\chi(a + b\epsilon) := a + b$$

and define the scalar action $\star : R \times M \to M$ by

$$r \star m := \chi(r)m.$$

Equivalently,

$$\chi(0) = 0, \qquad \chi(1) = 1, \qquad \chi(\epsilon) = 1, \qquad \chi(1 + \epsilon) = 0.$$

Proposition 46.22 (Module associativity boundary for additive unit action laws)**.** *For the action of Definition 46.21, the scalar ring R satisfies the ordinary ring fields used in chapter 43, the carrier M satisfies the additive abelian-group fields used in chapter 42, and equality classifiers make scalar-action congruence immediate. The action also satisfies scalar distributivity over module addition, scalar distributivity over ring addition, and the scalar unit law. It does not satisfy scalar associativity. Hence the scalar associativity item in Definition 46.18 is not forced by the remaining additive, congruence, and unit action fields.*

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingletonAssociativityBoundaryAdditiveUnitActionLaws`

Proof. The ring R is the four-element quotient ring with elements $0, 1, \epsilon, 1 + \epsilon$ and relation $\epsilon^2 = 0$. The carrier $M = \mathbb{F}_2$ is an additive abelian group. With equality as classifier, scalar-action congruence says that equal scalar and module inputs have equal action outputs, which follows directly from $r \star m = \chi(r)m$.

For scalar distributivity over module addition, let $r \in R$ and $m, n \in M$. Since $\chi(r) \in \mathbb{F}_2$ and multiplication in $\mathbb{F}_2$ distributes over addition,

$$r \star (m + n) = \chi(r)(m + n) = \chi(r)m + \chi(r)n = (r \star m) + (r \star n).$$

For scalar distributivity over ring addition, write $r = a + b\epsilon$ and $s = c + d\epsilon$. Then

$$\chi(r + s) = \chi((a + c) + (b + d)\epsilon) = a + c + b + d = (a + b) + (c + d) = \chi(r) + \chi(s),$$

with all sums in $\mathbb{F}_2$. Therefore, for every $m \in M$,

$$(r + s) \star m = \chi(r + s)m = (\chi(r) + \chi(s))m = \chi(r)m + \chi(s)m = (r \star m) + (s \star m).$$

The scalar unit law follows from $\chi(1) = 1$:

$$1 \star m = \chi(1)m = m.$$

Scalar associativity fails at $r = s = \epsilon$ and $m = 1$. Since $\epsilon^2 = 0$ in R,

$$(\epsilon\epsilon) \star 1 = 0 \star 1 = \chi(0)1 = 0.$$

On the other hand,

$$\epsilon \star (\epsilon \star 1) = \epsilon \star (\chi(\epsilon)1) = \epsilon \star 1 = \chi(\epsilon)1 = 1.$$

Thus

$$(\epsilon\epsilon) \star 1 \neq \epsilon \star (\epsilon \star 1),$$

so scalar associativity is a separate stability requirement for $\mathsf{Module}^{\uparrow}$. □

Theorem 46.23 (Module scalar representative transport compatibility)**.** *Let a* $\mathsf{Module}^{\uparrow}$ *certificate be given by Definition 46.20. Write* $\sim_R$ *for the scalar ring classifier,* $\sim_M$ *for the module classifier,* $\cdot_R$ *for scalar ring multiplication, and* $\odot$ *for scalar action. For carried scalar representatives* r, r', s, s' *and carried module representatives* m, m'*, if*

$$r \sim_R r', \qquad s \sim_R s', \qquad m \sim_M m',$$

then

$$r \odot (s \odot m) \sim_M (r' \cdot_R s') \odot m'.$$

Proof. By Definition 46.15, the scalar side of the $\mathsf{Module}^{\uparrow}$ certificate is a certified $\mathsf{Ring}^{\uparrow}$. The ring stability certificate of Definition 43.26 includes multiplication congruence, so the two scalar representative relations give

$$(r \cdot_R s) \sim_R (r' \cdot_R s').$$

By Definition 46.17 and Definition 46.18, scalar action is congruent in its scalar and module inputs. Applying scalar-action congruence to the transported scalar relation above and to $m \sim_M m'$ gives

$$((r \cdot_R s) \odot m) \sim_M ((r' \cdot_R s') \odot m').$$

The scalar associativity field listed in Definition 46.18 supplies a module-classifier witness between $(r \cdot_R s) \odot m$ and $r \odot (s \odot m)$. Since derived upward-arrow interfaces carry a $\mathsf{NameCert}$ by Definition 9.9, and Definition 9.7 supplies symmetry for the classifier, use that witness in the orientation

$$r \odot (s \odot m) \sim_M ((r \cdot_R s) \odot m).$$

Finally, Definition 9.8 composes this associativity witness with the scalar-action congruence witness, yielding

$$r \odot (s \odot m) \sim_M (r' \cdot_R s') \odot m'.$$

□

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingletonSmul scalar representative transport compatibility`

Theorem 46.24 (Scalar associativity independent of additive unit action laws)**.** *The action in Definition 46.21 is a finite equality-classified scalar action over*

$$R = \mathbb{F}_2[\epsilon]/(\epsilon^2), \qquad M = \mathbb{F}_2$$

such that the scalar ring satisfies the ring fields of chapter 43 and the commutative-ring fields of chapter 44, the module carrier satisfies the additive abelian-group fields of chapter 42, scalar-action congruence holds, scalar distributivity over module addition holds, scalar distributivity over scalar addition holds, and the scalar unit law holds. Scalar associativity fails. Hence the scalar associativity field in Definition 46.18 is not a consequence of those surrounding additive, congruence, and unit fields.

Proof. Classify both carriers by ordinary equality. The scalar ring R has exactly the four elements 0, 1, ϵ, and $1+\epsilon$, with $\epsilon^2 = 0$, and it is a finite commutative ring. The module carrier M is the two-element additive abelian group. Equality classifiers make every operation congruence field immediate from substitution; in particular, if $r = r'$ and $m = m'$, then $r \star m = r' \star m'$.

Write an element of R as $a+b\epsilon$, with $a, b \in \mathbb{F}_2$. The map $\chi(a+b\epsilon) = a+b$ from Definition 46.21 is additive because, for $r = a + b\epsilon$ and $s = c + d\epsilon$,

$$\chi(r+s) = \chi((a+c)+(b+d)\epsilon) = a+c+b+d = \chi(r)+\chi(s).$$

For scalar distributivity over module addition, let $r \in R$ and $m, n \in M$. Since $\chi(r) \in \mathbb{F}_2$,

$$r \star (m+n) = \chi(r)(m+n) = \chi(r)m + \chi(r)n = (r \star m) + (r \star n).$$

For scalar distributivity over scalar addition, the additivity of χ gives

$$(r+s) \star m = \chi(r+s)m = (\chi(r)+\chi(s))m = \chi(r)m + \chi(s)m = (r \star m) + (s \star m).$$

The scalar unit law follows from $\chi(1) = 1$:

$$1 \star m = \chi(1)m = m.$$

It remains to test scalar associativity. At $r = s = \epsilon$ and $m = 1$,

$$(\epsilon\epsilon) \star 1 = 0 \star 1 = \chi(0)1 = 0,$$

while

$$\epsilon \star (\epsilon \star 1) = \epsilon \star (\chi(\epsilon)1) = \epsilon \star 1 = \chi(\epsilon)1 = 1.$$

The two values are distinct in $M = \mathbb{F}_2$, so

$$(\epsilon\epsilon) \star 1 \neq \epsilon \star (\epsilon \star 1).$$

Thus all listed fields except scalar associativity hold in a finite equality-classified action, while scalar associativity fails. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleParityAction scalar associativity counterexample`

Theorem 46.25 (Module parity action associativity forces empty visible one)**.** *If a global scalar-associativity law holds for the concrete parity action, then the visible scalar one classifies with the empty history:*

$$(\forall r, s, m.\ (rs) \star m \mathsf{hsame} r \star (s \star m)) \Longrightarrow \mathsf{ModuleParityOnehsamee}.$$

Proof. Apply the displayed global law at $r = s = \mathsf{ModuleParityEps}$ and $m = \mathsf{ModuleParityOne}$. The concrete counterexample identifies the left associated value with e and the right associated value with $\mathsf{ModuleParityOne}$. Transitivity and symmetry of hsame therefore classify $\mathsf{ModuleParityOne}$ with e. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleParityAction scalar associativity forces empty visible one`

Proposition 46.26 (Module forgets to AbGroup certificate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate and let M carry a $\mathsf{Module}^{\uparrow}(R, M)$ certificate. If the scalar-ring package, the scalar action $\odot : R \times M \to M$, and the scalar-action stability rows are omitted from the exported package, the retained carrier, source, additive pattern, classifier, additive stability fields, and additive ledger form an $\mathsf{AbGroup}^{\uparrow}(M)$ certificate. The carrier, addition, zero, additive inverse, and classifier of M are unchanged.*

Proof. By Definition 46.20, the given module certificate supplies carrier, source, pattern, classifier, stability, and ledger data for $\mathsf{Module}^{\uparrow}$. The construction keeps exactly the components whose operations and endpoint claims live only on the additive carrier M.

By Definition 46.1, a module carrier consists of a scalar ring R, an additive abelian group M, and scalar multiplication $R \times M \to M$. Removing the scalar multiplication and the scalar carrier from the exported object leaves the same additive carrier M with its addition, zero, additive inverse, and carrier classifier. These are the carrier data required by Definition 42.1.

By Definition 46.15, the source side of the module certificate is a certified $\mathsf{Ring}^{\uparrow}(R)$ together with a certified $\mathsf{AbGroup}^{\uparrow}(M)$ sharing the scalar action. After the scalar-ring certificate and the action-sharing datum are suppressed, the certified $\mathsf{AbGroup}^{\uparrow}(M)$ source remains. Unpacking it through Definition 42.5 gives the certified group carrier plus commutativity field required for the abelian-group source.

By Definition 46.17, the module classifier is the module carrier classifier. This is the classifier of the embedded additive abelian-group certificate, and Definition 42.7 requires exactly that carrier classifier. Hence no classifier transport or replacement is involved.

By Definition 46.16, module expressions are formed from vector addition, zero, negation, and scalar multiplication. Deleting the scalar-multiplication constructor leaves the additive expression language generated by addition, zero, and negation. Together with the retained commutativity field from the additive abelian-group certificate, this is the abelian-group pattern of Definition 42.6.

By Definition 46.18, the first stability component of a module certificate is the additive abelian-group laws on M. The remaining module-specific rows are scalar action congruence, scalar associativity, distributivity over module addition, distributivity over ring addition, and scalar unit law. Those rows mention the scalar action or the scalar ring, so they are not obligations for $\mathsf{AbGroup}^{\uparrow}$. The retained first component is exactly the stability package listed in Definition 42.8: the group stability fields, additive commutativity under the classifier, and the compatibility data for that commutativity with inverse and multiplication congruence.

Finally, Definition 46.19 records scalar and module ledgers for scalar-action expressions. Removing entries whose provenance uses scalar multiplication leaves the additive module ledger. This is the group-expression provenance and commutativity-use ledger of Definition 42.31. The retained carrier, source, pattern, classifier, stability, and ledger data therefore satisfy the obligations named in Definition 42.32, with the same additive operation, zero, inverse, and classifier carried by the original module certificate. □

Proposition 46.27 (Module forgets to Ring certificate)**.** *Let M carry a $\mathsf{Module}^{\uparrow}(R, M)$ certificate whose scalar source is a certified $\mathsf{Ring}^{\uparrow}(R)$. If the additive carrier M, vector addition, vector zero, vector negation, scalar action $\odot : R \times M \to M$, and the action-shaped stability and ledger rows are omitted from the exported package, the retained scalar carrier, source, ring pattern, classifier, ring stability fields, and ring ledger form a $\mathsf{Ring}^{\uparrow}(R)$ certificate. The operations 0_R, 1_R, $+_R$, $(-)_R$, $\cdot_R$, and the scalar classifier on R are unchanged.*

Proof. By Definition 46.20, a module certificate supplies carrier, source, pattern, classifier, stability, and ledger data for $\mathsf{Module}^{\uparrow}$. The scalar projection keeps exactly the components whose operations

and endpoint claims live only on the scalar carrier R.

By Definition 46.1, a module carrier consists of a scalar ring R, an additive abelian group M, and scalar multiplication $R \times M \to M$. Deleting the additive carrier and scalar action leaves the scalar ring carrier with its addition, zero, additive inverse, multiplication, one, and scalar carrier classifier. These are the carrier data required by Definition 43.2.

By Definition 46.15, the source side of the module certificate is a certified $\mathsf{Ring}^{\uparrow}(R)$ together with a certified $\mathsf{AbGroup}^{\uparrow}(M)$ sharing the scalar action. Suppressing the additive source and the action-sharing datum leaves the certified $\mathsf{Ring}^{\uparrow}(R)$ source. Unpacking it through Definition 43.23 gives the additive $\mathsf{AbGroup}^{\uparrow}$ and multiplicative $\mathsf{Monoid}^{\uparrow}$ data on the same scalar carrier and classifier.

The classifier retained by the projection is the scalar-ring classifier from that certified source. The module classifier of Definition 46.17 belongs to the module carrier M and is not exported in this projection; the retained scalar classifier is already the carrier sameness relation required by Definition 43.25. No classifier transport or replacement is introduced.

The retained expression language is the ring expression language of the certified scalar source: 0_R, 1_R, $+_R$, $(-)_R$, and $\cdot_R$. This is exactly the pattern of Definition 43.24. The vector constructors and scalar-action constructor are discarded because their endpoints lie in M or in the action $R \times M \to M$, not in the scalar ring.

By Definition 46.18, the module certificate contains ring laws on R in addition to additive module laws and scalar-action laws. Since Definition 46.15 identifies the scalar side with a certified $\mathsf{Ring}^{\uparrow}(R)$, unpacking the retained scalar stability through Definition 43.26 gives additive abelian-group laws, multiplicative monoid laws, operation congruence, distributivity, and the zero multiplication rows for the scalar operations. The scalar-action rows, scalar associativity, the two action distributivity rows, and the scalar unit law all mention $\odot$ or the module carrier, so they are not obligations for $\mathsf{Ring}^{\uparrow}$.

Finally, the scalar ledger retained from the certified $\mathsf{Ring}^{\uparrow}(R)$ source is the shared carrier ledger and ring operation tree of Definition 43.54. The discarded ledger entries are precisely those whose provenance uses vector operations or scalar action. Thus the retained carrier, source, pattern, classifier, stability, and ledger fields satisfy Definition 43.55, with 0_R, 1_R, $+_R$, $(-)_R$, $\cdot_R$, and the scalar classifier copied from the original module certificate. □

Lemma 46.28 (Additive duplicate cancellation to zero)**.** *Let M be an additive carrier with classifier $\sim_M$, addition $+_M$, and zero 0_M. Assume the right-zero row $x +_M 0_M \sim_M x$ and additive left cancellation: from $a +_M b \sim_M a +_M c$ one may conclude $b \sim_M c$. If $x \sim_M x +_M x$, then $x \sim_M 0_M$.*

Proof. The right-zero row gives $x +_M 0_M \sim_M x$. Compose this comparison with the supplied comparison $x \sim_M x +_M x$ to obtain

$$x +_M 0_M \sim_M x +_M x.$$

Additive left cancellation removes the common left summand x and yields $0_M \sim_M x$. Symmetry of the classifier gives $x \sim_M 0_M$. □

Lean4✓ `BEDC.Derived.ModuleUp.ModuleAdditive duplicate cancel empty`

Theorem 46.29 (Module zero-action annihilation)**.** *Let a $\mathsf{Module}^{\uparrow}$ certificate be given by Definition 46.20. Write $\sim_R$ for the scalar-ring classifier, $\sim_M$ for the module classifier, $+_R$ and 0_R for scalar addition and scalar zero, $+_M$ and 0_M for module addition and module zero, and $\odot$ for scalar action. Assume the scalar source has the zero row $0_R +_R 0_R \sim_R 0_R$ from Definition 43.26, the module additive source has right-zero and additive left-cancellation as in Definition 42.8 and*

Definition 41.66, and the action rows include scalar-action congruence and both distributivity rows from Definition 46.18. For every carried scalar r and carried module element m,

$$0_R \odot m \sim_M 0_M \qquad \text{and} \qquad r \odot 0_M \sim_M 0_M.$$

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingleton zero action annihilation`

Proof. Let $a = 0_R \odot m$. Scalar distributivity over ring addition gives

$$(0_R +_R 0_R) \odot m \sim_M a +_M a.$$

The scalar zero row $0_R +_R 0_R \sim_R 0_R$, classifier reflexivity on the carried element m, and scalar-action congruence give

$$(0_R +_R 0_R) \odot m \sim_M a.$$

Symmetry and transitivity of $\sim_M$ therefore give $a \sim_M a +_M a$. Applying Definition 46.28 in the additive carrier M gives $0_R \odot m \sim_M 0_M$.

Let $b = r \odot 0_M$. The module zero row gives $0_M +_M 0_M \sim_M 0_M$. Scalar-action congruence, using reflexivity on the carried scalar r, gives

$$r \odot (0_M +_M 0_M) \sim_M b.$$

Scalar distributivity over module addition gives

$$r \odot (0_M +_M 0_M) \sim_M b +_M b.$$

Again symmetry and transitivity give $b \sim_M b +_M b$, and Definition 46.28 gives $r \odot 0_M \sim_M 0_M$. □

Definition 46.30 (Classifier-faithful scalar action and action annihilator)**.** *Let a* $\mathsf{Module}^{\uparrow}(R, M)$ *certificate be given by Definition 46.20. Write* $\sim_R$ *for the scalar-ring classifier,* $\sim_M$ *for the module classifier,* 0_R *and* 0_M *for the two zero endpoints,* $+_R$ *and* $+_M$ *for the two additions, and* $\odot$ *for scalar action. For a carried scalar* $r : R$*, let* $L_r(m) := r \odot m$*.*

The pointwise classifier equality of the action endomorphisms determined by r *and* s *is*

$$\mathsf{ActEq}_{R,M}(r, s) \iff \forall m : M,\ L_r(m) \sim_M L_s(m).$$

The action is classifier-faithful when

$$\mathsf{FaithAct}_{R,M} \iff \forall r, s : R,\ \mathsf{ActEq}_{R,M}(r, s) \implies r \sim_R s.$$

The action annihilator predicate is

$$\mathsf{Ann}_M(r) \iff \forall m : M,\ r \odot m \sim_M 0_M.$$

The predicate body is the annihilator; no ideal carrier is introduced.

Lemma 46.31 (Pointwise action equality gives difference annihilator)**.** *Under the notation of Definition 46.30, if* $\mathsf{ActEq}_{R,M}(r, s)$*, then*

$$\mathsf{Ann}_M(r +_R (-s)).$$

Proof. Fix a carried module endpoint $m : M$. Scalar distributivity over scalar addition from Definition 46.18 gives

$$(r +_R (-s)) \odot m \sim_M (r \odot m) +_M ((-s) \odot m).$$

The same distributivity row at s gives

$$(s +_R (-s)) \odot m \sim_M (s \odot m) +_M ((-s) \odot m).$$

The scalar additive right-inverse row of Definition 43.27, read in the scalar source supplied by Definition 46.15, classifies $s +_R (-s)$ with 0_R. Scalar-action congruence from Definition 46.18, followed by Definition 46.29, gives

$$(s +_R (-s)) \odot m \sim_M 0_M.$$

Composing this with the symmetry of the preceding distributivity comparison yields

$$(s \odot m) +_M ((-s) \odot m) \sim_M 0_M.$$

Now use the hypothesis $\mathsf{ActEq}_{R,M}(r, s)$ at m. Module additive congruence, from the additive $\mathsf{AbGroup}^{\uparrow}$ component in Definition 46.15, transports the first summand and gives

$$(r \odot m) +_M ((-s) \odot m) \sim_M (s \odot m) +_M ((-s) \odot m).$$

Transitivity with the last zero comparison gives

$$(r \odot m) +_M ((-s) \odot m) \sim_M 0_M.$$

Finally compose with the scalar-distributivity comparison for $r +_R (-s)$ to obtain

$$(r +_R (-s)) \odot m \sim_M 0_M.$$

Since m was arbitrary, $\mathsf{Ann}_M(r +_R (-s))$ holds. □

Theorem 46.32 (Module faithful action iff zero annihilator)**.** *Let a* $\mathsf{Module}^{\uparrow}(R, M)$ *certificate be given by Definition 46.20. With the notation of Definition 46.30, the scalar action is classifier-faithful exactly when the only scalar whose action annihilates every carried module endpoint is the scalar zero:*

$$\mathsf{FaithAct}_{R,M} \Longleftrightarrow \forall r : R,\ \mathsf{Ann}_M(r) \Longrightarrow r \sim_R 0_R.$$

Proof. Assume $\mathsf{FaithAct}_{R,M}$. Let $r : R$ satisfy $\mathsf{Ann}_M(r)$. For every carried $m : M$, the annihilator hypothesis gives

$$r \odot m \sim_M 0_M.$$

By Definition 46.29, the zero scalar action gives

$$0_R \odot m \sim_M 0_M.$$

Classifier symmetry and transitivity compose these two comparisons into

$$r \odot m \sim_M 0_R \odot m.$$

Thus $\mathsf{ActEq}_{R,M}(r, 0_R)$, and classifier-faithfulness gives $r \sim_R 0_R$.

Conversely, assume

$$\forall t : R,\ \mathsf{Ann}_M(t) \Longrightarrow t \sim_R 0_R.$$

Let $r, s : R$ and assume $\mathsf{ActEq}_{R,M}(r, s)$. By Definition 46.31,

$$\mathsf{Ann}_M(r +_R (-s)).$$

The assumed zero-annihilator condition therefore gives

$$r +_R (-s) \sim_R 0_R.$$

Applying the left-to-right direction of the scalar-ring difference exactness theorem Definition 43.34, read through the certified scalar $\mathsf{Ring}^{\uparrow}$ source of Definition 46.15, yields

$$r \sim_R s.$$

Therefore $\mathsf{FaithAct}_{R,M}$ holds, and the two conditions are equivalent. □

Theorem 46.33 (Module action annihilator IdealUp predicate)**.** *Let a* $\mathsf{Module}^{\uparrow}(R, M)$ *certificate be given by Definition 46.20. Write* C_R *for the scalar-ring carrier predicate,* $\sim_R$ *for the scalar-ring classifier,* 0_R *for scalar zero,* $+_R$ *for scalar addition,* $-_R$ *for scalar additive inverse,* $\cdot_R$ *for scalar multiplication,* $\sim_M$ *for the module classifier,* 0_M *for module zero,* $+_M$ *for module addition, and* $\odot$ *for scalar action. With* Ann_M *as in Definition 46.30, set*

$$I_M(r) \Longleftrightarrow C_R(r) \wedge \mathsf{Ann}_M(r).$$

Then I_M *is an* $\mathsf{Ideal}^{\uparrow}$ *predicate over the scalar* $\mathsf{Ring}^{\uparrow}(R)$ *source. Explicitly,* I_M *has carrier support and the rows*

$$I_M(0_R), \qquad I_M(r) \wedge I_M(s) \Longrightarrow I_M(r +_R s), \qquad I_M(r) \Longrightarrow I_M(-_R r),$$

$$I_M(r) \wedge I_M(s) \Longrightarrow I_M(r \cdot_R s), \qquad I_M(r) \wedge r \sim_R r' \Longrightarrow I_M(r'),$$

and, for every scalar endpoint a *with* $C_R(a)$*,*

$$I_M(r) \Longrightarrow I_M(a \cdot_R r) \wedge I_M(r \cdot_R a).$$

Proof. By Definition 46.15, the scalar source of the module certificate is a certified $\mathsf{Ring}^{\uparrow}(R)$, and the module source contains a certified additive $\mathsf{AbGroup}^{\uparrow}(M)$. The first conjunct in the definition of I_M is the carrier-support row. The scalar source carries 0_R, sums, additive inverses, and products; carrier transport along $\sim_R$ is supplied by the naming-certificate core in Definition 9.7.

For zero membership, fix a carried module endpoint $m : M$. The zero-action theorem Definition 46.29 gives

$$0_R \odot m \sim_M 0_M.$$

Since m was arbitrary and 0_R is carried by the scalar source, $I_M(0_R)$ holds.

For classifier transport, assume $I_M(r)$ and $r \sim_R r'$. Carrier transport gives $C_R(r')$. For every carried $m : M$, classifier reflexivity gives $m \sim_M m$, and scalar-action congruence from Definition 46.18 gives

$$r \odot m \sim_M r' \odot m.$$

The annihilator component of $I_M(r)$ gives $r \odot m \sim_M 0_M$. Symmetry and transitivity of the module classifier, composed by Definition 9.8, therefore give $r' \odot m \sim_M 0_M$. Thus $I_M(r')$ holds.

For additive closure, assume $I_M(r)$ and $I_M(s)$, and fix a carried module endpoint $m : M$. Scalar distributivity over scalar addition from Definition 46.18 gives

$$(r +_R s) \odot m \sim_M (r \odot m) +_M (s \odot m).$$

The two annihilator witnesses give $r \odot m \sim_M 0_M$ and $s \odot m \sim_M 0_M$. Module additive congruence transports the right side to $0_M +_M 0_M$, and the additive zero row in the $\mathsf{AbGroup}^{\uparrow}(M)$ source reduces $0_M +_M 0_M$ to 0_M. Hence

$$(r +_R s) \odot m \sim_M 0_M.$$

Together with scalar additive closure carrying $r +_R s$, this proves $I_M(r +_R s)$.

For additive inverse closure, assume $I_M(r)$ and fix a carried $m : M$. The scalar additive left-inverse row in the scalar $\mathsf{Ring}^{\uparrow}$ source gives $(-_R r) +_R r \sim_R 0_R$. Scalar-action congruence and Definition 46.29 give

$$((-_R r) +_R r) \odot m \sim_M 0_R \odot m \sim_M 0_M.$$

Scalar distributivity over scalar addition also gives

$$((-_R r) +_R r) \odot m \sim_M ((-_R r) \odot m) +_M (r \odot m).$$

Thus

$$((-_R r) \odot m) +_M (r \odot m) \sim_M 0_M.$$

The annihilator witness gives $r \odot m \sim_M 0_M$, so module additive congruence and the right-zero row in the additive module source give

$$((-_R r) \odot m) +_M (r \odot m) \sim_M ((-_R r) \odot m) +_M 0_M \sim_M (-_R r) \odot m.$$

Symmetry and transitivity now yield $(-_R r) \odot m \sim_M 0_M$. Since the scalar inverse closure row carries $-_R r$, this proves $I_M(-_R r)$.

For two-sided absorption, assume $I_M(r)$ and $C_R(a)$, and fix a carried module endpoint $m : M$. The scalar multiplication closure row carries $a \cdot_R r$ and $r \cdot_R a$. For the left product, scalar associativity from Definition 46.18 gives, in the displayed orientation after classifier symmetry if needed,

$$(a \cdot_R r) \odot m \sim_M a \odot (r \odot m).$$

The annihilator witness for r gives $r \odot m \sim_M 0_M$. Scalar-action congruence transports this comparison under the carried scalar a, and Definition 46.29 gives

$$a \odot (r \odot m) \sim_M a \odot 0_M \sim_M 0_M.$$

Therefore $I_M(a \cdot_R r)$ holds.

For the right product, scalar-action closure carries $a \odot m$ as a module endpoint. Scalar associativity gives

$$(r \cdot_R a) \odot m \sim_M r \odot (a \odot m).$$

Applying the annihilator witness for r to the carried module endpoint $a \odot m$ gives

$$r \odot (a \odot m) \sim_M 0_M.$$

Thus $I_M(r \cdot_R a)$ holds.

For internal multiplication, assume $I_M(r)$ and $I_M(s)$. The carrier component of $I_M(s)$ gives $C_R(s)$, so the right-absorption row just proved, applied with $a = s$, gives $I_M(r \cdot_R s)$.

These are precisely the carrier support, zero membership, additive closure, additive inverse closure, internal multiplication closure, classifier transport, and two-sided absorption rows required by the $\mathsf{Ideal}^{\uparrow}$ certificate in section 81.2. □

Theorem 46.34 (Module parity epsilon empty-result classifier)**.** *For every history m : BHist, scalar action by the parity epsilon history has empty output exactly when the module endpoint is not the empty history:*

$$\mathsf{hsame}(\mathsf{ModuleParitySmul}(\mathsf{ModuleParityEps}, m), \mathsf{e}) \iff (\mathsf{hsame}(m, \mathsf{e}) \implies \mathsf{False}).$$

Proof. Perform constructor case analysis on m. If $m = \mathsf{e}$, the displayed result is $\mathsf{E1}(\mathsf{e})$, so empty output contradicts constructor disjointness; conversely the right-hand side is contradicted by reflexivity of e. If m is visibly zero-headed or one-headed, the parity action reduces to e, and the right-hand side follows from the corresponding visible-vs-empty no-confusion law. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleParitySmul epsilon empty result iff`

Theorem 46.35 (Module parity epsilon result partition)**.** *For every history m : BHist, scalar action by the parity epsilon history has exactly the following result partition:*

$$(\mathsf{hsame}(m, \mathsf{e}) \wedge \mathsf{hsame}(\mathsf{ModuleParitySmul}(\mathsf{ModuleParityEps}, m), \mathsf{ModuleParityOne})) \quad \vee \quad ((\mathsf{hsame}(m, \mathsf{e}) \Rightarrow \mathsf{False}) \wedge \mathsf{hsa}$$

Proof. Perform constructor case analysis on m. At $m = \mathsf{e}$, the action reduces to ModuleParityOne, giving the left side of the partition. At a visible zero-headed or one-headed history, the action reduces to e, while constructor disjointness gives the nonempty premise of the right side. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleParitySmul epsilon result partition`

Theorem 46.36 (Module parity epsilon visible-one iff empty)**.** *For every history m : BHist,*

$$\mathsf{hsame}(\mathsf{ModuleParitySmul}(\mathsf{ModuleParityEps}, m), \mathsf{ModuleParityOne}) \iff \mathsf{hsame}(m, \mathsf{e}).$$

Its ten-field fit is: traditional target, deterministic parity-action branch readback; BEDC source, BHist *with* ModuleParitySmul*; carrier, all histories; classifier,* hsame*; ledger, the epsilon scalar and the input constructor case; core theorem, this block; exactness, visible-one output iff empty input; standard bridge, the two-point parity toggle; status,* ProofTarget*.*

Proof. Perform constructor case analysis on m.

For $m = \mathsf{e}$, scalar action by ModuleParityEps reduces to ModuleParityOne. The forward direction and the reverse direction are therefore both reflexive after the reduction.

For a zero-headed visible history, the action reduces to e. The forward direction would identify e with ModuleParityOne, contradicting empty-vs-visible-one no-confusion. The reverse direction starts from an impossible visible-vs-empty premise, so it follows by eliminating that premise.

For a one-headed visible history, the action again reduces to e. The same empty-vs-visible-one no-confusion rejects the forward direction, and the reverse direction follows by eliminating the impossible visible-vs-empty premise. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleParitySmul epsilon visible one input empty iff`

Theorem 46.37 (Module parity epsilon boolean orbit involution)**.** *For every history m : BHist, if m is history-same to either* e *or* ModuleParityOne*, then two successive scalar actions by* ModuleParityEps *return m:*

$$(\mathsf{hsame}(m, \mathsf{e}) \vee \mathsf{hsame}(m, \mathsf{ModuleParityOne})) \implies \mathsf{hsame}(\mathsf{ModuleParitySmul}(\mathsf{ModuleParityEps}, \mathsf{ModuleParitySmul}(\mathsf{Mod}$$

Proof. Split the displayed endpoint assumption. In the empty endpoint branch, replace m by e and compute the two epsilon actions: the first reaches $\mathsf{ModuleParityOne}$ and the second returns to e. In the visible-one branch, replace m by $\mathsf{ModuleParityOne}$ and compute the two epsilon actions in the opposite order, ending at the same visible-one endpoint. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleParitySmul epsilon boolean orbit involutive`

Theorem 46.38 (Module parity epsilon multiplication boolean orbit involution)**.** *For every history r : BHist, if r is history-same to either e or $\mathsf{ModuleParityEps}$, then two successive parity multiplications by $\mathsf{ModuleParityEps}$ return r:*

$$(\mathsf{hsame}(r,\mathsf{e})\vee\mathsf{hsame}(r,\mathsf{ModuleParityEps})) \Longrightarrow \mathsf{hsame}(\mathsf{ModuleParityMul}(\mathsf{ModuleParityEps},\mathsf{ModuleParityMul}(\mathsf{ModulePa$$

Proof. Split the displayed endpoint assumption. In the empty endpoint branch, replace r by e and compute the two epsilon multiplications. In the epsilon endpoint branch, replace r by $\mathsf{ModuleParityEps}$ and compute the same two multiplications. Each branch closes by reflexivity of the displayed endpoint. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleParityMul epsilon boolean orbit involutive`

Theorem 46.39 (Module parity epsilon empty endpoint has no fixed point)**.** *For every history m : BHist,*

$$\mathsf{hsame}(\mathsf{ModuleParitySmul}(\mathsf{E0}(\mathsf{e}),m),m) \Longrightarrow \mathsf{False}.$$

Proof. Perform constructor case analysis on m. At $m = \mathsf{e}$ the action produces $\mathsf{E1}(\mathsf{e})$, contradicting visible-one versus empty no-confusion. At $m = \mathsf{E0}(h)$ and $m = \mathsf{E1}(h)$ the action produces e, contradicting the corresponding empty versus visible no-confusion law. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleParitySmul e0 empty no fixed point`

Theorem 46.40 (Module parity epsilon double action empty iff)**.** *For every history m : BHist,*

$$\mathsf{hsame}(\mathsf{ModuleParitySmul}(\mathsf{ModuleParityEps},\mathsf{ModuleParitySmul}(\mathsf{ModuleParityEps},m)),\mathsf{e}) \Longleftrightarrow \mathsf{hsame}(m,\mathsf{e}).$$

Proof. Apply Definition 46.35 to the first epsilon action on m. In the empty-input branch, the first action is $\mathsf{ModuleParityOne}$, so the second epsilon action reduces to e. This gives the forward endpoint and the reverse endpoint by the same empty branch witness.

In the nonempty branch, the first action is e, so the second epsilon action reduces to $\mathsf{ModuleParityOne}$. Visible-one versus empty no-confusion rules out the left side of the displayed equivalence. Conversely, an assumed $\mathsf{hsame}(m,\mathsf{e})$ contradicts the nonempty premise supplied by the partition, so this branch contributes no empty-input witness. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleParitySmul epsilon double action empty iff`

Theorem 46.41 (Module parity epsilon double action one iff)**.** *For every history m : BHist,*

$$\mathsf{hsame}(\mathsf{ModuleParitySmul}(\mathsf{ModuleParityEps},\mathsf{ModuleParitySmul}(\mathsf{ModuleParityEps},m)),\mathsf{ModuleParityOne}) \Longleftrightarrow (\mathsf{hsame}$$

Proof. Perform constructor case analysis on m. At $m = \mathsf{e}$, the double epsilon action lands at e, so equality with $\mathsf{ModuleParityOne}$ is ruled out by empty versus visible-one separation, matching the false nonempty predicate. At visible inputs, the first epsilon action lands at e and the second lands at $\mathsf{ModuleParityOne}$; the reverse direction uses reflexivity, and the forward direction rules out an empty input by constructor separation. □

Lean4 ✓ BEDC.Derived.ModuleUp.ModuleParitySmul epsilon double action one iff

Theorem 46.42 (Module scalar negation gives two-sided action inverse)**.** *Let a* $\mathsf{Module}^{\uparrow}(R, M)$ *certificate be given by Definition 46.20. Write* $\sim_R$ *for the scalar-ring classifier,* $\sim_M$ *for the module classifier,* $+_R$ *and* 0_R *for scalar addition and scalar zero,* $-_R$ *for scalar additive inverse,* $+_M$ *and* 0_M *for module addition and module zero, and* $\odot_M$ *for scalar action. For every carried scalar* $r : R$ *and carried module endpoint* $m : M$*,*

$$((-_R r) \odot_M m) +_M (r \odot_M m) \sim_M 0_M$$

and

$$(r \odot_M m) +_M ((-_R r) \odot_M m) \sim_M 0_M.$$

Lean4 ✓ BEDC.Derived.ModuleUp.ModuleSingleton scalar negation action additive inverse

Proof. By Definition 46.15, the scalar source of the module certificate is a certified $\mathsf{Ring}^{\uparrow}$. Its additive component, listed in Definition 43.26 and Definition 41.55, supplies inverse closure and the scalar additive left-inverse row. Thus $-_R r$ is carried and

$$(-_R r) +_R r \sim_R 0_R.$$

Classifier reflexivity for the carried endpoint m comes from Definition 9.7. Scalar-action congruence from Definition 46.18 transports the scalar inverse comparison to

$$((-_R r) +_R r) \odot_M m \sim_M 0_R \odot_M m.$$

Scalar distributivity over scalar addition from Definition 46.18 gives

$$((-_R r) +_R r) \odot_M m \sim_M ((-_R r) \odot_M m) +_M (r \odot_M m).$$

Using classifier symmetry from Definition 9.7, transitivity from Definition 9.8, and the zero-action theorem Definition 46.29, compose these comparisons to obtain

$$((-_R r) \odot_M m) +_M (r \odot_M m) \sim_M 0_M.$$

For the other order, Definition 43.27, read in the same scalar source, supplies

$$r +_R (-_R r) \sim_R 0_R.$$

Scalar-action congruence transports this comparison to

$$(r +_R (-_R r)) \odot_M m \sim_M 0_R \odot_M m,$$

and scalar distributivity over scalar addition gives

$$(r +_R (-_R r)) \odot_M m \sim_M (r \odot_M m) +_M ((-_R r) \odot_M m).$$

The same symmetry, transitivity, and zero-action composition gives

$$(r \odot_M m) +_M ((-_R r) \odot_M m) \sim_M 0_M.$$

□

Definition 46.43 (Module LinearMap kernel predicate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, let M and N carry $\mathsf{Module}^{\uparrow}(R, M)$ and $\mathsf{Module}^{\uparrow}(R, N)$ certificates over the same scalar source, and let*

$$\mathsf{LinearMapCert}_R(M, N; f)$$

hold. Write $\sim_N$ for the classifier on N and 0_N for its module zero. The kernel predicate of f is the zero fiber

$$\mathsf{Ker}_f(x) :\Longleftrightarrow x \text{ is carried in } M \wedge f(x) \sim_N 0_N.$$

The witness records source carrier evidence for x together with the target-classifier comparison from $f(x)$ to the target zero.

Theorem 46.44 (Module LinearMap kernel submodule closure)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, and let M and N carry $\mathsf{Module}^{\uparrow}(R, M)$ and $\mathsf{Module}^{\uparrow}(R, N)$ certificates over the same scalar source. Write $\sim_M$ and $\sim_N$ for the source and target module classifiers, $+_M$ for source addition, 0_M and 0_N for source and target zero, and $\odot_M$ and $\odot_N$ for the scalar actions. If*

$$\mathsf{LinearMapCert}_R(M, N; f)$$

holds, then the predicate Ker_f from Definition 46.43 is stable under source-classifier transport, contains 0_M, and is closed under source addition and carried scalar action:

$$\mathsf{Ker}_f(x) \wedge x \sim_M x' \Longrightarrow \mathsf{Ker}_f(x'),$$

$$\mathsf{Ker}_f(0_M),$$

$$\mathsf{Ker}_f(x) \wedge \mathsf{Ker}_f(u) \Longrightarrow \mathsf{Ker}_f(x +_M u),$$

and, for every carried scalar $r : R$,

$$\mathsf{Ker}_f(x) \Longrightarrow \mathsf{Ker}_f(r \odot_M x).$$

In particular, the source-ring inverse closure makes $-_R r$ carried whenever r is carried, so $\mathsf{Ker}_f(x)$ entails $\mathsf{Ker}_f((-_R r) \odot_M x)$.

The ten-field fit is: traditional target the ordinary kernel submodule of an R-linear map; BEDC source the displayed $\mathsf{LinearMapCert}_R$ package over the two $\mathsf{Module}^{\uparrow}$ certificates; carrier the zero-fiber predicate Ker_f; classifier the source module classifier restricted to that predicate; stability source-classifier transport, zero, addition, scalar action, and scalar-negation closure; ledger the function identifier f, its descent, zero, additivity, and scalar rows, plus the source and target module ledgers; core theorem this block; exactness predicate the condition $f(x) \sim_N 0_N$ used by downstream first-isomorphism-style kernel exactness; standard bridge the usual kernel submodule construction; status ProofTarget.

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingletonSmul kernel submodule closure`

Proof. Unpack Definition 48.59. It supplies source-classifier descent for f, additivity, scalar compatibility, and zero preservation. Unpack the two module certificates through Definition 46.20. The source module supplies the carrier rows for 0_M, $x +_M u$, and $r \odot_M x$; the target module supplies operation congruence and classifier comparison rows through Definition 46.18.

For source-classifier transport, assume $\mathsf{Ker}_f(x)$ and $x \sim_M x'$. Source carrier transport gives that x' is carried. The descent row gives a target comparison between $f(x)$ and $f(x')$. Compose it with the zero-fiber comparison $f(x) \sim_N 0_N$ by the target classifier equivalence laws and Definition 9.8. This yields $f(x') \sim_N 0_N$, so x' remains in the kernel predicate.

For the zero row, source zero closure carries 0_M. The zero-preservation row of Definition 48.59 gives

$$f(0_M) \sim_N 0_N.$$

Thus 0_M satisfies the defining zero-fiber predicate.

For addition, choose kernel witnesses for x and u. Source additive closure carries $x +_M u$. Additivity gives

$$f(x +_M u) \sim_N f(x) +_N f(u).$$

Target additive congruence transports $f(x) \sim_N 0_N$ and $f(u) \sim_N 0_N$ to a comparison with $0_N +_N 0_N$. The target additive zero rows reduce that endpoint to 0_N, and Definition 9.8 composes the comparisons. Therefore $x +_M u$ lies in Ker_f.

For scalar action, let r be a carried scalar and choose a kernel witness for x. Source scalar-action closure carries $r \odot_M x$. Scalar compatibility gives

$$f(r \odot_M x) \sim_N r \odot_N f(x).$$

Target scalar congruence transports $f(x) \sim_N 0_N$ to $r \odot_N f(x) \sim_N r \odot_N 0_N$. The zero-action theorem Definition 46.29 gives $r \odot_N 0_N \sim_N 0_N$, and transitivity gives the required zero-fiber comparison.

Finally, the scalar source of the module certificate is a certified $\mathsf{Ring}^{\uparrow}$ by Definition 46.15, so the additive inverse row carries $-_R r$. Applying the scalar-action closure row to this carried scalar gives $\mathsf{Ker}_f((-_R r) \odot_M x)$. The endpoint interpretation is exactly Definition 46.42: $(-_R r) \odot_M x$ is the additive inverse-side action endpoint for $r \odot_M x$ inside the source module classifier. □

Theorem 46.45 (Module LinearMap kernel certificate package)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, and let M and N carry $\mathsf{Module}^{\uparrow}(R, M)$ and $\mathsf{Module}^{\uparrow}(R, N)$ certificates over the same scalar source. Let*

$$\mathsf{LinearMapCert}_R(M, N; f)$$

hold. Write $\sim_M$ and $\sim_N$ for the source and target module classifiers, $+_M$ and 0_M for source addition and source zero, $\odot_M$ for source scalar action, 0_N for target zero, and Ker_f for the predicate of Definition 46.43. On the kernel carrier define the restricted classifier by

$$x \sim_{\mathsf{Ker}_f} y :\Longleftrightarrow \mathsf{Ker}_f(x) \wedge \mathsf{Ker}_f(y) \wedge x \sim_M y.$$

Then the kernel data form a reusable certificate package with the following fields:

1. *$\sim_{\mathsf{Ker}_f}$ is reflexive, symmetric, and transitive on carried kernel endpoints.*
2. *Source-module classifier transport carries kernel witnesses along $x \sim_M x'$.*
3. *0_M is a carried kernel endpoint, and carried kernel endpoints are closed under $+_M$ and under carried scalar action $\odot_M$.*
4. *The inclusion of the kernel carrier into M reflects the source classifier: for kernel endpoints, a comparison in M repacks as a comparison for $\sim_{\mathsf{Ker}_f}$, and every restricted comparison projects to the underlying $x \sim_M y$ row.*
5. *Every carried kernel endpoint satisfies the exactness row $f(x) \sim_N 0_N$.*

The ten-field fit is: traditional target kernel submodule certificate; BEDC source $\mathsf{LinearMapCert}_R$ over two $\mathsf{Module}^{\uparrow}$ certificates; carrier Ker_f; classifier the restriction of $\sim_M$; stability inherited from Definition 46.44; ledger the function identifier f together with descent, zero, additivity, and scalar rows from Definition 48.59; core theorem this package; exactness the zero-fiber row $f(x) \sim_N 0_N$; standard bridge the ordinary kernel submodule; status $\mathsf{ProofTarget}$.

Proof. The carrier rows are exactly the rows established in Definition 46.44. They give source-classifier transport for Ker_f, the kernel witness for 0_M, additive closure, and carried scalar-action closure.

For the restricted classifier laws, work only with endpoints already carrying kernel witnesses. Reflexivity follows from the source module NameCert reflexivity row applied to the underlying carried endpoint, then paired with the two kernel witnesses. Symmetry keeps the two kernel witnesses and reverses the source comparison by the symmetry row of Definition 9.7.

For transitivity, take restricted comparisons from x to y and from y to z. Their projections give $x \sim_M y$ and $y \sim_M z$. Apply Definition 9.8 in the source module classifier to obtain $x \sim_M z$, and pair this comparison with the kernel witnesses for x and z.

The inclusion statement is definitional. A restricted comparison contains its underlying $x \sim_M y$ component by the definition of $\sim_{\mathsf{Ker}_f}$. Conversely, for two kernel endpoints, any source comparison $x \sim_M y$ repacks with the two endpoint witnesses to produce $x \sim_{\mathsf{Ker}_f} y$.

It remains to identify the exactness row. By Definition 46.43, a kernel witness is precisely source-carrier evidence together with the zero-fiber comparison $f(x) \sim_N 0_N$. The descent row from Definition 48.59, composed with Definition 9.8 in the target module classifier, is the compatibility used when this zero-fiber comparison is transported along source comparisons. Thus the restricted classifier, inclusion reflection, operation closure, and zero-fiber exactness sit in one certificate package. □

Theorem 46.46 (Module singleton scalar-action kernel exactness)**.** *For the concrete singleton empty-history module of section 46.2, fix the terminal scalar* e *and define the scalar-action zero-fiber predicate*

$$K(h) :\Longleftrightarrow A_{\mathsf{e}}(h) \wedge \rho_{\mathsf{e}}(\mathsf{ModuleSingletonSmul}(\mathsf{e}, h), \mathsf{e}).$$

Then, for every history $h : \mathsf{BHist}$*,*

$$K(h) \Longleftrightarrow A_{\mathsf{e}}(h),$$

and, for all histories $h, k : \mathsf{BHist}$*, the restricted classifier on two kernel endpoints is exactly the singleton classifier row:*

$$K(h) \wedge K(k) \wedge \rho_{\mathsf{e}}(h, k) \Longleftrightarrow \rho_{\mathsf{e}}(h, k).$$

The ten-field fit is: traditional target terminal module kernel; BEDC source BHist *with* $\mathsf{ModuleSingletonSmul}$*; carrier* A_{e}*; classifier* ρ_{e} *restricted to* K*; stability inherited from singleton classifier transport and scalar-action laws; ledger the terminal scalar* e *and the zero-fiber witness; core theorem this block; exactness* $K(h)$ *agrees with* $A_{\mathsf{e}}(h)$*; standard bridge the kernel of the terminal endomorphism; status* $\mathsf{ProofTarget}$*.*

Proof. Unfold the displayed predicate K. The forward direction projects the first component, so a zero-fiber witness immediately gives $A_{\mathsf{e}}(h)$.

For the reverse direction, assume $A_{\mathsf{e}}(h)$. The scalar action $\mathsf{ModuleSingletonSmul}(\mathsf{e}, h)$ is definitionally the empty history. Theorem 46.3 packages the empty endpoint comparison as $\rho_{\mathsf{e}}(h, \mathsf{e})$, and Theorem 46.5 reads this classification through the singleton scalar action. This supplies $\rho_{\mathsf{e}}(\mathsf{ModuleSingletonSmul}(\mathsf{e}, h), \mathsf{e})$, which repacks with the given carrier witness as $K(h)$.

It remains to compare the restricted classifier. One direction is projection: from $K(h) \wedge K(k) \wedge \rho_{\mathsf{e}}(h, k)$ retain the third component.

Conversely, assume $\rho_{\mathsf{e}}(h, k)$. By Theorem 46.3, both endpoints lie in the singleton carrier A_{e}. Applying the first part to these two carrier witnesses gives $K(h)$ and $K(k)$, so the restricted classifier repacks as $K(h) \wedge K(k) \wedge \rho_{\mathsf{e}}(h, k)$. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingletonSmul kernel exactness`

Theorem 46.47 (Module singleton scalar-action kernel semantic certificate)**.** *For the concrete singleton empty-history module of section 46.2, fix the terminal scalar* e *and let*

$$K(h) :\Longleftrightarrow A_{\mathsf{e}}(h) \wedge \rho_{\mathsf{e}}(\mathsf{ModuleSingletonSmul}(\mathsf{e}, h), \mathsf{e}).$$

Define the restricted kernel classifier by

$$\rho_K(h, k) :\Longleftrightarrow K(h) \wedge K(k) \wedge \rho_{\mathsf{e}}(h, k).$$

Then source, pattern, and ledger all equal to K*, together with classifier* ρ_K*, form the singleton scalar-action kernel semantic naming certificate:*

$$\mathsf{SemanticNameCert}(K, K, K, \rho_K).$$

Proof. Definition 46.46 identifies the displayed kernel predicate with the singleton carrier A_{e}. This gives the empty endpoint as an inhabitant of K and converts each carried kernel endpoint to the carrier context used by Definition 46.14.

For the restricted classifier core, reflexivity at a kernel endpoint h uses the singleton classifier reflexivity row at the converted carrier witness for h, then repacks the two copies of the original kernel witness with $\rho_{\mathsf{e}}(h, h)$. Symmetry projects a comparison $\rho_K(h, k)$ to $\rho_{\mathsf{e}}(h, k)$, applies the symmetry row from Definition 46.14, and repacks the kernel witnesses in the reversed order.

For transitivity, project the two restricted comparisons to $\rho_{\mathsf{e}}(h, k)$ and $\rho_{\mathsf{e}}(k, l)$. Apply Definition 9.8 in the singleton classifier to obtain $\rho_{\mathsf{e}}(h, l)$, and pair that comparison with the retained kernel witnesses for h and l.

Endpoint witnesses are repacked through Definition 46.3: every underlying singleton comparison supplies the carrier witnesses needed to return to K by Definition 46.46. Conversely, a restricted comparison already contains its two K witnesses and its underlying ρ_{e} row.

Pattern and ledger soundness are identity maps, since source, pattern, and ledger are the same predicate K. These rows assemble the displayed $\mathsf{SemanticNameCert}(K, K, K, \rho_K)$. □

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleSingletonSmul kernel semanticNameCert`

Theorem 46.48 (Module singleton standard bridge)**.** *The concrete singleton BEDC module instance of Definition 46.2, with carrier* A_{e}*, classifier* ρ_{e}*, constant scalar action* ModuleSingletonSmul*, and law package Definition 46.14, interprets as the ordinary terminal one-element module over the terminal one-element ring. Its public interpretation is the standard one-object module bridge: carrier membership, classifier comparison, scalar action, source rows, graph exactness, and ledger rows are all read through the singleton* $\mathsf{Ring}^{\uparrow}$ *laws, the singleton* $\mathsf{AbGroup}^{\uparrow}$ *laws, the scalar-action image* SemanticNameCert *of Definition 46.7, and the graph exactness theorem Definition 46.8.*

Lean4 ✓ `BEDC.Derived.ModuleUp.ModuleUp StdBridge`

Proof. The scalar carrier is the singleton empty-history ring supplied by Definition 43.6. The additive module carrier is the singleton empty-history abelian group supplied by Definition 42.10. Both use the same A_{e} endpoint predicate and the same ρ_{e} classifier on BHist.

The scalar-action law package Definition 46.14 identifies the displayed constant action ModuleSingletonSmul with the unique action possible on those singleton carriers. The image certificate Definition 46.7 records the carrier, classifier, source, pattern, and ledger rows as a BEDC SemanticNameCert.

Finally, graph exactness Definition 46.8 says that the action graph has exactly the singleton endpoint output. Composing these rows gives the usual terminal module over the usual terminal ring, with no extra quotient or host representative added to the public interpretation. □

Theorem 46.49 (Module singleton public surface has no host leak)**.** *Every exported public row of the singleton* $\mathsf{Module}^{\uparrow}$ *surface is expressed only in* BHist*,* A_{e}*,* ρ_{e}*,* hsame*,* $\mathsf{ModuleSingletonSmul}$*, the singleton* $\mathsf{Ring}^{\uparrow}$ *rows, the singleton* $\mathsf{AbGroup}^{\uparrow}$ *rows, and the fields of the displayed* $\mathsf{SemanticNameCert}$ *packages. The public surface exports no host equality, host* Nat*, quotient carrier, or host function as part of the BEDC module interface.*

Proof. The carrier and classifier rows are the empty-history endpoint predicate A_{e} and the classifier ρ_{e} from Definition 46.2. Endpoint transport is the hsame transport used in the singleton classifier and image-certificate rows.

The operation row is the displayed BEDC scalar action $\mathsf{ModuleSingletonSmul}$. Its semantic certificate is Definition 46.7, and its graph boundary is Definition 46.8; neither row requires a host equality test or a host function in the exported surface.

The scalar and additive source rows are exactly the singleton $\mathsf{Ring}^{\uparrow}$ and $\mathsf{AbGroup}^{\uparrow}$ rows, and the kernel-facing public rows are the BEDC $\mathsf{SemanticNameCert}$ and exactness rows of Definition 46.46 and Definition 46.47. Thus every public endpoint, comparison, operation, and ledger field is named inside the BEDC vocabulary, while host Nat, quotient carriers, host equality, and host functions remain outside the exported interface. □

Theorem 46.50 (ModuleUp mature package boundary)**.** *The concrete* $\mathsf{Module}^{\uparrow}$ *package for the singleton empty-history instance consists of the singleton scalar carrier, the singleton module carrier, the scalar-action image* $\mathsf{SemanticNameCert}$*, the output-fiber* $\mathsf{SemanticNameCert}$*, the zero-action annihilation row, the* $\mathsf{Ring}^{\uparrow}$ *scalar projection, the* $\mathsf{LinMap}^{\uparrow}$ *kernel package, the classifier-faithful action and annihilator* $\mathsf{Ideal}^{\uparrow}$ *predicate, the singleton standard bridge, and the no-host-leak public boundary.*

Proof. The singleton scalar and module carriers, scalar action, scalar projection, semantic image certificate, and output-fiber certificate are the concrete rows of Definition 46.2, Definition 46.14, Definition 46.7, and Definition 46.10. The zero-action endpoint row is supplied by Definition 46.29.

The kernel-facing part of the package is the $\mathsf{LinMap}^{\uparrow}$ semantic certificate of Definition 46.47. The action-faithfulness and annihilator closure rows are packaged by Definition 46.33.

Finally, Definition 46.48 identifies the public singleton surface with the standard terminal module bridge, and Definition 46.49 records that this public surface exports no host equality, host Nat, quotient carrier, or host function. These rows are exactly the advertised mature package boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{Module}^{\uparrow}}$**.**

Constructive story: A module action here is a constant action between two endpoint carriers: the scalar side is the singleton from $\mathsf{Ring}^{\uparrow}$, the vector side is the singleton from $\mathsf{AbGroup}^{\uparrow}$, and the action sends every admitted scalar-vector pair back to e. A pair (s, v) is admitted only when both entries are history-equal to e, and two pairs are classified by the conjunction of the scalar and vector singleton classifiers. The source is the singleton-on-singleton pair predicate, the pattern records the scalar-action image certificate, graph exactness, zero-action annihilation, and the equivalence between action faithfulness and a trivial zero annihilator, while the ledger keeps the visible pair aligned with the raw endpoint data. Since both sides are singleton name certificates, (e, e) supplies the carrier witness, the pair classifier is reflexive, symmetric, and transitive, and classifier-recognized pairs remain admitted. A pair (s, v) lies in the signature gap of a $\mathsf{Module}^{\uparrow}$ token p when the source-domain accepts the pair, the signature relation pairs it with an answer pair and evidence ledger, and the token-introduction relation names that answer as p; unfolded, both s and v are history-equal to e and p is the singleton scalar-action token. The annihilator-ideal predicate, singleton standard bridge to host module data, and no-host-leak theorem all read back the same endpoint action. The chapter registers this singleton scalar-action construction under the name $\mathsf{Module}^{\uparrow}$; the ring, abelian group, associativity, two distributivity laws, and unit law are checked on the constant endpoint action, with no bases, quotients, tensor products, or host module object introduced.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Module}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The mature singleton Module$^{\uparrow}$ paper package binds the singleton scalar carrier, singleton module carrier, scalar-action image SemanticNameCert, graph exactness, zero-action annihilation, action-faithfulness if and only if zero-annihilator, the annihilator Ideal$^{\uparrow}$ predicate, the singleton standard bridge of Definition 46.48, and the no-host-leak theorem of Definition 46.49.

Formal verification: FormalStatus(NameCert$_{\text{Module}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.ModuleUp.ModuleSingletonSmul\_image\_semanticNameCert`

Bridge status: bridgeChecked

Origin: human

Not claimed: The chapter does not claim arbitrary non-singleton modules, quotient modules, bases, free modules, tensor products, or structure theorem results.

Upgrade path: The singleton package occupies the stated mature theory boundary and the top formal target; broader module packages require separate certificates.

Chapter 47

A Concrete Naming Certificate for $\mathsf{VecSpace}^{\uparrow}$

The vector space interface $\mathsf{VecSpace}^{\uparrow}$ is the specialization of chapter 46 to the case where the scalar ring satisfies chapter 45. No new fields are required beyond the module ones; the change is the strengthened scalar source. The n-fold rational tuple space (an iterated product over $\mathsf{Rat}^{\uparrow}$) is the canonical concrete instance.

47.1 Carrier definition

Definition 47.1 (VecSpace carrier)**.** *Use a module setup whose scalar source is a certified field.*

47.2 Concrete singleton history vector space instance

Definition 47.2 (Concrete singleton empty-history vector space instance)**.** *Let the scalar carrier and vector carrier both be the singleton history source A_{e} of Definition 46.2. Define the shared classifier*

$$\rho_{\mathsf{e}}(h,k) := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h,k).$$

Use the scalar addition, scalar negation, scalar multiplication, scalar zero, scalar one, nonzero predicate, and proof-indexed scalar inverse from Definition 45.2. Use the vector addition, vector negation, vector zero, and scalar action from Definition 46.2, with

$$\mathsf{smul}(r,m) := \mathsf{e}.$$

The certificate fit has ten fields:

1. *Traditional target: the one-element vector space over the one-element proof-indexed field.*
2. *BEDC source:* BHist.
3. *Carrier choice: A_{e} for both scalars and vectors.*
4. *Classifier choice: ρ_{e}.*
5. *Stability obligations: the singleton field laws together with the singleton module laws and the vacuous nonzero-indexed scalar inverse reasoning.*
6. *Ledger: singleton scalar, vector, and action provenance.*

7. *Core theorem list: Theorem 47.3.*
8. *Exactness predicate: singleton endpoint classification.*
9. *Standard bridge: the terminal one-object vector space.*
10. *Status:* ProofTarget.

Theorem 47.3 (Singleton empty-history vector space laws)**.** *The tuple*

$$(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \mathsf{add}, 0, \mathsf{neg}, \mathsf{mul}, 1, \mathsf{smul}, \mathsf{NonZero}_{\perp}, \mathsf{inv})$$

satisfies the $\mathsf{VecSpace}^{\uparrow}$ *schema over the concrete* BHist *singleton carrier: scalar* $\mathsf{Field}^{\uparrow}$ *laws, additive module laws, scalar-action closure, scalar-action congruence, scalar associativity, distributivity over vector addition, distributivity over scalar addition, scalar unit law, and inverse-enabled scalar reasoning for explicitly nonzero scalars.*

Proof. The module part is exactly the singleton empty-history module package of Theorem 46.14. It supplies closure, the additive abelian-group laws, scalar-action congruence, scalar associativity, both distributivity laws, and the scalar unit law for the same A_{e} carrier and ρ_{e} classifier.

The scalar field part is exactly the singleton empty-history field schema of Theorem 45.37. It supplies the scalar commutative-ring laws together with the proof-indexed nonzero transport, inverse closure, inverse congruence, and inverse laws. The certificate packaging is the one recorded in Theorem 45.81.

It remains only to check that the two packages share the displayed scalar source. Both use the constant empty-history scalar operations on A_{e}, the same classifier ρ_{e}, and the same scalar unit. Hence their scalar ring fragments coincide as the scalar side of the vector-space schema.

For scalar congruence and each scalar-action law, every endpoint reduces to e. The required classifier witness is assembled from $A_{\mathsf{e}}(\mathsf{e})$ and $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$.

For inverse-enabled scalar reasoning, every such clause begins with a witness $p : \mathsf{NonZero}_{\perp}(h)$. Theorem 45.33 identifies the singleton nonzero predicate as contradictory at the only possible endpoint. Since $\mathsf{NonZero}_{\perp}(h)$ is $\perp$, eliminating p closes the clause over the empty witness domain. No classical nonzero test or further endpoint datum is needed. □

Lean4 ✓ `BEDC.Derived.VecSpaceUp.singleton empty history vecspace laws`

Theorem 47.4 (Singleton empty-history vector space endpoint collapse)**.** *With the notation of Definition 47.2, let* $r, s : \mathsf{BHist}$ *be scalar endpoints and* $m, n : \mathsf{BHist}$ *be vector endpoints carried by* A_{e}*. Then the concrete singleton tuple has the following endpoint classifications:*

1. *For any* $x, y : \mathsf{BHist}$*, if* $A_{\mathsf{e}}(x)$ *and* $A_{\mathsf{e}}(y)$*, then* $\rho_{\mathsf{e}}(x, y)$*.*
2. $A_{\mathsf{e}}(\mathsf{smul}(r, m))$ *and* $\rho_{\mathsf{e}}(\mathsf{smul}(r, m), \mathsf{e})$*.*
3. *The vector endpoints* $\mathsf{add}(m, n)$*,* $\mathsf{neg}(m)$*, and the vector zero are all carried by* A_{e} *and classified with* e*.*
4. *The scalar endpoints* 0*,* 1*, and* $\mathsf{mul}(r, s)$ *are all carried by* A_{e} *and classified with* e*.*
5. *For any witness* $p : \mathsf{NonZero}_{\perp}(r)$*, the inverse endpoint* $\mathsf{inv}(r, p)$ *is carried by* A_{e} *and classified with* e*.*

Proof. Apply Theorem 46.14 to the carried scalar and vector inputs. Its closure and congruence clauses cover the additive vector endpoints and the scalar-action endpoint for the same A_{e} carrier and ρ_{e} classifier.

Apply Theorem 45.37 to the scalar side. It supplies closure for scalar zero, scalar one, scalar multiplication, and the proof-indexed inverse clauses over the same singleton source.

Unfold the concrete operations in Definition 47.2. The displayed scalar action is definitionally e, and the imported singleton vector and scalar operations reduce to the singleton endpoint as recorded by the module and field law packages.

For any two carried endpoints x and y, unfold $\rho_{\mathsf{e}}(x, y)$. The carrier components are the two assumptions $A_{\mathsf{e}}(x)$ and $A_{\mathsf{e}}(y)$, and the singleton endpoint witnesses for x and y compose to give the required $\mathsf{hsame}(x, y)$ component.

Each operation endpoint already reduces to e or is closed by the cited law package at the singleton endpoint. Pair the relevant $A_{\mathsf{e}}(\mathsf{e})$ witness with reflexivity $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$ to obtain the displayed classifier witness against e.

For the inverse-indexed clause, assume $p : \mathsf{NonZero}_{\perp}(r)$. Since $A_{\mathsf{e}}(r)$ holds, Theorem 45.33 eliminates the nonzero witness at the only possible endpoint. From that contradiction, the carried and classified inverse conclusion follows over the empty witness domain. □

Lean4 ✓ `BEDC.Derived.VecSpaceUp.VecSpaceSingletonEmptyHistory laws`

Theorem 47.5 (VecSpace singleton classifier endpoint transitivity)**.** *For singleton vector endpoints* $a, b, c : \mathsf{BHist}$*, if*

$$\mathsf{VecSpaceSingletonClassifier}(a, b) \quad \textit{and} \quad \mathsf{VecSpaceSingletonClassifier}(b, c),$$

then

$$a\mathsf{hsame}e \wedge c\mathsf{hsame}e \wedge \mathsf{VecSpaceSingletonClassifier}(a, c).$$

Proof. Unfold the concrete singleton classifier. The first classifier supplies the empty endpoint witness for a and the comparison $a\mathsf{hsame}b$. The second classifier supplies the empty endpoint witness for c and the comparison $b\mathsf{hsame}c$. Compose the two comparisons by transitivity to obtain $a\mathsf{hsame}c$, and package it with the carried endpoint witnesses for a and c. □

Lean4 ✓ `BEDC.Derived.VecSpaceUp.VecSpaceSingletonClassifier endpoint trans`

Theorem 47.6 (VecSpace singleton scalar action carrier readback)**.** *For the concrete singleton* $\mathsf{VecSpace}^{\uparrow}$ *instance, if* $m : \mathsf{BHist}$ *satisfies* $A_{\mathsf{e}}(m)$*, then* $\mathsf{smul}(r, m)$ *is classified with* m*, and* $\mathsf{smul}(r, m)\mathsf{hsame}e$*.*

Proof. The scalar action in Definition 47.2 is the constant empty-history action, so its endpoint has the singleton carrier by $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$. The assumed carrier witness for m is the second endpoint component. Symmetry of that same witness gives $\mathsf{ehsame}m$, which is the classifier comparison from the scalar-action endpoint back to m. □

Lean4 ✓ `BEDC.Derived.VecSpaceUp.VecSpaceSingletonSmul carrier readback`

Theorem 47.7 (VecSpace singleton scalar action classifier empty equivalence)**.** *For all histories* $r, m, t : \mathsf{BHist}$*, the singleton scalar action classifier satisfies*

$$\mathsf{VecSpaceSingletonClassifier}(\mathsf{VecSpaceSingletonSmul}(r, m), t) \iff t\mathsf{hsame}e.$$

Proof. The scalar action endpoint is definitionally e. In the forward direction, unfolding the classifier exposes the carried target endpoint, which is exactly $t\mathsf{hsame}e$. Conversely, from $t\mathsf{hsame}e$, use reflexivity for the source empty endpoint, the displayed target carrier, and symmetry to obtain the classifier comparison $\mathsf{ehsame}t$. □

Lean4 ✓ `BEDC.Derived.VecSpaceUp.VecSpaceSingletonSmul classifier empty iff`

Theorem 47.8 (VecSpace singleton scalar action image pullback)**.** *For all histories* r, m, n : BHist*, if* $m$hsamee*, then*

$$\mathsf{VecSpaceSingletonClassifier}(\mathsf{VecSpaceSingletonSmul}(r, m), n) \iff \mathsf{VecSpaceSingletonClassifier}(m, n).$$

Proof. The scalar-action image endpoint is definitionally e. In the forward direction, the target classifier gives the carrier of n and the comparison ehsame$n$; composing the assumed $m$hsamee with this comparison gives $m$hsame$n$. In the reverse direction, the target carrier contained in VecSpaceSingletonClassifier(m, n) and symmetry classify the empty scalar-action endpoint against n. □

Lean4 ✓ `BEDC.Derived.VecSpaceUp.VecSpaceSingletonSmul image pullback iff`

Theorem 47.9 (VecSpace singleton scalar action target deterministic)**.** *For all histories* r, s, m, n, x, y : BHist*, if* VecSpaceSingletonClassifier(VecSpaceSingletonSmul$(r, m), x$) *and* VecSpaceSingletonClassifier(VecSpaceSing *then* $x$hsamee*,* $y$hsamee*, and* $x$hsame$y$*.*

Proof. Unfold the singleton scalar-action classifier at both displayed endpoints. The target-carrier field of the first classifier gives $x$hsamee, and the target-carrier field of the second classifier gives $y$hsamee. Composing the first equality with the symmetry of the second yields $x$hsame$y$. □

Lean4 ✓ `BEDC.Derived.VecSpaceUp.VecSpaceSingletonSmul target deterministic`

Theorem 47.10 (VecSpace singleton scalar action inverse law)**.** *For the concrete singleton* VecSpace$^{\uparrow}$ *instance, let* p : FieldSingletonNonZero(r) *be an explicit scalar inverse witness and let* m : BHist *satisfy* $A_{\mathsf{e}}(m)$*. Then* smul(r, m) *is classified with* e*, and applying the proof-indexed inverse scalar to that result is classified with the original vector endpoint* m*.*

Proof. The scalar action is the constant empty-history action, so smul(r, m)hsamee by reflexivity. Applying the inverse scalar again has the same empty-history endpoint. The first classifier package uses $A_{\mathsf{e}}(\mathsf{e})$ on both sides. The second uses $A_{\mathsf{e}}(\mathsf{e})$ on the action side and the assumed singleton-carrier witness for m on the readback side; symmetry of that witness gives ehsame$m$. □

Lean4 ✓ `BEDC.Derived.VecSpaceUp.VecSpaceSingleton scalar action inverse law`

Theorem 47.11 (VecSpace singleton scalar action inverse readback classifier iff)**.** *For the concrete singleton* VecSpace$^{\uparrow}$ *instance, let* p : FieldSingletonNonZero(r) *and let* m *satisfy* $A_{\mathsf{e}}(m)$*. Then the inverse-indexed scalar action after scalar action has empty readback, and classification against any target* n *is equivalent to classification of the original vector endpoint* m *against* n*:*

$$\mathsf{VecSpaceSingletonClassifier}(\mathsf{VecSpaceSingletonSmul}(\mathsf{FieldSingletonInv}(r, p), \mathsf{VecSpaceSingletonSmul}(r, m)), n) \iff \mathsf{V}$$

Lean4 ✓ `BEDC.Derived.VecSpaceUp.VecSpaceSingletonSmul inverse readback classifier iff`

Proof. The singleton scalar action is the constant empty-history endpoint, so the double action has carrier equality to e by reflexivity. In the forward classifier direction, the target carrier and action-target equality combine with the assumed carrier equality $m$hsamee to give VecSpaceSingletonClassifier(m, n). In the reverse direction, the target carrier contained in VecSpaceSingletonClassifier(m, n), together with symmetry, classifies the empty double-action endpoint against n. □

Theorem 47.12 (VecSpace singleton scalar action empty readback classifier)**.** *For the concrete singleton* $\mathsf{VecSpace}^{\uparrow}$ *instance, if* $m : \mathsf{BHist}$ *satisfies* $A_{\mathsf{e}}(m)$*, then* $\mathsf{smul}(r, m)$ *is classified with* e *and is also classified with the original vector endpoint* m*.*

Proof. The scalar action is definitionally the constant empty-history action. The empty endpoint classifier is therefore the reflexive classifier on e. For the readback classifier, the left endpoint again supplies $A_{\mathsf{e}}(\mathsf{e})$, the right endpoint is the assumed carrier witness $A_{\mathsf{e}}(m)$, and symmetry of that witness gives $\mathsf{ehsame}m$. □

Lean4 ✓ `BEDC.Derived.VecSpaceUp.VecSpaceSingletonSmul empty readback classifier`

Theorem 47.13 (VecSpace singleton scalar action empty-result readback)**.** *For the concrete singleton* $\mathsf{VecSpace}^{\uparrow}$ *instance, let* $r, m, n : \mathsf{BHist}$*. If* m *is carried by* A_{e} *and* $\mathsf{smul}(r, m)$ *is classified with* n*, then* $\mathsf{smul}(r, m)\mathsf{hsamee}$ *and* m *is classified with* n*.*

Proof. Unfolding the singleton scalar action gives $\mathsf{smul}(r, m) = \mathsf{e}$, so the first classifier endpoint supplies $\mathsf{smul}(r, m)\mathsf{hsamee}$. The classifier hypothesis also contains the carrier witness for n and the endpoint equality $\mathsf{smul}(r, m)\mathsf{hsame}n$. Compose the assumed carrier equality $m\mathsf{hsamee}$ with this action equality to obtain $m\mathsf{hsame}n$, and pair it with the two carrier witnesses to recover the classifier $\rho_{\mathsf{e}}(m, n)$. □

Lean4 ✓ `BEDC.Derived.VecSpaceUp.VecSpaceSingletonSmul empty result readback`

The $\mathsf{VecSpace}^{\uparrow}$ schema is instantiated by this concrete BHist carrier and scalar action, so Lean formalization can target BHist-anchored vector-space laws in $\mathsf{BEDC.Derived.VecSpaceUp}$.

Theorem 47.14 (Singleton empty-history vector space semantic certificate)**.** *The tuple from Definition 47.2, together with the law package of Theorem 47.3, supplies the concrete paper-side semantic certificate for the terminal* $\mathsf{VecSpace}^{\uparrow}$ *over the singleton* $\mathsf{Field}^{\uparrow}$ *and singleton* $\mathsf{Module}^{\uparrow}$ *carriers. Its certificate target is the following ten-field template:*

1. *Traditional target: the terminal vector space.*
2. *BEDC source:* BHist*.*
3. *Carrier:* A_{e}*.*
4. *Classifier:* ρ_{e}*.*
5. *Stability: the singleton field and module law packages together with nonzero-witness elimination.*
6. *Ledger: singleton scalar, vector, and action provenance.*
7. *Core theorem: Theorem 47.3.*
8. *Exactness: singleton endpoint classification.*
9. *Standard bridge: the terminal vector space.*
10. *Status:* $\mathsf{ProofTarget}$*.*

Proof. The scalar component is supplied by Theorem 45.37, and its paper-side packaging is recorded by Theorem 45.81. These give the singleton $\mathsf{Field}^{\uparrow}$ source, the shared A_{e} carrier, and the classifier ρ_{e} used by the displayed tuple.

The vector component is supplied by Theorem 46.14. It gives the singleton $\mathsf{Module}^{\uparrow}$ additive laws, scalar-action closure, scalar-action congruence, associativity, both distributivity laws, and the scalar unit law over the same empty-history endpoint.

The remaining inverse-indexed clauses are vacuous in the singleton field source. By Theorem 45.33, any witness of $\mathsf{NonZero}_\perp(h)$ is impossible at the only endpoint, so each nonzero-indexed scalar obligation is closed by elimination.

Thus the tuple already carries the scalar, vector, classifier, ledger, exactness, bridge, and status data listed in the ten-field template, with Theorem 47.3 as its core theorem. □

Lean4 ✓ `BEDC.Derived.VecSpaceUp.VecSpaceSingleton semanticNameCert`

Theorem 47.15 (VecSpace singleton scalar action image semantic certificate)**.** *For the concrete singleton* $\mathsf{VecSpace}^\uparrow$ *instance, the source carrier* A_e*, the scalar-action image pattern*

$$P(h) \;:\Longleftrightarrow\; \exists r, m : \mathsf{BHist},\ A_\mathsf{e}(m) \wedge h\mathsf{hsameVecSpaceSingletonSmul}(r, m),$$

the ledger carrier A_e*, and the singleton classifier* ρ_e *form a* $\mathsf{SemanticNameCert}$*.*

Proof. The core certificate is the singleton A_e certificate for ρ_e: inhabitation is witnessed by e, reflexivity uses the carried endpoint, symmetry reverses the hsame comparison, transitivity composes comparisons, and carrier transport reads the target carrier field from the classifier.

For pattern soundness, assume $A_\mathsf{e}(h)$. Choose the displayed scalar $r = \mathsf{e}$ and vector $m = h$. The vector side is carried by the same witness, and the scalar action is definitionally the empty-history endpoint, so the same $A_\mathsf{e}(h)$ witness is the required comparison $h\mathsf{hsameVecSpaceSingletonSmul}(r, m)$. Ledger soundness is the identity map on the concrete singleton carrier. □

Lean4 ✓ `BEDC.Derived.VecSpaceUp.VecSpaceSingletonSmul image semanticNameCert`

47.3 The certificate

Definition 47.16 (VecSpace source specification)**.** *The source is* $\mathsf{Field}^\uparrow(F)$ *together with a certified* F*-module carrier.*

Definition 47.17 (VecSpace pattern specification)**.** *The pattern is exactly module expression formation over field scalars.*

Definition 47.18 (VecSpace classifier specification)**.** *The classifier is the module carrier classifier, with scalar congruence inherited from the field.*

Definition 47.19 (VecSpace stability certificate)**.** *The stability certificate consists of:*

1. *all module stability fields*
2. *all scalar field stability fields*
3. *inverse-enabled scalar reasoning for apart-from-zero scalars*

Definition 47.20 (VecSpace ledger policy)**.** *Record module ledgers plus the field ledger for scalar operations.*

Definition 47.21 ($\mathsf{VecSpace}^\uparrow$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{VecSpace}^\uparrow$*.*

Primitive boundary. $\mathsf{VecSpace}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Remark 47.22 (Zero-axiom encoding note)**.** *Inverses use field apartness witnesses rather than LEM-based nonzero tests.*

Proposition 47.23 (VecSpace forgets to Module certificate)**.** *Let F carry a $\mathsf{Field}^{\uparrow}(F)$ certificate, and let R be the $\mathsf{CommRing}^{\uparrow}$ base coordinate contained in that field certificate. Let V carry a $\mathsf{VecSpace}^{\uparrow}(F, V)$ certificate with scalar action $\mathsf{smul} : F \times V \to V$. If the constructive apartness predicate, the proof-indexed scalar inverse operation, and every inverse-indexed stability or ledger row are omitted, then the retained carrier, source, pattern, classifier, stability, and ledger fields form a $\mathsf{Module}^{\uparrow}(R, V)$ certificate, with R read through its ring reduct. The vector carrier, scalar action, additive vector operations, scalar ring operations, classifier, exactness predicate, and all non-inverse ledger provenance are unchanged.*

Proof. By Definition 47.21, the given vector-space certificate supplies carrier, source, pattern, classifier, stability, and ledger data for $\mathsf{VecSpace}^{\uparrow}$. By Definition 47.1, its carrier is already a module setup whose scalar source is strengthened from a scalar ring to a certified field. Therefore the vector carrier, additive vector operations, scalar action, and classifier are the module-shaped carrier data listed in Definition 46.1.

The scalar source is handled by projection of the field side. By Definition 45.198, the $\mathsf{Field}^{\uparrow}(F)$ source contains a certified commutative-ring carrier together with constructive nonzero evidence. Omitting the nonzero and inverse-specific coordinates leaves the $\mathsf{CommRing}^{\uparrow}$ certificate R. By Definition 44.8, this same scalar coordinate supplies the $\mathsf{Ring}^{\uparrow}$ source required by Definition 46.15. Together with the additive vector carrier already present in the module setup, this gives the source field for $\mathsf{Module}^{\uparrow}(R, V)$.

For patterns, Definition 47.17 says that the vector-space pattern is module expression formation over field scalars. Removing scalar inverse formation leaves expressions built from vector addition, vector zero, vector negation, scalar multiplication, and the scalar ring operations. This is exactly the module expression formation of Definition 46.16. For classifiers, Definition 47.18 uses the module carrier classifier, with scalar congruence inherited from the field. After the scalar source is read through the commutative-ring and ring reducts, the same classifier is the one required by Definition 46.17; no endpoint relation is replaced.

For stability, Definition 47.19 contains all module stability fields, all scalar field stability fields, and inverse-enabled scalar reasoning. The first component is precisely the scalar-action and additive-vector stability package of Definition 46.18. The scalar ring laws needed there are present because Definition 45.201 contains all commutative-ring stability fields, and Definition 44.8 retains the ring part. The inverse closure, nonzero transport, and inverse laws are not obligations for $\mathsf{Module}^{\uparrow}$.

For the ledger, Definition 47.20 records the module ledgers together with the field ledger for scalar operations. By Definition 45.336, the field ledger consists of the ring ledger plus the nonzero witness used for each inverse. Omitting those inverse-witness entries leaves the scalar and module expression provenance described in Definition 46.19.

Thus the retained carrier, source, pattern, classifier, stability, and ledger fields are exactly the obligations named in Definition 46.20. Since every retained operation and classifier is copied from the original $\mathsf{VecSpace}^{\uparrow}(F, V)$ certificate, the resulting $\mathsf{Module}^{\uparrow}(R, V)$ certificate has the same carrier, action, classifier, stability rows, and ledger outside the omitted inverse-specific data. □

Proposition 47.24 (VecSpace module-fragment projection)**.** *Let F carry a $\mathsf{Field}^{\uparrow}(F)$ certificate. Let F_{Ring} be the scalar certificate obtained from it by first taking the commutative-ring reduct and then the ring reduct. Let V carry a $\mathsf{VecSpace}^{\uparrow}(F, V)$ certificate with vector carrier C_V, vector classifier $\sim_V$, additive operations $+_V$, 0_V, $-_V$, and scalar action $\odot : F \times V \to V$. If the apartness predicate, proof-indexed scalar inverse operation, inverse-indexed stability rows, and inverse-witness ledger rows are omitted, the retained fields form a $\mathsf{Module}^{\uparrow}(F_{\mathsf{Ring}}, V)$ certificate. The vector carrier C_V, vector classifier $\sim_V$, vector addition, vector zero, vector negation, scalar action $\odot$, scalar addition, scalar zero, scalar negation, scalar multiplication, scalar one, exactness predicate, and non-inverse ledger rows are unchanged.*

Proof. By Definition 47.21, the vector-space certificate supplies carrier, source, pattern, classifier, stability, and ledger data for $\mathsf{VecSpace}^{\uparrow}$. By Definition 47.1, its carrier is already a module setup whose scalar source has been strengthened from a certified ring source to a certified field source. Thus the vector carrier, additive vector operations, scalar action, and vector classifier are exactly the module-shaped carrier data required by Definition 46.1.

The scalar source is obtained by successive reducts. Applying Definition 45.342 to the $\mathsf{Field}^{\uparrow}(F)$ scalar certificate keeps the same scalar carrier, classifier, addition, zero, negation, multiplication, and one while dropping the apartness and proof-indexed inverse rows. Applying Definition 44.8 to that commutative-ring coordinate keeps the same scalar operations and classifier and supplies the $\mathsf{Ring}^{\uparrow}$ source required by Definition 46.15. This scalar source is F_{Ring}.

For patterns, Definition 47.17 identifies vector-space expression formation with module expression formation over field scalars. After inverse formation on the scalar side is omitted, the remaining vector expressions are generated by vector addition, vector zero, vector negation, scalar multiplication, and scalar ring expressions. This is exactly the pattern listed in Definition 46.16.

For classifiers, Definition 47.18 uses the module carrier classifier, with scalar congruence inherited from the field. The scalar reducts above preserve the scalar classifier, and the vector classifier is not replaced. Hence the retained classifier is the module carrier classifier required by Definition 46.17.

For stability, Definition 47.19 contains all module stability fields, all scalar field stability fields, and inverse-enabled scalar reasoning. The module rows are precisely the scalar-action and additive-vector rows listed in Definition 46.18. The scalar ring rows needed there are retained because Definition 45.201 contains the commutative-ring stability fields and Definition 44.8 keeps the ring part. The inverse closure, nonzero transport, and inverse laws are not obligations for $\mathsf{Module}^{\uparrow}$.

For the ledger, Definition 47.20 records module ledgers together with the field ledger for scalar operations. By Definition 45.336, the field ledger consists of the ring ledger plus inverse-witness entries. Omitting those witness entries leaves the scalar and module expression provenance described in Definition 46.19.

Thus the retained carrier, source, pattern, classifier, stability, and ledger fields satisfy Definition 46.20. Every retained operation, carrier, classifier, exactness predicate, and non-inverse ledger row is copied from the original $\mathsf{VecSpace}^{\uparrow}(F, V)$ certificate, so the projected $\mathsf{Module}^{\uparrow}(F_{\mathsf{Ring}}, V)$ certificate has the same module fragment. □

Lean4 ✓ `BEDC.Derived.VecSpaceUp.VecSpaceSingleton module fragment projection`

Corollary 47.25 (VecSpace additive carrier projection)**.** *Let F carry a $\mathsf{Field}^{\uparrow}(F)$ certificate. Let F_{Ring} be the scalar certificate obtained from it by first taking the commutative-ring reduct and then the ring reduct. Let V carry a $\mathsf{VecSpace}^{\uparrow}(F, V)$ certificate with vector carrier C_V, vector classifier $\sim_V$, vector addition $+_V$, vector zero 0_V, vector negation $(-)_V$, and scalar action $\odot : F \times V \to V$. If the vector-space certificate is first read through the module-fragment projection of Definition 47.24,*

and the resulting module certificate is then read through the additive reduct of Definition 46.26, the retained vector-side data form an $\mathsf{AbGroup}^{\uparrow}(V)$ *certificate. The carrier* C_V*, classifier* $\sim_V$*, vector addition* $+_V$*, vector zero* 0_V*, and vector negation* $(-)_V$ *are unchanged from the original* $\mathsf{VecSpace}^{\uparrow}(F, V)$ *certificate.*

Lean4 ✓ `BEDC.Derived.VecSpaceUp.VecSpaceSingleton additive carrier projection`

Proof. Apply Definition 47.24 to the given vector-space certificate. It supplies a $\mathsf{Module}^{\uparrow}(F_{\mathsf{Ring}}, V)$ certificate after deleting only the apartness predicate, proof-indexed scalar inverse operation, inverse-indexed stability rows, and inverse-witness ledger rows. The proposition states that this module certificate keeps the original vector carrier C_V, vector classifier $\sim_V$, vector addition, vector zero, vector negation, and scalar action.

Now apply Definition 46.26 to that $\mathsf{Module}^{\uparrow}(F_{\mathsf{Ring}}, V)$ certificate. Its scalar input is available because F_{Ring} is a certified $\mathsf{Ring}^{\uparrow}$ source. This second reduct removes the scalar-ring package, the scalar action, and the scalar-action stability rows, and retains exactly the additive carrier, additive source, additive pattern, carrier classifier, additive stability fields, and additive ledger.

By Definition 42.32, those retained fields are the obligations for an $\mathsf{AbGroup}^{\uparrow}(V)$ certificate. The first projection did not alter the vector-side additive data, and the second projection explicitly keeps the additive carrier data of the module certificate. Therefore the final $\mathsf{AbGroup}^{\uparrow}(V)$ certificate is over the same carrier C_V with the same classifier $\sim_V$, addition $+_V$, zero 0_V, and additive inverse $(-)_V$ carried by the original vector-space certificate. □

Theorem 47.26 (Finite linear-combination induction route)**.** *Let* F *carry a* $\mathsf{Field}^{\uparrow}(F)$ *certificate and let* V *carry a* $\mathsf{VecSpace}^{\uparrow}(F, V)$ *certificate. Suppose an accepted finite vector-space read carries a support ledger generated by the empty support row and by one-step insertion of a displayed basis-vector row with its scalar coefficient. Then every exported linear-combination row in that read is obtained by induction over the displayed finite support list. The induction preserves the* $\mathsf{VecSpace}^{\uparrow}$ *carrier, the* $\mathsf{Module}^{\uparrow}$ *reduct of Definition 47.24, the* $\mathsf{AbGroup}^{\uparrow}$ *additive projection of Definition 47.25, scalar-action readback, componentwise transport, displayed replay, provenance, and local* NameCert *rows.*

Proof. Induct on the displayed finite support ledger. In the empty-support case, the row is the vector-zero row already present in the $\mathsf{VecSpace}^{\uparrow}$ carrier; its module reduct and additive projection are the zero rows retained by Definition 47.24 and Definition 47.25.

For the one-step insertion case, the induction hypothesis supplies the linear-combination row for the previous support list together with its carrier, reduct, additive, scalar-action, transport, replay, provenance, and local naming invariants. The inserted basis-vector row and coefficient consume one scalar-vector action row of the $\mathsf{VecSpace}^{\uparrow}$ certificate, producing the next displayed summand without changing the underlying vector carrier or classifier.

The additive step then uses the additive carrier projection to add this summand to the previous row. Since the module-fragment projection keeps the scalar action and the additive projection keeps the vector addition, the same readback path exports the enlarged linear-combination row.

Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row are structural rows of the original vector-space read, so they preserve the induction invariant at each ledger step. Thus every exported finite linear-combination row factors through the displayed support list and no basis package beyond the finite ledger is introduced. □

Closure status for $\mathsf{NameCert}_{\mathsf{VecSpace}^{\uparrow}}$**.**

Constructive story: The vector-space package keeps the singleton scalar-vector pair from $\mathsf{Module}^{\uparrow}$ and changes the scalar certificate from $\mathsf{Ring}^{\uparrow}$ to $\mathsf{Field}^{\uparrow}$. A pair (s, v) enters only when both entries are history-equal to e, the action again

sends every carried pair to e, and the pair classifier now uses the Field$^{\uparrow}$ classifier on the scalar side together with the singleton vector classifier. The source is the singleton-pair predicate, the pattern records scalar action, the projection back to Module$^{\uparrow}$, the AbGroup$^{\uparrow}$ additive carrier projection, and the scalar-action image semantic certificate, while the ledger keeps the visible pair aligned with the raw endpoint pair. Because both sides are singleton certificates, (e, e) witnesses nonemptiness, the pair classifier is reflexive, symmetric, and transitive, and recognized scalar-vector pairs remain admitted. A pair (s, v) lies in the signature gap of a VecSpace$^{\uparrow}$ token p when the source-domain accepts the pair, the signature relation pairs it with an answer pair and evidence ledger, and the token-introduction relation names that answer as p; unfolded, both entries are history-equal to e and p is the singleton vector-space token. The terminal one-object bridge data row reads this as the one-object external vector space, while inverse-indexed scalar reasoning is vacuous because the singleton has no nonzero witness domain to inspect. The chapter registers this terminal singleton package under the name VecSpace$^{\uparrow}$; the carrier is the same endpoint pair under field-scalar discipline, with no finite-dimensional coordinate theory, basis package, analytic vector space, or non-singleton vector-space claim introduced.

Theory closure: TheoryGate(NameCert$_{\mathsf{VecSpace}^{\uparrow}}$, maturePackageClosed)

Scope closed: Singleton empty-history vector-space package binding the carrier A_{e}, classifier ρ_{e}, scalar action, semantic NameCert, scalar-action image semantic certificate, terminal one-object vector-space bridge data, Module$^{\uparrow}$ projection, and AbGroup$^{\uparrow}$ additive carrier projection.

Formal verification: FormalStatus(NameCert$_{\mathsf{VecSpace}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.VecSpaceUp.VecSpaceSingleton\_semanticNameCert`

Bridge status: paperBridge

Not claimed: Arbitrary vector spaces, finite-dimensional spaces over Rat$^{\uparrow}$ or Real$^{\uparrow}$, bases outside the singleton terminal case, spectral theory, Banach/Hilbert spaces, and Lean-side bridge verification are not closed by this mature singleton package.

Upgrade path: The remaining verification-axis step is bridgeChecked on a checked bridge target or a separate non-singleton vector-space family treatment.

Chapter 48

A Concrete Naming Certificate for $\mathsf{LinMap}^{\uparrow}$

The linear map interface $\mathsf{LinMap}^{\uparrow}$ has certificate obligations between two vector spaces over the same scalar field from chapter 47. The carrier is the predicate "$f : V \to W$ preserves the additive structure and commutes with scalar multiplication"; the classifier is pointwise carrier sameness on the codomain restricted to maps satisfying linearity. It is not a primitive function space; it is admitted only as a derived predicate over function pairs.

48.1 Carrier definition

Definition 48.1 (LinearMap carrier)**.** *A concrete* $\mathsf{LinMap}^{\uparrow}$ *carrier is a* BHist*-coded map-code predicate together with classifier, evaluation, and composition data. For the singleton empty-history instance, the public map-code carrier is*

$$L_{\mathsf{e}}(f) := \mathsf{hsame}(f, \mathsf{e}),$$

the pointwise classifier is

$$\lambda_{\mathsf{e}}(f, g) := L_{\mathsf{e}}(f) \wedge L_{\mathsf{e}}(g) \wedge \mathsf{hsame}(f, g),$$

the evaluator is

$$\mathsf{ev}_{\mathsf{e}}(f, x) := \mathsf{e},$$

and the composition operation is

$$\mathsf{comp}_{\mathsf{e}}(g, f) := \mathsf{e}.$$

The required closure, congruence, additivity, scalar compatibility, identity, zero-map, and composition laws are supplied by Theorem 48.3.

Lean4 (definition) `BEDC.Derived.LinearMapUp.LinearMapSingletonCarrier`
Lean4 (definition) `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier`
Lean4 (definition) `BEDC.Derived.LinearMapUp.LinearMapSingletonEval`
Lean4 (definition) `BEDC.Derived.LinearMapUp.LinearMapSingletonComp`

48.2 Concrete singleton empty-history linear map instance

Definition 48.2 (Concrete singleton empty-history linear map instance)**.** *Use the singleton empty-history vector space of Definition 47.2 as both source and target. Its scalar, source-vector, and target-vector carriers are the singleton history source A_{e} of Definition 36.169 at $a_0 = \mathsf{e}$. The map-code carrier is the same existing singleton predicate*

$$A_{\mathsf{e}} : \mathsf{BHist} \to \mathsf{Prop},$$

and the map-code classifier is the existing singleton classifier ρ_{e}. The realized action is the constant endpoint action

$$\Lambda_{\mathsf{e}}(f, x) := \mathsf{e}$$

for every admitted map code f and singleton vector input x. The same endpoint action may be displayed as

$$F_{\mathsf{e}}(h) := \mathsf{e}.$$

The linear-map carrier on public map codes and its pointwise map classifier are

$$L_{\mathsf{e}}(f) := \mathsf{hsame}(f, \mathsf{e}), \qquad \lambda_{\mathsf{e}}(f, g) := L_{\mathsf{e}}(f) \wedge L_{\mathsf{e}}(g) \wedge \mathsf{hsame}(f, g).$$

The pointwise evaluation is

$$\mathsf{ev}_{\mathsf{e}}(f, h) := F_{\mathsf{e}}(h).$$

The identity, zero-map, and composition code are

$$\mathsf{id}_{\mathsf{e}} := \mathsf{e}, \qquad \mathsf{zeroMap}_{\mathsf{e}} := \mathsf{e}, \qquad \mathsf{comp}_{\mathsf{e}}(g, f) := \mathsf{e}.$$

This certificate has ten fields:

1. *Traditional target: the terminal one-map linear map space between the singleton vector space and itself.*
2. *BEDC source:* BHist.
3. *Carrier choice: A_{e} for source vectors, target vectors, and map codes.*
4. *Classifier choice: ρ_{e} for endpoint and map-code equality.*
5. *Stability obligations: output closure, pointwise classifier congruence, additivity, scalar compatibility, zero preservation, identity closure, and composition closure.*
6. *Ledger: singleton map-code provenance for F_{e}, id_{e}, $\mathsf{zeroMap}_{\mathsf{e}}$, and $\mathsf{comp}_{\mathsf{e}}$.*
7. *Core theorem list: Theorem 48.3.*
8. *Exactness predicate: singleton endpoint classification.*
9. *Standard bridge: the terminal one-map linear hom space.*
10. *Status:* $\mathsf{ProofTarget}$.

Theorem 48.3 (Singleton empty-history linear map laws)**.** *The tuple*

$$(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \Lambda_{\mathsf{e}}, \mathsf{e}, \mathsf{comp}_{\mathsf{e}})$$

satisfies the $\mathsf{LinMap}^{\uparrow}$ schema over the singleton vector space, where the displayed empty-history code supplies the identity and zero-map slots.

Proof. The source and target vector-space laws are those of Theorem 47.3. They supply the singleton scalar laws, vector closure, additive laws, scalar-action closure, and scalar-action congruence for the same A_{e} carrier and ρ_{e} classifier.

Output closure is $A_{\mathsf{e}}(\mathsf{e})$, since $\Lambda_{\mathsf{e}}(f, x)$ is definitionally e. Pointwise classifier congruence is immediate because $\Lambda_{\mathsf{e}}(f, x)$ and $\Lambda_{\mathsf{e}}(g, y)$ are both e, so the required endpoint comparison is the singleton ρ_{e} witness.

For additivity, $\Lambda_{\mathsf{e}}(f, \mathsf{add}(x, y))$ and $\mathsf{add}(\Lambda_{\mathsf{e}}(f, x), \Lambda_{\mathsf{e}}(f, y))$ are both classified with e. The vector-space theorem supplies closure for the displayed addition endpoint, and the singleton classifier supplies the endpoint comparison.

For scalar compatibility, $\Lambda_{\mathsf{e}}(f, \mathsf{smul}(r, x))$ and $\mathsf{smul}(r, \Lambda_{\mathsf{e}}(f, x))$ are again classified with e. Scalar-action closure and congruence come from the singleton vector-space laws, so no additional map-specific datum is needed.

Zero preservation compares $\Lambda_{\mathsf{e}}(f, 0)$ with the singleton vector zero. Both sides are e, and the required classification is the same ρ_{e} endpoint witness.

The identity and zero-map codes are e, and their action on any carried input x reduces to e. The input carrier witness $A_{\mathsf{e}}(x)$ together with ρ_{e} gives the required singleton endpoint classification.

For composition closure, every composite map code and every realized output reduce to e. The carrier witness for e and reflexivity inside ρ_{e} close the composition law and the comparison of the two evaluation orders. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingleton empty history laws`
Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingleton laws`

Theorem 48.4 (Singleton empty-history linear map public-code exactness)**.** *For the concrete instance of Definition 48.2, for all public map codes f, g and vector code x, if $L_{\mathsf{e}}(f)$, $L_{\mathsf{e}}(g)$, and $A_{\mathsf{e}}(x)$, then*

$$\lambda_{\mathsf{e}}(f, \mathsf{id}_{\mathsf{e}}) \wedge \lambda_{\mathsf{e}}(\mathsf{zeroMap}_{\mathsf{e}}, \mathsf{id}_{\mathsf{e}}) \wedge \lambda_{\mathsf{e}}(\mathsf{comp}_{\mathsf{e}}(g, f), \mathsf{id}_{\mathsf{e}}) \wedge \rho_{\mathsf{e}}(\mathsf{ev}_{\mathsf{e}}(f, x), x).$$

Its per-object fit is: traditional target terminal one-map hom exactness; BEDC source BHist *over the singleton vector-space instance; carrier A_{e} for vectors and map codes; classifier ρ_{e} and λ_{e}; stability obligations public-code exactness, evaluation exactness, and composition collapse; ledger singleton map-code provenance; core theorem this block; exactness predicate the displayed classifier collapse; standard bridge terminal linear hom; status* ProofTarget.

Proof. The three public map-code endpoints id_{e}, $\mathsf{zeroMap}_{\mathsf{e}}$, and $\mathsf{comp}_{\mathsf{e}}(g, f)$ reduce to e. The hypotheses $L_{\mathsf{e}}(f)$ and $L_{\mathsf{e}}(g)$ give the nontrivial singleton witnesses for the two displayed input map codes.

The classifier component of each map-code comparison is $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$. Since both advertised comparison partners reduce to the empty history, the reflexive singleton classifier closes the identity, zero-map, and composite-code clauses.

For evaluation, $\mathsf{ev}_{\mathsf{e}}(f, x)$ is $F_{\mathsf{e}}(x)$ and therefore reduces to e. The carrier hypothesis $A_{\mathsf{e}}(x)$ supplies the endpoint witness for the input vector, and ρ_{e} supplies the reflexive comparison between the realized endpoint and x in the singleton carrier. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingleton public empty code exactness`

Theorem 48.5 (Singleton linear-map classifier append split empty)**.** *For all histories p, q, h :* BHist*,*

$$\lambda_{\mathsf{e}}(\mathsf{append}(p, q), h)$$

holds exactly when $L_{\mathsf{e}}(p)$, $L_{\mathsf{e}}(q)$, and $L_{\mathsf{e}}(h)$ all hold.

Proof. The forward direction reads the first carrier field of $\lambda_{\mathsf{e}}(\mathsf{append}(p,q),h)$ as $\mathsf{hsame}(\mathsf{append}(p,q),\mathsf{e})$. Empty-result inversion for BEDC append splits this into $p\mathsf{hsamee}$ and $q\mathsf{hsamee}$, while the second classifier field gives $h\mathsf{hsamee}$.

Conversely, the three singleton carrier witnesses show that $\mathsf{append}(p,q)$ is empty and that h is empty. These are the two carrier fields of λ_{e}, and composing the empty endpoint comparison with the symmetry of the h-carrier gives the classifier comparison between $\mathsf{append}(p,q)$ and h. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier append split empty iff`

Theorem 48.6 (Singleton linear-map classifier visible right append exclusion)**.** *For all histories $p,q,h : \mathsf{BHist}$, neither appending a visible right component to p can be classified by the singleton linear-map classifier:*

$$\lambda_{\mathsf{e}}(\mathsf{append}(p,\mathsf{E0}(q)),h) \Longrightarrow \bot, \qquad \lambda_{\mathsf{e}}(\mathsf{append}(p,\mathsf{E1}(q)),h) \Longrightarrow \bot.$$

Proof. Unfold the classifier and read its left carrier field. The field says that $\mathsf{append}(p,\mathsf{E0}(q))$ or $\mathsf{append}(p,\mathsf{E1}(q))$ is history-same to e. Empty-append inversion would then force the visible right component itself to be e, contradicting constructor no-confusion for $\mathsf{E0}$ and $\mathsf{E1}$. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier append visible left absurd`

Theorem 48.7 (Singleton linear-map classifier visible prefix exclusion)**.** *For all histories $p,q,h : \mathsf{BHist}$, neither visible prefix can be classified after append by the singleton linear-map classifier:*

$$\lambda_{\mathsf{e}}(\mathsf{append}(\mathsf{E0}(p),q),h) \Longrightarrow \bot, \qquad \lambda_{\mathsf{e}}(\mathsf{append}(\mathsf{E1}(p),q),h) \Longrightarrow \bot.$$

Proof. The singleton classifier requires its left argument to be empty. Applying empty-append inversion to this carrier clause forces the visible prefix $\mathsf{E0}(p)$ or $\mathsf{E1}(p)$ to be e, which is impossible by constructor no-confusion. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier append visible prefix absurd`

Theorem 48.8 (Singleton linear-map classifier append-pair carrier exactness)**.** *For all histories $p,q,r,s : \mathsf{BHist}$,*

$$\lambda_{\mathsf{e}}(\mathsf{append}(p,q),\mathsf{append}(r,s))$$

holds exactly when all four endpoint histories lie in the singleton carrier:

$$L_{\mathsf{e}}(p) \wedge L_{\mathsf{e}}(q) \wedge L_{\mathsf{e}}(r) \wedge L_{\mathsf{e}}(s).$$

Proof. The forward direction reads the two carrier fields of the displayed classifier. Empty-append inversion splits $\mathsf{append}(p,q)\mathsf{hsamee}$ into the two endpoint carrier witnesses for p and q, and it splits $\mathsf{append}(r,s)\mathsf{hsamee}$ into the two endpoint carrier witnesses for r and s.

Conversely, the four singleton carrier witnesses reconstruct empty witnesses for both appended histories. These are the two carrier fields of λ_{e}, and transitivity with symmetry of the right appended empty witness supplies the classifier comparison between the two appended histories. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier append pair carrier iff`

Theorem 48.9 (Singleton linear-map classifier append pair empty)**.** *For all histories $p,q,r,s : \mathsf{BHist}$,*

$$\lambda_{\mathsf{e}}(\mathsf{append}(p,q),\mathsf{append}(r,s)) \Longleftrightarrow L_{\mathsf{e}}(p) \wedge L_{\mathsf{e}}(q) \wedge L_{\mathsf{e}}(r) \wedge L_{\mathsf{e}}(s).$$

Proof. The forward direction unfolds the singleton classifier. Its two carrier clauses classify both appended histories with e, and empty-append inversion splits those clauses into the four endpoint carrier witnesses.

Conversely, the four singleton carrier witnesses assemble the two appended histories as empty histories. These become the two carrier clauses of λ_{e}, and composing the left appended empty witness with symmetry of the right one gives the classifier comparison between the appended endpoints. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier append pair empty iff`

Theorem 48.10 (Singleton linear-map classifier continuation closure)**.** *For histories* P, P', Q, Q', L, R : BHist*, if* $\lambda_{\mathsf{e}}(P, P')$ *and* $\lambda_{\mathsf{e}}(Q, Q')$*, and if*

$$\mathsf{Cont}(P, Q, L) \qquad \textit{and} \qquad \mathsf{Cont}(P', Q', R),$$

then $\lambda_{\mathsf{e}}(L, R)$*.*

Proof. The two singleton linear-map classifier witnesses identify all four continuation inputs with e. Transport each continuation ledger to the empty-empty ledger and compare against $\mathsf{Cont}(\mathsf{e}, \mathsf{e}, \mathsf{e})$. This gives $L\mathsf{hsamee}$ and $R\mathsf{hsamee}$, and those carrier clauses compose through symmetry on the right endpoint to close $\lambda_{\mathsf{e}}(L, R)$. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier continuation closed`

Theorem 48.11 (Singleton linear-map continuation pair factors)**.** *For histories* p, q, r, s, t, u : BHist*, if*

$$\mathsf{Cont}(p, q, r) \qquad \textit{and} \qquad \mathsf{Cont}(s, t, u),$$

then

$$\lambda_{\mathsf{e}}(r, u) \iff L_{\mathsf{e}}(p) \wedge L_{\mathsf{e}}(q) \wedge L_{\mathsf{e}}(s) \wedge L_{\mathsf{e}}(t).$$

Proof. Read both continuation ledgers as append endpoints. The singleton linear-map classifier between those endpoints is exactly the append-pair classifier exactness theorem, which splits the two empty append endpoints into the four displayed singleton carrier factors and rebuilds the classifier from them. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier continuation pair factors iff`

Theorem 48.12 (Singleton linear-map continuation append-source classifier)**.** *For histories* p, q, r, h, t : BHist*, if* $\mathsf{Cont}(\mathsf{append}(p, q), r, h)$*, then*

$$\lambda_{\mathsf{e}}(h, t) \iff L_{\mathsf{e}}(p) \wedge L_{\mathsf{e}}(q) \wedge L_{\mathsf{e}}(r) \wedge L_{\mathsf{e}}(t).$$

Proof. The continuation displays h as $\mathsf{append}(\mathsf{append}(p, q), r)$. The forward direction splits the left classifier carrier through empty-append inversion twice, exposing p, q, r; the right classifier carrier gives t. Conversely, the three source carriers rebuild the nested empty append carrier, and symmetry on the target carrier closes the singleton classifier. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier continuation append source classifier iff`

Theorem 48.13 (Singleton linear-map continuation append-pair classifier)**.** *For histories* p, q, r, s, h, t : BHist*, if* $\mathsf{Cont}(\mathsf{append}(p, q), \mathsf{append}(r, s), h)$*, then*

$$\lambda_{\mathsf{e}}(h, t) \iff L_{\mathsf{e}}(p) \wedge L_{\mathsf{e}}(q) \wedge L_{\mathsf{e}}(r) \wedge L_{\mathsf{e}}(s) \wedge L_{\mathsf{e}}(t).$$

Proof. The continuation displays h as the append of the two appended endpoints. The forward direction reads the left carrier field of the classifier and splits that empty append once for the two displayed endpoints, then once more inside each endpoint to expose the four source carrier witnesses; the target carrier field supplies t. Conversely, the four source carrier witnesses rebuild both displayed endpoints as empty histories, then rebuild their continuation result as empty, and symmetry on the target carrier completes the singleton classifier. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier continuation append pair classifier iff`

Theorem 48.14 (Singleton linear-map append-source visible result exclusion)**.** *For histories* p, q, r, s : BHist*, if* p, q, r *lie in the singleton linear-map carrier, then no continuation from the appended source* $\mathsf{append}(p, q)$ *through* r *can have either visible result:*

$$\mathsf{Cont}(\mathsf{append}(p, q), r, \mathsf{E0}(s)) \Longrightarrow \bot, \qquad \mathsf{Cont}(\mathsf{append}(p, q), r, \mathsf{E1}(s)) \Longrightarrow \bot.$$

Proof. The three singleton carrier witnesses identify p, q, and r with e. The displayed continuation therefore reads the visible result as the append of three empty histories, hence as e. Constructor no-confusion for $\mathsf{E0}$ and $\mathsf{E1}$ rules out both visible endpoints. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonCarrier continuation append source visible result absurd`

Theorem 48.15 (Singleton linear-map continuation append-target classifier)**.** *For histories* p, q, r, h, t : BHist*, if* $\mathsf{Cont}(p, \mathsf{append}(q, r), h)$*, then*

$$\lambda_{\mathsf{e}}(h, t) \iff L_{\mathsf{e}}(p) \wedge L_{\mathsf{e}}(q) \wedge L_{\mathsf{e}}(r) \wedge L_{\mathsf{e}}(t).$$

Proof. The continuation displays h as $\mathsf{append}(p, \mathsf{append}(q, r))$. In the forward direction, empty-append inversion first exposes p and the right appended endpoint, then splits that endpoint into q and r; the target carrier field supplies t. In the reverse direction, the q and r carriers rebuild the right append, the p carrier rebuilds the continuation result carrier, and the target carrier completes the classifier. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier continuation append target classifier iff`

Theorem 48.16 (Singleton linear-map left continuation closure)**.** *For histories* P, P', Q, L : BHist*, if* $\lambda_{\mathsf{e}}(P, P')$*,* $L_{\mathsf{e}}(Q)$*, and* $\mathsf{Cont}(P, Q, L)$*, then* $L_{\mathsf{e}}(L)$ *and* $\lambda_{\mathsf{e}}(L, \mathsf{e})$*.*

Proof. The classifier witness identifies P with e, while the singleton carrier identifies Q with e. Transporting the continuation ledger to $\mathsf{Cont}(\mathsf{e}, \mathsf{e}, \mathsf{e})$ gives $L\mathsf{hsamee}$, which is the desired singleton carrier and the left endpoint of the classifier against e. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier continuation left closed`

Theorem 48.17 (Singleton linear-map right continuation closure)**.** *For histories* P, Q, Q', R : BHist*, if* $L_{\mathsf{e}}(P)$*,* $\lambda_{\mathsf{e}}(Q, Q')$*, and* $\mathsf{Cont}(P, Q, R)$*, then* $L_{\mathsf{e}}(R)$ *and* $\lambda_{\mathsf{e}}(R, \mathsf{e})$*.*

Proof. The singleton carrier identifies the left continuation input P with e, and the classifier witness identifies the right continuation input Q with e. Transporting $\mathsf{Cont}(P, Q, R)$ to the empty-empty continuation ledger therefore gives $R\mathsf{hsamee}$. This is the singleton carrier for R, and with the reflexive carrier of e it packages the classifier $\lambda_{\mathsf{e}}(R, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier continuation right closed`

Theorem 48.18 (Singleton linear map composition associativity empty classifier)**.** *For singleton linear map codes f, g, h, if each code lies in L_{e}, then both associations of the composite code classify with e, and the two associated composite codes classify with each other:*

$$\lambda_{\mathsf{e}}(\mathsf{comp}_{\mathsf{e}}(h, \mathsf{comp}_{\mathsf{e}}(g, f)), \mathsf{e}) \wedge \lambda_{\mathsf{e}}(\mathsf{comp}_{\mathsf{e}}(\mathsf{comp}_{\mathsf{e}}(h, g), f), \mathsf{e}) \wedge \lambda_{\mathsf{e}}(\mathsf{comp}_{\mathsf{e}}(h, \mathsf{comp}_{\mathsf{e}}(g, f)), \mathsf{comp}_{\mathsf{e}}(\mathsf{comp}_{\mathsf{e}}(h, g), f)).$$

Proof. The singleton composition code is definitionally e for every pair of inputs. Therefore both associated composites reduce to e, and each displayed classifier is the reflexive singleton map-code classifier at the empty history. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingleton comp assoc empty classifier`

Theorem 48.19 (Singleton linear-map classifier append left cancellation)**.** *For all $P, Q, R : \mathsf{BHist}$, if $L_{\mathsf{e}}(P)$, then*

$$\lambda_{\mathsf{e}}(\mathsf{append}(P, Q), \mathsf{append}(P, R)) \iff \lambda_{\mathsf{e}}(Q, R).$$

Proof. For the forward direction, unfold the singleton classifier. The carrier clauses say that both appended histories are classified with e. Applying the empty-append inversion to each carrier clause gives $Q\mathsf{hsamee}$ and $R\mathsf{hsamee}$. These two endpoint witnesses compose, with symmetry on the right one, to give $Q\mathsf{hsame}R$.

For the reverse direction, the hypothesis $L_{\mathsf{e}}(P)$ identifies the left prefix with e. The two appended histories therefore reduce through the left-empty continuation law to Q and R. The carrier clauses and classifier comparison supplied by $\lambda_{\mathsf{e}}(Q, R)$ transport along those reductions to rebuild the prefixed singleton classifier. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier append left cancel iff`

Theorem 48.20 (Singleton linear-map classifier append right cancellation)**.** *For all $P, Q, R : \mathsf{BHist}$, if $L_{\mathsf{e}}(P)$, then*

$$\lambda_{\mathsf{e}}(\mathsf{append}(Q, P), \mathsf{append}(R, P)) \iff \lambda_{\mathsf{e}}(Q, R).$$

Proof. For the forward direction, unfold the singleton classifier. The carrier clauses classify both right-suffixed histories with e. Empty-append inversion splits these clauses and gives $Q\mathsf{hsamee}$ and $R\mathsf{hsamee}$. Composing the first endpoint witness with the symmetry of the second gives $Q\mathsf{hsame}R$, which closes $\lambda_{\mathsf{e}}(Q, R)$.

Conversely, the hypothesis $L_{\mathsf{e}}(P)$ supplies the certified empty suffix. Together with the two carrier fields of $\lambda_{\mathsf{e}}(Q, R)$, empty-append composition classifies both $\mathsf{append}(Q, P)$ and $\mathsf{append}(R, P)$ with e. These two endpoint witnesses compose through symmetry to rebuild the right-suffixed classifier. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier append right cancel iff`

Theorem 48.21 (Singleton linear-map classifier append two-sided cancellation)**.** *For all $P, Q, R, S : \mathsf{BHist}$, if $L_{\mathsf{e}}(P)$ and $L_{\mathsf{e}}(S)$, then*

$$\lambda_{\mathsf{e}}(\mathsf{append}(P, Q), \mathsf{append}(R, S)) \iff \lambda_{\mathsf{e}}(Q, R).$$

Proof. For the forward direction, unfold the singleton classifier. The two carrier clauses classify $\mathsf{append}(P, Q)$ and $\mathsf{append}(R, S)$ with e. Empty-append inversion gives $Q\mathsf{hsamee}$ and $R\mathsf{hsamee}$, and these endpoint witnesses compose to close $\lambda_{\mathsf{e}}(Q, R)$.

Conversely, $L_{\mathsf{e}}(P)$ and $L_{\mathsf{e}}(S)$ combine with the carrier fields of $\lambda_{\mathsf{e}}(Q, R)$ to classify the two appended histories with e. The two resulting endpoint witnesses compose, with symmetry on the right, to rebuild the two-sided appended classifier. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier append two sided cancel iff`

Theorem 48.22 (Singleton evaluation append-input classifier readback)**.** *For histories f, x, y, h, classifying the singleton evaluation of an appended input against h is exactly the singleton carrier condition on h:*

$$\mathsf{LinearMapSingletonClassifier}(\mathsf{LinearMapSingletonEval}(f, x \cdot y), h) \iff \mathsf{LinearMapSingletonCarrier}(h).$$

Proof. The singleton evaluator always returns e. In the forward direction, the classifier already contains the carrier witness for its right endpoint. In the reverse direction, the carrier witness for h combines with reflexivity at e and symmetry of the displayed carrier equality to form the restricted singleton classifier. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval append input classifier iff`

Theorem 48.23 (Singleton evaluation append-context classifier readback)**.** *For histories p, f, x, h : BHist, classifying a singleton evaluation after an appended context is exactly the pair of singleton carrier conditions on the context and the target:*

$$\mathsf{LinearMapSingletonClassifier}(\mathsf{append}(p, \mathsf{LinearMapSingletonEval}(f, x)), h) \iff \mathsf{LinearMapSingletonCarrier}(p) \wedge \mathsf{LinearM}$$

Proof. The singleton evaluator returns e. In the forward direction, the left carrier field classifies $\mathsf{append}(p, \mathsf{e})$ with e, and empty-append inversion exposes $p\mathsf{hsamee}$; the right classifier carrier gives $h\mathsf{hsamee}$.

Conversely, $p\mathsf{hsamee}$ combines with reflexivity at the evaluator result to classify $\mathsf{append}(p, \mathsf{LinearMapSingletonEva}$ with e. The target carrier for h and symmetry on that carrier witness then assemble the restricted singleton classifier. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval append context classifier iff`

Theorem 48.24 (Singleton linear-map evaluation context pair classifier)**.** *For histories p, q, f, x, g, y : BHist,*

$$\mathsf{LinearMapSingletonClassifier}(\mathsf{append}(p, \mathsf{LinearMapSingletonEval}(f, x)), \mathsf{append}(q, \mathsf{LinearMapSingletonEval}(g, y))) \iff$$

Proof. Both singleton evaluation tails are definitionally e. The append-pair classifier exactness splits the two appended endpoints into four singleton carrier obligations; the two evaluation-tail obligations are closed by reflexivity at e, leaving exactly the two context carriers. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier eval context pair iff`

Theorem 48.25 (Singleton evaluation continuation classifier)**.** *For histories f, x, y, r, h : BHist, if*

$$\mathsf{Cont}(\mathsf{LinearMapSingletonEval}(f, x), y, r),$$

then classifying the continuation result r against h is equivalent to the two exposed endpoints y and h lying in the singleton carrier:

$$\mathsf{LinearMapSingletonClassifier}(r, h) \iff \mathsf{LinearMapSingletonCarrier}(y) \wedge \mathsf{LinearMapSingletonCarrier}(h).$$

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval continuation classifier iff`

Proof. The singleton evaluator returns e, so the continuation ledger displays r as $\mathsf{append}(\mathsf{e}, y)$. In the forward direction, the classifier field $r\mathsf{hsamee}$ and the left-unit append equation identify y with e, while the right classifier carrier gives the singleton witness for h. Conversely, singleton witnesses for y and h identify r with e through the same continuation ledger and left-unit append equation, and the two singleton carrier witnesses assemble the restricted classifier. □

Definition 48.26 (Concrete singleton linear-map evaluation graph carrier)**.** *For the concrete singleton empty-history* $\mathsf{LinMap}^{\uparrow}$ *instance, the evaluation graph row is the* BHist*-anchored visible triple* (f, x, y) *satisfying*

$$L_{\mathsf{e}}(f) \wedge A_{\mathsf{e}}(x) \wedge \rho_{\mathsf{e}}(\mathsf{LinearMapSingletonEval}(f, x), y).$$

Its ledger exposes exactly the map-code row f, the input-vector row x, the output endpoint y, and the continuation provenance row that relates $\mathsf{LinearMapSingletonEval}(f, x)$ *to y through* Cont *when such a continuation is displayed. No host function equality or quotient witness is part of the graph carrier.*

Theorem 48.27 (Singleton linear-map evaluation graph package)**.** *For the evaluation graph carrier of Definition 48.26, the following finite singleton package holds.*

1. *Output closure: every graph row has $A_{\mathsf{e}}(y)$, and every admitted $L_{\mathsf{e}}(f)$ and $A_{\mathsf{e}}(x)$ determines the singleton output row $\rho_{\mathsf{e}}(\mathsf{LinearMapSingletonEval}(f, x), \mathsf{e})$.*
2. *Pointwise classifier transport: replacing f, x, or y along λ_{e} and ρ_{e} preserves the graph row and its continuation provenance.*
3. *Identity and zero-map evaluation collapse: for every carried input x, the identity and zero-map codes evaluate to the same singleton endpoint and classify with the displayed x-row.*
4. *Composition evaluation collapse: if f, g, and x are carried, the graph row for* LinearMapSingletonEval(LinearMapS *and the graph row read through the continuation of* $\mathsf{LinearMapSingletonEval}(f, x)$ *by g expose the same singleton endpoint classifier.*

The package exports no host function equality, no quotient row, and no hidden selector row.

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEvaluationGraph package`

Proof. The carrier row is built over the same singleton empty-history table as Definition 48.3. Output closure follows because every evaluation endpoint is definitionally e, while Definition 48.4 supplies the public code, identity-code, zero-code, composite-code, and endpoint exactness rows.

For pointwise transport, use the existing singleton evaluation classifier readbacks in this file. They reduce each transported endpoint classifier to the same singleton carrier obligations for the visible map code, input vector, and output endpoint.

The identity and zero-map clauses are the identity and zero-map rows of the public-code exactness theorem, read through the graph definition. The continuation classifier Definition 48.25 repackages the same output endpoint as a continuation provenance row when a continuation is displayed.

For composition, apply Definition 48.3 to the singleton composition operation and then apply the existing composition continuation classifier in this file. Both the direct composite evaluation and the stagewise continuation evaluation reduce to e, so the endpoint classifier is the singleton ρ_{e} row. Since the construction only reads the finite BHist graph ledger, no host function equality, quotient carrier, or hidden selector can be exported. □

Theorem 48.28 (Singleton evaluation composition continuation classifier)**.** *If g, f, x lie in the singleton linear-map carrier and* $\mathsf{Cont}(\mathsf{LinearMapSingletonEval}(f, x), g, r)$*, then the composed evaluation endpoint classifies against the continuation result:*

$$\mathsf{LinearMapSingletonClassifier}(\mathsf{LinearMapSingletonEval}(\mathsf{LinearMapSingletonComp}(g, f), x), r).$$

Proof. The continuation readback theorem applied to $\mathsf{Cont}(\mathsf{LinearMapSingletonEval}(f, x), g, r)$ carries the result r whenever g is carried. The composed singleton evaluation endpoint is e, so the singleton classifier is assembled from the endpoint carrier, the result carrier, and symmetry of the result carrier witness. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval comp continuation classifier`

Theorem 48.29 (Singleton evaluation context continuation classifier)**.** *For histories p, f, x, y, r, h :* BHist*, if*

$$\mathsf{Cont}(\mathsf{append}(p, \mathsf{LinearMapSingletonEval}(f, x)), y, r),$$

then classifying the continuation result r against h is equivalent to all three exposed endpoints lying in the singleton carrier:

$$\mathsf{LinearMapSingletonClassifier}(r, h) \iff \mathsf{LinearMapSingletonCarrier}(p) \wedge \mathsf{LinearMapSingletonCarrier}(y) \wedge \mathsf{LinearMapSingle}$$

Proof. In the forward direction, the result classifier transports the continuation to an empty result. Empty-result inversion splits the continuation into an empty context append and an empty continuation input, append empty-result inversion recovers the carrier witness for p, and the target carrier comes from the classifier.

Conversely, the singleton evaluator returns e, so the carrier witness for p makes the context append carried by e. Together with the carrier witness for y, continuation transport carries r by e, and the carrier witness for h assembles the restricted singleton classifier. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval context continuation classifier iff`

Theorem 48.30 (Singleton evaluation nonempty endpoint empty-result exclusion)**.** *For histories p, f, x, y, r :* BHist*, if either p or y is not singleton-carried, then*

$$\mathsf{Cont}(\mathsf{append}(p, \mathsf{LinearMapSingletonEval}(f, x)), y, r) \wedge r\mathsf{hsamee} \implies \bot.$$

Proof. Transport the continuation result to e. Empty-result inversion makes both endpoints empty, and append empty-result inversion gives the singleton carrier witness for p; either non-carrier hypothesis is contradicted. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval context nonempty endpoint continuation result absurd`

Theorem 48.31 (Singleton evaluation visible context continuation exclusion)**.** *For histories p, f, x, y, r, h :* BHist*, a singleton evaluation with a visible context prefix cannot have a classified continuation result:*

$$\mathsf{Cont}(\mathsf{append}(\mathsf{E0}(p), \mathsf{LinearMapSingletonEval}(f, x)), y, r) \implies (\mathsf{LinearMapSingletonClassifier}(r, h) \implies \bot),$$

and the same statement holds with $\mathsf{E1}(p)$ *in place of* $\mathsf{E0}(p)$*.*

Proof. The context-continuation classifier readback says any such classifier forces the visible context prefix to lie in the singleton carrier. That carrier is hsame to e, contradicting constructor separation for the visible head. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval context continuation visible context absurd`

Theorem 48.32 (Singleton evaluation continuation append target carrier)**.** *For histories* f, x, y, p, q : BHist*, if*

$$\mathsf{Cont}(\mathsf{LinearMapSingletonEval}(f, x), y, \mathsf{append}(p, q)),$$

then the exposed continuation input is in the singleton carrier exactly when both append factors are:

$$\mathsf{LinearMapSingletonCarrier}(y) \iff \mathsf{LinearMapSingletonCarrier}(p) \wedge \mathsf{LinearMapSingletonCarrier}(q).$$

Proof. The singleton evaluator returns e, so the continuation ledger identifies $\mathsf{append}(p, q)$ with $\mathsf{append}(\mathsf{e}, y)$. The left-unit law for append identifies this with y. Thus a singleton carrier witness for y turns into an empty-result witness for $\mathsf{append}(p, q)$, which append empty-result inversion splits into carrier witnesses for p and q. Conversely, carrier witnesses for both factors assemble an empty-result witness for $\mathsf{append}(p, q)$, and the same continuation ledger and left-unit law carry it back to y. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval continuation append target carrier iff`

Theorem 48.33 (Singleton evaluation continuation visible result exclusion)**.** *For histories* f, x, y, p : BHist*, if* $\mathsf{LinearMapSingletonCarrier}(y)$*, then the continuation result of the singleton evaluator cannot be either visible endpoint:*

$$\mathsf{Cont}(\mathsf{LinearMapSingletonEval}(f, x), y, \mathsf{E0}(p)) \Longrightarrow \bot, \qquad \mathsf{Cont}(\mathsf{LinearMapSingletonEval}(f, x), y, \mathsf{E1}(p)) \Longrightarrow \bot.$$

Proof. The continuation ledger identifies each displayed result with $\mathsf{append}(\mathsf{e}, y)$. The append left-unit law and the carrier witness for y force that result to be history-same to e. Constructor no-confusion for E0 and E1 closes the two visible cases. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval continuation visible result absurd`

Theorem 48.34 (Singleton evaluation context continuation visible result exclusion)**.** *For histories* p, f, x, y, z : BHist*, if both* p *and* y *lie in the singleton linear-map carrier, then the continuation result of the prefixed singleton evaluator cannot be either visible endpoint:*

$$\mathsf{Cont}(\mathsf{append}(p, \mathsf{LinearMapSingletonEval}(f, x)), y, \mathsf{E0}(z)) \Longrightarrow \bot, \qquad \mathsf{Cont}(\mathsf{append}(p, \mathsf{LinearMapSingletonEval}(f, x)),$$

Proof. The singleton evaluator returns e, so the carrier witness for p makes the prefixed evaluator history empty. Transporting the displayed continuation against the right-unit empty continuation forces each displayed result to be hsame to e. Constructor no-confusion excludes both visible endpoint results. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval context continuation visible result absurd`

Theorem 48.35 (Singleton evaluation visible target classifier exclusion)**.** *For histories* f, x, p : BHist*, the singleton evaluator cannot classify against either visible target endpoint:*

$$\mathsf{LinearMapSingletonClassifier}(\mathsf{LinearMapSingletonEval}(f, x), \mathsf{E0}(p)) \Longrightarrow \bot, \qquad \mathsf{LinearMapSingletonClassifier}(\mathsf{LinearMa}$$

Proof. The singleton evaluator returns e, but the classifier still requires its right endpoint to lie in the singleton carrier. Thus a classifier witness against $\mathsf{E0}(p)$ or $\mathsf{E1}(p)$ would force that visible endpoint to be history-same to e. Constructor no-confusion for the two visible constructors closes both cases. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval visible target classifier absurd`

Theorem 48.36 (Singleton evaluation continuation visible target exclusion)**.** *For histories* f, x, y, r, p : BHist*, if*

$$\mathsf{Cont}(\mathsf{LinearMapSingletonEval}(f, x), y, r),$$

then both visible target classifier claims are impossible:

$$\mathsf{LinearMapSingletonClassifier}(r, \mathsf{E0}(p)) \Longrightarrow \bot, \qquad \mathsf{LinearMapSingletonClassifier}(r, \mathsf{E1}(p)) \Longrightarrow \bot.$$

The ten-field fit is: traditional target terminal linear-map continuation result exclusion; BEDC source BHist*,* Cont*, and the singleton* $\mathsf{LinMap}^{\uparrow}$ *evaluator; carrier* LinearMapSingletonCarrier*; classifier* LinearMapSingletonClassifier*; stability from continuation classifier readback and constructor no-confusion; ledger continuation result endpoint; core theorem this block; exactness visible-target impossibility; standard bridge terminal linear hom; status* ProofTarget*.*

Proof. Apply Theorem 48.25 to the displayed continuation with target $\mathsf{E0}(p)$. A classifier witness for $\mathsf{E0}(p)$ then forces $\mathsf{LinearMapSingletonCarrier}(\mathsf{E0}(p))$.

Apply the same continuation classifier readback with target $\mathsf{E1}(p)$. A classifier witness for $\mathsf{E1}(p)$ forces $\mathsf{LinearMapSingletonCarrier}(\mathsf{E1}(p))$.

Unfolding the singleton carrier makes each witness a history-sameness proof from the visible endpoint to e. Constructor no-confusion for E0 and E1 contradicts those histories being empty, so both displayed classifier claims imply ⊥. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval continuation visible target classifier absurd`

Theorem 48.37 (Singleton evaluation continuation visible input exclusion)**.** *For histories* f, x, p, r, h : BHist*, each visible continuation input prevents a singleton-classified continuation result:*

$$\mathsf{Cont}(\mathsf{LinearMapSingletonEval}(f, x), \mathsf{E0}(p), r) \Longrightarrow (\mathsf{LinearMapSingletonClassifier}(r, h) \Longrightarrow \bot),$$

and

$$\mathsf{Cont}(\mathsf{LinearMapSingletonEval}(f, x), \mathsf{E1}(p), r) \Longrightarrow (\mathsf{LinearMapSingletonClassifier}(r, h) \Longrightarrow \bot).$$

The ten-field fit is: traditional target terminal linear-map continuation input exclusion; BEDC source BHist*,* Cont*, and the singleton evaluator; carrier* LinearMapSingletonCarrier*; classifier* LinearMapSingletonClas*stability from continuation classifier readback plus constructor separation; ledger continuation input endpoint; core theorem this block; exactness visible-input impossibility; standard bridge terminal linear hom; status* ProofTarget*.*

Proof. Apply Theorem 48.25 to the first displayed continuation with continuation input $\mathsf{E0}(p)$. A classifier witness for r against h then forces $\mathsf{LinearMapSingletonCarrier}(\mathsf{E0}(p))$.

Apply the same continuation classifier readback to the second displayed continuation with continuation input $\mathsf{E1}(p)$. A classifier witness for r against h forces $\mathsf{LinearMapSingletonCarrier}(\mathsf{E1}(p))$.

Unfolding the singleton carrier turns each carrier witness into a history-sameness proof from the visible continuation input to e. Constructor no-confusion for $\mathsf{E0}$ and $\mathsf{E1}$ contradicts those histories being empty, so each visible continuation input case implies $\bot$. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval continuation visible input classifier absurd`

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval continuation visible input absurd`

The $\mathsf{LinMap}^{\uparrow}$ schema is instantiated by this concrete BHist carrier and singleton action, so later Lean work can target BHist-anchored linear-map laws instead of only abstract function fields.

Theorem 48.38 (Singleton evaluation context continuation append-target carrier)**.** *For histories* $p, f, x, y, q, r : \mathsf{BHist}$*, if*

$$\mathsf{Cont}(\mathsf{append}(p, \mathsf{LinearMapSingletonEval}(f, x)), y, \mathsf{append}(q, r)),$$

then the prefixed singleton evaluator and continuation input lie in the singleton carrier exactly when both exposed result factors do:

$$\mathsf{LinearMapSingletonCarrier}(p) \wedge \mathsf{LinearMapSingletonCarrier}(y) \iff \mathsf{LinearMapSingletonCarrier}(q) \wedge \mathsf{LinearMapSingletonC}$$

Proof. The singleton evaluator returns e. From carrier witnesses for p and y, the continuation result is transported against the right-unit empty continuation, forcing $\mathsf{append}(q, r)$ to be empty and hence splitting into singleton carrier witnesses for q and r. Conversely, carrier witnesses for q and r assemble an empty-result witness for $\mathsf{append}(q, r)$; transporting the displayed continuation to the empty result and applying empty-result inversion splits the prefixed evaluator and the continuation input, yielding carrier witnesses for p and y. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval context continuation append target carrier iff`

Theorem 48.39 (Singleton evaluation context append-input/result carrier exactness)**.** *For histories* $p, f, x, y, z, q, r : \mathsf{BHist}$*, if*

$$\mathsf{Cont}(\mathsf{append}(p, \mathsf{LinearMapSingletonEval}(f, x)), \mathsf{append}(y, z), \mathsf{append}(q, r)),$$

then the prefixed singleton evaluator and both exposed input factors lie in the singleton carrier exactly when both exposed result factors do:

$$\mathsf{LinearMapSingletonCarrier}(p) \wedge \mathsf{LinearMapSingletonCarrier}(y) \wedge \mathsf{LinearMapSingletonCarrier}(z) \iff \mathsf{LinearMapSingletonC}$$

Proof. Apply append-target carrier exactness with continuation input $\mathsf{append}(y, z)$. The forward direction combines carrier witnesses for y and z into a carrier witness for the appended input. The reverse direction splits the recovered appended-input carrier by empty-append inversion. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval context append input result carrier iff`

Theorem 48.40 (Singleton linear-map classifier continuation visible source exclusion)**.** *For histories $p, q, r, h : \mathsf{BHist}$, no continuation whose source is $\mathsf{E0}(p)$ or $\mathsf{E1}(p)$ can have a result classified by the singleton linear-map classifier:*

$$\mathsf{Cont}(\mathsf{E0}(p), q, r) \Longrightarrow (\mathsf{LinearMapSingletonClassifier}(r, h) \Longrightarrow \bot),$$

and

$$\mathsf{Cont}(\mathsf{E1}(p), q, r) \Longrightarrow (\mathsf{LinearMapSingletonClassifier}(r, h) \Longrightarrow \bot).$$

Proof. The singleton classifier gives $r\mathsf{hsamee}$. Transport the displayed continuation result to e and apply empty-result inversion for Cont. The source endpoint is forced to be e, contradicting constructor separation for $\mathsf{E0}$ or $\mathsf{E1}$. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier continuation visible source absurd`

Theorem 48.41 (Singleton linear-map classifier continuation visible target exclusion)**.** *For histories $p, q, r, h : \mathsf{BHist}$, no continuation whose target is $\mathsf{E0}(p)$ or $\mathsf{E1}(p)$ can have a result classified by the singleton linear-map classifier:*

$$\mathsf{Cont}(q, \mathsf{E0}(p), r) \Longrightarrow (\mathsf{LinearMapSingletonClassifier}(r, h) \Longrightarrow \bot),$$

and

$$\mathsf{Cont}(q, \mathsf{E1}(p), r) \Longrightarrow (\mathsf{LinearMapSingletonClassifier}(r, h) \Longrightarrow \bot).$$

Proof. The singleton classifier gives $r\mathsf{hsamee}$. Transport the displayed continuation result to e and apply empty-result inversion for Cont. The target endpoint is forced to be e, contradicting constructor separation for $\mathsf{E0}$ or $\mathsf{E1}$. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier continuation visible target absurd`

Theorem 48.42 (Singleton evaluation context continuation append-result carrier exactness)**.** *For histories $p, f, x, y, q, r : \mathsf{BHist}$, if the context p is carried by the singleton linear-map carrier and*

$$\mathsf{Cont}(\mathsf{append}(p, \mathsf{LinearMapSingletonEval}(f, x)), y, \mathsf{append}(q, r)),$$

then the continuation input y is singleton-carried exactly when both append result components are singleton-carried:

$$\mathsf{LinearMapSingletonCarrier}(y) \Longleftrightarrow \mathsf{LinearMapSingletonCarrier}(q) \wedge \mathsf{LinearMapSingletonCarrier}(r).$$

Proof. The singleton evaluator returns e, so the carried context p carries the left continuation endpoint. If y is carried, continuation determinacy against the empty unit carries $\mathsf{append}(q, r)$, and append empty-result inversion splits this into carriers for q and r.

Conversely, carriers for q and r carry the displayed append result. Moving the continuation result to e and inverting the empty continuation exposes $y\mathsf{hsamee}$. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval context continuation append result carrier iff`

Theorem 48.43 (Singleton linear-map append-source append-result classifier exactness)**.** *For histories* $p, q, r, s, t, h : \mathsf{BHist}$*, if*

$$\mathsf{Cont}(\mathsf{append}(p, q), r, \mathsf{append}(s, t)),$$

then

$$\lambda_{\mathsf{e}}(\mathsf{append}(s, t), h) \iff L_{\mathsf{e}}(p) \wedge L_{\mathsf{e}}(q) \wedge L_{\mathsf{e}}(r) \wedge L_{\mathsf{e}}(s) \wedge L_{\mathsf{e}}(t) \wedge L_{\mathsf{e}}(h).$$

Proof. Apply the append-source classifier exactness theorem to the displayed continuation. In the forward direction, the singleton classifier carries the append result, and empty-append inversion splits it into carriers for s and t. Conversely, carriers for p, q, r rebuild the continuation source as an empty endpoint; the displayed continuation then carries $\mathsf{append}(s, t)$, closing the singleton classifier with the carrier of h. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonClassifier continuation append source append result iff`

Theorem 48.44 (Singleton evaluation composition continuation pair classifier)**.** *If* g *lies in the singleton linear-map carrier and* $\mathsf{Cont}(\mathsf{LinearMapSingletonEval}(f, x), g, r)$*, while the composed evaluation endpoint continues through* e *to* s*, then the two continuation results are classified by the singleton linear-map classifier:*

$$\mathsf{LinearMapSingletonClassifier}(r, s).$$

Proof. The singleton evaluator and singleton composition evaluator both expose e as their source endpoint. Transporting the first continuation along the carrier witness for g carries r by the singleton carrier. Transporting the second continuation along the empty endpoint carries s. The two empty endpoint readbacks compose to the displayed singleton classifier. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval comp continuation pair classifier`

Theorem 48.45 (Singleton evaluation context composition continuation pair classifier)**.** *If* p *and* y *lie in the singleton linear-map carrier, the contextual evaluation endpoint* $\mathsf{append}(p, \mathsf{LinearMapSingletonEval}(f, x))$ *continues through* y *to* r*, and the composed evaluation endpoint continues through* e *to* s*, then the two continuation results are classified:*

$$\mathsf{LinearMapSingletonClassifier}(r, s).$$

Proof. The singleton evaluator has empty carrier. Combining it with the carrier of p carries the contextual source endpoint. Transporting the first continuation against the empty right unit therefore carries r. The composed evaluation source and empty continuation input similarly carry s. These two empty endpoint readbacks compose to the singleton classifier relation. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonEval context comp continuation pair classifier`

Theorem 48.46 (Singleton composition continuation pair classifier)**.** *If two continuations start from the concrete singleton composition endpoint* $\mathsf{LinearMapSingletonComp}(g, f)$ *and continue through carried histories* y *and* z *to* r *and* s*, then the two results are classified:*

$$\mathsf{Cont}(\mathsf{LinearMapSingletonComp}(g, f), y, r) \wedge \mathsf{Cont}(\mathsf{LinearMapSingletonComp}(g, f), z, s) \wedge L_{\mathsf{e}}(y) \wedge L_{\mathsf{e}}(z) \Longrightarrow \mathsf{LinearMapS}$$

Proof. The concrete singleton composition endpoint is e. Transport the first continuation along the carrier witness for y to carry r, and transport the second along the carrier witness for z to carry s. The two empty endpoint readbacks compose by symmetry and transitivity into the singleton classifier. □

48.3 The certificate

Definition 48.47 (LinearMap source specification)**.** *The source is a pair of vector spaces over the same certified field.*

Definition 48.48 (LinearMap pattern specification)**.** *The pattern is function-with-law formation: map data together with linearity witnesses.*

Definition 48.49 (LinearMap classifier specification)**.** *The classifier relates two linear maps when their outputs are codomain-classified the same for every input witness.*

Definition 48.50 (LinearMap stability certificate)**.** *The stability certificate consists of:*

1. *pointwise classifier reflexivity*
2. *pointwise classifier transitivity*
3. *preservation of zero derived from linearity*
4. *additivity preservation*
5. *scalar-compatibility preservation*
6. *closure under identity and composition*

Definition 48.51 (LinearMap ledger policy)**.** *Record the function identifier, its linearity witnesses, and codomain ledgers for pointwise comparisons.*

Definition 48.52 ($\mathsf{LinMap}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{LinMap}^{\uparrow}$*.*

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapUp StdBridge`

Primitive boundary. $\mathsf{LinMap}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Remark 48.53 (Zero-axiom encoding note)**.** *Avoids funext by using pointwise classifier sameness instead of equality of functions.*

Theorem 48.54 (LinearMap terminal standard bridge)**.** *The singleton empty-history public map-code surface of Definition 48.2 and Definition 48.4 interprets in the terminal one-object, one-arrow linear-hom space. Every carried public code maps to the unique hom, evaluation sends the unique carried vector to itself, composition sends the unique composable hom pair to the unique hom, and the return interpretation is classified by* λ_{e} *and* ρ_{e}*.*

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingleton terminal standard bridge`

Proof. The public-code exactness theorem identifies every carried public map code with the empty-history identity code under λ_{e}, and it gives the same collapse for the zero code, the composed code, and the evaluation readback. Thus the identity, zero, composition, and evaluation rows all land in the same singleton code class.

The terminal standard object has one object endpoint and one hom endpoint. After the public surface has collapsed to the empty-history code class, both directions of the bridge are forced: a carried public code can only interpret as the unique terminal hom, and the unique terminal hom can only be represented by the carried empty-history public code.

For vectors, the singleton carrier supplies only the empty endpoint, so evaluation of the unique hom at the unique carried vector returns that vector. The map-code comparison is the λ_{e} classification already supplied by exactness, and the vector readback is the singleton ρ_{e} classification. No host function extensionality is used; the argument is only constructor collapse and carrier-aware classifier transport on the singleton surface. □

Theorem 48.55 (LinearMap pointwise classifier equivalence)**.** *Let F carry a $\mathsf{Field}^{\uparrow}(F)$ certificate, and let V and W carry $\mathsf{VecSpace}^{\uparrow}(F,V)$ and $\mathsf{VecSpace}^{\uparrow}(F,W)$ certificates. Write C_V and C_W for source and codomain carrier predicates, and write $\sim_W$ for a codomain classifier supplied by $\mathsf{NameCert}(C_W, \sim_W)$. Let $\mathsf{Lin}_{V,W}(f)$ be the carried $\mathsf{LinMap}^{\uparrow}(V,W)$ map-code predicate from Definition 48.1; in particular, a witness of $\mathsf{Lin}_{V,W}(f)$ includes output closure $C_V(x) \Longrightarrow C_W(f(x))$. Define the pointwise $\mathsf{LinMap}^{\uparrow}$ classifier by*

$$f \sim_{\mathsf{LinMap}^{\uparrow}(V,W)} g :\Longleftrightarrow \mathsf{Lin}_{V,W}(f) \wedge \mathsf{Lin}_{V,W}(g) \wedge \forall x,\ C_V(x) \Longrightarrow f(x) \sim_W g(x).$$

Then $\sim_{\mathsf{LinMap}^{\uparrow}(V,W)}$ is reflexive, symmetric, and transitive on carried linear-map codes:

$$\begin{aligned}
&\mathsf{Lin}_{V,W}(f) \Longrightarrow f \sim_{\mathsf{LinMap}^{\uparrow}(V,W)} f,\\
&f \sim_{\mathsf{LinMap}^{\uparrow}(V,W)} g \Longrightarrow g \sim_{\mathsf{LinMap}^{\uparrow}(V,W)} f,\\
&f \sim_{\mathsf{LinMap}^{\uparrow}(V,W)} g \wedge g \sim_{\mathsf{LinMap}^{\uparrow}(V,W)} h \Longrightarrow f \sim_{\mathsf{LinMap}^{\uparrow}(V,W)} h.
\end{aligned}$$

Proof. By Definition 9.7, the codomain $\mathsf{NameCert}(C_W, \sim_W)$ supplies reflexivity for carried codomain outputs, symmetry for $\sim_W$, and transitivity for composable $\sim_W$ witnesses. By Definition 48.49, the $\mathsf{LinMap}^{\uparrow}$ classifier is the pointwise codomain comparison over all carried source inputs, together with the two carried map-code endpoints.

For reflexivity, assume $\mathsf{Lin}_{V,W}(f)$ and let x be a carried source input. Output closure in the linear-map carrier gives $C_W(f(x))$. Codomain reflexivity gives $f(x) \sim_W f(x)$. The two endpoint carrier fields are both the given $\mathsf{Lin}_{V,W}(f)$ witness, so the pointwise classifier relates f to itself.

For symmetry, assume $f \sim_{\mathsf{LinMap}^{\uparrow}(V,W)} g$. Its endpoint fields give $\mathsf{Lin}_{V,W}(f)$ and $\mathsf{Lin}_{V,W}(g)$. For each carried x, the pointwise field gives $f(x) \sim_W g(x)$; codomain symmetry gives $g(x) \sim_W f(x)$. Swapping the endpoint carrier fields and using these reversed pointwise comparisons gives $g \sim_{\mathsf{LinMap}^{\uparrow}(V,W)} f$.

For transitivity, assume $f \sim_{\mathsf{LinMap}^{\uparrow}(V,W)} g$ and $g \sim_{\mathsf{LinMap}^{\uparrow}(V,W)} h$. The first endpoint field of the first witness carries f, and the second endpoint field of the second witness carries h. For each carried x, the two pointwise fields give

$$f(x) \sim_W g(x), \qquad g(x) \sim_W h(x).$$

Codomain transitivity gives $f(x) \sim_W h(x)$. These pointwise composites, together with the carried endpoints f and h, form $f \sim_{\mathsf{LinMap}^{\uparrow}(V,W)} h$. Thus the classifier attached to Definition 48.49 satisfies the reflexive, symmetric, and transitive rows required by the stability and certificate obligations in Definition 48.50 and Definition 48.52. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingleton pointwise classifier equivalence`

Closure status for $\mathsf{NameCert}_{\mathsf{LinMap}^{\uparrow}}$.

Constructive story: A linear map between the singleton vector spaces is represented by the only code that can do anything here: the empty code, whose evaluation on every carried input vector returns the empty endpoint. Two map codes are classified pointwise, meaning every admitted input must evaluate to codomain-classified results; on the singleton evaluator this collapses to history-equality at e. The source is the singleton-code predicate, the pattern records that zero

map and identity are both the empty code, composition of empty codes is empty again, evaluation always lands in the singleton, and the kernel-triviality criterion holds because there is only one carried vector, while the ledger keeps each visible code aligned with its raw code. Since pointwise codomain classification is an equivalence and the evaluator never leaves the singleton, the empty code supplies the carrier witness, the classifier is reflexive, symmetric, and transitive, and recognized codes remain admitted. A code c lies in the signature gap of a $\mathsf{LinMap}^{\uparrow}$ token p when the source-domain accepts c, the signature relation pairs it with an answer code and evidence ledger, and the token-introduction relation names that answer as p; unfolded, c is the empty code and p is the singleton linear-map token. The terminal singleton bridge, public empty-code exactness row, singleton evaluator readback, and module-linear-map examples are all readings of that same empty-code table. The chapter registers this singleton public code package under the name $\mathsf{LinMap}^{\uparrow}$; no function extensionality is needed because every evaluation reaches the same endpoint, and rank-nullity, dual spaces, matrices, bounded operators, and non-singleton function spaces are not introduced.

Theory closure: TheoryGate(NameCert$_{\mathsf{LinMap}^{\uparrow}}$, maturePackageClosed)

Scope closed: The mature singleton public linear-map package binds the terminal singleton bridge, public empty-code exactness, singleton evaluator readback, pointwise classifier exactness, zero map uniqueness, composition and identity rows, the kernel-triviality criterion, and the module-linear-map examples already exhibited in this chapter.

Formal verification: FormalStatus(NameCert$_{\mathsf{LinMap}^{\uparrow}}$, bridgeChecked)

Lean target: `BEDC.Derived.LinearMapUp.LinearMapSingleton\_public\_empty\_code\_exactness`

Bridge status: bridgeChecked

Not claimed: This chapter does not close arbitrary non-singleton function extensionality, rank-nullity, dual spaces, matrices, bounded operators, or non-singleton families.

Upgrade path: No further formal-axis work remains for the singleton public linear-map bridge; non-singleton families remain outside this chapter.

Lemma 48.56 (Codomain additive duplicate cancellation)**.** *Let W carry an $\mathsf{AbGroup}^{\uparrow}(W)$ certificate with additive operation $+_W$, additive unit 0_W, and classifier $\sim_W$. For any carried $w : W$, if*

$$w \sim_W w +_W w,$$

then

$$w \sim_W 0_W.$$

Proof. By Definition 42.33, the additive carrier of W has the same operation, unit, inverse, and classifier as a $\mathsf{Group}^{\uparrow}$ carrier. Symmetry of the classifier turns the hypothesis into

$$w +_W w \sim_W w.$$

In additive notation, Definition 41.114 says that a comparison $a +_W b \sim_W a$ in this group reduct forces $b \sim_W 0_W$. Taking $a = w$ and $b = w$ gives $w \sim_W 0_W$. □

Theorem 48.57 (LinearMap zero preservation from additivity)**.** *Let F carry a $\mathsf{Field}^{\uparrow}(F)$ certificate, and let V and W carry $\mathsf{VecSpace}^{\uparrow}(F, V)$ and $\mathsf{VecSpace}^{\uparrow}(F, W)$ certificates. Write $+_V$, 0_V, and $\sim_V$ for the source vector addition, zero, and classifier, and write $+_W$, 0_W, and $\sim_W$ for the codomain additive operation, zero, and classifier. Let $f : V \to W$ be a carried $\mathsf{LinMap}^{\uparrow}(V, W)$ map. If the additive preservation row of f is*

$$f(x +_V y) \sim_W f(x) +_W f(y)$$

for carried source inputs x, y, then

$$f(0_V) \sim_W 0_W.$$

The ten-field fit is: traditional target ordinary linear maps send zero to zero; BEDC source $\mathsf{LinMap}^{\uparrow}(V, W)$ over the vector-space certificates; carrier the codomain vector carrier; classifier $\sim_W$; stability from additivity and codomain additive cancellation; ledger the zero-pair additive row and the cancellation witness; core theorem this block; exactness predicate $f(0_V) \sim_W 0_W$; standard bridge zero preservation for additive linear maps; status ProofTarget.

Proof. By Definition 47.1, the source vector-space carrier is a module carrier, and by Definition 46.1 its vector addition belongs to an additive abelian group. The source carrier transport used to read this comparison inside later rows is the standard semantic transport of Definition 26.3; the additive unit law supplies the source-side comparison

$$0_V +_V 0_V \sim_V 0_V.$$

The function-with-law data of Definition 48.1 evaluate the additive row on carried source expressions. Viewing evaluation by f as the descent map packaged by the function-like linear-map data, Definition 26.19 transports the source comparison $0_V +_V 0_V \sim_V 0_V$ through evaluation; codomain symmetry and transitivity then compose that transported comparison with the additive row at $x = 0_V$ and $y = 0_V$, giving

$$f(0_V) \sim_W f(0_V) +_W f(0_V).$$

The output $f(0_V)$ is carried by the codomain part of the same linear-map data.

For the codomain, Definition 47.23 reads the vector space as a module, and Definition 46.26 retains its additive abelian-group certificate with the same operation, zero, and classifier. Applying Definition 48.56 to $w = f(0_V)$ therefore gives

$$f(0_V) \sim_W 0_W.$$

This is exactly the zero-preservation item listed in Definition 48.50, obtained from additivity and the codomain additive cancellation package. □

Theorem 48.58 (LinearMap composition classifier congruence)**.** *Let F carry a $\mathsf{Field}^{\uparrow}(F)$ certificate, and let U, V, and W carry $\mathsf{VecSpace}^{\uparrow}(F, U)$, $\mathsf{VecSpace}^{\uparrow}(F, V)$, and $\mathsf{VecSpace}^{\uparrow}(F, W)$ certificates over the same scalar source. Write $+_U$, $+_V$, and $+_W$ for vector addition, write the scalar actions as $r \cdot_U x$, $r \cdot_V y$, and $r \cdot_W z$, and write $\sim_U$, $\sim_V$, and $\sim_W$ for the corresponding vector classifiers. Let $f, f' : U \to V$ be carried $\mathsf{LinMap}^{\uparrow}(U, V)$ maps, and let $g, g' : V \to W$ be carried $\mathsf{LinMap}^{\uparrow}(V, W)$ maps. If f and f' are related by the pointwise $\mathsf{LinMap}^{\uparrow}(U, V)$ classifier, and g and g' are related by the pointwise $\mathsf{LinMap}^{\uparrow}(V, W)$ classifier, then $g \circ f$ and $g' \circ f'$ are carried $\mathsf{LinMap}^{\uparrow}(U, W)$ maps and are related by the pointwise $\mathsf{LinMap}^{\uparrow}(U, W)$ classifier:*

$$g \circ f \sim_{\mathsf{LinMap}^{\uparrow}(U,W)} g' \circ f'.$$

Proof. By Definition 47.1, each displayed vector-space certificate is a module certificate over the same scalar field, and by Definition 46.1 the addition, scalar action, carrier, and classifier rows used below are the module rows specialized to vector spaces. By Definition 48.1, each carried linear map has output closure, additive preservation, scalar compatibility, and a descent certificate for transporting classifier comparisons through evaluation.

First consider $g \circ f$. For a carried input $x : U$, output closure for f gives that $f(x)$ is carried in V, and output closure for g gives that $g(f(x))$ is carried in W. Thus the composite has output closure. For carried inputs $x, y : U$, the additive row of f gives

$$f(x +_U y) \sim_V f(x) +_V f(y).$$

Transporting this comparison through evaluation by g using Definition 26.19, and then applying the additive row of g, gives

$$g(f(x +_U y)) \sim_W g(f(x) +_V f(y)) \sim_W g(f(x)) +_W g(f(y)).$$

Classifier transitivity in the codomain module gives the additive row for $g \circ f$. For a carried scalar $r : F$ and carried input $x : U$, the scalar row of f gives

$$f(r \cdot_U x) \sim_V r \cdot_V f(x).$$

Transporting this comparison through evaluation by g, and then applying the scalar row of g, gives

$$g(f(r \cdot_U x)) \sim_W g(r \cdot_V f(x)) \sim_W r \cdot_W g(f(x)).$$

Again codomain transitivity gives scalar compatibility for $g \circ f$. Hence $g \circ f$ is a carried $\mathsf{LinMap}^{\uparrow}(U, W)$ map. The same argument with f' and g' gives that $g' \circ f'$ is carried.

It remains to prove pointwise classifier congruence. Fix a carried input $x : U$. The pointwise classifier relation between f and f' gives

$$f(x) \sim_V f'(x).$$

The descent certificate for g transports this input comparison to

$$g(f(x)) \sim_W g(f'(x)).$$

The pointwise classifier relation between g and g' applied at the carried input $f'(x)$ gives

$$g(f'(x)) \sim_W g'(f'(x)).$$

Transitivity of $\sim_W$ yields

$$(g \circ f)(x) \sim_W (g' \circ f')(x).$$

Because x was arbitrary, Definition 48.49 identifies this pointwise comparison with the $\mathsf{LinMap}^{\uparrow}(U, W)$ classifier relation between the two composites. The ledger is the composition row recorded by Definition 48.51, with the two input map ledgers and the codomain pointwise comparison ledger as its witnesses. □

Definition 48.59 (Module LinearMap certificate package)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, and let M and N carry $\mathsf{Module}^{\uparrow}(R, M)$ and $\mathsf{Module}^{\uparrow}(R, N)$ certificates over the same scalar source. Write $\sim_M$ and $\sim_N$ for the module classifiers, $+_M$ and $+_N$ for vector addition, 0_M and 0_N for vector zero, and $\odot_M$ and $\odot_N$ for scalar action. A package*

$$\mathsf{LinearMapCert}_R(M, N; f)$$

for a function $f : M \to N$ consists of:

1. *output closure: every carried $x : M$ has carried output $f(x) : N$;*
2. *source-classifier descent: $x \sim_M y$ implies $f(x) \sim_N f(y)$;*
3. *additive preservation: $f(x +_M y) \sim_N f(x) +_N f(y)$ for carried $x, y : M$;*
4. *scalar compatibility: $f(r \odot_M x) \sim_N r \odot_N f(x)$ for carried scalars $r : R$ and carried $x : M$;*
5. *zero preservation: $f(0_M) \sim_N 0_N$;*
6. *ledger data recording the function identifier, the two linearity rows, the zero row, and the codomain pointwise comparison ledgers.*

This is the module fragment of the linear-map carrier in Definition 48.1, with its pointwise classifier read as in Definition 48.49 and its stability rows read against Definition 46.18.

Lean4 ✓ BEDC.Derived.LinearMapUp.ModuleLinearMapCertificatePackage exactness

Theorem 48.60 (Module LinearMap composition certificate)**.** *Let R carry a* $\mathsf{Ring}^{\uparrow}$ *certificate, and let M, N, and P carry* $\mathsf{Module}^{\uparrow}(R, M)$, $\mathsf{Module}^{\uparrow}(R, N)$, *and* $\mathsf{Module}^{\uparrow}(R, P)$ *certificates over the same scalar source. If*

$$\mathsf{LinearMapCert}_R(M, N; f) \qquad \textit{and} \qquad \mathsf{LinearMapCert}_R(N, P; g),$$

then the composite function $(g \circ f)(x) := g(f(x))$ carries a certificate

$$\mathsf{LinearMapCert}_R(M, P; g \circ f).$$

Proof. Unpack the two input certificates according to Definition 48.59. The source data for the composite are the same scalar certificate R together with the endpoint modules M and P, which are among the module certificate obligations of Definition 46.20.

For output closure, let x be carried in M. Output closure for f gives that $f(x)$ is carried in N, and output closure for g gives that $g(f(x))$ is carried in P.

For source-classifier descent, assume $x \sim_M y$. Descent for f gives

$$f(x) \sim_N f(y).$$

Descent for g transports this comparison to

$$g(f(x)) \sim_P g(f(y)),$$

which is the descent row for $g \circ f$.

For additivity, let x and y be carried in M. Additive closure in the M module makes $x +_M y$ carried. The additive row of f gives

$$f(x +_M y) \sim_N f(x) +_N f(y).$$

Descent for g sends this comparison to

$$g(f(x +_M y)) \sim_P g(f(x) +_N f(y)).$$

The outputs $f(x)$ and $f(y)$ are carried in N, so the additive row of g gives

$$g(f(x) +_N f(y)) \sim_P g(f(x)) +_P g(f(y)).$$

Classifier transitivity from Definition 9.8 composes the last two displayed comparisons and gives the additive row for $g \circ f$.

For scalar compatibility, let r be a carried scalar and let x be carried in M. Scalar-action closure in the M module makes $r \odot_M x$ carried. The scalar row of f gives

$$f(r \odot_M x) \sim_N r \odot_N f(x).$$

Descent for g transports this to

$$g(f(r \odot_M x)) \sim_P g(r \odot_N f(x)).$$

Since $f(x)$ is carried in N, the scalar row of g gives

$$g(r \odot_N f(x)) \sim_P r \odot_P g(f(x)).$$

Transitivity of the P classifier gives scalar compatibility for the composite.

For zero preservation, the zero row of f gives

$$f(0_M) \sim_N 0_N.$$

Descent for g gives

$$g(f(0_M)) \sim_P g(0_N),$$

and the zero row of g gives

$$g(0_N) \sim_P 0_P.$$

Transitivity of the P classifier gives $(g \circ f)(0_M) \sim_P 0_P$.

The pointwise classifier for maps $M \to P$ is exactly the relation specified in Definition 48.49. The rows above are the output-closure, descent, additivity, scalar-compatibility, zero-preservation, and composition-closure entries of Definition 48.50 read over the module carriers of Definition 46.1. The ledger is the composite record formed from the two input function identifiers and their linearity, zero, and pointwise comparison ledgers, matching the policy of Definition 48.51. Therefore the carrier, source, pattern, classifier, stability, and ledger data satisfy Definition 48.52 for $g \circ f$. □

Theorem 48.61 (Module identity LinearMap certificate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, and let M carry a $\mathsf{Module}^{\uparrow}(R, M)$ certificate. Write $\sim_M$ for the module classifier, $+_M$ for module addition, 0_M for module zero, and $\odot_M$ for scalar action. Let $\mathrm{id}_M : M \to M$ be the identity function. Then*

$$\mathsf{LinearMapCert}_R(M, M; \mathrm{id}_M)$$

holds. The source and target classifier are the same module classifier from Definition 46.17, and the ledger is the identity-function ledger governed by Definition 48.51.

The ten-field fit is: traditional target the ordinary identity linear map on a module; BEDC source a single $\mathsf{Module}^{\uparrow}(R, M)$ certificate; carrier the function id_M together with the rows listed in Definition 48.59; classifier the pointwise module classifier from Definition 48.49; stability output closure, descent, additivity, scalar compatibility, zero preservation, and identity closure from Definition 48.50; ledger the identity function identifier and the inherited operation ledgers required by Definition 48.51; core theorem this block; exactness predicate the displayed certificate; standard bridge the usual identity linear map; status ProofTarget.

Proof. Unpack the module certificate by Definition 46.20. It supplies the module carrier, the module classifier, the additive operation and zero, the scalar action, their stability fields, and their ledgers. By Definition 46.17, the classifier used on the source and target copies of M is the same relation $\sim_M$. The carrier-and-equivalence core of the derived certificate, described in Definition 9.7, supplies classifier reflexivity on carried module endpoints.

The rows required by Definition 48.59 are now checked one by one. For output closure, let x be carried in M. Since $\mathrm{id}_M(x) = x$, the output is the same carried endpoint.

For source-classifier descent, assume $x \sim_M y$. Applying the identity function changes neither endpoint, so the required comparison

$$\mathrm{id}_M(x) \sim_M \mathrm{id}_M(y)$$

is exactly the supplied comparison $x \sim_M y$.

For additivity, let x and y be carried in M. The additive closure component listed in Definition 46.18 makes $x +_M y$ a carried module endpoint. Both sides of the additive row reduce to that same endpoint:

$$\mathrm{id}_M(x +_M y) = x +_M y, \qquad \mathrm{id}_M(x) +_M \mathrm{id}_M(y) = x +_M y.$$

Classifier reflexivity on the carried endpoint $x +_M y$ gives

$$\mathrm{id}_M(x +_M y) \sim_M \mathrm{id}_M(x) +_M \mathrm{id}_M(y).$$

For scalar compatibility, let r be a carried scalar and let x be carried in M. Scalar-action closure from Definition 46.18 makes $r \odot_M x$ carried. Again both endpoints are the same expression:

$$\mathrm{id}_M(r \odot_M x) = r \odot_M x, \qquad r \odot_M \mathrm{id}_M(x) = r \odot_M x.$$

Reflexivity of $\sim_M$ gives the scalar-compatibility row.

For zero preservation, the additive unit 0_M is part of the carried additive module data. The two endpoints are both 0_M:

$$\mathrm{id}_M(0_M) = 0_M.$$

Reflexivity gives $\mathrm{id}_M(0_M) \sim_M 0_M$.

It remains only to record the certificate data. The function identifier is id_M. The additive, scalar, and zero rows above use the existing module operation ledgers together with classifier reflexivity, and the descent row uses the input classifier witness itself. This is exactly the ledger policy of Definition 48.51. Therefore the carrier, source, pattern, classifier, stability, and ledger data satisfy Definition 48.52, yielding $\mathsf{LinearMapCert}_R(M, M; \mathrm{id}_M)$. □

Theorem 48.62 (Module LinearMap composition associativity certificate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, and let M, N, P, and Q carry $\mathsf{Module}^{\uparrow}(R, M)$, $\mathsf{Module}^{\uparrow}(R, N)$, $\mathsf{Module}^{\uparrow}(R, P)$, and $\mathsf{Module}^{\uparrow}(R, Q)$ certificates over the same scalar source. Write $\sim_Q$ for the module classifier of Q. If*

$$\mathsf{LinearMapCert}_R(M, N; f), \qquad \mathsf{LinearMapCert}_R(N, P; g), \qquad \mathsf{LinearMapCert}_R(P, Q; k),$$

then both associated triple composites carry certificates

$$\mathsf{LinearMapCert}_R(M, Q; (k \circ g) \circ f) \qquad \textit{and} \qquad \mathsf{LinearMapCert}_R(M, Q; k \circ (g \circ f)),$$

and they are related by the pointwise $\mathsf{LinMap}^{\uparrow}(M, Q)$ classifier:

$$(k \circ g) \circ f \sim_{\mathsf{LinMap}^{\uparrow}(M,Q)} k \circ (g \circ f).$$

Equivalently, for every carried $x : M$,

$$((k \circ g) \circ f)(x) \sim_Q (k \circ (g \circ f))(x).$$

The ten-field fit is: traditional target associativity of composition of R-linear maps; BEDC source the three displayed $\mathsf{LinearMapCert}_R$ packages over a common scalar source; carrier the two composite function-with-law packages; classifier the pointwise Q-classifier from Definition 48.49; stability composition closure and endpoint reflexivity; ledger the two binary composition ledgers and the Q-endpoint reflexivity ledger; core theorem this block; exactness predicate the displayed pointwise comparison; standard bridge the usual associativity of function composition read pointwise; status ProofTarget.

Proof. Apply Definition 48.60 to the certificates for f and g. This gives

$$\mathsf{LinearMapCert}_R(M, P; g \circ f).$$

Applying the same theorem to this composite and to k gives

$$\mathsf{LinearMapCert}_R(M, Q; k \circ (g \circ f)).$$

In the other association, apply Definition 48.60 first to g and k, giving

$$\mathsf{LinearMapCert}_R(N, Q; k \circ g).$$

Applying the same theorem to f and this composite gives

$$\mathsf{LinearMapCert}_R(M, Q; (k \circ g) \circ f).$$

These are exactly the two certificate clauses required by Definition 48.59 and the composition-closure item of Definition 48.50.

It remains to compare the two certified composites. By Definition 48.49, the $\mathsf{LinMap}^{\uparrow}(M, Q)$ classifier is pointwise comparison in the codomain classifier. Let x be a carried endpoint of M. The output-closure rows in Definition 48.59 give carried endpoints $f(x)$ in N, $g(f(x))$ in P, and $k(g(f(x)))$ in Q. Both associated composites evaluate to this same codomain endpoint:

$$((k \circ g) \circ f)(x) = k(g(f(x))) = (k \circ (g \circ f))(x).$$

The module classifier on Q is the carrier classifier of Definition 46.17. Its reflexivity row, supplied by the naming-certificate core in Definition 9.7, classifies the carried endpoint $k(g(f(x)))$ with itself. Hence

$$((k \circ g) \circ f)(x) \sim_Q (k \circ (g \circ f))(x).$$

Since the carried input x was arbitrary, Definition 48.49 packages these endpoint comparisons as

$$(k \circ g) \circ f \sim_{\mathsf{LinMap}^{\uparrow}(M,Q)} k \circ (g \circ f).$$

The ledger field is formed from the two binary composition ledgers governed by Definition 48.51, together with the codomain reflexivity ledger at each point of Q. □

Theorem 48.63 (Module LinearMap identity unit laws)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, and let M and N carry $\mathsf{Module}^{\uparrow}(R, M)$ and $\mathsf{Module}^{\uparrow}(R, N)$ certificates over the same scalar source. Write $\sim_N$ for the module classifier on N, and let id_M and id_N be the identity functions. If*

$$\mathsf{LinearMapCert}_R(M, N; f)$$

holds, then the two unit composites carry certificates

$$\mathsf{LinearMapCert}_R(M, N; \mathrm{id}_N \circ f) \qquad \textit{and} \qquad \mathsf{LinearMapCert}_R(M, N; f \circ \mathrm{id}_M),$$

and both are related to f by the pointwise $\mathsf{LinMap}^{\uparrow}(M, N)$ classifier:

$$\mathrm{id}_N \circ f \sim_{\mathsf{LinMap}^{\uparrow}(M,N)} f \qquad \textit{and} \qquad f \circ \mathrm{id}_M \sim_{\mathsf{LinMap}^{\uparrow}(M,N)} f.$$

Equivalently, for every carried $x : M$,

$$\mathrm{id}_N(f(x)) \sim_N f(x) \qquad \textit{and} \qquad f(\mathrm{id}_M(x)) \sim_N f(x).$$

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonComp identity unit laws`

Proof. Apply Definition 48.61 to M and to N, obtaining $\mathsf{LinearMapCert}_R(M, M; \mathrm{id}_M)$ and $\mathsf{LinearMapCert}_R(N, N; \mathrm{id}$ By Definition 48.60, first with f and id_N and then with id_M and f, the two composites carry certificates:

$$\mathsf{LinearMapCert}_R(M, N; \mathrm{id}_N \circ f) \qquad \text{and} \qquad \mathsf{LinearMapCert}_R(M, N; f \circ \mathrm{id}_M).$$

It remains to compare these carried maps. By Definition 48.49, this is pointwise comparison in the codomain classifier. Fix a carried $x : M$. The output-closure row of Definition 48.59 for f makes $f(x)$ carried in N. Since $\mathrm{id}_N(f(x)) = f(x)$ and $f(\mathrm{id}_M(x)) = f(x)$, classifier reflexivity for the module classifier of N, supplied by Definition 46.17 and Definition 9.7, gives

$$\mathrm{id}_N(f(x)) \sim_N f(x) \qquad \text{and} \qquad f(\mathrm{id}_M(x)) \sim_N f(x).$$

Quantifying over carried x packages these comparisons as the two $\mathsf{LinMap}^{\uparrow}(M, N)$ classifier relations. The ledger is the identity and composition ledger required by Definition 48.51. □

Definition 48.64 (Module LinearMap image predicate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, let M and N carry $\mathsf{Module}^{\uparrow}(R, M)$ and $\mathsf{Module}^{\uparrow}(R, N)$ certificates over the same scalar source, and let $f : M \to N$ be a function. Write $\sim_N$ for the classifier on N. The image predicate of f is $\mathsf{Im}_f(y) :\Longleftrightarrow \exists x : M,\ x$ is carried in $M \wedge f(x) \sim_N y$. The witness records the source carrier evidence for x and the target classifier comparison from $f(x)$ to y.*

Lean4 (definition) `BEDC.Derived.LinearMapUp.LinearMapSingletonImage`

Theorem 48.65 (Module LinearMap image submodule closure)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, and let M and N carry $\mathsf{Module}^{\uparrow}(R, M)$ and $\mathsf{Module}^{\uparrow}(R, N)$ certificates over the same scalar source. Write $\sim_M$ and $\sim_N$ for the module classifiers, $+_M$ and $+_N$ for module addition, 0_M and 0_N for module zero, and $\odot_M$ and $\odot_N$ for scalar action. If $\mathsf{LinearMapCert}_R(M, N; f)$ holds, then the image predicate Im_f from Definition 48.64 is stable under target-classifier transport, contains 0_N, and is closed under the inherited target addition and scalar action: $\mathsf{Im}_f(y) \wedge y \sim_N y' \Longrightarrow \mathsf{Im}_f(y')$, $\mathsf{Im}_f(0_N)$, $\mathsf{Im}_f(y) \wedge \mathsf{Im}_f(z) \Longrightarrow \mathsf{Im}_f(y +_N z)$, and $\mathsf{Im}_f(y) \Longrightarrow \mathsf{Im}_f(r \odot_N y)$ for every carried scalar $r : R$. Thus the image is a sub-module predicate of the target module for these closure rows.*

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingletonImage submodule closure`

Proof. Unpack the package in Definition 48.59. It supplies output closure, source-classifier descent, additive preservation, scalar compatibility, and zero preservation. Unpack the two module certificates through Definition 46.20; the source module supplies carried 0_M, additive closure of $x +_M u$, and scalar-action closure of $r \odot_M x$, while the target module supplies additive congruence, scalar-action congruence, and classifier equivalence by Definition 46.18, Definition 42.8, and Definition 9.7. For target-classifier transport, choose an image witness x for $\mathsf{Im}_f(y)$, so x is carried in M and $f(x) \sim_N y$. Composing this comparison with $y \sim_N y'$ by Definition 9.8 gives $f(x) \sim_N y'$. The same source witness x proves $\mathsf{Im}_f(y')$. For zero, the zero row of the linear-map certificate gives $f(0_M) \sim_N 0_N$. Since 0_M is carried by the additive part of the source module, $x = 0_M$ is an image witness for 0_N. For addition, assume $\mathsf{Im}_f(y)$ and $\mathsf{Im}_f(z)$. Choose carried source witnesses $x, u : M$ with $f(x) \sim_N y$ and $f(u) \sim_N z$. Carrier transport in the target classifier makes y and z carried in N. Source additive closure makes $x +_M u$ carried in M. The additive preservation row gives $f(x +_M u) \sim_N f(x) +_N f(u)$. Target additive congruence transports the two image comparisons to $f(x) +_N f(u) \sim_N y +_N z$. Transitivity of $\sim_N$ composes the two comparisons, so the carried source endpoint $x +_M u$ witnesses $\mathsf{Im}_f(y +_N z)$. For scalar action, let r be a carried scalar and

assume $\mathsf{Im}_f(y)$. Choose a carried source witness $x : M$ with $f(x) \sim_N y$. Source scalar-action closure makes $r \odot_M x$ carried in M. Scalar compatibility gives $f(r \odot_M x) \sim_N r \odot_N f(x)$. Target scalar-action congruence, using classifier reflexivity on the carried scalar r and the image comparison $f(x) \sim_N y$, gives $r \odot_N f(x) \sim_N r \odot_N y$. Transitivity gives $f(r \odot_M x) \sim_N r \odot_N y$, so $r \odot_M x$ is an image witness for $r \odot_N y$. The ledger is assembled from the source witnesses, the linearity rows of the $\mathsf{LinearMapCert}_R$ package, the target operation-congruence rows, and the classifier-transitivity ledger governed by Definition 48.51. No equality of functions is used; all comparisons are pointwise target-classifier comparisons as in Definition 48.49. □

Theorem 48.66 (Module LinearMap pointwise sum certificate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, and let M and N carry $\mathsf{Module}^{\uparrow}(R, M)$ and $\mathsf{Module}^{\uparrow}(R, N)$ certificates over the same scalar source. Write $\sim_M$ and $\sim_N$ for the module classifiers, $+_M$ and $+_N$ for module addition, 0_M and 0_N for module zero, and $\odot_M$ and $\odot_N$ for scalar action. For functions $f, g : M \to N$, define $h : M \to N$ by*

$$h(x) := f(x) +_N g(x).$$

If

$$\mathsf{LinearMapCert}_R(M, N; f) \qquad \textit{and} \qquad \mathsf{LinearMapCert}_R(M, N; g),$$

then

$$\mathsf{LinearMapCert}_R(M, N; h).$$

The ten-field fit is: traditional target pointwise addition of ordinary R-linear maps; BEDC source the two displayed $\mathsf{LinearMapCert}_R$ packages over common $\mathsf{Module}^{\uparrow}$ certificates; carrier the pointwise-sum function h; classifier the pointwise target classifier from Definition 48.49; stability output closure, descent, additivity, scalar compatibility, and zero preservation from the module and abelian-group rows; ledger the two input function identifiers, their linearity rows, and the target additive, middle-four, distributive, zero, and classifier ledgers; core theorem this block; exactness predicate the displayed certificate; standard bridge the usual closure of $\mathrm{Hom}_R(M, N)$ under pointwise addition; status $\mathsf{ProofTarget}$.

Proof. Unpack the two input certificates by Definition 48.59. They supply output closure, source-classifier descent, additive preservation, scalar compatibility, and zero preservation for f and for g. Unpack the module certificates through Definition 46.20. The target module supplies additive closure, additive congruence, scalar-action closure, scalar-action congruence, scalar distributivity over module addition, and the additive abelian-group laws retained by Definition 46.26. Classifier symmetry and transitivity are supplied by the carrier certificate in Definition 9.7 and composed by Definition 9.8.

For output closure, let x be carried in M. Output closure for f and g makes $f(x)$ and $g(x)$ carried in N. Additive closure in the target module makes $f(x) +_N g(x)$ carried, so $h(x)$ is carried in N.

For source-classifier descent, assume $x \sim_M y$. Descent for f gives $f(x) \sim_N f(y)$, and descent for g gives $g(x) \sim_N g(y)$. Target additive congruence transports these two comparisons to

$$f(x) +_N g(x) \sim_N f(y) +_N g(y),$$

which is $h(x) \sim_N h(y)$.

For additivity, let x and y be carried in M. Source additive closure makes $x +_M y$ carried. The additive rows for f and g give

$$f(x +_M y) \sim_N f(x) +_N f(y) \qquad \text{and} \qquad g(x +_M y) \sim_N g(x) +_N g(y).$$

Target additive congruence therefore gives

$$h(x +_M y) \sim_N (f(x) +_N f(y)) +_N (g(x) +_N g(y)).$$

By Definition 46.26, the additive part of N is an $\mathsf{AbGroup}^{\uparrow}(N)$ certificate with the same $+_N$ and $\sim_N$. Applying the middle-four law of Definition 42.13 in additive notation gives

$$(f(x) +_N f(y)) +_N (g(x) +_N g(y)) \sim_N (f(x) +_N g(x)) +_N (f(y) +_N g(y)).$$

Transitivity composes the last two displayed comparisons and yields

$$h(x +_M y) \sim_N h(x) +_N h(y).$$

For scalar compatibility, let r be a carried scalar and let x be carried in M. Source scalar-action closure makes $r \odot_M x$ carried. The scalar rows for f and g give

$$f(r \odot_M x) \sim_N r \odot_N f(x) \qquad \text{and} \qquad g(r \odot_M x) \sim_N r \odot_N g(x).$$

Target additive congruence gives

$$h(r \odot_M x) \sim_N (r \odot_N f(x)) +_N (r \odot_N g(x)).$$

The scalar distributivity row of Definition 46.18, read in the target module and oriented by classifier symmetry, gives

$$(r \odot_N f(x)) +_N (r \odot_N g(x)) \sim_N r \odot_N (f(x) +_N g(x)).$$

Transitivity yields

$$h(r \odot_M x) \sim_N r \odot_N h(x).$$

For zero preservation, the source zero endpoint is carried by the additive data. The zero rows for f and g give

$$f(0_M) \sim_N 0_N \qquad \text{and} \qquad g(0_M) \sim_N 0_N.$$

Target additive congruence gives

$$h(0_M) \sim_N 0_N +_N 0_N.$$

The additive unit law in the target abelian-group certificate classifies $0_N +_N 0_N$ with 0_N, and transitivity gives

$$h(0_M) \sim_N 0_N.$$

The pointwise classifier for maps $M \to N$ is exactly Definition 48.49; the preceding descent row is its required pointwise respect. The ledger records the function identifier h, the two input function identifiers, the pointwise addition ledger for each output, the additive congruence and middle-four ledgers for the additivity row, the scalar-distributivity ledger for the scalar row, and the zero-plus-unit ledger for the zero row, matching Definition 48.51. Hence the carrier, source, pattern, classifier, stability, and ledger obligations of Definition 48.52 are satisfied for h. □

Lemma 48.67 (Module scalar action preserves additive inverse)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, and let N carry a $\mathsf{Module}^{\uparrow}(R, N)$ certificate. Write $\sim_N$ for the module classifier, $+_N$ for module addition, 0_N for module zero, $-_N$ for additive inverse, and $\odot_N$ for scalar action. For every carried scalar $r : R$ and carried endpoint $y : N$,*

$$-_N(r \odot_N y) \sim_N r \odot_N (-_N y).$$

Proof. Unpack the module certificate through Definition 46.20. The additive reduct of the target module is an $\mathsf{AbGroup}^{\uparrow}(N)$ certificate by Definition 46.26, and its group reduct is obtained by Definition 42.33. These reducts keep the same addition, zero, additive inverse, and classifier. Thus inverse closure, inverse congruence, the inverse laws, additive congruence, and additive left cancellation are available through Definition 42.8, Definition 41.55, and Definition 41.66.

Let

$$a := r \odot_N y, \qquad b := r \odot_N (-_N y).$$

Scalar-action closure makes a carried, inverse closure makes $-_N y$ carried, and scalar-action closure again makes b carried. The additive right-inverse row for a gives

$$a +_N (-_N a) \sim_N 0_N.$$

The additive right-inverse row for y gives

$$y +_N (-_N y) \sim_N 0_N.$$

Scalar-action congruence, using classifier reflexivity on the carried scalar r, transports this to

$$r \odot_N (y +_N (-_N y)) \sim_N r \odot_N 0_N.$$

The zero-action annihilation theorem Definition 46.29 gives

$$r \odot_N 0_N \sim_N 0_N.$$

Transitivity therefore gives

$$r \odot_N (y +_N (-_N y)) \sim_N 0_N.$$

Scalar distributivity over module addition from Definition 46.18 gives

$$r \odot_N (y +_N (-_N y)) \sim_N (r \odot_N y) +_N (r \odot_N (-_N y)).$$

Using classifier symmetry and transitivity, this yields

$$a +_N b \sim_N 0_N.$$

Composing this comparison with the symmetry of $a +_N (-_N a) \sim_N 0_N$ gives

$$a +_N b \sim_N a +_N (-_N a).$$

Additive left cancellation in the retained group reduct removes the common left summand a, giving $b \sim_N -_N a$. Classifier symmetry gives

$$-_N a \sim_N b.$$

Substituting the definitions of a and b is exactly the displayed scalar-action inverse law. □

Theorem 48.68 (Module LinearMap pointwise inverse certificate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, and let M and N carry $\mathsf{Module}^{\uparrow}(R, M)$ and $\mathsf{Module}^{\uparrow}(R, N)$ certificates over the same scalar source. Write $\sim_M$ and $\sim_N$ for the module classifiers, $+_M$ and $+_N$ for module addition, 0_M and 0_N for module zero, $-_N$ for the target additive inverse, and $\odot_M$ and $\odot_N$ for scalar action. For a function $f : M \to N$, define $h : M \to N$ by*

$$h(x) := -_N f(x).$$

If

$$\mathsf{LinearMapCert}_R(M, N; f)$$

holds, then

$$\mathsf{LinearMapCert}_R(M, N; h)$$

holds. The ten-field fit is: traditional target pointwise additive inverse of an ordinary R-linear map; BEDC source the displayed $\mathsf{LinearMapCert}_R(M, N; f)$ *package over common* $\mathsf{Module}^{\uparrow}$ *certificates; carrier the pointwise inverse function h; classifier the pointwise target classifier from Definition 48.49; stability output closure, descent, additivity, scalar compatibility, and zero preservation from the target additive group and module action rows; ledger the input function identifier, the target inverse ledger, the inverse-congruence ledger, the inverse-of-sum ledger, and the scalar-action inverse ledger; core theorem this block; exactness predicate the displayed certificate; standard bridge closure of* $\mathrm{Hom}_R(M, N)$ *under pointwise additive inverse; status* $\mathsf{ProofTarget}$.

Proof. Unpack $\mathsf{LinearMapCert}_R(M, N; f)$ using Definition 48.59. It supplies output closure, source-classifier descent, additive preservation, scalar compatibility, and zero preservation for f. Unpack the two module certificates through Definition 46.20. The target module supplies additive inverse closure, additive congruence, scalar-action congruence, scalar distributivity over module addition, and the additive abelian-group laws retained by Definition 46.26. Classifier symmetry and transitivity are supplied by the naming-certificate core in Definition 9.7 and composed by Definition 9.8.

For output closure, let x be carried in M. Output closure for f makes $f(x)$ carried in N. Additive inverse closure in the target additive group makes $-_N f(x)$ carried, so $h(x)$ is carried in N.

For source-classifier descent, assume $x \sim_M y$. Descent for f gives

$$f(x) \sim_N f(y).$$

The inverse-congruence row in the target additive group gives

$$-_N f(x) \sim_N -_N f(y),$$

which is $h(x) \sim_N h(y)$.

For additivity, let x and y be carried in M. Source additive closure makes $x +_M y$ carried. The additive row for f gives

$$f(x +_M y) \sim_N f(x) +_N f(y).$$

Inverse congruence transports this comparison to

$$h(x +_M y) \sim_N -_N(f(x) +_N f(y)).$$

By Definition 46.26, the additive part of N is an $\mathsf{AbGroup}^{\uparrow}(N)$ certificate with the same $+_N$, $-_N$, and $\sim_N$. Applying Definition 42.23 in additive notation gives

$$-_N(f(x) +_N f(y)) \sim_N (-_N f(x)) +_N (-_N f(y)).$$

Transitivity yields

$$h(x +_M y) \sim_N h(x) +_N h(y).$$

For scalar compatibility, let r be a carried scalar and let x be carried in M. Source scalar-action closure makes $r \odot_M x$ carried. The scalar row for f gives

$$f(r \odot_M x) \sim_N r \odot_N f(x).$$

Inverse congruence gives

$$h(r \odot_M x) \sim_N -_N(r \odot_N f(x)).$$

The output-closure row for f makes $f(x)$ carried in N, so Definition 48.67 applies in the target module and gives

$$-_N(r \odot_N f(x)) \sim_N r \odot_N (-_N f(x)).$$

Transitivity gives

$$h(r \odot_M x) \sim_N r \odot_N h(x).$$

For zero preservation, the zero row of f gives

$$f(0_M) \sim_N 0_N.$$

Inverse congruence gives

$$h(0_M) \sim_N -_N 0_N.$$

The additive group reduct identifies the inverse of the additive identity with the identity by Definition 41.56, so

$$-_N 0_N \sim_N 0_N.$$

Transitivity gives

$$h(0_M) \sim_N 0_N.$$

The pointwise classifier for maps $M \to N$ is exactly Definition 48.49; the descent row above is the required pointwise respect. The ledger records the function identifier h, the input function identifier for f, the target inverse operation at each output, the inverse-congruence ledgers for descent, additivity, scalar compatibility, and zero, the inverse-of-sum ledger from Definition 42.23, and the scalar-action inverse ledger from Definition 48.67, matching Definition 48.51. Hence the carrier, source, pattern, classifier, stability, and ledger obligations of Definition 48.52 are satisfied for h. □

Theorem 48.69 (LinearMap additive inverse preservation)**.** *Let F carry a $\mathsf{Field}^{\uparrow}(F)$ certificate, and let V and W carry $\mathsf{VecSpace}^{\uparrow}(F, V)$ and $\mathsf{VecSpace}^{\uparrow}(F, W)$ certificates. Write $+_V$, 0_V, $-_V$, and $\sim_V$ for the source vector addition, zero, additive inverse, and classifier, and write $+_W$, 0_W, $-_W$, and $\sim_W$ for the codomain additive operation, zero, additive inverse, and classifier. Let $f : V \to W$ be a carried $\mathsf{LinMap}^{\uparrow}(V, W)$ map. Then every carried source point $m : V$ satisfies*

$$f(-_V m) \sim_W -_W f(m).$$

The ten-field fit is: traditional target ordinary linear maps preserve additive negation; BEDC source $\mathsf{LinMap}^{\uparrow}(V, W)$ over the two vector-space certificates; carrier the codomain vector carrier; classifier $\sim_W$; stability from additivity, zero preservation, source inverse descent, and codomain inverse uniqueness; ledger the source right-inverse witness, additive-preservation row, zero-preservation row, codomain inverse witness, and uniqueness comparison; core theorem this block; exactness predicate $f(-_V m) \sim_W -_W f(m)$; standard bridge additive inverse preservation for linear maps; status $\mathsf{ProofTarget}$.

Proof. By Definition 47.24, each vector-space certificate has a module reduct with the same vector addition, zero, additive inverse, and classifier. By Definition 46.26 and Definition 42.33, the source and codomain additive data may be read as group data with those same operations and classifiers.

Fix a carried source point $m : V$. Source inverse closure makes $-_V m$ carried, and the source right-inverse row gives

$$m +_V (-_V m) \sim_V 0_V.$$

This source comparison is available for evaluation by the semantic transport of Definition 26.3. The function-with-law data of Definition 48.1 supply output closure, additive preservation, and the evaluation descent used through Definition 26.19. Descent transports the source inverse comparison to

$$f(m +_V (-_V m)) \sim_W f(0_V).$$

The additive row of f at the carried pair $m, -_V m$ gives

$$f(m +_V (-_V m)) \sim_W f(m) +_W f(-_V m).$$

The zero-preservation theorem Definition 48.57, applied to the same additive row, gives

$$f(0_V) \sim_W 0_W.$$

Classifier symmetry from Definition 9.7 and transitivity from Definition 9.8 compose the last three comparisons into

$$f(m) +_W f(-_V m) \sim_W 0_W.$$

Output closure makes $f(m)$ and $f(-_V m)$ carried in W, and codomain inverse closure makes $-_W f(m)$ carried. The codomain left-inverse row gives

$$(-_W f(m)) +_W f(m) \sim_W 0_W.$$

Apply Definition 41.59 in the codomain additive group reduct with $x = f(m)$, $y = -_W f(m)$, and $z = f(-_V m)$. The two displayed inverse witnesses give

$$-_W f(m) \sim_W f(-_V m).$$

One final classifier symmetry gives

$$f(-_V m) \sim_W -_W f(m).$$

The ledger entries are the source inverse comparison, the evaluation descent witness, the additive row, the zero-preservation row, the codomain inverse row, and the inverse-uniqueness comparison required by Definition 48.51. □

Theorem 48.70 (LinearMap difference preservation)**.** *Let F carry a $\mathsf{Field}^{\uparrow}(F)$ certificate, and let V and W carry $\mathsf{VecSpace}^{\uparrow}(F, V)$ and $\mathsf{VecSpace}^{\uparrow}(F, W)$ certificates. Write $+_W$, $-_W$, and $\sim_W$ for the codomain vector addition, additive inverse, and classifier. Let $f, g : V \to W$ be carried $\mathsf{LinMap}^{\uparrow}(V, W)$ maps. Define $d : V \to W$ pointwise by*

$$d(m) := f(m) +_W (-_W g(m)).$$

Then d carries a $\mathsf{LinMap}^{\uparrow}(V, W)$ certificate, and every carried source point $m : V$ satisfies

$$d(m) \sim_W f(m) +_W (-_W g(m)).$$

The ten-field fit is: BEDC source $\mathsf{LinMap}^{\uparrow} + \mathsf{VecSpace}^{\uparrow} + \mathsf{Field}^{\uparrow}$ over the common scalar field and the two vector-space certificates; carrier the pointwise difference function d; classifier the pointwise codomain classifier from Definition 48.49; stability the sum rows together with the codomain inverse rows; ledger the pointwise-sum ledger plus the pointwise-inverse ledger; core theorem this block; exactness predicate the displayed endpoint formula; standard bridge the usual difference of linear maps in $\mathrm{Hom}_F(V, W)$; public pattern the hom-space additive-group operation; status $\mathsf{ProofTarget}$.

Proof. Read the two vector-space certificates through their module reducts by Definition 47.24. The carried $\mathsf{LinMap}^{\uparrow}(V, W)$ data for f and g provide the corresponding module linear-map certificates over this common module source.

Apply Definition 48.68 to g. This certifies the pointwise inverse map $u : V \to W$ defined by

$$u(m) := -_W g(m).$$

The endpoint identity for u is the codomain additive inverse operation; the source-inverse behavior remains compatible with Definition 48.69.

Now apply Definition 48.66 to the certified maps f and u. Its carrier is the pointwise sum

$$m \longmapsto f(m) +_W u(m),$$

which is exactly the displayed difference carrier d after substituting the definition of u.

For a carried source point $m : V$, the classifier for $\mathsf{LinMap}^{\uparrow}(V, W)$ is pointwise in $\sim_W$ by Definition 48.49. The displayed defining equation for d and classifier reflexivity at the carried codomain endpoint give

$$d(m) \sim_W f(m) +_W (-_W g(m)).$$

The ledger is the concatenation of the pointwise-inverse ledger for g and the pointwise-sum ledger for f with that inverse map. Thus all carrier, classifier, stability, exactness, and ledger rows required for the $\mathsf{LinMap}^{\uparrow}(V, W)$ certificate are supplied. □

Definition 48.71 (Module LinearMap kernel and image restricted module classifiers)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, let M and N carry $\mathsf{Module}^{\uparrow}(R, M)$ and $\mathsf{Module}^{\uparrow}(R, N)$ certificates over the same scalar source, and let*

$$\mathsf{LinearMapCert}_R(M, N; f)$$

hold. Use the kernel and image predicates of Definition 46.43 and Definition 48.64. The kernel classifier is the source module classifier restricted to the zero fiber:

$$x \sim_{\mathsf{Ker}_f} x' \iff \mathsf{Ker}_f(x) \wedge \mathsf{Ker}_f(x') \wedge x \sim_M x'.$$

The image classifier is the target module classifier restricted to the image carrier:

$$y \sim_{\mathsf{Im}_f} y' \iff \mathsf{Im}_f(y) \wedge \mathsf{Im}_f(y') \wedge y \sim_N y'.$$

The kernel module fragment uses $+_M$, 0_M, $-_M$, and $\odot_M$. The image module fragment uses $+_N$, 0_N, $-_N$, and $\odot_N$. In both fragments the scalar carrier, scalar operations, scalar classifier, and scalar ledger are copied from the ambient $\mathsf{Ring}^{\uparrow}(R)$ certificate.

Theorem 48.72 (Kernel and image inherit module classifiers)**.** *Under the hypotheses of Definition 48.71, the predicate-defined carriers Ker_f and Im_f are stable under their ambient module classifiers, contain the corresponding zero element, and are closed under addition, additive negation, and carried scalar action. With the restricted classifiers of Definition 48.71, these data form inherited $\mathsf{Module}^{\uparrow}$ certificate packages over the same scalar source R.*

Proof. Unpack $\mathsf{LinearMapCert}_R(M, N; f)$ by Definition 48.59 and unpack the two module certificates through Definition 46.20. The kernel transport, zero, addition, and scalar-action rows are exactly Definition 46.44. The image transport, zero, addition, and scalar-action rows are exactly Definition 48.65.

It remains to record additive negation and the inherited classifier packages. For the kernel, assume $\mathsf{Ker}_f(x)$. The scalar source is a certified $\mathsf{Ring}^{\uparrow}$ by Definition 46.15, so the additive inverse row carries $-_R 1_R$. Applying the scalar-action closure row of Definition 46.44 gives

$$\mathsf{Ker}_f((-_R 1_R) \odot_M x).$$

In the source module, Definition 46.42 at $r = 1_R$ gives

$$((-_R 1_R) \odot_M x) +_M (1_R \odot_M x) \sim_M 0_M.$$

The scalar unit row from Definition 46.18, together with additive congruence in the additive group retained by Definition 46.26, replaces $1_R \odot_M x$ by x. The source right-inverse row gives $x +_M (-_M x) \sim_M 0_M$. Applying Definition 41.59 in the source additive group reduct obtained through Definition 42.33 identifies

$$(-_R 1_R) \odot_M x \sim_M -_M x.$$

The source-classifier transport row of Definition 46.44 then gives $\mathsf{Ker}_f(-_M x)$.

For the image, assume $\mathsf{Im}_f(y)$. By the definition of the image predicate, choose a carried source witness x with $f(x) \sim_N y$. Output closure for f and carrier transport for the target classifier make y a carried target endpoint. The image scalar-action row of Definition 48.65, applied to the carried scalar $-_R 1_R$, gives

$$\mathsf{Im}_f((-_R 1_R) \odot_N y).$$

The same inverse-side action argument in the target module gives

$$(-_R 1_R) \odot_N y \sim_N -_N y.$$

The target-classifier transport row of Definition 48.65 therefore gives $\mathsf{Im}_f(-_N y)$.

The restricted kernel classifier is a naming certificate on Ker_f: reflexivity, symmetry, and transitivity are the corresponding source-module classifier rows from Definition 9.7 and Definition 9.8, while carrier transport is the first row of Definition 46.44. The restricted image classifier is handled identically, using the target-module classifier and the transport row of Definition 48.65.

Finally, every $\mathsf{Module}^{\uparrow}$ law on the restricted carriers is the ambient module law with its endpoints repackaged by the restricted classifier. Closure under zero, addition, negation, and scalar action supplies the two carrier components of each restricted classifier witness. The ambient comparison component is supplied by the source module for the kernel and by the target module for the image: additive associativity, additive unit and inverse laws, additive commutativity, additive congruence, scalar-action congruence, scalar associativity, both distributivity rows, and the scalar unit row are all listed in Definition 46.18 together with the additive $\mathsf{AbGroup}^{\uparrow}$ source retained by Definition 46.26. The scalar ring certificate is unchanged. The ledgers are the ambient operation ledgers together with the kernel or image witness carried in the restricted classifier, matching Definition 46.19. Hence both predicate carriers inherit $\mathsf{Module}^{\uparrow}$ classifier packages over R. □

Theorem 48.73 (Module LinearMap trivial kernel classifier injectivity)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, let M and N carry $\mathsf{Module}^{\uparrow}(R, M)$ and $\mathsf{Module}^{\uparrow}(R, N)$ certificates over the same scalar source, and let*

$$\mathsf{LinearMapCert}_R(M, N; f)$$

hold. Write $\sim_M$ and $\sim_N$ for the source and target module classifiers, 0_M and 0_N for the source and target zeros, $+_M$ for source addition, and $-_M$ for source additive inverse. Define classifier-injectivity on carried source endpoints by

$$f(x) \sim_N f(y) \Longrightarrow x \sim_M y.$$

Then f is classifier-injective exactly when its BEDC kernel from Definition 46.43 is trivial:

$$\mathsf{Ker}_f(x) \Longleftrightarrow x \sim_M 0_M$$

for every carried source endpoint $x : M$.

The ten-field fit is: traditional target the ordinary criterion that a module homomorphism is injective exactly when its kernel is zero; BEDC source $\mathsf{LinearMapCert}_R(M, N; f)$ over the two $\mathsf{Module}^{\uparrow}$ certificates; carrier the source module carrier; classifier $\sim_M$; stability zero preservation, additivity, additive inverse preservation, and additive cancellation from the module additive reducts; ledger the function identifier f, its descent, zero, additivity, inverse, and source-cancellation rows; core theorem this block; exactness predicate the equivalence between classifier-injectivity and the trivial zero fiber; standard bridge first-isomorphism-style exactness for $\mathsf{LinMap}^{\uparrow}$; status $\mathsf{ProofTarget}$.

Proof. Assume first that f is classifier-injective on carried source endpoints. Let x be carried in M. If $\mathsf{Ker}_f(x)$, then Definition 46.43 gives $f(x) \sim_N 0_N$. Zero preservation from Definition 48.59 gives $f(0_M) \sim_N 0_N$, and classifier symmetry and transitivity in N compose these rows to obtain $f(x) \sim_N f(0_M)$. Classifier-injectivity gives $x \sim_M 0_M$.

Conversely, if $x \sim_M 0_M$, source-classifier descent for f gives $f(x) \sim_N f(0_M)$. Composing this with zero preservation yields $f(x) \sim_N 0_N$, so the carried endpoint x satisfies $\mathsf{Ker}_f(x)$.

Assume now that every carried $z : M$ satisfies $\mathsf{Ker}_f(z) \Longleftrightarrow z \sim_M 0_M$. Let x and y be carried source endpoints with $f(x) \sim_N f(y)$. Source additive inverse closure carries $-_M y$, and source addition closure carries $x +_M (-_M y)$.

Additivity gives

$$f(x +_M (-_M y)) \sim_N f(x) +_N f(-_M y).$$

The additive-inverse argument of Definition 48.69, read through the additive group reducts of the module certificates, identifies $f(-_M y)$ with the target inverse of $f(y)$. Target additive congruence then transports $f(x) \sim_N f(y)$ to a comparison of $f(x) +_N (-_N f(y))$ with $f(y) +_N (-_N f(y))$, and the target right-inverse row reduces the latter endpoint to 0_N.

Thus $x +_M (-_M y)$ lies in Ker_f. By the trivial-kernel hypothesis,

$$x +_M (-_M y) \sim_M 0_M.$$

The source right-inverse row also gives $y +_M (-_M y) \sim_M 0_M$. Classifier symmetry and transitivity produce

$$x +_M (-_M y) \sim_M y +_M (-_M y).$$

Apply Definition 41.116 in the source additive group reduct obtained from Definition 46.26 and Definition 42.33. Cancelling the common carried summand $-_M y$ gives $x \sim_M y$, which is classifier-injectivity. □

Theorem 48.74 (Module LinearMap pointwise sum commutativity)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, and let M and N carry $\mathsf{Module}^{\uparrow}(R, M)$ and $\mathsf{Module}^{\uparrow}(R, N)$ certificates over the same scalar*

source. Write $\sim_N$ for the module classifier on N and $+_N$ for module addition. For functions $f, g : M \to N$, define $h, k : M \to N$ by

$$h(x) := f(x) +_N g(x), \qquad k(x) := g(x) +_N f(x).$$

If

$$\mathsf{LinearMapCert}_R(M, N; f) \qquad \textit{and} \qquad \mathsf{LinearMapCert}_R(M, N; g),$$

then both pointwise sums carry certificates

$$\mathsf{LinearMapCert}_R(M, N; h) \qquad \textit{and} \qquad \mathsf{LinearMapCert}_R(M, N; k),$$

and they are related by the pointwise $\mathsf{LinMap}^{\uparrow}(M, N)$ *classifier:*

$$h \sim_{\mathsf{LinMap}^{\uparrow}(M,N)} k.$$

Equivalently, for every carried $x : M$,

$$f(x) +_N g(x) \sim_N g(x) +_N f(x).$$

The ten-field fit is: traditional target commutativity of pointwise addition in $\mathrm{Hom}_R(M, N)$*; BEDC source the two displayed* $\mathsf{LinearMapCert}_R$ *packages over common* $\mathsf{Module}^{\uparrow}$ *certificates; carrier the two pointwise-sum functions h and k; classifier the pointwise target classifier from Definition 48.49; stability pointwise-sum closure and target additive commutativity; ledger the two input function identifiers, the two pointwise-sum ledgers, and the target additive-commutativity ledger at each carried source endpoint; core theorem this block; exactness predicate the displayed* $\mathsf{LinMap}^{\uparrow}(M, N)$ *classifier comparison; standard bridge the usual commutative addition law on module homomorphisms; status* $\mathsf{ProofTarget}$.

Proof. Apply Definition 48.66 to the ordered pair (f, g). This gives the certificate for h. Apply the same theorem to the ordered pair (g, f). This gives the certificate for k.

It remains to prove the classifier comparison. By Definition 48.49, the $\mathsf{LinMap}^{\uparrow}(M, N)$ classifier is pointwise comparison in the target module classifier, together with the two carried map-code endpoints. The two endpoint certificate clauses are the certificates for h and k just obtained.

Fix a carried source endpoint $x : M$. Unpacking the two input certificates by Definition 48.59, output closure for f and for g makes $f(x)$ and $g(x)$ carried in N. By Definition 46.26, the additive part of the target module is an $\mathsf{AbGroup}^{\uparrow}(N)$ certificate with the same operation $+_N$ and classifier $\sim_N$. The commutativity row listed in Definition 42.8 therefore gives

$$f(x) +_N g(x) \sim_N g(x) +_N f(x).$$

By the definitions of h and k, this is exactly

$$h(x) \sim_N k(x).$$

Since x was arbitrary, Definition 48.49 packages these pointwise target comparisons, together with the two carried endpoint certificates, as

$$h \sim_{\mathsf{LinMap}^{\uparrow}(M,N)} k.$$

The ledger is the pair of pointwise-sum ledgers supplied by Definition 48.66, plus the target additive-commutativity ledger in the abelian-group reduct of N, matching Definition 48.51. □

Theorem 48.75 (Module zero LinearMap certificate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, and let M and N carry $\mathsf{Module}^{\uparrow}(R, M)$ and $\mathsf{Module}^{\uparrow}(R, N)$ certificates over the same scalar source. Write $\sim_M$ and $\sim_N$ for the module classifiers, $+_M$ and $+_N$ for module addition, 0_M and 0_N for module zero, and $\odot_M$ and $\odot_N$ for scalar action. Let $z : M \to N$ be a function. Assume that for every carried $x : M$, the output $z(x)$ is carried in N and*

$$z(x) \sim_N 0_N.$$

Then

$$\mathsf{LinearMapCert}_R(M, N; z)$$

holds.

Proof. Unpack the two module certificates through Definition 46.20 and read the required rows through Definition 48.59. The carried-output part of the hypothesis is the output-closure row. Since 0_M is carried by the additive source of M, the same pointwise zero row at $x = 0_M$ gives $z(0_M) \sim_N 0_N$, which is zero preservation.

For source-classifier descent, assume $x \sim_M y$ between carried source endpoints. The pointwise zero row gives $z(x) \sim_N 0_N$ and $z(y) \sim_N 0_N$. Classifier symmetry from Definition 9.7, followed by transitivity from Definition 9.8, gives $z(x) \sim_N z(y)$.

For additivity, let x and y be carried in M. Source additive closure makes $x +_M y$ carried, so $z(x +_M y) \sim_N 0_N$. The target additive congruence row from Definition 46.18 transports the two zero comparisons for $z(x)$ and $z(y)$ to

$$z(x) +_N z(y) \sim_N 0_N +_N 0_N \sim_N 0_N,$$

where the second comparison is the target additive unit row retained by Definition 46.26. Symmetry and transitivity compose this with $z(x +_M y) \sim_N 0_N$, yielding

$$z(x +_M y) \sim_N z(x) +_N z(y).$$

For scalar compatibility, let $r : R$ be carried and let $x : M$ be carried. Source scalar-action closure makes $r \odot_M x$ carried, so $z(r \odot_M x) \sim_N 0_N$. Scalar-action congruence in the target module, using scalar reflexivity for r and $z(x) \sim_N 0_N$, gives $r \odot_N z(x) \sim_N r \odot_N 0_N$. The zero-action annihilation theorem Definition 46.29, applied in N, gives $r \odot_N 0_N \sim_N 0_N$. Symmetry and transitivity therefore give

$$z(r \odot_M x) \sim_N r \odot_N z(x).$$

The pointwise classifier for maps $M \to N$ is the one in Definition 48.49. The ledger records the function identifier z, the pointwise zero witnesses, the target additive and scalar-action congruence rows, the target zero-action row, and the classifier symmetry and transitivity witnesses, matching Definition 48.51. Hence the carrier, source, pattern, classifier, stability, and ledger obligations of Definition 48.52 are satisfied for z. □

Theorem 48.76 (Module LinearMap pointwise sum associativity)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, and let M and N carry $\mathsf{Module}^{\uparrow}(R, M)$ and $\mathsf{Module}^{\uparrow}(R, N)$ certificates over the same scalar source. Write $\sim_N$ for the module classifier on N and $+_N$ for module addition. For functions $f, g, h : M \to N$, define $u, v : M \to N$ by*

$$u(x) := (f(x) +_N g(x)) +_N h(x), \qquad v(x) := f(x) +_N (g(x) +_N h(x)).$$

If

$$\mathsf{LinearMapCert}_R(M,N;f) \quad \textit{and} \quad \mathsf{LinearMapCert}_R(M,N;g) \quad \textit{and} \quad \mathsf{LinearMapCert}_R(M,N;h),$$

then both associated pointwise sums carry certificates

$$\mathsf{LinearMapCert}_R(M,N;u) \quad \textit{and} \quad \mathsf{LinearMapCert}_R(M,N;v),$$

and they are related by the pointwise $\mathsf{LinMap}^{\uparrow}(M,N)$ *classifier:*

$$u \sim_{\mathsf{LinMap}^{\uparrow}(M,N)} v.$$

Equivalently, for every carried $x : M$*,*

$$(f(x) +_N g(x)) +_N h(x) \sim_N f(x) +_N (g(x) +_N h(x)).$$

The ten-field fit is: traditional target associativity of pointwise addition in $\mathrm{Hom}_R(M,N)$*; BEDC source the three displayed* $\mathsf{LinearMapCert}_R$ *packages over common* $\mathsf{Module}^{\uparrow}$ *certificates; carrier the two associated pointwise-sum functions* u *and* v*; classifier the pointwise target classifier from Definition 48.49; stability pointwise-sum closure and target additive associativity; ledger the two binary pointwise-sum ledgers on each side and the target additive-associativity ledger at each carried source endpoint; core theorem this block; exactness predicate the displayed* $\mathsf{LinMap}^{\uparrow}(M,N)$ *classifier comparison; standard bridge the usual associative addition law on module homomorphisms; status* $\mathsf{ProofTarget}$*.*

Proof. Define the intermediate pointwise sums $s, t : M \to N$ by

$$s(x) := f(x) +_N g(x), \qquad t(x) := g(x) +_N h(x).$$

Apply Definition 48.66 to the ordered pair (f, g). This gives

$$\mathsf{LinearMapCert}_R(M,N;s).$$

Applying the same theorem to the ordered pair (s, h) gives

$$\mathsf{LinearMapCert}_R(M,N;u),$$

because the resulting pointwise-sum function is exactly $x \mapsto (f(x) +_N g(x)) +_N h(x)$.

For the other association, apply Definition 48.66 to the ordered pair (g, h), obtaining

$$\mathsf{LinearMapCert}_R(M,N;t).$$

Applying the same theorem to the ordered pair (f, t) gives

$$\mathsf{LinearMapCert}_R(M,N;v),$$

because the resulting pointwise-sum function is exactly $x \mapsto f(x) +_N (g(x) +_N h(x))$.

It remains to compare the two carried pointwise sums. By Definition 48.49, the $\mathsf{LinMap}^{\uparrow}(M,N)$ classifier is pointwise comparison in the target module classifier, together with the two carried map-code endpoints. The carried endpoint clauses are the two certificates for u and v just obtained.

Fix a carried source endpoint $x : M$. Unpacking the three input certificates by Definition 48.59, output closure for f, g, and h makes $f(x)$, $g(x)$, and $h(x)$ carried in N. By Definition 46.26, the

additive part of the target module is an $\mathsf{AbGroup}^{\uparrow}(N)$ certificate with the same operation $+_N$ and classifier $\sim_N$. The additive associativity row listed in Definition 42.8 therefore gives

$$(f(x) +_N g(x)) +_N h(x) \sim_N f(x) +_N (g(x) +_N h(x)).$$

By the definitions of u and v, this is exactly

$$u(x) \sim_N v(x).$$

Since x was arbitrary, Definition 48.49 packages these pointwise target comparisons, together with the two carried endpoint certificates, as

$$u \sim_{\mathsf{LinMap}^{\uparrow}(M,N)} v.$$

The ledger is the pair of binary pointwise-sum ledgers on each associated side supplied by Definition 48.66, plus the target additive-associativity ledger in the abelian-group reduct of N, matching Definition 48.51. □

Theorem 48.77 (Module LinearMap pointwise zero additive identity)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, and let M and N carry $\mathsf{Module}^{\uparrow}(R, M)$ and $\mathsf{Module}^{\uparrow}(R, N)$ certificates over the same scalar source. Write $\sim_N$ for the module classifier on N, write $+_N$ for module addition, and write 0_N for module zero. For functions $f, z : M \to N$, define $p, q : M \to N$ by*

$$p(x) := f(x) +_N z(x), \qquad q(x) := z(x) +_N f(x).$$

Assume that

$$\mathsf{LinearMapCert}_R(M, N; f)$$

holds, and assume that z is pointwise zero: for every carried $x : M$, the output $z(x)$ is carried in N and

$$z(x) \sim_N 0_N.$$

Then z, p, and q carry LinearMap certificates,

$$\mathsf{LinearMapCert}_R(M, N; z), \qquad \mathsf{LinearMapCert}_R(M, N; p), \qquad \mathsf{LinearMapCert}_R(M, N; q),$$

and the two pointwise sums are classified with f in $\mathsf{LinMap}^{\uparrow}(M, N)$:

$$p \sim_{\mathsf{LinMap}^{\uparrow}(M,N)} f \qquad \text{and} \qquad q \sim_{\mathsf{LinMap}^{\uparrow}(M,N)} f.$$

Equivalently, for every carried $x : M$,

$$f(x) +_N z(x) \sim_N f(x) \qquad \text{and} \qquad z(x) +_N f(x) \sim_N f(x).$$

The ten-field fit is: traditional target the additive identity law in $\mathrm{Hom}_R(M, N)$; BEDC source the displayed $\mathsf{LinearMapCert}_R(M, N; f)$ package and the pointwise-zero rows for z over common $\mathsf{Module}^{\uparrow}$ certificates; carrier the pointwise-zero map z and the two pointwise-sum functions p and q; classifier the pointwise target classifier from Definition 48.49; stability zero-map certification, pointwise-sum closure, and target additive unit laws; ledger the input function identifier, the pointwise-zero witnesses, the two pointwise-sum ledgers, and the left and right target additive-unit ledgers at each carried source endpoint; core theorem this block; exactness predicate the two displayed $\mathsf{LinMap}^{\uparrow}(M, N)$ classifier comparisons; standard bridge the usual zero identity law for module homomorphisms; status ProofTarget.

Proof. Apply Definition 48.75 to the pointwise-zero rows for z. This gives

$$\mathsf{LinearMapCert}_R(M, N; z).$$

Apply Definition 48.66 to the ordered pair (f, z). This gives the certificate for p. Apply the same pointwise-sum theorem to the ordered pair (z, f). This gives the certificate for q.

It remains to prove the two classifier comparisons with f. By Definition 48.49, the $\mathsf{LinMap}^{\uparrow}(M, N)$ classifier is pointwise comparison in the target module classifier, together with the carried map-code endpoints. The endpoint clauses are the certificate for f assumed above and the certificates for p and q just obtained.

Fix a carried source endpoint $x : M$. Unpacking the certificate for f through Definition 48.59, output closure makes $f(x)$ carried in N. The pointwise-zero hypothesis makes $z(x)$ carried in N and gives

$$z(x) \sim_N 0_N.$$

By Definition 46.26, the additive part of the target module is an $\mathsf{AbGroup}^{\uparrow}(N)$ certificate with the same operation $+_N$, zero 0_N, and classifier $\sim_N$. Classifier reflexivity for the carried endpoint $f(x)$, together with target additive congruence, gives

$$f(x) +_N z(x) \sim_N f(x) +_N 0_N.$$

The right additive-unit row in the retained abelian-group certificate gives

$$f(x) +_N 0_N \sim_N f(x).$$

Transitivity of the target classifier yields

$$p(x) = f(x) +_N z(x) \sim_N f(x).$$

Similarly, target additive congruence applied to $z(x) \sim_N 0_N$ and reflexivity of $f(x)$ gives

$$z(x) +_N f(x) \sim_N 0_N +_N f(x).$$

The left additive-unit row gives

$$0_N +_N f(x) \sim_N f(x),$$

and transitivity yields

$$q(x) = z(x) +_N f(x) \sim_N f(x).$$

Since x was arbitrary, Definition 48.49 packages these two families of target comparisons, together with the carried endpoint certificates, as

$$p \sim_{\mathsf{LinMap}^{\uparrow}(M,N)} f \qquad \text{and} \qquad q \sim_{\mathsf{LinMap}^{\uparrow}(M,N)} f.$$

The ledger is assembled from the zero-map certificate supplied by Definition 48.75, the two pointwise-sum certificates supplied by Definition 48.66, the target additive congruence rows, and the left and right additive-unit ledgers in the abelian-group reduct of N, matching Definition 48.51. □

Theorem 48.78 (Module LinearMap pointwise inverse sum zero classifier)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, and let M and N carry $\mathsf{Module}^{\uparrow}(R, M)$ and $\mathsf{Module}^{\uparrow}(R, N)$ certificates over the same scalar source. Write $\sim_N$ for the module classifier on N, $+_N$ for module addition, 0_N for module*

zero, and $-_N$ for target additive inverse. Let $f, z : M \to N$ be functions, and define $h, s, t : M \to N$ by

$$h(x) := -_N f(x), \qquad s(x) := f(x) +_N h(x), \qquad t(x) := h(x) +_N f(x).$$

Assume

$$\mathsf{LinearMapCert}_R(M, N; f)$$

and assume that z satisfies the zero-linear-map hypotheses of Definition 48.75: for every carried $x : M$, the output $z(x)$ is carried in N and

$$z(x) \sim_N 0_N.$$

Then the pointwise inverse and the two inverse sums carry certified linear-map packages

$$\mathsf{LinearMapCert}_R(M, N; h), \qquad \mathsf{LinearMapCert}_R(M, N; s), \qquad \mathsf{LinearMapCert}_R(M, N; t),$$

the zero map z carries a certified zero-linear-map package

$$\mathsf{LinearMapCert}_R(M, N; z),$$

and the two inverse sums are classified with z by the pointwise $\mathsf{LinMap}^{\uparrow}(M, N)$ classifier:

$$s \sim_{\mathsf{LinMap}^{\uparrow}(M,N)} z \qquad \text{and} \qquad t \sim_{\mathsf{LinMap}^{\uparrow}(M,N)} z.$$

Equivalently, for every carried $x : M$,

$$f(x) +_N (-_N f(x)) \sim_N 0_N \qquad \text{and} \qquad (-_N f(x)) +_N f(x) \sim_N 0_N,$$

and these pointwise zero rows classify both pointwise sums with every certified pointwise-zero representative z. The ten-field fit is: traditional target the additive inverse law in $\mathrm{Hom}_R(M, N)$; BEDC source the displayed $\mathsf{LinearMapCert}_R(M, N; f)$ package, the pointwise inverse construction, and the pointwise-zero witnesses for z; carrier the three functions h, s, and t; classifier the pointwise target classifier from Definition 48.49; stability pointwise inverse closure, pointwise-sum closure, target additive inverse laws, and zero-map classification; ledger the input function identifier, the inverse ledger, the two pointwise-sum ledgers, the target inverse-law ledgers at each carried source endpoint, and the zero-classifier comparison ledger; core theorem this block; exactness predicate the two displayed $\mathsf{LinMap}^{\uparrow}(M, N)$ classifier comparisons; standard bridge the usual equality $f + (-f) = 0 = (-f) + f$ in the additive group of module homomorphisms; status ProofTarget.

Proof. Apply Definition 48.68 to the input certificate for f. This gives

$$\mathsf{LinearMapCert}_R(M, N; h).$$

Apply Definition 48.66 to the ordered pair (f, h) and then to the ordered pair (h, f). This gives

$$\mathsf{LinearMapCert}_R(M, N; s) \qquad \text{and} \qquad \mathsf{LinearMapCert}_R(M, N; t).$$

It remains to identify these two certified sums with the chosen zero representative z. By Definition 48.80, it is enough to verify the zero-linear-map hypotheses for s and for t, because the same hypotheses are assumed for z.

Fix a carried source endpoint $x : M$. Unpacking the certificate for f through Definition 48.59, output closure makes $f(x)$ carried in N. The additive inverse closure row in the target module,

read through Definition 46.26, makes $h(x) = -_N f(x)$ carried. Target additive closure then makes both

$$s(x) = f(x) +_N h(x) \qquad \text{and} \qquad t(x) = h(x) +_N f(x)$$

carried in N.

The additive part of N is an $\mathsf{AbGroup}^{\uparrow}(N)$ certificate with the same $+_N$, 0_N, $-_N$, and $\sim_N$ by Definition 46.26. The right-inverse and left-inverse rows listed in Definition 42.8, applied to the carried endpoint $f(x)$, give

$$f(x) +_N (-_N f(x)) \sim_N 0_N \qquad \text{and} \qquad (-_N f(x)) +_N f(x) \sim_N 0_N.$$

By the definitions of h, s, and t, these are exactly

$$s(x) \sim_N 0_N \qquad \text{and} \qquad t(x) \sim_N 0_N.$$

Thus s and t satisfy the carried-output and pointwise-zero hypotheses of Definition 48.75.

Apply Definition 48.80 to the pair (s, z). The zero hypotheses for s are the rows just proved, and the zero hypotheses for z are assumed. This supplies the zero-linear-map certificate for z and the classifier comparison

$$s \sim_{\mathsf{LinMap}^{\uparrow}(M,N)} z.$$

Apply the same theorem to the pair (t, z). This supplies the classifier comparison

$$t \sim_{\mathsf{LinMap}^{\uparrow}(M,N)} z.$$

The certificate clauses for s and t are also the pointwise-sum certificates already obtained from Definition 48.66. The ledger is the inverse certificate ledger for h, the two pointwise-sum ledgers for s and t, the target additive inverse-law ledgers at each carried input, and the zero-classifier uniqueness ledger of Definition 48.80, matching Definition 48.51. □

Theorem 48.79 (Module zero LinearMap image is the zero fiber)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}$ certificate, and let M and N carry $\mathsf{Module}^{\uparrow}(R, M)$ and $\mathsf{Module}^{\uparrow}(R, N)$ certificates over the same scalar source. Write $\sim_N$ for the module classifier on N, and write 0_M and 0_N for the source and target zeros. Let $z : M \to N$ be a function satisfying the zero-linear-map hypotheses of Definition 48.75: for every carried $x : M$, the output $z(x)$ is carried in N and*

$$z(x) \sim_N 0_N.$$

Then z carries a certified linear-map package

$$\mathsf{LinearMapCert}_R(M, N; z),$$

and its image predicate from Definition 48.64 is exactly the target zero fiber. More precisely, for every endpoint $y : N$,

$$\mathsf{Im}_z(y) \Longrightarrow y \text{ is carried in } N \wedge y \sim_N 0_N,$$

and for every carried endpoint $y : N$,

$$y \sim_N 0_N \Longrightarrow \mathsf{Im}_z(y).$$

The ten-field fit is: traditional target the image of the zero module homomorphism is the zero submodule; BEDC source the displayed pointwise-zero hypotheses over common $\mathsf{Module}^{\uparrow}$ certificates;

carrier the image predicate Im_z*; classifier the target module classifier* $\sim_N$*; stability the carried target zero, carrier transport, and classifier symmetry and transitivity rows; ledger the source-zero witness* 0_M*, the pointwise zero row for* z*, and the image witness from Definition 48.64; core theorem this block; exactness predicate the equivalence between image membership and the target zero fiber on carried endpoints; standard bridge the ordinary statement* $\mathrm{im}(0) = \{0\}$ *for module homomorphisms; status* $\mathsf{ProofTarget}$*.*

Proof. Apply Definition 48.75 to the pointwise-zero hypotheses for z. This gives

$$\mathsf{LinearMapCert}_R(M, N; z).$$

Assume first that $\mathsf{Im}_z(y)$. By Definition 48.64, choose a carried source witness $x : M$ with

$$z(x) \sim_N y.$$

The pointwise-zero hypothesis gives that $z(x)$ is carried in N and gives

$$z(x) \sim_N 0_N.$$

Carrier transport for the target naming certificate in Definition 9.7, applied to $z(x) \sim_N y$, makes y carried in N. Classifier symmetry changes $z(x) \sim_N y$ into $y \sim_N z(x)$. Composing this with $z(x) \sim_N 0_N$ by Definition 9.8 gives

$$y \sim_N 0_N.$$

Thus image membership forces membership in the target zero fiber.

Conversely, let y be carried in N and assume

$$y \sim_N 0_N.$$

The source module certificate, unpacked through Definition 46.20, carries 0_M. Applying the pointwise-zero hypothesis at 0_M gives a carried target endpoint $z(0_M)$ and a comparison

$$z(0_M) \sim_N 0_N.$$

Classifier symmetry changes the assumed comparison into $0_N \sim_N y$. Transitivity in the target classifier then gives

$$z(0_M) \sim_N y.$$

The carried source endpoint 0_M, together with this comparison, is an image witness in the sense of Definition 48.64. Hence $\mathsf{Im}_z(y)$.

The two implications identify Im_z with the target zero fiber on carried target endpoints. The ledger uses one displayed image witness in the first direction and the distinguished carried source-zero witness in the second direction, together with the pointwise-zero row for z and the target classifier symmetry and transitivity rows, matching Definition 48.51. □

Theorem 48.80 (Module zero LinearMap classifier uniqueness)**.** *Let* R *carry a* $\mathsf{Ring}^{\uparrow}$ *scalar certificate, and let* M *and* N *carry* $\mathsf{Module}^{\uparrow}(R, M)$ *and* $\mathsf{Module}^{\uparrow}(R, N)$ *certificates over the same scalar source. Write* $\sim_N$ *for the codomain module classifier and* 0_N *for the codomain zero. Let* $z, z' : M \to N$ *be functions. Assume that both functions satisfy the zero-linear-map hypotheses of Definition 48.75: for every carried* $x : M$*, the outputs* $z(x)$ *and* $z'(x)$ *are carried in* N *and*

$$z(x) \sim_N 0_N \qquad \textit{and} \qquad z'(x) \sim_N 0_N.$$

Then both functions carry certified zero linear-map packages

$$\mathsf{LinearMapCert}_R(M, N; z) \qquad \textit{and} \qquad \mathsf{LinearMapCert}_R(M, N; z'),$$

and the pointwise $\mathsf{LinMap}^{\uparrow}(M, N)$ *classifier identifies them:*

$$z \sim_{\mathsf{LinMap}^{\uparrow}(M,N)} z'.$$

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapSingleton zero classifier uniqueness`

Proof. Apply Definition 48.75 to the pointwise zero witnesses for z. This gives $\mathsf{LinearMapCert}_R(M, N; z)$. Apply the same theorem to the pointwise zero witnesses for z'. This gives $\mathsf{LinearMapCert}_R(M, N; z')$.

It remains to compare the two carried map endpoints. By Definition 48.49, the $\mathsf{LinMap}^{\uparrow}(M, N)$ classifier is pointwise comparison in the codomain module classifier, together with the two carried linear-map endpoints just obtained.

Fix a carried source endpoint $x : M$. The hypotheses give

$$z(x) \sim_N 0_N \qquad \text{and} \qquad z'(x) \sim_N 0_N.$$

Classifier symmetry in the codomain $\mathsf{NameCert}$ changes the second comparison into $0_N \sim_N z'(x)$. Codomain transitivity, as recorded by Definition 9.8, composes it with $z(x) \sim_N 0_N$ and yields

$$z(x) \sim_N z'(x).$$

Since x was arbitrary, Definition 48.49 packages these pointwise codomain comparisons, together with the two certified endpoint packages, as

$$z \sim_{\mathsf{LinMap}^{\uparrow}(M,N)} z'.$$

The ledger is the pair of zero-linear-map ledgers supplied by Definition 48.75, plus the codomain classifier symmetry and transitivity witnesses, matching Definition 48.51. □

Definition 48.81 (LinearMap evaluation-graph carrier)**.** *Let F carry a $\mathsf{Field}^{\uparrow}(F)$ certificate, and let V and W carry $\mathsf{VecSpace}^{\uparrow}(F, V)$ and $\mathsf{VecSpace}^{\uparrow}(F, W)$ certificates over the same scalar source. A $\mathsf{LinMap}^{\uparrow}(V, W)$ evaluation-graph packet is a finite BHist family with the following rows:*

1. *a source vector-space row naming the carrier, addition, zero, additive inverse, scalar action, and classifier of V;*
2. *a target vector-space row naming the corresponding data of W;*
3. *an evaluation graph row G_f whose entries record carried source endpoints $x : V$, carried target endpoints $y : W$, and graph witnesses $f(x) \sim_W y$;*
4. *an additivity ledger row stating that every carried pair $x, u : V$ has a graph witness for $x +_V u$ whose target endpoint is classified with $f(x) +_W f(u)$;*
5. *a scalar-compatibility ledger row stating that every carried scalar $a : F$ and carried $x : V$ have a graph witness for $a \odot_V x$ whose target endpoint is classified with $a \odot_W f(x)$;*
6. *a pointwise classifier row comparing two such graph packets by target-classifier comparison at each carried source endpoint;*
7. *continuation rows showing that evaluation, additivity, and scalar-compatibility entries remain visible after the relevant Cont routes and context appends;*

8. *a* Pkg *provenance row recording the function identifier, the source and target vector-space packages, the three graph ledgers, and the finite history addresses used by the packet;*
9. *a* NameCert *row asserting reflexivity, symmetry, transitivity, carrier transport, and ledger exactness for the pointwise graph classifier.*

Theorem 48.82 (LinearMap evaluation-graph NameCert obligations)**.** *Every evaluation-graph packet of Definition 48.81 supplies the local* $\mathsf{LinMap}^{\uparrow}(V, W)$ *NameCert obligation surface: carrier admission for the map-code, pointwise classifier transport along the target* NameCert*, additivity stability, scalar-compatibility stability, and exact recovery of the displayed graph, additivity, scalar, continuation,* Pkg*, and naming ledgers. Conversely, any finite* BHist *packet carrying precisely those rows is admitted by the evaluation-graph carrier and determines the same pointwise* $\mathsf{LinMap}^{\uparrow}(V, W)$ *classifier.*

Proof. Carrier admission reads the source and target vector-space rows through the $\mathsf{VecSpace}^{\uparrow}$ certificates and then reads their module fragments through Definition 47.24. The output-closure part of the graph row gives the carried target endpoint for each carried source input, so the packet has the map-code carrier required by Definition 48.1.

Pointwise classifier transport is inherited from the target NameCert. For each carried source endpoint, the graph row gives a target classifier comparison, and Definition 48.49 packages those target comparisons as the $\mathsf{LinMap}^{\uparrow}(V, W)$ classifier. Reflexivity, symmetry, and transitivity are the pointwise rows isolated in Definition 48.55.

Additivity and scalar compatibility are the two stability ledgers. The additivity row is the same law used in Definition 48.50; the scalar row is the vector-space form of the module certificate in Definition 48.59. The zero and inverse consequences available in Definition 48.75, Definition 48.80, and Definition 48.69 show that no separate function-extensional equality is needed.

Finally, the continuation rows are checked by the singleton evaluation and composition continuation surfaces in Definition 48.38, Definition 48.39, and Definition 48.44. Since every public read is one of the listed BHist rows, the Pkg row and the NameCert row recover exactly the carrier, classifier, stability, and ledger fields of Definition 48.52. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapEvaluationGraphNameCertObligations`

Theorem 48.83 (LinearMap evaluation-graph composition closure)**.** *Let* F *carry a* $\mathsf{Field}^{\uparrow}(F)$ *certificate, and let* U*,* V*, and* W *carry* $\mathsf{VecSpace}^{\uparrow}(F, U)$*,* $\mathsf{VecSpace}^{\uparrow}(F, V)$*, and* $\mathsf{VecSpace}^{\uparrow}(F, W)$ *certificates over the same scalar source. If* G_f *is an accepted evaluation-graph packet for* $f : U \to V$ *and* G_g *is an accepted evaluation-graph packet for* $g : V \to W$*, with the target vector-space row of* G_f *matching the source vector-space row of* G_g*, then the* Cont*-spliced graph packet for* $g \circ f : U \to W$ *is an accepted evaluation-graph packet. Its pointwise classifier is the target classifier of* W*, its additivity ledger is the composite of the additivity ledgers of* G_f *and* G_g*, and its scalar-compatibility ledger is the composite of their scalar ledgers.*

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapEvaluationGraph composition closure`

Proof. The matching middle row identifies the target classifier and operations of the first packet with the source classifier and operations of the second packet. Thus every carried $u : U$ evaluated by G_f produces a carried middle endpoint in V, and the carrier-admission row of G_g evaluates that endpoint in W. Splicing the two Cont routes gives the graph row for $g(f(u))$.

For additivity, the first packet classifies $f(u +_U u')$ with $f(u) +_V f(u')$. The second packet transports that middle classifier comparison through its pointwise descent row and then applies its

own additivity ledger to classify $g(f(u) +_V f(u'))$ with $g(f(u)) +_W g(f(u'))$. The target NameCert in W composes these comparisons into the displayed additivity ledger for $g \circ f$.

The scalar row is parallel. The first packet classifies $f(a \odot_U u)$ with $a \odot_V f(u)$. The second packet transports along the shared middle classifier and applies scalar compatibility in the target vector space, yielding a comparison with $a \odot_W g(f(u))$.

All pointwise comparisons are recorded as target-classifier rows in W, so Definition 48.49 supplies the composite $\mathsf{LinMap}^{\uparrow}(U, W)$ classifier. The Pkg provenance is the ordered pair of input packet identifiers together with the spliced continuation address, and the exactness clause follows because no row outside the two accepted graph packets and their shared middle vector-space row is read. □

Theorem 48.84 (LinearMap evaluation-graph composition proof interface)**.** *Let F carry a $\mathsf{Field}^{\uparrow}(F)$ certificate, and let U, V, and W carry vector-space rows over the same scalar source. Suppose that G_f is an accepted evaluation-graph packet for $f : U \to V$, that G_g is an accepted evaluation-graph packet for $g : V \to W$, that the target vector-space row of G_f is* hsame *as the source vector-space row of G_g, that target-classifier transport is available in W, and that the displayed* Cont *provenance row splices the two graph reads through the shared middle row. Then these finite data determine exactly the nine rows of Definition 48.81 for $g \circ f$: the source vector-space row, the target vector-space row, the evaluation graph row, the additivity row, the scalar row, the pointwise target classifier row, the continuation row, the* Pkg *provenance row, and the naming row.*

Consequently the composite packet satisfies the local NameCert obligation surface of Definition 48.82.

Proof. The two accepted packets are finite BHist packets, so their source vector-space rows, target vector-space rows, additivity rows, scalar rows, target classifier rows, Cont rows, Pkg rows, and naming rows are already present as carried history rows. The hsame middle hypothesis identifies the target vector-space row of G_f with the source vector-space row of G_g, so the composite source row is read from G_f and the composite target row is read from G_g.

For the evaluation graph row, follow the Cont provenance from a carried source endpoint through G_f to the middle vector-space row and then through G_g to the target row of W. The target-classifier transport in W records the resulting pointwise classifier row for $g \circ f$.

For the additivity row, read the additivity row of G_f in the middle vector space, transport it across the shared target classifier row, and then read the additivity row of G_g in W. The scalar row is obtained by the same route, using the scalar rows of the two packets and the same target classifier row in W.

The Pkg row is the paired provenance of the two input packets together with the spliced Cont address, and the naming row records that this finite packet is the graph packet for $g \circ f$. These are exactly the nine rows specified by Definition 48.81, and Definition 48.83 supplies the accepted composite packet. Applying Definition 48.82 to those rows gives the stated local NameCert obligation surface. □

Lean4 ✓ `BEDC.Derived.LinearMapUp.LinearMapEvaluationGraphCompositionProofInterface`

Chapter 49

A Concrete Naming Certificate for $\mathsf{Mat}^{\uparrow}$

The matrix interface $\mathsf{Mat}^{\uparrow}$ has certificate obligations over a scalar ring from chapter 43 and two natural-number dimensions from chapter 28. The carrier is functions $\mathsf{Fin}(n) \times \mathsf{Fin}(m) \to R$; the classifier is pointwise scalar sameness on all index pairs. Matrix addition and multiplication are derived operations governed by the ring's certificate fields. It is not a primitive matrix type; it is admitted only as a derived function carrier.

49.1 Carrier definition

Definition 49.1 (Matrix carrier)**.** *Use functions* $\mathsf{Fin}(n) \times \mathsf{Fin}(m) \to R$ *with* $n, m : \mathsf{Nat}^{\uparrow}$ *and scalar ring* R*.*

Theorem 49.2 (Matrix singleton carrier visible exclusion)**.** *For every history* $p : \mathsf{BHist}$*, neither visible-headed history lies in the singleton matrix carrier:*

$$A_{\mathsf{e}}(\mathsf{E0}(p)) \to \bot \qquad \textit{and} \qquad A_{\mathsf{e}}(\mathsf{E1}(p)) \to \bot.$$

Proof. Unfold the singleton matrix carrier as history-sameness to e. The two displayed histories have visible BEDC constructors, and constructor separation rules out history-sameness between either visible endpoint and e. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonCarrier visible absurd`

49.2 Concrete singleton empty-history matrix instance

Definition 49.3 (Concrete singleton empty-history matrix instance)**.** *Let* A_{e} *be the singleton history source of Definition 36.169 at* $a_0 = \mathsf{e}$*. Use the classifier*

$$\rho_{\mathsf{e}}(h, k) \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h, k).$$

The row-dimension witness and column-dimension witness are both represented by the empty unary history e*. The scalar side is the singleton empty-history ring of Definition 43.5, and the row and column vector layers are read through the singleton empty-history vector-space instance of Definition 47.2.*

The matrix carrier is the same singleton source A_{e} on BHist *codes. Define the displayed matrix operations by*

$$0_M := \mathsf{e}, \qquad I_M := \mathsf{e}, \qquad M \oplus N := \mathsf{append}(M, N), \qquad M \odot N := \mathsf{append}(M, N).$$

The certificate fit has ten fields:

1. *Traditional target: the terminal singleton matrix algebra.*
2. *BEDC source:* BHist *together with the singleton ring and* $\mathsf{VecSpace}^{\uparrow}$ *layers.*
3. *Carrier choice:* A_{e}.
4. *Classifier choice:* ρ_{e}.
5. *Stability obligations: closure, zero laws, identity laws, associativity, and congruence for the displayed operations.*
6. *Ledger: the singleton endpoint together with row and column witnesses represented by* e.
7. *Core theorem list: Theorem 49.48.*
8. *Exactness predicate: singleton endpoint classification.*
9. *Standard bridge: the terminal matrix object.*
10. *Status:* ProofTarget.

Definition 49.4 (Matrix singleton power)**.** *For histories M and e,* $\mathsf{MatrixSingletonPow}(M, e)$ *is the concrete power ledger obtained by recursion over the exponent history: the empty exponent returns I_M, a one-headed exponent multiplies the previous ledger by M, and the zero-headed branch returns the singleton zero endpoint.*

Lean4 (definition) `BEDC.Derived.MatrixUp.MatrixSingletonPow`

Theorem 49.5 (Matrix singleton power empty-exponent classifier iff)**.** *For histories M, h :* BHist*, the singleton classifier of the empty exponent power ledger against h is exactly the singleton carrier condition on h:*

$$\mathsf{MatrixSingletonClassifier}(\mathsf{MatrixSingletonPow}(M, \mathsf{e}), h) \iff \mathsf{MatrixSingletonCarrier}(h).$$

Proof. The empty exponent branch of MatrixSingletonPow is $\mathsf{MatrixSingletonOne} = \mathsf{e}$. The forward implication reads the right carrier field from the classifier. Conversely, a singleton carrier witness for h combines with the empty carrier of e and symmetry of hsame to assemble the singleton classifier. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow empty exponent classifier iff`

Theorem 49.6 (Matrix singleton power zero-head exponent classifier iff)**.** *For histories M, e, h :* BHist*, the singleton classifier of a zero-headed exponent power ledger against h is exactly the singleton carrier condition on h:*

$$\mathsf{MatrixSingletonClassifier}(\mathsf{MatrixSingletonPow}(M, \mathsf{E0}(e)), h) \iff \mathsf{MatrixSingletonCarrier}(h).$$

Proof. The zero-headed exponent branch of MatrixSingletonPow is $\mathsf{MatrixSingletonZero} = \mathsf{e}$. The classifier therefore has the same right-endpoint readback as the empty singleton endpoint: forward projection gives the carrier of h, and the reverse direction repacks the empty carrier of e, the carrier of h, and the corresponding hsame comparison. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow zero head exponent classifier iff`

Theorem 49.7 (Matrix singleton power carrier closure)**.** *If M is carried by the singleton matrix carrier and e is unary, then the power ledger is again carried by the singleton matrix carrier:*

$$A_{\mathsf{e}}(M) \wedge \mathsf{Unary}(e) \quad \Longrightarrow \quad A_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(M, e)).$$

Proof. Proceed by induction on the unary exponent. The empty exponent returns $I_M = \mathsf{e}$, hence is carried by A_{e}. In the one-headed case, the induction hypothesis carries the previous power ledger, while the hypothesis carries M; the displayed multiplication is append, so append empty-result exactness carries the product ledger. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow carrier closed`

Theorem 49.8 (Matrix singleton power nonempty unary input carrier exactness)**.** *If the exponent e is unary and not history-same as* e*, then the singleton carrier condition on the power ledger is exactly the singleton carrier condition on the input matrix:*

$$\mathsf{Unary}(e) \wedge (\mathsf{hsame}(e, \mathsf{e}) \to \bot) \quad \Longrightarrow \quad (A_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(M, e)) \Longleftrightarrow A_{\mathsf{e}}(M)).$$

Proof. The unary, nonempty exponent has a one-headed form. In that branch the power ledger is the displayed append product of the previous power ledger and M. Append empty-result exactness therefore recovers $A_{\mathsf{e}}(M)$ from the carried power ledger. Conversely, carrier closure for singleton powers carries the power ledger from $A_{\mathsf{e}}(M)$ and $\mathsf{Unary}(e)$. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow carrier nonempty unary input iff`

Theorem 49.9 (Matrix singleton positive power continuation result carrier iff)**.** *Let M, e, y, r :* BHist*. If e is unary and not history-same to* e*, and if* $\mathsf{Cont}(\mathsf{MatrixSingletonPow}(M, e), y, r)$*, then the displayed continuation result is carried exactly when both the base matrix and the right continuation input are carried:*

$$A_{\mathsf{e}}(r) \Longleftrightarrow A_{\mathsf{e}}(M) \wedge A_{\mathsf{e}}(y).$$

Proof. For the forward direction, transport the continuation result to e and invert empty continuation results. This gives carrier witnesses for the power source and for y; positive-exponent power carrier exactness recovers $A_{\mathsf{e}}(M)$ from the power source carrier. Conversely, $A_{\mathsf{e}}(M)$ carries the positive power source, and together with $A_{\mathsf{e}}(y)$ append empty-result exactness identifies the displayed continuation result with e. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow positive exponent continuation result carrier iff`

Theorem 49.10 (Matrix singleton power positive exponent classifier iff)**.** *Let M, e, h :* BHist*. If e is unary and not history-same to* e*, then the singleton classifier of the positive power ledger against h is exactly the pair of singleton carrier conditions on the base and the displayed endpoint:*

$$\mathsf{MatrixSingletonClassifier}(\mathsf{MatrixSingletonPow}(M, e), h) \Longleftrightarrow \mathsf{MatrixSingletonCarrier}(M) \wedge \mathsf{MatrixSingletonCarrier}(h).$$

Proof. The forward direction reads the carried power endpoint from the classifier and uses positive-exponent carrier exactness to recover the singleton carrier of M; the right endpoint carrier is already part of the classifier. Conversely, the singleton carrier of M and unary exponent closure carry the positive power ledger, and the carried endpoint h completes the singleton classifier by transitivity through e. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow positive exponent classifier iff`

Theorem 49.11 (Matrix singleton power nonempty unary suffix base carrier)**.** *If tail is unary and not history-same as* e*, then a singleton carrier witness for the power ledger over* $\mathsf{append}(e, tail)$ *recovers the base matrix carrier:*

$$\mathsf{Unary}(tail) \wedge (\mathsf{hsame}(tail, \mathsf{e}) \to \bot) \wedge A_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(M, \mathsf{append}(e, tail))) \quad \Longrightarrow \quad A_{\mathsf{e}}(M).$$

Proof. The unary, nonempty suffix cannot be e and cannot start with $\mathsf{E0}$. Thus it has the form $\mathsf{E1}(t)$, so the appended exponent also exposes a one-headed power branch. In that branch the power ledger is the append product of the previous power ledger and M, and append empty-result inversion projects the right factor carrier $A_{\mathsf{e}}(M)$. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow nonempty unary suffix base carrier`

Theorem 49.12 (Matrix singleton positive-exponent continuation readback)**.** *If the exponent* e *is unary and not history-same as* e*, then its one-headed tail exposes the concrete successor continuation for the power ledger:*

$$\mathsf{Unary}(e) \wedge (\mathsf{hsame}(e, \mathsf{e}) \to \bot) \quad \Longrightarrow \quad \exists t.\ \mathsf{Unary}(t) \wedge \mathsf{Cont}(\mathsf{MatrixSingletonPow}(M, t), M, \mathsf{MatrixSingletonPow}(M, e)).$$

Proof. Unary nonempty histories have a one-headed tail. In that branch the recursive definition of $\mathsf{MatrixSingletonPow}$ is the append product of the predecessor power ledger with M, so the continuation is the displayed append step. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow positive exponent cont readback`

Theorem 49.13 (Matrix singleton unary exponent cases)**.** *For a unary exponent, the singleton power ledger has exactly the BEDC empty-or-successor shape needed for power readback: the empty exponent classifies the power ledger against* I_M*, while a one-headed exponent exposes a unary tail and the displayed continuation by the base matrix:*

$$\rho_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(M, e), I_M) \quad \vee \quad \exists t.\ \mathsf{Unary}(t) \wedge \mathsf{Cont}(\mathsf{MatrixSingletonPow}(M, t), M, \mathsf{MatrixSingletonPow}(M, e)$$

Proof. Inspect the exponent history. The empty case unfolds to $I_M = \mathsf{e}$ and closes by singleton classifier reflexivity. The zero-headed case is impossible for a unary exponent. The one-headed case returns its tail and the defining append continuation of $\mathsf{MatrixSingletonPow}$. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow unary exponent cases`

Theorem 49.14 (Matrix singleton unary exponent carrier or base carrier)**.** *If a unary-exponent power ledger is singleton-carried, then either the exponent is the empty history or the base matrix itself is singleton-carried:*

$$\mathsf{Unary}(e) \wedge A_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(M, e)) \Longrightarrow \mathsf{hsame}(e, \mathsf{e}) \vee A_{\mathsf{e}}(M).$$

Proof. Inspect the unary exponent. The empty branch supplies $\mathsf{hsame}(e, \mathsf{e})$. The zero-headed branch contradicts unary membership. In the one-headed branch the power ledger unfolds as an append product whose right factor is M; append empty-result inversion projects the singleton carrier of M. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow unary exponent carrier or base carrier`

Theorem 49.15 (Matrix singleton positive-exponent empty continuation base carrier)**.** *If e is unary and not history-same as* e*, and a continuation from* $\mathsf{MatrixSingletonPow}(M, e)$ *has result history-same to* e*, then the base matrix M lies in the singleton matrix carrier:*

$$A_{\mathsf{e}}(M).$$

Proof. Transport the continuation result to the concrete empty endpoint and invert the empty-result continuation. This carries the power ledger itself by A_{e}. The nonempty unary power carrier exactness theorem then reads the carriedness of the base matrix M back from the carried power ledger. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow positive exponent empty continuation base carrier`

Theorem 49.16 (Matrix singleton positive-tail empty continuation factors)**.** *Suppose depth is unary and depth* $= \mathsf{E1}(tail)$*. If a continuation from* $\mathsf{MatrixSingletonPow}(M, depth)$ *has result history-same as* e*, then the predecessor power, the base matrix, and the continuation argument are all singleton-carried:*

$$\mathsf{Cont}(\mathsf{MatrixSingletonPow}(M, depth), y, r) \wedge r\mathsf{hsamee} \Longrightarrow A_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(M, tail)) \wedge A_{\mathsf{e}}(M) \wedge A_{\mathsf{e}}(y).$$

Proof. Transport the continuation result to e and invert the empty-result continuation. The source is the one-headed power branch, hence the append of $\mathsf{MatrixSingletonPow}(M, tail)$ with M. Empty append inversion gives the predecessor carrier and the base carrier, while continuation inversion also gives the carriedness of y. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow positive tail empty continuation factors`

Theorem 49.17 (Matrix singleton power append positive suffix continuation readback)**.** *If $suffix$ is unary and not history-same as* e*, then the power ledger over* $\mathsf{append}(pref, suffix)$ *exposes the successor continuation at the same prefix:*

$$\exists tail.\ \mathsf{Unary}(tail) \wedge \mathsf{Cont}(\mathsf{MatrixSingletonPow}(M, \mathsf{append}(pref, tail)), M, \mathsf{MatrixSingletonPow}(M, \mathsf{append}(pref, suffi$$

Proof. Unary nonempty suffixes have a one-headed tail. After substituting $suffix = \mathsf{E1}(tail)$, the appended exponent is itself one-headed with payload $\mathsf{append}(pref, tail)$. The recursive power ledger therefore unfolds to the displayed continuation by M. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow append positive suffix cont readback`

Theorem 49.18 (Matrix singleton power append positive suffix classifier readback)**.** *If M is carried by the singleton matrix carrier, $pref$ and $suffix$ are unary, and $suffix$ is not history-same as* e*, then the append-positive suffix readback supplies a unary tail whose successor multiplication classifies the original appended power ledger:*

$$\exists tail.\ \mathsf{Unary}(tail) \wedge \rho_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(M, \mathsf{append}(pref, suffix)), \mathsf{MatrixSingletonMul}(\mathsf{MatrixSingletonPow}(M, \mathsf{a}$$

Proof. The positive-suffix readback exposes a unary tail and the continuation from $\mathsf{MatrixSingletonPow}(M, \mathsf{append}($ by M to the original appended power ledger. Carrier closure gives the source power carrier, and append empty-result exactness carries the displayed multiplication endpoint. The continuation equation gives the classifier comparison. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow append positive suffix classifier readback`

Theorem 49.19 (Matrix singleton power append positive suffix classifier exact carrier criterion)**.** *If $pref$ and $suffix$ are unary histories and $suffix$ is not history-same as* e*, then the singleton classifier of the append-positive power ledger against h is exactly the pair of singleton carrier facts for M and h:*

$$\rho_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(M, \mathsf{append}(pref, suffix)), h) \iff A_{\mathsf{e}}(M) \wedge A_{\mathsf{e}}(h).$$

Proof. The forward direction reads the carriedness of h from the classifier and applies nonempty unary suffix base-carrier readback to the carried power ledger. Conversely, unary append closure carries the appended power from $A_{\mathsf{e}}(M)$, and the two singleton carrier witnesses compare the endpoints through e. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow append positive suffix classifier iff`

Theorem 49.20 (Matrix singleton power successor classifier)**.** *For histories M, e :* BHist*, if M is carried by the singleton matrix carrier and e is unary, then the one-headed power ledger is classified against the displayed successor multiplication:*

$$A_{\mathsf{e}}(M) \wedge \mathsf{Unary}(e) \quad \Longrightarrow \quad \rho_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(M, \mathsf{E1}(e)), \mathsf{MatrixSingletonMul}(\mathsf{MatrixSingletonPow}(M, e), M)).$$

Proof. The one-headed power branch unfolds to the displayed multiplication endpoint. The carrier closure theorem carries the predecessor power ledger, and the input hypothesis carries M. Since multiplication is append, append empty-result exactness carries the displayed multiplication endpoint, and reflexivity of hsame supplies the classifier comparison. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow succ classifier`

Theorem 49.21 (Matrix singleton power successor continuation classifier)**.** *For histories M, e, r :* BHist*, if M is carried by the singleton matrix carrier, e is unary, and*

$$\mathsf{Cont}(\mathsf{MatrixSingletonPow}(M, e), M, r),$$

then the one-headed power ledger is classified against r:

$$\rho_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(M, \mathsf{E1}(e)), r).$$

Proof. Carrier closure carries the predecessor power ledger. Together with the carrier of M, append empty-result exactness carries the one-headed power endpoint. The displayed continuation identifies r with the same append endpoint, so r is carried by the singleton matrix carrier and is hsame to the one-headed power ledger. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow succ continuation classifier`

Theorem 49.22 (Matrix singleton power visible-base successor continuation empty-result absurd)**.** *For any singleton-carried continuation right input y, a successor power whose base has a visible head cannot continue to the empty result:*

$$\mathsf{Cont}(\mathsf{MatrixSingletonPow}(\mathsf{E0}(m), \mathsf{E1}(e)), y, r) \wedge r\mathsf{hsamee} \Longrightarrow \bot,$$

and the same statement holds with $\mathsf{E1}(m)$ *in place of* $\mathsf{E0}(m)$*.*

Proof. Transport the displayed continuation along $r\mathsf{hsamee}$ and invert the empty continuation result. The source side is the successor power endpoint, which unfolds to an append whose right factor is the visible base. Append empty-result inversion would identify $\mathsf{E0}(m)$, respectively $\mathsf{E1}(m)$, with e, contradicting BEDC constructor separation. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow visible base succ continuation empty result absurd`

Theorem 49.23 (Matrix singleton power positive-exponent visible-base empty-result exclusion)**.** *For unary nonempty exponent e, a singleton matrix power whose base has a visible head cannot continue to an empty result:*

$$\mathsf{Cont}(\mathsf{MatrixSingletonPow}(\mathsf{E0}(m), e), y, r) \wedge r\mathsf{hsamee} \Longrightarrow \bot,$$

and the same statement holds with $\mathsf{E1}(m)$ in place of $\mathsf{E0}(m)$.

Proof. Transport the continuation along $r\mathsf{hsamee}$ and invert the empty result. The nonempty-unary power carrier exactness theorem then turns the empty power endpoint into a singleton carrier witness for the visible base, contradicting constructor separation. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow positive exponent visible base continuation empty result absurd`

Theorem 49.24 (Matrix singleton power visible-base appended positive-suffix empty-result exclusion)**.** *If $pref$ and $suffix$ are unary histories and $suffix \not\mathsf{hsamee}$, then neither visible-base singleton power over $\mathsf{append}(pref, suffix)$ can continue to an empty result:*

$$\mathsf{Cont}(\mathsf{MatrixSingletonPow}(\mathsf{E0}(m), \mathsf{append}(pref, suffix)), y, r) \wedge r\mathsf{hsamee} \Longrightarrow \bot,$$

and the same statement holds with $\mathsf{E1}(m)$ in place of $\mathsf{E0}(m)$.

Proof. Unary append closure makes $\mathsf{append}(pref, suffix)$ a unary exponent. If that exponent were empty, append empty-result exactness would force $suffix\mathsf{hsamee}$, contrary to the positive-suffix hypothesis. The positive-exponent visible-base carrier exclusion therefore rules out the source carrier recovered by transporting the continuation result to e and inverting the empty continuation. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow visible base append positive suffix continuation empty result absurd`

Theorem 49.25 (Matrix singleton power nonempty-base empty-result exclusion)**.** *For unary nonempty exponent e, if the base matrix M is not singleton-carried, then*

$$\mathsf{Cont}(\mathsf{MatrixSingletonPow}(M, e), y, r) \wedge r\mathsf{hsamee} \Longrightarrow \bot.$$

Proof. Transport the continuation result to e and invert the empty continuation. The source carrier for $\mathsf{MatrixSingletonPow}(M, e)$ transfers through positive-unary power exactness to a singleton carrier witness for M, contradicting the base non-carrier hypothesis. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow nonempty base continuation result absurd`

Theorem 49.26 (Matrix singleton power append exponent classifier)**.** *If M is carried by the singleton matrix carrier and w, q are unary histories, then the power ledger over the appended exponent is classified with the product of the two factor power ledgers:*

$$A_{\mathsf{e}}(M) \wedge \mathsf{Unary}(w) \wedge \mathsf{Unary}(q) \quad \Longrightarrow \quad \rho_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(M, \mathsf{append}(w, q)), \mathsf{MatrixSingletonMul}(\mathsf{MatrixSingleton}$$

Proof. Append closure makes $\mathsf{append}(w, q)$ unary, so power carrier closure carries the left ledger. The same closure carries each factor ledger; append empty-result exactness then carries their displayed product. Since both endpoints are carried by A_{e}, transitivity through e supplies the classifier comparison. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow append exponent classifier`

Theorem 49.27 (Matrix singleton power append successor right exponent classifier)**.** *If M is carried by the singleton matrix carrier and w, q are unary histories, then the append exponent with right successor is classified by the left power and the nested right multiplication endpoint:*

$$\rho_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(M, \mathsf{append}(w, \mathsf{E1}(q))), \mathsf{MatrixSingletonMul}(\mathsf{MatrixSingletonPow}(M, w), \mathsf{MatrixSingletonMul}(\mathsf{M}$$

Proof. Unary closure carries $\mathsf{append}(w, \mathsf{E1}(q))$. Singleton power closure carries the composite power, the left power, and the right predecessor power. Append empty-result exactness carries the inner multiplication by M and then the outer multiplication by the left power. Since both endpoints are carried by A_{e}, transitivity through e supplies the classifier comparison. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow append succ right exponent classifier`

Theorem 49.28 (Matrix singleton power append exponent commuted classifier)**.** *If M is carried by the singleton matrix carrier and w, q are unary histories, then the two power ledgers obtained by the two append orders of the exponent histories are singleton-classified:*

$$A_{\mathsf{e}}(M) \wedge \mathsf{Unary}(w) \wedge \mathsf{Unary}(q) \quad \Longrightarrow \quad \rho_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(M, \mathsf{append}(w, q)), \mathsf{MatrixSingletonPow}(M, \mathsf{append}(q, w$$

Proof. Unary append closure makes both $\mathsf{append}(w, q)$ and $\mathsf{append}(q, w)$ unary. Singleton power carrier closure carries both power ledgers from $A_{\mathsf{e}}(M)$. Since both endpoints are carried by A_{e}, transitivity through e supplies the classifier comparison. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow append exponent comm classifier`

Theorem 49.29 (Matrix singleton power append exponent classifier iff)**.** *If M is carried by the singleton matrix carrier and a, b are unary histories, then the classifier of the append-exponent power ledger against h is exactly the singleton carrier condition on h:*

$$\mathsf{MatrixSingletonClassifier}(\mathsf{MatrixSingletonPow}(M, \mathsf{append}(a, b)), h) \Longleftrightarrow \mathsf{MatrixSingletonCarrier}(h).$$

Proof. Unary closure under append makes $\mathsf{append}(a, b)$ a unary exponent. The power carrier theorem therefore carries $\mathsf{MatrixSingletonPow}(M, \mathsf{append}(a, b))$. The forward direction reads the right carrier field from the classifier. In the reverse direction, that carried power endpoint and the carrier witness for h assemble the restricted singleton classifier. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow append exponent classifier iff`

Theorem 49.30 (Matrix singleton power successor endpoint exactness)**.** *For histories* M, e : BHist*, if* $A_{\mathsf{e}}(M)$ *and* $\mathsf{Unary}(e)$*, then the successor power is carried:*

$$A_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(M, \mathsf{E1}(e))).$$

Moreover, the successor power is exactly classified with both displayed singleton multiplication endpoints:

$$\rho_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(M, \mathsf{E1}(e)), \mathsf{MatrixSingletonPow}(M, e) \odot M) \quad \textit{and} \quad \rho_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(M, \mathsf{E1}(e)), M \odot \mathsf{Ma}$$

Proof. Unfold the one-headed exponent clause of $\mathsf{MatrixSingletonPow}$. The successor ledger is the displayed singleton product $\mathsf{MatrixSingletonPow}(M, e) \odot M$.

The carrier closure theorem for powers gives $A_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(M, e))$ from $A_{\mathsf{e}}(M)$ and $\mathsf{Unary}(e)$. Combining this carrier with $A_{\mathsf{e}}(M)$, the singleton multiplication closure in Theorem 49.48 carries both append endpoints $\mathsf{MatrixSingletonPow}(M, e) \odot M$ and $M \odot \mathsf{MatrixSingletonPow}(M, e)$.

For the first classifier, the unfolded successor ledger is the same append endpoint, so the singleton classifier closes by reflexivity and the carried endpoint witness. For the second classifier, both append endpoints classify as empty singleton endpoints; transitivity through e compares them and supplies ρ_{e}. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow succ endpoint exactness`
Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow successor endpoint exactness`

Definition 49.31 (Matrix singleton identity-power concrete instance)**.** *The concrete identity-power schema for* $\mathsf{Mat}^{\uparrow}$ *uses* $\mathsf{MatrixSingletonCarrier}$ *as carrier,* $\mathsf{MatrixSingletonClassifier}$ *as classifier,* $\mathsf{UnaryHistory}$ *as the exponent carrier, and* $\mathsf{MatrixSingletonPow}$ *as the action. Its source rows are the singleton matrix carrier row for the base, the unary history row for the exponent, the empty-exponent identity row, and the successor-step multiplication row over the singleton power ledger.*

Theorem 49.32 (Matrix singleton identity-power law)**.** *For the concrete instance of Definition 49.31, the empty exponent acts as the singleton identity endpoint, unary exponents preserve the singleton matrix carrier, and the successor exponent is classified by the displayed multiplication step:*

$$\mathsf{MatrixSingletonClassifier}(\mathsf{MatrixSingletonPow}(M, \mathsf{e}), h) \iff \mathsf{MatrixSingletonCar}$$
$$\mathsf{MatrixSingletonCarrier}(M) \wedge \mathsf{UnaryHistory}(e) \implies \mathsf{MatrixSingletonCarrier}(\mathsf{MatrixSingleto}$$
$$\mathsf{MatrixSingletonCarrier}(M) \wedge \mathsf{UnaryHistory}(e) \implies \mathsf{MatrixSingletonClassifier}(\mathsf{MatrixSingletonPow}(M, \mathsf{E1}(e)), \mathsf{MatrixSin}$$

Thus the singleton power rows expose a concrete BHist *carrier and action surface for* $\mathsf{Mat}^{\uparrow}$ *rather than only an abstract operator schema.*

Proof. The empty-exponent identity row is exactly Definition 49.5. It unfolds the empty branch of $\mathsf{MatrixSingletonPow}$ to the singleton identity endpoint and identifies its classifier with the carrier condition on the comparison endpoint.

Carrier closure under unary exponents is Definition 49.7. It gives the carried power ledger from a singleton-carried base and a unary exponent, so the action stays inside $\mathsf{MatrixSingletonCarrier}$.

The successor step is Definition 49.20, strengthened by Definition 49.30. These rows classify the one-headed exponent ledger by the displayed singleton multiplication endpoint, completing the concrete carrier/action schema. □

Theorem 49.33 (Matrix singleton identity-power schema handoff)**.** *The data* MatrixSingletonCarrier*,* MatrixSingletonClassifier*,* UnaryHistory*, and* MatrixSingletonPow *provide the concrete* $\mathsf{Mat}^{\uparrow}$ *power schema handoff consumed by algebra and control chapters. The handoff exports the base carrier, exponent carrier, identity endpoint, unary power closure, successor endpoint, classifier,* hsame *transport,* Cont*, and* Pkg *rows as finite* BHist *rows.*

Proof. The instance data are exactly the four fields named in Definition 49.31. The law in Definition 49.32 identifies the empty exponent with the singleton identity endpoint, proves unary carrier closure, and records the successor action through the displayed multiplication row.

The carrier component is closed by Definition 49.7. The successor endpoint is exact by Definition 49.30. Therefore each exported row is a BHist, hsame, Cont, or Pkg row already present in the concrete singleton packet, so downstream algebra and control consumers receive a finite carrier/action handoff rather than abstract matrix-power parameters. □

Theorem 49.34 (Matrix singleton classifier append split empty)**.** *For* $M, N, h : \mathsf{BHist}$*,*

$$\rho_{\mathsf{e}}(\mathsf{append}(M, N), h) \iff M\mathsf{hsamee} \wedge N\mathsf{hsamee} \wedge A_{\mathsf{e}}(h).$$

Proof. The forward direction reads the left carrier component of $\rho_{\mathsf{e}}(\mathsf{append}(M, N), h)$ as $\mathsf{append}(M, N)\mathsf{hsamee}$. Empty-result inversion for append splits this endpoint witness into $M\mathsf{hsamee}$ and $N\mathsf{hsamee}$, while the right carrier component supplies $A_{\mathsf{e}}(h)$.

Conversely, $M\mathsf{hsamee}$ and $N\mathsf{hsamee}$ reconstruct the singleton carrier witness for $\mathsf{append}(M, N)$. Together with $A_{\mathsf{e}}(h)$, transitivity of hsame through e gives the classifier comparison. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonClassifier append split empty iff`

Theorem 49.35 (Matrix singleton add-mul classifier iff)**.** *For* $M, N : \mathsf{BHist}$*, the singleton matrix classifier relates the displayed addition and multiplication results exactly when both inputs are singleton empty endpoints:*

$$\rho_{\mathsf{e}}(M \oplus N, M \odot N) \iff M\mathsf{hsamee} \wedge N\mathsf{hsamee}.$$

Proof. Both displayed operations are the same BEDC append spine $\mathsf{append}(M, N)$. In the forward direction, the left carrier component of $\rho_{\mathsf{e}}(M \oplus N, M \odot N)$ says that this append spine is hsame to e. Empty-result inversion for append splits it into the two endpoint witnesses $M\mathsf{hsamee}$ and $N\mathsf{hsamee}$.

Conversely, the two endpoint witnesses reconstruct the singleton carrier for $\mathsf{append}(M, N)$. Since $M \oplus N$ and $M \odot N$ unfold to that same append spine, reflexivity of hsame supplies the classifier relation between the displayed operation results. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddMul classifier iff`

Theorem 49.36 (Matrix singleton add-mul continuation result iff)**.** *For singleton-carrier inputs* M *and* N*, a continuation from the displayed addition result to the displayed multiplication result has result* R *exactly when* R *is itself a singleton carrier:*

$$\mathsf{Cont}(M \oplus N, M \odot N, R) \iff A_{\mathsf{e}}(R).$$

Proof. The two displayed operations both unfold to the same append spine $\mathsf{append}(M, N)$. The singleton witnesses for M and N collapse that spine to e. The forward direction compares the displayed continuation with the right-unit continuation at e; the reverse direction transports the result carrier back to that same empty continuation. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddMul continuation result iff`

Theorem 49.37 (Matrix singleton add-mul continuation empty-result factors)**.** *For histories* $M, N, R : \mathsf{BHist}$*, if* $\mathsf{Cont}(M \oplus N, M \odot N, R)$*, then the displayed continuation result is empty exactly when both matrix inputs are empty:*

$$R\mathsf{hsamee} \iff M\mathsf{hsamee} \wedge N\mathsf{hsamee}.$$

Proof. For the forward direction, transport the displayed continuation along $R\mathsf{hsamee}$ and invert the empty continuation result. The source factor is $M \oplus N$, which unfolds to $\mathsf{append}(M, N)$, so append empty-result inversion gives $M\mathsf{hsamee}$ and $N\mathsf{hsamee}$.

Conversely, the two input endpoint witnesses collapse both displayed operations to the empty history. Continuation determinacy compares the given continuation with the BEDC right-unit continuation at e, identifying the result with e. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddMul continuation empty result factors iff`

Theorem 49.38 (Matrix singleton multiplication continuation result carrier)**.** *For histories* $M, N, h, r : \mathsf{BHist}$*, any continuation from* h *through the singleton multiplication endpoint has singleton result exactly when the source and both multiplication inputs are singleton carriers:*

$$\mathsf{Cont}(h, M \odot N, r) \Longrightarrow (A_{\mathsf{e}}(r) \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(M) \wedge A_{\mathsf{e}}(N)).$$

Proof. In the forward direction, transport the displayed continuation result along $r\mathsf{hsamee}$ and invert the empty continuation result. The target endpoint is $M \odot N$, which unfolds to $\mathsf{append}(M, N)$, so append empty-result inversion supplies the two multiplication input carriers. The same continuation inversion supplies the source carrier.

Conversely, the source carrier and the two multiplication input carriers collapse the target endpoint to e. Continuation respect for hsame compares the displayed continuation with the right-unit continuation at e, giving the singleton result carrier. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonMulContinuation result carrier iff`

Definition 49.39 (Matrix singleton entry projection package)**.** *The matrix singleton entry projection package fixes the matrix carrier to* A_{e}*, fixes the matrix classifier to* ρ_{e}*, and reads the displayed row and column dimensions from the* $\mathsf{Nat}^{\uparrow}$ *rows already carried by the singleton matrix instance. Its entry projection operation sends every carried unary row to the* BHist *endpoint* e*.*

Theorem 49.40 (Matrix singleton entry projection laws)**.** *In the matrix singleton entry projection package, every projected entry of a carried singleton matrix is carried by* A_{e}*. Projected entries are stable under* ρ_{e} *and under the displayed* hsame *ledger. Moreover, the projected entries of the displayed singleton addition result and of the displayed singleton multiplication result are classified with* e*.*

Proof. Unfold the package. The carrier is A_{e}, the classifier is ρ_{e}, and every entry projection is the constant endpoint e on the carried unary rows. Hence each projected entry is immediately an A_{e} entry and is related to the singleton endpoint by ρ_{e}.

For stability, use the definition of ρ_{e} together with the displayed hsame ledger. Transporting a carried singleton matrix along ρ_{e} keeps the projected endpoint equal to e, so the projected entry remains in the same singleton classifier row.

For the displayed addition and multiplication results, apply Definition 49.36, Definition 49.37, and Definition 49.38. The local continuation laws identify the result endpoints with A_{e}, and the constant entry projection classifies their projected entries with e. No function-space carrier or Fin-indexed matrix carrier is introduced. □

Theorem 49.41 (Matrix singleton add-mul visible-left continuation result nonempty)**.** *For any histories m, N, R, if the shared left input of the displayed singleton addition and multiplication has a visible head, then a continuation from the addition endpoint to the multiplication endpoint cannot have empty result:*

$$\mathsf{Cont}(\mathsf{E0}(m) \oplus N, \mathsf{E0}(m) \odot N, R) \wedge R\mathsf{hsamee} \Longrightarrow \bot,$$

and the same statement holds with $\mathsf{E1}(m)$ in place of $\mathsf{E0}(m)$.

Proof. Apply the continuation empty-result factor theorem for displayed singleton addition and multiplication. An empty result forces the left input factor to be empty. This contradicts constructor separation for $\mathsf{E0}(m)$ in the first case and for $\mathsf{E1}(m)$ in the second case. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddMul visible left continuation result nonempty`

Theorem 49.42 (Matrix singleton classifier visible right append exclusion)**.** *For histories h, p, q : BHist, a singleton matrix classifier witness cannot target an append whose right factor has a visible head:*

$$\rho_{\mathsf{e}}(h, \mathsf{append}(p, \mathsf{e0}(q))) \to \bot \qquad \textit{and} \qquad \rho_{\mathsf{e}}(h, \mathsf{append}(p, \mathsf{e1}(q))) \to \bot.$$

Proof. Unfold the singleton matrix classifier. A classifier witness supplies the target carrier endpoint $\mathsf{append}(p, \mathsf{e0}(q))\mathsf{hsamee}$ in the first case, or $\mathsf{append}(p, \mathsf{e1}(q))\mathsf{hsamee}$ in the second case. Empty-result inversion for append forces the visible right factor itself to be e, contradicting the disjointness of each visible constructor from e. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonClassifier append visible right absurd`

Theorem 49.43 (Matrix singleton classifier append pair carrier)**.** *For M, N, P, Q : BHist,*

$$\rho_{\mathsf{e}}(\mathsf{append}(M, N), \mathsf{append}(P, Q)) \quad \Longleftrightarrow \quad A_{\mathsf{e}}(M) \wedge A_{\mathsf{e}}(N) \wedge A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q).$$

Proof. The classifier exposes singleton carrier witnesses for both append endpoints. Empty-result inversion for append splits these witnesses into the four displayed endpoint carriers. Conversely, the four endpoint carriers rebuild the two empty append endpoints, and transitivity of hsame through e supplies the classifier comparison between them. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonClassifier append pair carrier iff`

Theorem 49.44 (Matrix singleton classifier self-context split)**.** *For histories a, x, b : BHist,*

$$\rho_{\mathsf{e}}(\mathsf{append}(a, \mathsf{append}(x, a)), b) \Longleftrightarrow A_{\mathsf{e}}(a) \wedge \rho_{\mathsf{e}}(x, b).$$

Proof. The forward implication splits the source carrier of the classifier twice by empty-result inversion for append. This gives the carrier witness for the repeated context a and the carrier witness for the middle history x; the target carrier field and transitivity through e rebuild $\rho_{\mathsf{e}}(x, b)$.

Conversely, the carrier for a and the source carrier inside $\rho_{\mathsf{e}}(x, b)$ rebuild the inner and outer empty append endpoints. The target carrier is inherited from $\rho_{\mathsf{e}}(x, b)$, and both endpoints compare through the empty history. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonClassifier append self context split iff`

Theorem 49.45 (Matrix singleton classifier append-left cancellation)**.** *For histories* P, Q, R : BHist*,*

$$\rho_{\mathsf{e}}(\mathsf{append}(R, P), \mathsf{append}(R, Q)) \iff A_{\mathsf{e}}(R) \wedge \rho_{\mathsf{e}}(P, Q).$$

Proof. In the forward direction, the two carrier fields say that $\mathsf{append}(R, P)$ and $\mathsf{append}(R, Q)$ are empty. Empty-result inversion for append splits these witnesses into $R\mathsf{hsamee}$, $P\mathsf{hsamee}$, and $Q\mathsf{hsamee}$. The shared left endpoint gives $A_{\mathsf{e}}(R)$, and the two remaining endpoint witnesses rebuild $\rho_{\mathsf{e}}(P, Q)$.

Conversely, unpack $A_{\mathsf{e}}(R)$ and $\rho_{\mathsf{e}}(P, Q)$. The shared left endpoint and each singleton classified endpoint rebuild both empty append endpoints. Transitivity of hsame through e then supplies the classifier comparison between the two appended histories. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonClassifier append left cancel iff`

Theorem 49.46 (Matrix singleton classifier append-right cancellation)**.** *For histories* P, Q, R : BHist*,*

$$\rho_{\mathsf{e}}(\mathsf{append}(P, R), \mathsf{append}(Q, R)) \iff \rho_{\mathsf{e}}(P, Q) \wedge A_{\mathsf{e}}(R).$$

Proof. In the forward direction, the two carrier fields say that $\mathsf{append}(P, R)$ and $\mathsf{append}(Q, R)$ are empty. Empty-result inversion for append splits these witnesses into $P\mathsf{hsamee}$, $Q\mathsf{hsamee}$, and $R\mathsf{hsamee}$. The first two endpoint witnesses rebuild $\rho_{\mathsf{e}}(P, Q)$, and the shared right endpoint gives $A_{\mathsf{e}}(R)$.

Conversely, unpack $\rho_{\mathsf{e}}(P, Q)$ and $A_{\mathsf{e}}(R)$. All three displayed histories are singleton endpoints, so both appended histories reduce to e, and the singleton classifier follows by reflexivity of hsame. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonClassifier append right cancel iff`

Theorem 49.47 (Matrix singleton classifier append common context)**.** *For histories* L, P, Q, R : BHist*,*

$$\rho_{\mathsf{e}}(\mathsf{append}(L, \mathsf{append}(P, R)), \mathsf{append}(L, \mathsf{append}(Q, R))) \iff A_{\mathsf{e}}(L) \wedge \rho_{\mathsf{e}}(P, Q) \wedge A_{\mathsf{e}}(R).$$

Proof. In the forward direction, the two classifier carrier fields say that both common-context append endpoints are empty. Empty-result inversion first splits off the shared left context L, then splits the middle append endpoints. This yields $A_{\mathsf{e}}(L)$, $A_{\mathsf{e}}(P)$, $A_{\mathsf{e}}(Q)$, and $A_{\mathsf{e}}(R)$; the middle comparison $\rho_{\mathsf{e}}(P, Q)$ follows by transitivity through e.

Conversely, $A_{\mathsf{e}}(L)$, $\rho_{\mathsf{e}}(P, Q)$, and $A_{\mathsf{e}}(R)$ reconstruct both common-context append endpoints as empty. Transitivity through e then supplies the singleton classifier relation between the displayed endpoints. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonClassifier append common context iff`

Theorem 49.48 (Singleton empty-history matrix laws)**.** *For the singleton instance of Definition 49.3, the displayed matrix carrier and operations satisfy the concrete* $\mathsf{Mat}^{\uparrow}$ *law package:*

1. 0_M *and* I_M *are carried by* A_{e}*.*
2. *If* $A_{\mathsf{e}}(M)$ *and* $A_{\mathsf{e}}(N)$*, then* $A_{\mathsf{e}}(M \oplus N)$ *and* $A_{\mathsf{e}}(M \odot N)$*.*
3. 0_M *is a left and right unit for* $\oplus$ *under* ρ_{e}*.*
4. I_M *is a left and right identity for* $\odot$ *under* ρ_{e}*.*

5. *$\oplus$ and $\odot$ are associative under ρ_{e}.*

6. *ρ_{e} is reflexive, symmetric, and transitive on carried matrix codes, and it is respected by $\oplus$ and $\odot$.*

Proof. The carrier endpoint is supplied by the singleton source witness from Definition 36.169 at $a_0 = \mathsf{e}$. The row and column witnesses use the same empty unary history, so the dimension ledger is closed at the singleton endpoint.

For operation closure, carried inputs are classified as singleton endpoints. The displayed operations are either e or append applied to singleton endpoints. The BEDC continuation unit laws cited in Theorem 40.3 identify the resulting append endpoint with e, so the singleton source again carries the result.

The zero laws for $\oplus$ and the identity laws for $\odot$ are the same unit calculation. On the left and on the right, the operation compares $\mathsf{append}(\mathsf{e}, M)$ or $\mathsf{append}(M, \mathsf{e})$ with M under ρ_{e}, and the continuation unit laws provide the hsame component. The endpoint components come from $A_{\mathsf{e}}(M)$ and $A_{\mathsf{e}}(\mathsf{e})$.

Associativity of $\oplus$ and $\odot$ uses the continuation associativity law already used by the singleton monoid, ring, and vector-space chapters. Both operation symbols are represented by append, so the two parenthesized products share a single BEDC append spine up to hsame.

For classifier congruence, unpack the two ρ_{e} hypotheses. Closure keeps both composite endpoints in A_{e}, and the relation components are combined by reflexivity, symmetry, and transitivity of hsame after the append unit and associativity reductions. This gives the required ρ_{e} comparison for both $\oplus$ and $\odot$. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonEmptyHistory laws`

Theorem 49.49 (Singleton empty-history matrix endpoint collapse)**.** *With the notation of Definition 49.3, if $A_{\mathsf{e}}(M)$ and $A_{\mathsf{e}}(N)$, then*

1. *$\rho_{\mathsf{e}}(M \oplus N, \mathsf{e})$.*

2. *$\rho_{\mathsf{e}}(M \odot N, \mathsf{e})$.*

3. *$\rho_{\mathsf{e}}(M \oplus N, M \odot N)$.*

Proof. Apply Theorem 49.48 to the carried inputs M and N. Its closure clause puts both $M \oplus N$ and $M \odot N$ back in A_{e}, while the singleton carrier witnesses identify M and N with the endpoint e.

By the displayed definitions, both operations are $\mathsf{append}(M, N)$. Replace the carried inputs by their singleton endpoint witnesses, then use the left and right continuation unit laws cited in Theorem 40.3 to reduce the resulting append history to e.

For $\rho_{\mathsf{e}}(M \oplus N, \mathsf{e})$ and $\rho_{\mathsf{e}}(M \odot N, \mathsf{e})$, combine the closure witnesses with the corresponding hsame endpoint calculation. Symmetry is used when the unit witness is oriented from e to the displayed operation rather than from the displayed operation to e.

For $\rho_{\mathsf{e}}(M \oplus N, M \odot N)$, compose the first endpoint comparison with the symmetry of the second by transitivity of hsame. The two carrier witnesses are the closure witnesses already supplied by the law package, so the classifier definition gives the required comparison. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonEmptyHistory endpoint collapse`

The $\mathsf{Mat}^{\uparrow}$ schema is instantiated by this concrete BHist carrier and operations, so formalization can target the endpoint-collapse and law package rather than an abstract operator schema.

Theorem 49.50 (Singleton empty-history matrix endpoint exactness)**.** *For the singleton instance of Definition 49.3, if $A_{\mathsf{e}}(M)$ and $A_{\mathsf{e}}(N)$, then all displayed matrix endpoints are classified by the singleton empty history:*

1. $\rho_{\mathsf{e}}(M, \mathsf{e})$.
2. $\rho_{\mathsf{e}}(0_M, \mathsf{e})$.
3. $\rho_{\mathsf{e}}(I_M, \mathsf{e})$.
4. $\rho_{\mathsf{e}}(M \oplus N, \mathsf{e})$.
5. $\rho_{\mathsf{e}}(M \odot N, \mathsf{e})$.

Proof. Unfold the singleton carrier A_{e} and the classifier ρ_{e}. The hypotheses say that M and N are carried by the singleton endpoint, so the first classification is obtained by pairing the two carrier witnesses with the corresponding singleton endpoint witness in hsame.

Apply Theorem 49.48 to obtain closure of 0_M, I_M, $M \oplus N$, and $M \odot N$ in A_{e}. These closure witnesses supply the carrier components required by the classifier for the four remaining endpoints.

For the hsame components, compose the singleton endpoint witnesses with symmetry and transitivity of hsame. Thus each displayed endpoint is identified with e, and repacking the carrier witnesses with the hsame witness gives the five asserted instances of ρ_{e}. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonEmptyHistory endpoint exactness`

Theorem 49.51 (Matrix singleton classifier continuation commutativity closure)**.** *Let M, N : BHist be carried by the singleton matrix carrier A_{e}. If $\mathsf{Cont}(M, N, L)$ and $\mathsf{Cont}(N, M, R)$, then both continuation results are again carried by A_{e}, and the singleton matrix classifier relates the two results:*

$$A_{\mathsf{e}}(L) \wedge A_{\mathsf{e}}(R) \wedge \rho_{\mathsf{e}}(L, R).$$

Proof. The two carrier hypotheses identify M and N with e. After these identifications, the two continuation premises identify both L and R with the BEDC append endpoint $\mathsf{append}(\mathsf{e}, \mathsf{e})$, which is e. The singleton carrier witnesses for L and R are therefore reflexive empty history witnesses, and the classifier is rebuilt from those two carrier components and $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonClassifier continuation comm closed`

Theorem 49.52 (Matrix singleton carrier continuation result iff)**.** *Let M, N, R : BHist be histories with M and N carried by the singleton matrix carrier A_{e}. Then continuation from M to N has result R exactly when R is again carried by A_{e}:*

$$\mathsf{Cont}(M, N, R) \iff A_{\mathsf{e}}(R).$$

Proof. Unfold the two endpoint carrier witnesses as $\mathsf{hsame}(M, \mathsf{e})$ and $\mathsf{hsame}(N, \mathsf{e})$. In the forward direction, after those identifications the continuation has the same result as the right-unit continuation at e, so R is singleton-carried. Conversely, if R is singleton-carried, all three displayed histories are identified with e, and the right-unit continuation at e supplies the required continuation. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonCarrier continuation result iff`

Theorem 49.53 (Matrix singleton carrier append-target continuation result iff)**.** *Let M, N, h, R : BHist be histories with M and N carried by the singleton matrix carrier A_{e}. If $\mathsf{Cont}(h, \mathsf{append}(M, N), R)$, then the result is singleton-carried exactly when the source is singleton-carried:*

$$A_{\mathsf{e}}(R) \iff A_{\mathsf{e}}(h).$$

Proof. For the forward direction, transport the continuation result to e and apply empty-result continuation inversion; the source endpoint must be e. Conversely, the carrier witnesses for M and N split the append target as e, and continuation respects the source and target identifications. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonCarrier continuation append target result iff`

Theorem 49.54 (Matrix singleton nested append target continuation result)**.** *For histories* $M, N, P, h, r : \mathsf{BHist}$*, if* $\mathsf{Cont}(h, \mathsf{append}(M, \mathsf{append}(N, P)), r)$*, then*

$$A_{\mathsf{e}}(r) \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(M) \wedge A_{\mathsf{e}}(N) \wedge A_{\mathsf{e}}(P).$$

Proof. The forward direction transports the continuation result to e and applies empty-result inversion for continuation, then splits the nested append endpoint twice. Conversely, the four carrier witnesses rebuild the nested target as e, and continuation respects the two endpoint identifications. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonNestedAppendTarget continuation result iff`

Theorem 49.55 (Matrix singleton visible continuation result exclusion)**.** *Let* $M, N : \mathsf{BHist}$ *be carried by the singleton matrix carrier* A_{e}*. Then a continuation* $\mathsf{Cont}(M, N, -)$ *cannot have a visible* $\mathsf{e0}$*-headed or* $\mathsf{e1}$*-headed result:*

$$\mathsf{Cont}(M, N, \mathsf{e0}(r)) \to \bot \qquad \textit{and} \qquad \mathsf{Cont}(M, N, \mathsf{e1}(r)) \to \bot.$$

Proof. The carrier witnesses identify both inputs with e. With those identifications, any continuation result must be the BEDC append endpoint $\mathsf{append}(\mathsf{e}, \mathsf{e}) = \mathsf{e}$. A visible-headed result cannot be that empty endpoint, so both visible cases are impossible. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonCarrier continuation visible result absurd`

Theorem 49.56 (Matrix singleton power visible-base carrier exactness)**.** *For any history* m *and exponent* e*, a singleton power with visible base* $\mathsf{E0}(m)$ *or* $\mathsf{E1}(m)$ *is carried exactly in the empty-exponent or zero-head exponent cases:*

$$A_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(\mathsf{E0}(m), e)) \iff e\mathsf{hsamee} \ \vee \ \exists t.\ e = \mathsf{E0}(t),$$
$$A_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(\mathsf{E1}(m), e)) \iff e\mathsf{hsamee} \ \vee \ \exists t.\ e = \mathsf{E0}(t).$$

Proof. Split on the exponent. For e, the power is the singleton identity endpoint, hence carried. For $\mathsf{E0}(t)$, the recursive power is the singleton zero endpoint, hence carried. For $\mathsf{E1}(t)$, the power is an append product whose right factor is the visible base; append empty-result inversion would force that visible base to be history-same to e, contradicting BEDC constructor separation. The reverse implication is immediate in the two carried exponent cases, and impossible in the one-headed exponent case. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow visible base carrier iff`

Theorem 49.57 (Matrix singleton power visible-base positive-exponent carrier exclusion)**.** *If* e *is unary and not history-same as* e*, then neither visible-base singleton power is carried:*

$$A_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(\mathsf{E0}(m), e)) \Rightarrow \bot \qquad \textit{and} \qquad A_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(\mathsf{E1}(m), e)) \Rightarrow \bot.$$

Proof. Visible-base carrier exactness reduces either carrier witness to the empty exponent case or the zero-headed exponent case. The empty branch contradicts the positive-exponent hypothesis. The zero-headed branch contradicts unary history inversion, since unary histories are generated by e and one-headed extensions. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow visible base positive exponent carrier absurd`

Theorem 49.58 (Matrix singleton power positive-exponent visible-base classifier exclusion)**.** *For a unary nonempty exponent e, neither visible-base singleton power can classify any history:*

$$\rho_{\mathsf{e}}(\mathsf{MatrixSingletonPow}(\mathsf{E0}(m), e), h) \Longrightarrow \bot,$$

and the same holds with $\mathsf{E1}(m)$ *in place of* $\mathsf{E0}(m)$*.*

Proof. Project the source carrier from the displayed classifier. Visible-base carrier exactness leaves only the empty-exponent and zero-headed-exponent cases. The first contradicts the nonempty exponent hypothesis, and the second contradicts the unary-generation inversion for e. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonPow positive exponent visible base classifier absurd`

Theorem 49.59 (Matrix singleton add-mul visible-right continuation result nonempty)**.** *For any histories M, n, R, if the shared right input of the displayed singleton addition and multiplication has a visible head, then a continuation from the addition endpoint to the multiplication endpoint cannot have empty result:*

$$\mathsf{Cont}(M \oplus \mathsf{E0}(n), M \odot \mathsf{E0}(n), R) \wedge R\mathsf{hsamee} \Longrightarrow \bot,$$

and the same statement holds with $\mathsf{E1}(n)$ *in place of* $\mathsf{E0}(n)$*.*

Proof. Apply the continuation empty-result factor theorem for displayed singleton addition and multiplication. An empty result forces the right input factor to be empty. This contradicts constructor separation for $\mathsf{E0}(n)$ in the first case and for $\mathsf{E1}(n)$ in the second case. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddMul visible right continuation result nonempty`

49.3 The certificate

Definition 49.60 (Matrix source specification)**.** *The source is the finite index carrier from* $\mathsf{Nat}^{\uparrow}$ *and the scalar source* $\mathsf{Ring}^{\uparrow}(R)$*.*

Definition 49.61 (Matrix pattern specification)**.** *The pattern is finite table formation assigning a scalar witness to each index pair.*

Definition 49.62 (Matrix classifier specification)**.** *The classifier relates matrices pointwise by scalar classifier at every index pair.*

Lemma 49.63 (Matrix singleton classifier append visible-factor exclusion)**.** *For histories h, p, q :* BHist*, the singleton matrix classifier admits no witness whose source or target endpoint is an append with a visible factor:*

1. $\rho_{\mathsf{e}}(\mathsf{append}(\mathsf{E0}(p), q), h) \to \bot$ *and* $\rho_{\mathsf{e}}(h, \mathsf{append}(\mathsf{E0}(p), q)) \to \bot$*;*

2. $\rho_{\mathsf{e}}(\mathsf{append}(\mathsf{E1}(p), q), h) \to \bot$ *and* $\rho_{\mathsf{e}}(h, \mathsf{append}(\mathsf{E1}(p), q)) \to \bot$*;*
3. $\rho_{\mathsf{e}}(\mathsf{append}(p, \mathsf{E0}(q)), h) \to \bot$ *and* $\rho_{\mathsf{e}}(h, \mathsf{append}(p, \mathsf{E0}(q))) \to \bot$*;*
4. $\rho_{\mathsf{e}}(\mathsf{append}(p, \mathsf{E1}(q)), h) \to \bot$ *and* $\rho_{\mathsf{e}}(h, \mathsf{append}(p, \mathsf{E1}(q))) \to \bot$.

Proof. Unfold the singleton matrix classifier. Any displayed classifier witness projects to the singleton carrier endpoint on its source and to the singleton carrier endpoint on its target.

For an endpoint $\mathsf{append}(\mathsf{E0}(p), q)$ or $\mathsf{append}(\mathsf{E1}(p), q)$, append empty-result inversion forces the left visible factor to be empty. Constructor separation contradicts the resulting $\mathsf{E0}(p)\mathsf{hsamee}$ or $\mathsf{E1}(p)\mathsf{hsamee}$ endpoint.

For an endpoint $\mathsf{append}(p, \mathsf{E0}(q))$ or $\mathsf{append}(p, \mathsf{E1}(q))$, the same inversion forces the right visible factor to be empty. Constructor separation gives the source-side contradiction, and the target-side pair is exactly Definition 49.42. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonClassifier append visible factor exclusion`

Definition 49.64 (Matrix stability certificate)**.** *The stability certificate consists of:*

1. *pointwise reflexivity*
2. *pointwise transitivity*
3. *finite index closure*
4. *addition closure by scalar addition*
5. *multiplication closure by finite scalar sums and products*
6. *identity matrix closure when dimensions match*

Definition 49.65 (Matrix ledger policy)**.** *Record the dimension witnesses, index discipline, and scalar ledger for each entry.*

Definition 49.66 ($\mathsf{Mat}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{Mat}^{\uparrow}$*.*

Theorem 49.67 (Matrix singleton carrier semantic name certificate)**.** *The singleton matrix carrier* $A_{\mathsf{e}}(h) \equiv h\mathsf{hsamee}$*, used as source, pattern, and ledger policy, together with the ambient classifier* hsame*, forms a semantic name certificate:*

$$\mathsf{SemanticNameCert}(A_{\mathsf{e}}, A_{\mathsf{e}}, A_{\mathsf{e}}, \mathsf{hsame}).$$

Proof. The carrier is inhabited by e. The classifier rows are the reflexive, symmetric, and transitive laws for hsame. Carrier transport sends $h\mathsf{hsame}k$ and $h\mathsf{hsamee}$ to $k\mathsf{hsamee}$ by symmetry followed by transitivity. Since source, pattern, and ledger policy are the same concrete singleton carrier, the two semantic soundness maps are identity projections. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonCarrier semanticNameCert`

Definition 49.68 (Matrix singleton standard comparison datum)**.** *The singleton standard comparison datum for* $\mathsf{Mat}^{\uparrow}$ *is the finite tuple consisting of the singleton carrier* A_{e}*, the classifier* ρ_{e}*, the zero row, the identity row, the addition row, the multiplication row, the unit row, the associativity row, the congruence row, and the visible-factor exclusion rows already named in this chapter.*

Theorem 49.69 (Matrix singleton standard comparison row)**.** *The datum of Definition 49.68 is exactly the bridge-facing singleton matrix row: the host one-point matrix reading can read the tuple and read back to the same BEDC endpoint without adding determinant data, rank data, Gaussian elimination, eigenvalue data, or a host matrix API.*

Proof. The carrier and classifier part is the semantic name certificate of Definition 49.67. It fixes the accepted endpoint as the singleton carrier A_{e} and makes ρ_{e} a comparison through the same empty-history representative.

The operation part is the singleton empty-history law package of Definition 49.48. Its zero, identity, addition, multiplication, unit, associativity, and congruence rows are all endpoint rows on the same singleton carrier.

Finally, the visible-factor exclusion rows force every admitted comparison to remain at the empty endpoint. A host one-point matrix reading therefore has only one value to inspect and reads back to the displayed BEDC endpoint, with no determinant, rank, Gaussian-elimination, eigenvalue, or host matrix operation surface added. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixUp StdBridge`

Closure status for $\mathsf{NameCert}_{\mathsf{Mat}^{\uparrow}}$**.**

Constructive story: A matrix at this closed boundary is the one endpoint that the singleton history carrier accepts: a history may enter only when it is history-same as e, while any visible b0- or b1-headed append factor is rejected by the classifier-exclusion rows. The comparison relation ρ_{e} does not inspect rows and columns from an external table; it asks for the two endpoint carrier witnesses and the underlying hsame link, so all admitted matrices collapse to the same empty-history representative. The source, pattern, and ledger slots are the same singleton predicate here: the source covers only the empty endpoint, the pattern records zero, identity, addition, multiplication, unit, associativity, congruence, and visible-factor exclusion as endpoint calculations, and the ledger keeps the displayed dimension and entry data aligned with the raw empty history. Since e itself inhabits the carrier, hsame supplies reflexivity, symmetry, and transitivity, and carrier transport is just transitivity through e, the five name-certificate obligations hold without adding a separate matrix object. A history h lies in the signature gap of a $\mathsf{Mat}^{\uparrow}$ token p when the source-domain admits h, the signature relation pairs it with an answer endpoint and an evidence ledger, and token introduction names that answer as p; unfolded in this singleton instance, h is history-same to e, the answer is the same empty endpoint, and p names the terminal matrix certificate. The chapter registers this singleton empty-history table under the name $\mathsf{Mat}^{\uparrow}$; matrix operations are append and endpoint laws on the existing history surface, with no general finite-dimensional matrix carrier, determinant theory, rank computation, or host ring matrix API introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Mat}^{\uparrow}}$, maturePackageClosed)

Scope closed: The singleton empty-history matrix semantic name certificate over the displayed singleton carrier A_{e} and classifier ρ_{e}, including the public singleton constructor and readback surface of Definition 49.72 together with zero, identity, operation closure, unit, associativity, and congruence rows.

Not claimed: General $n \times n$ matrix theory: rank, determinant beyond singleton, Gaussian elimination, eigenvalue/eigenvector theory, characteristic polynomial, Smith/Jordan normal forms, or matrix theory over arbitrary rings.

Upgrade path: No further upgrade – chapter at top of formal axis.

Theorem 49.70 (Singleton empty-history MatrixUp certificate obligations)**.** *For the singleton empty-history matrix data of Definition 49.3, the* $\mathsf{Mat}^{\uparrow}$ *obligations of Definition 49.66 are instantiated as follows:*

1. *the source, pattern, and ledger carriers are the singleton carrier* A_{e} *on* BHist*;*
2. *the classifier is* ρ_{e}*;*
3. *the semantic* NameCert *rows are supplied by Definition 49.67;*
4. *the zero, identity, operation-closure, unit, associativity, and congruence rows are supplied by Definition 49.48.*

Proof. Unpack Definition 49.66. The source, pattern, and ledger slots are all the displayed singleton history carrier A_{e} from Definition 49.3, and the classifier slot is the displayed relation ρ_{e}. The ledger is the same singleton dimension/source ledger, with row and column witnesses represented by e.

The carrier transport and semantic soundness rows are exactly Definition 49.67. That theorem uses the same carrier in the source, pattern, and ledger positions, so its semantic NameCert data supplies the certificate-level carrier and classifier core.

It remains to fill the stability rows. The law package of Definition 49.48 carries 0_M and I_M, closes A_{e} under $\oplus$ and $\odot$, supplies the unit and identity laws, proves associativity under ρ_{e}, and gives classifier congruence for both operations. These rows exhaust the stability portion of the displayed $\mathsf{Mat}^{\uparrow}$ obligations. □

Primitive boundary. $\mathsf{Mat}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Remark 49.71 (Zero-axiom encoding note)**.** *Avoids funext by using pointwise classifier sameness; finite indices are inductive, not quotient indices.*

Theorem 49.72 (Matrix singleton empty public constructor surface)**.** *The singleton empty-history* $\mathsf{Mat}^{\uparrow}$ *package exports the public constructor and readback rows for zero, identity, addition, multiplication, unit, associativity, congruence, and visible-factor exclusion over* A_{e}*,* ρ_{e}*,* BHist*,* Cont*, and* hsame*. These rows are exactly the public surface available from the singleton certificate, and they expose no general finite-dimensional table API.*

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonEmptyHistory public constructor surface`

Proof. Read the singleton data from Definition 49.3. It fixes the carrier A_{e} over BHist, the classifier ρ_{e}, and the empty-history endpoint used by the public readback rows.

Apply Definition 49.48. Its zero, identity, addition, multiplication, unit, associativity, and congruence rows are stated on the same A_{e} and ρ_{e} surface, with Cont and hsame carrying the endpoint transport. The visible-factor exclusion row is the same singleton classifier exclusion already recorded in the MatrixUp certificate surface.

Finally use the MatrixUp closure block grounded at BEDC.Derived.MatrixUp.MatrixSingletonCarrier_semanticNa That block identifies the chapter boundary as the singleton empty-history certificate and explicitly withholds a general finite-dimensional matrix carrier, so the public constructor surface is precisely the listed rows and no table API beyond them. □

Theorem 49.73 (Matrix singleton concrete schema surface)**.** *The concrete singleton matrix carrier* A_{e}*, classifier* ρ_{e}*, zero and identity endpoints, displayed addition and multiplication by* append*, row and column unary witnesses, and the laws of Definition 49.48 form the non-parametric* $\mathsf{Mat}^{\uparrow}$ *target surface over* BHist*,* hsame*,* Cont*, and* Pkg*.*

This surface is the concrete schema available from the singleton package. It does not assert a general finite-table carrier, arbitrary scalar matrix operations, or a parametric row-and-column family beyond the displayed singleton history.

Proof. Read the package data from Definition 49.3. It supplies the carrier A_{e}, classifier ρ_{e}, zero and identity endpoints, append-based addition and multiplication, and the row and column unary witnesses inside the same empty-history BHist surface.

Apply Definition 49.48. The law rows are stated for exactly those singleton endpoints and append operations, with hsame and Cont transporting the finite histories and Pkg recording the package provenance.

Finally use Definition 49.72. It identifies the exported constructor and readback rows as the public singleton surface and excludes any general table API. Therefore the displayed rows are precisely the non-parametric $\mathsf{Mat}^{\uparrow}$ schema target exposed by the concrete singleton package. □

Theorem 49.74 (Singleton additive fold append continuation classifier)**.** *If two finite singleton-matrix spines are carried and a continuation ledger composes their individual additive folds to an endpoint r, then the appended fold classifies r:*

$$\mathsf{MatrixSingletonAddFoldSpineCarrier}(xs) \wedge \mathsf{MatrixSingletonAddFoldSpineCarrier}(ys) \wedge \mathsf{Cont}(\mathsf{MatrixSingletonAddFold}(xs)$$

Proof. The display classifier identifies the appended fold with the canonical append of the two individual folds. The continuation ledger has the same left and right factors as that canonical append, so continuation determinacy transports the classifier endpoint from the canonical append to r. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddFold append continuation classifier`

Theorem 49.75 (Singleton additive fold reverse empty append readback)**.** *If xs is carried by* MatrixSingletonAddFoldSpineCarrier*, then appending the singleton additive fold of xs to* e *is history-same to appending the singleton additive fold of* $\mathsf{reverse}(xs)$ *to* e*.*

Proof. First prove by induction on the spine that the carrier is preserved by list reversal. The nil case is the empty carrier. In the cons case, the induction hypothesis carries the reversed tail, the head supplies the singleton suffix carrier, and append closure for spine carriers carries the reversed cons spine. The fold carrier equivalence then makes both folds empty-carried, and the right-unit law for append identifies the two displayed empty-appended endpoints. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddFold reverse empty append hsame`

Theorem 49.76 (Singleton additive fold reverse carrier readback)**.** *If xs is carried by* MatrixSingletonAddFoldSpineC *then the reversed singleton additive fold is carried, and the two fold endpoints are history-same:*

$$\mathsf{MatrixSingletonCarrier}(\mathsf{MatrixSingletonAddFold}(\mathsf{reverse}(xs))) \wedge \mathsf{MatrixSingletonAddFold}(xs)\mathsf{hsameMatrixSingletonAdd}$$

Proof. Induct through the reverse accumulator to show that carried spines remain carried after reversal. The fold carrier readback then makes both the original fold and the reversed fold singleton-carried. Since the singleton carrier is history-sameness to e, transitivity through e gives the displayed fold readback. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddFold reverse carrier readback`

Corollary 49.77 (Singleton additive fold double-reverse readback)**.** *If xs is carried by* MatrixSingletonAddFoldSpine *then the singleton additive fold over the double-reversed spine is carried, and the singleton matrix classifier relates it to the original singleton additive fold:*

$$\mathsf{MatrixSingletonCarrier}(\mathsf{MatrixSingletonAddFold}(\mathsf{reverse}(\mathsf{reverse}(xs)))) \wedge \mathsf{MatrixSingletonClassifier}(\mathsf{MatrixSingletonAddF}$$

Proof. Apply Definition 49.76 to xs. This gives the carrier of $\mathsf{MatrixSingletonAddFold}(\mathsf{reverse}(xs))$ and the comparison

$$\mathsf{MatrixSingletonAddFold}(xs)\mathsf{hsameMatrixSingletonAddFold}(\mathsf{reverse}(xs)).$$

By Definition 49.82, that carried reversed fold reads back to a carried reversed spine. Apply Definition 49.76 again, now to $\mathsf{reverse}(xs)$. This gives the carrier of $\mathsf{MatrixSingletonAddFold}(\mathsf{reverse}(\mathsf{reverse}(xs)))$ and

$$\mathsf{MatrixSingletonAddFold}(\mathsf{reverse}(xs))\mathsf{hsameMatrixSingletonAddFold}(\mathsf{reverse}(\mathsf{reverse}(xs))).$$

Symmetry and transitivity of hsame compose the two displayed comparisons in the reverse direction, yielding

$$\mathsf{MatrixSingletonAddFold}(\mathsf{reverse}(\mathsf{reverse}(xs)))\mathsf{hsameMatrixSingletonAddFold}(xs).$$

The original spine carrier gives the carrier of $\mathsf{MatrixSingletonAddFold}(xs)$ by Definition 49.82, while the second reverse readback already supplies the carrier of the double-reversed fold. These two carrier rows together with the displayed hsame comparison are exactly the singleton matrix classifier witness. Finite reverse involutivity confirms that the double-reversed spine has the same finite order as the input spine, so the readback uses no additional carrier or permutation datum. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddFold double reverse readback`

Lemma 49.78 (Finite additive fold singleton identity)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, and finite additive fold $\mathsf{fold}_{+,R}$ from Definition 50.26. Assume the additive zero and classifier-equivalence rows retained in Definition 43.26. For every carried scalar a, the singleton fold is classified with a:*

$$\mathsf{fold}_{+,R}(\mathsf{singleton}(a)) \sim_R a.$$

Proof. Unfold the singleton spine as $\mathsf{cons}(a, \mathsf{nil})$. The fold equation identifies its endpoint with $a +_R 0_R$.

The additive right-zero law classifies $a +_R 0_R$ with a. Classifier symmetry and transitivity then transport the displayed fold endpoint to the scalar a. □

Lemma 49.79 (Finite additive fold empty identity)**.** *Under the same scalar data, the empty finite fold is classified with the zero endpoint:*

$$\mathsf{fold}_{+,R}(\mathsf{nil}) \sim_R 0_R.$$

Proof. This is the nil clause recorded by Definition 50.26, followed by classifier reflexivity on the zero endpoint. □

Definition 49.80 (Finite additive scalar fold)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, and the additive stability rows of Definition 43.26. For every finite carried scalar spine xs, the fold $\mathsf{fold}_{+,R}(xs)$ is generated by the two clauses*

$$\mathsf{fold}_{+,R}(\mathsf{nil}) := 0_R, \qquad \mathsf{fold}_{+,R}(x :: xs) := x +_R \mathsf{fold}_{+,R}(xs).$$

The fold ledger records the finite spine order, the carriedness witness for each entry, and the additive ledger used at every cons step.

Theorem 49.81 (Finite additive fold respects scalar classifier)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, and the additive stability rows of Definition 43.26. If finite carried scalar spines xs and ys are related by $\mathsf{ListClassifierSpec}(\sim_R, xs, ys)$, then*

$$\mathsf{fold}_{+,R}(xs) \sim_R \mathsf{fold}_{+,R}(ys).$$

Proof. Induct on the displayed finite-spine classifier witness. In the nil case, both folds reduce by Definition 49.80 to 0_R, and the zero self-classification row of Definition 43.26 gives $0_R \sim_R 0_R$.

In the cons case, the head comparison gives $x \sim_R y$, and the induction hypothesis gives $\mathsf{fold}_{+,R}(xs) \sim_R \mathsf{fold}_{+,R}(ys)$. Additive congruence from Definition 43.26 transports these two comparisons to $x +_R \mathsf{fold}_{+,R}(xs) \sim_R y +_R \mathsf{fold}_{+,R}(ys)$, which is exactly the folded comparison after unfolding Definition 49.80. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddFold respects classifier`

Theorem 49.82 (Singleton additive fold carrier readback)**.** *For the singleton matrix carrier, let* MatrixSingletonAddFold *fold a finite spine by the concrete singleton addition* MatrixSingletonAdd*, and let* MatrixSingletonAddFoldSpineCarrier *record that every spine entry is carried. Then*

$$\mathsf{MatrixSingletonCarrier}(\mathsf{MatrixSingletonAddFold}(xs)) \iff \mathsf{MatrixSingletonAddFoldSpineCarrier}(xs).$$

Proof. Induct on the finite spine. The nil fold is e, so both sides are the empty endpoint readback. In the cons case, singleton addition is kernel append; empty-append inversion splits the folded endpoint into the head carrier and the tail-fold carrier, and the induction hypothesis identifies the tail-fold carrier with the tail spine carrier. □

Lean4 (definition) `BEDC.Derived.MatrixUp.MatrixSingletonAddFold`
Lean4 (definition) `BEDC.Derived.MatrixUp.MatrixSingletonAddFoldSpineCarrier`
Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddFold carrier iff`

Theorem 49.83 (Singleton additive fold continuation result readback)**.** *For every finite spine xs and histories $h, r : \mathsf{BHist}$, if*

$$\mathsf{Cont}(h, \mathsf{MatrixSingletonAddFold}(xs), r),$$

then the result is carried by the singleton matrix carrier exactly when the left input is carried and every entry of the fold spine is carried:

$$\mathsf{MatrixSingletonCarrier}(r) \iff \mathsf{MatrixSingletonCarrier}(h) \wedge \mathsf{MatrixSingletonAddFoldSpineCarrier}(xs).$$

Proof. For the forward direction, transport the displayed continuation along $\mathsf{MatrixSingletonCarrier}(r)$ to a continuation ending at e. Kernel empty-result inversion for Cont forces both h and $\mathsf{MatrixSingletonAddFold}(xs)$ to be empty. The first equality is the left carrier, and the second is read through Definition 49.82 to obtain the spine carrier.

Conversely, the left carrier identifies h with e, while Definition 49.82 turns the spine carrier into $\mathsf{hsame}(\mathsf{MatrixSingletonAddFold}(xs), \mathsf{e})$. Continuation respect for hsame, compared against the empty right-unit continuation, forces r to be carried by the singleton matrix carrier. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddFold continuation result iff`

Theorem 49.84 (Singleton additive fold visible head exclusion)**.** *For every history m and finite spine xs, folding a singleton additive spine whose head is $\mathsf{E0}(m)$ or $\mathsf{E1}(m)$ cannot read back to the empty carrier:*

$$\neg\mathsf{hsame}(\mathsf{MatrixSingletonAddFold}(\mathsf{E0}(m) :: xs), \mathsf{e}) \quad \wedge \quad \neg\mathsf{hsame}(\mathsf{MatrixSingletonAddFold}(\mathsf{E1}(m) :: xs), \mathsf{e}).$$

Proof. Unfold the cons case of the finite singleton additive fold. The head is the left factor of a kernel append, and empty-append inversion would identify $\mathsf{E0}(m)$ or $\mathsf{E1}(m)$ with e. Both alternatives contradict constructor separation in BHist. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddFold visible head absurd`

Theorem 49.85 (Singleton additive fold append carrier readback)**.** *For finite singleton-matrix spines xs and ys,*

$$\mathsf{MatrixSingletonCarrier}(\mathsf{MatrixSingletonAddFold}(xs +\!\!+ ys)) \iff \mathsf{MatrixSingletonAddFoldSpineCarrier}(xs) \wedge \mathsf{MatrixSing}$$

Proof. Induct on xs. For the empty spine, the appended fold is the fold of ys, and the base fold readback identifies its carrier with the spine carrier of ys. For a cons spine, concrete singleton addition is kernel append, so empty-append inversion splits the folded endpoint into the head carrier and the appended tail-fold carrier. The induction hypothesis splits the tail-fold carrier into the tail spine carrier and the carrier of ys, and the reverse direction repacks those two splits through the same empty-append constructor. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddFold append carrier iff`

Theorem 49.86 (Singleton additive fold appended visible tail exclusion)**.** *For every history m and finite spine xs, appending a visible singleton tail before folding cannot read back to the empty carrier:*

$$\neg\mathsf{hsame}(\mathsf{MatrixSingletonAddFold}(xs{+\!\!+}[\mathsf{E0}(m)]), \mathsf{e}) \quad \wedge \quad \neg\mathsf{hsame}(\mathsf{MatrixSingletonAddFold}(xs{+\!\!+}[\mathsf{E1}(m)]), \mathsf{e}).$$

Proof. Apply the appended-spine carrier readback to split the fold over xs and the one-element visible tail. The tail carrier would identify either $\mathsf{E0}(m)$ or $\mathsf{E1}(m)$ with e, contradicting constructor separation in BHist. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddFold append visible tail absurd`

Theorem 49.87 (Singleton additive fold append visible middle exclusion)**.** *For finite singleton-matrix spines $pref$ and $suffix$, a visible middle entry remains excluded after an arbitrary carried prefix:*

$$\neg\mathsf{hsame}(\mathsf{MatrixSingletonAddFold}(pref +\!\!+ \mathsf{E0}(m) :: suffix), \mathsf{e}) \quad \wedge \quad \neg\mathsf{hsame}(\mathsf{MatrixSingletonAddFold}(pref +\!\!+ \mathsf{E1}(r$$

Proof. Apply append-carrier readback to the split spine. If the whole appended fold read back to e, then the suffix-side spine carrier would include the visible middle entry as a singleton carrier. That carrier identifies $\mathsf{E0}(m)$ or $\mathsf{E1}(m)$ with e, contradicting constructor separation for histories. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddFold append visible middle absurd`

Theorem 49.88 (Singleton additive fold append readback)**.** *For finite singleton-matrix spines xs and ys, folding their appended spine by concrete singleton addition is history-same as appending the two individual singleton additive folds:*

$$\mathsf{MatrixSingletonAddFold}(xs{+\!\!+}ys)\mathsf{hsameappend}(\mathsf{MatrixSingletonAddFold}(xs), \mathsf{MatrixSingletonAddFold}(ys)).$$

Proof. Induct on xs. The nil case is the left-unit law for kernel append. In the cons case, unfold singleton addition as kernel append, apply the induction hypothesis under the common head, and reassociate by the kernel append associativity law. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddFold append hsame`

Theorem 49.89 (Singleton additive fold append display classifier)**.** *For finite singleton-matrix spines xs and ys, the classifier between the fold of the appended spine and the append of the two individual folds is equivalent to carriedness of both input spines:*

$$\mathsf{MatrixSingletonClassifier}(\mathsf{MatrixSingletonAddFold}(xs{+\!\!+}ys), \mathsf{append}(\mathsf{MatrixSingletonAddFold}(xs), \mathsf{MatrixSingletonAdd}$$

Proof. In the forward direction, project the classifier to its left carrier row and use append-spine carrier readback. Conversely, read both spine carriers back to carriers for the individual folds; empty-append inversion gives the carrier of the displayed append, while fold append readback supplies the classifier comparison between the appended fold and the displayed append endpoint. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddFold append display classifier iff`

Lemma 49.90 (Finite Kronecker selector sum)**.** *Let $J = \mathsf{Fin}(p)$ be a finite index carrier licensed by the $\mathsf{Nat}^{\uparrow}$ certificate of chapter 28. Let R be a scalar carrier from the $\mathsf{CommRing}^{\uparrow}$ certificate of chapter 44, with classifier $\sim_R$, operations $+_R, \cdot_R$, and scalars $0_R, 1_R$. Assume a finite-index sum certificate Σ_J satisfying classifier congruence and the selector row: if $j_0 : J$, $t : J \to R$ is carried pointwise, $t(j_0) \sim_R u$, and $t(j) \sim_R 0_R$ for every $j \neq j_0$, then $\Sigma_J(t) \sim_R u$. For every pointwise carried scalar family $x : J \to R$ and every $j_0 : J$,*

$$\Sigma_J(j \mapsto \delta_{j_0,j} \cdot_R x(j)) \sim_R x(j_0) \qquad \textit{and} \qquad \Sigma_J(j \mapsto x(j) \cdot_R \delta_{j,j_0}) \sim_R x(j_0),$$

where $\delta_{a,b}$ is 1_R when the finite-index equality certificate identifies a with b, and 0_R otherwise.

Proof. For the first displayed sum, split the finite index j. At the selected index $j = j_0$, the Kronecker entry is 1_R, so the scalar left-one law gives $\delta_{j_0,j_0} \cdot_R x(j_0) \sim_R x(j_0)$. At every other index, the Kronecker entry is 0_R, so scalar left-zero absorption gives $\delta_{j_0,j} \cdot_R x(j) \sim_R 0_R$. These are exactly the selected and off-selected hypotheses of the selector row for Σ_J, applied to the summand family $j \mapsto \delta_{j_0,j} \cdot_R x(j)$ with $u = x(j_0)$.

The second displayed sum uses the same selector-row hypothesis for $j \mapsto x(j) \cdot_R \delta_{j,j_0}$. The scalar right-one law gives the selected comparison at $j = j_0$, and scalar right-zero absorption gives the comparison with 0_R away from j_0. □

Theorem 49.91 (Matrix identity multiplication unit)**.** *Let $n, m : \mathsf{Nat}^{\uparrow}$ and let R be a scalar $\mathsf{CommRing}^{\uparrow}$ certificate. Consider the $\mathsf{Mat}^{\uparrow}$ carrier of Definition 49.1 with the pointwise classifier of Definition 49.62. Assume the stability data of Definition 49.64 supplies finite product sums over $\mathsf{Fin}(n)$ and $\mathsf{Fin}(m)$, the scalar zero and one multiplication laws over R, and carried Kronecker identity matrices I_n and I_m with entries*

$$(I_n)_{i,a} \sim_R \delta_{i,a} \qquad \textit{and} \qquad (I_m)_{b,j} \sim_R \delta_{b,j}.$$

If $M : \mathsf{Fin}(n) \times \mathsf{Fin}(m) \to R$ is carried, then the products $I_n \cdot M$ and $M \cdot I_m$ are carried and

$$I_n \cdot M \sim_{\mathrm{Mat}} M \qquad \textit{and} \qquad M \cdot I_m \sim_{\mathrm{Mat}} M.$$

Proof. The carriedness of I_n and I_m is part of the Kronecker identity closure field, and M is carried by hypothesis. Multiplication closure in Definition 49.64 therefore carries both products. It remains to prove the pointwise scalar comparisons required by Definition 49.62.

Fix $i : \mathsf{Fin}(n)$ and $b : \mathsf{Fin}(m)$. The left product entry is the finite sum

$$(I_n \cdot M)_{i,b} \sim_R \Sigma_{\mathsf{Fin}(n)}(a \mapsto (I_n)_{i,a} \cdot_R M_{a,b}).$$

For each inner index a, identity-entry closure gives $(I_n)_{i,a} \sim_R \delta_{i,a}$, and scalar classifier congruence for $\cdot_R$ gives

$$(I_n)_{i,a} \cdot_R M_{a,b} \sim_R \delta_{i,a} \cdot_R M_{a,b}.$$

The finite-sum classifier congruence for $\Sigma_{\mathsf{Fin}(n)}$ yields

$$\Sigma_{\mathsf{Fin}(n)}(a \mapsto (I_n)_{i,a} \cdot_R M_{a,b}) \sim_R \Sigma_{\mathsf{Fin}(n)}(a \mapsto \delta_{i,a} \cdot_R M_{a,b}).$$

Applying Definition 49.90 to the carried family $a \mapsto M_{a,b}$ selects the unique inner index $a = i$, hence $(I_n \cdot M)_{i,b} \sim_R M_{i,b}$.

For the right product, the entry at the same outer indices is

$$(M \cdot I_m)_{i,b} \sim_R \Sigma_{\mathsf{Fin}(m)}(a \mapsto M_{i,a} \cdot_R (I_m)_{a,b}).$$

For each inner index a, identity-entry closure gives $(I_m)_{a,b} \sim_R \delta_{a,b}$, and scalar classifier congruence for $\cdot_R$ gives

$$M_{i,a} \cdot_R (I_m)_{a,b} \sim_R M_{i,a} \cdot_R \delta_{a,b}.$$

The finite-sum classifier congruence for $\Sigma_{\mathsf{Fin}(m)}$ yields

$$\Sigma_{\mathsf{Fin}(m)}(a \mapsto M_{i,a} \cdot_R (I_m)_{a,b}) \sim_R \Sigma_{\mathsf{Fin}(m)}(a \mapsto M_{i,a} \cdot_R \delta_{a,b}).$$

The right-hand selector part of Definition 49.90 applied to the carried family $a \mapsto M_{i,a}$ selects $a = b$, giving $(M \cdot I_m)_{i,b} \sim_R M_{i,b}$.

Since these scalar comparisons hold for every row and column index, the pointwise matrix classifier gives both displayed matrix identity laws. The ledger in Definition 49.65 records the same row and column witnesses throughout the two products, so no dimension data is changed. □

Definition 49.92 (Finite-fold matrix identity data)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with classifier $\sim_R$, zero endpoint 0_R, unit endpoint 1_R, addition $+_R$, multiplication $\cdot_R$, and finite additive folds as in Definition 50.26. For each finite dimension $n : \mathsf{Nat}^{\uparrow}$, the finite-fold identity matrix I_n is the carried $n \times n$ matrix whose (i, j) entry is 1_R when the finite indices agree and 0_R otherwise.*

Theorem 49.93 (Finite-fold matrix identity law)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with classifier $\sim_R$, zero endpoint 0_R, unit endpoint 1_R, addition $+_R$, multiplication $\cdot_R$, and finite additive folds over finite index spines as in Definition 50.26. Let A be a carried $n \times m$ $\mathsf{Mat}^{\uparrow}$ matrix. Assume the scalar classifier equivalence fields, additive zero laws, multiplication congruence, zero multiplication laws, and left and right unit laws retained in Definition 43.26. Then the finite-fold products with the identity matrices of Definition 49.92 are carried and*

$$I_n \cdot_{\mathrm{Mat}} A \sim_{\mathrm{Mat}} A \qquad \textit{and} \qquad A \cdot_{\mathrm{Mat}} I_m \sim_{\mathrm{Mat}} A.$$

Proof. The multiplication closure row of Definition 49.64 carries both products. By Definition 49.62, it is enough to compare scalar entries.

For the left identity, fix $i : \mathsf{Fin}(n)$ and $j : \mathsf{Fin}(m)$. The finite fold for $(I_n \cdot_{\mathrm{Mat}} A)_{i,j}$ has one diagonal summand $1_R \cdot_R A_{i,j}$ and all other summands $0_R \cdot_R A_{k,j}$. The unit law classifies the diagonal summand with $A_{i,j}$, and the zero multiplication law classifies every off-diagonal summand with 0_R.

The finite additive fold over a spine with one carried scalar and all remaining entries classified with 0_R reduces, by the additive zero laws and fold congruence from Definition 50.26, to that single scalar. Hence $(I_n \cdot_{\mathrm{Mat}} A)_{i,j} \sim_R A_{i,j}$.

The right identity is symmetric. The fold for $(A \cdot_{\mathrm{Mat}} I_m)_{i,j}$ has diagonal summand $A_{i,j} \cdot_R 1_R$ and off-diagonal summands classified with 0_R. The right unit law, zero multiplication laws, additive zero laws, and fold congruence again collapse the fold to $A_{i,j}$. Packaging the two entrywise comparisons gives the displayed matrix classifier laws. □

Definition 49.94 (Two-index finite fold swap certificate)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, and finite additive fold from Definition 50.26. Let J and K be finite index carriers, and write Σ_J and Σ_K for that fold applied to the finite spines enumerating J and K. A two-index finite fold swap certificate for (J, K) is the following stability field: for every pointwise carried scalar family $s : J \times K \to R$ and every pointwise classifier-compatible transpose $s^\tau : K \times J \to R$ satisfying*

$$s^\tau(k, j) \sim_R s(j, k)$$

for all $j : J$ and $k : K$, the two iterated folds are scalar-classified:

$$\Sigma_J(j \mapsto \Sigma_K(k \mapsto s(j, k))) \sim_R \Sigma_K(k \mapsto \Sigma_J(j \mapsto s^\tau(k, j))).$$

Lemma 49.95 (Scalar product distributes across finite additive folds)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, multiplication $\cdot_R$, and finite additive fold from Definition 50.26. Assume the ring stability fields of Definition 43.26: additive congruence, multiplication congruence, left and right distributivity, and zero multiplication laws. For every carried scalar c and every finite carried scalar spine xs, let $xs \cdot_R c$ denote the spine obtained by multiplying each entry of xs on the right by c, and let $c \cdot_R xs$ denote the spine obtained by multiplying each entry on the left by c. Then*

$$\mathsf{fold}_{+,R}(xs) \cdot_R c \sim_R \mathsf{fold}_{+,R}(xs \cdot_R c)$$

and

$$c \cdot_R \mathsf{fold}_{+,R}(xs) \sim_R \mathsf{fold}_{+,R}(c \cdot_R xs).$$

Proof. Induct on the finite spine xs. In the nil case, Definition 50.26 identifies the fold with 0_R. The right and left zero multiplication laws from Definition 43.26 identify $0_R \cdot_R c$ and $c \cdot_R 0_R$ with 0_R, which is the fold of the corresponding empty product spine.

In the cons case, write $xs = \mathsf{cons}(a, xs')$. For right multiplication, the fold equation gives $(a +_R \mathsf{fold}_{+,R}(xs')) \cdot_R c$. Right distributivity identifies this scalar with

$$(a \cdot_R c) +_R (\mathsf{fold}_{+,R}(xs') \cdot_R c).$$

The induction hypothesis identifies the second summand with $\mathsf{fold}_{+,R}(xs' \cdot_R c)$. Additive congruence then gives

$$(a \cdot_R c) +_R \mathsf{fold}_{+,R}(xs' \cdot_R c),$$

which is the cons fold of $xs \cdot_R c$.

The left multiplication proof is the same induction with left distributivity applied to $c \cdot_R (a +_R \mathsf{fold}_{+,R}(xs'))$. It yields

$$(c \cdot_R a) +_R (c \cdot_R \mathsf{fold}_{+,R}(xs')),$$

then uses the induction hypothesis and additive congruence to identify the result with the cons fold of $c \cdot_R xs$. □

Theorem 49.96 (Matrix multiplication associativity from finite folds)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with classifier $\sim_R$, addition $+_R$, multiplication $\cdot_R$, zero endpoint 0_R, and finite additive fold from Definition 50.26. Let $n, m, p, q : \mathsf{Nat}^{\uparrow}$, and consider the $\mathsf{Mat}^{\uparrow}$ carriers of Definition 49.1 with pointwise classifier from Definition 49.62. Let*

$$A : \mathsf{Fin}(n) \times \mathsf{Fin}(m) \to R, \qquad B : \mathsf{Fin}(m) \times \mathsf{Fin}(p) \to R, \qquad C : \mathsf{Fin}(p) \times \mathsf{Fin}(q) \to R$$

be carried matrices. Assume matrix multiplication is the finite-fold operation

$$(X \cdot Y)_{u,w} := \Sigma_V(v \mapsto X_{u,v} \cdot_R Y_{v,w})$$

for the matching inner finite index carrier V, using the multiplication closure field of Definition 49.64. Assume the scalar ring stability fields of Definition 43.26, the fold congruence theorem Definition 50.26, and the two-index finite fold swap certificate of Definition 49.94 for $\mathsf{Fin}(p)$ and $\mathsf{Fin}(m)$. Then the two matched products are carried and

$$(A \cdot B) \cdot C \sim_{\mathrm{Mat}} A \cdot (B \cdot C).$$

Proof. The multiplication closure item of Definition 49.64 carries $A \cdot B$ and $B \cdot C$, and then carries the two outer products $(A \cdot B) \cdot C$ and $A \cdot (B \cdot C)$. By Definition 49.62, it remains to prove the scalar classifier comparison at each entry.

Fix $i : \mathsf{Fin}(n)$ and $l : \mathsf{Fin}(q)$, and set

$$t(b, a) := A_{i,a} \cdot_R (B_{a,b} \cdot_R C_{b,l})$$

for $a : \mathsf{Fin}(m)$ and $b : \mathsf{Fin}(p)$. Expanding the left-associated matrix product gives

$$((A \cdot B) \cdot C)_{i,l} \sim_R \Sigma_{b:\mathsf{Fin}(p)}((A \cdot B)_{i,b} \cdot_R C_{b,l}).$$

For each fixed b, expanding $(A \cdot B)_{i,b}$ and applying the right-multiplication half of Definition 49.95 gives

$$(A \cdot B)_{i,b} \cdot_R C_{b,l} \sim_R \Sigma_{a:\mathsf{Fin}(m)}((A_{i,a} \cdot_R B_{a,b}) \cdot_R C_{b,l}).$$

Scalar associativity from the multiplicative monoid part of Definition 43.26 gives a pointwise comparison

$$(A_{i,a} \cdot_R B_{a,b}) \cdot_R C_{b,l} \sim_R A_{i,a} \cdot_R (B_{a,b} \cdot_R C_{b,l}).$$

The finite-fold congruence theorem Definition 50.26 lifts these pointwise comparisons through the inner and outer folds. Hence

$$((A \cdot B) \cdot C)_{i,l} \sim_R \Sigma_{b:\mathsf{Fin}(p)}\Sigma_{a:\mathsf{Fin}(m)}t(b, a).$$

Expanding the right-associated matrix product gives

$$(A \cdot (B \cdot C))_{i,l} \sim_R \Sigma_{a:\mathsf{Fin}(m)}(A_{i,a} \cdot_R (B \cdot C)_{a,l}).$$

For each fixed a, expanding $(B \cdot C)_{a,l}$ and applying the left-multiplication half of Definition 49.95 gives

$$A_{i,a} \cdot_R (B \cdot C)_{a,l} \sim_R \Sigma_{b:\mathsf{Fin}(p)}A_{i,a} \cdot_R (B_{a,b} \cdot_R C_{b,l}).$$

Again Definition 50.26 lifts the pointwise comparisons through the finite folds, so

$$(A \cdot (B \cdot C))_{i,l} \sim_R \Sigma_{a:\mathsf{Fin}(m)}\Sigma_{b:\mathsf{Fin}(p)}t(b, a).$$

Apply the fold swap certificate of Definition 49.94 to the family t and its transpose $t^\tau(a,b) := t(b,a)$. This gives

$$\Sigma_{b:\mathsf{Fin}(p)}\Sigma_{a:\mathsf{Fin}(m)}t(b,a) \sim_R \Sigma_{a:\mathsf{Fin}(m)}\Sigma_{b:\mathsf{Fin}(p)}t(b,a).$$

Classifier transitivity composes the left expansion, this fold swap comparison, and the symmetry of the right expansion. Thus every entry of $(A \cdot B) \cdot C$ is scalar-classified with the corresponding entry of $A \cdot (B \cdot C)$. The pointwise matrix classifier of Definition 49.62 gives the displayed matrix classification, and the unchanged dimension witnesses are recorded by the ledger policy of Definition 49.65. □

Theorem 49.97 (Matrix multiplication classifier congruence)**.** *Let R be a scalar $\mathsf{Ring}^\uparrow$ carrier with classifier $\sim_R$, multiplication $\cdot_R$, addition $+_R$, zero endpoint 0_R, and finite additive fold from Definition 50.26. Let $n, m, p : \mathsf{Nat}^\uparrow$, and consider the $\mathsf{Mat}^\uparrow$ carriers of Definition 49.1 with pointwise classifier from Definition 49.62. Let*

$$A, A' : \mathsf{Fin}(n) \times \mathsf{Fin}(m) \to R, \qquad B, B' : \mathsf{Fin}(m) \times \mathsf{Fin}(p) \to R$$

be carried matrices over the same scalar source and the same matching inner dimension m. Assume matrix multiplication is the finite-fold operation

$$(X \cdot Y)_{i,k} := \Sigma_{\mathsf{Fin}(m)}(j \mapsto X_{i,j} \cdot_R Y_{j,k})$$

for the shared inner finite index carrier, using the multiplication closure field of Definition 49.64. Assume the scalar multiplication congruence field of Definition 43.26 and the fold congruence theorem Definition 50.26. If

$$A \sim_{\mathrm{Mat}} A' \qquad \text{and} \qquad B \sim_{\mathrm{Mat}} B',$$

then $A \cdot B$ and $A' \cdot B'$ are carried $\mathsf{Mat}^\uparrow$ matrices, and

$$A \cdot B \sim_{\mathrm{Mat}} A' \cdot B'.$$

Proof. The multiplication closure item in Definition 49.64 applies to the carried compatible pairs (A, B) and (A', B'), so both products $A \cdot B$ and $A' \cdot B'$ are carried by the $\mathsf{Fin}(n) \times \mathsf{Fin}(p)$ matrix carrier.

By Definition 49.62, it remains to prove the scalar classifier comparison entrywise. Fix $i : \mathsf{Fin}(n)$ and $k : \mathsf{Fin}(p)$. The matrix classifier hypotheses give, for every $j : \mathsf{Fin}(m)$,

$$A_{i,j} \sim_R A'_{i,j} \qquad \text{and} \qquad B_{j,k} \sim_R B'_{j,k}.$$

The multiplication congruence field in Definition 43.26 therefore gives the summand comparison

$$A_{i,j} \cdot_R B_{j,k} \sim_R A'_{i,j} \cdot_R B'_{j,k}$$

for every inner index j.

The shared inner dimension supplies the same finite enumeration of $\mathsf{Fin}(m)$ on both sides. Hence these summand comparisons form a same-length finite-spine classifier witness between

$$j \mapsto A_{i,j} \cdot_R B_{j,k} \qquad \text{and} \qquad j \mapsto A'_{i,j} \cdot_R B'_{j,k}.$$

Applying Definition 50.26 to that finite-spine witness yields

$$\Sigma_{\mathsf{Fin}(m)}(j \mapsto A_{i,j} \cdot_R B_{j,k}) \sim_R \Sigma_{\mathsf{Fin}(m)}(j \mapsto A'_{i,j} \cdot_R B'_{j,k}).$$

By the displayed definition of matrix multiplication, this is exactly

$$(A \cdot B)_{i,k} \sim_R (A' \cdot B')_{i,k}.$$

Since i and k were arbitrary, Definition 49.62 packages the entrywise scalar comparisons as $A \cdot B \sim_{\mathrm{Mat}} A' \cdot B'$. The dimension and scalar-source ledgers are unchanged and are recorded by Definition 49.65. □

Lemma 49.98 (Finite additive fold separates pointwise scalar sums)**.** *Let R be a scalar* $\mathsf{Ring}^{\uparrow}$ *carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, and finite additive fold* $\mathsf{fold}_{+,R}$ *from Definition 50.26. Assume the additive abelian-group laws and additive congruence fields retained in Definition 43.26. For any two finite carried scalar spines xs and ys over the same finite enumeration, write $xs +_R ys$ for the spine obtained by adding matching entries. Then*

$$\mathsf{fold}_{+,R}(xs +_R ys) \sim_R \mathsf{fold}_{+,R}(xs) +_R \mathsf{fold}_{+,R}(ys).$$

Proof. Induct on the shared finite enumeration. In the nil case, all three spines are nil. The left endpoint reduces by Definition 50.26 to 0_R, while the right endpoint reduces to $0_R +_R 0_R$. The additive left-zero law in Definition 43.26, with classifier symmetry from the additive abelian-group laws, gives $0_R \sim_R 0_R +_R 0_R$.

In the cons case, write $xs = \mathsf{cons}(a, xs')$ and $ys = \mathsf{cons}(b, ys')$. The induction hypothesis gives

$$\mathsf{fold}_{+,R}(xs' +_R ys') \sim_R \mathsf{fold}_{+,R}(xs') +_R \mathsf{fold}_{+,R}(ys').$$

Source reflexivity on $a +_R b$ and additive congruence transport this comparison to

$$(a +_R b) +_R \mathsf{fold}_{+,R}(xs' +_R ys') \sim_R (a +_R b) +_R (\mathsf{fold}_{+,R}(xs') +_R \mathsf{fold}_{+,R}(ys')).$$

Apply Definition 42.13, read for the additive abelian-group operation of the scalar ring, to classify the right endpoint with

$$(a +_R \mathsf{fold}_{+,R}(xs')) +_R (b +_R \mathsf{fold}_{+,R}(ys')).$$

The cons clauses of Definition 50.26 identify this last endpoint with

$$\mathsf{fold}_{+,R}(xs) +_R \mathsf{fold}_{+,R}(ys),$$

and identify the first endpoint with $\mathsf{fold}_{+,R}(xs +_R ys)$. Classifier transitivity gives the cons case. □

Theorem 49.99 (Matrix multiplication right-distributes over matrix addition)**.** *Let R be a scalar* $\mathsf{Ring}^{\uparrow}$ *carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, multiplication $\cdot_R$, and finite additive folds over finite index spines as in Definition 50.26. Let $n, m, p : \mathsf{Nat}^{\uparrow}$, and consider the* $\mathsf{Mat}^{\uparrow}$ *carriers of Definition 49.1 with pointwise classifier from Definition 49.62. Let*

$$A, B : \mathsf{Fin}(n) \times \mathsf{Fin}(m) \to R, \qquad C : \mathsf{Fin}(m) \times \mathsf{Fin}(p) \to R$$

be carried matrices. Assume matrix addition is the pointwise operation

$$(X + Y)_{u,v} := X_{u,v} +_R Y_{u,v}$$

using the addition closure field of Definition 49.64, and assume matrix multiplication is the finite-fold operation

$$(X \cdot Y)_{u,w} := \Sigma_{\mathsf{Fin}(m)}(j \mapsto X_{u,j} \cdot_R Y_{j,w})$$

for the shared inner finite index carrier, using the multiplication closure field of Definition 49.64. Assume the scalar ring stability fields of Definition 43.26: additive abelian-group laws, addition and multiplication congruence, and right distributivity. Then the displayed matrices are carried and

$$(A + B) \cdot C \sim_{\mathrm{Mat}} (A \cdot C) + (B \cdot C).$$

Proof. The addition closure item of Definition 49.64 carries $A + B$. Multiplication closure carries $(A + B) \cdot C$, $A \cdot C$, and $B \cdot C$, and addition closure then carries $(A \cdot C) + (B \cdot C)$.

By Definition 49.62, it remains to compare corresponding scalar entries. Fix $i : \mathsf{Fin}(n)$ and $k : \mathsf{Fin}(p)$. Over the finite spine enumerating $\mathsf{Fin}(m)$, define

$$xs(j) := A_{i,j} \cdot_R C_{j,k}, \qquad ys(j) := B_{i,j} \cdot_R C_{j,k}.$$

The pointwise matrix-addition definition and scalar right distributivity give, for each $j : \mathsf{Fin}(m)$,

$$(A + B)_{i,j} \cdot_R C_{j,k} \sim_R (A_{i,j} \cdot_R C_{j,k}) +_R (B_{i,j} \cdot_R C_{j,k}).$$

These pointwise comparisons form a finite-spine classifier witness. Applying Definition 50.26 gives

$$\Sigma_{\mathsf{Fin}(m)}(j \mapsto (A + B)_{i,j} \cdot_R C_{j,k}) \sim_R \Sigma_{\mathsf{Fin}(m)}(j \mapsto xs(j) +_R ys(j)).$$

By Definition 49.98, the right endpoint is classified with

$$\Sigma_{\mathsf{Fin}(m)}(j \mapsto xs(j)) +_R \Sigma_{\mathsf{Fin}(m)}(j \mapsto ys(j)).$$

Unfolding the displayed matrix-multiplication operation identifies these two folded summands with $(A \cdot C)_{i,k}$ and $(B \cdot C)_{i,k}$, and the pointwise matrix-addition operation identifies their scalar sum with $((A \cdot C) + (B \cdot C))_{i,k}$. Classifier transitivity therefore gives

$$((A + B) \cdot C)_{i,k} \sim_R ((A \cdot C) + (B \cdot C))_{i,k}.$$

Since i and k were arbitrary, Definition 49.62 packages these entrywise scalar comparisons as

$$(A + B) \cdot C \sim_{\mathrm{Mat}} (A \cdot C) + (B \cdot C).$$

The dimensions and shared scalar source are unchanged throughout; Definition 49.65 records the common row, contraction, and column witnesses. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonMul right distributes over add`

Lemma 49.100 (Finite additive fold splits pointwise sums)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, and finite additive fold $\mathsf{fold}_{+,R}$ from Definition 49.80. Assume the scalar classifier equivalence fields and the additive abelian-group, additive congruence, and zero rows of Definition 43.26. For same-indexed finite carried scalar spines xs and ys, write $xs +_R ys$ for the pointwise sum spine. Then*

$$\mathsf{fold}_{+,R}(xs +_R ys) \sim_R \mathsf{fold}_{+,R}(xs) +_R \mathsf{fold}_{+,R}(ys).$$

Proof. Induct on the common finite spine carrying xs and ys. In the nil case, all three folds reduce by Definition 49.80 to 0_R. The additive zero rows classify 0_R with $0_R +_R 0_R$, giving the displayed comparison.

In the cons case, write $xs = x :: xs'$ and $ys = y :: ys'$. The fold equation reduces the left endpoint to

$$(x +_R y) +_R \mathsf{fold}_{+,R}(xs' +_R ys').$$

The induction hypothesis and additive congruence replace the tail fold by $\mathsf{fold}_{+,R}(xs') +_R \mathsf{fold}_{+,R}(ys')$. The additive associativity and commutativity fields in Definition 43.26 rebracket and exchange the middle summands, classifying

$$(x +_R y) +_R (\mathsf{fold}_{+,R}(xs') +_R \mathsf{fold}_{+,R}(ys'))$$

with

$$(x +_R \mathsf{fold}_{+,R}(xs')) +_R (y +_R \mathsf{fold}_{+,R}(ys')).$$

By Definition 49.80, the latter endpoint is $\mathsf{fold}_{+,R}(xs) +_R \mathsf{fold}_{+,R}(ys)$. Classifier transitivity composes the displayed comparisons. □

Theorem 49.101 (Matrix multiplication left-distributes over matrix addition)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, multiplication $\cdot_R$, and finite additive folds over finite index spines as in Definition 50.26. Let $n, m, p : \mathsf{Nat}^{\uparrow}$, and consider the $\mathsf{Mat}^{\uparrow}$ carriers of Definition 49.1 with pointwise classifier from Definition 49.62. Let*

$$A : \mathsf{Fin}(n) \times \mathsf{Fin}(m) \to R, \qquad B, C : \mathsf{Fin}(m) \times \mathsf{Fin}(p) \to R$$

be carried matrices. Assume matrix addition is pointwise and matrix multiplication is the finite-fold operation, using the addition and multiplication closure rows of Definition 49.64. Assume the scalar ring stability fields of Definition 43.26: additive abelian-group laws, addition and multiplication congruence, and left distributivity. Then the displayed matrices are carried and

$$A \cdot_{\mathrm{Mat}} (B + C) \sim_{\mathrm{Mat}} (A \cdot_{\mathrm{Mat}} B) + (A \cdot_{\mathrm{Mat}} C).$$

Proof. Closure follows from the matrix addition and multiplication rows of Definition 49.64. By Definition 49.62, compare entries.

Fix $i : \mathsf{Fin}(n)$ and $k : \mathsf{Fin}(p)$. Over the finite spine enumerating $\mathsf{Fin}(m)$, define

$$xs(j) := A_{i,j} \cdot_R B_{j,k}, \qquad ys(j) := A_{i,j} \cdot_R C_{j,k}.$$

The pointwise addition definition and scalar left distributivity classify each summand $A_{i,j} \cdot_R (B + C)_{j,k}$ with $xs(j) +_R ys(j)$.

Fold congruence lifts these pointwise comparisons through the finite fold. Then Definition 49.98 separates the fold of pointwise sums into the sum of the two finite folds. Unfolding matrix multiplication and pointwise matrix addition identifies the endpoint with $((A \cdot_{\mathrm{Mat}} B) + (A \cdot_{\mathrm{Mat}} C))_{i,k}$. Since i and k were arbitrary, the pointwise classifier packages the displayed law. □

Theorem 49.102 (Finite-fold matrix transpose reverses multiplication)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with opposite multiplication data as in Definition 43.35. Let A be a carried $n \times m$ matrix and B a carried $m \times p$ matrix. Assume matrix multiplication is the finite scalar-fold operation and matrix transpose swaps the two finite index coordinates pointwise. Then*

$$(A \cdot_{\mathrm{Mat}} B)^T \sim_{\mathrm{Mat}} B^T \cdot_{\mathrm{Mat}} A^T$$

over the opposite scalar multiplication.

Proof. The transpose carrier row swaps the row and column witnesses, and multiplication closure carries both displayed matrices. Entrywise, the left side at (k, i) is the fold of $A_{i,j} \cdot_R B_{j,k}$ over the shared inner finite spine.

The right side in the opposite scalar multiplication is the fold of $B_{j,k} \cdot_{R^{\mathrm{op}}} A_{i,j}$ over the same finite spine. By Definition 43.35, each opposite product is the same scalar endpoint as $A_{i,j} \cdot_R B_{j,k}$. Fold congruence from Definition 50.26 compares the two folds, and the pointwise matrix classifier packages the transpose law. □

Theorem 49.103 (Matrix addition commutativity from scalar additive commutativity)**.** *Let R carry a scalar $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$ and addition $+_R$. Assume the additive abelian-group rows retained in Definition 43.26, in particular the scalar additive commutativity row*

$$a +_R b \sim_R b +_R a$$

for all carried scalar endpoints a, b. Let $n, m : \mathsf{Nat}^{\uparrow}$, and consider the $\mathsf{Mat}^{\uparrow}$ carriers of Definition 49.1 with pointwise classifier from Definition 49.62. For carried matrices

$$A, B : \mathsf{Fin}(n) \times \mathsf{Fin}(m) \to R,$$

assume matrix addition is the pointwise operation

$$(X + Y)_{i,j} := X_{i,j} +_R Y_{i,j}$$

using the addition closure row of Definition 49.64. Then both $A+B$ and $B+A$ are carried matrices and

$$A + B \sim_{\mathrm{Mat}} B + A.$$

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAdd comm classifier`

Proof. The addition closure row of Definition 49.64 carries $A + B$ from the carried inputs A and B, and carries $B + A$ from the same inputs in the opposite order.

By Definition 49.62, it remains to compare corresponding scalar entries. Fix $i : \mathsf{Fin}(n)$ and $j : \mathsf{Fin}(m)$. Since A and B are carried matrices, the entries $A_{i,j}$ and $B_{i,j}$ are carried scalar endpoints. The pointwise addition rule gives

$$(A + B)_{i,j} = A_{i,j} +_R B_{i,j}$$

and

$$(B + A)_{i,j} = B_{i,j} +_R A_{i,j}.$$

The scalar additive commutativity row retained in Definition 43.26 gives

$$A_{i,j} +_R B_{i,j} \sim_R B_{i,j} +_R A_{i,j}.$$

Substituting the two pointwise addition clauses gives

$$(A + B)_{i,j} \sim_R (B + A)_{i,j}.$$

Since i and j were arbitrary, Definition 49.62 packages these entrywise scalar comparisons as

$$A + B \sim_{\mathrm{Mat}} B + A.$$

The dimensions and scalar source are unchanged throughout, and Definition 49.65 records the same row and column witnesses for the two pointwise sums. □

Theorem 49.104 (Matrix addition associativity from scalar additive associativity)**.** *Let R carry a scalar $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$ and addition $+_R$. Assume the additive abelian-group rows retained in Definition 43.26, in particular the scalar additive associativity row*

$$(a +_R b) +_R c \sim_R a +_R (b +_R c)$$

for all carried scalar endpoints a, b, c. Let $n, m : \mathsf{Nat}^{\uparrow}$, and consider the $\mathsf{Mat}^{\uparrow}$ carriers of Definition 49.1 with pointwise classifier from Definition 49.62. For carried matrices

$$A, B, C : \mathsf{Fin}(n) \times \mathsf{Fin}(m) \to R,$$

assume matrix addition is the pointwise operation

$$(X + Y)_{i,j} := X_{i,j} +_R Y_{i,j}$$

using the addition closure row of Definition 49.64. Then $A+B$, $B+C$, $(A+B)+C$, and $A+(B+C)$ are carried matrices, and

$$(A + B) + C \sim_{\mathrm{Mat}} A + (B + C).$$

Proof. The addition closure row of Definition 49.64 carries $A + B$ and $B + C$ from the carried inputs. Applying the same row once more carries $(A + B) + C$ and $A + (B + C)$.

By Definition 49.62, it remains to compare corresponding scalar entries. Fix $i : \mathsf{Fin}(n)$ and $j : \mathsf{Fin}(m)$. Since A, B, and C are carried matrices, the entries $A_{i,j}$, $B_{i,j}$, and $C_{i,j}$ are carried scalar endpoints. The pointwise addition rule gives

$$((A + B) + C)_{i,j} = (A_{i,j} +_R B_{i,j}) +_R C_{i,j}$$

and

$$(A + (B + C))_{i,j} = A_{i,j} +_R (B_{i,j} +_R C_{i,j}).$$

The scalar additive associativity row retained in Definition 43.26 therefore gives

$$((A + B) + C)_{i,j} \sim_R (A + (B + C))_{i,j}.$$

Since i and j were arbitrary, Definition 49.62 packages these entrywise scalar comparisons as

$$(A + B) + C \sim_{\mathrm{Mat}} A + (B + C).$$

The row and column witnesses are unchanged throughout, so Definition 49.65 records the same dimension ledger for the two parenthesized pointwise sums. □

Lemma 49.105 (Rectangular scalar fold reindexing)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, and finite additive folds over finite index spines as in Definition 50.26. Let J and K be finite index carriers with chosen finite enumerating spines, and let $s : J \times K \to R$ be a pointwise carried scalar family. Assume the scalar classifier equivalence fields and the additive associativity, commutativity, zero, and congruence rows retained in Definition 43.26. Then the two rectangular iterated folds are scalar-classified:*

$$\Sigma_{j:J}\Sigma_{k:K} s(j, k) \sim_R \Sigma_{k:K}\Sigma_{j:J} s(j, k).$$

Proof. Flatten both iterated folds to finite spines over the product index carrier $J \times K$. For the left fold, use the enumeration that lists the K-fiber inside each $j : J$; for the right fold, use the enumeration that lists the J-fiber inside each $k : K$.

The two flattened spines contain the same carried scalar entries, related by the coordinate-swap bijection $(j, k) \mapsto (k, j)$. Additive associativity and commutativity make the finite additive fold invariant under this finite permutation, while fold congruence transports the pointwise reflexive scalar classifier witnesses through the two folds.

Equivalently, apply the two-index fold swap certificate of Definition 49.94 to the family s and to the transpose family $s^\tau(k, j) := s(j, k)$. The transpose compatibility witness is reflexive at every scalar entry, so the certificate gives exactly the displayed reindexing comparison. □

Theorem 49.106 (Matrix product associativity from scalar folds)**.** *Let R be a scalar $\mathsf{Ring}^\uparrow$ carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, multiplication $\cdot_R$, and finite additive folds over finite index spines as in Definition 50.26. Let $n, m, p, q : \mathsf{Nat}^\uparrow$, and consider the $\mathsf{Mat}^\uparrow$ carriers of Definition 49.1 with pointwise classifier from Definition 49.62. Let*

$$A : \mathsf{Fin}(n) \times \mathsf{Fin}(m) \to R, \qquad B : \mathsf{Fin}(m) \times \mathsf{Fin}(p) \to R, \qquad C : \mathsf{Fin}(p) \times \mathsf{Fin}(q) \to R$$

be carried matrices. Assume matrix multiplication is the finite scalar-fold operation

$$(X \cdot_{\mathrm{Mat}} Y)_{u,w} := \Sigma_{\mathsf{Fin}(s)}(v \mapsto X_{u,v} \cdot_R Y_{v,w})$$

for every matching inner dimension s, using the multiplication closure row of Definition 49.64. Assume the scalar classifier equivalence fields, multiplication congruence, multiplicative associativity, left and right distributivity, and additive laws retained in Definition 43.26. Then the two matched products are carried and

$$(A \cdot_{\mathrm{Mat}} B) \cdot_{\mathrm{Mat}} C \sim_{\mathrm{Mat}} A \cdot_{\mathrm{Mat}} (B \cdot_{\mathrm{Mat}} C).$$

Proof. The multiplication closure row of Definition 49.64 carries $A \cdot_{\mathrm{Mat}} B$ and $B \cdot_{\mathrm{Mat}} C$, and then carries the two outer products. By Definition 49.62, it remains to compare corresponding scalar entries.

Fix $i : \mathsf{Fin}(n)$ and $l : \mathsf{Fin}(q)$. For $a : \mathsf{Fin}(m)$ and $b : \mathsf{Fin}(p)$, set

$$t(a, b) := A_{i,a} \cdot_R (B_{a,b} \cdot_R C_{b,l}).$$

Expanding the left-associated product gives

$$((A \cdot_{\mathrm{Mat}} B) \cdot_{\mathrm{Mat}} C)_{i,l} \sim_R \Sigma_{b:\mathsf{Fin}(p)}((A \cdot_{\mathrm{Mat}} B)_{i,b} \cdot_R C_{b,l}).$$

For each fixed b, the inner product definition and the right-multiplication half of Definition 49.95 classify the summand with

$$\Sigma_{a:\mathsf{Fin}(m)}((A_{i,a} \cdot_R B_{a,b}) \cdot_R C_{b,l}).$$

Scalar multiplicative associativity from Definition 43.26 gives the pointwise comparison

$$(A_{i,a} \cdot_R B_{a,b}) \cdot_R C_{b,l} \sim_R A_{i,a} \cdot_R (B_{a,b} \cdot_R C_{b,l}).$$

Using Definition 50.26 for the inner and outer finite spines yields

$$((A \cdot_{\mathrm{Mat}} B) \cdot_{\mathrm{Mat}} C)_{i,l} \sim_R \Sigma_{b:\mathsf{Fin}(p)}\Sigma_{a:\mathsf{Fin}(m)} t(a, b).$$

Expanding the right-associated product gives

$$(A \cdot_{\mathrm{Mat}} (B \cdot_{\mathrm{Mat}} C))_{i,l} \sim_R \Sigma_{a:\mathsf{Fin}(m)}(A_{i,a} \cdot_R (B \cdot_{\mathrm{Mat}} C)_{a,l}).$$

For each fixed a, the inner product definition and the left-multiplication half of Definition 49.95 classify the summand with

$$\Sigma_{b:\mathsf{Fin}(p)} A_{i,a} \cdot_R (B_{a,b} \cdot_R C_{b,l}).$$

Again Definition 50.26 lifts the pointwise comparisons through the finite folds, so

$$(A \cdot_{\mathrm{Mat}} (B \cdot_{\mathrm{Mat}} C))_{i,l} \sim_R \Sigma_{a:\mathsf{Fin}(m)} \Sigma_{b:\mathsf{Fin}(p)} t(a,b).$$

Apply Definition 49.105 to the family $s(b,a) := t(a,b)$ over $\mathsf{Fin}(p) \times \mathsf{Fin}(m)$. It gives

$$\Sigma_{b:\mathsf{Fin}(p)} \Sigma_{a:\mathsf{Fin}(m)} t(a,b) \sim_R \Sigma_{a:\mathsf{Fin}(m)} \Sigma_{b:\mathsf{Fin}(p)} t(a,b).$$

Classifier transitivity composes the left expansion, this rectangular fold reindexing, and the symmetry of the right expansion. Thus every entry of $(A \cdot_{\mathrm{Mat}} B) \cdot_{\mathrm{Mat}} C$ is scalar-classified with the corresponding entry of $A \cdot_{\mathrm{Mat}} (B \cdot_{\mathrm{Mat}} C)$. The pointwise classifier of Definition 49.62 packages these entrywise comparisons as the displayed matrix classifier, and Definition 49.65 records that the dimension witnesses are unchanged. □

Theorem 49.107 (Matrix multiplication reassociation classifier transport)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with classifier $\sim_R$, addition $+_R$, multiplication $\cdot_R$, zero endpoint 0_R, and finite additive folds over finite index spines as in Definition 50.26. Let $n, m, p, q : \mathsf{Nat}^{\uparrow}$, and consider the compatible $\mathsf{Mat}^{\uparrow}$ carriers of Definition 49.1 with pointwise classifier from Definition 49.62. Let*

$$A, A' : \mathsf{Fin}(n) \times \mathsf{Fin}(m) \to R, \qquad B, B' : \mathsf{Fin}(m) \times \mathsf{Fin}(p) \to R, \qquad C, C' : \mathsf{Fin}(p) \times \mathsf{Fin}(q) \to R$$

be carried matrices over the same scalar source and matching finite dimensions. Assume matrix multiplication is the finite-fold operation

$$(X \cdot Y)_{u,w} := \Sigma_V (v \mapsto X_{u,v} \cdot_R Y_{v,w})$$

for every matching inner finite index carrier V, using the multiplication closure field of Definition 49.64. Assume the scalar classifier equivalence fields, multiplication congruence, multiplicative associativity, left and right distributivity, additive laws, zero multiplication laws, the fold congruence theorem Definition 50.26, and the two-index finite fold swap certificate of Definition 49.94 required by Definition 49.96 and Definition 49.97. If

$$A \sim_{\mathrm{Mat}} A', \qquad B \sim_{\mathrm{Mat}} B', \qquad C \sim_{\mathrm{Mat}} C',$$

then the two reassociated products $(A \cdot B) \cdot C$ and $A' \cdot (B' \cdot C')$ are carried $\mathsf{Mat}^{\uparrow}$ matrices, and

$$(A \cdot B) \cdot C \sim_{\mathrm{Mat}} A' \cdot (B' \cdot C').$$

Proof. Apply Definition 49.97 to the hypotheses $A \sim_{\mathrm{Mat}} A'$ and $B \sim_{\mathrm{Mat}} B'$. This carries $A \cdot B$ and $A' \cdot B'$ and gives

$$A \cdot B \sim_{\mathrm{Mat}} A' \cdot B'.$$

Apply Definition 49.97 again to this product comparison and to $C \sim_{\mathrm{Mat}} C'$. The compatible dimensions are unchanged, so it carries the two outer left-associated products and gives

$$(A \cdot B) \cdot C \sim_{\mathrm{Mat}} (A' \cdot B') \cdot C'.$$

Now apply Definition 49.96 to the carried triple A', B', C'. The same scalar fold source and the same finite dimension ledger carry $B' \cdot C'$ and $A' \cdot (B' \cdot C')$, and the theorem supplies

$$(A' \cdot B') \cdot C' \sim_{\mathrm{Mat}} A' \cdot (B' \cdot C').$$

Matrix-classifier transitivity composes the two displayed comparisons. The conclusion follows, with all carrier witnesses obtained from the multiplication closure field and all dimension witnesses preserved by Definition 49.65. □

The ten-field fit is: traditional target, reassociation under matrix equality; BEDC source, $\mathsf{Mat}^{\uparrow} + \mathsf{Ring}^{\uparrow} + \mathsf{Nat}^{\uparrow}$; carrier, finite matrix carriers; classifier, pointwise scalar sameness; stability, multiplication classifier congruence plus finite-fold associativity; ledger, unchanged dimensions and scalar source; core theorem, reassociation classifier transport; exactness, pointwise scalar classification; standard bridge, finite-dimensional matrix algebra; status, $\mathsf{ProofTarget}$.

Definition 49.108 (Matrix transpose over a certified scalar carrier)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier and let $n, m : \mathsf{Nat}^{\uparrow}$. For a carried matrix $X : \mathsf{Fin}(n) \times \mathsf{Fin}(m) \to R$ from Definition 49.1, define its transpose by*

$$(X^{\mathsf{T}})_{j,i} := X_{i,j}$$

for $j : \mathsf{Fin}(m)$ and $i : \mathsf{Fin}(n)$. The carriedness witness at the transposed index (j, i) is the scalar witness already assigned to the original entry $X_{i,j}$ by the matrix pattern of Definition 49.61.

Theorem 49.109 (Matrix transpose reverses product over the opposite ring)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, multiplication $\cdot_R$, and finite additive fold $\Sigma_{\mathsf{Fin}(m)}$ as in Definition 50.26. Let R^{op} be the opposite ring data of Definition 43.35, certified by Definition 43.36; thus R^{op} has the same carrier, classifier, zero endpoint, and addition as R, and multiplication*

$$x \cdot_{R^{\mathrm{op}}} y := y \cdot_R x.$$

Let $n, m, p : \mathsf{Nat}^{\uparrow}$ and let

$$A : \mathsf{Fin}(n) \times \mathsf{Fin}(m) \to R, \qquad B : \mathsf{Fin}(m) \times \mathsf{Fin}(p) \to R$$

be carried matrices. Consider the $\mathsf{Mat}^{\uparrow}$ carriers of Definition 49.1 with pointwise classifier from Definition 49.62, and write $\sim_{\mathrm{Mat},R^{\mathrm{op}}}$ for that classifier over the opposite scalar source. Assume matrix multiplication over any certified scalar ring is the finite-fold operation

$$(X \cdot_S Y)_{u,w} := \Sigma_V(v \mapsto X_{u,v} \cdot_S Y_{v,w})$$

for the matching inner finite index carrier V, using the multiplication closure field of Definition 49.64. Then $(A \cdot_R B)^{\mathsf{T}}$ and $B^{\mathsf{T}} \cdot_{R^{\mathrm{op}}} A^{\mathsf{T}}$ are carried $\mathsf{Mat}^{\uparrow}$ matrices over R^{op}, and

$$(A \cdot_R B)^{\mathsf{T}} \sim_{\mathrm{Mat},R^{\mathrm{op}}} B^{\mathsf{T}} \cdot_{R^{\mathrm{op}}} A^{\mathsf{T}}.$$

Proof. The product $A \cdot_R B$ is carried by the multiplication closure row of Definition 49.64. Since the opposite ring has the same scalar carrier and classifier by Definition 43.35, Definition 49.108 carries $(A \cdot_R B)^{\mathsf{T}}$ over R^{op}. The same transpose definition carries B^{T} and A^{T} over R^{op}, and the multiplication closure row over the certified opposite ring carries $B^{\mathsf{T}} \cdot_{R^{\mathrm{op}}} A^{\mathsf{T}}$.

It remains to compare entries. Fix $k : \mathsf{Fin}(p)$ and $i : \mathsf{Fin}(n)$. Expanding the left endpoint gives

$$((A \cdot_R B)^{\mathsf{T}})_{k,i} = (A \cdot_R B)_{i,k} \sim_R \Sigma_{\mathsf{Fin}(m)}(j \mapsto A_{i,j} \cdot_R B_{j,k}).$$

Expanding the product over the opposite ring gives

$$(B^{\mathsf{T}} \cdot_{R^{\mathrm{op}}} A^{\mathsf{T}})_{k,i} \sim_R \Sigma_{\mathsf{Fin}(m)}(j \mapsto (B^{\mathsf{T}})_{k,j} \cdot_{R^{\mathrm{op}}} (A^{\mathsf{T}})_{j,i}).$$

By transpose readback and opposite multiplication, this last finite spine is the same as

$$\Sigma_{\mathsf{Fin}(m)}(j \mapsto B_{j,k} \cdot_{R^{\mathrm{op}}} A_{i,j}) = \Sigma_{\mathsf{Fin}(m)}(j \mapsto A_{i,j} \cdot_R B_{j,k}).$$

The two displayed expansions end at the same finite scalar spine. The finite additive fold over R^{op} uses the same zero endpoint and the same addition as the fold over R, so the pointwise reflexive scalar classifier witness, lifted through Definition 50.26, compares the folded endpoints. Classifier transitivity composes the left expansion with this fold comparison and the symmetry of the right expansion.

Thus for every k and i,

$$((A \cdot_R B)^{\mathsf{T}})_{k,i} \sim_R (B^{\mathsf{T}} \cdot_{R^{\mathrm{op}}} A^{\mathsf{T}})_{k,i}.$$

The pointwise matrix classifier of Definition 49.62 packages these scalar comparisons as the displayed $\mathsf{Mat}^{\uparrow}$ classification over R^{op}. The row-column swap and the unchanged scalar source are recorded by the dimension and scalar ledger of Definition 49.65. □

Theorem 49.110 (Matrix transpose preserves matrix addition)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with classifier $\sim_R$ and addition $+_R$. Let $n, m : \mathsf{Nat}^{\uparrow}$, and consider the $\mathsf{Mat}^{\uparrow}$ carriers of Definition 49.1 with pointwise classifier from Definition 49.62. For carried matrices*

$$A, B : \mathsf{Fin}(n) \times \mathsf{Fin}(m) \to R,$$

assume matrix addition on each matching $\mathsf{Mat}^{\uparrow}$ carrier is the pointwise operation

$$(X + Y)_{u,v} := X_{u,v} +_R Y_{u,v}$$

for matching indices u, v, using the addition closure row of Definition 49.64. Then $(A + B)^{\mathsf{T}}$ and $A^{\mathsf{T}} + B^{\mathsf{T}}$ are carried $\mathsf{Mat}^{\uparrow}$ matrices over $\mathsf{Fin}(m) \times \mathsf{Fin}(n)$, and

$$(A + B)^{\mathsf{T}} \sim_{\mathrm{Mat}} A^{\mathsf{T}} + B^{\mathsf{T}}.$$

Proof. The addition closure row of Definition 49.64 carries $A + B$ over $\mathsf{Fin}(n) \times \mathsf{Fin}(m)$. Applying Definition 49.108 carries $(A + B)^{\mathsf{T}}$ over $\mathsf{Fin}(m) \times \mathsf{Fin}(n)$: at the transposed index (j, i) its scalar witness is the carriedness witness for $(A+B)_{i,j}$ supplied by the matrix pattern of Definition 49.61.

The same transpose definition carries A^{T} and B^{T} over $\mathsf{Fin}(m) \times \mathsf{Fin}(n)$. Applying the pointwise addition closure row in that swapped matrix carrier carries $A^{\mathsf{T}} + B^{\mathsf{T}}$. The ledger records the same scalar source and the exchanged finite index witnesses, as in Definition 49.65.

It remains to compare entries. Fix $j : \mathsf{Fin}(m)$ and $i : \mathsf{Fin}(n)$. Expanding the transpose and pointwise addition clauses gives

$$((A + B)^{\mathsf{T}})_{j,i} = (A + B)_{i,j} = A_{i,j} +_R B_{i,j}.$$

Expanding the transposed pointwise sum gives

$$(A^{\mathsf{T}} + B^{\mathsf{T}})_{j,i} = (A^{\mathsf{T}})_{j,i} +_R (B^{\mathsf{T}})_{j,i} = A_{i,j} +_R B_{i,j}.$$

The two displayed endpoints are the same carried scalar sum, so scalar classifier reflexivity gives

$$((A + B)^{\mathsf{T}})_{j,i} \sim_R (A^{\mathsf{T}} + B^{\mathsf{T}})_{j,i}.$$

Since j and i were arbitrary, the pointwise classifier of Definition 49.62 packages these scalar comparisons as

$$(A + B)^{\mathsf{T}} \sim_{\mathrm{Mat}} A^{\mathsf{T}} + B^{\mathsf{T}}.$$

□

Theorem 49.111 (Matrix transpose fixes the finite-fold identity matrix)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with classifier $\sim_R$, zero endpoint 0_R, and unit endpoint 1_R. Let $n : \mathsf{Nat}^{\uparrow}$, and let I_n be the finite-fold identity matrix of Definition 49.92. Consider the square $\mathsf{Mat}^{\uparrow}$ carrier over $\mathsf{Fin}(n) \times \mathsf{Fin}(n)$ from Definition 49.1, with pointwise classifier from Definition 49.62. Then I_n^{T} is carried and*

$$I_n^{\mathsf{T}} \sim_{\mathrm{Mat}} I_n.$$

Proof. The identity datum of Definition 49.92 carries I_n pointwise: each entry is the scalar endpoint 1_R on the diagonal and 0_R off the diagonal. Applying Definition 49.108 to this carried square matrix carries I_n^{T} over the same finite row and column carrier, since the transposed index pair again lies in $\mathsf{Fin}(n) \times \mathsf{Fin}(n)$.

It remains to compare entries. Fix $i, j : \mathsf{Fin}(n)$. By transpose readback,

$$(I_n^{\mathsf{T}})_{i,j} = (I_n)_{j,i}.$$

By the identity-matrix definition, $(I_n)_{j,i}$ is classified with the Kronecker endpoint $\delta_{j,i}$ and $(I_n)_{i,j}$ is classified with $\delta_{i,j}$. The finite-index equality certificate is symmetric: if j and i are identified, then i and j are identified as well, so both Kronecker endpoints are 1_R; if they are not identified, both Kronecker endpoints are 0_R. Scalar classifier reflexivity for the carried endpoints 1_R and 0_R, followed by the scalar classifier symmetry and transitivity fields, therefore gives

$$(I_n)_{j,i} \sim_R (I_n)_{i,j}.$$

Combining this comparison with the transpose readback yields

$$(I_n^{\mathsf{T}})_{i,j} \sim_R (I_n)_{i,j}.$$

Since the indices i and j were arbitrary, the pointwise matrix classifier packages these scalar comparisons as

$$I_n^{\mathsf{T}} \sim_{\mathrm{Mat}} I_n.$$

□

Theorem 49.112 (Two-index fold swap from finite permutation invariance)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, and finite additive fold $\mathsf{fold}_{+,R}$ from Definition 50.26. Assume the scalar classifier equivalence fields and the additive associativity, commutativity, zero, and congruence rows retained in Definition 43.26. Let J and K be finite index carriers with chosen finite enumerating spines, and write Σ_J and Σ_K for the corresponding finite folds of scalar families over those spines. Suppose the fold is finite-permutation invariant: whenever finite carried scalar spines xs and ys are related by a bijection of their finite position spines and every matched pair of entries is related by $\sim_R$, then*

$$\mathsf{fold}_{+,R}(xs) \sim_R \mathsf{fold}_{+,R}(ys).$$

For every pointwise carried scalar family $s : J \times K \to R$ and every pointwise carried transpose family $s^{\tau} : K \times J \to R$ satisfying

$$s^{\tau}(k, j) \sim_R s(j, k)$$

for all $j : J$ and $k : K$, the two iterated folds satisfy

$$\Sigma_J(j \mapsto \Sigma_K(k \mapsto s(j,k))) \sim_R \Sigma_K(k \mapsto \Sigma_J(j \mapsto s^\tau(k,j))).$$

Thus the field specified in Definition 49.94 is derivable from the finite-permutation invariant additive fold.

Proof. For a family $u : J \times K \to R$, let $\mathsf{Row}_{J,K}(u)$ be the finite scalar spine obtained by concatenating, in the chosen J-order, the chosen K-spine $k \mapsto u(j,k)$ for each row j. For a family $v : K \times J \to R$, let $\mathsf{Col}_{K,J}(v)$ be the analogous K-major spine.

First compare the iterated fold with the flattened row spine. The finite-fold append law used here is obtained by induction on a finite spine xs:

$$\mathsf{fold}_{+,R}(xs{+}{+}ys) \sim_R \mathsf{fold}_{+,R}(xs) +_R \mathsf{fold}_{+,R}(ys).$$

In the nil case this is the additive zero law after unfolding Definition 50.26. In the cons case, unfold the fold on the cons spine, apply the induction hypothesis inside the right summand by additive congruence, and rebracket by additive associativity. Applying this append law while inducting on the finite spine enumerating J gives

$$\Sigma_J(j \mapsto \Sigma_K(k \mapsto s(j,k))) \sim_R \mathsf{fold}_{+,R}(\mathsf{Row}_{J,K}(s)).$$

The same argument with the two index carriers interchanged, followed by classifier symmetry, gives

$$\mathsf{fold}_{+,R}(\mathsf{Col}_{K,J}(s^\tau)) \sim_R \Sigma_K(k \mapsto \Sigma_J(j \mapsto s^\tau(k,j))).$$

The transposition map sends the occurrence indexed by (j,k) in $\mathsf{Row}_{J,K}(s)$ to the occurrence indexed by (k,j) in $\mathsf{Col}_{K,J}(s^\tau)$. Since the chosen spines enumerate J and K without loss or duplication, this map is a bijection of the two finite position spines. At matched positions the hypothesis gives $s^\tau(k,j) \sim_R s(j,k)$, and classifier symmetry gives the orientation $s(j,k) \sim_R s^\tau(k,j)$. Finite-permutation invariance therefore yields

$$\mathsf{fold}_{+,R}(\mathsf{Row}_{J,K}(s)) \sim_R \mathsf{fold}_{+,R}(\mathsf{Col}_{K,J}(s^\tau)).$$

Classifier transitivity composes the row-flattening comparison, the permutation-invariance comparison, and the column-unflattening comparison, giving the displayed two-index fold swap. □

Definition 49.113 (Finite-fold zero matrix data)**.** *Let R be a scalar $\mathsf{Ring}^\uparrow$ carrier with classifier $\sim_R$ and zero endpoint 0_R. For $n, m : \mathsf{Nat}^\uparrow$, the carried zero matrix datum over $\mathsf{Fin}(n) \times \mathsf{Fin}(m)$ is the table*

$$Z_{n,m} : \mathsf{Fin}(n) \times \mathsf{Fin}(m) \to R, \qquad (Z_{n,m})_{i,j} := 0_R.$$

It is carried by the $\mathsf{Mat}^\uparrow$ carrier of Definition 49.1 exactly when every displayed entry is carried by the scalar source, and its classifier endpoint is the pointwise scalar-zero table specified by Definition 49.62.

Theorem 49.114 (Finite-fold matrix zero multiplication law)**.** *Let R be a scalar $\mathsf{Ring}^\uparrow$ carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, multiplication $\cdot_R$, and finite additive folds over finite index spines as in Definition 49.80. Let $n, m, p : \mathsf{Nat}^\uparrow$, and consider the $\mathsf{Mat}^\uparrow$ carriers of Definition 49.1 with pointwise classifier from Definition 49.62. Let*

$$A : \mathsf{Fin}(n) \times \mathsf{Fin}(m) \to R, \qquad B : \mathsf{Fin}(m) \times \mathsf{Fin}(p) \to R$$

be carried matrices. Assume matrix multiplication is the finite scalar-fold operation

$$(X \cdot_{\mathrm{Mat}} Y)_{u,w} := \Sigma_{\mathsf{Fin}(s)}(v \mapsto X_{u,v} \cdot_R Y_{v,w})$$

for every matching inner dimension s, using the multiplication closure row of Definition 49.64. Assume the scalar classifier equivalence fields, multiplication closure and congruence, additive closure and congruence, and the left and right zero multiplication laws retained in Definition 43.26. Then $Z_{n,m} \cdot_{\mathrm{Mat}} B$ and $A \cdot_{\mathrm{Mat}} Z_{m,p}$ are carried $\mathsf{Mat}^{\uparrow}$ matrices over $\mathsf{Fin}(n) \times \mathsf{Fin}(p)$, and

$$Z_{n,m} \cdot_{\mathrm{Mat}} B \sim_{\mathrm{Mat}} Z_{n,p} \qquad \textit{and} \qquad A \cdot_{\mathrm{Mat}} Z_{m,p} \sim_{\mathrm{Mat}} Z_{n,p}.$$

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixFiniteFoldZeroMatrix multiplication law`

Proof. The zero matrix data of Definition 49.113 carries $Z_{n,m}$ and $Z_{m,p}$ pointwise from the scalar zero endpoint. The multiplication closure row of Definition 49.64 therefore carries the two products $Z_{n,m} \cdot_{\mathrm{Mat}} B$ and $A \cdot_{\mathrm{Mat}} Z_{m,p}$.

By Definition 49.62, it remains to compare entries with the pointwise zero table $Z_{n,p}$. Fix $i : \mathsf{Fin}(n)$ and $k : \mathsf{Fin}(p)$. The left product entry expands to

$$\Sigma_{\mathsf{Fin}(m)}(j \mapsto (Z_{n,m})_{i,j} \cdot_R B_{j,k}).$$

Each summand is scalar-classified with 0_R by the displayed definition of $Z_{n,m}$ and the left zero multiplication law in Definition 43.26.

Induct on the finite spine enumerating $\mathsf{Fin}(m)$. In the nil case, Definition 49.80 identifies the fold with 0_R. In the cons case, the head summand is classified with 0_R, and the induction hypothesis classifies the tail fold with 0_R. Additive congruence transports these comparisons to the cons fold, and the additive zero law retained in Definition 43.26 classifies the resulting endpoint with 0_R.

The right product entry expands to

$$\Sigma_{\mathsf{Fin}(m)}(j \mapsto A_{i,j} \cdot_R (Z_{m,p})_{j,k}).$$

Now each summand is scalar-classified with 0_R by the displayed definition of $Z_{m,p}$ and the right zero multiplication law. The same finite-spine induction reduces this fold to 0_R.

Since i and k were arbitrary, Definition 49.62 packages the two entrywise scalar-zero comparisons as matrix classifier witnesses against $Z_{n,p}$. The row, contraction, column, and scalar-source witnesses are unchanged, and Definition 49.65 records that the only non-structural provenance used by the endpoint comparison is scalar zero multiplication. □

This certificate fits the standard ten-field reading as follows. The traditional target is zero absorption for finite matrix multiplication. The BEDC source is $\mathsf{Mat}^{\uparrow}$ over $\mathsf{Ring}^{\uparrow}$ and $\mathsf{Nat}^{\uparrow}$. The carrier is the finite table carrier on $\mathsf{Fin}(n) \times \mathsf{Fin}(m)$. The classifier is the pointwise scalar classifier. Stability consists of matrix multiplication closure together with scalar zero multiplication and additive fold closure. The ledger keeps the row, inner, column, and scalar-source witnesses fixed and records scalar-zero provenance. The core theorem is Definition 49.114. Exactness is the pointwise zero endpoint $Z_{n,p}$. The standard bridge is the usual finite matrix interpretation of carried tables and finite scalar folds. The formalization status is ProofTarget.

Theorem 49.115 (Finite-fold zero matrix additive identity)**.** *Let R carry a scalar $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, and addition $+_R$. Assume the scalar source carries 0_R, and assume the scalar classifier equivalence fields, addition closure, and scalar additive left-zero*

and right-zero laws retained in Definition 43.26. Let $n, m : \mathsf{Nat}^{\uparrow}$, and consider the $\mathsf{Mat}^{\uparrow}$ carrier of Definition 49.1 with pointwise classifier from Definition 49.62. Let

$$A : \mathsf{Fin}(n) \times \mathsf{Fin}(m) \to R$$

be a carried matrix, and let $Z_{n,m}$ be the zero matrix datum of Definition 49.113. Assume matrix addition is the pointwise operation

$$(X + Y)_{i,j} := X_{i,j} +_R Y_{i,j}$$

using the addition closure row of Definition 49.64. Then $A + Z_{n,m}$ and $Z_{n,m} + A$ are carried $\mathsf{Mat}^{\uparrow}$ matrices over $\mathsf{Fin}(n) \times \mathsf{Fin}(m)$, and

$$A + Z_{n,m} \sim_{\mathrm{Mat}} A \qquad \textit{and} \qquad Z_{n,m} + A \sim_{\mathrm{Mat}} A.$$

Consequently,

$$A + Z_{n,m} \sim_{\mathrm{Mat}} Z_{n,m} + A.$$

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonZero additive identity`

Proof. The zero matrix datum of Definition 49.113 carries $Z_{n,m}$ pointwise from the carried scalar zero endpoint. Since A is carried, the addition closure row of Definition 49.64 carries both pointwise sums $A + Z_{n,m}$ and $Z_{n,m} + A$.

By Definition 49.62, it remains to compare entries. Fix $i : \mathsf{Fin}(n)$ and $j : \mathsf{Fin}(m)$. The pointwise addition rule and the definition of $Z_{n,m}$ give

$$(A + Z_{n,m})_{i,j} = A_{i,j} +_R 0_R.$$

The scalar additive right-zero law retained in Definition 43.26 classifies this endpoint with $A_{i,j}$, so

$$(A + Z_{n,m})_{i,j} \sim_R A_{i,j}.$$

For the other order, the same pointwise rule gives

$$(Z_{n,m} + A)_{i,j} = 0_R +_R A_{i,j}.$$

The scalar additive left-zero law classifies this endpoint with $A_{i,j}$, hence

$$(Z_{n,m} + A)_{i,j} \sim_R A_{i,j}.$$

Since i and j were arbitrary, Definition 49.62 packages the two entrywise scalar comparisons as the displayed matrix classifier witnesses against A. Applying scalar symmetry to the second entrywise comparison and scalar transitivity with the first gives

$$(A + Z_{n,m})_{i,j} \sim_R (Z_{n,m} + A)_{i,j}$$

for every index pair, so the same pointwise classifier packages the final displayed consequence. The dimensions, row witness, column witness, and scalar source are unchanged, as recorded by Definition 49.65. □

Lean4 ✓ `BEDC.Derived.MatrixUp.MatrixSingletonAddFold zero prefix absorption`

Theorem 49.116 (Zero matrix transpose swaps dimensions)**.** *Let R be a scalar $\mathsf{Ring}^{\uparrow}$ carrier with classifier $\sim_R$ and zero endpoint 0_R. Assume the scalar source carries 0_R and that the scalar classifier reflexivity row retained in Definition 43.26 is available. Let $n, m : \mathsf{Nat}^{\uparrow}$, and consider the $\mathsf{Mat}^{\uparrow}$ carriers of Definition 49.1 with pointwise classifier from Definition 49.62. Let $Z_{n,m}$ and $Z_{m,n}$ be the zero matrix data of Definition 49.113. Then $(Z_{n,m}^{\mathsf{T}})$ is carried as an $m \times n$ $\mathsf{Mat}^{\uparrow}$ matrix, and*

$$Z_{n,m}^{\mathsf{T}} \sim_{\mathrm{Mat}} Z_{m,n}.$$

Proof. The zero matrix datum $Z_{n,m}$ is carried pointwise from the carried scalar endpoint 0_R by Definition 49.113. Applying the transpose carrier clause of Definition 49.108 carries $Z_{n,m}^{\mathsf{T}}$ over $\mathsf{Fin}(m) \times \mathsf{Fin}(n)$: at an index (j, i) its scalar witness is the witness already assigned to $(Z_{n,m})_{i,j}$.

It remains to compare entries with the zero matrix of the swapped shape. Fix $j : \mathsf{Fin}(m)$ and $i : \mathsf{Fin}(n)$. Expanding the transpose definition gives

$$(Z_{n,m}^{\mathsf{T}})_{j,i} = (Z_{n,m})_{i,j}.$$

Expanding the zero matrix data at the original and swapped index pairs gives

$$(Z_{n,m})_{i,j} = 0_R \qquad \text{and} \qquad (Z_{m,n})_{j,i} = 0_R.$$

Thus both scalar endpoints at the displayed matrix position are the same carried zero endpoint. Scalar classifier reflexivity gives

$$(Z_{n,m}^{\mathsf{T}})_{j,i} \sim_R (Z_{m,n})_{j,i}.$$

Since j and i were arbitrary, the pointwise matrix classifier of Definition 49.62 packages these scalar comparisons as

$$Z_{n,m}^{\mathsf{T}} \sim_{\mathrm{Mat}} Z_{m,n}.$$

The dimension ledger is exactly the row-column swap recorded by Definition 49.65, and the scalar source is unchanged. □

Chapter 50

A Concrete Naming Certificate for $\mathsf{Poly}^{\uparrow}$

The polynomial interface $\mathsf{Poly}^{\uparrow}$ has certificate obligations over a scalar ring from chapter 43 as finite coefficient sequences from chapter 36, normalized to remove trailing zeros so that the highest-index entry is nonzero (or the sequence is empty for the zero polynomial). The classifier is structural sameness on the normalized representative. Polynomial addition and multiplication are derived operations governed by the ring's certificate fields.

50.1 Concrete singleton zero-polynomial instance

Definition 50.1 (Singleton zero-polynomial instance)**.** *Let A_{e} be the singleton history source of Definition 36.169 at $a_0 = \mathsf{e}$. Use the singleton empty-history scalar ring of Definition 43.5. Define the polynomial classifier*

$$\rho_{\mathsf{e}}(h, k) \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h, k).$$

The normalized coefficient-list representative is e, and the singleton normalization map on admitted endpoints is $\mathsf{norm}_{\mathsf{e}}(h) := \mathsf{e}$. The polynomial carrier is A_{e} on BHist endpoints. Define the displayed polynomial operations by

$$0_P := \mathsf{e}, \qquad 1_P := \mathsf{e}, \qquad P \oplus_P Q := \mathsf{append}(P, Q), \qquad P \odot_P Q := \mathsf{append}(P, Q).$$

This tuple is the concrete zero-polynomial instance of the $\mathsf{Poly}^{\uparrow}$ certificate schema over the singleton BEDC history carrier.

Theorem 50.2 (Singleton zero-polynomial laws)**.** *For the singleton instance of Definition 50.1, the displayed polynomial carrier and operations satisfy the concrete $\mathsf{Poly}^{\uparrow}$ law package:*

1. *0_P and 1_P are carried by A_{e}.*
2. *If $A_{\mathsf{e}}(P)$ and $A_{\mathsf{e}}(Q)$, then $A_{\mathsf{e}}(P \oplus_P Q)$ and $A_{\mathsf{e}}(P \odot_P Q)$.*
3. *0_P is a left and right unit for $\oplus_P$ under ρ_{e}.*
4. *1_P is a left and right identity for $\odot_P$ under ρ_{e}.*
5. *$\oplus_P$ and $\odot_P$ are associative under ρ_{e}.*
6. *Left and right distributivity of $\odot_P$ over $\oplus_P$ hold under ρ_{e}.*

7. $\mathsf{norm_e}(\mathsf{norm_e}(P))$ *is classified with* $\mathsf{norm_e}(P)$ *by* ρ_{e}.

The $\mathsf{Poly}^{\uparrow}$ *schema is represented by this concrete* BHist *carrier and its displayed operations, so Lean formalization can target* BEDC.Derived.PolynomialUp *through a carrier certificate instead of abstract operator-only statements.*

Proof. The carrier endpoint is the singleton source of Definition 36.169 at $a_0 = \mathsf{e}$. Thus 0_P, 1_P, and the normalized representative e are all carried by the same reflexive endpoint witness.

For closure under $\oplus_P$ and $\odot_P$, carried inputs reduce to the singleton endpoint under ρ_{e}. The displayed operations are BEDC append endpoints. The continuation unit and associativity laws used in Theorem 40.3, together with Theorem 43.6, identify those append endpoints with the singleton class of e.

The additive unit laws and multiplicative identity laws are the same endpoint calculation. On the left and on the right, the comparison is between $\mathsf{append}(\mathsf{e}, P)$ or $\mathsf{append}(P, \mathsf{e})$ and P. The append unit laws provide the hsame component, while the carrier witnesses come from $A_{\mathsf{e}}(P)$ and $A_{\mathsf{e}}(\mathsf{e})$.

Associativity for both operations follows from BEDC append associativity. The two parenthesized endpoints are related by the same continuation spine, and the singleton classifier packages that relation with the already established carrier closure.

For distributivity, every term appearing on either side is a carried singleton endpoint after the closure step. Both sides are therefore classified with e, and transitivity of hsame supplies the displayed ρ_{e} relation.

Finally, normalization idempotence is immediate because $\mathsf{norm_e}$ is the constant endpoint e on admitted inputs. Both iterated and one-step normalization have the same carried endpoint, so reflexivity of hsame gives the classifier witness. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialUp StdBridge`

50.2 Carrier definition

Definition 50.3 (Polynomial carrier)**.** *Use finite coefficient lists over a scalar ring, normalized by removing trailing zero coefficients.*

50.3 Concrete singleton history polynomial instance

Definition 50.4 (Concrete singleton history polynomial instance)**.** *Let* A_{e} *be the singleton history source of Definition 36.169 at* $a_0 = \mathsf{e}$. *Define*

$$\rho_{\mathsf{e}}(h, k) := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h, k).$$

Set the polynomial code carrier to A_{e} *on* BHist. *Define the displayed polynomial operations by*

$$\mathsf{normalize}_P(h) := \mathsf{e}, \qquad 0_P := \mathsf{e}, \qquad 1_P := \mathsf{e}, \qquad \mathsf{add}_P(f, g) := \mathsf{append}(f, g), \qquad \mathsf{mul}_P(f, g) := \mathsf{append}(f, g).$$

The ledger is the empty normalized coefficient list over the singleton empty-history ring of Definition 43.5.

Theorem 50.5 (Singleton history polynomial laws)**.** *The tuple*

$$(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \mathsf{normalize}_P, 0_P, 1_P, \mathsf{add}_P, \mathsf{mul}_P)$$

satisfies the $\mathsf{Poly}^{\uparrow}$ *law package over* BHist*: normalization closure, normalization idempotence, zero and one closure, addition and multiplication closure, additive zero laws, multiplicative zero laws, multiplicative one laws, associativity, distributivity, and congruence under* ρ_{e}*.*

Proof. Definition 36.169 at $a_0 = \mathsf{e}$ supplies the singleton source witness $A_{\mathsf{e}}(\mathsf{e})$. The same endpoint is the scalar zero and scalar unit carrier supplied by Theorem 43.6.

Normalization closure holds because $\mathsf{normalize}_P(h)$ is the endpoint e. Normalization idempotence compares $\mathsf{normalize}_P(\mathsf{normalize}_P(h))$ with $\mathsf{normalize}_P(h)$, and both sides are the same carried endpoint.

The constants 0_P and 1_P are both e, so zero closure and one closure are exactly $A_{\mathsf{e}}(\mathsf{e})$. Addition closure and multiplication closure use empty-result inversion for BEDC append: if both inputs are singleton-carried, then both inputs are e, and the appended result is again singleton-carried.

The additive zero laws, multiplicative zero laws, and multiplicative one laws all reduce to a comparison of an appended empty endpoint with the carried endpoint. Each classifier goal is assembled from the two endpoint witnesses and the corresponding history-sameness witness.

Associativity and distributivity have no remaining endpoint computation after the displayed operations are unfolded under singleton-carrier hypotheses. The left-associated, right-associated, left-distributive, and right-distributive terms are all singleton-carried, so ρ_{e} packages the same singleton carrier witnesses with the BEDC append associativity witness.

For congruence under ρ_{e}, assume the inputs are pairwise related by ρ_{e}. The operation outputs are singleton-carried on both sides for normalization, addition, and multiplication. The output relation is the singleton classifier witness built from the carrier witnesses and history-sameness. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.singleton empty history polynomial laws`

Theorem 50.6 (Polynomial singleton classifier empty addition split)**.** *For singleton-history polynomial codes* P, Q, h*, the classifier relation between* $\mathsf{add}_P(P, Q)$ *and* h *holds exactly when* P *and* Q *are each history-same to* e *and* h *is singleton-carried:*

$$\rho_{\mathsf{e}}(\mathsf{add}_P(P, Q), h) \quad \Longleftrightarrow \quad \mathsf{hsame}(P, \mathsf{e}) \wedge \mathsf{hsame}(Q, \mathsf{e}) \wedge A_{\mathsf{e}}(h).$$

Proof. Unfold the singleton classifier. The left carrier field says that $\mathsf{append}(P, Q)$ is history-same to e. Empty-result inversion for BEDC append splits this into $\mathsf{hsame}(P, \mathsf{e})$ and $\mathsf{hsame}(Q, \mathsf{e})$, while the right carrier field is exactly $A_{\mathsf{e}}(h)$. Conversely, after the two endpoint sameness witnesses identify P and Q with e, the classifier is rebuilt from the singleton carrier of e, the given carrier of h, and symmetry of the carrier witness for h. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonClassifier add split empty iff`

Theorem 50.7 (Polynomial singleton add visible-left exclusion)**.** *For histories* $P, Q, h : \mathsf{BHist}$*, no singleton polynomial classifier witness can classify an addition endpoint whose left source begins with a visible constructor:*

$$\rho_{\mathsf{e}}(\mathsf{add}_P(\mathsf{e0}(P), Q), h) \Rightarrow \bot, \qquad \rho_{\mathsf{e}}(\mathsf{add}_P(\mathsf{e1}(P), Q), h) \Rightarrow \bot.$$

Proof. Unfold add_P to BEDC append and unfold the singleton classifier. The source carrier field says the appended endpoint is history-same to e. Empty-result inversion for append then forces the visible left source itself to be e, contradicting constructor separation for $\mathsf{e0}$ or $\mathsf{e1}$. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonClassifier add visible left absurd`

Theorem 50.8 (Polynomial singleton add visible-right exclusion)**.** *For histories $P, Q, h : \mathsf{BHist}$, no singleton polynomial classifier witness can classify an addition endpoint whose right source begins with a visible constructor:*

$$\rho_{\mathsf{e}}(\mathsf{add}_P(P, \mathsf{e0}(Q)), h) \Rightarrow \bot, \qquad \rho_{\mathsf{e}}(\mathsf{add}_P(P, \mathsf{e1}(Q)), h) \Rightarrow \bot.$$

Proof. Again the classifier source carrier identifies the BEDC append endpoint with e. Empty-result inversion for append separates the left and right source endpoints, so the visible right endpoint would have to be e. This is excluded by the disjointness of visible BHist constructors from the empty history. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonClassifier add visible right absurd`

Theorem 50.9 (Polynomial singleton classifier append-left cancellation)**.** *For singleton-carried P, adding the same BEDC append context on the left of two singleton polynomial endpoints preserves and reflects the singleton classifier:*

$$A_{\mathsf{e}}(P) \Longrightarrow (\rho_{\mathsf{e}}(\mathsf{append}(P, Q), \mathsf{append}(P, R)) \Longleftrightarrow \rho_{\mathsf{e}}(Q, R)).$$

Proof. In the forward direction, the classifier says that both appended endpoints are singleton-carried. Empty append inversion splits the two endpoint carriers, giving $Q\mathsf{hsamee}$ and $R\mathsf{hsamee}$, and these witnesses rebuild $\rho_{\mathsf{e}}(Q, R)$. Conversely, the singleton carrier of P identifies the left context with e, so both appended endpoints reduce to the original classified endpoints Q and R. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonClassifier append left cancel iff`

Theorem 50.10 (Polynomial singleton classifier append-right cancellation)**.** *For singleton-carried P, adding the same BEDC append context on the right of two singleton polynomial endpoints preserves and reflects the singleton classifier:*

$$A_{\mathsf{e}}(P) \Longrightarrow (\rho_{\mathsf{e}}(\mathsf{append}(Q, P), \mathsf{append}(R, P)) \Longleftrightarrow \rho_{\mathsf{e}}(Q, R)).$$

Proof. In the forward direction, the two appended endpoints are singleton-carried. Empty append inversion splits those carrier witnesses into $Q\mathsf{hsamee}$, $P\mathsf{hsamee}$, and $R\mathsf{hsamee}$, so the recovered witnesses for Q and R rebuild $\rho_{\mathsf{e}}(Q, R)$.

For the reverse direction, combine the supplied singleton carrier for P with the two endpoint carriers in $\rho_{\mathsf{e}}(Q, R)$. Empty append inversion rebuilds singleton carrier witnesses for both right-appended endpoints, and transitivity through e supplies their classifier comparison. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonClassifier append right cancel iff`

Theorem 50.11 (Polynomial singleton classifier append-pair carrier exactness)**.** *For histories $P, Q, R, S : \mathsf{BHist}$, the singleton polynomial classifier relates the two appended endpoints exactly when all four factors are carried by the singleton carrier:*

$$\rho_{\mathsf{e}}(\mathsf{append}(P, Q), \mathsf{append}(R, S)) \Longleftrightarrow A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q) \wedge A_{\mathsf{e}}(R) \wedge A_{\mathsf{e}}(S).$$

Proof. Unfold the singleton classifier. In the forward direction, the two carrier fields identify $\mathsf{append}(P, Q)$ and $\mathsf{append}(R, S)$ with e, and empty-result inversion for append splits these into the four singleton carrier witnesses. Conversely, if all four factors are singleton-carried, each factor is identified with e, so both appended endpoints reduce to e and the classifier is rebuilt from reflexivity of $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonClassifier append pair carrier iff`

Theorem 50.12 (Polynomial singleton classifier self-context split)**.** *For histories a, x, b : BHist, the singleton polynomial classifier splits the repeated self-context around x into the carrier of that context and the classifier of the middle endpoint:*

$$\rho_{\mathsf{e}}(\mathsf{append}(a, \mathsf{append}(x, a)), b) \iff A_{\mathsf{e}}(a) \wedge \rho_{\mathsf{e}}(x, b).$$

Proof. Unfold the singleton classifier. The forward direction applies empty-result inversion to the outer append carrier and then to the inner append carrier, extracting $A_{\mathsf{e}}(a)$ and $A_{\mathsf{e}}(x)$. Together with the target carrier field, these witnesses rebuild $\rho_{\mathsf{e}}(x, b)$ by transitivity through e.

Conversely, use $A_{\mathsf{e}}(a)$ and the source carrier in $\rho_{\mathsf{e}}(x, b)$ to rebuild the inner append as empty, then rebuild the full self-context endpoint as empty. The target carrier and empty-history comparison come from the middle classifier data. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonClassifier append self context split iff`

Theorem 50.13 (Polynomial singleton normalized append classifier carrier)**.** *For histories P, Q, h, classifying h against the normalized singleton append endpoint is exactly the singleton carrier predicate on h:*

$$\rho_{\mathsf{e}}(\mathsf{normalize}_P(\mathsf{append}(P, Q)), h) \quad \iff \quad A_{\mathsf{e}}(h).$$

Proof. The singleton normalization endpoint is e. In the forward direction, the right carrier field of ρ_{e} is precisely $A_{\mathsf{e}}(h)$. Conversely, a carrier witness for h combines with reflexivity of e and symmetry of the same carrier witness to rebuild the singleton classifier. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonNormalize append classifier carrier iff`

Theorem 50.14 (Polynomial singleton append distributivity is classified)**.** *For singleton-carried polynomial endpoints P, Q, R, the displayed append forms of the two distributivity comparisons are classified by ρ_{e}:*

$$\rho_{\mathsf{e}}(\mathsf{append}(P, \mathsf{append}(Q, R)), \mathsf{append}(\mathsf{append}(P, Q), \mathsf{append}(P, R)))$$

and

$$\rho_{\mathsf{e}}(\mathsf{append}(\mathsf{append}(P, Q), R), \mathsf{append}(\mathsf{append}(P, R), \mathsf{append}(Q, R))).$$

Proof. The singleton carrier is closed under BEDC append: once an input is identified with e, appending it to another singleton-carried endpoint again produces a singleton-carried endpoint. Applying this closure to all displayed append trees shows that both sides of each comparison are carried by A_{e}. Each classifier is then assembled by transitivity through e: the left append tree is history-same to e, and the right append tree is history-same to e. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingleton append distrib classified`

Theorem 50.15 (Polynomial singleton classifier continuation commutativity closure)**.** *Let P, Q : BHist be carried by the singleton polynomial carrier A_{e}. If $\mathsf{Cont}(P, Q, L)$ and $\mathsf{Cont}(Q, P, R)$, then both continuation results are carried by A_{e}, and the singleton polynomial classifier relates them:*

$$A_{\mathsf{e}}(L) \wedge A_{\mathsf{e}}(R) \wedge \rho_{\mathsf{e}}(L, R).$$

Proof. The carrier hypotheses reduce P and Q to the empty history. The two continuation witnesses then reduce L and R to the same endpoint $\mathsf{append}(\mathsf{e},\mathsf{e}) = \mathsf{e}$. Repacking the reflexive empty-history carrier witnesses for the two results with $\mathsf{hsame}(\mathsf{e},\mathsf{e})$ gives the singleton classifier comparison. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonClassifier continuation comm closed`

Theorem 50.16 (Polynomial singleton classifier continuation closure)**.** *Let P, P', Q, Q', L, R : BHist. If the singleton polynomial classifier relates P with P' and Q with Q', and if*

$$\mathsf{Cont}(P, Q, L) \qquad \textit{and} \qquad \mathsf{Cont}(P', Q', R),$$

then the singleton polynomial classifier relates the continuation results:

$$\rho_{\mathsf{e}}(L, R).$$

Proof. Each classifier witness supplies singleton carrier evidence for its two endpoints. Thus all four continuation inputs are internally the empty history. Transporting the two continuation witnesses to the canonical empty-empty continuation shows $L\mathsf{hsamee}$ and $R\mathsf{hsamee}$. These carrier witnesses, together with transitivity through e, rebuild $\rho_{\mathsf{e}}(L, R)$. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonClassifier continuation closed`

Theorem 50.17 (Polynomial singleton continuation result against empty is classified)**.** *Let P, Q, r : BHist be singleton-carried polynomial endpoints. If $\mathsf{Cont}(P, Q, r)$, then the continuation result is classified against the empty singleton endpoint:*

$$\rho_{\mathsf{e}}(r, \mathsf{e}).$$

Proof. The two singleton carrier witnesses identify P and Q with e. The continuation ledger then identifies r with $\mathsf{append}(\mathsf{e},\mathsf{e}) = \mathsf{e}$. The classifier is rebuilt from the empty-history carrier witnesses on both endpoints and reflexivity of $\mathsf{hsame}(\mathsf{e},\mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonClassifier cont result empty classified`

Theorem 50.18 (Polynomial singleton classifier continuation result empty witness iff)**.** *For a history r : BHist, r is classified with the singleton empty polynomial endpoint exactly when it is the continuation result of two singleton-carried polynomial endpoints:*

$$\exists P, Q : \mathsf{BHist},\ A_{\mathsf{e}}(P) \wedge A_{\mathsf{e}}(Q) \wedge \mathsf{Cont}(P, Q, r) \quad \Longleftrightarrow \quad \rho_{\mathsf{e}}(r, \mathsf{e}).$$

Proof. In the forward direction, the two carrier witnesses identify P and Q with e. The continuation witness then identifies r with $\mathsf{append}(\mathsf{e},\mathsf{e})$, hence with e, and the singleton classifier is assembled from the two empty endpoint carrier witnesses and reflexive hsame.

Conversely, if $\rho_{\mathsf{e}}(r, \mathsf{e})$ holds, take $P = \mathsf{e}$ and $Q = r$. The left endpoint is carried by reflexivity, the right endpoint is carried by the left carrier field of the classifier, and the empty-source continuation witness gives $\mathsf{Cont}(\mathsf{e}, r, r)$. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonClassifier cont result empty witness iff`

The $\mathsf{Poly}^{\uparrow}$ schema is instantiated by this concrete BHist carrier and the displayed BHist-valued operations, so later formalization can target BHist-anchored polynomial laws rather than abstract coefficient operators.

50.4 The certificate

Definition 50.19 (Polynomial source specification)**.** *The source is* $\mathsf{List}^{\uparrow}(R)$ *over a certified scalar ring* $\mathsf{Ring}^{\uparrow}(R)$*, restricted to normalized lists.*

Definition 50.20 (Polynomial pattern specification)**.** *The pattern is finite coefficient-sequence generation followed by canonical trimming.*

Definition 50.21 (Polynomial classifier specification)**.** *The classifier is structural list sameness on normalized coefficient lists.*

Definition 50.22 (Polynomial stability certificate)**.** *The stability certificate consists of:*

1. *normalization removes trailing zeros*
2. *normalization is idempotent*
3. *zero polynomial represented by empty list*
4. *structural reflexivity and transitivity*
5. *addition and multiplication closure after normalization*

Definition 50.23 (Polynomial ledger policy)**.** *Record the original coefficient list and its normalized representative.*

Definition 50.24 ($\mathsf{Poly}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{Poly}^{\uparrow}$*.*

Primitive boundary. $\mathsf{Poly}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Remark 50.25 (Zero-axiom encoding note)**.** *Replaces quotienting by trailing-zero equivalence with normalization.*

Closure status for $\mathsf{NameCert}_{\mathsf{Poly}^{\uparrow}}$**.**

Constructive story: A polynomial at the mature singleton boundary is a normalized coefficient list whose visible representative is always the empty history: the carrier accepts exactly the histories classified with e, and normalization sends every admitted code back to that endpoint. The classifier is the restricted singleton relation ρ_{e}, so two polynomial codes agree only by carrying both endpoints in A_{e} and showing the underlying histories are hsame, rather than quotienting arbitrary lists by trailing-zero equivalence. The source is the normalized coefficient-list discipline over the singleton ring, the pattern records zero, one, raw addition, multiplication, normalization idempotence, trim compatibility, literal associativity, evaluation, and readback rows, and the ledger keeps the original coefficient list visible together with its normalized empty representative. Because e supplies the carrier witness, hsame is reflexive, symmetric, and transitive, and the singleton carrier transports along history-sameness, the five name-certificate obligations are discharged before any external polynomial algebra is consulted. A history h lies in the signature gap of a $\mathsf{Poly}^{\uparrow}$ token p when the source-domain accepts h, the signature relation pairs it with a normalized answer and evidence ledger, and token introduction names that answer as p; here this reduces to h being an admitted singleton code whose normalized coefficient list is e, so p names the terminal zero-polynomial value. The checked standard bridge reads the same endpoint as the one-point normalized polynomial table and reads it back to the empty BEDC representative, preserving addition, multiplication, evaluation, and trimming as endpoint laws. The chapter registers this normalized singleton construction under the name $\mathsf{Poly}^{\uparrow}$; it closes the displayed zero-polynomial surface without forming quotient classes, importing universal polynomial properties, or adding a derivative/evaluation theory beyond the stated rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Poly}^{\uparrow}}, \mathsf{maturePackageClosed})$

Scope closed: The paper-side scope is exactly the terminal singleton-history polynomial certificate together with the normal-form boundary, raw addition trim compatibility, literal multiplication associativity, and singleton evaluation and readback rows stated in this chapter and its included polynomial child files.

Formal verification: FormalStatus(NameCert$_{\mathsf{Poly}\uparrow}$, bridgeChecked)
Lean target: `BEDC.Derived.PolynomialUp.singleton\_empty\_history\_polynomial\_laws`
Bridge status: bridgeChecked
Not claimed: This chapter does not close general polynomial algebra over arbitrary scalar rings, quotient-style trailing-zero equivalence, universal polynomial properties, derivative theory, or evaluation theory.
Upgrade path: No further upgrade – chapter at top of formal axis.

Theorem 50.26 (Finite additive fold congruence for coefficient lists)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero 0_R, and addition $+$. Assume $0_R \sim_R 0_R$ and the additive congruence field*

$$a \sim_R a' \text{ and } b \sim_R b' \quad \Longrightarrow \quad (a+b) \sim_R (a'+b')$$

for all scalar endpoints. These are among the additive ring fields retained in Definition 43.26; when the scalar source is presented by the commutative-ring certificate, Definition 44.8 keeps these additive fields unchanged.

Let fold_+ be the finite recursive coefficient fold on finite coefficient spines, satisfying

$$\mathsf{fold}_+(\mathsf{nil}) = 0_R, \qquad \mathsf{fold}_+(\mathsf{cons}(a, xs')) = a + \mathsf{fold}_+(xs').$$

For finite coefficient spines $xs, ys : \mathsf{ListCarrier}(R)$, if their same-length pointwise scalar comparison is represented by the structural classifier witness

$$\mathsf{ListClassifierSpec}(\sim_R, xs, ys)$$

from Definition 36.12, then

$$\mathsf{fold}_+(xs) \sim_R \mathsf{fold}_+(ys).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonAddFold list classifier hsame`

Proof. Induct on the structural classifier witness. By Definition 36.13, the nil case is the nil-nil constructor and the cons case is the cons-cons constructor; mixed nil-cons shapes have no classifier witness. The same structural witness also records the equal finite-spine length by Definition 36.31.

In the nil-nil case, the two fold equations identify both fold endpoints with 0_R. The assumed zero self-classification $0_R \sim_R 0_R$ gives the fold comparison.

In the cons-cons case, write the two spines as $\mathsf{cons}(a, xs')$ and $\mathsf{cons}(b, ys')$. The constructor clause supplies the head comparison $a \sim_R b$ and the tail classifier witness $\mathsf{ListClassifierSpec}(\sim_R, xs', ys')$. The induction hypothesis gives $\mathsf{fold}_+(xs') \sim_R \mathsf{fold}_+(ys')$. Applying the additive congruence field from Definition 43.26 to these two comparisons yields

$$(a + \mathsf{fold}_+(xs')) \sim_R (b + \mathsf{fold}_+(ys')).$$

The cons fold equations identify these endpoints with $\mathsf{fold}_+(\mathsf{cons}(a, xs'))$ and $\mathsf{fold}_+(\mathsf{cons}(b, ys'))$, giving the displayed fold comparison. □

Theorem 50.27 (Zero convolution summands fold to zero)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero 0_R, and addition $+$, equipped with the additive fields retained in Definition 43.26: zero self-classification, classifier transitivity, additive congruence, and the additive left-zero law. For a commutative-ring scalar source, these are unchanged by Definition 44.8.*

Let fold_+ be the finite recursive coefficient fold from Definition 50.26. Let $\mathsf{summ}_I : \mathsf{ListCarrier}(R)$ be the finite spine of scalar summands selected by a raw Cauchy convolution index spine I, and

let $\mathsf{zero}_I : \mathsf{ListCarrier}(R)$ *be the same finite spine with every entry replaced by* 0_R*. If the all-zero summand condition is represented by the structural witness*

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{summ}_I, \mathsf{zero}_I),$$

then

$$\mathsf{fold}_+(\mathsf{summ}_I) \sim_R 0_R.$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonAddFold zero remainder empty`

Proof. The displayed hypothesis is a finite-spine classifier witness as in Definition 36.12. By Definition 36.13, its only possible constructor cases are nil-nil and cons-cons. Induct on this structural witness.

In the nil-nil case, both spines are nil. The fold equation from Definition 50.26 identifies the left endpoint with 0_R, and zero self-classification supplies $0_R \sim_R 0_R$.

In the cons-cons case, write the summand spine as $\mathsf{cons}(a, xs')$ and the matching zero spine as $\mathsf{cons}(0_R, zs')$. The constructor clause gives the head comparison $a \sim_R 0_R$ and the tail witness $\mathsf{ListClassifierSpec}(\sim_R, xs', zs')$. The induction hypothesis gives

$$\mathsf{fold}_+(xs') \sim_R 0_R.$$

Applying additive congruence from Definition 43.26 to the head comparison and this tail comparison yields

$$(a + \mathsf{fold}_+(xs')) \sim_R (0_R + 0_R).$$

The additive left-zero law identifies $0_R + 0_R$ with 0_R. Classifier transitivity composes these two comparisons. The cons fold equation then identifies $a + \mathsf{fold}_+(xs')$ with $\mathsf{fold}_+(\mathsf{cons}(a, xs'))$, giving the claimed fold comparison for the cons spine. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialZeroRemainder addFold empty classified`

Definition 50.28 (Classified zero remainder spine)**.** *Let* R *be a scalar carrier with classifier* $\sim_R$ *and zero endpoint* 0_R*. For a finite coefficient spine* $t : \mathsf{ListCarrier}(R)$*,* $\mathsf{ZeroRem}_R(t)$ *means that every displayed coefficient in* t *is scalar-classified as zero. It is the finite-spine predicate generated by the nil clause and the cons clause*

$$a \sim_R 0_R \quad \textit{and} \quad \mathsf{ZeroRem}_R(t') \quad \Longrightarrow \quad \mathsf{ZeroRem}_R(\mathsf{cons}(a, t')).$$

Lean4 (definition) `BEDC.Derived.PolynomialUp.PolynomialZeroRemainder`

Lemma 50.29 (Trim invariance under a common classified spine and zero remainders)**.** *Let* R *be a scalar carrier with classifier* $\sim_R$*, zero endpoint* 0_R*, and scalar certificate* $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$*. Assume* $0_R \sim_R 0_R$*. For a commutative-ring scalar source, Definition 44.8 keeps the underlying ring carrier, zero endpoint, and classifier unchanged. Let* trim_R *be the canonical polynomial trimming operation specified by Definition 50.20 and Definition 50.22.*

For finite coefficient spines $p, q, r, s : \mathsf{ListCarrier}(R)$*, if*

$$\mathsf{ListClassifierSpec}(\sim_R, p, q), \qquad \mathsf{ZeroRem}_R(r), \qquad \mathsf{ZeroRem}_R(s)$$

hold, then the normalized representatives are structurally list-same:

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(p{+}{+}r), \mathsf{trim}_R(q{+}{+}s)).$$

Proof. By Definition 36.31, the classified common spines p and q have the same finite length. The proof is by induction on the displayed witness $\mathsf{ListClassifierSpec}(\sim_R, p, q)$ from Definition 36.12.

First record the zero-remainder base fact. An induction on $\mathsf{ZeroRem}_R(t)$, using the trailing-zero removal and empty zero-polynomial clauses in Definition 50.22, identifies $\mathsf{trim}_R(t)$ with nil. Hence two zero-remainder spines trim to endpoints classified by the nil clause of $\mathsf{ListClassifierSpec}$.

In the nil-nil case for the common spine, p and q are both nil. The two original lists are exactly the remainders r and s, so the zero-remainder base fact gives the nil-nil classifier witness for their trims.

In the cons-cons case, write

$$p = \mathsf{cons}(a, p'), \qquad q = \mathsf{cons}(b, q').$$

The classifier constructor supplies $a \sim_R b$ and a tail witness $\mathsf{ListClassifierSpec}(\sim_R, p', q')$. Applying the induction hypothesis to p', q' with the same zero remainders gives

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(p' {+}{+} r), \mathsf{trim}_R(q' {+}{+} s)).$$

By Definition 36.13, the two trimmed tails have matching nil or cons shape; the mixed shapes are impossible.

If the trimmed tails are cons spines, canonical trimming keeps the displayed heads because a nonempty normalized tail contains a nonzero highest entry. The cons clause of $\mathsf{ListClassifierSpec}$ then combines the head witness $a \sim_R b$ with the classified trimmed tails.

If the trimmed tails are both nil, the canonical cons-trim clause tests only whether the displayed head is scalar-classified as zero. The head witness $a \sim_R b$, together with the symmetry and transitivity fields of cert_R, gives

$$a \sim_R 0_R \iff b \sim_R 0_R.$$

Thus the two trim computations take the same branch. In the dropped-head branch, both normalized representatives are nil and the nil clause classifies them. In the retained-head branch, both normalized representatives are singleton spines, and the cons clause classifies them using $a \sim_R b$ and the nil-tail classifier.

These cases exhaust the structural classifier witness by Definition 36.13. Finally, Definition 50.21 reads the resulting finite-spine classifier as structural sameness of the two normalized polynomial representatives. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonAddFold common spine zero remainder hsame`

Definition 50.30 (Polynomial raw addition comparison data)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, and addition $+$. For finite coefficient spines, the zero-padded raw addition radd_R is the recursion*

$$\begin{aligned}
\mathsf{radd}_R(\mathsf{nil}, \mathsf{nil}) &= \mathsf{nil}, \\
\mathsf{radd}_R(\mathsf{cons}(a, x), \mathsf{nil}) &= \mathsf{cons}(a + 0_R, \mathsf{radd}_R(x, \mathsf{nil})), \\
\mathsf{radd}_R(\mathsf{nil}, \mathsf{cons}(b, y)) &= \mathsf{cons}(0_R + b, \mathsf{radd}_R(\mathsf{nil}, y)), \\
\mathsf{radd}_R(\mathsf{cons}(a, x), \mathsf{cons}(b, y)) &= \mathsf{cons}(a + b, \mathsf{radd}_R(x, y)).
\end{aligned}$$

For the canonical trim trim_R specified by Definition 50.20 and Definition 50.22, write the polynomial raw classifier as

$$\mathsf{PolySame}_R(x, y) \iff \mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(x), \mathsf{trim}_R(y)).$$

This is the normalized structural classifier of Definition 50.21 applied to raw coefficient spines.

Lean4 (definition) `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd`

Lemma 50.31 (Raw addition zero-tail trim stability)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, and scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$. Assume $0_R \sim_R 0_R$ and the additive fields retained in Definition 43.26: classifier transitivity, additive congruence, and the additive zero laws. For a commutative-ring scalar source, these fields are unchanged by Definition 44.8.*

For finite coefficient spines $x, y, z : \mathsf{ListCarrier}(R)$, if $\mathsf{ZeroRem}_R(z)$ holds in the sense of Definition 50.28, then

$$\mathsf{PolySame}_R(\mathsf{radd}_R(x{+}{+}z, y), \mathsf{radd}_R(x, y))$$

and

$$\mathsf{PolySame}_R(\mathsf{radd}_R(x, y{+}{+}z), \mathsf{radd}_R(x, y)).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd left zero tail addFold invariance`

Proof. The nil spine is a zero remainder by the nil clause of Definition 50.28. Consider the left-input statement. The recursion in Definition 50.30 scans the two raw sums coefficient by coefficient. Induct on the displayed finite spines, first through the common prefix x and then through the zero remainder z after x is exhausted.

At a position where both raw sums use the same ordinary coefficient from x, source reflexivity from cert_R and additive congruence classify the two displayed sum coefficients. At a position where the extended input supplies a zero-remainder coefficient a while the unextended input supplies the padding coefficient 0_R, the hypothesis $a \sim_R 0_R$ and source reflexivity on the other displayed coefficient classify $a + b$ with $0_R + b$. If the other input is also padding, additive congruence classifies $a + 0_R$ with $0_R + 0_R$, and the additive zero law plus transitivity classifies this exposed coefficient as 0_R.

Thus the raw sum $\mathsf{radd}_R(x{+}{+}z, y)$ decomposes as $c{+}{+}t$ so that $\mathsf{ListClassifierSpec}(\sim_R, c, \mathsf{radd}_R(x, y))$ holds and $\mathsf{ZeroRem}_R(t)$ holds. Applying Definition 50.29 with the common classified spines c and $\mathsf{radd}_R(x, y)$, the zero remainder t, and the nil zero remainder gives

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(\mathsf{radd}_R(x{+}{+}z, y)), \mathsf{trim}_R(\mathsf{radd}_R(x, y))).$$

By Definition 50.30, this is the first displayed $\mathsf{PolySame}_R$ claim.

The right-input statement is the same coefficient scan with the zero-remainder coefficient appearing in the right summand. The non-padding comparison is $b + a$ against $b + 0_R$, handled by additive congruence from $a \sim_R 0_R$ and source reflexivity on b; the padding comparison is $0_R + a$ against $0_R + 0_R$, handled by additive congruence, the additive zero law, and transitivity. The resulting decomposition and the same application of Definition 50.29 give the second displayed $\mathsf{PolySame}_R$ claim. □

Theorem 50.32 (Polynomial raw addition two-sided trim compatibility)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, and scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$. Assume the additive ring fields cited in Definition 50.31. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{radd}_R(p, q), \mathsf{radd}_R(\mathsf{trim}_R(p), \mathsf{trim}_R(q))).$$

Proof. Put $p_0 = \mathsf{trim}_R(p)$ and $q_0 = \mathsf{trim}_R(q)$. By the trailing-zero removal clause in Definition 50.22, the canonical trim decompositions present

$$p = p_0{+}{+}z_p, \qquad q = q_0{+}{+}z_q,$$

with $\mathsf{ZeroRem}_R(z_p)$ and $\mathsf{ZeroRem}_R(z_q)$.

Apply the left-input part of Definition 50.31 to p_0, q, z_p. After substituting the first trim decomposition, this gives

$$\mathsf{PolySame}_R(\mathsf{radd}_R(p, q), \mathsf{radd}_R(p_0, q)).$$

Apply the right-input part of the same lemma to p_0, q_0, z_q. After substituting the second trim decomposition, this gives

$$\mathsf{PolySame}_R(\mathsf{radd}_R(p_0, q), \mathsf{radd}_R(p_0, q_0)).$$

Unfold $\mathsf{PolySame}_R$ using Definition 50.30. The two displayed witnesses are structural list-classifier witnesses between the three normalized coefficient spines. Transitivity of $\sim_R$ from cert_R and Definition 36.15 compose them, giving

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(\mathsf{radd}_R(p, q)), \mathsf{trim}_R(\mathsf{radd}_R(p_0, q_0))).$$

Substituting $p_0 = \mathsf{trim}_R(p)$ and $q_0 = \mathsf{trim}_R(q)$, this is exactly the asserted polynomial classifier comparison. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd two sided trim compatibility`

Proposition 50.33 (Polynomial raw addition right zero-tail invariance)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, and scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$. Assume $0_R \sim_R 0_R$ and the additive fields retained in Definition 43.26: classifier transitivity, additive congruence, and the additive zero laws. For a commutative-ring scalar source, these fields are unchanged by Definition 44.8.*

For finite coefficient spines $p, q, t : \mathsf{ListCarrier}(R)$, if $\mathsf{ZeroRem}_R(t)$ holds in the sense of Definition 50.28, then

$$\mathsf{PolySame}_R(\mathsf{radd}_R(p, q{+}{+}t), \mathsf{radd}_R(p, q)).$$

Proof. Apply Definition 50.31 with $x = p$, $y = q$, and $z = t$, and read its second displayed conclusion. The hypothesis on t is exactly the classified zero-tail condition from Definition 50.28; Definition 50.30 identifies the displayed relation as the normalized polynomial classifier. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd right zero tail addFold invariance`

Definition 50.34 (Polynomial normalized singleton representative)**.** *Let R be a scalar carrier with classifier $\sim_R$ and zero endpoint 0_R. For a scalar coefficient c, define*

$$\mathsf{NormOne}_R(c) \iff \neg(c \sim_R 0_R).$$

Thus the singleton coefficient spine $\mathsf{cons}(c, \mathsf{nil})$ is a normalized singleton representative exactly when $\mathsf{NormOne}_R(c)$ holds, while nil is the empty zero-polynomial representative. This is the one-coefficient boundary of the trailing-zero convention in Definition 50.3 and the canonical trimming rule in Definition 50.22.

Lean4 (definition) `BEDC.Derived.PolynomialUp.PolynomialSingletonNormalizedRepresentative`

Proposition 50.35 (Raw polynomial addition leaves singleton normal form)**.** *Let R be a scalar ring carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, and canonical trim trim_R as in Definition 50.20 and Definition 50.22. Let radd_R and $\mathsf{PolySame}_R$ be the raw addition and normalized raw classifier of Definition 50.30. For scalar sources presented through $\mathsf{CommRing}^{\uparrow}$, Definition 44.8 reads these as the retained $\mathsf{Ring}^{\uparrow}$ addition, zero endpoint, and classifier.*

Suppose a and b are classified nonzero and add to a coefficient classified as zero:

$$\neg(a \sim_R 0_R), \qquad \neg(b \sim_R 0_R), \qquad (a+b) \sim_R 0_R.$$

Set

$$p := \mathsf{cons}(a, \mathsf{nil}), \qquad q := \mathsf{cons}(b, \mathsf{nil}).$$

Then p and q are normalized singleton representatives, but their raw zero-padded sum is not a normalized singleton representative:

$$\mathsf{NormOne}_R(a) \wedge \mathsf{NormOne}_R(b),$$

$$\mathsf{radd}_R(p, q) = \mathsf{cons}(a+b, \mathsf{nil}),$$

$$\neg\mathsf{NormOne}_R(a+b).$$

Moreover its canonical normalized representative is the empty zero representative, and this is exactly what the polynomial classifier records:

$$\mathsf{trim}_R(\mathsf{radd}_R(p, q)) = \mathsf{nil}, \qquad \mathsf{PolySame}_R(\mathsf{radd}_R(p, q), \mathsf{nil}).$$

Proof. By Definition 50.166, the assumptions $\neg(a \sim_R 0_R)$ and $\neg(b \sim_R 0_R)$ are precisely the witnesses $\mathsf{NormOne}_R(a)$ and $\mathsf{NormOne}_R(b)$, so p and q are normalized singleton representatives.

Unfolding p and q, the cons-cons branch of the raw addition recursion in Definition 50.30 gives

$$\mathsf{radd}_R(p, q) = \mathsf{cons}(a+b, \mathsf{radd}_R(\mathsf{nil}, \mathsf{nil})).$$

The nil-nil branch gives $\mathsf{radd}_R(\mathsf{nil}, \mathsf{nil}) = \mathsf{nil}$, hence

$$\mathsf{radd}_R(p, q) = \mathsf{cons}(a+b, \mathsf{nil}).$$

The coefficient hypothesis $(a+b) \sim_R 0_R$ contradicts any witness of $\mathsf{NormOne}_R(a+b)$, since such a witness is a proof of $\neg((a+b) \sim_R 0_R)$. Therefore $\neg\mathsf{NormOne}_R(a+b)$, so the raw singleton spine is not admitted as a normalized singleton representative.

The same coefficient hypothesis activates the trailing-zero clause of the canonical trim from Definition 50.22. Therefore the singleton spine $\mathsf{cons}(a+b, \mathsf{nil})$ trims to nil, and the raw-sum computation above gives

$$\mathsf{trim}_R(\mathsf{radd}_R(p, q)) = \mathsf{nil}.$$

The empty zero-polynomial clause gives $\mathsf{trim}_R(\mathsf{nil}) = \mathsf{nil}$. Unfolding $\mathsf{PolySame}_R$ from Definition 50.30, the classifier goal is

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{nil}, \mathsf{nil}),$$

which is the nil-nil constructor of the finite-spine classifier from Definition 36.12, as isolated by Definition 36.13. Hence $\mathsf{PolySame}_R(\mathsf{radd}_R(p, q), \mathsf{nil})$ holds. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd singleton normal form boundary`

Definition 50.36 (Polynomial singleton constant-source schema instance)**.** *The concrete constant-source instance for* $\mathsf{Poly}^{\uparrow}$ *uses the singleton empty-history polynomial carrier. Its coefficient source is the existing singleton scalar carrier, its polynomial constructor is the constant singleton coefficient row* $\mathsf{cons}(c, \mathsf{nil})$*, and its evaluation row is the singleton evaluation readback* $\mathsf{PolynomialSingletonEval}$ *at the displayed evaluation endpoint. The classifier is the singleton polynomial classifier on these* BHist *rows, not an abstract coefficient equivalence.*

Theorem 50.37 (Polynomial singleton constant evaluation boundary)**.** *Every constant-source singleton polynomial from Definition 50.168 evaluates to the displayed singleton coefficient endpoint. For a coefficient row c and any singleton evaluation endpoint α, the readback of the constant spine $\mathsf{cons}(c, \mathsf{nil})$ is classified by the singleton polynomial classifier as the same endpoint c; at the empty-history endpoint, the zero constant-term readback gives the same classifier boundary. Thus the evaluation classifier exported by this concrete instance is exactly the singleton coefficient classifier.*

Proof. The carrier is the one-coefficient boundary isolated by Definition 50.166 and Definition 50.167: a constant-source row is presented by the singleton spine $\mathsf{cons}(c, \mathsf{nil})$, with no additional coefficient family or abstract scalar quotient.

The singleton evaluation readback applies the checked singleton row PolynomialSingletonEval_singleton, which identifies evaluation of $\mathsf{cons}(c, \mathsf{nil})$ with the coefficient endpoint c under the singleton polynomial classifier. At the empty-history endpoint, PolynomialSingletonEval_zero_constant_term gives the same endpoint boundary for the zero constant-term readback.

Therefore the only classifier visible in the concrete constant-source schema is the singleton polynomial classifier already attached to the coefficient row. Repacking the carrier, constructor, and evaluation readback gives the stated boundary. □

Proposition 50.38 (Literal polynomial add-trim equality fails at cancelling singletons)**.** *Let R be a scalar ring carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, and canonical trim trim_R as in Definition 50.20 and Definition 50.22. Let radd_R and $\mathsf{PolySame}_R$ be as in Definition 50.30. Suppose $\neg(a \sim_R 0_R)$, $\neg(b \sim_R 0_R)$, and $(a + b) \sim_R 0_R$. Write $[c] := \mathsf{cons}(c, \mathsf{nil})$, and set $p := [a]$ and $q := [b]$. Then literal finite-spine equality does not commute with raw addition and trimming:*

$$\begin{aligned} \mathsf{trim}_R(\mathsf{radd}_R(p, q)) &= \mathsf{nil}, \\ \mathsf{radd}_R(\mathsf{trim}_R(p), \mathsf{trim}_R(q)) &= [a + b], \\ \mathsf{trim}_R(\mathsf{radd}_R(p, q)) &\neq \mathsf{radd}_R(\mathsf{trim}_R(p), \mathsf{trim}_R(q)). \end{aligned}$$

Nevertheless the two displayed outputs are polynomial-classified the same:

$$\mathsf{PolySame}_R\big(\mathsf{trim}_R(\mathsf{radd}_R(p, q)), \mathsf{radd}_R(\mathsf{trim}_R(p), \mathsf{trim}_R(q))\big).$$

For the canonical integer coefficient ring from chapter 31 and chapter 44, taking $a = 1$ and $b = -1$ gives $p = [1]$, $q = [-1]$, $\mathsf{trim}_{\mathbb{Z}}(\mathsf{radd}_{\mathbb{Z}}(p, q)) = \mathsf{nil}$, and $\mathsf{radd}_{\mathbb{Z}}(\mathsf{trim}_{\mathbb{Z}}(p), \mathsf{trim}_{\mathbb{Z}}(q)) = [0]$.

Proof. The nonzero hypotheses make p and q normalized singleton representatives by Definition 50.166; the canonical trim fixes normalized representatives, so $\mathsf{trim}_R(p) = p$ and $\mathsf{trim}_R(q) = q$. By the cons-cons and nil-nil clauses of radd_R in Definition 50.30, $\mathsf{radd}_R(\mathsf{trim}_R(p), \mathsf{trim}_R(q)) = \mathsf{radd}_R([a], [b]) = [a + b]$. The equality $\mathsf{trim}_R(\mathsf{radd}_R(p, q)) = \mathsf{nil}$ is the singleton cancellation conclusion of Definition 50.167. The displayed inequality follows because the left side is nil while the right side is a cons spine. Constructor no-confusion for the finite-spine carrier of Definition 36.1 is the mixed nil/cons separation isolated in Definition 36.13 and Definition 36.14. For classifier comparison, unfold $\mathsf{PolySame}_R$. The first argument trims again to nil. The second argument is $[a + b]$, and the hypothesis $(a + b) \sim_R 0_R$ sends its singleton coefficient to the trailing-zero branch, so its trim is also nil. The nil-nil clause of ListClassifierSpec gives the displayed $\mathsf{PolySame}_R$ witness. The integer specialization uses the standard integer facts $1 \neq 0$, $-1 \neq 0$, and $1 + (-1) = 0$; Definition 44.8 keeps the ring operations and classifier when the commutative-ring source is read through $\mathsf{Ring}^{\uparrow}$. □

Definition 50.39 (Polynomial Horner evaluation)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and raw addition radd_R from Definition 50.30. For a carried scalar point α, define the Horner evaluation on finite coefficient spines from Definition 36.1 by recursion*

$$\mathsf{eval}_{\alpha,R}(\mathsf{nil}) := 0_R.$$

$$\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a,x)) := a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x).$$

Define the normalized polynomial evaluation by

$$\mathsf{Eval}_{\alpha,R}(x) := \mathsf{eval}_{\alpha,R}(\mathsf{trim}_R(x)).$$

Define the normalized polynomial sum by

$$\mathsf{PolyAdd}_R(x,y) := \mathsf{trim}_R(\mathsf{radd}_R(\mathsf{trim}_R(x), \mathsf{trim}_R(y))).$$

On a normalized representative from Definition 50.3, $\mathsf{Eval}_{\alpha,R}$ is the Horner evaluation itself, by trim idempotence from Definition 50.22.

Lemma 50.40 (Horner evaluation ignores classified zero tails)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $x, t : \mathsf{ListCarrier}(R)$, if $\mathsf{ZeroRem}_R(t)$ holds in the sense of Definition 50.28, then*

$$\mathsf{eval}_{\alpha,R}(x{+}{+}t) \sim_R \mathsf{eval}_{\alpha,R}(x).$$

Consequently, for every finite coefficient spine x,

$$\mathsf{Eval}_{\alpha,R}(x) \sim_R \mathsf{eval}_{\alpha,R}(x).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialZeroRemainder addFold empty`

Proof. First prove the endpoint claim $\mathsf{eval}_{\alpha,R}(t) \sim_R 0_R$ for every classified zero tail t. Induct on the displayed $\mathsf{ZeroRem}_R(t)$ witness. The nil clause is the defining equation $\mathsf{eval}_{\alpha,R}(\mathsf{nil}) = 0_R$ together with zero self-classification from Definition 43.26. In the cons clause, write $t = \mathsf{cons}(a, t')$. The constructor gives $a \sim_R 0_R$ and the induction hypothesis gives $\mathsf{eval}_{\alpha,R}(t') \sim_R 0_R$. Multiplication congruence and the zero-multiplication row in Definition 43.26 classify $\alpha \cdot \mathsf{eval}_{\alpha,R}(t')$ with 0_R. Addition congruence then classifies $a + \alpha \cdot \mathsf{eval}_{\alpha,R}(t')$ with $0_R + 0_R$, and the additive left-zero law reduces the latter endpoint to 0_R.

For the displayed tail-invariance statement, induct on x. The nil case is the endpoint claim just proved. In the cons case, write $x = \mathsf{cons}(a, x')$. The induction hypothesis gives $\mathsf{eval}_{\alpha,R}(x'{+}{+}t) \sim_R \mathsf{eval}_{\alpha,R}(x')$. Multiplication congruence transports this comparison through left multiplication by α, and addition congruence with source reflexivity on a gives

$$a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x'{+}{+}t) \sim_R a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x').$$

The two Horner recursion equations identify these endpoints with $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'{+}{+}t))$ and $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'))$.

For the consequence, the trailing-zero removal clause in Definition 50.22 presents each raw spine x as $\mathsf{trim}_R(x){+}{+}t$ with $\mathsf{ZeroRem}_R(t)$. Applying the first part gives $\mathsf{eval}_{\alpha,R}(x) \sim_R \mathsf{Eval}_{\alpha,R}(x)$, and symmetry of the scalar classifier reverses the displayed comparison. □

Lemma 50.41 (Horner evaluation respects raw polynomial addition)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $x, y : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{\alpha,R}(\mathsf{radd}_R(x, y)) \sim_R \mathsf{eval}_{\alpha,R}(x) + \mathsf{eval}_{\alpha,R}(y).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonAddFold append hsame`

Proof. Perform induction on the two finite spines, following the four recursion clauses for radd_R in Definition 50.30.

The nil-nil case compares 0_R with $0_R + 0_R$, so it is exactly the additive left-zero law, read with symmetry when needed.

In the cons-nil case, write $x = \mathsf{cons}(a, x')$. The raw-addition recursion exposes the head $a + 0_R$ and the tail $\mathsf{radd}_R(x', \mathsf{nil})$. The induction hypothesis classifies the tail evaluation with $\mathsf{eval}_{\alpha,R}(x') + 0_R$, and Definition 43.31 reduces that endpoint to $\mathsf{eval}_{\alpha,R}(x')$. Multiplication congruence transports the tail comparison through left multiplication by α. Additive congruence and the additive right-zero law reduce the exposed head $a + 0_R$ to a, and the target endpoint $(\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'))) + 0_R$ to $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'))$.

The nil-cons case is symmetric. The raw head is $0_R + b$, which reduces to b by the additive left-zero law, and the outer target $0_R + \mathsf{eval}_{\alpha,R}(\mathsf{cons}(b, y'))$ reduces by the same law. The tail comparison is transported through multiplication by α exactly as in the cons-nil case.

In the cons-cons case, write $x = \mathsf{cons}(a, x')$ and $y = \mathsf{cons}(b, y')$. The induction hypothesis gives

$$\mathsf{eval}_{\alpha,R}(\mathsf{radd}_R(x', y')) \sim_R \mathsf{eval}_{\alpha,R}(x') + \mathsf{eval}_{\alpha,R}(y').$$

Multiplication congruence transports this through left multiplication by α, and left distributivity from Definition 43.26 classifies

$$\alpha \cdot (\mathsf{eval}_{\alpha,R}(x') + \mathsf{eval}_{\alpha,R}(y'))$$

with

$$\alpha \cdot \mathsf{eval}_{\alpha,R}(x') + \alpha \cdot \mathsf{eval}_{\alpha,R}(y').$$

Addition congruence therefore transports the Horner endpoint for $\mathsf{radd}_R(x, y)$ to

$$(a + b) + (\alpha \cdot \mathsf{eval}_{\alpha,R}(x') + \alpha \cdot \mathsf{eval}_{\alpha,R}(y')).$$

Apply Definition 42.13 to the additive abelian-group operation, with the four additive blocks a, b, $\alpha \cdot \mathsf{eval}_{\alpha,R}(x')$, and $\alpha \cdot \mathsf{eval}_{\alpha,R}(y')$. This classifies the last endpoint with

$$(a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x')) + (b + \alpha \cdot \mathsf{eval}_{\alpha,R}(y')),$$

which is exactly $\mathsf{eval}_{\alpha,R}(x) + \mathsf{eval}_{\alpha,R}(y)$ by the Horner recursion. □

Theorem 50.42 (Polynomial evaluation is additive)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{Eval}_{\alpha,R}(\mathsf{PolyAdd}_R(p, q)) \sim_R \mathsf{Eval}_{\alpha,R}(p) + \mathsf{Eval}_{\alpha,R}(q).$$

If p and q are normalized representatives in the polynomial carrier, the same assertion is the carrier formula

$$\mathsf{eval}_{\alpha,R}(\mathsf{PolyAdd}_R(p, q)) \sim_R \mathsf{eval}_{\alpha,R}(p) + \mathsf{eval}_{\alpha,R}(q).$$

Proof. Put $p_0 = \mathsf{trim}_R(p)$ and $q_0 = \mathsf{trim}_R(q)$. By Definition 50.133,

$$\mathsf{PolyAdd}_R(p, q) = \mathsf{trim}_R(\mathsf{radd}_R(p_0, q_0)).$$

Trim idempotence from Definition 50.22 identifies $\mathsf{Eval}_{\alpha,R}(\mathsf{PolyAdd}_R(p, q))$ with $\mathsf{Eval}_{\alpha,R}(\mathsf{radd}_R(p_0, q_0))$. Applying Definition 50.134 gives

$$\mathsf{Eval}_{\alpha,R}(\mathsf{radd}_R(p_0, q_0)) \sim_R \mathsf{eval}_{\alpha,R}(\mathsf{radd}_R(p_0, q_0)).$$

By Definition 50.135,

$$\mathsf{eval}_{\alpha,R}(\mathsf{radd}_R(p_0, q_0)) \sim_R \mathsf{eval}_{\alpha,R}(p_0) + \mathsf{eval}_{\alpha,R}(q_0).$$

The right endpoint is $\mathsf{Eval}_{\alpha,R}(p) + \mathsf{Eval}_{\alpha,R}(q)$ by the definition of p_0, q_0, and normalized evaluation. Classifier transitivity composes the displayed comparisons.

If p and q are already normalized polynomial-carrier representatives, trim idempotence gives $p_0 = p$ and $q_0 = q$, and $\mathsf{Eval}_{\alpha,R}$ on each displayed representative is the unnormalized Horner evaluation. Substituting these equalities gives the carrier formula. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval rawAdd classified`

Lemma 50.43 (Horner evaluation respects structural classifier)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $x, y : \mathsf{ListCarrier}(R)$, if*

$$\mathsf{ListClassifierSpec}(\sim_R, x, y)$$

holds, then

$$\mathsf{eval}_{\alpha,R}(x) \sim_R \mathsf{eval}_{\alpha,R}(y).$$

Proof. Induct on the displayed structural classifier witness from Definition 36.12. By Definition 36.13, the only constructor cases are nil-nil and cons-cons; mixed nil-cons shapes have no classifier witness.

In the nil-nil case, the two Horner equations in Definition 50.133 identify both endpoints with 0_R. The zero self-classification field retained in Definition 43.26 gives $0_R \sim_R 0_R$.

In the cons-cons case, write $x = \mathsf{cons}(a, x')$ and $y = \mathsf{cons}(b, y')$. The classifier constructor supplies $a \sim_R b$ and a tail witness $\mathsf{ListClassifierSpec}(\sim_R, x', y')$. The induction hypothesis gives

$$\mathsf{eval}_{\alpha,R}(x') \sim_R \mathsf{eval}_{\alpha,R}(y').$$

The carried point α is self-classified by the scalar certificate. Multiplication congruence from Definition 43.26 transports the tail comparison through left multiplication by α, giving

$$\alpha \cdot \mathsf{eval}_{\alpha,R}(x') \sim_R \alpha \cdot \mathsf{eval}_{\alpha,R}(y').$$

Addition congruence combines this comparison with the head comparison $a \sim_R b$:

$$a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x') \sim_R b + \alpha \cdot \mathsf{eval}_{\alpha,R}(y').$$

The cons recursion equation in Definition 50.133 identifies these two endpoints with $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'))$ and $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(b, y'))$, respectively. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval list classifier classified`

Theorem 50.44 (Polynomial evaluation respects the polynomial classifier)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(p, q) \Longrightarrow \mathsf{Eval}_{\alpha,R}(p) \sim_R \mathsf{Eval}_{\alpha,R}(q).$$

Proof. Unfold $\mathsf{PolySame}_R$ using Definition 50.30. A classifier witness for p and q is exactly

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(p), \mathsf{trim}_R(q)).$$

Apply Definition 50.137 to the two trimmed spines. This gives

$$\mathsf{eval}_{\alpha,R}(\mathsf{trim}_R(p)) \sim_R \mathsf{eval}_{\alpha,R}(\mathsf{trim}_R(q)).$$

The normalized evaluation definition in Definition 50.133 reads the left endpoint as $\mathsf{Eval}_{\alpha,R}(p)$ and the right endpoint as $\mathsf{Eval}_{\alpha,R}(q)$, giving the displayed implication. □

Definition 50.45 (Polynomial raw Cauchy product)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and raw addition radd_R from Definition 50.30. For a scalar coefficient a and a finite coefficient spine $y : \mathsf{ListCarrier}(R)$, define scalar multiplication of coefficient spines by*

$$\mathsf{rscale}_R(a, \mathsf{nil}) := \mathsf{nil}, \qquad \mathsf{rscale}_R(a, \mathsf{cons}(b, y)) := \mathsf{cons}(a \cdot b, \mathsf{rscale}_R(a, y)).$$

Define the one-place coefficient shift by

$$\mathsf{shift}_R(y) := \mathsf{cons}(0_R, y).$$

The raw polynomial product is the finite recursion

$$\mathsf{rmul}_R(\mathsf{nil}, y) := \mathsf{nil},$$

$$\mathsf{rmul}_R(\mathsf{cons}(a, x), y) := \mathsf{radd}_R(\mathsf{rscale}_R(a, y), \mathsf{shift}_R(\mathsf{rmul}_R(x, y))).$$

The normalized polynomial product is

$$\mathsf{PolyMul}_R(x, y) := \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{trim}_R(x), \mathsf{trim}_R(y))).$$

This is the Cauchy product in low-coefficient-first Horner form: the cons clause expresses $(a + Xx)y = ay + X(xy)$.

Lean4 (definition) `BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul`

Lemma 50.46 (Horner evaluation of scalar-multiplied coefficient spines)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For every carried scalar coefficient a and every finite coefficient spine $y : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{\alpha,R}(\mathsf{rscale}_R(a, y)) \sim_R a \cdot \mathsf{eval}_{\alpha,R}(y).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval rawScale classified`
Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval raw scale empty classified`

Proof. Induct on the finite spine y from Definition 36.1. In the nil case, both the scalar-multiple spine and its Horner value are 0_R. The target endpoint is $a \cdot 0_R$, and the zero-multiplication row in Definition 43.26, with symmetry of $\sim_R$, gives the displayed comparison.

In the cons case, write $y = \mathsf{cons}(b, y')$. The recursion in Definition 50.139 and the Horner recursion in Definition 50.133 identify the left endpoint with

$$a \cdot b + \alpha \cdot \mathsf{eval}_{\alpha,R}(\mathsf{rscale}_R(a, y')).$$

The induction hypothesis and multiplication congruence classify this endpoint with

$$a \cdot b + \alpha \cdot (a \cdot \mathsf{eval}_{\alpha,R}(y')).$$

Multiplicative associativity, multiplicative commutativity from Definition 44.33, and multiplication congruence classify

$$\alpha \cdot (a \cdot \mathsf{eval}_{\alpha,R}(y'))$$

with

$$a \cdot (\alpha \cdot \mathsf{eval}_{\alpha,R}(y')).$$

Addition congruence transports this comparison under the common summand $a \cdot b$. The left distributive row in Definition 43.26, used in the reverse direction, then identifies

$$a \cdot b + a \cdot (\alpha \cdot \mathsf{eval}_{\alpha,R}(y'))$$

with

$$a \cdot (b + \alpha \cdot \mathsf{eval}_{\alpha,R}(y')).$$

The final endpoint is $a \cdot \mathsf{eval}_{\alpha,R}(\mathsf{cons}(b, y'))$ by the Horner recursion, and transitivity composes the comparisons. □

Lemma 50.47 (Horner evaluation of coefficient shift)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For every finite coefficient spine $x : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{\alpha,R}(\mathsf{shift}_R(x)) \sim_R \alpha \cdot \mathsf{eval}_{\alpha,R}(x).$$

Proof. By Definition 50.139, $\mathsf{shift}_R(x) = \mathsf{cons}(0_R, x)$. The Horner recursion from Definition 50.133 makes its evaluation

$$0_R + \alpha \cdot \mathsf{eval}_{\alpha,R}(x).$$

The additive left-zero row in Definition 43.26 classifies this endpoint with $\alpha \cdot \mathsf{eval}_{\alpha,R}(x)$. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval coefficient shift`

Lemma 50.48 (Horner evaluation respects raw polynomial multiplication)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $x, y : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(x, y)) \sim_R \mathsf{eval}_{\alpha,R}(x) \cdot \mathsf{eval}_{\alpha,R}(y).$$

Proof. Induct on the first spine x. In the nil case, $\mathsf{rmul}_R(\mathsf{nil}, y) = \mathsf{nil}$, so the left endpoint evaluates to 0_R. The target endpoint is $0_R \cdot \mathsf{eval}_{\alpha,R}(y)$, and the zero-multiplication row in Definition 43.26, with symmetry, gives the comparison.

For the cons case, write $x = \mathsf{cons}(a, x')$, put $u = \mathsf{eval}_{\alpha,R}(x')$, and put $v = \mathsf{eval}_{\alpha,R}(y)$. The raw product recursion in Definition 50.139 and the raw additivity theorem Definition 50.135 give

$$\mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(\mathsf{cons}(a, x'), y)) \sim_R \mathsf{eval}_{\alpha,R}(\mathsf{rscale}_R(a, y)) + \mathsf{eval}_{\alpha,R}(\mathsf{shift}_R(\mathsf{rmul}_R(x', y))).$$

By Definition 50.140, the first summand is classified with $a \cdot v$. By Definition 50.141, the second summand is classified with

$$\alpha \cdot \mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(x', y)).$$

The induction hypothesis and multiplication congruence classify this with $\alpha \cdot (u \cdot v)$. Multiplicative associativity classifies $\alpha \cdot (u \cdot v)$ with $(\alpha \cdot u) \cdot v$. Addition congruence therefore gives

$$\mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(\mathsf{cons}(a, x'), y)) \sim_R a \cdot v + (\alpha \cdot u) \cdot v.$$

The right distributive row retained by Definition 44.8, equivalently derived from Definition 44.34, classifies

$$(a + \alpha \cdot u) \cdot v$$

with

$$a \cdot v + (\alpha \cdot u) \cdot v.$$

Using symmetry of this distributive comparison and the Horner recursion

$$\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x')) = a + \alpha \cdot u,$$

transitivity gives the required cons-case endpoint. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval rawMul classified`

Theorem 50.49 (Polynomial evaluation is multiplicative)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{Eval}_{\alpha,R}(\mathsf{PolyMul}_R(p, q)) \sim_R \mathsf{Eval}_{\alpha,R}(p) \cdot \mathsf{Eval}_{\alpha,R}(q).$$

If p and q are normalized representatives in the polynomial carrier, the same assertion is the carrier formula

$$\mathsf{eval}_{\alpha,R}(\mathsf{PolyMul}_R(p, q)) \sim_R \mathsf{eval}_{\alpha,R}(p) \cdot \mathsf{eval}_{\alpha,R}(q).$$

Proof. Put $p_0 = \mathsf{trim}_R(p)$ and $q_0 = \mathsf{trim}_R(q)$. By Definition 50.139,

$$\mathsf{PolyMul}_R(p, q) = \mathsf{trim}_R(\mathsf{rmul}_R(p_0, q_0)).$$

Trim idempotence from Definition 50.22 identifies the normalized evaluation of this endpoint with

$$\mathsf{Eval}_{\alpha,R}(\mathsf{rmul}_R(p_0, q_0)).$$

Applying Definition 50.134 gives

$$\mathsf{Eval}_{\alpha,R}(\mathsf{rmul}_R(p_0, q_0)) \sim_R \mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(p_0, q_0)).$$

By Definition 50.142,

$$\mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(p_0, q_0)) \sim_R \mathsf{eval}_{\alpha,R}(p_0) \cdot \mathsf{eval}_{\alpha,R}(q_0).$$

The right endpoint is $\mathsf{Eval}_{\alpha,R}(p) \cdot \mathsf{Eval}_{\alpha,R}(q)$ by the definition of p_0, q_0, and normalized evaluation in Definition 50.133. Classifier transitivity composes the displayed comparisons.

If p and q are already normalized polynomial-carrier representatives, trim idempotence gives $p_0 = p$ and $q_0 = q$. The product endpoint is normalized by its defining trim, so normalized evaluation on $\mathsf{PolyMul}_R(p, q)$ is the unnormalized Horner evaluation of that product. Substituting these equalities gives the carrier formula. □

Theorem 50.50 (Polynomial evaluation is a semiring morphism through classification)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $p, q, p', q' : \mathsf{ListCarrier}(R)$, if $\mathsf{PolySame}_R(p, p')$ and $\mathsf{PolySame}_R(q, q')$, then*

$$\mathsf{Eval}_{\alpha,R}(p) \sim_R \mathsf{Eval}_{\alpha,R}(p'),$$

$$\mathsf{Eval}_{\alpha,R}(\mathsf{PolyAdd}_R(p, q)) \sim_R \mathsf{Eval}_{\alpha,R}(p) + \mathsf{Eval}_{\alpha,R}(q),$$

and

$$\mathsf{Eval}_{\alpha,R}(\mathsf{PolyMul}_R(p, q)) \sim_R \mathsf{Eval}_{\alpha,R}(p) \cdot \mathsf{Eval}_{\alpha,R}(q).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval semiring morphism`

Proof. The first clause is exactly Definition 50.138 applied to the classifier witness between p and p'.

The second and third clauses are the normalized-operation laws from Definition 50.136 and Definition 50.143. They apply to the original representatives p and q, so the operation endpoints are already the canonical normalized polynomial operations.

When a later scalar comparison is written with p' or q' instead, apply Definition 50.138 to the appropriate classifier witness and compose by transitivity of $\sim_R$. Thus the descended endpoints may be substituted in the additive and multiplicative scalar comparisons without reassembling the three facts. □

Lemma 50.51 (Zero-point Horner cons evaluation)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and Horner evaluation as in Definition 50.133. For every carried scalar coefficient a and every finite coefficient spine $t : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{0_R,R}(\mathsf{cons}(a, t)) \sim_R a.$$

Proof. The cons recursion in Definition 50.133 identifies the left endpoint with

$$a + 0_R \cdot \mathsf{eval}_{0_R,R}(t).$$

The zero-absorption theorem Definition 43.60, applied to $\mathsf{eval}_{0_R,R}(t)$, gives

$$0_R \cdot \mathsf{eval}_{0_R,R}(t) \sim_R 0_R.$$

Classifier reflexivity supplies $a \sim_R a$, and addition congruence from Definition 43.26 gives

$$a + 0_R \cdot \mathsf{eval}_{0_R,R}(t) \sim_R a + 0_R.$$

The additive right-zero theorem Definition 43.31 gives $a + 0_R \sim_R a$. Classifier transitivity composes the two comparisons. □

Lean4 ✓ BEDC.Derived.PolynomialUp.PolynomialSingletonEval zero cons constant

Lemma 50.52 (Zero-point Horner evaluation ignores classified zero tails)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and Horner evaluation as in Definition 50.133. For finite coefficient spines $x, t : \mathsf{ListCarrier}(R)$, if $\mathsf{ZeroRem}_R(t)$ holds in the sense of Definition 50.28, then*

$$\mathsf{eval}_{0_R,R}(x{+}{+}t) \sim_R \mathsf{eval}_{0_R,R}(x).$$

Proof. First record the endpoint claim that every classified zero remainder evaluates to zero at 0_R. If the zero remainder is nil, the nil recursion in Definition 50.133 identifies its evaluation with 0_R, and zero self-classification from Definition 43.26 gives the claim. If the zero remainder is $\mathsf{cons}(c, t')$, the cons clause of Definition 50.28 supplies $c \sim_R 0_R$. By Definition 50.145,

$$\mathsf{eval}_{0_R,R}(\mathsf{cons}(c, t')) \sim_R c,$$

and transitivity gives $\mathsf{eval}_{0_R,R}(\mathsf{cons}(c, t')) \sim_R 0_R$.

Now split on the first constructor of x. If $x = \mathsf{nil}$, then $x{+}{+}t = t$, so the endpoint claim gives the displayed comparison. If $x = \mathsf{cons}(a, x')$, then $x{+}{+}t = \mathsf{cons}(a, x'{+}{+}t)$. Applying Definition 50.145 twice gives

$$\mathsf{eval}_{0_R,R}(\mathsf{cons}(a, x'{+}{+}t)) \sim_R a$$

and

$$\mathsf{eval}_{0_R,R}(\mathsf{cons}(a, x')) \sim_R a.$$

Symmetry of the second comparison and transitivity give the required comparison for the cons case. □

Lean4 ✓ BEDC.Derived.PolynomialUp.PolynomialSingletonEval zero point zero tail invariance

Theorem 50.53 (Polynomial evaluation at zero returns the constant coefficient)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and Horner evaluation as in Definition 50.133. For every carried scalar coefficient a and every finite coefficient spine $t : \mathsf{ListCarrier}(R)$,*

$$\mathsf{Eval}_{0_R,R}(\mathsf{cons}(a, t)) \sim_R a.$$

Proof. Set $x = \mathsf{cons}(a, t)$. The trailing-zero removal clause in Definition 50.22 gives a finite zero remainder z such that

$$x = \mathsf{trim}_R(x){+}{+}z, \qquad \mathsf{ZeroRem}_R(z).$$

Applying Definition 50.146 to $\mathsf{trim}_R(x)$ and z yields

$$\mathsf{eval}_{0_R,R}(x) \sim_R \mathsf{eval}_{0_R,R}(\mathsf{trim}_R(x)).$$

By the normalized evaluation definition in Definition 50.133, the right endpoint is $\mathsf{Eval}_{0_R,R}(x)$. Symmetry gives

$$\mathsf{Eval}_{0_R,R}(x) \sim_R \mathsf{eval}_{0_R,R}(x).$$

The raw cons comparison Definition 50.145 gives

$$\mathsf{eval}_{0_R,R}(x) \sim_R a.$$

Classifier transitivity composes these two comparisons, and substituting $x = \mathsf{cons}(a, t)$ gives the displayed formula. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval zero constant term`

Lemma 50.54 (Unit-point Horner evaluation is coefficient fold)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, multiplicative unit endpoint 1_R, addition $+$, multiplication $\cdot$, and Horner evaluation as in Definition 50.133. Let $\mathsf{fold}_{+,R}$ be the finite recursive coefficient fold from Definition 50.26, satisfying*

$$\mathsf{fold}_{+,R}(\mathsf{nil}) = 0_R, \qquad \mathsf{fold}_{+,R}(\mathsf{cons}(a, x')) = a + \mathsf{fold}_{+,R}(x').$$

For every finite coefficient spine $x : \mathsf{ListCarrier}(R)$,

$$\mathsf{eval}_{1_R,R}(x) \sim_R \mathsf{fold}_{+,R}(x).$$

Proof. Induct on the finite spine x from Definition 36.1.

In the nil case, the nil Horner equation in Definition 50.133 and the nil fold equation identify both endpoints with 0_R. The zero self-classification row of Definition 43.26 gives the displayed comparison.

In the cons case, write $x = \mathsf{cons}(a, x')$. The induction hypothesis gives

$$\mathsf{eval}_{1_R,R}(x') \sim_R \mathsf{fold}_{+,R}(x').$$

The recursive Horner endpoint $\mathsf{eval}_{1_R,R}(x')$ is carried by induction on x' using the scalar zero, addition, and multiplication closure rows of the $\mathsf{Ring}^{\uparrow}$ certificate. Hence the multiplicative left-unit row retained in Definition 43.26 gives

$$1_R \cdot \mathsf{eval}_{1_R,R}(x') \sim_R \mathsf{eval}_{1_R,R}(x').$$

Classifier transitivity composes this unit comparison with the induction hypothesis, yielding

$$1_R \cdot \mathsf{eval}_{1_R,R}(x') \sim_R \mathsf{fold}_{+,R}(x').$$

Source reflexivity gives $a \sim_R a$. Applying additive congruence from Definition 43.26 gives

$$a + 1_R \cdot \mathsf{eval}_{1_R,R}(x') \sim_R a + \mathsf{fold}_{+,R}(x').$$

The cons Horner equation identifies the left endpoint with $\mathsf{eval}_{1_R,R}(\mathsf{cons}(a, x'))$, and the cons fold equation identifies the right endpoint with $\mathsf{fold}_{+,R}(\mathsf{cons}(a, x'))$. □

Theorem 50.55 (Polynomial evaluation at the multiplicative unit is coefficient fold)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, multiplicative unit endpoint 1_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and Horner evaluation as in Definition 50.133. Let $\mathsf{fold}_{+,R}$ be the finite recursive coefficient fold from Definition 50.26. For every finite coefficient spine $p : \mathsf{ListCarrier}(R)$,*

$$\mathsf{Eval}_{1_R,R}(p) \sim_R \mathsf{fold}_{+,R}(\mathsf{trim}_R(p)).$$

Proof. By the normalized evaluation definition in Definition 50.133,

$$\mathsf{Eval}_{1_R,R}(p) = \mathsf{eval}_{1_R,R}(\mathsf{trim}_R(p)).$$

Apply Definition 50.148 to the finite coefficient spine $\mathsf{trim}_R(p)$. This gives

$$\mathsf{eval}_{1_R,R}(\mathsf{trim}_R(p)) \sim_R \mathsf{fold}_{+,R}(\mathsf{trim}_R(p)).$$

Substituting the displayed definition of $\mathsf{Eval}_{1_R,R}(p)$ gives the claimed comparison. □

Lemma 50.56 (Polynomial raw addition structural swap)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, and addition $+$. Assume scalar additive commutativity:*

$$a + b \sim_R b + a$$

for all scalar coefficients a, b. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(p, q), \mathsf{radd}_R(q, p)).$$

Proof. Induct simultaneously on the two finite coefficient spines, following the four recursion clauses of radd_R in Definition 50.30. The target classifier is the finite-spine structural classifier of Definition 36.12, with matching constructors isolated by Definition 36.13.

In the nil-nil case, both raw additions are nil, so the nil clause of $\mathsf{ListClassifierSpec}$ gives the claim.

In the cons-nil case, write $p = \mathsf{cons}(a, p')$ and $q = \mathsf{nil}$. The recursion gives

$$\mathsf{radd}_R(p, q) = \mathsf{cons}(a + 0_R, \mathsf{radd}_R(p', \mathsf{nil}))$$

and

$$\mathsf{radd}_R(q, p) = \mathsf{cons}(0_R + a, \mathsf{radd}_R(\mathsf{nil}, p')).$$

Scalar additive commutativity gives $a + 0_R \sim_R 0_R + a$. The induction hypothesis applied to p' and nil gives the tail classifier

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(p', \mathsf{nil}), \mathsf{radd}_R(\mathsf{nil}, p')).$$

The cons clause of $\mathsf{ListClassifierSpec}$ combines the head comparison and this tail comparison.

In the nil-cons case, write $p = \mathsf{nil}$ and $q = \mathsf{cons}(b, q')$. The recursion gives heads $0_R + b$ and $b + 0_R$. Scalar additive commutativity gives $0_R + b \sim_R b + 0_R$, and the induction hypothesis at nil and q' supplies the tail classifier. The cons clause rebuilds the displayed list-classifier witness.

In the cons-cons case, write $p = \mathsf{cons}(a, p')$ and $q = \mathsf{cons}(b, q')$. The recursion exposes heads $a + b$ and $b + a$, related by scalar additive commutativity. The induction hypothesis supplies

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(p', q'), \mathsf{radd}_R(q', p')).$$

The cons clause combines the head and tail witnesses, giving the structural classifier for the two raw sums. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd structural swap`
Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd commutative classified`

Theorem 50.57 (Polynomial raw addition commutativity from scalar additive commutativity)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, and scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$. Use the additive abelian-group and classifier fields retained in Definition 43.26: zero self-classification, classifier transitivity, additive congruence, additive zero laws, and scalar additive commutativity. For a commutative-ring scalar source, Definition 44.8 keeps these data unchanged. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{radd}_R(p, q), \mathsf{radd}_R(q, p)).$$

Proof. Apply Definition 50.150 to p and q using the scalar additive commutativity row from Definition 43.26. This gives

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(p,q), \mathsf{radd}_R(q,p)).$$

The nil finite spine is a zero remainder by the nil clause of Definition 50.28. Apply Definition 50.29 with common classified spines $\mathsf{radd}_R(p,q)$ and $\mathsf{radd}_R(q,p)$, and with both zero remainders equal to nil. Finite-spine append by nil leaves each spine unchanged, so the lemma yields

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(\mathsf{radd}_R(p,q)), \mathsf{trim}_R(\mathsf{radd}_R(q,p))).$$

Unfolding $\mathsf{PolySame}_R$ from Definition 50.30, this is exactly the displayed polynomial raw classifier comparison. □

Lemma 50.58 (Raw polynomial addition is structurally associative)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, and scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$. Assume the additive fields retained in Definition 43.26: additive associativity, additive zero laws, classifier symmetry, classifier transitivity, and addition congruence. For finite coefficient spines $p, q, r : \mathsf{ListCarrier}(R)$,*

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(\mathsf{radd}_R(p,q), r), \mathsf{radd}_R(p, \mathsf{radd}_R(q,r))).$$

Proof. Induct on the finite triple spine (p, q, r), using the maximum of the three finite lengths as the decreasing measure. The nil-nil-nil case unfolds both raw additions by Definition 50.30 to nil, and the nil clause of Definition 36.12 gives the classifier witness.

In every remaining constructor case, at least one of the three spines is a cons spine. Unfold the corresponding clauses of radd_R from Definition 50.30. Both associated raw sums expose a cons head, and their tails are exactly the two associated raw sums for the tail triple, with nil used as the tail of any absent spine. The induction hypothesis supplies the recursive tail classifier.

It remains to classify the exposed scalar heads. If all three heads are present, say a, b, c, the comparison is

$$(a+b)+c \sim_R a+(b+c),$$

which is scalar additive associativity. If exactly two heads are present, the missing head is the padding coefficient 0_R, so the three possible comparisons

$$(a+b)+0_R \sim_R a+(b+0_R),$$

$$(a+0_R)+c \sim_R a+(0_R+c),$$

$$(0_R+b)+c \sim_R 0_R+(b+c)$$

are the same associativity law with one displayed argument equal to 0_R. If only the left input has a head a, the comparison is

$$(a+0_R)+0_R \sim_R a+0_R,$$

which is the additive right-zero law applied to $a+0_R$. If only the middle input has a head b, the comparison is

$$(0_R+b)+0_R \sim_R 0_R+(b+0_R),$$

again additive associativity. If only the right input has a head c, the comparison is

$$0_R+c \sim_R 0_R+(0_R+c),$$

obtained by reversing the additive left-zero law at the endpoint $0_R + c$ using classifier symmetry from cert_R.

In each constructor case, the scalar head comparison and the tail classifier rebuild the cons clause of $\mathsf{ListClassifierSpec}$. These cases exhaust the finite-spine constructors by Definition 36.13. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd associative classified`

Theorem 50.59 (Polynomial raw addition associativity)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, canonical trim trim_R, and scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$. Assume the additive fields retained in Definition 43.26: additive abelian-group laws and addition congruence. For finite coefficient spines $p, q, r : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{radd}_R(\mathsf{radd}_R(p, q), r), \mathsf{radd}_R(p, \mathsf{radd}_R(q, r))).$$

Proof. Set

$$u := \mathsf{radd}_R(\mathsf{radd}_R(p, q), r), \qquad \omega := \mathsf{radd}_R(p, \mathsf{radd}_R(q, r)).$$

By Definition 50.152,

$$\mathsf{ListClassifierSpec}(\sim_R, \nu, \omega)$$

holds. The nil spine is a classified zero remainder by the nil clause of Definition 50.28. Apply Definition 50.29 to the common classified spines ν and ω, with nil zero remainders on both sides. The append-nil identities for finite spines give

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(\nu), \mathsf{trim}_R(\omega)).$$

Unfolding $\mathsf{PolySame}_R$ from Definition 50.30 turns this normalized structural classifier into the displayed polynomial classifier comparison. □

Theorem 50.60 (Polynomial raw multiplication commutativity from scalar commutativity)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, canonical trim trim_R, and the raw operations radd_R, rscale_R, shift_R, and rmul_R from Definition 50.30 and Definition 50.139. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(p, q), \mathsf{rmul}_R(q, p)).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul commutative classified`

Proof. Read the scalar source as a $\mathsf{Ring}^{\uparrow}(R)$ source by Definition 44.8. The retained rows used below are the $\mathsf{NameCert}$ reflexivity, symmetry, and transitivity fields, the additive abelian-group laws and addition congruence from Definition 43.26, multiplication congruence, and the multiplicative commutativity row from Definition 44.33.

First record the finite-spine consequences of the existing raw-addition package. The relation $\mathsf{PolySame}_R$ is reflexive, symmetric, and transitive after unfolding Definition 50.30; this is exactly structural list-classifier reflexivity, Definition 36.47, and Definition 36.15 applied to the two trimmed representatives.

Raw addition is compatible with $\mathsf{PolySame}_R$ in both inputs. Indeed, Definition 50.32 reduces both raw sums to sums of their trimmed inputs. The two displayed trimmed-input classifiers give a structural classifier between the two trimmed raw sums by induction on the two list-classifier witnesses in Definition 36.12; the exposed heads are handled by addition congruence, with $0_R \sim_R 0_R$ in the padding branches. Transitivity and symmetry of $\mathsf{PolySame}_R$ compose these three comparisons.

The shift operation preserves $\mathsf{PolySame}_R$. If $\mathsf{PolySame}_R(x, y)$ holds, write the trim decompositions supplied by Definition 50.22 as $x = x_0{+}{+}z$ and $y = y_0{+}{+}w$, with $\mathsf{ListClassifierSpec}(\sim_R, x_0, y_0)$ and zero remainders z, w. Then

$$\mathsf{shift}_R(x) = (\mathsf{cons}(0_R, x_0)){+}{+}z, \qquad \mathsf{shift}_R(y) = (\mathsf{cons}(0_R, y_0)){+}{+}w.$$

The cons classifier built from $0_R \sim_R 0_R$ and the classifier on x_0, y_0, followed by Definition 50.29, gives $\mathsf{PolySame}_R(\mathsf{shift}_R(x), \mathsf{shift}_R(y))$. The same argument, with 0_R replaced by classified heads $h \sim_R h'$, shows that $h \sim_R h'$ and $\mathsf{PolySame}_R(t, t')$ imply

$$\mathsf{PolySame}_R(\mathsf{cons}(h, t), \mathsf{cons}(h', t')).$$

Zero remainders are closed under raw addition: induct on the two zero-remainder witnesses from Definition 50.28. In the cons-cons branch, addition congruence sends $a + b$ to $0_R + 0_R$, and the additive left-zero law reduces that endpoint to 0_R; the cons-nil and nil-cons branches use the additive right-zero and left-zero laws. Hence $\mathsf{rmul}_R(s, \mathsf{nil})$ is a zero remainder for every finite spine s, by induction on s using Definition 50.139: the cons step combines $\mathsf{rscale}_R(a, \mathsf{nil}) = \mathsf{nil}$, the zero-remainder closure of shift_R, and raw-addition closure. Applying Definition 50.29 with common spine nil gives

$$\mathsf{PolySame}_R(\mathsf{nil}, \mathsf{rmul}_R(s, \mathsf{nil})).$$

The key auxiliary recursion is right-cons expansion: for every scalar coefficient a and finite spines x, q,

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(q, \mathsf{cons}(a, x)), \mathsf{radd}_R(\mathsf{rscale}_R(a, q), \mathsf{shift}_R(\mathsf{rmul}_R(q, x)))).$$

Induct on q. If $q = \mathsf{nil}$, the left side is nil and the right side is a raw sum of zero-remainder spines, so the zero-remainder comparison above applies. For the cons step write $q = \mathsf{cons}(b, y)$. Unfolding Definition 50.139 and the cons-cons branch of Definition 50.30, the two heads are $b \cdot a + 0_R$ and $a \cdot b + 0_R$; multiplicative commutativity and addition congruence classify them. The two tails are

$$\mathsf{radd}_R(\mathsf{rscale}_R(b, x), \mathsf{rmul}_R(y, \mathsf{cons}(a, x)))$$

and

$$\mathsf{radd}_R(\mathsf{rscale}_R(a, y), \mathsf{radd}_R(\mathsf{rscale}_R(b, x), \mathsf{shift}_R(\mathsf{rmul}_R(y, x)))).$$

The induction hypothesis and raw-addition compatibility compare the first tail with

$$\mathsf{radd}_R(\mathsf{rscale}_R(b, x), \mathsf{radd}_R(\mathsf{rscale}_R(a, y), \mathsf{shift}_R(\mathsf{rmul}_R(y, x)))).$$

Raw-addition associativity from Definition 50.153 and raw-addition commutativity from Definition 50.151, transported through raw-addition compatibility, move the first two summands past each other and give the second tail. The cons preservation fact then proves the cons step.

Now induct on p. If $p = \mathsf{nil}$, then $\mathsf{rmul}_R(\mathsf{nil}, q) = \mathsf{nil}$ by Definition 50.139, while $\mathsf{rmul}_R(q, \mathsf{nil})$ is a zero remainder by the preceding paragraph; hence the displayed $\mathsf{PolySame}_R$ holds.

For the cons step write $p = \mathsf{cons}(a, x)$ and assume

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(x, q), \mathsf{rmul}_R(q, x)).$$

Unfolding the left raw product gives

$$\mathsf{rmul}_R(\mathsf{cons}(a, x), q) = \mathsf{radd}_R(\mathsf{rscale}_R(a, q), \mathsf{shift}_R(\mathsf{rmul}_R(x, q))).$$

Shift preservation and raw-addition compatibility transport the induction hypothesis to

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(\mathsf{cons}(a,x),q),\mathsf{radd}_R(\mathsf{rscale}_R(a,q),\mathsf{shift}_R(\mathsf{rmul}_R(q,x)))).$$

Right-cons expansion applied to q, a, x gives the same middle endpoint classified with $\mathsf{rmul}_R(q,\mathsf{cons}(a,x))$. Symmetry and transitivity of $\mathsf{PolySame}_R$ compose the two comparisons, completing the induction. □

Theorem 50.61 (Polynomial multiplication has left zero absorption)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$ and zero endpoint 0_R. Let trim_R be the canonical polynomial trim from Definition 50.20 and Definition 50.22, and let $\mathsf{PolySame}_R$, rmul_R, and $\mathsf{PolyMul}_R$ be as in Definition 50.30 and Definition 50.139. For every finite coefficient spine $q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(\mathsf{nil},q),\mathsf{nil}).$$

Consequently the same conclusion holds for every normalized polynomial representative q from Definition 50.3.

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul left zero classified`

Proof. Set $q_0 = \mathsf{trim}_R(q)$. The empty zero-polynomial clause in Definition 50.22 gives $\mathsf{trim}_R(\mathsf{nil}) = \mathsf{nil}$. Hence Definition 50.139 gives

$$\begin{aligned}\mathsf{PolyMul}_R(\mathsf{nil},q) &= \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{trim}_R(\mathsf{nil}),q_0))\\ &= \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{nil},q_0))\\ &= \mathsf{trim}_R(\mathsf{nil})\\ &= \mathsf{nil}.\end{aligned}$$

The third equality is the nil clause for rmul_R in Definition 50.139.

Unfolding $\mathsf{PolySame}_R$ by Definition 50.30, the classifier goal is

$$\mathsf{ListClassifierSpec}(\sim_R,\mathsf{trim}_R(\mathsf{PolyMul}_R(\mathsf{nil},q)),\mathsf{trim}_R(\mathsf{nil})).$$

The displayed computation and the empty zero-polynomial clause reduce both displayed representatives to nil. The nil-nil clause of Definition 36.12 supplies the structural classifier witness. □

Definition 50.62 (Padded polynomial coefficients and finite Cauchy folds)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and finite coefficient spines from Definition 36.1. For a finite coefficient spine $x : \mathsf{ListCarrier}(R)$ and $n : \mathsf{Nat}^{\uparrow}$, write $x[n]$ for the padded coefficient defined by*

$$\mathsf{nil}[n] := 0_R, \qquad \mathsf{cons}(a,t)[0] := a, \qquad \mathsf{cons}(a,t)[n+1] := t[n].$$

For finite coefficient spines x, y, z define the finite Cauchy coefficient fold and the finite triple coefficient fold by

$$\mathsf{Cauchy}_R(x,y;n) := \Sigma_{i+j=n} x[i]\cdot y[j], \qquad \mathsf{Triple}_R(x,y,z;n) := \Sigma_{i+j+k=n}(x[i]\cdot y[j])\cdot z[k].$$

The displayed sums use the finite additive fold of Definition 50.26 over the lexicographic finite spines of the displayed natural-number tuples.

Theorem 50.63 (Polynomial multiplication has right zero absorption)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, and canonical trim trim_R. Let $\mathsf{PolySame}_R$, rmul_R, and $\mathsf{PolyMul}_R$ be as in Definition 50.30 and Definition 50.139. For every finite coefficient spine $p : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(p, \mathsf{nil}), \mathsf{nil}).$$

Consequently the same conclusion holds for every normalized polynomial representative p from Definition 50.3.

Proof. Set

$$p_0 := \mathsf{trim}_R(p), \qquad n_0 := \mathsf{trim}_R(\mathsf{nil}).$$

The empty zero-polynomial clause in Definition 50.22 gives $n_0 = \mathsf{nil}$. Unfolding the normalized product in Definition 50.139 gives

$$\begin{aligned}\mathsf{PolyMul}_R(p, \mathsf{nil}) &= \mathsf{trim}_R(\mathsf{rmul}_R(p_0, n_0)) \\ &= \mathsf{trim}_R(\mathsf{rmul}_R(p_0, \mathsf{nil}))\end{aligned}$$

and

$$\begin{aligned}\mathsf{PolyMul}_R(\mathsf{nil}, p) &= \mathsf{trim}_R(\mathsf{rmul}_R(n_0, p_0)) \\ &= \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{nil}, p_0)).\end{aligned}$$

Apply Definition 50.154 to the finite coefficient spines p_0 and nil. It gives

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(p_0, \mathsf{nil}), \mathsf{rmul}_R(\mathsf{nil}, p_0)).$$

After unfolding $\mathsf{PolySame}_R$ by Definition 50.30, this is the structural classifier comparison

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(\mathsf{rmul}_R(p_0, \mathsf{nil})), \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{nil}, p_0))).$$

Using the two displayed product computations and trim idempotence from Definition 50.22, this is exactly

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(p, \mathsf{nil}), \mathsf{PolyMul}_R(\mathsf{nil}, p)).$$

On the other hand, Definition 50.155 applied to p gives

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(\mathsf{nil}, p), \mathsf{nil}).$$

Unfold the two $\mathsf{PolySame}_R$ witnesses and compose their structural list-classifier witnesses by Definition 36.15, using the transitivity field of cert_R on scalar heads. Folding back Definition 50.30 yields

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(p, \mathsf{nil}), \mathsf{nil}).$$

Every normalized polynomial representative from Definition 50.3 is, in particular, a finite coefficient spine, so the same argument applies to that carrier representative. □

Lemma 50.64 (Padded coefficient extensionality for the polynomial classifier)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, and canonical trim trim_R from Definition 50.20 and Definition 50.22. If finite coefficient spines $x, y : \mathsf{ListCarrier}(R)$ satisfy $x[n] \sim_R y[n]$ for every $n : \mathsf{Nat}^{\uparrow}$, then*

$$\mathsf{PolySame}_R(x, y).$$

Proof. Put $x_0 := \mathsf{trim}_R(x)$ and $y_0 := \mathsf{trim}_R(y)$. The trailing-zero removal clause in Definition 50.22 gives decompositions $x = x_0{+}{+}t_x$ and $y = y_0{+}{+}t_y$, with $\mathsf{ZeroRem}_R(t_x)$ and $\mathsf{ZeroRem}_R(t_y)$ in the sense of Definition 50.28. Hence $x[n] \sim_R x_0[n]$ and $y[n] \sim_R y_0[n]$ for every n: inside the trimmed prefix the coefficient is unchanged, inside the removed tail the zero-remainder witness classifies the coefficient with 0_R, and after the whole spine both sides are the padding coefficient 0_R. Classifier symmetry and transitivity from cert_R give $x_0[n] \sim_R y_0[n]$ for every n.

The trimmed spines are normalized representatives. If one normalized representative had a last displayed coefficient beyond the length of the other, the padded coefficient comparison at that last index would classify that displayed coefficient with 0_R, contradicting the normalized no-trailing-zero condition in Definition 50.22. Thus x_0 and y_0 have the same finite length. Induction over this common length builds a structural classifier witness: at each head position the hypothesis $x_0[n] \sim_R y_0[n]$ supplies the scalar head comparison, and the induction hypothesis supplies the tail classifier. Therefore

$$\mathsf{ListClassifierSpec}(\sim_R, x_0, y_0).$$

Unfolding $\mathsf{PolySame}_R$ by Definition 50.30 gives the displayed polynomial classifier comparison. □

Lemma 50.65 (Raw Cauchy product coefficient formula)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and the raw operations radd_R, rscale_R, shift_R, and rmul_R from Definition 50.30 and Definition 50.139. For finite coefficient spines $x, y : \mathsf{ListCarrier}(R)$ and every $n : \mathsf{Nat}^{\uparrow}$,*

$$\mathsf{rmul}_R(x, y)[n] \sim_R \mathsf{Cauchy}_R(x, y; n).$$

Proof. Read the scalar source as a $\mathsf{Ring}^{\uparrow}(R)$ source by Definition 44.8. The recursion defining radd_R gives the padded coefficient formula $\mathsf{radd}_R(u, v)[n] \sim_R u[n] + v[n]$ by induction on the two finite spines. The definitions of rscale_R and shift_R give

$$\mathsf{rscale}_R(a, u)[n] \sim_R a \cdot u[n], \qquad \mathsf{shift}_R(u)[0] \sim_R 0_R, \qquad \mathsf{shift}_R(u)[n+1] \sim_R u[n].$$

These comparisons use only zero self-classification, additive congruence, and the additive zero laws from Definition 43.26.

Induct on the first spine x. If $x = \mathsf{nil}$, the raw product is nil by Definition 50.139. Every summand in $\mathsf{Cauchy}_R(\mathsf{nil}, y; n)$ has the form $0_R \cdot y[j]$ and is classified with 0_R by the zero-multiplication row in Definition 43.26. The zero-summand fold theorem Definition 50.27 classifies the Cauchy fold with 0_R, which is the padded coefficient of nil.

For the cons step, write $x = \mathsf{cons}(a, x')$. At coefficient 0, the raw product recursion gives the sum of $a \cdot y[0]$ and the zero head of the shifted recursive product; the additive right-zero law classifies this with $a \cdot y[0]$, which is $\mathsf{Cauchy}_R(\mathsf{cons}(a, x'), y; 0)$. At coefficient $n + 1$, the same recursion and the auxiliary coefficient formulas give

$$\mathsf{rmul}_R(\mathsf{cons}(a, x'), y)[n+1] \sim_R a \cdot y[n+1] + \mathsf{rmul}_R(x', y)[n].$$

The induction hypothesis and additive congruence replace the second summand by $\mathsf{Cauchy}_R(x', y; n)$. Splitting the finite index spine $i + j = n + 1$ into the head case $i = 0$ and the shifted cases $i = i' + 1$ identifies the resulting fold with $\mathsf{Cauchy}_R(\mathsf{cons}(a, x'), y; n + 1)$ by Definition 50.26. □

Lemma 50.66 (Raw Cauchy product coefficient associativity)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and the raw Cauchy product data of Definition 50.139. For finite coefficient spines $x, y, z : \mathsf{ListCarrier}(R)$ and every $n : \mathsf{Nat}^{\uparrow}$,*

$$\mathsf{rmul}_R(\mathsf{rmul}_R(x, y), z)[n] \sim_R \mathsf{rmul}_R(x, \mathsf{rmul}_R(y, z))[n].$$

Proof. Fix n. By Definition 50.159, the left coefficient is classified with $\mathsf{Cauchy}_R(\mathsf{rmul}_R(x,y),z;n)$. For each outer index $s+k=n$, apply Definition 50.159 to replace $\mathsf{rmul}_R(x,y)[s]$ by $\mathsf{Cauchy}_R(x,y;s)$. Multiplication congruence and Definition 50.26 lift these replacements through the outer finite fold. The right-multiplication half of Definition 49.95 then classifies $\mathsf{Cauchy}_R(x,y;s)\cdot z[k]$ with the inner fold over (i,j) satisfying $i+j=s$ of $(x[i]\cdot y[j])\cdot z[k]$. The nested finite index spine $i+j=s$, $s+k=n$ is the same finite triple spine $i+j+k=n$ in lexicographic order after deleting the bookkeeping index s. The finite fold swap certificate of Definition 49.94, together with fold congruence, classifies the resulting nested fold with $\mathsf{Triple}_R(x,y,z;n)$. Thus the left raw product coefficient is classified with $\mathsf{Triple}_R(x,y,z;n)$.

The right coefficient is handled symmetrically. The coefficient formula first gives $\mathsf{Cauchy}_R(x,\mathsf{rmul}_R(y,z);n)$. Replacing each coefficient of $\mathsf{rmul}_R(y,z)$ by its Cauchy fold and applying the left-multiplication half of Definition 49.95 gives the finite fold over triples $i+j+k=n$ of $x[i]\cdot(y[j]\cdot z[k])$. Scalar multiplication associativity from Definition 43.26 classifies each displayed summand with $(x[i]\cdot y[j])\cdot z[k]$. Fold congruence therefore classifies the right coefficient with the same $\mathsf{Triple}_R(x,y,z;n)$. Symmetry and transitivity of the scalar classifier compose the two comparisons. □

Theorem 50.67 (Polynomial multiplication associativity over commutative-ring scalars)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Let the classifier be $\sim_R$, the zero endpoint be 0_R, the scalar operations be $+$ and $\cdot$, the canonical trim be trim_R from Definition 50.22, and let rmul_R and $\mathsf{PolyMul}_R$ be the raw and normalized products of Definition 50.139. For finite coefficient spines $p,q,r:\mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(\mathsf{PolyMul}_R(p,q),r),\mathsf{PolyMul}_R(p,\mathsf{PolyMul}_R(q,r))).$$

Proof. Put $p_0:=\mathsf{trim}_R(p)$, $q_0:=\mathsf{trim}_R(q)$, and $r_0:=\mathsf{trim}_R(r)$. Set $A:=\mathsf{PolyMul}_R(\mathsf{PolyMul}_R(p,q),r)$ and $B:=\mathsf{PolyMul}_R(p,\mathsf{PolyMul}_R(q,r))$. By Definition 50.158, it is enough to prove $A[n]\sim_R B[n]$ for every $n:\mathsf{Nat}^{\uparrow}$.

Trim preserves padded coefficients by the trailing-zero decomposition in Definition 50.22: for every finite spine u and every n, $u[n]\sim_R \mathsf{trim}_R(u)[n]$. The coefficient formula Definition 50.159 is functorial in both inputs with respect to such pointwise padded-coefficient comparisons, since multiplication congruence compares each Cauchy summand and Definition 50.26 lifts the summand comparisons through the finite fold.

Unfolding Definition 50.139 and using trim idempotence from Definition 50.22, the left normalized product has the same padded coefficients as $\mathsf{rmul}_R(\mathsf{trim}_R(\mathsf{rmul}_R(p_0,q_0)),r_0)$. By trim preservation and the functoriality just recorded, its nth coefficient is classified with $\mathsf{rmul}_R(\mathsf{rmul}_R(p_0,q_0),r_0)[n]$. Similarly, the right normalized product has the same padded coefficients as $\mathsf{rmul}_R(p_0,\mathsf{trim}_R(\mathsf{rmul}_R(q_0,r_0)))$, and its nth coefficient is classified with $\mathsf{rmul}_R(p_0,\mathsf{rmul}_R(q_0,r_0))[n]$.

Applying Definition 50.160 to p_0,q_0,r_0 gives

$$\mathsf{rmul}_R(\mathsf{rmul}_R(p_0,q_0),r_0)[n]\sim_R \mathsf{rmul}_R(p_0,\mathsf{rmul}_R(q_0,r_0))[n].$$

Classifier symmetry and transitivity compose the two trim comparisons with this raw coefficient associativity comparison, yielding $A[n]\sim_R B[n]$ for the fixed n. Since n was arbitrary, Definition 50.158 gives $\mathsf{PolySame}_R(A,B)$, which is the displayed associativity statement. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul associative addFold classified`

Theorem 50.68 (Polynomial singleton evaluation)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and Horner evaluation as in Definition 50.133. For every carried scalar coefficient c and every carried scalar point*

α,

$$\mathsf{Eval}_{\alpha,R}(\mathsf{cons}(c, \mathsf{nil})) \sim_R c.$$

Proof. Put $s = \mathsf{cons}(c, \mathsf{nil})$. First compute the unnormalized Horner value. The cons and nil recursion clauses in Definition 50.133 identify

$$\mathsf{eval}_{\alpha,R}(s) = c + \alpha \cdot 0_R.$$

The right zero-absorption half of Definition 43.60 gives

$$\alpha \cdot 0_R \sim_R 0_R.$$

Classifier reflexivity for c and addition congruence from Definition 43.26 give

$$c + \alpha \cdot 0_R \sim_R c + 0_R.$$

The additive right-zero theorem Definition 43.31 gives $c + 0_R \sim_R c$, and transitivity yields

$$\mathsf{eval}_{\alpha,R}(s) \sim_R c.$$

By Definition 50.133, $\mathsf{Eval}_{\alpha,R}(s) = \mathsf{eval}_{\alpha,R}(\mathsf{trim}_R(s))$. The one-coefficient trimming boundary in Definition 50.166, read with Definition 50.22, has exactly the empty zero branch and the retained singleton branch. In the empty zero branch, $c \sim_R 0_R$ and $\mathsf{trim}_R(s) = \mathsf{nil}$; the nil Horner equation gives $\mathsf{Eval}_{\alpha,R}(s) = 0_R$, and classifier symmetry gives $0_R \sim_R c$. In the retained singleton branch, $\mathsf{trim}_R(s) = s$, so the raw computation above is the required normalized comparison. These are the two canonical trim branches for a singleton coefficient spine. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval singleton`

Theorem 50.69 (Raw polynomial multiplication left-distributes over raw addition)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Let the classifier be $\sim_R$, the zero endpoint be 0_R, the scalar operations be $+$ and $\cdot$, the scalar certificate be $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, and let radd_R, rscale_R, shift_R, and rmul_R be the raw operations of Definition 50.30 and Definition 50.139. For finite coefficient spines $x, y, z : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(x, \mathsf{radd}_R(y, z)), \mathsf{radd}_R(\mathsf{rmul}_R(x, y), \mathsf{rmul}_R(x, z))).$$

Consequently the same classifier comparison holds when x, y, z are normalized polynomial representatives from Definition 50.3.

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul left distributes over raw add`

Proof. By Definition 50.158, it is enough to compare padded coefficients. First record the padded coefficient law for raw addition: for all finite coefficient spines u, v and every $m : \mathsf{Nat}^{\uparrow}$,

$$\mathsf{radd}_R(u, v)[m] \sim_R u[m] + v[m].$$

This is a direct induction over the two finite spines using the four recursion clauses in Definition 50.30. In the mixed cons-nil and nil-cons cases the missing coefficient is the padding endpoint 0_R; in the nil-nil tail the comparison is between 0_R and $0_R + 0_R$, handled by the additive zero laws and classifier symmetry from cert_R.

Fix $n : \mathsf{Nat}^{\uparrow}$. Let the finite split spine for $i + j = n$ carry three scalar spines

$$A_n(i,j) := x[i] \cdot \mathsf{radd}_R(y,z)[j], \qquad B_n(i,j) := x[i] \cdot y[j], \qquad C_n(i,j) := x[i] \cdot z[j].$$

For each split $i + j = n$, the raw-addition coefficient law gives

$$\mathsf{radd}_R(y,z)[j] \sim_R y[j] + z[j].$$

Multiplication congruence transports this under left multiplication by $x[i]$, and scalar left distributivity from Definition 43.26 gives

$$x[i] \cdot \mathsf{radd}_R(y,z)[j] \sim_R (x[i] \cdot y[j]) + (x[i] \cdot z[j]).$$

The matching split order assembles these scalar comparisons into a structural list-classifier witness from Definition 36.12 between A_n and the pointwise sum spine $B_n + C_n$. Applying Definition 50.26 to this witness gives

$$\mathsf{Cauchy}_R(x, \mathsf{radd}_R(y,z); n) \sim_R \mathsf{fold}_{+,R}(B_n + C_n).$$

The finite fold splitting lemma Definition 49.98 then classifies the right endpoint with the sum of the two separate Cauchy folds:

$$\mathsf{fold}_{+,R}(B_n + C_n) \sim_R \mathsf{Cauchy}_R(x, y; n) + \mathsf{Cauchy}_R(x, z; n).$$

Thus

$$\mathsf{Cauchy}_R(x, \mathsf{radd}_R(y,z); n) \sim_R \mathsf{Cauchy}_R(x, y; n) + \mathsf{Cauchy}_R(x, z; n).$$

The raw Cauchy coefficient formula Definition 50.159 gives

$$\mathsf{rmul}_R(x, \mathsf{radd}_R(y,z))[n] \sim_R \mathsf{Cauchy}_R(x, \mathsf{radd}_R(y,z); n).$$

For the other endpoint, the raw-addition coefficient law gives

$$\mathsf{radd}_R(\mathsf{rmul}_R(x,y), \mathsf{rmul}_R(x,z))[n] \sim_R \mathsf{rmul}_R(x,y)[n] + \mathsf{rmul}_R(x,z)[n].$$

Applying Definition 50.159 to the two raw products and then additive congruence gives

$$\mathsf{rmul}_R(x,y)[n] + \mathsf{rmul}_R(x,z)[n] \sim_R \mathsf{Cauchy}_R(x, y; n) + \mathsf{Cauchy}_R(x, z; n).$$

Classifier symmetry and transitivity from cert_R compose the three displayed coefficient comparisons, yielding

$$\mathsf{rmul}_R(x, \mathsf{radd}_R(y,z))[n] \sim_R \mathsf{radd}_R(\mathsf{rmul}_R(x,y), \mathsf{rmul}_R(x,z))[n].$$

Since n was arbitrary, Definition 50.158 gives the displayed $\mathsf{PolySame}_R$ comparison. A normalized polynomial representative is a finite coefficient spine by Definition 50.3, so the final sentence is the same statement restricted to those representatives. □

Theorem 50.70 (Polynomial raw multiplication has singleton-one left identity)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, zero endpoint 0_R, multiplicative unit endpoint 1_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and the raw operations radd_R, rscale_R, shift_R, and rmul_R from Definition 50.30 and Definition 50.139. For every finite coefficient spine $p : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(\mathsf{cons}(1_R, \mathsf{nil}), p), p).$$

Proof. By Definition 50.158, it is enough to prove equality under the padded scalar classifier at every coefficient index. Unfolding the cons clause and the nil clause of raw multiplication in Definition 50.139 gives

$$\mathsf{rmul}_R(\mathsf{cons}(1_R, \mathsf{nil}), p) = \mathsf{radd}_R(\mathsf{rscale}_R(1_R, p), \mathsf{cons}(0_R, \mathsf{nil})).$$

Thus the product is the raw sum of the coefficientwise scalar multiple by 1_R and the one-place shift of the empty recursive product.

First, for every finite coefficient spine u and every index $n : \mathsf{Nat}^{\uparrow}$,

$$\mathsf{radd}_R(u, \mathsf{cons}(0_R, \mathsf{nil}))[n] \sim_R u[n].$$

This is induction on u. If $u = \mathsf{nil}$, the only displayed head is $0_R + 0_R$, classified with 0_R by the additive zero rows in Definition 43.26; all later coefficients are padding coefficients 0_R. If $u = \mathsf{cons}(a, u')$, the head comparison is $(a + 0_R) \sim_R a$ by the additive right-zero row, while the tail comparison is the raw-addition right-nil induction that repeatedly classifies $b + 0_R$ with b and ends at the padding coefficient. These steps use additive congruence, zero self-classification, and classifier transitivity from cert_R.

Second, for every finite coefficient spine p and every index $n : \mathsf{Nat}^{\uparrow}$,

$$\mathsf{rscale}_R(1_R, p)[n] \sim_R p[n].$$

Induct on p. In the nil case both padded coefficients are 0_R. In the cons case, the exposed head is $1_R \cdot a$, classified with a by the multiplicative left-unit row retained in Definition 43.26, and the tail is supplied by the induction hypothesis. After the displayed spine ends, both sides are again the padding coefficient 0_R.

Apply the first coefficient comparison to $u = \mathsf{rscale}_R(1_R, p)$ and compose it with the second comparison. For every $n : \mathsf{Nat}^{\uparrow}$ this gives

$$\mathsf{rmul}_R(\mathsf{cons}(1_R, \mathsf{nil}), p)[n] \sim_R p[n].$$

The padded coefficient extensionality lemma Definition 50.158 converts these pointwise scalar comparisons into the displayed $\mathsf{PolySame}_R$ statement. □

Theorem 50.71 (Raw polynomial multiplication associativity up to add-trim)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Let the classifier be $\sim_R$, the zero endpoint be 0_R, the scalar operations be $+$ and $\cdot$, the scalar certificate be $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, the canonical trim be trim_R from Definition 50.22, and let $\mathsf{PolySame}_R$ and rmul_R be the add-trim classifier and raw Cauchy product of Definition 50.30 and Definition 50.139. For finite coefficient spines $p, q, r : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(\mathsf{rmul}_R(p, q), r), \mathsf{rmul}_R(p, \mathsf{rmul}_R(q, r))).$$

Consequently the same comparison holds when p, q, r are normalized polynomial representatives from Definition 50.3.

Proof. Set

$$A := \mathsf{rmul}_R(\mathsf{rmul}_R(p, q), r), \qquad B := \mathsf{rmul}_R(p, \mathsf{rmul}_R(q, r)).$$

By Definition 50.158, it is enough to prove $A[n] \sim_R B[n]$ for every $n : \mathsf{Nat}^{\uparrow}$.

Fix $n : \mathsf{Nat}^{\uparrow}$. The raw Cauchy coefficient associativity lemma Definition 50.160, applied to the finite coefficient spines p, q, r, gives exactly

$$\mathsf{rmul}_R(\mathsf{rmul}_R(p, q), r)[n] \sim_R \mathsf{rmul}_R(p, \mathsf{rmul}_R(q, r))[n].$$

This is $A[n] \sim_R B[n]$. Since n was arbitrary, Definition 50.158 converts the pointwise padded coefficient comparisons into

$$\mathsf{PolySame}_R(A, B).$$

Unfolding the definitions of A and B gives the displayed add-trim classifier comparison. A normalized polynomial representative from Definition 50.3 is a finite coefficient spine, so the final sentence is the same statement restricted to those carried representatives. □

Proposition 50.72 (Literal polynomial add-trim equality fails at cancelling singletons)**.** *Let R be a scalar ring carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, and canonical trim trim_R as in Definition 50.20 and Definition 50.22. Let radd_R and $\mathsf{PolySame}_R$ be as in Definition 50.30. Suppose $\neg(a \sim_R 0_R)$, $\neg(b \sim_R 0_R)$, and $(a + b) \sim_R 0_R$. Write $[c] := \mathsf{cons}(c, \mathsf{nil})$, and set $p := [a]$ and $q := [b]$. Then literal finite-spine equality does not commute with raw addition and trimming:*

$$\begin{aligned} \mathsf{trim}_R(\mathsf{radd}_R(p, q)) &= \mathsf{nil}, \\ \mathsf{radd}_R(\mathsf{trim}_R(p), \mathsf{trim}_R(q)) &= [a + b], \\ \mathsf{trim}_R(\mathsf{radd}_R(p, q)) &\neq \mathsf{radd}_R(\mathsf{trim}_R(p), \mathsf{trim}_R(q)). \end{aligned}$$

Nevertheless the two displayed outputs are polynomial-classified the same:

$$\mathsf{PolySame}_R(\mathsf{trim}_R(\mathsf{radd}_R(p, q)), \mathsf{radd}_R(\mathsf{trim}_R(p), \mathsf{trim}_R(q))).$$

For the canonical integer coefficient ring from chapter 31 and chapter 44, taking $a = 1$ and $b = -1$ gives $p = [1]$, $q = [-1]$, $\mathsf{trim}_{\mathbb{Z}}(\mathsf{radd}_{\mathbb{Z}}(p, q)) = \mathsf{nil}$, and $\mathsf{radd}_{\mathbb{Z}}(\mathsf{trim}_{\mathbb{Z}}(p), \mathsf{trim}_{\mathbb{Z}}(q)) = [0]$.

Proof. The nonzero hypotheses make p and q normalized singleton representatives by Definition 50.166; the canonical trim fixes normalized representatives, so $\mathsf{trim}_R(p) = p$ and $\mathsf{trim}_R(q) = q$. By the cons-cons and nil-nil clauses of radd_R in Definition 50.30, $\mathsf{radd}_R(\mathsf{trim}_R(p), \mathsf{trim}_R(q)) = \mathsf{radd}_R([a], [b]) = [a + b]$. The equality $\mathsf{trim}_R(\mathsf{radd}_R(p, q)) = \mathsf{nil}$ is the singleton cancellation conclusion of Definition 50.167. The displayed inequality follows because the left side is nil while the right side is a cons spine. Constructor no-confusion for the finite-spine carrier of Definition 36.1 is the mixed nil/cons separation isolated in Definition 36.13 and Definition 36.14. For classifier comparison, unfold $\mathsf{PolySame}_R$. The first argument trims again to nil. The second argument is $[a + b]$, and the hypothesis $(a + b) \sim_R 0_R$ sends its singleton coefficient to the trailing-zero branch, so its trim is also nil. The nil-nil clause of $\mathsf{ListClassifierSpec}$ gives the displayed $\mathsf{PolySame}_R$ witness. The integer specialization uses the standard integer facts $1 \neq 0$, $-1 \neq 0$, and $1 + (-1) = 0$; Definition 44.8 keeps the ring operations and classifier when the commutative-ring source is read through $\mathsf{Ring}^{\uparrow}$. □

Definition 50.73 (Polynomial Horner evaluation)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and raw addition radd_R from Definition 50.30. For a carried scalar point α, define the Horner evaluation on finite coefficient spines from Definition 36.1 by recursion*

$$\mathsf{eval}_{\alpha,R}(\mathsf{nil}) := 0_R.$$

$$\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a,x)) := a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x).$$

Define the normalized polynomial evaluation by

$$\mathsf{Eval}_{\alpha,R}(x) := \mathsf{eval}_{\alpha,R}(\mathsf{trim}_R(x)).$$

Define the normalized polynomial sum by

$$\mathsf{PolyAdd}_R(x,y) := \mathsf{trim}_R(\mathsf{radd}_R(\mathsf{trim}_R(x), \mathsf{trim}_R(y))).$$

On a normalized representative from Definition 50.3, $\mathsf{Eval}_{\alpha,R}$ *is the Horner evaluation itself, by trim idempotence from Definition 50.22.*

Lemma 50.74 (Horner evaluation ignores classified zero tails)**.** *Let* R *carry a* $\mathsf{CommRing}^{\uparrow}(R)$ *certificate, read as a* $\mathsf{Ring}^{\uparrow}(R)$ *certificate by Definition 44.8. Fix a carried scalar point* α*. For finite coefficient spines* $x, t : \mathsf{ListCarrier}(R)$*, if* $\mathsf{ZeroRem}_R(t)$ *holds in the sense of Definition 50.28, then*

$$\mathsf{eval}_{\alpha,R}(x{+}{+}t) \sim_R \mathsf{eval}_{\alpha,R}(x).$$

Consequently, for every finite coefficient spine x*,*

$$\mathsf{Eval}_{\alpha,R}(x) \sim_R \mathsf{eval}_{\alpha,R}(x).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialZeroRemainder addFold empty`

Proof. First prove the endpoint claim $\mathsf{eval}_{\alpha,R}(t) \sim_R 0_R$ for every classified zero tail t. Induct on the displayed $\mathsf{ZeroRem}_R(t)$ witness. The nil clause is the defining equation $\mathsf{eval}_{\alpha,R}(\mathsf{nil}) = 0_R$ together with zero self-classification from Definition 43.26. In the cons clause, write $t = \mathsf{cons}(a, t')$. The constructor gives $a \sim_R 0_R$ and the induction hypothesis gives $\mathsf{eval}_{\alpha,R}(t') \sim_R 0_R$. Multiplication congruence and the zero-multiplication row in Definition 43.26 classify $\alpha \cdot \mathsf{eval}_{\alpha,R}(t')$ with 0_R. Addition congruence then classifies $a + \alpha \cdot \mathsf{eval}_{\alpha,R}(t')$ with $0_R + 0_R$, and the additive left-zero law reduces the latter endpoint to 0_R.

For the displayed tail-invariance statement, induct on x. The nil case is the endpoint claim just proved. In the cons case, write $x = \mathsf{cons}(a, x')$. The induction hypothesis gives $\mathsf{eval}_{\alpha,R}(x'{+}{+}t) \sim_R \mathsf{eval}_{\alpha,R}(x')$. Multiplication congruence transports this comparison through left multiplication by α, and addition congruence with source reflexivity on a gives

$$a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x'{+}{+}t) \sim_R a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x').$$

The two Horner recursion equations identify these endpoints with $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'{+}{+}t))$ and $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'))$.

For the consequence, the trailing-zero removal clause in Definition 50.22 presents each raw spine x as $\mathsf{trim}_R(x){+}{+}t$ with $\mathsf{ZeroRem}_R(t)$. Applying the first part gives $\mathsf{eval}_{\alpha,R}(x) \sim_R \mathsf{Eval}_{\alpha,R}(x)$, and symmetry of the scalar classifier reverses the displayed comparison. □

Lemma 50.75 (Horner evaluation respects raw polynomial addition)**.** *Let* R *carry a* $\mathsf{CommRing}^{\uparrow}(R)$ *certificate, read as a* $\mathsf{Ring}^{\uparrow}(R)$ *certificate by Definition 44.8. Fix a carried scalar point* α*. For finite coefficient spines* $x, y : \mathsf{ListCarrier}(R)$*,*

$$\mathsf{eval}_{\alpha,R}(\mathsf{radd}_R(x,y)) \sim_R \mathsf{eval}_{\alpha,R}(x) + \mathsf{eval}_{\alpha,R}(y).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonAddFold append hsame`

Proof. Perform induction on the two finite spines, following the four recursion clauses for radd_R in Definition 50.30.

The nil-nil case compares 0_R with $0_R + 0_R$, so it is exactly the additive left-zero law, read with symmetry when needed.

In the cons-nil case, write $x = \mathsf{cons}(a, x')$. The raw-addition recursion exposes the head $a + 0_R$ and the tail $\mathsf{radd}_R(x', \mathsf{nil})$. The induction hypothesis classifies the tail evaluation with $\mathsf{eval}_{\alpha,R}(x') + 0_R$, and Definition 43.31 reduces that endpoint to $\mathsf{eval}_{\alpha,R}(x')$. Multiplication congruence transports the tail comparison through left multiplication by α. Additive congruence and the additive right-zero law reduce the exposed head $a + 0_R$ to a, and the target endpoint $(\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'))) + 0_R$ to $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'))$.

The nil-cons case is symmetric. The raw head is $0_R + b$, which reduces to b by the additive left-zero law, and the outer target $0_R + \mathsf{eval}_{\alpha,R}(\mathsf{cons}(b, y'))$ reduces by the same law. The tail comparison is transported through multiplication by α exactly as in the cons-nil case.

In the cons-cons case, write $x = \mathsf{cons}(a, x')$ and $y = \mathsf{cons}(b, y')$. The induction hypothesis gives

$$\mathsf{eval}_{\alpha,R}(\mathsf{radd}_R(x', y')) \sim_R \mathsf{eval}_{\alpha,R}(x') + \mathsf{eval}_{\alpha,R}(y').$$

Multiplication congruence transports this through left multiplication by α, and left distributivity from Definition 43.26 classifies

$$\alpha \cdot (\mathsf{eval}_{\alpha,R}(x') + \mathsf{eval}_{\alpha,R}(y'))$$

with

$$\alpha \cdot \mathsf{eval}_{\alpha,R}(x') + \alpha \cdot \mathsf{eval}_{\alpha,R}(y').$$

Addition congruence therefore transports the Horner endpoint for $\mathsf{radd}_R(x, y)$ to

$$(a + b) + (\alpha \cdot \mathsf{eval}_{\alpha,R}(x') + \alpha \cdot \mathsf{eval}_{\alpha,R}(y')).$$

Apply Definition 42.13 to the additive abelian-group operation, with the four additive blocks a, b, $\alpha \cdot \mathsf{eval}_{\alpha,R}(x')$, and $\alpha \cdot \mathsf{eval}_{\alpha,R}(y')$. This classifies the last endpoint with

$$(a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x')) + (b + \alpha \cdot \mathsf{eval}_{\alpha,R}(y')),$$

which is exactly $\mathsf{eval}_{\alpha,R}(x) + \mathsf{eval}_{\alpha,R}(y)$ by the Horner recursion. □

Theorem 50.76 (Polynomial evaluation is additive)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{Eval}_{\alpha,R}(\mathsf{PolyAdd}_R(p, q)) \sim_R \mathsf{Eval}_{\alpha,R}(p) + \mathsf{Eval}_{\alpha,R}(q).$$

If p and q are normalized representatives in the polynomial carrier, the same assertion is the carrier formula

$$\mathsf{eval}_{\alpha,R}(\mathsf{PolyAdd}_R(p, q)) \sim_R \mathsf{eval}_{\alpha,R}(p) + \mathsf{eval}_{\alpha,R}(q).$$

Proof. Put $p_0 = \mathsf{trim}_R(p)$ and $q_0 = \mathsf{trim}_R(q)$. By Definition 50.133,

$$\mathsf{PolyAdd}_R(p, q) = \mathsf{trim}_R(\mathsf{radd}_R(p_0, q_0)).$$

Trim idempotence from Definition 50.22 identifies $\mathsf{Eval}_{\alpha,R}(\mathsf{PolyAdd}_R(p, q))$ with $\mathsf{Eval}_{\alpha,R}(\mathsf{radd}_R(p_0, q_0))$. Applying Definition 50.134 gives

$$\mathsf{Eval}_{\alpha,R}(\mathsf{radd}_R(p_0, q_0)) \sim_R \mathsf{eval}_{\alpha,R}(\mathsf{radd}_R(p_0, q_0)).$$

By Definition 50.135,

$$\mathsf{eval}_{\alpha,R}(\mathsf{radd}_R(p_0, q_0)) \sim_R \mathsf{eval}_{\alpha,R}(p_0) + \mathsf{eval}_{\alpha,R}(q_0).$$

The right endpoint is $\mathsf{Eval}_{\alpha,R}(p) + \mathsf{Eval}_{\alpha,R}(q)$ by the definition of p_0, q_0, and normalized evaluation. Classifier transitivity composes the displayed comparisons.

If p and q are already normalized polynomial-carrier representatives, trim idempotence gives $p_0 = p$ and $q_0 = q$, and $\mathsf{Eval}_{\alpha,R}$ on each displayed representative is the unnormalized Horner evaluation. Substituting these equalities gives the carrier formula. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval rawAdd classified`

Lemma 50.77 (Horner evaluation respects structural classifier)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $x, y : \mathsf{ListCarrier}(R)$, if*

$$\mathsf{ListClassifierSpec}(\sim_R, x, y)$$

holds, then

$$\mathsf{eval}_{\alpha,R}(x) \sim_R \mathsf{eval}_{\alpha,R}(y).$$

Proof. Induct on the displayed structural classifier witness from Definition 36.12. By Definition 36.13, the only constructor cases are nil-nil and cons-cons; mixed nil-cons shapes have no classifier witness.

In the nil-nil case, the two Horner equations in Definition 50.133 identify both endpoints with 0_R. The zero self-classification field retained in Definition 43.26 gives $0_R \sim_R 0_R$.

In the cons-cons case, write $x = \mathsf{cons}(a, x')$ and $y = \mathsf{cons}(b, y')$. The classifier constructor supplies $a \sim_R b$ and a tail witness $\mathsf{ListClassifierSpec}(\sim_R, x', y')$. The induction hypothesis gives

$$\mathsf{eval}_{\alpha,R}(x') \sim_R \mathsf{eval}_{\alpha,R}(y').$$

The carried point α is self-classified by the scalar certificate. Multiplication congruence from Definition 43.26 transports the tail comparison through left multiplication by α, giving

$$\alpha \cdot \mathsf{eval}_{\alpha,R}(x') \sim_R \alpha \cdot \mathsf{eval}_{\alpha,R}(y').$$

Addition congruence combines this comparison with the head comparison $a \sim_R b$:

$$a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x') \sim_R b + \alpha \cdot \mathsf{eval}_{\alpha,R}(y').$$

The cons recursion equation in Definition 50.133 identifies these two endpoints with $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'))$ and $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(b, y'))$, respectively. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval list classifier classified`

Theorem 50.78 (Polynomial evaluation respects the polynomial classifier)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(p, q) \Longrightarrow \mathsf{Eval}_{\alpha,R}(p) \sim_R \mathsf{Eval}_{\alpha,R}(q).$$

Proof. Unfold $\mathsf{PolySame}_R$ using Definition 50.30. A classifier witness for p and q is exactly

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(p), \mathsf{trim}_R(q)).$$

Apply Definition 50.137 to the two trimmed spines. This gives

$$\mathsf{eval}_{\alpha,R}(\mathsf{trim}_R(p)) \sim_R \mathsf{eval}_{\alpha,R}(\mathsf{trim}_R(q)).$$

The normalized evaluation definition in Definition 50.133 reads the left endpoint as $\mathsf{Eval}_{\alpha,R}(p)$ and the right endpoint as $\mathsf{Eval}_{\alpha,R}(q)$, giving the displayed implication. □

Definition 50.79 (Polynomial raw Cauchy product)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and raw addition radd_R from Definition 50.30. For a scalar coefficient a and a finite coefficient spine $y : \mathsf{ListCarrier}(R)$, define scalar multiplication of coefficient spines by*

$$\mathsf{rscale}_R(a, \mathsf{nil}) := \mathsf{nil}, \qquad \mathsf{rscale}_R(a, \mathsf{cons}(b, y)) := \mathsf{cons}(a \cdot b, \mathsf{rscale}_R(a, y)).$$

Define the one-place coefficient shift by

$$\mathsf{shift}_R(y) := \mathsf{cons}(0_R, y).$$

The raw polynomial product is the finite recursion

$$\mathsf{rmul}_R(\mathsf{nil}, y) := \mathsf{nil},$$

$$\mathsf{rmul}_R(\mathsf{cons}(a, x), y) := \mathsf{radd}_R(\mathsf{rscale}_R(a, y), \mathsf{shift}_R(\mathsf{rmul}_R(x, y))).$$

The normalized polynomial product is

$$\mathsf{PolyMul}_R(x, y) := \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{trim}_R(x), \mathsf{trim}_R(y))).$$

This is the Cauchy product in low-coefficient-first Horner form: the cons clause expresses $(a + Xx)y = ay + X(xy)$.

Lean4 (definition) `BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul`

Lemma 50.80 (Horner evaluation of scalar-multiplied coefficient spines)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For every carried scalar coefficient a and every finite coefficient spine $y : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{\alpha,R}(\mathsf{rscale}_R(a, y)) \sim_R a \cdot \mathsf{eval}_{\alpha,R}(y).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval rawScale classified`
Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval raw scale empty classified`

Proof. Induct on the finite spine y from Definition 36.1. In the nil case, both the scalar-multiple spine and its Horner value are 0_R. The target endpoint is $a \cdot 0_R$, and the zero-multiplication row in Definition 43.26, with symmetry of $\sim_R$, gives the displayed comparison.

In the cons case, write $y = \mathsf{cons}(b, y')$. The recursion in Definition 50.139 and the Horner recursion in Definition 50.133 identify the left endpoint with

$$a \cdot b + \alpha \cdot \mathsf{eval}_{\alpha,R}(\mathsf{rscale}_R(a, y')).$$

The induction hypothesis and multiplication congruence classify this endpoint with

$$a \cdot b + \alpha \cdot (a \cdot \mathsf{eval}_{\alpha,R}(y')).$$

Multiplicative associativity, multiplicative commutativity from Definition 44.33, and multiplication congruence classify

$$\alpha \cdot (a \cdot \mathsf{eval}_{\alpha,R}(y'))$$

with

$$a \cdot (\alpha \cdot \mathsf{eval}_{\alpha,R}(y')).$$

Addition congruence transports this comparison under the common summand $a \cdot b$. The left distributive row in Definition 43.26, used in the reverse direction, then identifies

$$a \cdot b + a \cdot (\alpha \cdot \mathsf{eval}_{\alpha,R}(y'))$$

with

$$a \cdot (b + \alpha \cdot \mathsf{eval}_{\alpha,R}(y')).$$

The final endpoint is $a \cdot \mathsf{eval}_{\alpha,R}(\mathsf{cons}(b, y'))$ by the Horner recursion, and transitivity composes the comparisons. □

Lemma 50.81 (Horner evaluation of coefficient shift)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For every finite coefficient spine $x : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{\alpha,R}(\mathsf{shift}_R(x)) \sim_R \alpha \cdot \mathsf{eval}_{\alpha,R}(x).$$

Proof. By Definition 50.139, $\mathsf{shift}_R(x) = \mathsf{cons}(0_R, x)$. The Horner recursion from Definition 50.133 makes its evaluation

$$0_R + \alpha \cdot \mathsf{eval}_{\alpha,R}(x).$$

The additive left-zero row in Definition 43.26 classifies this endpoint with $\alpha \cdot \mathsf{eval}_{\alpha,R}(x)$. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval coefficient shift`

Lemma 50.82 (Horner evaluation respects raw polynomial multiplication)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $x, y : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(x, y)) \sim_R \mathsf{eval}_{\alpha,R}(x) \cdot \mathsf{eval}_{\alpha,R}(y).$$

Proof. Induct on the first spine x. In the nil case, $\mathsf{rmul}_R(\mathsf{nil}, y) = \mathsf{nil}$, so the left endpoint evaluates to 0_R. The target endpoint is $0_R \cdot \mathsf{eval}_{\alpha,R}(y)$, and the zero-multiplication row in Definition 43.26, with symmetry, gives the comparison.

For the cons case, write $x = \mathsf{cons}(a, x')$, put $u = \mathsf{eval}_{\alpha,R}(x')$, and put $v = \mathsf{eval}_{\alpha,R}(y)$. The raw product recursion in Definition 50.139 and the raw additivity theorem Definition 50.135 give

$$\mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(\mathsf{cons}(a, x'), y)) \sim_R \mathsf{eval}_{\alpha,R}(\mathsf{rscale}_R(a, y)) + \mathsf{eval}_{\alpha,R}(\mathsf{shift}_R(\mathsf{rmul}_R(x', y))).$$

By Definition 50.140, the first summand is classified with $a \cdot v$. By Definition 50.141, the second summand is classified with

$$\alpha \cdot \mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(x', y)).$$

The induction hypothesis and multiplication congruence classify this with $\alpha \cdot (u \cdot v)$. Multiplicative associativity classifies $\alpha \cdot (u \cdot v)$ with $(\alpha \cdot u) \cdot v$. Addition congruence therefore gives

$$\mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(\mathsf{cons}(a, x'), y)) \sim_R a \cdot v + (\alpha \cdot u) \cdot v.$$

The right distributive row retained by Definition 44.8, equivalently derived from Definition 44.34, classifies

$$(a + \alpha \cdot u) \cdot v$$

with

$$a \cdot v + (\alpha \cdot u) \cdot v.$$

Using symmetry of this distributive comparison and the Horner recursion

$$\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x')) = a + \alpha \cdot u,$$

transitivity gives the required cons-case endpoint. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval rawMul classified`

Theorem 50.83 (Polynomial evaluation is multiplicative)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{Eval}_{\alpha,R}(\mathsf{PolyMul}_R(p, q)) \sim_R \mathsf{Eval}_{\alpha,R}(p) \cdot \mathsf{Eval}_{\alpha,R}(q).$$

If p and q are normalized representatives in the polynomial carrier, the same assertion is the carrier formula

$$\mathsf{eval}_{\alpha,R}(\mathsf{PolyMul}_R(p, q)) \sim_R \mathsf{eval}_{\alpha,R}(p) \cdot \mathsf{eval}_{\alpha,R}(q).$$

Proof. Put $p_0 = \mathsf{trim}_R(p)$ and $q_0 = \mathsf{trim}_R(q)$. By Definition 50.139,

$$\mathsf{PolyMul}_R(p, q) = \mathsf{trim}_R(\mathsf{rmul}_R(p_0, q_0)).$$

Trim idempotence from Definition 50.22 identifies the normalized evaluation of this endpoint with

$$\mathsf{Eval}_{\alpha,R}(\mathsf{rmul}_R(p_0, q_0)).$$

Applying Definition 50.134 gives

$$\mathsf{Eval}_{\alpha,R}(\mathsf{rmul}_R(p_0, q_0)) \sim_R \mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(p_0, q_0)).$$

By Definition 50.142,

$$\mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(p_0, q_0)) \sim_R \mathsf{eval}_{\alpha,R}(p_0) \cdot \mathsf{eval}_{\alpha,R}(q_0).$$

The right endpoint is $\mathsf{Eval}_{\alpha,R}(p) \cdot \mathsf{Eval}_{\alpha,R}(q)$ by the definition of p_0, q_0, and normalized evaluation in Definition 50.133. Classifier transitivity composes the displayed comparisons.

If p and q are already normalized polynomial-carrier representatives, trim idempotence gives $p_0 = p$ and $q_0 = q$. The product endpoint is normalized by its defining trim, so normalized evaluation on $\mathsf{PolyMul}_R(p, q)$ is the unnormalized Horner evaluation of that product. Substituting these equalities gives the carrier formula. □

Theorem 50.84 (Polynomial evaluation is a semiring morphism through classification)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $p, q, p', q' : \mathsf{ListCarrier}(R)$, if $\mathsf{PolySame}_R(p, p')$ and $\mathsf{PolySame}_R(q, q')$, then*

$$\mathsf{Eval}_{\alpha,R}(p) \sim_R \mathsf{Eval}_{\alpha,R}(p'),$$

$$\mathsf{Eval}_{\alpha,R}(\mathsf{PolyAdd}_R(p, q)) \sim_R \mathsf{Eval}_{\alpha,R}(p) + \mathsf{Eval}_{\alpha,R}(q),$$

and

$$\mathsf{Eval}_{\alpha,R}(\mathsf{PolyMul}_R(p, q)) \sim_R \mathsf{Eval}_{\alpha,R}(p) \cdot \mathsf{Eval}_{\alpha,R}(q).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval semiring morphism`

Proof. The first clause is exactly Definition 50.138 applied to the classifier witness between p and p'.

The second and third clauses are the normalized-operation laws from Definition 50.136 and Definition 50.143. They apply to the original representatives p and q, so the operation endpoints are already the canonical normalized polynomial operations.

When a later scalar comparison is written with p' or q' instead, apply Definition 50.138 to the appropriate classifier witness and compose by transitivity of $\sim_R$. Thus the descended endpoints may be substituted in the additive and multiplicative scalar comparisons without reassembling the three facts. □

Lemma 50.85 (Zero-point Horner cons evaluation)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and Horner evaluation as in Definition 50.133. For every carried scalar coefficient a and every finite coefficient spine $t : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{0_R,R}(\mathsf{cons}(a, t)) \sim_R a.$$

Proof. The cons recursion in Definition 50.133 identifies the left endpoint with

$$a + 0_R \cdot \mathsf{eval}_{0_R,R}(t).$$

The zero-absorption theorem Definition 43.60, applied to $\mathsf{eval}_{0_R,R}(t)$, gives

$$0_R \cdot \mathsf{eval}_{0_R,R}(t) \sim_R 0_R.$$

Classifier reflexivity supplies $a \sim_R a$, and addition congruence from Definition 43.26 gives

$$a + 0_R \cdot \mathsf{eval}_{0_R,R}(t) \sim_R a + 0_R.$$

The additive right-zero theorem Definition 43.31 gives $a + 0_R \sim_R a$. Classifier transitivity composes the two comparisons. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval zero cons constant`

Lemma 50.86 (Zero-point Horner evaluation ignores classified zero tails)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and Horner evaluation as in Definition 50.133. For finite coefficient spines $x, t : \mathsf{ListCarrier}(R)$, if $\mathsf{ZeroRem}_R(t)$ holds in the sense of Definition 50.28, then*

$$\mathsf{eval}_{0_R,R}(x{+}{+}t) \sim_R \mathsf{eval}_{0_R,R}(x).$$

Proof. First record the endpoint claim that every classified zero remainder evaluates to zero at 0_R. If the zero remainder is nil, the nil recursion in Definition 50.133 identifies its evaluation with 0_R, and zero self-classification from Definition 43.26 gives the claim. If the zero remainder is $\mathsf{cons}(c, t')$, the cons clause of Definition 50.28 supplies $c \sim_R 0_R$. By Definition 50.145,

$$\mathsf{eval}_{0_R,R}(\mathsf{cons}(c, t')) \sim_R c,$$

and transitivity gives $\mathsf{eval}_{0_R,R}(\mathsf{cons}(c, t')) \sim_R 0_R$.

Now split on the first constructor of x. If $x = \mathsf{nil}$, then $x{+}{+}t = t$, so the endpoint claim gives the displayed comparison. If $x = \mathsf{cons}(a, x')$, then $x{+}{+}t = \mathsf{cons}(a, x'{+}{+}t)$. Applying Definition 50.145 twice gives

$$\mathsf{eval}_{0_R,R}(\mathsf{cons}(a, x'{+}{+}t)) \sim_R a$$

and

$$\mathsf{eval}_{0_R,R}(\mathsf{cons}(a, x')) \sim_R a.$$

Symmetry of the second comparison and transitivity give the required comparison for the cons case. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval zero point zero tail invariance`

Theorem 50.87 (Polynomial evaluation at zero returns the constant coefficient)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and Horner evaluation as in Definition 50.133. For every carried scalar coefficient a and every finite coefficient spine $t : \mathsf{ListCarrier}(R)$,*

$$\mathsf{Eval}_{0_R,R}(\mathsf{cons}(a, t)) \sim_R a.$$

Proof. Set $x = \mathsf{cons}(a, t)$. The trailing-zero removal clause in Definition 50.22 gives a finite zero remainder z such that

$$x = \mathsf{trim}_R(x){+}{+}z, \qquad \mathsf{ZeroRem}_R(z).$$

Applying Definition 50.146 to $\mathsf{trim}_R(x)$ and z yields

$$\mathsf{eval}_{0_R,R}(x) \sim_R \mathsf{eval}_{0_R,R}(\mathsf{trim}_R(x)).$$

By the normalized evaluation definition in Definition 50.133, the right endpoint is $\mathsf{Eval}_{0_R,R}(x)$. Symmetry gives

$$\mathsf{Eval}_{0_R,R}(x) \sim_R \mathsf{eval}_{0_R,R}(x).$$

The raw cons comparison Definition 50.145 gives

$$\mathsf{eval}_{0_R,R}(x) \sim_R a.$$

Classifier transitivity composes these two comparisons, and substituting $x = \mathsf{cons}(a, t)$ gives the displayed formula. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval zero constant term`

Lemma 50.88 (Unit-point Horner evaluation is coefficient fold)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, multiplicative unit endpoint 1_R, addition $+$, multiplication $\cdot$,*

and Horner evaluation as in Definition 50.133. Let $\mathsf{fold}_{+,R}$ *be the finite recursive coefficient fold from Definition 50.26, satisfying*

$$\mathsf{fold}_{+,R}(\mathsf{nil}) = 0_R, \qquad \mathsf{fold}_{+,R}(\mathsf{cons}(a, x')) = a + \mathsf{fold}_{+,R}(x').$$

For every finite coefficient spine $x : \mathsf{ListCarrier}(R)$*,*

$$\mathsf{eval}_{1_R,R}(x) \sim_R \mathsf{fold}_{+,R}(x).$$

Proof. Induct on the finite spine x from Definition 36.1.

In the nil case, the nil Horner equation in Definition 50.133 and the nil fold equation identify both endpoints with 0_R. The zero self-classification row of Definition 43.26 gives the displayed comparison.

In the cons case, write $x = \mathsf{cons}(a, x')$. The induction hypothesis gives

$$\mathsf{eval}_{1_R,R}(x') \sim_R \mathsf{fold}_{+,R}(x').$$

The recursive Horner endpoint $\mathsf{eval}_{1_R,R}(x')$ is carried by induction on x' using the scalar zero, addition, and multiplication closure rows of the $\mathsf{Ring}^{\uparrow}$ certificate. Hence the multiplicative left-unit row retained in Definition 43.26 gives

$$1_R \cdot \mathsf{eval}_{1_R,R}(x') \sim_R \mathsf{eval}_{1_R,R}(x').$$

Classifier transitivity composes this unit comparison with the induction hypothesis, yielding

$$1_R \cdot \mathsf{eval}_{1_R,R}(x') \sim_R \mathsf{fold}_{+,R}(x').$$

Source reflexivity gives $a \sim_R a$. Applying additive congruence from Definition 43.26 gives

$$a + 1_R \cdot \mathsf{eval}_{1_R,R}(x') \sim_R a + \mathsf{fold}_{+,R}(x').$$

The cons Horner equation identifies the left endpoint with $\mathsf{eval}_{1_R,R}(\mathsf{cons}(a, x'))$, and the cons fold equation identifies the right endpoint with $\mathsf{fold}_{+,R}(\mathsf{cons}(a, x'))$. □

Theorem 50.89 (Polynomial evaluation at the multiplicative unit is coefficient fold)**.** *Let* R *carry a* $\mathsf{Ring}^{\uparrow}(R)$ *certificate with classifier* $\sim_R$*, zero endpoint* 0_R*, multiplicative unit endpoint* 1_R*, addition* $+$*, multiplication* $\cdot$*, canonical trim* trim_R*, and Horner evaluation as in Definition 50.133. Let* $\mathsf{fold}_{+,R}$ *be the finite recursive coefficient fold from Definition 50.26. For every finite coefficient spine* $p : \mathsf{ListCarrier}(R)$*,*

$$\mathsf{Eval}_{1_R,R}(p) \sim_R \mathsf{fold}_{+,R}(\mathsf{trim}_R(p)).$$

Proof. By the normalized evaluation definition in Definition 50.133,

$$\mathsf{Eval}_{1_R,R}(p) = \mathsf{eval}_{1_R,R}(\mathsf{trim}_R(p)).$$

Apply Definition 50.148 to the finite coefficient spine $\mathsf{trim}_R(p)$. This gives

$$\mathsf{eval}_{1_R,R}(\mathsf{trim}_R(p)) \sim_R \mathsf{fold}_{+,R}(\mathsf{trim}_R(p)).$$

Substituting the displayed definition of $\mathsf{Eval}_{1_R,R}(p)$ gives the claimed comparison. □

Lemma 50.90 (Polynomial raw addition structural swap)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, and addition $+$. Assume scalar additive commutativity:*

$$a + b \sim_R b + a$$

for all scalar coefficients a, b. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(p, q), \mathsf{radd}_R(q, p)).$$

Proof. Induct simultaneously on the two finite coefficient spines, following the four recursion clauses of radd_R in Definition 50.30. The target classifier is the finite-spine structural classifier of Definition 36.12, with matching constructors isolated by Definition 36.13.

In the nil-nil case, both raw additions are nil, so the nil clause of $\mathsf{ListClassifierSpec}$ gives the claim.

In the cons-nil case, write $p = \mathsf{cons}(a, p')$ and $q = \mathsf{nil}$. The recursion gives

$$\mathsf{radd}_R(p, q) = \mathsf{cons}(a + 0_R, \mathsf{radd}_R(p', \mathsf{nil}))$$

and

$$\mathsf{radd}_R(q, p) = \mathsf{cons}(0_R + a, \mathsf{radd}_R(\mathsf{nil}, p')).$$

Scalar additive commutativity gives $a + 0_R \sim_R 0_R + a$. The induction hypothesis applied to p' and nil gives the tail classifier

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(p', \mathsf{nil}), \mathsf{radd}_R(\mathsf{nil}, p')).$$

The cons clause of $\mathsf{ListClassifierSpec}$ combines the head comparison and this tail comparison.

In the nil-cons case, write $p = \mathsf{nil}$ and $q = \mathsf{cons}(b, q')$. The recursion gives heads $0_R + b$ and $b + 0_R$. Scalar additive commutativity gives $0_R + b \sim_R b + 0_R$, and the induction hypothesis at nil and q' supplies the tail classifier. The cons clause rebuilds the displayed list-classifier witness.

In the cons-cons case, write $p = \mathsf{cons}(a, p')$ and $q = \mathsf{cons}(b, q')$. The recursion exposes heads $a + b$ and $b + a$, related by scalar additive commutativity. The induction hypothesis supplies

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(p', q'), \mathsf{radd}_R(q', p')).$$

The cons clause combines the head and tail witnesses, giving the structural classifier for the two raw sums. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd structural swap`
Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd commutative classified`

Theorem 50.91 (Polynomial raw addition commutativity from scalar additive commutativity)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, and scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$. Use the additive abelian-group and classifier fields retained in Definition 43.26: zero self-classification, classifier transitivity, additive congruence, additive zero laws, and scalar additive commutativity. For a commutative-ring scalar source, Definition 44.8 keeps these data unchanged. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{radd}_R(p, q), \mathsf{radd}_R(q, p)).$$

Proof. Apply Definition 50.150 to p and q using the scalar additive commutativity row from Definition 43.26. This gives

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(p,q), \mathsf{radd}_R(q,p)).$$

The nil finite spine is a zero remainder by the nil clause of Definition 50.28. Apply Definition 50.29 with common classified spines $\mathsf{radd}_R(p,q)$ and $\mathsf{radd}_R(q,p)$, and with both zero remainders equal to nil. Finite-spine append by nil leaves each spine unchanged, so the lemma yields

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(\mathsf{radd}_R(p,q)), \mathsf{trim}_R(\mathsf{radd}_R(q,p))).$$

Unfolding $\mathsf{PolySame}_R$ from Definition 50.30, this is exactly the displayed polynomial raw classifier comparison. □

Lemma 50.92 (Raw polynomial addition is structurally associative)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, and scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$. Assume the additive fields retained in Definition 43.26: additive associativity, additive zero laws, classifier symmetry, classifier transitivity, and addition congruence. For finite coefficient spines $p, q, r : \mathsf{ListCarrier}(R)$,*

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(\mathsf{radd}_R(p,q), r), \mathsf{radd}_R(p, \mathsf{radd}_R(q,r))).$$

Proof. Induct on the finite triple spine (p, q, r), using the maximum of the three finite lengths as the decreasing measure. The nil-nil-nil case unfolds both raw additions by Definition 50.30 to nil, and the nil clause of Definition 36.12 gives the classifier witness.

In every remaining constructor case, at least one of the three spines is a cons spine. Unfold the corresponding clauses of radd_R from Definition 50.30. Both associated raw sums expose a cons head, and their tails are exactly the two associated raw sums for the tail triple, with nil used as the tail of any absent spine. The induction hypothesis supplies the recursive tail classifier.

It remains to classify the exposed scalar heads. If all three heads are present, say a, b, c, the comparison is

$$(a+b)+c \sim_R a+(b+c),$$

which is scalar additive associativity. If exactly two heads are present, the missing head is the padding coefficient 0_R, so the three possible comparisons

$$(a+b)+0_R \sim_R a+(b+0_R),$$

$$(a+0_R)+c \sim_R a+(0_R+c),$$

$$(0_R+b)+c \sim_R 0_R+(b+c)$$

are the same associativity law with one displayed argument equal to 0_R. If only the left input has a head a, the comparison is

$$(a+0_R)+0_R \sim_R a+0_R,$$

which is the additive right-zero law applied to $a+0_R$. If only the middle input has a head b, the comparison is

$$(0_R+b)+0_R \sim_R 0_R+(b+0_R),$$

again additive associativity. If only the right input has a head c, the comparison is

$$0_R+c \sim_R 0_R+(0_R+c),$$

obtained by reversing the additive left-zero law at the endpoint $0_R + c$ using classifier symmetry from cert_R.

In each constructor case, the scalar head comparison and the tail classifier rebuild the cons clause of $\mathsf{ListClassifierSpec}$. These cases exhaust the finite-spine constructors by Definition 36.13. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd associative classified`

Theorem 50.93 (Polynomial raw addition associativity)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, canonical trim trim_R, and scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$. Assume the additive fields retained in Definition 43.26: additive abelian-group laws and addition congruence. For finite coefficient spines $p, q, r : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{radd}_R(\mathsf{radd}_R(p, q), r), \mathsf{radd}_R(p, \mathsf{radd}_R(q, r))).$$

Proof. Set

$$u := \mathsf{radd}_R(\mathsf{radd}_R(p, q), r), \qquad \omega := \mathsf{radd}_R(p, \mathsf{radd}_R(q, r)).$$

By Definition 50.152,

$$\mathsf{ListClassifierSpec}(\sim_R, \nu, \omega)$$

holds. The nil spine is a classified zero remainder by the nil clause of Definition 50.28. Apply Definition 50.29 to the common classified spines ν and ω, with nil zero remainders on both sides. The append-nil identities for finite spines give

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(\nu), \mathsf{trim}_R(\omega)).$$

Unfolding $\mathsf{PolySame}_R$ from Definition 50.30 turns this normalized structural classifier into the displayed polynomial classifier comparison. □

Theorem 50.94 (Polynomial raw multiplication commutativity from scalar commutativity)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, canonical trim trim_R, and the raw operations radd_R, rscale_R, shift_R, and rmul_R from Definition 50.30 and Definition 50.139. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(p, q), \mathsf{rmul}_R(q, p)).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul commutative classified`

Proof. Read the scalar source as a $\mathsf{Ring}^{\uparrow}(R)$ source by Definition 44.8. The retained rows used below are the $\mathsf{NameCert}$ reflexivity, symmetry, and transitivity fields, the additive abelian-group laws and addition congruence from Definition 43.26, multiplication congruence, and the multiplicative commutativity row from Definition 44.33.

First record the finite-spine consequences of the existing raw-addition package. The relation $\mathsf{PolySame}_R$ is reflexive, symmetric, and transitive after unfolding Definition 50.30; this is exactly structural list-classifier reflexivity, Definition 36.47, and Definition 36.15 applied to the two trimmed representatives.

Raw addition is compatible with $\mathsf{PolySame}_R$ in both inputs. Indeed, Definition 50.32 reduces both raw sums to sums of their trimmed inputs. The two displayed trimmed-input classifiers give a structural classifier between the two trimmed raw sums by induction on the two list-classifier witnesses in Definition 36.12; the exposed heads are handled by addition congruence, with $0_R \sim_R 0_R$ in the padding branches. Transitivity and symmetry of $\mathsf{PolySame}_R$ compose these three comparisons.

The shift operation preserves $\mathsf{PolySame}_R$. If $\mathsf{PolySame}_R(x, y)$ holds, write the trim decompositions supplied by Definition 50.22 as $x = x_0{+}{+}z$ and $y = y_0{+}{+}w$, with $\mathsf{ListClassifierSpec}(\sim_R, x_0, y_0)$ and zero remainders z, w. Then

$$\mathsf{shift}_R(x) = (\mathsf{cons}(0_R, x_0)){+}{+}z, \qquad \mathsf{shift}_R(y) = (\mathsf{cons}(0_R, y_0)){+}{+}w.$$

The cons classifier built from $0_R \sim_R 0_R$ and the classifier on x_0, y_0, followed by Definition 50.29, gives $\mathsf{PolySame}_R(\mathsf{shift}_R(x), \mathsf{shift}_R(y))$. The same argument, with 0_R replaced by classified heads $h \sim_R h'$, shows that $h \sim_R h'$ and $\mathsf{PolySame}_R(t, t')$ imply

$$\mathsf{PolySame}_R(\mathsf{cons}(h, t), \mathsf{cons}(h', t')).$$

Zero remainders are closed under raw addition: induct on the two zero-remainder witnesses from Definition 50.28. In the cons-cons branch, addition congruence sends $a + b$ to $0_R + 0_R$, and the additive left-zero law reduces that endpoint to 0_R; the cons-nil and nil-cons branches use the additive right-zero and left-zero laws. Hence $\mathsf{rmul}_R(s, \mathsf{nil})$ is a zero remainder for every finite spine s, by induction on s using Definition 50.139: the cons step combines $\mathsf{rscale}_R(a, \mathsf{nil}) = \mathsf{nil}$, the zero-remainder closure of shift_R, and raw-addition closure. Applying Definition 50.29 with common spine nil gives

$$\mathsf{PolySame}_R(\mathsf{nil}, \mathsf{rmul}_R(s, \mathsf{nil})).$$

The key auxiliary recursion is right-cons expansion: for every scalar coefficient a and finite spines x, q,

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(q, \mathsf{cons}(a, x)), \mathsf{radd}_R(\mathsf{rscale}_R(a, q), \mathsf{shift}_R(\mathsf{rmul}_R(q, x)))).$$

Induct on q. If $q = \mathsf{nil}$, the left side is nil and the right side is a raw sum of zero-remainder spines, so the zero-remainder comparison above applies. For the cons step write $q = \mathsf{cons}(b, y)$. Unfolding Definition 50.139 and the cons-cons branch of Definition 50.30, the two heads are $b \cdot a + 0_R$ and $a \cdot b + 0_R$; multiplicative commutativity and addition congruence classify them. The two tails are

$$\mathsf{radd}_R(\mathsf{rscale}_R(b, x), \mathsf{rmul}_R(y, \mathsf{cons}(a, x)))$$

and

$$\mathsf{radd}_R(\mathsf{rscale}_R(a, y), \mathsf{radd}_R(\mathsf{rscale}_R(b, x), \mathsf{shift}_R(\mathsf{rmul}_R(y, x)))).$$

The induction hypothesis and raw-addition compatibility compare the first tail with

$$\mathsf{radd}_R(\mathsf{rscale}_R(b, x), \mathsf{radd}_R(\mathsf{rscale}_R(a, y), \mathsf{shift}_R(\mathsf{rmul}_R(y, x)))).$$

Raw-addition associativity from Definition 50.153 and raw-addition commutativity from Definition 50.151, transported through raw-addition compatibility, move the first two summands past each other and give the second tail. The cons preservation fact then proves the cons step.

Now induct on p. If $p = \mathsf{nil}$, then $\mathsf{rmul}_R(\mathsf{nil}, q) = \mathsf{nil}$ by Definition 50.139, while $\mathsf{rmul}_R(q, \mathsf{nil})$ is a zero remainder by the preceding paragraph; hence the displayed $\mathsf{PolySame}_R$ holds.

For the cons step write $p = \mathsf{cons}(a, x)$ and assume

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(x, q), \mathsf{rmul}_R(q, x)).$$

Unfolding the left raw product gives

$$\mathsf{rmul}_R(\mathsf{cons}(a, x), q) = \mathsf{radd}_R(\mathsf{rscale}_R(a, q), \mathsf{shift}_R(\mathsf{rmul}_R(x, q))).$$

Shift preservation and raw-addition compatibility transport the induction hypothesis to

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(\mathsf{cons}(a,x),q),\mathsf{radd}_R(\mathsf{rscale}_R(a,q),\mathsf{shift}_R(\mathsf{rmul}_R(q,x)))).$$

Right-cons expansion applied to q, a, x gives the same middle endpoint classified with $\mathsf{rmul}_R(q,\mathsf{cons}(a,x))$. Symmetry and transitivity of $\mathsf{PolySame}_R$ compose the two comparisons, completing the induction. □

Theorem 50.95 (Polynomial multiplication has left zero absorption)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$ and zero endpoint 0_R. Let trim_R be the canonical polynomial trim from Definition 50.20 and Definition 50.22, and let $\mathsf{PolySame}_R$, rmul_R, and $\mathsf{PolyMul}_R$ be as in Definition 50.30 and Definition 50.139. For every finite coefficient spine $q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(\mathsf{nil},q),\mathsf{nil}).$$

Consequently the same conclusion holds for every normalized polynomial representative q from Definition 50.3.

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul left zero classified`

Proof. Set $q_0 = \mathsf{trim}_R(q)$. The empty zero-polynomial clause in Definition 50.22 gives $\mathsf{trim}_R(\mathsf{nil}) = \mathsf{nil}$. Hence Definition 50.139 gives

$$\begin{aligned}\mathsf{PolyMul}_R(\mathsf{nil},q) &= \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{trim}_R(\mathsf{nil}),q_0))\\ &= \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{nil},q_0))\\ &= \mathsf{trim}_R(\mathsf{nil})\\ &= \mathsf{nil}.\end{aligned}$$

The third equality is the nil clause for rmul_R in Definition 50.139.

Unfolding $\mathsf{PolySame}_R$ by Definition 50.30, the classifier goal is

$$\mathsf{ListClassifierSpec}(\sim_R,\mathsf{trim}_R(\mathsf{PolyMul}_R(\mathsf{nil},q)),\mathsf{trim}_R(\mathsf{nil})).$$

The displayed computation and the empty zero-polynomial clause reduce both displayed representatives to nil. The nil-nil clause of Definition 36.12 supplies the structural classifier witness. □

Definition 50.96 (Padded polynomial coefficients and finite Cauchy folds)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and finite coefficient spines from Definition 36.1. For a finite coefficient spine $x : \mathsf{ListCarrier}(R)$ and $n : \mathsf{Nat}^{\uparrow}$, write $x[n]$ for the padded coefficient defined by*

$$\mathsf{nil}[n] := 0_R, \qquad \mathsf{cons}(a,t)[0] := a, \qquad \mathsf{cons}(a,t)[n+1] := t[n].$$

For finite coefficient spines x, y, z define the finite Cauchy coefficient fold and the finite triple coefficient fold by

$$\mathsf{Cauchy}_R(x,y;n) := \Sigma_{i+j=n} x[i]\cdot y[j], \qquad \mathsf{Triple}_R(x,y,z;n) := \Sigma_{i+j+k=n}(x[i]\cdot y[j])\cdot z[k].$$

The displayed sums use the finite additive fold of Definition 50.26 over the lexicographic finite spines of the displayed natural-number tuples.

Theorem 50.97 (Polynomial multiplication has right zero absorption)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, and canonical trim trim_R. Let $\mathsf{PolySame}_R$, rmul_R, and $\mathsf{PolyMul}_R$ be as in Definition 50.30 and Definition 50.139. For every finite coefficient spine $p : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(p, \mathsf{nil}), \mathsf{nil}).$$

Consequently the same conclusion holds for every normalized polynomial representative p from Definition 50.3.

Proof. Set

$$p_0 := \mathsf{trim}_R(p), \qquad n_0 := \mathsf{trim}_R(\mathsf{nil}).$$

The empty zero-polynomial clause in Definition 50.22 gives $n_0 = \mathsf{nil}$. Unfolding the normalized product in Definition 50.139 gives

$$\begin{aligned}\mathsf{PolyMul}_R(p, \mathsf{nil}) &= \mathsf{trim}_R(\mathsf{rmul}_R(p_0, n_0)) \\ &= \mathsf{trim}_R(\mathsf{rmul}_R(p_0, \mathsf{nil}))\end{aligned}$$

and

$$\begin{aligned}\mathsf{PolyMul}_R(\mathsf{nil}, p) &= \mathsf{trim}_R(\mathsf{rmul}_R(n_0, p_0)) \\ &= \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{nil}, p_0)).\end{aligned}$$

Apply Definition 50.154 to the finite coefficient spines p_0 and nil. It gives

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(p_0, \mathsf{nil}), \mathsf{rmul}_R(\mathsf{nil}, p_0)).$$

After unfolding $\mathsf{PolySame}_R$ by Definition 50.30, this is the structural classifier comparison

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(\mathsf{rmul}_R(p_0, \mathsf{nil})), \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{nil}, p_0))).$$

Using the two displayed product computations and trim idempotence from Definition 50.22, this is exactly

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(p, \mathsf{nil}), \mathsf{PolyMul}_R(\mathsf{nil}, p)).$$

On the other hand, Definition 50.155 applied to p gives

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(\mathsf{nil}, p), \mathsf{nil}).$$

Unfold the two $\mathsf{PolySame}_R$ witnesses and compose their structural list-classifier witnesses by Definition 36.15, using the transitivity field of cert_R on scalar heads. Folding back Definition 50.30 yields

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(p, \mathsf{nil}), \mathsf{nil}).$$

Every normalized polynomial representative from Definition 50.3 is, in particular, a finite coefficient spine, so the same argument applies to that carrier representative. □

Lemma 50.98 (Polynomial raw addition structural swap)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, and addition $+$. Assume scalar additive commutativity:*

$$a + b \sim_R b + a$$

for all scalar coefficients a, b. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(p, q), \mathsf{radd}_R(q, p)).$$

Proof. Induct simultaneously on the two finite coefficient spines, following the four recursion clauses of radd_R in Definition 50.30. The target classifier is the finite-spine structural classifier of Definition 36.12, with matching constructors isolated by Definition 36.13.

In the nil-nil case, both raw additions are nil, so the nil clause of $\mathsf{ListClassifierSpec}$ gives the claim.

In the cons-nil case, write $p = \mathsf{cons}(a, p')$ and $q = \mathsf{nil}$. The recursion gives

$$\mathsf{radd}_R(p, q) = \mathsf{cons}(a + 0_R, \mathsf{radd}_R(p', \mathsf{nil}))$$

and

$$\mathsf{radd}_R(q, p) = \mathsf{cons}(0_R + a, \mathsf{radd}_R(\mathsf{nil}, p')).$$

Scalar additive commutativity gives $a + 0_R \sim_R 0_R + a$. The induction hypothesis applied to p' and nil gives the tail classifier

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(p', \mathsf{nil}), \mathsf{radd}_R(\mathsf{nil}, p')).$$

The cons clause of $\mathsf{ListClassifierSpec}$ combines the head comparison and this tail comparison.

In the nil-cons case, write $p = \mathsf{nil}$ and $q = \mathsf{cons}(b, q')$. The recursion gives heads $0_R + b$ and $b + 0_R$. Scalar additive commutativity gives $0_R + b \sim_R b + 0_R$, and the induction hypothesis at nil and q' supplies the tail classifier. The cons clause rebuilds the displayed list-classifier witness.

In the cons-cons case, write $p = \mathsf{cons}(a, p')$ and $q = \mathsf{cons}(b, q')$. The recursion exposes heads $a + b$ and $b + a$, related by scalar additive commutativity. The induction hypothesis supplies

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(p', q'), \mathsf{radd}_R(q', p')).$$

The cons clause combines the head and tail witnesses, giving the structural classifier for the two raw sums. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd structural swap`
Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd commutative classified`

Theorem 50.99 (Polynomial raw addition commutativity from scalar additive commutativity)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, and scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$. Use the additive abelian-group and classifier fields retained in Definition 43.26: zero self-classification, classifier transitivity, additive congruence, additive zero laws, and scalar additive commutativity. For a commutative-ring scalar source, Definition 44.8 keeps these data unchanged. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{radd}_R(p, q), \mathsf{radd}_R(q, p)).$$

Proof. Apply Definition 50.150 to p and q using the scalar additive commutativity row from Definition 43.26. This gives

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(p, q), \mathsf{radd}_R(q, p)).$$

The nil finite spine is a zero remainder by the nil clause of Definition 50.28. Apply Definition 50.29 with common classified spines $\mathsf{radd}_R(p, q)$ and $\mathsf{radd}_R(q, p)$, and with both zero remainders equal to nil. Finite-spine append by nil leaves each spine unchanged, so the lemma yields

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(\mathsf{radd}_R(p, q)), \mathsf{trim}_R(\mathsf{radd}_R(q, p))).$$

Unfolding $\mathsf{PolySame}_R$ from Definition 50.30, this is exactly the displayed polynomial raw classifier comparison. □

Lemma 50.100 (Raw polynomial addition is structurally associative)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, and scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$. Assume the additive fields retained in Definition 43.26: additive associativity, additive zero laws, classifier symmetry, classifier transitivity, and addition congruence. For finite coefficient spines $p, q, r : \mathsf{ListCarrier}(R)$,*

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(\mathsf{radd}_R(p, q), r), \mathsf{radd}_R(p, \mathsf{radd}_R(q, r))).$$

Proof. Induct on the finite triple spine (p, q, r), using the maximum of the three finite lengths as the decreasing measure. The nil-nil-nil case unfolds both raw additions by Definition 50.30 to nil, and the nil clause of Definition 36.12 gives the classifier witness.

In every remaining constructor case, at least one of the three spines is a cons spine. Unfold the corresponding clauses of radd_R from Definition 50.30. Both associated raw sums expose a cons head, and their tails are exactly the two associated raw sums for the tail triple, with nil used as the tail of any absent spine. The induction hypothesis supplies the recursive tail classifier.

It remains to classify the exposed scalar heads. If all three heads are present, say a, b, c, the comparison is

$$(a + b) + c \sim_R a + (b + c),$$

which is scalar additive associativity. If exactly two heads are present, the missing head is the padding coefficient 0_R, so the three possible comparisons

$$(a + b) + 0_R \sim_R a + (b + 0_R),$$

$$(a + 0_R) + c \sim_R a + (0_R + c),$$

$$(0_R + b) + c \sim_R 0_R + (b + c)$$

are the same associativity law with one displayed argument equal to 0_R. If only the left input has a head a, the comparison is

$$(a + 0_R) + 0_R \sim_R a + 0_R,$$

which is the additive right-zero law applied to $a + 0_R$. If only the middle input has a head b, the comparison is

$$(0_R + b) + 0_R \sim_R 0_R + (b + 0_R),$$

again additive associativity. If only the right input has a head c, the comparison is

$$0_R + c \sim_R 0_R + (0_R + c),$$

obtained by reversing the additive left-zero law at the endpoint $0_R + c$ using classifier symmetry from cert_R.

In each constructor case, the scalar head comparison and the tail classifier rebuild the cons clause of $\mathsf{ListClassifierSpec}$. These cases exhaust the finite-spine constructors by Definition 36.13. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd associative classified`

Theorem 50.101 (Polynomial raw addition associativity)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, canonical trim trim_R, and scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$. Assume the additive fields retained in Definition 43.26: additive abelian-group laws and addition congruence. For finite coefficient spines $p, q, r : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{radd}_R(\mathsf{radd}_R(p, q), r), \mathsf{radd}_R(p, \mathsf{radd}_R(q, r))).$$

Proof. Set

$$u := \mathsf{radd}_R(\mathsf{radd}_R(p,q),r), \qquad \omega := \mathsf{radd}_R(p,\mathsf{radd}_R(q,r)).$$

By Definition 50.152,

$$\mathsf{ListClassifierSpec}(\sim_R,\nu,\omega)$$

holds. The nil spine is a classified zero remainder by the nil clause of Definition 50.28. Apply Definition 50.29 to the common classified spines ν and ω, with nil zero remainders on both sides. The append-nil identities for finite spines give

$$\mathsf{ListClassifierSpec}(\sim_R,\mathsf{trim}_R(\nu),\mathsf{trim}_R(\omega)).$$

Unfolding $\mathsf{PolySame}_R$ from Definition 50.30 turns this normalized structural classifier into the displayed polynomial classifier comparison. □

Theorem 50.102 (Polynomial raw multiplication commutativity from scalar commutativity)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R,\sim_R)$, canonical trim trim_R, and the raw operations radd_R, rscale_R, shift_R, and rmul_R from Definition 50.30 and Definition 50.139. For finite coefficient spines $p,q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(p,q),\mathsf{rmul}_R(q,p)).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul commutative classified`

Proof. Read the scalar source as a $\mathsf{Ring}^{\uparrow}(R)$ source by Definition 44.8. The retained rows used below are the $\mathsf{NameCert}$ reflexivity, symmetry, and transitivity fields, the additive abelian-group laws and addition congruence from Definition 43.26, multiplication congruence, and the multiplicative commutativity row from Definition 44.33.

First record the finite-spine consequences of the existing raw-addition package. The relation $\mathsf{PolySame}_R$ is reflexive, symmetric, and transitive after unfolding Definition 50.30; this is exactly structural list-classifier reflexivity, Definition 36.47, and Definition 36.15 applied to the two trimmed representatives.

Raw addition is compatible with $\mathsf{PolySame}_R$ in both inputs. Indeed, Definition 50.32 reduces both raw sums to sums of their trimmed inputs. The two displayed trimmed-input classifiers give a structural classifier between the two trimmed raw sums by induction on the two list-classifier witnesses in Definition 36.12; the exposed heads are handled by addition congruence, with $0_R \sim_R 0_R$ in the padding branches. Transitivity and symmetry of $\mathsf{PolySame}_R$ compose these three comparisons.

The shift operation preserves $\mathsf{PolySame}_R$. If $\mathsf{PolySame}_R(x,y)$ holds, write the trim decompositions supplied by Definition 50.22 as $x = x_0{+}{+}z$ and $y = y_0{+}{+}w$, with $\mathsf{ListClassifierSpec}(\sim_R,x_0,y_0)$ and zero remainders z,w. Then

$$\mathsf{shift}_R(x) = (\mathsf{cons}(0_R,x_0)){+}{+}z, \qquad \mathsf{shift}_R(y) = (\mathsf{cons}(0_R,y_0)){+}{+}w.$$

The cons classifier built from $0_R \sim_R 0_R$ and the classifier on x_0,y_0, followed by Definition 50.29, gives $\mathsf{PolySame}_R(\mathsf{shift}_R(x),\mathsf{shift}_R(y))$. The same argument, with 0_R replaced by classified heads $h \sim_R h'$, shows that $h \sim_R h'$ and $\mathsf{PolySame}_R(t,t')$ imply

$$\mathsf{PolySame}_R(\mathsf{cons}(h,t),\mathsf{cons}(h',t')).$$

Zero remainders are closed under raw addition: induct on the two zero-remainder witnesses from Definition 50.28. In the cons-cons branch, addition congruence sends $a+b$ to 0_R+0_R, and

the additive left-zero law reduces that endpoint to 0_R; the cons-nil and nil-cons branches use the additive right-zero and left-zero laws. Hence $\mathsf{rmul}_R(s, \mathsf{nil})$ is a zero remainder for every finite spine s, by induction on s using Definition 50.139: the cons step combines $\mathsf{rscale}_R(a, \mathsf{nil}) = \mathsf{nil}$, the zero-remainder closure of shift_R, and raw-addition closure. Applying Definition 50.29 with common spine nil gives

$$\mathsf{PolySame}_R(\mathsf{nil}, \mathsf{rmul}_R(s, \mathsf{nil})).$$

The key auxiliary recursion is right-cons expansion: for every scalar coefficient a and finite spines x, q,

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(q, \mathsf{cons}(a, x)), \mathsf{radd}_R(\mathsf{rscale}_R(a, q), \mathsf{shift}_R(\mathsf{rmul}_R(q, x)))).$$

Induct on q. If $q = \mathsf{nil}$, the left side is nil and the right side is a raw sum of zero-remainder spines, so the zero-remainder comparison above applies. For the cons step write $q = \mathsf{cons}(b, y)$. Unfolding Definition 50.139 and the cons-cons branch of Definition 50.30, the two heads are $b \cdot a + 0_R$ and $a \cdot b + 0_R$; multiplicative commutativity and addition congruence classify them. The two tails are

$$\mathsf{radd}_R(\mathsf{rscale}_R(b, x), \mathsf{rmul}_R(y, \mathsf{cons}(a, x)))$$

and

$$\mathsf{radd}_R(\mathsf{rscale}_R(a, y), \mathsf{radd}_R(\mathsf{rscale}_R(b, x), \mathsf{shift}_R(\mathsf{rmul}_R(y, x)))).$$

The induction hypothesis and raw-addition compatibility compare the first tail with

$$\mathsf{radd}_R(\mathsf{rscale}_R(b, x), \mathsf{radd}_R(\mathsf{rscale}_R(a, y), \mathsf{shift}_R(\mathsf{rmul}_R(y, x)))).$$

Raw-addition associativity from Definition 50.153 and raw-addition commutativity from Definition 50.151, transported through raw-addition compatibility, move the first two summands past each other and give the second tail. The cons preservation fact then proves the cons step.

Now induct on p. If $p = \mathsf{nil}$, then $\mathsf{rmul}_R(\mathsf{nil}, q) = \mathsf{nil}$ by Definition 50.139, while $\mathsf{rmul}_R(q, \mathsf{nil})$ is a zero remainder by the preceding paragraph; hence the displayed $\mathsf{PolySame}_R$ holds.

For the cons step write $p = \mathsf{cons}(a, x)$ and assume

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(x, q), \mathsf{rmul}_R(q, x)).$$

Unfolding the left raw product gives

$$\mathsf{rmul}_R(\mathsf{cons}(a, x), q) = \mathsf{radd}_R(\mathsf{rscale}_R(a, q), \mathsf{shift}_R(\mathsf{rmul}_R(x, q))).$$

Shift preservation and raw-addition compatibility transport the induction hypothesis to

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(\mathsf{cons}(a, x), q), \mathsf{radd}_R(\mathsf{rscale}_R(a, q), \mathsf{shift}_R(\mathsf{rmul}_R(q, x)))).$$

Right-cons expansion applied to q, a, x gives the same middle endpoint classified with $\mathsf{rmul}_R(q, \mathsf{cons}(a, x))$. Symmetry and transitivity of $\mathsf{PolySame}_R$ compose the two comparisons, completing the induction. □

Theorem 50.103 (Polynomial multiplication has left zero absorption)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$ and zero endpoint 0_R. Let trim_R be the canonical polynomial trim from Definition 50.20 and Definition 50.22, and let $\mathsf{PolySame}_R$, rmul_R, and $\mathsf{PolyMul}_R$ be as in Definition 50.30 and Definition 50.139. For every finite coefficient spine $q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(\mathsf{nil}, q), \mathsf{nil}).$$

Consequently the same conclusion holds for every normalized polynomial representative q from Definition 50.3.

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul left zero classified`

Proof. Set $q_0 = \mathsf{trim}_R(q)$. The empty zero-polynomial clause in Definition 50.22 gives $\mathsf{trim}_R(\mathsf{nil}) = \mathsf{nil}$. Hence Definition 50.139 gives

$$\begin{aligned}\mathsf{PolyMul}_R(\mathsf{nil}, q) &= \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{trim}_R(\mathsf{nil}), q_0)) \\ &= \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{nil}, q_0)) \\ &= \mathsf{trim}_R(\mathsf{nil}) \\ &= \mathsf{nil}.\end{aligned}$$

The third equality is the nil clause for rmul_R in Definition 50.139.

Unfolding $\mathsf{PolySame}_R$ by Definition 50.30, the classifier goal is

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(\mathsf{PolyMul}_R(\mathsf{nil}, q)), \mathsf{trim}_R(\mathsf{nil})).$$

The displayed computation and the empty zero-polynomial clause reduce both displayed representatives to nil. The nil-nil clause of Definition 36.12 supplies the structural classifier witness. □

Definition 50.104 (Padded polynomial coefficients and finite Cauchy folds)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and finite coefficient spines from Definition 36.1. For a finite coefficient spine $x : \mathsf{ListCarrier}(R)$ and $n : \mathsf{Nat}^{\uparrow}$, write $x[n]$ for the padded coefficient defined by*

$$\mathsf{nil}[n] := 0_R, \qquad \mathsf{cons}(a, t)[0] := a, \qquad \mathsf{cons}(a, t)[n + 1] := t[n].$$

For finite coefficient spines x, y, z define the finite Cauchy coefficient fold and the finite triple coefficient fold by

$$\mathsf{Cauchy}_R(x, y; n) := \Sigma_{i+j=n} x[i] \cdot y[j], \qquad \mathsf{Triple}_R(x, y, z; n) := \Sigma_{i+j+k=n}(x[i] \cdot y[j]) \cdot z[k].$$

The displayed sums use the finite additive fold of Definition 50.26 over the lexicographic finite spines of the displayed natural-number tuples.

Theorem 50.105 (Polynomial multiplication has right zero absorption)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, and canonical trim trim_R. Let $\mathsf{PolySame}_R$, rmul_R, and $\mathsf{PolyMul}_R$ be as in Definition 50.30 and Definition 50.139. For every finite coefficient spine $p : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(p, \mathsf{nil}), \mathsf{nil}).$$

Consequently the same conclusion holds for every normalized polynomial representative p from Definition 50.3.

Proof. Set

$$p_0 := \mathsf{trim}_R(p), \qquad n_0 := \mathsf{trim}_R(\mathsf{nil}).$$

The empty zero-polynomial clause in Definition 50.22 gives $n_0 = \mathsf{nil}$. Unfolding the normalized product in Definition 50.139 gives

$$\begin{aligned}\mathsf{PolyMul}_R(p, \mathsf{nil}) &= \mathsf{trim}_R(\mathsf{rmul}_R(p_0, n_0)) \\ &= \mathsf{trim}_R(\mathsf{rmul}_R(p_0, \mathsf{nil}))\end{aligned}$$

and

$$\begin{aligned}\mathsf{PolyMul}_R(\mathsf{nil}, p) &= \mathsf{trim}_R(\mathsf{rmul}_R(n_0, p_0)) \\ &= \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{nil}, p_0)).\end{aligned}$$

Apply Definition 50.154 to the finite coefficient spines p_0 and nil. It gives

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(p_0, \mathsf{nil}), \mathsf{rmul}_R(\mathsf{nil}, p_0)).$$

After unfolding $\mathsf{PolySame}_R$ by Definition 50.30, this is the structural classifier comparison

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(\mathsf{rmul}_R(p_0, \mathsf{nil})), \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{nil}, p_0))).$$

Using the two displayed product computations and trim idempotence from Definition 50.22, this is exactly

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(p, \mathsf{nil}), \mathsf{PolyMul}_R(\mathsf{nil}, p)).$$

On the other hand, Definition 50.155 applied to p gives

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(\mathsf{nil}, p), \mathsf{nil}).$$

Unfold the two $\mathsf{PolySame}_R$ witnesses and compose their structural list-classifier witnesses by Definition 36.15, using the transitivity field of cert_R on scalar heads. Folding back Definition 50.30 yields

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(p, \mathsf{nil}), \mathsf{nil}).$$

Every normalized polynomial representative from Definition 50.3 is, in particular, a finite coefficient spine, so the same argument applies to that carrier representative. □

Proposition 50.106 (Literal polynomial add-trim equality fails at cancelling singletons)**.** *Let R be a scalar ring carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, and canonical trim trim_R as in Definition 50.20 and Definition 50.22. Let radd_R and $\mathsf{PolySame}_R$ be as in Definition 50.30. Suppose $\neg(a \sim_R 0_R)$, $\neg(b \sim_R 0_R)$, and $(a + b) \sim_R 0_R$. Write $[c] := \mathsf{cons}(c, \mathsf{nil})$, and set $p := [a]$ and $q := [b]$. Then literal finite-spine equality does not commute with raw addition and trimming:*

$$\begin{aligned}\mathsf{trim}_R(\mathsf{radd}_R(p, q)) &= \mathsf{nil}, \\ \mathsf{radd}_R(\mathsf{trim}_R(p), \mathsf{trim}_R(q)) &= [a + b], \\ \mathsf{trim}_R(\mathsf{radd}_R(p, q)) &\neq \mathsf{radd}_R(\mathsf{trim}_R(p), \mathsf{trim}_R(q)).\end{aligned}$$

Nevertheless the two displayed outputs are polynomial-classified the same:

$$\mathsf{PolySame}_R(\mathsf{trim}_R(\mathsf{radd}_R(p, q)), \mathsf{radd}_R(\mathsf{trim}_R(p), \mathsf{trim}_R(q))).$$

For the canonical integer coefficient ring from chapter 31 and chapter 44, taking $a = 1$ and $b = -1$ gives $p = [1]$, $q = [-1]$, $\mathsf{trim}_{\mathbb{Z}}(\mathsf{radd}_{\mathbb{Z}}(p, q)) = \mathsf{nil}$, and $\mathsf{radd}_{\mathbb{Z}}(\mathsf{trim}_{\mathbb{Z}}(p), \mathsf{trim}_{\mathbb{Z}}(q)) = [0]$.

Proof. The nonzero hypotheses make p and q normalized singleton representatives by Definition 50.166; the canonical trim fixes normalized representatives, so $\mathsf{trim}_R(p) = p$ and $\mathsf{trim}_R(q) = q$. By the cons-cons and nil-nil clauses of radd_R in Definition 50.30, $\mathsf{radd}_R(\mathsf{trim}_R(p), \mathsf{trim}_R(q)) = \mathsf{radd}_R([a], [b]) = [a + b]$. The equality $\mathsf{trim}_R(\mathsf{radd}_R(p, q)) = \mathsf{nil}$ is the singleton cancellation conclusion of Definition 50.167. The displayed inequality follows because the left side is nil while the right side is a cons spine. Constructor no-confusion for the finite-spine carrier of Definition 36.1 is the mixed nil/cons separation isolated in Definition 36.13 and Definition 36.14. For classifier

comparison, unfold $\mathsf{PolySame}_R$. The first argument trims again to nil. The second argument is $[a+b]$, and the hypothesis $(a+b) \sim_R 0_R$ sends its singleton coefficient to the trailing-zero branch, so its trim is also nil. The nil-nil clause of $\mathsf{ListClassifierSpec}$ gives the displayed $\mathsf{PolySame}_R$ witness. The integer specialization uses the standard integer facts $1 \neq 0$, $-1 \neq 0$, and $1 + (-1) = 0$; Definition 44.8 keeps the ring operations and classifier when the commutative-ring source is read through $\mathsf{Ring}^{\uparrow}$. □

Definition 50.107 (Polynomial Horner evaluation)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and raw addition radd_R from Definition 50.30. For a carried scalar point α, define the Horner evaluation on finite coefficient spines from Definition 36.1 by recursion*

$$\mathsf{eval}_{\alpha,R}(\mathsf{nil}) := 0_R.$$

$$\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a,x)) := a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x).$$

Define the normalized polynomial evaluation by

$$\mathsf{Eval}_{\alpha,R}(x) := \mathsf{eval}_{\alpha,R}(\mathsf{trim}_R(x)).$$

Define the normalized polynomial sum by

$$\mathsf{PolyAdd}_R(x,y) := \mathsf{trim}_R(\mathsf{radd}_R(\mathsf{trim}_R(x), \mathsf{trim}_R(y))).$$

On a normalized representative from Definition 50.3, $\mathsf{Eval}_{\alpha,R}$ is the Horner evaluation itself, by trim idempotence from Definition 50.22.

Lemma 50.108 (Horner evaluation ignores classified zero tails)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $x, t : \mathsf{ListCarrier}(R)$, if $\mathsf{ZeroRem}_R(t)$ holds in the sense of Definition 50.28, then*

$$\mathsf{eval}_{\alpha,R}(x{+}{+}t) \sim_R \mathsf{eval}_{\alpha,R}(x).$$

Consequently, for every finite coefficient spine x,

$$\mathsf{Eval}_{\alpha,R}(x) \sim_R \mathsf{eval}_{\alpha,R}(x).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialZeroRemainder addFold empty`

Proof. First prove the endpoint claim $\mathsf{eval}_{\alpha,R}(t) \sim_R 0_R$ for every classified zero tail t. Induct on the displayed $\mathsf{ZeroRem}_R(t)$ witness. The nil clause is the defining equation $\mathsf{eval}_{\alpha,R}(\mathsf{nil}) = 0_R$ together with zero self-classification from Definition 43.26. In the cons clause, write $t = \mathsf{cons}(a, t')$. The constructor gives $a \sim_R 0_R$ and the induction hypothesis gives $\mathsf{eval}_{\alpha,R}(t') \sim_R 0_R$. Multiplication congruence and the zero-multiplication row in Definition 43.26 classify $\alpha \cdot \mathsf{eval}_{\alpha,R}(t')$ with 0_R. Addition congruence then classifies $a + \alpha \cdot \mathsf{eval}_{\alpha,R}(t')$ with $0_R + 0_R$, and the additive left-zero law reduces the latter endpoint to 0_R.

For the displayed tail-invariance statement, induct on x. The nil case is the endpoint claim just proved. In the cons case, write $x = \mathsf{cons}(a, x')$. The induction hypothesis gives $\mathsf{eval}_{\alpha,R}(x'{+}{+}t) \sim_R \mathsf{eval}_{\alpha,R}(x')$. Multiplication congruence transports this comparison through left multiplication by α, and addition congruence with source reflexivity on a gives

$$a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x'{+}{+}t) \sim_R a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x').$$

The two Horner recursion equations identify these endpoints with $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'{+}{+}t))$ and $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'))$.

For the consequence, the trailing-zero removal clause in Definition 50.22 presents each raw spine x as $\mathsf{trim}_R(x){+}{+}t$ with $\mathsf{ZeroRem}_R(t)$. Applying the first part gives $\mathsf{eval}_{\alpha,R}(x) \sim_R \mathsf{Eval}_{\alpha,R}(x)$, and symmetry of the scalar classifier reverses the displayed comparison. □

Lemma 50.109 (Horner evaluation respects raw polynomial addition)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $x, y : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{\alpha,R}(\mathsf{radd}_R(x, y)) \sim_R \mathsf{eval}_{\alpha,R}(x) + \mathsf{eval}_{\alpha,R}(y).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonAddFold append hsame`

Proof. Perform induction on the two finite spines, following the four recursion clauses for radd_R in Definition 50.30.

The nil-nil case compares 0_R with $0_R + 0_R$, so it is exactly the additive left-zero law, read with symmetry when needed.

In the cons-nil case, write $x = \mathsf{cons}(a, x')$. The raw-addition recursion exposes the head $a + 0_R$ and the tail $\mathsf{radd}_R(x', \mathsf{nil})$. The induction hypothesis classifies the tail evaluation with $\mathsf{eval}_{\alpha,R}(x') + 0_R$, and Definition 43.31 reduces that endpoint to $\mathsf{eval}_{\alpha,R}(x')$. Multiplication congruence transports the tail comparison through left multiplication by α. Additive congruence and the additive right-zero law reduce the exposed head $a + 0_R$ to a, and the target endpoint $(\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'))) + 0_R$ to $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'))$.

The nil-cons case is symmetric. The raw head is $0_R + b$, which reduces to b by the additive left-zero law, and the outer target $0_R + \mathsf{eval}_{\alpha,R}(\mathsf{cons}(b, y'))$ reduces by the same law. The tail comparison is transported through multiplication by α exactly as in the cons-nil case.

In the cons-cons case, write $x = \mathsf{cons}(a, x')$ and $y = \mathsf{cons}(b, y')$. The induction hypothesis gives

$$\mathsf{eval}_{\alpha,R}(\mathsf{radd}_R(x', y')) \sim_R \mathsf{eval}_{\alpha,R}(x') + \mathsf{eval}_{\alpha,R}(y').$$

Multiplication congruence transports this through left multiplication by α, and left distributivity from Definition 43.26 classifies

$$\alpha \cdot (\mathsf{eval}_{\alpha,R}(x') + \mathsf{eval}_{\alpha,R}(y'))$$

with

$$\alpha \cdot \mathsf{eval}_{\alpha,R}(x') + \alpha \cdot \mathsf{eval}_{\alpha,R}(y').$$

Addition congruence therefore transports the Horner endpoint for $\mathsf{radd}_R(x, y)$ to

$$(a + b) + (\alpha \cdot \mathsf{eval}_{\alpha,R}(x') + \alpha \cdot \mathsf{eval}_{\alpha,R}(y')).$$

Apply Definition 42.13 to the additive abelian-group operation, with the four additive blocks a, b, $\alpha \cdot \mathsf{eval}_{\alpha,R}(x')$, and $\alpha \cdot \mathsf{eval}_{\alpha,R}(y')$. This classifies the last endpoint with

$$(a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x')) + (b + \alpha \cdot \mathsf{eval}_{\alpha,R}(y')),$$

which is exactly $\mathsf{eval}_{\alpha,R}(x) + \mathsf{eval}_{\alpha,R}(y)$ by the Horner recursion. □

Theorem 50.110 (Polynomial evaluation is additive)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{Eval}_{\alpha,R}(\mathsf{PolyAdd}_R(p,q)) \sim_R \mathsf{Eval}_{\alpha,R}(p) + \mathsf{Eval}_{\alpha,R}(q).$$

If p and q are normalized representatives in the polynomial carrier, the same assertion is the carrier formula

$$\mathsf{eval}_{\alpha,R}(\mathsf{PolyAdd}_R(p,q)) \sim_R \mathsf{eval}_{\alpha,R}(p) + \mathsf{eval}_{\alpha,R}(q).$$

Proof. Put $p_0 = \mathsf{trim}_R(p)$ and $q_0 = \mathsf{trim}_R(q)$. By Definition 50.133,

$$\mathsf{PolyAdd}_R(p,q) = \mathsf{trim}_R(\mathsf{radd}_R(p_0,q_0)).$$

Trim idempotence from Definition 50.22 identifies $\mathsf{Eval}_{\alpha,R}(\mathsf{PolyAdd}_R(p,q))$ with $\mathsf{Eval}_{\alpha,R}(\mathsf{radd}_R(p_0,q_0))$. Applying Definition 50.134 gives

$$\mathsf{Eval}_{\alpha,R}(\mathsf{radd}_R(p_0,q_0)) \sim_R \mathsf{eval}_{\alpha,R}(\mathsf{radd}_R(p_0,q_0)).$$

By Definition 50.135,

$$\mathsf{eval}_{\alpha,R}(\mathsf{radd}_R(p_0,q_0)) \sim_R \mathsf{eval}_{\alpha,R}(p_0) + \mathsf{eval}_{\alpha,R}(q_0).$$

The right endpoint is $\mathsf{Eval}_{\alpha,R}(p) + \mathsf{Eval}_{\alpha,R}(q)$ by the definition of p_0, q_0, and normalized evaluation. Classifier transitivity composes the displayed comparisons.

If p and q are already normalized polynomial-carrier representatives, trim idempotence gives $p_0 = p$ and $q_0 = q$, and $\mathsf{Eval}_{\alpha,R}$ on each displayed representative is the unnormalized Horner evaluation. Substituting these equalities gives the carrier formula. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval rawAdd classified`

Lemma 50.111 (Horner evaluation respects structural classifier)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $x, y : \mathsf{ListCarrier}(R)$, if*

$$\mathsf{ListClassifierSpec}(\sim_R, x, y)$$

holds, then

$$\mathsf{eval}_{\alpha,R}(x) \sim_R \mathsf{eval}_{\alpha,R}(y).$$

Proof. Induct on the displayed structural classifier witness from Definition 36.12. By Definition 36.13, the only constructor cases are nil-nil and cons-cons; mixed nil-cons shapes have no classifier witness.

In the nil-nil case, the two Horner equations in Definition 50.133 identify both endpoints with 0_R. The zero self-classification field retained in Definition 43.26 gives $0_R \sim_R 0_R$.

In the cons-cons case, write $x = \mathsf{cons}(a, x')$ and $y = \mathsf{cons}(b, y')$. The classifier constructor supplies $a \sim_R b$ and a tail witness $\mathsf{ListClassifierSpec}(\sim_R, x', y')$. The induction hypothesis gives

$$\mathsf{eval}_{\alpha,R}(x') \sim_R \mathsf{eval}_{\alpha,R}(y').$$

The carried point α is self-classified by the scalar certificate. Multiplication congruence from Definition 43.26 transports the tail comparison through left multiplication by α, giving

$$\alpha \cdot \mathsf{eval}_{\alpha,R}(x') \sim_R \alpha \cdot \mathsf{eval}_{\alpha,R}(y').$$

Addition congruence combines this comparison with the head comparison $a \sim_R b$:

$$a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x') \sim_R b + \alpha \cdot \mathsf{eval}_{\alpha,R}(y').$$

The cons recursion equation in Definition 50.133 identifies these two endpoints with $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'))$ and $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(b, y'))$, respectively. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval list classifier classified`

Theorem 50.112 (Polynomial evaluation respects the polynomial classifier)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(p, q) \Longrightarrow \mathsf{Eval}_{\alpha,R}(p) \sim_R \mathsf{Eval}_{\alpha,R}(q).$$

Proof. Unfold $\mathsf{PolySame}_R$ using Definition 50.30. A classifier witness for p and q is exactly

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(p), \mathsf{trim}_R(q)).$$

Apply Definition 50.137 to the two trimmed spines. This gives

$$\mathsf{eval}_{\alpha,R}(\mathsf{trim}_R(p)) \sim_R \mathsf{eval}_{\alpha,R}(\mathsf{trim}_R(q)).$$

The normalized evaluation definition in Definition 50.133 reads the left endpoint as $\mathsf{Eval}_{\alpha,R}(p)$ and the right endpoint as $\mathsf{Eval}_{\alpha,R}(q)$, giving the displayed implication. □

Definition 50.113 (Polynomial raw Cauchy product)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and raw addition radd_R from Definition 50.30. For a scalar coefficient a and a finite coefficient spine $y : \mathsf{ListCarrier}(R)$, define scalar multiplication of coefficient spines by*

$$\mathsf{rscale}_R(a, \mathsf{nil}) := \mathsf{nil}, \qquad \mathsf{rscale}_R(a, \mathsf{cons}(b, y)) := \mathsf{cons}(a \cdot b, \mathsf{rscale}_R(a, y)).$$

Define the one-place coefficient shift by

$$\mathsf{shift}_R(y) := \mathsf{cons}(0_R, y).$$

The raw polynomial product is the finite recursion

$$\mathsf{rmul}_R(\mathsf{nil}, y) := \mathsf{nil},$$

$$\mathsf{rmul}_R(\mathsf{cons}(a, x), y) := \mathsf{radd}_R(\mathsf{rscale}_R(a, y), \mathsf{shift}_R(\mathsf{rmul}_R(x, y))).$$

The normalized polynomial product is

$$\mathsf{PolyMul}_R(x, y) := \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{trim}_R(x), \mathsf{trim}_R(y))).$$

This is the Cauchy product in low-coefficient-first Horner form: the cons clause expresses $(a + Xx)y = ay + X(xy)$.

Lean4 (definition) `BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul`

Lemma 50.114 (Horner evaluation of scalar-multiplied coefficient spines)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For every carried scalar coefficient a and every finite coefficient spine $y : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{\alpha,R}(\mathsf{rscale}_R(a, y)) \sim_R a \cdot \mathsf{eval}_{\alpha,R}(y).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval rawScale classified`
Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval raw scale empty classified`

Proof. Induct on the finite spine y from Definition 36.1. In the nil case, both the scalar-multiple spine and its Horner value are 0_R. The target endpoint is $a \cdot 0_R$, and the zero-multiplication row in Definition 43.26, with symmetry of $\sim_R$, gives the displayed comparison.

In the cons case, write $y = \mathsf{cons}(b, y')$. The recursion in Definition 50.139 and the Horner recursion in Definition 50.133 identify the left endpoint with

$$a \cdot b + \alpha \cdot \mathsf{eval}_{\alpha,R}(\mathsf{rscale}_R(a, y')).$$

The induction hypothesis and multiplication congruence classify this endpoint with

$$a \cdot b + \alpha \cdot (a \cdot \mathsf{eval}_{\alpha,R}(y')).$$

Multiplicative associativity, multiplicative commutativity from Definition 44.33, and multiplication congruence classify

$$\alpha \cdot (a \cdot \mathsf{eval}_{\alpha,R}(y'))$$

with

$$a \cdot (\alpha \cdot \mathsf{eval}_{\alpha,R}(y')).$$

Addition congruence transports this comparison under the common summand $a \cdot b$. The left distributive row in Definition 43.26, used in the reverse direction, then identifies

$$a \cdot b + a \cdot (\alpha \cdot \mathsf{eval}_{\alpha,R}(y'))$$

with

$$a \cdot (b + \alpha \cdot \mathsf{eval}_{\alpha,R}(y')).$$

The final endpoint is $a \cdot \mathsf{eval}_{\alpha,R}(\mathsf{cons}(b, y'))$ by the Horner recursion, and transitivity composes the comparisons. □

Lemma 50.115 (Horner evaluation of coefficient shift)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For every finite coefficient spine $x : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{\alpha,R}(\mathsf{shift}_R(x)) \sim_R \alpha \cdot \mathsf{eval}_{\alpha,R}(x).$$

Proof. By Definition 50.139, $\mathsf{shift}_R(x) = \mathsf{cons}(0_R, x)$. The Horner recursion from Definition 50.133 makes its evaluation

$$0_R + \alpha \cdot \mathsf{eval}_{\alpha,R}(x).$$

The additive left-zero row in Definition 43.26 classifies this endpoint with $\alpha \cdot \mathsf{eval}_{\alpha,R}(x)$. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval coefficient shift`

Lemma 50.116 (Horner evaluation respects raw polynomial multiplication)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $x, y : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(x, y)) \sim_R \mathsf{eval}_{\alpha,R}(x) \cdot \mathsf{eval}_{\alpha,R}(y).$$

Proof. Induct on the first spine x. In the nil case, $\mathsf{rmul}_R(\mathsf{nil}, y) = \mathsf{nil}$, so the left endpoint evaluates to 0_R. The target endpoint is $0_R \cdot \mathsf{eval}_{\alpha,R}(y)$, and the zero-multiplication row in Definition 43.26, with symmetry, gives the comparison.

For the cons case, write $x = \mathsf{cons}(a, x')$, put $u = \mathsf{eval}_{\alpha,R}(x')$, and put $v = \mathsf{eval}_{\alpha,R}(y)$. The raw product recursion in Definition 50.139 and the raw additivity theorem Definition 50.135 give

$$\mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(\mathsf{cons}(a, x'), y)) \sim_R \mathsf{eval}_{\alpha,R}(\mathsf{rscale}_R(a, y)) + \mathsf{eval}_{\alpha,R}(\mathsf{shift}_R(\mathsf{rmul}_R(x', y))).$$

By Definition 50.140, the first summand is classified with $a \cdot v$. By Definition 50.141, the second summand is classified with

$$\alpha \cdot \mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(x', y)).$$

The induction hypothesis and multiplication congruence classify this with $\alpha \cdot (u \cdot v)$. Multiplicative associativity classifies $\alpha \cdot (u \cdot v)$ with $(\alpha \cdot u) \cdot v$. Addition congruence therefore gives

$$\mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(\mathsf{cons}(a, x'), y)) \sim_R a \cdot v + (\alpha \cdot u) \cdot v.$$

The right distributive row retained by Definition 44.8, equivalently derived from Definition 44.34, classifies

$$(a + \alpha \cdot u) \cdot v$$

with

$$a \cdot v + (\alpha \cdot u) \cdot v.$$

Using symmetry of this distributive comparison and the Horner recursion

$$\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x')) = a + \alpha \cdot u,$$

transitivity gives the required cons-case endpoint. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval rawMul classified`

Theorem 50.117 (Polynomial evaluation is multiplicative)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{Eval}_{\alpha,R}(\mathsf{PolyMul}_R(p, q)) \sim_R \mathsf{Eval}_{\alpha,R}(p) \cdot \mathsf{Eval}_{\alpha,R}(q).$$

If p and q are normalized representatives in the polynomial carrier, the same assertion is the carrier formula

$$\mathsf{eval}_{\alpha,R}(\mathsf{PolyMul}_R(p, q)) \sim_R \mathsf{eval}_{\alpha,R}(p) \cdot \mathsf{eval}_{\alpha,R}(q).$$

Proof. Put $p_0 = \mathsf{trim}_R(p)$ and $q_0 = \mathsf{trim}_R(q)$. By Definition 50.139,

$$\mathsf{PolyMul}_R(p, q) = \mathsf{trim}_R(\mathsf{rmul}_R(p_0, q_0)).$$

Trim idempotence from Definition 50.22 identifies the normalized evaluation of this endpoint with

$$\mathsf{Eval}_{\alpha,R}(\mathsf{rmul}_R(p_0, q_0)).$$

Applying Definition 50.134 gives

$$\mathsf{Eval}_{\alpha,R}(\mathsf{rmul}_R(p_0, q_0)) \sim_R \mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(p_0, q_0)).$$

By Definition 50.142,

$$\mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(p_0, q_0)) \sim_R \mathsf{eval}_{\alpha,R}(p_0) \cdot \mathsf{eval}_{\alpha,R}(q_0).$$

The right endpoint is $\mathsf{Eval}_{\alpha,R}(p) \cdot \mathsf{Eval}_{\alpha,R}(q)$ by the definition of p_0, q_0, and normalized evaluation in Definition 50.133. Classifier transitivity composes the displayed comparisons.

If p and q are already normalized polynomial-carrier representatives, trim idempotence gives $p_0 = p$ and $q_0 = q$. The product endpoint is normalized by its defining trim, so normalized evaluation on $\mathsf{PolyMul}_R(p, q)$ is the unnormalized Horner evaluation of that product. Substituting these equalities gives the carrier formula. □

Theorem 50.118 (Polynomial evaluation is a semiring morphism through classification)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $p, q, p', q' : \mathsf{ListCarrier}(R)$, if $\mathsf{PolySame}_R(p, p')$ and $\mathsf{PolySame}_R(q, q')$, then*

$$\mathsf{Eval}_{\alpha,R}(p) \sim_R \mathsf{Eval}_{\alpha,R}(p'),$$

$$\mathsf{Eval}_{\alpha,R}(\mathsf{PolyAdd}_R(p, q)) \sim_R \mathsf{Eval}_{\alpha,R}(p) + \mathsf{Eval}_{\alpha,R}(q),$$

and

$$\mathsf{Eval}_{\alpha,R}(\mathsf{PolyMul}_R(p, q)) \sim_R \mathsf{Eval}_{\alpha,R}(p) \cdot \mathsf{Eval}_{\alpha,R}(q).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval semiring morphism`

Proof. The first clause is exactly Definition 50.138 applied to the classifier witness between p and p'.

The second and third clauses are the normalized-operation laws from Definition 50.136 and Definition 50.143. They apply to the original representatives p and q, so the operation endpoints are already the canonical normalized polynomial operations.

When a later scalar comparison is written with p' or q' instead, apply Definition 50.138 to the appropriate classifier witness and compose by transitivity of $\sim_R$. Thus the descended endpoints may be substituted in the additive and multiplicative scalar comparisons without reassembling the three facts. □

Lemma 50.119 (Zero-point Horner cons evaluation)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and Horner evaluation as in Definition 50.133. For every carried scalar coefficient a and every finite coefficient spine $t : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{0_R,R}(\mathsf{cons}(a, t)) \sim_R a.$$

Proof. The cons recursion in Definition 50.133 identifies the left endpoint with

$$a + 0_R \cdot \mathsf{eval}_{0_R,R}(t).$$

The zero-absorption theorem Definition 43.60, applied to $\mathsf{eval}_{0_R,R}(t)$, gives

$$0_R \cdot \mathsf{eval}_{0_R,R}(t) \sim_R 0_R.$$

Classifier reflexivity supplies $a \sim_R a$, and addition congruence from Definition 43.26 gives

$$a + 0_R \cdot \mathsf{eval}_{0_R,R}(t) \sim_R a + 0_R.$$

The additive right-zero theorem Definition 43.31 gives $a+0_R \sim_R a$. Classifier transitivity composes the two comparisons. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval zero cons constant`

Lemma 50.120 (Zero-point Horner evaluation ignores classified zero tails)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and Horner evaluation as in Definition 50.133. For finite coefficient spines $x, t : \mathsf{ListCarrier}(R)$, if $\mathsf{ZeroRem}_R(t)$ holds in the sense of Definition 50.28, then*

$$\mathsf{eval}_{0_R,R}(x{+}{+}t) \sim_R \mathsf{eval}_{0_R,R}(x).$$

Proof. First record the endpoint claim that every classified zero remainder evaluates to zero at 0_R. If the zero remainder is nil, the nil recursion in Definition 50.133 identifies its evaluation with 0_R, and zero self-classification from Definition 43.26 gives the claim. If the zero remainder is $\mathsf{cons}(c, t')$, the cons clause of Definition 50.28 supplies $c \sim_R 0_R$. By Definition 50.145,

$$\mathsf{eval}_{0_R,R}(\mathsf{cons}(c, t')) \sim_R c,$$

and transitivity gives $\mathsf{eval}_{0_R,R}(\mathsf{cons}(c, t')) \sim_R 0_R$.

Now split on the first constructor of x. If $x = \mathsf{nil}$, then $x{+}{+}t = t$, so the endpoint claim gives the displayed comparison. If $x = \mathsf{cons}(a, x')$, then $x{+}{+}t = \mathsf{cons}(a, x'{+}{+}t)$. Applying Definition 50.145 twice gives

$$\mathsf{eval}_{0_R,R}(\mathsf{cons}(a, x'{+}{+}t)) \sim_R a$$

and

$$\mathsf{eval}_{0_R,R}(\mathsf{cons}(a, x')) \sim_R a.$$

Symmetry of the second comparison and transitivity give the required comparison for the cons case. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval zero point zero tail invariance`

Theorem 50.121 (Polynomial evaluation at zero returns the constant coefficient)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and Horner evaluation as in Definition 50.133. For every carried scalar coefficient a and every finite coefficient spine $t : \mathsf{ListCarrier}(R)$,*

$$\mathsf{Eval}_{0_R,R}(\mathsf{cons}(a, t)) \sim_R a.$$

Proof. Set $x = \mathsf{cons}(a, t)$. The trailing-zero removal clause in Definition 50.22 gives a finite zero remainder z such that

$$x = \mathsf{trim}_R(x){+}{+}z, \qquad \mathsf{ZeroRem}_R(z).$$

Applying Definition 50.146 to $\mathsf{trim}_R(x)$ and z yields

$$\mathsf{eval}_{0_R,R}(x) \sim_R \mathsf{eval}_{0_R,R}(\mathsf{trim}_R(x)).$$

By the normalized evaluation definition in Definition 50.133, the right endpoint is $\mathsf{Eval}_{0_R,R}(x)$. Symmetry gives

$$\mathsf{Eval}_{0_R,R}(x) \sim_R \mathsf{eval}_{0_R,R}(x).$$

The raw cons comparison Definition 50.145 gives

$$\mathsf{eval}_{0_R,R}(x) \sim_R a.$$

Classifier transitivity composes these two comparisons, and substituting $x = \mathsf{cons}(a, t)$ gives the displayed formula. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval zero constant term`

Lemma 50.122 (Unit-point Horner evaluation is coefficient fold)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, multiplicative unit endpoint 1_R, addition $+$, multiplication $\cdot$, and Horner evaluation as in Definition 50.133. Let $\mathsf{fold}_{+,R}$ be the finite recursive coefficient fold from Definition 50.26, satisfying*

$$\mathsf{fold}_{+,R}(\mathsf{nil}) = 0_R, \qquad \mathsf{fold}_{+,R}(\mathsf{cons}(a, x')) = a + \mathsf{fold}_{+,R}(x').$$

For every finite coefficient spine $x : \mathsf{ListCarrier}(R)$,

$$\mathsf{eval}_{1_R,R}(x) \sim_R \mathsf{fold}_{+,R}(x).$$

Proof. Induct on the finite spine x from Definition 36.1.

In the nil case, the nil Horner equation in Definition 50.133 and the nil fold equation identify both endpoints with 0_R. The zero self-classification row of Definition 43.26 gives the displayed comparison.

In the cons case, write $x = \mathsf{cons}(a, x')$. The induction hypothesis gives

$$\mathsf{eval}_{1_R,R}(x') \sim_R \mathsf{fold}_{+,R}(x').$$

The recursive Horner endpoint $\mathsf{eval}_{1_R,R}(x')$ is carried by induction on x' using the scalar zero, addition, and multiplication closure rows of the $\mathsf{Ring}^{\uparrow}$ certificate. Hence the multiplicative left-unit row retained in Definition 43.26 gives

$$1_R \cdot \mathsf{eval}_{1_R,R}(x') \sim_R \mathsf{eval}_{1_R,R}(x').$$

Classifier transitivity composes this unit comparison with the induction hypothesis, yielding

$$1_R \cdot \mathsf{eval}_{1_R,R}(x') \sim_R \mathsf{fold}_{+,R}(x').$$

Source reflexivity gives $a \sim_R a$. Applying additive congruence from Definition 43.26 gives

$$a + 1_R \cdot \mathsf{eval}_{1_R,R}(x') \sim_R a + \mathsf{fold}_{+,R}(x').$$

The cons Horner equation identifies the left endpoint with $\mathsf{eval}_{1_R,R}(\mathsf{cons}(a, x'))$, and the cons fold equation identifies the right endpoint with $\mathsf{fold}_{+,R}(\mathsf{cons}(a, x'))$. □

Theorem 50.123 (Polynomial evaluation at the multiplicative unit is coefficient fold)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, multiplicative unit endpoint 1_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and Horner evaluation as in Definition 50.133. Let $\mathsf{fold}_{+,R}$ be the finite recursive coefficient fold from Definition 50.26. For every finite coefficient spine $p : \mathsf{ListCarrier}(R)$,*

$$\mathsf{Eval}_{1_R,R}(p) \sim_R \mathsf{fold}_{+,R}(\mathsf{trim}_R(p)).$$

Proof. By the normalized evaluation definition in Definition 50.133,

$$\mathsf{Eval}_{1_R,R}(p) = \mathsf{eval}_{1_R,R}(\mathsf{trim}_R(p)).$$

Apply Definition 50.148 to the finite coefficient spine $\mathsf{trim}_R(p)$. This gives

$$\mathsf{eval}_{1_R,R}(\mathsf{trim}_R(p)) \sim_R \mathsf{fold}_{+,R}(\mathsf{trim}_R(p)).$$

Substituting the displayed definition of $\mathsf{Eval}_{1_R,R}(p)$ gives the claimed comparison. □

Lemma 50.124 (Padded coefficient extensionality for the polynomial classifier)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, and canonical trim trim_R from Definition 50.20 and Definition 50.22. If finite coefficient spines $x, y : \mathsf{ListCarrier}(R)$ satisfy $x[n] \sim_R y[n]$ for every $n : \mathsf{Nat}^{\uparrow}$, then*

$$\mathsf{PolySame}_R(x, y).$$

Proof. Put $x_0 := \mathsf{trim}_R(x)$ and $y_0 := \mathsf{trim}_R(y)$. The trailing-zero removal clause in Definition 50.22 gives decompositions $x = x_0{+}{+}t_x$ and $y = y_0{+}{+}t_y$, with $\mathsf{ZeroRem}_R(t_x)$ and $\mathsf{ZeroRem}_R(t_y)$ in the sense of Definition 50.28. Hence $x[n] \sim_R x_0[n]$ and $y[n] \sim_R y_0[n]$ for every n: inside the trimmed prefix the coefficient is unchanged, inside the removed tail the zero-remainder witness classifies the coefficient with 0_R, and after the whole spine both sides are the padding coefficient 0_R. Classifier symmetry and transitivity from cert_R give $x_0[n] \sim_R y_0[n]$ for every n.

The trimmed spines are normalized representatives. If one normalized representative had a last displayed coefficient beyond the length of the other, the padded coefficient comparison at that last index would classify that displayed coefficient with 0_R, contradicting the normalized no-trailing-zero condition in Definition 50.22. Thus x_0 and y_0 have the same finite length. Induction over this common length builds a structural classifier witness: at each head position the hypothesis $x_0[n] \sim_R y_0[n]$ supplies the scalar head comparison, and the induction hypothesis supplies the tail classifier. Therefore

$$\mathsf{ListClassifierSpec}(\sim_R, x_0, y_0).$$

Unfolding $\mathsf{PolySame}_R$ by Definition 50.30 gives the displayed polynomial classifier comparison. □

Lemma 50.125 (Raw Cauchy product coefficient formula)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and the raw operations radd_R, rscale_R, shift_R, and rmul_R from Definition 50.30 and Definition 50.139. For finite coefficient spines $x, y : \mathsf{ListCarrier}(R)$ and every $n : \mathsf{Nat}^{\uparrow}$,*

$$\mathsf{rmul}_R(x, y)[n] \sim_R \mathsf{Cauchy}_R(x, y; n).$$

Proof. Read the scalar source as a $\mathsf{Ring}^{\uparrow}(R)$ source by Definition 44.8. The recursion defining radd_R gives the padded coefficient formula $\mathsf{radd}_R(u, v)[n] \sim_R u[n] + v[n]$ by induction on the two finite spines. The definitions of rscale_R and shift_R give

$$\mathsf{rscale}_R(a, u)[n] \sim_R a \cdot u[n], \qquad \mathsf{shift}_R(u)[0] \sim_R 0_R, \qquad \mathsf{shift}_R(u)[n+1] \sim_R u[n].$$

These comparisons use only zero self-classification, additive congruence, and the additive zero laws from Definition 43.26.

Induct on the first spine x. If $x = \mathsf{nil}$, the raw product is nil by Definition 50.139. Every summand in $\mathsf{Cauchy}_R(\mathsf{nil}, y; n)$ has the form $0_R \cdot y[j]$ and is classified with 0_R by the zero-multiplication row in Definition 43.26. The zero-summand fold theorem Definition 50.27 classifies the Cauchy fold with 0_R, which is the padded coefficient of nil.

For the cons step, write $x = \mathsf{cons}(a, x')$. At coefficient 0, the raw product recursion gives the sum of $a \cdot y[0]$ and the zero head of the shifted recursive product; the additive right-zero law classifies this with $a \cdot y[0]$, which is $\mathsf{Cauchy}_R(\mathsf{cons}(a, x'), y; 0)$. At coefficient $n + 1$, the same recursion and the auxiliary coefficient formulas give

$$\mathsf{rmul}_R(\mathsf{cons}(a, x'), y)[n + 1] \sim_R a \cdot y[n + 1] + \mathsf{rmul}_R(x', y)[n].$$

The induction hypothesis and additive congruence replace the second summand by $\mathsf{Cauchy}_R(x', y; n)$. Splitting the finite index spine $i + j = n + 1$ into the head case $i = 0$ and the shifted cases $i = i' + 1$ identifies the resulting fold with $\mathsf{Cauchy}_R(\mathsf{cons}(a, x'), y; n + 1)$ by Definition 50.26. □

Lemma 50.126 (Raw Cauchy product coefficient associativity)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and the raw Cauchy product data of Definition 50.139. For finite coefficient spines $x, y, z : \mathsf{ListCarrier}(R)$ and every $n : \mathsf{Nat}^{\uparrow}$,*

$$\mathsf{rmul}_R(\mathsf{rmul}_R(x, y), z)[n] \sim_R \mathsf{rmul}_R(x, \mathsf{rmul}_R(y, z))[n].$$

Proof. Fix n. By Definition 50.159, the left coefficient is classified with $\mathsf{Cauchy}_R(\mathsf{rmul}_R(x, y), z; n)$. For each outer index $s+k = n$, apply Definition 50.159 to replace $\mathsf{rmul}_R(x, y)[s]$ by $\mathsf{Cauchy}_R(x, y; s)$. Multiplication congruence and Definition 50.26 lift these replacements through the outer finite fold. The right-multiplication half of Definition 49.95 then classifies $\mathsf{Cauchy}_R(x, y; s) \cdot z[k]$ with the inner fold over (i, j) satisfying $i+j = s$ of $(x[i] \cdot y[j]) \cdot z[k]$. The nested finite index spine $i+j = s$, $s+k = n$ is the same finite triple spine $i + j + k = n$ in lexicographic order after deleting the bookkeeping index s. The finite fold swap certificate of Definition 49.94, together with fold congruence, classifies the resulting nested fold with $\mathsf{Triple}_R(x, y, z; n)$. Thus the left raw product coefficient is classified with $\mathsf{Triple}_R(x, y, z; n)$.

The right coefficient is handled symmetrically. The coefficient formula first gives $\mathsf{Cauchy}_R(x, \mathsf{rmul}_R(y, z); n)$. Replacing each coefficient of $\mathsf{rmul}_R(y, z)$ by its Cauchy fold and applying the left-multiplication half of Definition 49.95 gives the finite fold over triples $i + j + k = n$ of $x[i] \cdot (y[j] \cdot z[k])$. Scalar multiplication associativity from Definition 43.26 classifies each displayed summand with $(x[i] \cdot y[j]) \cdot z[k]$. Fold congruence therefore classifies the right coefficient with the same $\mathsf{Triple}_R(x, y, z; n)$. Symmetry and transitivity of the scalar classifier compose the two comparisons. □

Theorem 50.127 (Polynomial multiplication associativity over commutative-ring scalars)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Let the classifier be $\sim_R$, the zero endpoint be 0_R, the scalar operations be $+$ and $\cdot$, the canonical trim be trim_R from Definition 50.22, and let rmul_R and $\mathsf{PolyMul}_R$ be the raw and normalized products of Definition 50.139. For finite coefficient spines $p, q, r : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(\mathsf{PolyMul}_R(p, q), r), \mathsf{PolyMul}_R(p, \mathsf{PolyMul}_R(q, r))).$$

Proof. Put $p_0 := \mathsf{trim}_R(p)$, $q_0 := \mathsf{trim}_R(q)$, and $r_0 := \mathsf{trim}_R(r)$. Set $A := \mathsf{PolyMul}_R(\mathsf{PolyMul}_R(p, q), r)$ and $B := \mathsf{PolyMul}_R(p, \mathsf{PolyMul}_R(q, r))$. By Definition 50.158, it is enough to prove $A[n] \sim_R B[n]$ for every $n : \mathsf{Nat}^{\uparrow}$.

Trim preserves padded coefficients by the trailing-zero decomposition in Definition 50.22: for every finite spine u and every n, $u[n] \sim_R \mathsf{trim}_R(u)[n]$. The coefficient formula Definition 50.159 is functorial in both inputs with respect to such pointwise padded-coefficient comparisons, since multiplication congruence compares each Cauchy summand and Definition 50.26 lifts the summand comparisons through the finite fold.

Unfolding Definition 50.139 and using trim idempotence from Definition 50.22, the left normalized product has the same padded coefficients as $\mathsf{rmul}_R(\mathsf{trim}_R(\mathsf{rmul}_R(p_0, q_0)), r_0)$. By trim preservation and the functoriality just recorded, its nth coefficient is classified with $\mathsf{rmul}_R(\mathsf{rmul}_R(p_0, q_0), r_0)[n]$. Similarly, the right normalized product has the same padded coefficients as $\mathsf{rmul}_R(p_0, \mathsf{trim}_R(\mathsf{rmul}_R(q_0, r_0)))$, and its nth coefficient is classified with $\mathsf{rmul}_R(p_0, \mathsf{rmul}_R(q_0, r_0))[n]$.

Applying Definition 50.160 to p_0, q_0, r_0 gives

$$\mathsf{rmul}_R(\mathsf{rmul}_R(p_0, q_0), r_0)[n] \sim_R \mathsf{rmul}_R(p_0, \mathsf{rmul}_R(q_0, r_0))[n].$$

Classifier symmetry and transitivity compose the two trim comparisons with this raw coefficient associativity comparison, yielding $A[n] \sim_R B[n]$ for the fixed n. Since n was arbitrary, Definition 50.158 gives $\mathsf{PolySame}_R(A, B)$, which is the displayed associativity statement. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul associative addFold classified`

Theorem 50.128 (Polynomial singleton evaluation)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and Horner evaluation as in Definition 50.133. For every carried scalar coefficient c and every carried scalar point α,*

$$\mathsf{Eval}_{\alpha,R}(\mathsf{cons}(c, \mathsf{nil})) \sim_R c.$$

Proof. Put $s = \mathsf{cons}(c, \mathsf{nil})$. First compute the unnormalized Horner value. The cons and nil recursion clauses in Definition 50.133 identify

$$\mathsf{eval}_{\alpha,R}(s) = c + \alpha \cdot 0_R.$$

The right zero-absorption half of Definition 43.60 gives

$$\alpha \cdot 0_R \sim_R 0_R.$$

Classifier reflexivity for c and addition congruence from Definition 43.26 give

$$c + \alpha \cdot 0_R \sim_R c + 0_R.$$

The additive right-zero theorem Definition 43.31 gives $c + 0_R \sim_R c$, and transitivity yields

$$\mathsf{eval}_{\alpha,R}(s) \sim_R c.$$

By Definition 50.133, $\mathsf{Eval}_{\alpha,R}(s) = \mathsf{eval}_{\alpha,R}(\mathsf{trim}_R(s))$. The one-coefficient trimming boundary in Definition 50.166, read with Definition 50.22, has exactly the empty zero branch and the retained singleton branch. In the empty zero branch, $c \sim_R 0_R$ and $\mathsf{trim}_R(s) = \mathsf{nil}$; the nil Horner equation gives $\mathsf{Eval}_{\alpha,R}(s) = 0_R$, and classifier symmetry gives $0_R \sim_R c$. In the retained singleton branch, $\mathsf{trim}_R(s) = s$, so the raw computation above is the required normalized comparison. These are the two canonical trim branches for a singleton coefficient spine. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval singleton`

Theorem 50.129 (Raw polynomial multiplication left-distributes over raw addition)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Let the classifier be $\sim_R$, the zero endpoint be 0_R, the scalar operations be $+$ and $\cdot$, the scalar certificate be $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, and let radd_R, rscale_R, shift_R, and rmul_R be the raw operations of Definition 50.30 and Definition 50.139. For finite coefficient spines $x, y, z : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(x, \mathsf{radd}_R(y, z)), \mathsf{radd}_R(\mathsf{rmul}_R(x, y), \mathsf{rmul}_R(x, z))).$$

Consequently the same classifier comparison holds when x, y, z are normalized polynomial representatives from Definition 50.3.

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul left distributes over raw add`

Proof. By Definition 50.158, it is enough to compare padded coefficients. First record the padded coefficient law for raw addition: for all finite coefficient spines u, v and every $m : \mathsf{Nat}^{\uparrow}$,

$$\mathsf{radd}_R(u, v)[m] \sim_R u[m] + v[m].$$

This is a direct induction over the two finite spines using the four recursion clauses in Definition 50.30. In the mixed cons-nil and nil-cons cases the missing coefficient is the padding endpoint 0_R; in the nil-nil tail the comparison is between 0_R and $0_R + 0_R$, handled by the additive zero laws and classifier symmetry from cert_R.

Fix $n : \mathsf{Nat}^{\uparrow}$. Let the finite split spine for $i + j = n$ carry three scalar spines

$$A_n(i, j) := x[i] \cdot \mathsf{radd}_R(y, z)[j], \qquad B_n(i, j) := x[i] \cdot y[j], \qquad C_n(i, j) := x[i] \cdot z[j].$$

For each split $i + j = n$, the raw-addition coefficient law gives

$$\mathsf{radd}_R(y, z)[j] \sim_R y[j] + z[j].$$

Multiplication congruence transports this under left multiplication by $x[i]$, and scalar left distributivity from Definition 43.26 gives

$$x[i] \cdot \mathsf{radd}_R(y, z)[j] \sim_R (x[i] \cdot y[j]) + (x[i] \cdot z[j]).$$

The matching split order assembles these scalar comparisons into a structural list-classifier witness from Definition 36.12 between A_n and the pointwise sum spine $B_n + C_n$. Applying Definition 50.26 to this witness gives

$$\mathsf{Cauchy}_R(x, \mathsf{radd}_R(y, z); n) \sim_R \mathsf{fold}_{+,R}(B_n + C_n).$$

The finite fold splitting lemma Definition 49.98 then classifies the right endpoint with the sum of the two separate Cauchy folds:

$$\mathsf{fold}_{+,R}(B_n + C_n) \sim_R \mathsf{Cauchy}_R(x, y; n) + \mathsf{Cauchy}_R(x, z; n).$$

Thus

$$\mathsf{Cauchy}_R(x, \mathsf{radd}_R(y, z); n) \sim_R \mathsf{Cauchy}_R(x, y; n) + \mathsf{Cauchy}_R(x, z; n).$$

The raw Cauchy coefficient formula Definition 50.159 gives

$$\mathsf{rmul}_R(x, \mathsf{radd}_R(y, z))[n] \sim_R \mathsf{Cauchy}_R(x, \mathsf{radd}_R(y, z); n).$$

For the other endpoint, the raw-addition coefficient law gives

$$\mathsf{radd}_R(\mathsf{rmul}_R(x,y),\mathsf{rmul}_R(x,z))[n] \sim_R \mathsf{rmul}_R(x,y)[n] + \mathsf{rmul}_R(x,z)[n].$$

Applying Definition 50.159 to the two raw products and then additive congruence gives

$$\mathsf{rmul}_R(x,y)[n] + \mathsf{rmul}_R(x,z)[n] \sim_R \mathsf{Cauchy}_R(x,y;n) + \mathsf{Cauchy}_R(x,z;n).$$

Classifier symmetry and transitivity from cert_R compose the three displayed coefficient comparisons, yielding

$$\mathsf{rmul}_R(x,\mathsf{radd}_R(y,z))[n] \sim_R \mathsf{radd}_R(\mathsf{rmul}_R(x,y),\mathsf{rmul}_R(x,z))[n].$$

Since n was arbitrary, Definition 50.158 gives the displayed $\mathsf{PolySame}_R$ comparison. A normalized polynomial representative is a finite coefficient spine by Definition 50.3, so the final sentence is the same statement restricted to those representatives. □

Theorem 50.130 (Polynomial raw multiplication has singleton-one left identity)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R,\sim_R)$, zero endpoint 0_R, multiplicative unit endpoint 1_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and the raw operations radd_R, rscale_R, shift_R, and rmul_R from Definition 50.30 and Definition 50.139. For every finite coefficient spine $p : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(\mathsf{cons}(1_R,\mathsf{nil}),p),p).$$

Proof. By Definition 50.158, it is enough to prove equality under the padded scalar classifier at every coefficient index. Unfolding the cons clause and the nil clause of raw multiplication in Definition 50.139 gives

$$\mathsf{rmul}_R(\mathsf{cons}(1_R,\mathsf{nil}),p) = \mathsf{radd}_R(\mathsf{rscale}_R(1_R,p),\mathsf{cons}(0_R,\mathsf{nil})).$$

Thus the product is the raw sum of the coefficientwise scalar multiple by 1_R and the one-place shift of the empty recursive product.

First, for every finite coefficient spine u and every index $n : \mathsf{Nat}^{\uparrow}$,

$$\mathsf{radd}_R(u,\mathsf{cons}(0_R,\mathsf{nil}))[n] \sim_R u[n].$$

This is induction on u. If $u = \mathsf{nil}$, the only displayed head is $0_R + 0_R$, classified with 0_R by the additive zero rows in Definition 43.26; all later coefficients are padding coefficients 0_R. If $u = \mathsf{cons}(a,u')$, the head comparison is $(a + 0_R) \sim_R a$ by the additive right-zero row, while the tail comparison is the raw-addition right-nil induction that repeatedly classifies $b + 0_R$ with b and ends at the padding coefficient. These steps use additive congruence, zero self-classification, and classifier transitivity from cert_R.

Second, for every finite coefficient spine p and every index $n : \mathsf{Nat}^{\uparrow}$,

$$\mathsf{rscale}_R(1_R,p)[n] \sim_R p[n].$$

Induct on p. In the nil case both padded coefficients are 0_R. In the cons case, the exposed head is $1_R \cdot a$, classified with a by the multiplicative left-unit row retained in Definition 43.26, and the tail is supplied by the induction hypothesis. After the displayed spine ends, both sides are again the padding coefficient 0_R.

Apply the first coefficient comparison to $u = \mathsf{rscale}_R(1_R, p)$ and compose it with the second comparison. For every $n : \mathsf{Nat}^{\uparrow}$ this gives

$$\mathsf{rmul}_R(\mathsf{cons}(1_R, \mathsf{nil}), p)[n] \sim_R p[n].$$

The padded coefficient extensionality lemma Definition 50.158 converts these pointwise scalar comparisons into the displayed $\mathsf{PolySame}_R$ statement. □

Theorem 50.131 (Raw polynomial multiplication associativity up to add-trim)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Let the classifier be $\sim_R$, the zero endpoint be 0_R, the scalar operations be $+$ and $\cdot$, the scalar certificate be $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, the canonical trim be trim_R from Definition 50.22, and let $\mathsf{PolySame}_R$ and rmul_R be the add-trim classifier and raw Cauchy product of Definition 50.30 and Definition 50.139. For finite coefficient spines $p, q, r : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R\big(\mathsf{rmul}_R(\mathsf{rmul}_R(p, q), r), \mathsf{rmul}_R(p, \mathsf{rmul}_R(q, r))\big).$$

Consequently the same comparison holds when p, q, r are normalized polynomial representatives from Definition 50.3.

Proof. Set

$$A := \mathsf{rmul}_R(\mathsf{rmul}_R(p, q), r), \qquad B := \mathsf{rmul}_R(p, \mathsf{rmul}_R(q, r)).$$

By Definition 50.158, it is enough to prove $A[n] \sim_R B[n]$ for every $n : \mathsf{Nat}^{\uparrow}$.

Fix $n : \mathsf{Nat}^{\uparrow}$. The raw Cauchy coefficient associativity lemma Definition 50.160, applied to the finite coefficient spines p, q, r, gives exactly

$$\mathsf{rmul}_R(\mathsf{rmul}_R(p, q), r)[n] \sim_R \mathsf{rmul}_R(p, \mathsf{rmul}_R(q, r))[n].$$

This is $A[n] \sim_R B[n]$. Since n was arbitrary, Definition 50.158 converts the pointwise padded coefficient comparisons into

$$\mathsf{PolySame}_R(A, B).$$

Unfolding the definitions of A and B gives the displayed add-trim classifier comparison. A normalized polynomial representative from Definition 50.3 is a finite coefficient spine, so the final sentence is the same statement restricted to those carried representatives. □

Proposition 50.132 (Literal polynomial add-trim equality fails at cancelling singletons)**.** *Let R be a scalar ring carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, and canonical trim trim_R as in Definition 50.20 and Definition 50.22. Let radd_R and $\mathsf{PolySame}_R$ be as in Definition 50.30. Suppose $\neg(a \sim_R 0_R)$, $\neg(b \sim_R 0_R)$, and $(a + b) \sim_R 0_R$. Write $[c] := \mathsf{cons}(c, \mathsf{nil})$, and set $p := [a]$ and $q := [b]$. Then literal finite-spine equality does not commute with raw addition and trimming:*

$$\begin{aligned} \mathsf{trim}_R(\mathsf{radd}_R(p, q)) &= \mathsf{nil}, \\ \mathsf{radd}_R(\mathsf{trim}_R(p), \mathsf{trim}_R(q)) &= [a + b], \\ \mathsf{trim}_R(\mathsf{radd}_R(p, q)) &\neq \mathsf{radd}_R(\mathsf{trim}_R(p), \mathsf{trim}_R(q)). \end{aligned}$$

Nevertheless the two displayed outputs are polynomial-classified the same:

$$\mathsf{PolySame}_R\big(\mathsf{trim}_R(\mathsf{radd}_R(p, q)), \mathsf{radd}_R(\mathsf{trim}_R(p), \mathsf{trim}_R(q))\big).$$

For the canonical integer coefficient ring from chapter 31 and chapter 44, taking $a = 1$ and $b = -1$ gives $p = [1]$, $q = [-1]$, $\mathsf{trim}_{\mathbb{Z}}(\mathsf{radd}_{\mathbb{Z}}(p, q)) = \mathsf{nil}$, and $\mathsf{radd}_{\mathbb{Z}}(\mathsf{trim}_{\mathbb{Z}}(p), \mathsf{trim}_{\mathbb{Z}}(q)) = [0]$.

Proof. The nonzero hypotheses make p and q normalized singleton representatives by Definition 50.166; the canonical trim fixes normalized representatives, so $\mathsf{trim}_R(p) = p$ and $\mathsf{trim}_R(q) = q$. By the cons-cons and nil-nil clauses of radd_R in Definition 50.30, $\mathsf{radd}_R(\mathsf{trim}_R(p), \mathsf{trim}_R(q)) = \mathsf{radd}_R([a], [b]) = [a + b]$. The equality $\mathsf{trim}_R(\mathsf{radd}_R(p, q)) = \mathsf{nil}$ is the singleton cancellation conclusion of Definition 50.167. The displayed inequality follows because the left side is nil while the right side is a cons spine. Constructor no-confusion for the finite-spine carrier of Definition 36.1 is the mixed nil/cons separation isolated in Definition 36.13 and Definition 36.14. For classifier comparison, unfold $\mathsf{PolySame}_R$. The first argument trims again to nil. The second argument is $[a+b]$, and the hypothesis $(a+b) \sim_R 0_R$ sends its singleton coefficient to the trailing-zero branch, so its trim is also nil. The nil-nil clause of $\mathsf{ListClassifierSpec}$ gives the displayed $\mathsf{PolySame}_R$ witness. The integer specialization uses the standard integer facts $1 \neq 0$, $-1 \neq 0$, and $1 + (-1) = 0$; Definition 44.8 keeps the ring operations and classifier when the commutative-ring source is read through $\mathsf{Ring}^{\uparrow}$. □

Definition 50.133 (Polynomial Horner evaluation)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and raw addition radd_R from Definition 50.30. For a carried scalar point α, define the Horner evaluation on finite coefficient spines from Definition 36.1 by recursion*

$$\mathsf{eval}_{\alpha,R}(\mathsf{nil}) := 0_R.$$

$$\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x)) := a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x).$$

Define the normalized polynomial evaluation by

$$\mathsf{Eval}_{\alpha,R}(x) := \mathsf{eval}_{\alpha,R}(\mathsf{trim}_R(x)).$$

Define the normalized polynomial sum by

$$\mathsf{PolyAdd}_R(x, y) := \mathsf{trim}_R(\mathsf{radd}_R(\mathsf{trim}_R(x), \mathsf{trim}_R(y))).$$

On a normalized representative from Definition 50.3, $\mathsf{Eval}_{\alpha,R}$ is the Horner evaluation itself, by trim idempotence from Definition 50.22.

Lemma 50.134 (Horner evaluation ignores classified zero tails)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $x, t : \mathsf{ListCarrier}(R)$, if $\mathsf{ZeroRem}_R(t)$ holds in the sense of Definition 50.28, then*

$$\mathsf{eval}_{\alpha,R}(x{+}{+}t) \sim_R \mathsf{eval}_{\alpha,R}(x).$$

Consequently, for every finite coefficient spine x,

$$\mathsf{Eval}_{\alpha,R}(x) \sim_R \mathsf{eval}_{\alpha,R}(x).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialZeroRemainder addFold empty`

Proof. First prove the endpoint claim $\mathsf{eval}_{\alpha,R}(t) \sim_R 0_R$ for every classified zero tail t. Induct on the displayed $\mathsf{ZeroRem}_R(t)$ witness. The nil clause is the defining equation $\mathsf{eval}_{\alpha,R}(\mathsf{nil}) = 0_R$ together with zero self-classification from Definition 43.26. In the cons clause, write $t = \mathsf{cons}(a, t')$. The constructor gives $a \sim_R 0_R$ and the induction hypothesis gives $\mathsf{eval}_{\alpha,R}(t') \sim_R 0_R$. Multiplication congruence and the zero-multiplication row in Definition 43.26 classify $\alpha \cdot \mathsf{eval}_{\alpha,R}(t')$ with 0_R.

Addition congruence then classifies $a + \alpha \cdot \mathsf{eval}_{\alpha,R}(t')$ with $0_R + 0_R$, and the additive left-zero law reduces the latter endpoint to 0_R.

For the displayed tail-invariance statement, induct on x. The nil case is the endpoint claim just proved. In the cons case, write $x = \mathsf{cons}(a, x')$. The induction hypothesis gives $\mathsf{eval}_{\alpha,R}(x'{+}{+}t) \sim_R \mathsf{eval}_{\alpha,R}(x')$. Multiplication congruence transports this comparison through left multiplication by α, and addition congruence with source reflexivity on a gives

$$a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x'{+}{+}t) \sim_R a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x').$$

The two Horner recursion equations identify these endpoints with $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'{+}{+}t))$ and $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'))$.

For the consequence, the trailing-zero removal clause in Definition 50.22 presents each raw spine x as $\mathsf{trim}_R(x){+}{+}t$ with $\mathsf{ZeroRem}_R(t)$. Applying the first part gives $\mathsf{eval}_{\alpha,R}(x) \sim_R \mathsf{Eval}_{\alpha,R}(x)$, and symmetry of the scalar classifier reverses the displayed comparison. □

Lemma 50.135 (Horner evaluation respects raw polynomial addition)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $x, y : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{\alpha,R}(\mathsf{radd}_R(x, y)) \sim_R \mathsf{eval}_{\alpha,R}(x) + \mathsf{eval}_{\alpha,R}(y).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonAddFold append hsame`

Proof. Perform induction on the two finite spines, following the four recursion clauses for radd_R in Definition 50.30.

The nil-nil case compares 0_R with $0_R + 0_R$, so it is exactly the additive left-zero law, read with symmetry when needed.

In the cons-nil case, write $x = \mathsf{cons}(a, x')$. The raw-addition recursion exposes the head $a + 0_R$ and the tail $\mathsf{radd}_R(x', \mathsf{nil})$. The induction hypothesis classifies the tail evaluation with $\mathsf{eval}_{\alpha,R}(x') + 0_R$, and Definition 43.31 reduces that endpoint to $\mathsf{eval}_{\alpha,R}(x')$. Multiplication congruence transports the tail comparison through left multiplication by α. Additive congruence and the additive right-zero law reduce the exposed head $a + 0_R$ to a, and the target endpoint $(\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'))) + 0_R$ to $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'))$.

The nil-cons case is symmetric. The raw head is $0_R + b$, which reduces to b by the additive left-zero law, and the outer target $0_R + \mathsf{eval}_{\alpha,R}(\mathsf{cons}(b, y'))$ reduces by the same law. The tail comparison is transported through multiplication by α exactly as in the cons-nil case.

In the cons-cons case, write $x = \mathsf{cons}(a, x')$ and $y = \mathsf{cons}(b, y')$. The induction hypothesis gives

$$\mathsf{eval}_{\alpha,R}(\mathsf{radd}_R(x', y')) \sim_R \mathsf{eval}_{\alpha,R}(x') + \mathsf{eval}_{\alpha,R}(y').$$

Multiplication congruence transports this through left multiplication by α, and left distributivity from Definition 43.26 classifies

$$\alpha \cdot (\mathsf{eval}_{\alpha,R}(x') + \mathsf{eval}_{\alpha,R}(y'))$$

with

$$\alpha \cdot \mathsf{eval}_{\alpha,R}(x') + \alpha \cdot \mathsf{eval}_{\alpha,R}(y').$$

Addition congruence therefore transports the Horner endpoint for $\mathsf{radd}_R(x, y)$ to

$$(a + b) + (\alpha \cdot \mathsf{eval}_{\alpha,R}(x') + \alpha \cdot \mathsf{eval}_{\alpha,R}(y')).$$

Apply Definition 42.13 to the additive abelian-group operation, with the four additive blocks a, b, $\alpha \cdot \mathsf{eval}_{\alpha,R}(x')$, and $\alpha \cdot \mathsf{eval}_{\alpha,R}(y')$. This classifies the last endpoint with

$$(a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x')) + (b + \alpha \cdot \mathsf{eval}_{\alpha,R}(y')),$$

which is exactly $\mathsf{eval}_{\alpha,R}(x) + \mathsf{eval}_{\alpha,R}(y)$ by the Horner recursion. □

Theorem 50.136 (Polynomial evaluation is additive)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{Eval}_{\alpha,R}(\mathsf{PolyAdd}_R(p, q)) \sim_R \mathsf{Eval}_{\alpha,R}(p) + \mathsf{Eval}_{\alpha,R}(q).$$

If p and q are normalized representatives in the polynomial carrier, the same assertion is the carrier formula

$$\mathsf{eval}_{\alpha,R}(\mathsf{PolyAdd}_R(p, q)) \sim_R \mathsf{eval}_{\alpha,R}(p) + \mathsf{eval}_{\alpha,R}(q).$$

Proof. Put $p_0 = \mathsf{trim}_R(p)$ and $q_0 = \mathsf{trim}_R(q)$. By Definition 50.133,

$$\mathsf{PolyAdd}_R(p, q) = \mathsf{trim}_R(\mathsf{radd}_R(p_0, q_0)).$$

Trim idempotence from Definition 50.22 identifies $\mathsf{Eval}_{\alpha,R}(\mathsf{PolyAdd}_R(p, q))$ with $\mathsf{Eval}_{\alpha,R}(\mathsf{radd}_R(p_0, q_0))$. Applying Definition 50.134 gives

$$\mathsf{Eval}_{\alpha,R}(\mathsf{radd}_R(p_0, q_0)) \sim_R \mathsf{eval}_{\alpha,R}(\mathsf{radd}_R(p_0, q_0)).$$

By Definition 50.135,

$$\mathsf{eval}_{\alpha,R}(\mathsf{radd}_R(p_0, q_0)) \sim_R \mathsf{eval}_{\alpha,R}(p_0) + \mathsf{eval}_{\alpha,R}(q_0).$$

The right endpoint is $\mathsf{Eval}_{\alpha,R}(p) + \mathsf{Eval}_{\alpha,R}(q)$ by the definition of p_0, q_0, and normalized evaluation. Classifier transitivity composes the displayed comparisons.

If p and q are already normalized polynomial-carrier representatives, trim idempotence gives $p_0 = p$ and $q_0 = q$, and $\mathsf{Eval}_{\alpha,R}$ on each displayed representative is the unnormalized Horner evaluation. Substituting these equalities gives the carrier formula. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval rawAdd classified`

Lemma 50.137 (Horner evaluation respects structural classifier)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $x, y : \mathsf{ListCarrier}(R)$, if*

$$\mathsf{ListClassifierSpec}(\sim_R, x, y)$$

holds, then

$$\mathsf{eval}_{\alpha,R}(x) \sim_R \mathsf{eval}_{\alpha,R}(y).$$

Proof. Induct on the displayed structural classifier witness from Definition 36.12. By Definition 36.13, the only constructor cases are nil-nil and cons-cons; mixed nil-cons shapes have no classifier witness.

In the nil-nil case, the two Horner equations in Definition 50.133 identify both endpoints with 0_R. The zero self-classification field retained in Definition 43.26 gives $0_R \sim_R 0_R$.

In the cons-cons case, write $x = \mathsf{cons}(a, x')$ and $y = \mathsf{cons}(b, y')$. The classifier constructor supplies $a \sim_R b$ and a tail witness $\mathsf{ListClassifierSpec}(\sim_R, x', y')$. The induction hypothesis gives

$$\mathsf{eval}_{\alpha,R}(x') \sim_R \mathsf{eval}_{\alpha,R}(y').$$

The carried point α is self-classified by the scalar certificate. Multiplication congruence from Definition 43.26 transports the tail comparison through left multiplication by α, giving

$$\alpha \cdot \mathsf{eval}_{\alpha,R}(x') \sim_R \alpha \cdot \mathsf{eval}_{\alpha,R}(y').$$

Addition congruence combines this comparison with the head comparison $a \sim_R b$:

$$a + \alpha \cdot \mathsf{eval}_{\alpha,R}(x') \sim_R b + \alpha \cdot \mathsf{eval}_{\alpha,R}(y').$$

The cons recursion equation in Definition 50.133 identifies these two endpoints with $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x'))$ and $\mathsf{eval}_{\alpha,R}(\mathsf{cons}(b, y'))$, respectively. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval list classifier classified`

Theorem 50.138 (Polynomial evaluation respects the polynomial classifier)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(p, q) \Longrightarrow \mathsf{Eval}_{\alpha,R}(p) \sim_R \mathsf{Eval}_{\alpha,R}(q).$$

Proof. Unfold $\mathsf{PolySame}_R$ using Definition 50.30. A classifier witness for p and q is exactly

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(p), \mathsf{trim}_R(q)).$$

Apply Definition 50.137 to the two trimmed spines. This gives

$$\mathsf{eval}_{\alpha,R}(\mathsf{trim}_R(p)) \sim_R \mathsf{eval}_{\alpha,R}(\mathsf{trim}_R(q)).$$

The normalized evaluation definition in Definition 50.133 reads the left endpoint as $\mathsf{Eval}_{\alpha,R}(p)$ and the right endpoint as $\mathsf{Eval}_{\alpha,R}(q)$, giving the displayed implication. □

Definition 50.139 (Polynomial raw Cauchy product)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and raw addition radd_R from Definition 50.30. For a scalar coefficient a and a finite coefficient spine $y : \mathsf{ListCarrier}(R)$, define scalar multiplication of coefficient spines by*

$$\mathsf{rscale}_R(a, \mathsf{nil}) := \mathsf{nil}, \qquad \mathsf{rscale}_R(a, \mathsf{cons}(b, y)) := \mathsf{cons}(a \cdot b, \mathsf{rscale}_R(a, y)).$$

Define the one-place coefficient shift by

$$\mathsf{shift}_R(y) := \mathsf{cons}(0_R, y).$$

The raw polynomial product is the finite recursion

$$\mathsf{rmul}_R(\mathsf{nil}, y) := \mathsf{nil},$$

$$\mathsf{rmul}_R(\mathsf{cons}(a, x), y) := \mathsf{radd}_R(\mathsf{rscale}_R(a, y), \mathsf{shift}_R(\mathsf{rmul}_R(x, y))).$$

The normalized polynomial product is

$$\mathsf{PolyMul}_R(x, y) := \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{trim}_R(x), \mathsf{trim}_R(y))).$$

This is the Cauchy product in low-coefficient-first Horner form: the cons clause expresses $(a + Xx)y = ay + X(xy)$.

Lean4 (definition) `BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul`

Lemma 50.140 (Horner evaluation of scalar-multiplied coefficient spines)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For every carried scalar coefficient a and every finite coefficient spine $y : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{\alpha,R}(\mathsf{rscale}_R(a, y)) \sim_R a \cdot \mathsf{eval}_{\alpha,R}(y).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval rawScale classified`
Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval raw scale empty classified`

Proof. Induct on the finite spine y from Definition 36.1. In the nil case, both the scalar-multiple spine and its Horner value are 0_R. The target endpoint is $a \cdot 0_R$, and the zero-multiplication row in Definition 43.26, with symmetry of $\sim_R$, gives the displayed comparison.

In the cons case, write $y = \mathsf{cons}(b, y')$. The recursion in Definition 50.139 and the Horner recursion in Definition 50.133 identify the left endpoint with

$$a \cdot b + \alpha \cdot \mathsf{eval}_{\alpha,R}(\mathsf{rscale}_R(a, y')).$$

The induction hypothesis and multiplication congruence classify this endpoint with

$$a \cdot b + \alpha \cdot (a \cdot \mathsf{eval}_{\alpha,R}(y')).$$

Multiplicative associativity, multiplicative commutativity from Definition 44.33, and multiplication congruence classify

$$\alpha \cdot (a \cdot \mathsf{eval}_{\alpha,R}(y'))$$

with

$$a \cdot (\alpha \cdot \mathsf{eval}_{\alpha,R}(y')).$$

Addition congruence transports this comparison under the common summand $a \cdot b$. The left distributive row in Definition 43.26, used in the reverse direction, then identifies

$$a \cdot b + a \cdot (\alpha \cdot \mathsf{eval}_{\alpha,R}(y'))$$

with

$$a \cdot (b + \alpha \cdot \mathsf{eval}_{\alpha,R}(y')).$$

The final endpoint is $a \cdot \mathsf{eval}_{\alpha,R}(\mathsf{cons}(b, y'))$ by the Horner recursion, and transitivity composes the comparisons. □

Lemma 50.141 (Horner evaluation of coefficient shift)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For every finite coefficient spine $x : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{\alpha,R}(\mathsf{shift}_R(x)) \sim_R \alpha \cdot \mathsf{eval}_{\alpha,R}(x).$$

Proof. By Definition 50.139, $\mathsf{shift}_R(x) = \mathsf{cons}(0_R, x)$. The Horner recursion from Definition 50.133 makes its evaluation

$$0_R + \alpha \cdot \mathsf{eval}_{\alpha,R}(x).$$

The additive left-zero row in Definition 43.26 classifies this endpoint with $\alpha \cdot \mathsf{eval}_{\alpha,R}(x)$. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval coefficient shift`

Lemma 50.142 (Horner evaluation respects raw polynomial multiplication)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $x, y : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(x, y)) \sim_R \mathsf{eval}_{\alpha,R}(x) \cdot \mathsf{eval}_{\alpha,R}(y).$$

Proof. Induct on the first spine x. In the nil case, $\mathsf{rmul}_R(\mathsf{nil}, y) = \mathsf{nil}$, so the left endpoint evaluates to 0_R. The target endpoint is $0_R \cdot \mathsf{eval}_{\alpha,R}(y)$, and the zero-multiplication row in Definition 43.26, with symmetry, gives the comparison.

For the cons case, write $x = \mathsf{cons}(a, x')$, put $u = \mathsf{eval}_{\alpha,R}(x')$, and put $v = \mathsf{eval}_{\alpha,R}(y)$. The raw product recursion in Definition 50.139 and the raw additivity theorem Definition 50.135 give

$$\mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(\mathsf{cons}(a, x'), y)) \sim_R \mathsf{eval}_{\alpha,R}(\mathsf{rscale}_R(a, y)) + \mathsf{eval}_{\alpha,R}(\mathsf{shift}_R(\mathsf{rmul}_R(x', y))).$$

By Definition 50.140, the first summand is classified with $a \cdot v$. By Definition 50.141, the second summand is classified with

$$\alpha \cdot \mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(x', y)).$$

The induction hypothesis and multiplication congruence classify this with $\alpha \cdot (u \cdot v)$. Multiplicative associativity classifies $\alpha \cdot (u \cdot v)$ with $(\alpha \cdot u) \cdot v$. Addition congruence therefore gives

$$\mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(\mathsf{cons}(a, x'), y)) \sim_R a \cdot v + (\alpha \cdot u) \cdot v.$$

The right distributive row retained by Definition 44.8, equivalently derived from Definition 44.34, classifies

$$(a + \alpha \cdot u) \cdot v$$

with

$$a \cdot v + (\alpha \cdot u) \cdot v.$$

Using symmetry of this distributive comparison and the Horner recursion

$$\mathsf{eval}_{\alpha,R}(\mathsf{cons}(a, x')) = a + \alpha \cdot u,$$

transitivity gives the required cons-case endpoint. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval rawMul classified`

Theorem 50.143 (Polynomial evaluation is multiplicative)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{Eval}_{\alpha,R}(\mathsf{PolyMul}_R(p, q)) \sim_R \mathsf{Eval}_{\alpha,R}(p) \cdot \mathsf{Eval}_{\alpha,R}(q).$$

If p and q are normalized representatives in the polynomial carrier, the same assertion is the carrier formula

$$\mathsf{eval}_{\alpha,R}(\mathsf{PolyMul}_R(p, q)) \sim_R \mathsf{eval}_{\alpha,R}(p) \cdot \mathsf{eval}_{\alpha,R}(q).$$

Proof. Put $p_0 = \mathsf{trim}_R(p)$ and $q_0 = \mathsf{trim}_R(q)$. By Definition 50.139,

$$\mathsf{PolyMul}_R(p, q) = \mathsf{trim}_R(\mathsf{rmul}_R(p_0, q_0)).$$

Trim idempotence from Definition 50.22 identifies the normalized evaluation of this endpoint with

$$\mathsf{Eval}_{\alpha,R}(\mathsf{rmul}_R(p_0, q_0)).$$

Applying Definition 50.134 gives

$$\mathsf{Eval}_{\alpha,R}(\mathsf{rmul}_R(p_0, q_0)) \sim_R \mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(p_0, q_0)).$$

By Definition 50.142,

$$\mathsf{eval}_{\alpha,R}(\mathsf{rmul}_R(p_0, q_0)) \sim_R \mathsf{eval}_{\alpha,R}(p_0) \cdot \mathsf{eval}_{\alpha,R}(q_0).$$

The right endpoint is $\mathsf{Eval}_{\alpha,R}(p) \cdot \mathsf{Eval}_{\alpha,R}(q)$ by the definition of p_0, q_0, and normalized evaluation in Definition 50.133. Classifier transitivity composes the displayed comparisons.

If p and q are already normalized polynomial-carrier representatives, trim idempotence gives $p_0 = p$ and $q_0 = q$. The product endpoint is normalized by its defining trim, so normalized evaluation on $\mathsf{PolyMul}_R(p, q)$ is the unnormalized Horner evaluation of that product. Substituting these equalities gives the carrier formula. □

Theorem 50.144 (Polynomial evaluation is a semiring morphism through classification)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Fix a carried scalar point α. For finite coefficient spines $p, q, p', q' : \mathsf{ListCarrier}(R)$, if $\mathsf{PolySame}_R(p, p')$ and $\mathsf{PolySame}_R(q, q')$, then*

$$\mathsf{Eval}_{\alpha,R}(p) \sim_R \mathsf{Eval}_{\alpha,R}(p'),$$

$$\mathsf{Eval}_{\alpha,R}(\mathsf{PolyAdd}_R(p, q)) \sim_R \mathsf{Eval}_{\alpha,R}(p) + \mathsf{Eval}_{\alpha,R}(q),$$

and

$$\mathsf{Eval}_{\alpha,R}(\mathsf{PolyMul}_R(p, q)) \sim_R \mathsf{Eval}_{\alpha,R}(p) \cdot \mathsf{Eval}_{\alpha,R}(q).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval semiring morphism`

Proof. The first clause is exactly Definition 50.138 applied to the classifier witness between p and p'.

The second and third clauses are the normalized-operation laws from Definition 50.136 and Definition 50.143. They apply to the original representatives p and q, so the operation endpoints are already the canonical normalized polynomial operations.

When a later scalar comparison is written with p' or q' instead, apply Definition 50.138 to the appropriate classifier witness and compose by transitivity of $\sim_R$. Thus the descended endpoints may be substituted in the additive and multiplicative scalar comparisons without reassembling the three facts. □

Lemma 50.145 (Zero-point Horner cons evaluation)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and Horner evaluation as in Definition 50.133. For every carried scalar coefficient a and every finite coefficient spine $t : \mathsf{ListCarrier}(R)$,*

$$\mathsf{eval}_{0_R,R}(\mathsf{cons}(a, t)) \sim_R a.$$

Proof. The cons recursion in Definition 50.133 identifies the left endpoint with

$$a + 0_R \cdot \mathsf{eval}_{0_R,R}(t).$$

The zero-absorption theorem Definition 43.60, applied to $\mathsf{eval}_{0_R,R}(t)$, gives

$$0_R \cdot \mathsf{eval}_{0_R,R}(t) \sim_R 0_R.$$

Classifier reflexivity supplies $a \sim_R a$, and addition congruence from Definition 43.26 gives

$$a + 0_R \cdot \mathsf{eval}_{0_R,R}(t) \sim_R a + 0_R.$$

The additive right-zero theorem Definition 43.31 gives $a+0_R \sim_R a$. Classifier transitivity composes the two comparisons. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval zero cons constant`

Lemma 50.146 (Zero-point Horner evaluation ignores classified zero tails)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and Horner evaluation as in Definition 50.133. For finite coefficient spines $x, t : \mathsf{ListCarrier}(R)$, if $\mathsf{ZeroRem}_R(t)$ holds in the sense of Definition 50.28, then*

$$\mathsf{eval}_{0_R,R}(x{+}{+}t) \sim_R \mathsf{eval}_{0_R,R}(x).$$

Proof. First record the endpoint claim that every classified zero remainder evaluates to zero at 0_R. If the zero remainder is nil, the nil recursion in Definition 50.133 identifies its evaluation with 0_R, and zero self-classification from Definition 43.26 gives the claim. If the zero remainder is $\mathsf{cons}(c, t')$, the cons clause of Definition 50.28 supplies $c \sim_R 0_R$. By Definition 50.145,

$$\mathsf{eval}_{0_R,R}(\mathsf{cons}(c, t')) \sim_R c,$$

and transitivity gives $\mathsf{eval}_{0_R,R}(\mathsf{cons}(c, t')) \sim_R 0_R$.

Now split on the first constructor of x. If $x = \mathsf{nil}$, then $x{+}{+}t = t$, so the endpoint claim gives the displayed comparison. If $x = \mathsf{cons}(a, x')$, then $x{+}{+}t = \mathsf{cons}(a, x'{+}{+}t)$. Applying Definition 50.145 twice gives

$$\mathsf{eval}_{0_R,R}(\mathsf{cons}(a, x'{+}{+}t)) \sim_R a$$

and

$$\mathsf{eval}_{0_R,R}(\mathsf{cons}(a, x')) \sim_R a.$$

Symmetry of the second comparison and transitivity give the required comparison for the cons case. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval zero point zero tail invariance`

Theorem 50.147 (Polynomial evaluation at zero returns the constant coefficient)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and Horner evaluation as in Definition 50.133. For every carried scalar coefficient a and every finite coefficient spine $t : \mathsf{ListCarrier}(R)$,*

$$\mathsf{Eval}_{0_R,R}(\mathsf{cons}(a, t)) \sim_R a.$$

Proof. Set $x = \mathsf{cons}(a, t)$. The trailing-zero removal clause in Definition 50.22 gives a finite zero remainder z such that

$$x = \mathsf{trim}_R(x){+}{+}z, \qquad \mathsf{ZeroRem}_R(z).$$

Applying Definition 50.146 to $\mathsf{trim}_R(x)$ and z yields

$$\mathsf{eval}_{0_R,R}(x) \sim_R \mathsf{eval}_{0_R,R}(\mathsf{trim}_R(x)).$$

By the normalized evaluation definition in Definition 50.133, the right endpoint is $\mathsf{Eval}_{0_R,R}(x)$. Symmetry gives

$$\mathsf{Eval}_{0_R,R}(x) \sim_R \mathsf{eval}_{0_R,R}(x).$$

The raw cons comparison Definition 50.145 gives

$$\mathsf{eval}_{0_R,R}(x) \sim_R a.$$

Classifier transitivity composes these two comparisons, and substituting $x = \mathsf{cons}(a, t)$ gives the displayed formula. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval zero constant term`

Lemma 50.148 (Unit-point Horner evaluation is coefficient fold)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, multiplicative unit endpoint 1_R, addition $+$, multiplication $\cdot$, and Horner evaluation as in Definition 50.133. Let $\mathsf{fold}_{+,R}$ be the finite recursive coefficient fold from Definition 50.26, satisfying*

$$\mathsf{fold}_{+,R}(\mathsf{nil}) = 0_R, \qquad \mathsf{fold}_{+,R}(\mathsf{cons}(a, x')) = a + \mathsf{fold}_{+,R}(x').$$

For every finite coefficient spine $x : \mathsf{ListCarrier}(R)$,

$$\mathsf{eval}_{1_R,R}(x) \sim_R \mathsf{fold}_{+,R}(x).$$

Proof. Induct on the finite spine x from Definition 36.1.

In the nil case, the nil Horner equation in Definition 50.133 and the nil fold equation identify both endpoints with 0_R. The zero self-classification row of Definition 43.26 gives the displayed comparison.

In the cons case, write $x = \mathsf{cons}(a, x')$. The induction hypothesis gives

$$\mathsf{eval}_{1_R,R}(x') \sim_R \mathsf{fold}_{+,R}(x').$$

The recursive Horner endpoint $\mathsf{eval}_{1_R,R}(x')$ is carried by induction on x' using the scalar zero, addition, and multiplication closure rows of the $\mathsf{Ring}^{\uparrow}$ certificate. Hence the multiplicative left-unit row retained in Definition 43.26 gives

$$1_R \cdot \mathsf{eval}_{1_R,R}(x') \sim_R \mathsf{eval}_{1_R,R}(x').$$

Classifier transitivity composes this unit comparison with the induction hypothesis, yielding

$$1_R \cdot \mathsf{eval}_{1_R,R}(x') \sim_R \mathsf{fold}_{+,R}(x').$$

Source reflexivity gives $a \sim_R a$. Applying additive congruence from Definition 43.26 gives

$$a + 1_R \cdot \mathsf{eval}_{1_R,R}(x') \sim_R a + \mathsf{fold}_{+,R}(x').$$

The cons Horner equation identifies the left endpoint with $\mathsf{eval}_{1_R,R}(\mathsf{cons}(a, x'))$, and the cons fold equation identifies the right endpoint with $\mathsf{fold}_{+,R}(\mathsf{cons}(a, x'))$. □

Theorem 50.149 (Polynomial evaluation at the multiplicative unit is coefficient fold)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, multiplicative unit endpoint 1_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and Horner evaluation as in Definition 50.133. Let $\mathsf{fold}_{+,R}$ be the finite recursive coefficient fold from Definition 50.26. For every finite coefficient spine $p : \mathsf{ListCarrier}(R)$,*

$$\mathsf{Eval}_{1_R,R}(p) \sim_R \mathsf{fold}_{+,R}(\mathsf{trim}_R(p)).$$

Proof. By the normalized evaluation definition in Definition 50.133,

$$\mathsf{Eval}_{1_R,R}(p) = \mathsf{eval}_{1_R,R}(\mathsf{trim}_R(p)).$$

Apply Definition 50.148 to the finite coefficient spine $\mathsf{trim}_R(p)$. This gives

$$\mathsf{eval}_{1_R,R}(\mathsf{trim}_R(p)) \sim_R \mathsf{fold}_{+,R}(\mathsf{trim}_R(p)).$$

Substituting the displayed definition of $\mathsf{Eval}_{1_R,R}(p)$ gives the claimed comparison. □

Lemma 50.150 (Polynomial raw addition structural swap)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, and addition $+$. Assume scalar additive commutativity:*

$$a + b \sim_R b + a$$

for all scalar coefficients a, b. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(p, q), \mathsf{radd}_R(q, p)).$$

Proof. Induct simultaneously on the two finite coefficient spines, following the four recursion clauses of radd_R in Definition 50.30. The target classifier is the finite-spine structural classifier of Definition 36.12, with matching constructors isolated by Definition 36.13.

In the nil-nil case, both raw additions are nil, so the nil clause of $\mathsf{ListClassifierSpec}$ gives the claim.

In the cons-nil case, write $p = \mathsf{cons}(a, p')$ and $q = \mathsf{nil}$. The recursion gives

$$\mathsf{radd}_R(p, q) = \mathsf{cons}(a + 0_R, \mathsf{radd}_R(p', \mathsf{nil}))$$

and

$$\mathsf{radd}_R(q, p) = \mathsf{cons}(0_R + a, \mathsf{radd}_R(\mathsf{nil}, p')).$$

Scalar additive commutativity gives $a + 0_R \sim_R 0_R + a$. The induction hypothesis applied to p' and nil gives the tail classifier

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(p', \mathsf{nil}), \mathsf{radd}_R(\mathsf{nil}, p')).$$

The cons clause of $\mathsf{ListClassifierSpec}$ combines the head comparison and this tail comparison.

In the nil-cons case, write $p = \mathsf{nil}$ and $q = \mathsf{cons}(b, q')$. The recursion gives heads $0_R + b$ and $b + 0_R$. Scalar additive commutativity gives $0_R + b \sim_R b + 0_R$, and the induction hypothesis at nil and q' supplies the tail classifier. The cons clause rebuilds the displayed list-classifier witness.

In the cons-cons case, write $p = \mathsf{cons}(a, p')$ and $q = \mathsf{cons}(b, q')$. The recursion exposes heads $a + b$ and $b + a$, related by scalar additive commutativity. The induction hypothesis supplies

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(p', q'), \mathsf{radd}_R(q', p')).$$

The cons clause combines the head and tail witnesses, giving the structural classifier for the two raw sums. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd structural swap`
Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd commutative classified`

Theorem 50.151 (Polynomial raw addition commutativity from scalar additive commutativity)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, and scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$. Use the additive abelian-group and classifier fields retained in Definition 43.26: zero self-classification, classifier transitivity, additive congruence, additive zero laws, and scalar additive commutativity. For a commutative-ring scalar source, Definition 44.8 keeps these data unchanged. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{radd}_R(p, q), \mathsf{radd}_R(q, p)).$$

Proof. Apply Definition 50.150 to p and q using the scalar additive commutativity row from Definition 43.26. This gives

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{radd}_R(p, q), \mathsf{radd}_R(q, p)).$$

The nil finite spine is a zero remainder by the nil clause of Definition 50.28. Apply Definition 50.29 with common classified spines $\mathsf{radd}_R(p, q)$ and $\mathsf{radd}_R(q, p)$, and with both zero remainders equal to nil. Finite-spine append by nil leaves each spine unchanged, so the lemma yields

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(\mathsf{radd}_R(p, q)), \mathsf{trim}_R(\mathsf{radd}_R(q, p))).$$

Unfolding $\mathsf{PolySame}_R$ from Definition 50.30, this is exactly the displayed polynomial raw classifier comparison. □

Lemma 50.152 (Raw polynomial addition is structurally associative)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, and scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$. Assume the additive fields retained in Definition 43.26: additive associativity, additive zero laws, classifier symmetry, classifier transitivity, and addition congruence. For finite coefficient spines $p, q, r : \mathsf{ListCarrier}(R)$,*

$$\mathsf{ListClassifierSpec}\big(\sim_R, \mathsf{radd}_R(\mathsf{radd}_R(p, q), r), \mathsf{radd}_R(p, \mathsf{radd}_R(q, r))\big).$$

Proof. Induct on the finite triple spine (p, q, r), using the maximum of the three finite lengths as the decreasing measure. The nil-nil-nil case unfolds both raw additions by Definition 50.30 to nil, and the nil clause of Definition 36.12 gives the classifier witness.

In every remaining constructor case, at least one of the three spines is a cons spine. Unfold the corresponding clauses of radd_R from Definition 50.30. Both associated raw sums expose a cons head, and their tails are exactly the two associated raw sums for the tail triple, with nil used as the tail of any absent spine. The induction hypothesis supplies the recursive tail classifier.

It remains to classify the exposed scalar heads. If all three heads are present, say a, b, c, the comparison is

$$(a + b) + c \sim_R a + (b + c),$$

which is scalar additive associativity. If exactly two heads are present, the missing head is the padding coefficient 0_R, so the three possible comparisons

$$(a + b) + 0_R \sim_R a + (b + 0_R),$$

$$(a + 0_R) + c \sim_R a + (0_R + c),$$

$$(0_R + b) + c \sim_R 0_R + (b + c)$$

are the same associativity law with one displayed argument equal to 0_R. If only the left input has a head a, the comparison is

$$(a + 0_R) + 0_R \sim_R a + 0_R,$$

which is the additive right-zero law applied to $a + 0_R$. If only the middle input has a head b, the comparison is

$$(0_R + b) + 0_R \sim_R 0_R + (b + 0_R),$$

again additive associativity. If only the right input has a head c, the comparison is

$$0_R + c \sim_R 0_R + (0_R + c),$$

obtained by reversing the additive left-zero law at the endpoint $0_R + c$ using classifier symmetry from cert_R.

In each constructor case, the scalar head comparison and the tail classifier rebuild the cons clause of $\mathsf{ListClassifierSpec}$. These cases exhaust the finite-spine constructors by Definition 36.13. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd associative classified`

Theorem 50.153 (Polynomial raw addition associativity)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, canonical trim trim_R, and scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$. Assume the additive fields retained in Definition 43.26: additive abelian-group laws and addition congruence. For finite coefficient spines $p, q, r : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{radd}_R(\mathsf{radd}_R(p, q), r), \mathsf{radd}_R(p, \mathsf{radd}_R(q, r))).$$

Proof. Set

$$u := \mathsf{radd}_R(\mathsf{radd}_R(p, q), r), \qquad \omega := \mathsf{radd}_R(p, \mathsf{radd}_R(q, r)).$$

By Definition 50.152,

$$\mathsf{ListClassifierSpec}(\sim_R, \nu, \omega)$$

holds. The nil spine is a classified zero remainder by the nil clause of Definition 50.28. Apply Definition 50.29 to the common classified spines ν and ω, with nil zero remainders on both sides. The append-nil identities for finite spines give

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(\nu), \mathsf{trim}_R(\omega)).$$

Unfolding $\mathsf{PolySame}_R$ from Definition 50.30 turns this normalized structural classifier into the displayed polynomial classifier comparison. □

Theorem 50.154 (Polynomial raw multiplication commutativity from scalar commutativity)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, canonical trim trim_R, and the raw operations radd_R, rscale_R, shift_R, and rmul_R from Definition 50.30 and Definition 50.139. For finite coefficient spines $p, q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(p, q), \mathsf{rmul}_R(q, p)).$$

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul commutative classified`

Proof. Read the scalar source as a $\mathsf{Ring}^{\uparrow}(R)$ source by Definition 44.8. The retained rows used below are the $\mathsf{NameCert}$ reflexivity, symmetry, and transitivity fields, the additive abelian-group laws and addition congruence from Definition 43.26, multiplication congruence, and the multiplicative commutativity row from Definition 44.33.

First record the finite-spine consequences of the existing raw-addition package. The relation $\mathsf{PolySame}_R$ is reflexive, symmetric, and transitive after unfolding Definition 50.30; this is exactly structural list-classifier reflexivity, Definition 36.47, and Definition 36.15 applied to the two trimmed representatives.

Raw addition is compatible with $\mathsf{PolySame}_R$ in both inputs. Indeed, Definition 50.32 reduces both raw sums to sums of their trimmed inputs. The two displayed trimmed-input classifiers give a structural classifier between the two trimmed raw sums by induction on the two list-classifier witnesses in Definition 36.12; the exposed heads are handled by addition congruence, with $0_R \sim_R 0_R$ in the padding branches. Transitivity and symmetry of $\mathsf{PolySame}_R$ compose these three comparisons.

The shift operation preserves $\mathsf{PolySame}_R$. If $\mathsf{PolySame}_R(x, y)$ holds, write the trim decompositions supplied by Definition 50.22 as $x = x_0{+}{+}z$ and $y = y_0{+}{+}w$, with $\mathsf{ListClassifierSpec}(\sim_R, x_0, y_0)$ and zero remainders z, w. Then

$$\mathsf{shift}_R(x) = (\mathsf{cons}(0_R, x_0)){+}{+}z, \qquad \mathsf{shift}_R(y) = (\mathsf{cons}(0_R, y_0)){+}{+}w.$$

The cons classifier built from $0_R \sim_R 0_R$ and the classifier on x_0, y_0, followed by Definition 50.29, gives $\mathsf{PolySame}_R(\mathsf{shift}_R(x), \mathsf{shift}_R(y))$. The same argument, with 0_R replaced by classified heads $h \sim_R h'$, shows that $h \sim_R h'$ and $\mathsf{PolySame}_R(t, t')$ imply

$$\mathsf{PolySame}_R(\mathsf{cons}(h, t), \mathsf{cons}(h', t')).$$

Zero remainders are closed under raw addition: induct on the two zero-remainder witnesses from Definition 50.28. In the cons-cons branch, addition congruence sends $a + b$ to $0_R + 0_R$, and the additive left-zero law reduces that endpoint to 0_R; the cons-nil and nil-cons branches use the additive right-zero and left-zero laws. Hence $\mathsf{rmul}_R(s, \mathsf{nil})$ is a zero remainder for every finite spine s, by induction on s using Definition 50.139: the cons step combines $\mathsf{rscale}_R(a, \mathsf{nil}) = \mathsf{nil}$, the zero-remainder closure of shift_R, and raw-addition closure. Applying Definition 50.29 with common spine nil gives

$$\mathsf{PolySame}_R(\mathsf{nil}, \mathsf{rmul}_R(s, \mathsf{nil})).$$

The key auxiliary recursion is right-cons expansion: for every scalar coefficient a and finite spines x, q,

$$\mathsf{PolySame}_R\big(\mathsf{rmul}_R(q, \mathsf{cons}(a, x)), \mathsf{radd}_R(\mathsf{rscale}_R(a, q), \mathsf{shift}_R(\mathsf{rmul}_R(q, x)))\big).$$

Induct on q. If $q = \mathsf{nil}$, the left side is nil and the right side is a raw sum of zero-remainder spines, so the zero-remainder comparison above applies. For the cons step write $q = \mathsf{cons}(b, y)$. Unfolding Definition 50.139 and the cons-cons branch of Definition 50.30, the two heads are $b \cdot a + 0_R$ and $a \cdot b + 0_R$; multiplicative commutativity and addition congruence classify them. The two tails are

$$\mathsf{radd}_R(\mathsf{rscale}_R(b, x), \mathsf{rmul}_R(y, \mathsf{cons}(a, x)))$$

and

$$\mathsf{radd}_R(\mathsf{rscale}_R(a, y), \mathsf{radd}_R(\mathsf{rscale}_R(b, x), \mathsf{shift}_R(\mathsf{rmul}_R(y, x)))).$$

The induction hypothesis and raw-addition compatibility compare the first tail with

$$\mathsf{radd}_R(\mathsf{rscale}_R(b, x), \mathsf{radd}_R(\mathsf{rscale}_R(a, y), \mathsf{shift}_R(\mathsf{rmul}_R(y, x)))).$$

Raw-addition associativity from Definition 50.153 and raw-addition commutativity from Definition 50.151, transported through raw-addition compatibility, move the first two summands past each other and give the second tail. The cons preservation fact then proves the cons step.

Now induct on p. If $p = \mathsf{nil}$, then $\mathsf{rmul}_R(\mathsf{nil}, q) = \mathsf{nil}$ by Definition 50.139, while $\mathsf{rmul}_R(q, \mathsf{nil})$ is a zero remainder by the preceding paragraph; hence the displayed $\mathsf{PolySame}_R$ holds.

For the cons step write $p = \mathsf{cons}(a, x)$ and assume

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(x, q), \mathsf{rmul}_R(q, x)).$$

Unfolding the left raw product gives

$$\mathsf{rmul}_R(\mathsf{cons}(a, x), q) = \mathsf{radd}_R(\mathsf{rscale}_R(a, q), \mathsf{shift}_R(\mathsf{rmul}_R(x, q))).$$

Shift preservation and raw-addition compatibility transport the induction hypothesis to

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(\mathsf{cons}(a, x), q), \mathsf{radd}_R(\mathsf{rscale}_R(a, q), \mathsf{shift}_R(\mathsf{rmul}_R(q, x)))).$$

Right-cons expansion applied to q, a, x gives the same middle endpoint classified with $\mathsf{rmul}_R(q, \mathsf{cons}(a, x))$. Symmetry and transitivity of $\mathsf{PolySame}_R$ compose the two comparisons, completing the induction. □

Theorem 50.155 (Polynomial multiplication has left zero absorption)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$ and zero endpoint 0_R. Let trim_R be the canonical polynomial trim from Definition 50.20 and Definition 50.22, and let $\mathsf{PolySame}_R$, rmul_R, and $\mathsf{PolyMul}_R$ be as in Definition 50.30 and Definition 50.139. For every finite coefficient spine $q : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(\mathsf{nil}, q), \mathsf{nil}).$$

Consequently the same conclusion holds for every normalized polynomial representative q from Definition 50.3.

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul left zero classified`

Proof. Set $q_0 = \mathsf{trim}_R(q)$. The empty zero-polynomial clause in Definition 50.22 gives $\mathsf{trim}_R(\mathsf{nil}) = \mathsf{nil}$. Hence Definition 50.139 gives

$$\begin{aligned}\mathsf{PolyMul}_R(\mathsf{nil}, q) &= \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{trim}_R(\mathsf{nil}), q_0)) \\ &= \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{nil}, q_0)) \\ &= \mathsf{trim}_R(\mathsf{nil}) \\ &= \mathsf{nil}.\end{aligned}$$

The third equality is the nil clause for rmul_R in Definition 50.139.

Unfolding $\mathsf{PolySame}_R$ by Definition 50.30, the classifier goal is

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(\mathsf{PolyMul}_R(\mathsf{nil}, q)), \mathsf{trim}_R(\mathsf{nil})).$$

The displayed computation and the empty zero-polynomial clause reduce both displayed representatives to nil. The nil-nil clause of Definition 36.12 supplies the structural classifier witness. □

Definition 50.156 (Padded polynomial coefficients and finite Cauchy folds)**.** *Let R be a scalar carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and finite coefficient spines from Definition 36.1. For a finite coefficient spine $x : \mathsf{ListCarrier}(R)$ and $n : \mathsf{Nat}^{\uparrow}$, write $x[n]$ for the padded coefficient defined by*

$$\mathsf{nil}[n] := 0_R, \qquad \mathsf{cons}(a,t)[0] := a, \qquad \mathsf{cons}(a,t)[n+1] := t[n].$$

For finite coefficient spines x, y, z define the finite Cauchy coefficient fold and the finite triple coefficient fold by

$$\mathsf{Cauchy}_R(x,y;n) := \Sigma_{i+j=n} x[i] \cdot y[j], \qquad \mathsf{Triple}_R(x,y,z;n) := \Sigma_{i+j+k=n}(x[i] \cdot y[j]) \cdot z[k].$$

The displayed sums use the finite additive fold of Definition 50.26 over the lexicographic finite spines of the displayed natural-number tuples.

Theorem 50.157 (Polynomial multiplication has right zero absorption)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, and canonical trim trim_R. Let $\mathsf{PolySame}_R$, rmul_R, and $\mathsf{PolyMul}_R$ be as in Definition 50.30 and Definition 50.139. For every finite coefficient spine $p : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(p, \mathsf{nil}), \mathsf{nil}).$$

Consequently the same conclusion holds for every normalized polynomial representative p from Definition 50.3.

Proof. Set

$$p_0 := \mathsf{trim}_R(p), \qquad n_0 := \mathsf{trim}_R(\mathsf{nil}).$$

The empty zero-polynomial clause in Definition 50.22 gives $n_0 = \mathsf{nil}$. Unfolding the normalized product in Definition 50.139 gives

$$\begin{aligned} \mathsf{PolyMul}_R(p, \mathsf{nil}) &= \mathsf{trim}_R(\mathsf{rmul}_R(p_0, n_0)) \\ &= \mathsf{trim}_R(\mathsf{rmul}_R(p_0, \mathsf{nil})) \end{aligned}$$

and

$$\begin{aligned} \mathsf{PolyMul}_R(\mathsf{nil}, p) &= \mathsf{trim}_R(\mathsf{rmul}_R(n_0, p_0)) \\ &= \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{nil}, p_0)). \end{aligned}$$

Apply Definition 50.154 to the finite coefficient spines p_0 and nil. It gives

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(p_0, \mathsf{nil}), \mathsf{rmul}_R(\mathsf{nil}, p_0)).$$

After unfolding $\mathsf{PolySame}_R$ by Definition 50.30, this is the structural classifier comparison

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{trim}_R(\mathsf{rmul}_R(p_0, \mathsf{nil})), \mathsf{trim}_R(\mathsf{rmul}_R(\mathsf{nil}, p_0))).$$

Using the two displayed product computations and trim idempotence from Definition 50.22, this is exactly

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(p, \mathsf{nil}), \mathsf{PolyMul}_R(\mathsf{nil}, p)).$$

On the other hand, Definition 50.155 applied to p gives

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(\mathsf{nil}, p), \mathsf{nil}).$$

Unfold the two $\mathsf{PolySame}_R$ witnesses and compose their structural list-classifier witnesses by Definition 36.15, using the transitivity field of cert_R on scalar heads. Folding back Definition 50.30 yields

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(p, \mathsf{nil}), \mathsf{nil}).$$

Every normalized polynomial representative from Definition 50.3 is, in particular, a finite coefficient spine, so the same argument applies to that carrier representative. □

Lemma 50.158 (Padded coefficient extensionality for the polynomial classifier)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, and canonical trim trim_R from Definition 50.20 and Definition 50.22. If finite coefficient spines $x, y : \mathsf{ListCarrier}(R)$ satisfy $x[n] \sim_R y[n]$ for every $n : \mathsf{Nat}^{\uparrow}$, then*

$$\mathsf{PolySame}_R(x, y).$$

Proof. Put $x_0 := \mathsf{trim}_R(x)$ and $y_0 := \mathsf{trim}_R(y)$. The trailing-zero removal clause in Definition 50.22 gives decompositions $x = x_0{+}{+}t_x$ and $y = y_0{+}{+}t_y$, with $\mathsf{ZeroRem}_R(t_x)$ and $\mathsf{ZeroRem}_R(t_y)$ in the sense of Definition 50.28. Hence $x[n] \sim_R x_0[n]$ and $y[n] \sim_R y_0[n]$ for every n: inside the trimmed prefix the coefficient is unchanged, inside the removed tail the zero-remainder witness classifies the coefficient with 0_R, and after the whole spine both sides are the padding coefficient 0_R. Classifier symmetry and transitivity from cert_R give $x_0[n] \sim_R y_0[n]$ for every n.

The trimmed spines are normalized representatives. If one normalized representative had a last displayed coefficient beyond the length of the other, the padded coefficient comparison at that last index would classify that displayed coefficient with 0_R, contradicting the normalized no-trailing-zero condition in Definition 50.22. Thus x_0 and y_0 have the same finite length. Induction over this common length builds a structural classifier witness: at each head position the hypothesis $x_0[n] \sim_R y_0[n]$ supplies the scalar head comparison, and the induction hypothesis supplies the tail classifier. Therefore

$$\mathsf{ListClassifierSpec}(\sim_R, x_0, y_0).$$

Unfolding $\mathsf{PolySame}_R$ by Definition 50.30 gives the displayed polynomial classifier comparison. □

Lemma 50.159 (Raw Cauchy product coefficient formula)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and the raw operations radd_R, rscale_R, shift_R, and rmul_R from Definition 50.30 and Definition 50.139. For finite coefficient spines $x, y : \mathsf{ListCarrier}(R)$ and every $n : \mathsf{Nat}^{\uparrow}$,*

$$\mathsf{rmul}_R(x, y)[n] \sim_R \mathsf{Cauchy}_R(x, y; n).$$

Proof. Read the scalar source as a $\mathsf{Ring}^{\uparrow}(R)$ source by Definition 44.8. The recursion defining radd_R gives the padded coefficient formula $\mathsf{radd}_R(u, v)[n] \sim_R u[n] + v[n]$ by induction on the two finite spines. The definitions of rscale_R and shift_R give

$$\mathsf{rscale}_R(a, u)[n] \sim_R a \cdot u[n], \qquad \mathsf{shift}_R(u)[0] \sim_R 0_R, \qquad \mathsf{shift}_R(u)[n+1] \sim_R u[n].$$

These comparisons use only zero self-classification, additive congruence, and the additive zero laws from Definition 43.26.

Induct on the first spine x. If $x = \mathsf{nil}$, the raw product is nil by Definition 50.139. Every summand in $\mathsf{Cauchy}_R(\mathsf{nil}, y; n)$ has the form $0_R \cdot y[j]$ and is classified with 0_R by the zero-multiplication row in Definition 43.26. The zero-summand fold theorem Definition 50.27 classifies the Cauchy fold with 0_R, which is the padded coefficient of nil.

For the cons step, write $x = \mathsf{cons}(a, x')$. At coefficient 0, the raw product recursion gives the sum of $a \cdot y[0]$ and the zero head of the shifted recursive product; the additive right-zero law classifies this with $a \cdot y[0]$, which is $\mathsf{Cauchy}_R(\mathsf{cons}(a, x'), y; 0)$. At coefficient $n+1$, the same recursion and the auxiliary coefficient formulas give

$$\mathsf{rmul}_R(\mathsf{cons}(a, x'), y)[n+1] \sim_R a \cdot y[n+1] + \mathsf{rmul}_R(x', y)[n].$$

The induction hypothesis and additive congruence replace the second summand by $\mathsf{Cauchy}_R(x', y; n)$. Splitting the finite index spine $i+j = n+1$ into the head case $i = 0$ and the shifted cases $i = i'+1$ identifies the resulting fold with $\mathsf{Cauchy}_R(\mathsf{cons}(a, x'), y; n+1)$ by Definition 50.26. □

Lemma 50.160 (Raw Cauchy product coefficient associativity)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, and the raw Cauchy product data of Definition 50.139. For finite coefficient spines $x, y, z : \mathsf{ListCarrier}(R)$ and every $n : \mathsf{Nat}^{\uparrow}$,*

$$\mathsf{rmul}_R(\mathsf{rmul}_R(x, y), z)[n] \sim_R \mathsf{rmul}_R(x, \mathsf{rmul}_R(y, z))[n].$$

Proof. Fix n. By Definition 50.159, the left coefficient is classified with $\mathsf{Cauchy}_R(\mathsf{rmul}_R(x, y), z; n)$. For each outer index $s+k = n$, apply Definition 50.159 to replace $\mathsf{rmul}_R(x, y)[s]$ by $\mathsf{Cauchy}_R(x, y; s)$. Multiplication congruence and Definition 50.26 lift these replacements through the outer finite fold. The right-multiplication half of Definition 49.95 then classifies $\mathsf{Cauchy}_R(x, y; s) \cdot z[k]$ with the inner fold over (i, j) satisfying $i+j = s$ of $(x[i] \cdot y[j]) \cdot z[k]$. The nested finite index spine $i+j = s$, $s+k = n$ is the same finite triple spine $i+j+k = n$ in lexicographic order after deleting the bookkeeping index s. The finite fold swap certificate of Definition 49.94, together with fold congruence, classifies the resulting nested fold with $\mathsf{Triple}_R(x, y, z; n)$. Thus the left raw product coefficient is classified with $\mathsf{Triple}_R(x, y, z; n)$.

The right coefficient is handled symmetrically. The coefficient formula first gives $\mathsf{Cauchy}_R(x, \mathsf{rmul}_R(y, z); n)$. Replacing each coefficient of $\mathsf{rmul}_R(y, z)$ by its Cauchy fold and applying the left-multiplication half of Definition 49.95 gives the finite fold over triples $i+j+k = n$ of $x[i] \cdot (y[j] \cdot z[k])$. Scalar multiplication associativity from Definition 43.26 classifies each displayed summand with $(x[i] \cdot y[j]) \cdot z[k]$. Fold congruence therefore classifies the right coefficient with the same $\mathsf{Triple}_R(x, y, z; n)$. Symmetry and transitivity of the scalar classifier compose the two comparisons. □

Theorem 50.161 (Polynomial multiplication associativity over commutative-ring scalars)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Let the classifier be $\sim_R$, the zero endpoint be 0_R, the scalar operations be $+$ and $\cdot$, the canonical trim be trim_R from Definition 50.22, and let rmul_R and $\mathsf{PolyMul}_R$ be the raw and normalized products of Definition 50.139. For finite coefficient spines $p, q, r : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{PolyMul}_R(\mathsf{PolyMul}_R(p, q), r), \mathsf{PolyMul}_R(p, \mathsf{PolyMul}_R(q, r))).$$

Proof. Put $p_0 := \mathsf{trim}_R(p)$, $q_0 := \mathsf{trim}_R(q)$, and $r_0 := \mathsf{trim}_R(r)$. Set $A := \mathsf{PolyMul}_R(\mathsf{PolyMul}_R(p, q), r)$ and $B := \mathsf{PolyMul}_R(p, \mathsf{PolyMul}_R(q, r))$. By Definition 50.158, it is enough to prove $A[n] \sim_R B[n]$ for every $n : \mathsf{Nat}^{\uparrow}$.

Trim preserves padded coefficients by the trailing-zero decomposition in Definition 50.22: for every finite spine u and every n, $u[n] \sim_R \mathsf{trim}_R(u)[n]$. The coefficient formula Definition 50.159 is functorial in both inputs with respect to such pointwise padded-coefficient comparisons, since multiplication congruence compares each Cauchy summand and Definition 50.26 lifts the summand comparisons through the finite fold.

Unfolding Definition 50.139 and using trim idempotence from Definition 50.22, the left normalized product has the same padded coefficients as $\mathsf{rmul}_R(\mathsf{trim}_R(\mathsf{rmul}_R(p_0, q_0)), r_0)$. By trim preservation and the functoriality just recorded, its nth coefficient is classified with $\mathsf{rmul}_R(\mathsf{rmul}_R(p_0, q_0), r_0)[n]$. Similarly, the right normalized product has the same padded coefficients as $\mathsf{rmul}_R(p_0, \mathsf{trim}_R(\mathsf{rmul}_R(q_0, r_0)))$, and its nth coefficient is classified with $\mathsf{rmul}_R(p_0, \mathsf{rmul}_R(q_0, r_0))[n]$.

Applying Definition 50.160 to p_0, q_0, r_0 gives

$$\mathsf{rmul}_R(\mathsf{rmul}_R(p_0, q_0), r_0)[n] \sim_R \mathsf{rmul}_R(p_0, \mathsf{rmul}_R(q_0, r_0))[n].$$

Classifier symmetry and transitivity compose the two trim comparisons with this raw coefficient associativity comparison, yielding $A[n] \sim_R B[n]$ for the fixed n. Since n was arbitrary, Definition 50.158 gives $\mathsf{PolySame}_R(A, B)$, which is the displayed associativity statement. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul associative addFold classified`

Theorem 50.162 (Polynomial singleton evaluation)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, zero endpoint 0_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and Horner evaluation as in Definition 50.133. For every carried scalar coefficient c and every carried scalar point α,*

$$\mathsf{Eval}_{\alpha,R}(\mathsf{cons}(c, \mathsf{nil})) \sim_R c.$$

Proof. Put $s = \mathsf{cons}(c, \mathsf{nil})$. First compute the unnormalized Horner value. The cons and nil recursion clauses in Definition 50.133 identify

$$\mathsf{eval}_{\alpha,R}(s) = c + \alpha \cdot 0_R.$$

The right zero-absorption half of Definition 43.60 gives

$$\alpha \cdot 0_R \sim_R 0_R.$$

Classifier reflexivity for c and addition congruence from Definition 43.26 give

$$c + \alpha \cdot 0_R \sim_R c + 0_R.$$

The additive right-zero theorem Definition 43.31 gives $c + 0_R \sim_R c$, and transitivity yields

$$\mathsf{eval}_{\alpha,R}(s) \sim_R c.$$

By Definition 50.133, $\mathsf{Eval}_{\alpha,R}(s) = \mathsf{eval}_{\alpha,R}(\mathsf{trim}_R(s))$. The one-coefficient trimming boundary in Definition 50.166, read with Definition 50.22, has exactly the empty zero branch and the retained singleton branch. In the empty zero branch, $c \sim_R 0_R$ and $\mathsf{trim}_R(s) = \mathsf{nil}$; the nil Horner equation gives $\mathsf{Eval}_{\alpha,R}(s) = 0_R$, and classifier symmetry gives $0_R \sim_R c$. In the retained singleton branch, $\mathsf{trim}_R(s) = s$, so the raw computation above is the required normalized comparison. These are the two canonical trim branches for a singleton coefficient spine. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonEval singleton`

Theorem 50.163 (Raw polynomial multiplication left-distributes over raw addition)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Let the classifier be $\sim_R$, the zero endpoint be 0_R, the scalar operations be $+$ and $\cdot$, the scalar certificate be $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, and let radd_R, rscale_R, shift_R, and rmul_R be the raw operations of Definition 50.30 and Definition 50.139. For finite coefficient spines $x, y, z : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(x, \mathsf{radd}_R(y, z)), \mathsf{radd}_R(\mathsf{rmul}_R(x, y), \mathsf{rmul}_R(x, z))).$$

Consequently the same classifier comparison holds when x, y, z are normalized polynomial representatives from Definition 50.3.

Lean4 ✓ BEDC.Derived.PolynomialUp.PolynomialSingletonRawMul left distributes over raw add

Proof. By Definition 50.158, it is enough to compare padded coefficients. First record the padded coefficient law for raw addition: for all finite coefficient spines u, v and every $m : \mathsf{Nat}^{\uparrow}$,

$$\mathsf{radd}_R(u, v)[m] \sim_R u[m] + v[m].$$

This is a direct induction over the two finite spines using the four recursion clauses in Definition 50.30. In the mixed cons-nil and nil-cons cases the missing coefficient is the padding endpoint 0_R; in the nil-nil tail the comparison is between 0_R and $0_R + 0_R$, handled by the additive zero laws and classifier symmetry from cert_R.

Fix $n : \mathsf{Nat}^{\uparrow}$. Let the finite split spine for $i + j = n$ carry three scalar spines

$$A_n(i, j) := x[i] \cdot \mathsf{radd}_R(y, z)[j], \qquad B_n(i, j) := x[i] \cdot y[j], \qquad C_n(i, j) := x[i] \cdot z[j].$$

For each split $i + j = n$, the raw-addition coefficient law gives

$$\mathsf{radd}_R(y, z)[j] \sim_R y[j] + z[j].$$

Multiplication congruence transports this under left multiplication by $x[i]$, and scalar left distributivity from Definition 43.26 gives

$$x[i] \cdot \mathsf{radd}_R(y, z)[j] \sim_R (x[i] \cdot y[j]) + (x[i] \cdot z[j]).$$

The matching split order assembles these scalar comparisons into a structural list-classifier witness from Definition 36.12 between A_n and the pointwise sum spine $B_n + C_n$. Applying Definition 50.26 to this witness gives

$$\mathsf{Cauchy}_R(x, \mathsf{radd}_R(y, z); n) \sim_R \mathsf{fold}_{+,R}(B_n + C_n).$$

The finite fold splitting lemma Definition 49.98 then classifies the right endpoint with the sum of the two separate Cauchy folds:

$$\mathsf{fold}_{+,R}(B_n + C_n) \sim_R \mathsf{Cauchy}_R(x, y; n) + \mathsf{Cauchy}_R(x, z; n).$$

Thus

$$\mathsf{Cauchy}_R(x, \mathsf{radd}_R(y, z); n) \sim_R \mathsf{Cauchy}_R(x, y; n) + \mathsf{Cauchy}_R(x, z; n).$$

The raw Cauchy coefficient formula Definition 50.159 gives

$$\mathsf{rmul}_R(x, \mathsf{radd}_R(y, z))[n] \sim_R \mathsf{Cauchy}_R(x, \mathsf{radd}_R(y, z); n).$$

For the other endpoint, the raw-addition coefficient law gives

$$\mathsf{radd}_R(\mathsf{rmul}_R(x, y), \mathsf{rmul}_R(x, z))[n] \sim_R \mathsf{rmul}_R(x, y)[n] + \mathsf{rmul}_R(x, z)[n].$$

Applying Definition 50.159 to the two raw products and then additive congruence gives

$$\mathsf{rmul}_R(x, y)[n] + \mathsf{rmul}_R(x, z)[n] \sim_R \mathsf{Cauchy}_R(x, y; n) + \mathsf{Cauchy}_R(x, z; n).$$

Classifier symmetry and transitivity from cert_R compose the three displayed coefficient comparisons, yielding

$$\mathsf{rmul}_R(x, \mathsf{radd}_R(y, z))[n] \sim_R \mathsf{radd}_R(\mathsf{rmul}_R(x, y), \mathsf{rmul}_R(x, z))[n].$$

Since n was arbitrary, Definition 50.158 gives the displayed $\mathsf{PolySame}_R$ comparison. A normalized polynomial representative is a finite coefficient spine by Definition 50.3, so the final sentence is the same statement restricted to those representatives. □

Theorem 50.164 (Polynomial raw multiplication has singleton-one left identity)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with classifier $\sim_R$, scalar certificate $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, zero endpoint 0_R, multiplicative unit endpoint 1_R, addition $+$, multiplication $\cdot$, canonical trim trim_R, and the raw operations radd_R, rscale_R, shift_R, and rmul_R from Definition 50.30 and Definition 50.139. For every finite coefficient spine $p : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(\mathsf{cons}(1_R, \mathsf{nil}), p), p).$$

Proof. By Definition 50.158, it is enough to prove equality under the padded scalar classifier at every coefficient index. Unfolding the cons clause and the nil clause of raw multiplication in Definition 50.139 gives

$$\mathsf{rmul}_R(\mathsf{cons}(1_R, \mathsf{nil}), p) = \mathsf{radd}_R(\mathsf{rscale}_R(1_R, p), \mathsf{cons}(0_R, \mathsf{nil})).$$

Thus the product is the raw sum of the coefficientwise scalar multiple by 1_R and the one-place shift of the empty recursive product.

First, for every finite coefficient spine u and every index $n : \mathsf{Nat}^{\uparrow}$,

$$\mathsf{radd}_R(u, \mathsf{cons}(0_R, \mathsf{nil}))[n] \sim_R u[n].$$

This is induction on u. If $u = \mathsf{nil}$, the only displayed head is $0_R + 0_R$, classified with 0_R by the additive zero rows in Definition 43.26; all later coefficients are padding coefficients 0_R. If $u = \mathsf{cons}(a, u')$, the head comparison is $(a + 0_R) \sim_R a$ by the additive right-zero row, while the tail comparison is the raw-addition right-nil induction that repeatedly classifies $b + 0_R$ with b and ends at the padding coefficient. These steps use additive congruence, zero self-classification, and classifier transitivity from cert_R.

Second, for every finite coefficient spine p and every index $n : \mathsf{Nat}^{\uparrow}$,

$$\mathsf{rscale}_R(1_R, p)[n] \sim_R p[n].$$

Induct on p. In the nil case both padded coefficients are 0_R. In the cons case, the exposed head is $1_R \cdot a$, classified with a by the multiplicative left-unit row retained in Definition 43.26, and the tail is supplied by the induction hypothesis. After the displayed spine ends, both sides are again the padding coefficient 0_R.

Apply the first coefficient comparison to $u = \mathsf{rscale}_R(1_R, p)$ and compose it with the second comparison. For every $n : \mathsf{Nat}^{\uparrow}$ this gives

$$\mathsf{rmul}_R(\mathsf{cons}(1_R, \mathsf{nil}), p)[n] \sim_R p[n].$$

The padded coefficient extensionality lemma Definition 50.158 converts these pointwise scalar comparisons into the displayed $\mathsf{PolySame}_R$ statement. □

Theorem 50.165 (Raw polynomial multiplication associativity up to add-trim)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. Let the classifier be $\sim_R$, the zero endpoint be 0_R, the scalar operations be $+$ and $\cdot$, the scalar certificate be $\mathsf{cert}_R : \mathsf{NameCert}(R, \sim_R)$, the canonical trim be trim_R from Definition 50.22, and let $\mathsf{PolySame}_R$ and rmul_R be the add-trim classifier and raw Cauchy product of Definition 50.30 and Definition 50.139. For finite coefficient spines $p, q, r : \mathsf{ListCarrier}(R)$,*

$$\mathsf{PolySame}_R(\mathsf{rmul}_R(\mathsf{rmul}_R(p, q), r), \mathsf{rmul}_R(p, \mathsf{rmul}_R(q, r))).$$

Consequently the same comparison holds when p, q, r are normalized polynomial representatives from Definition 50.3.

Proof. Set

$$A := \mathsf{rmul}_R(\mathsf{rmul}_R(p,q),r), \qquad B := \mathsf{rmul}_R(p,\mathsf{rmul}_R(q,r)).$$

By Definition 50.158, it is enough to prove $A[n] \sim_R B[n]$ for every $n : \mathsf{Nat}^{\uparrow}$.

Fix $n : \mathsf{Nat}^{\uparrow}$. The raw Cauchy coefficient associativity lemma Definition 50.160, applied to the finite coefficient spines p, q, r, gives exactly

$$\mathsf{rmul}_R(\mathsf{rmul}_R(p,q),r)[n] \sim_R \mathsf{rmul}_R(p,\mathsf{rmul}_R(q,r))[n].$$

This is $A[n] \sim_R B[n]$. Since n was arbitrary, Definition 50.158 converts the pointwise padded coefficient comparisons into

$$\mathsf{PolySame}_R(A,B).$$

Unfolding the definitions of A and B gives the displayed add-trim classifier comparison. A normalized polynomial representative from Definition 50.3 is a finite coefficient spine, so the final sentence is the same statement restricted to those carried representatives. □

Proof. Put $s = \mathsf{cons}(c, \mathsf{nil})$. First compute the unnormalized Horner value. The cons and nil recursion clauses in Definition 50.133 identify

$$\mathsf{eval}_{\alpha,R}(s) = c + \alpha \cdot 0_R.$$

The right zero-absorption half of Definition 43.60 gives

$$\alpha \cdot 0_R \sim_R 0_R.$$

Classifier reflexivity for c and addition congruence from Definition 43.26 give

$$c + \alpha \cdot 0_R \sim_R c + 0_R.$$

The additive right-zero theorem Definition 43.31 gives $c + 0_R \sim_R c$, and transitivity yields

$$\mathsf{eval}_{\alpha,R}(s) \sim_R c.$$

By Definition 50.133, $\mathsf{Eval}_{\alpha,R}(s) = \mathsf{eval}_{\alpha,R}(\mathsf{trim}_R(s))$. The one-coefficient trimming boundary in Definition 50.166, read with Definition 50.22, has exactly the empty zero branch and the retained singleton branch. In the empty zero branch, $c \sim_R 0_R$ and $\mathsf{trim}_R(s) = \mathsf{nil}$; the nil Horner equation gives $\mathsf{Eval}_{\alpha,R}(s) = 0_R$, and classifier symmetry gives $0_R \sim_R c$. In the retained singleton branch, $\mathsf{trim}_R(s) = s$, so the raw computation above is the required normalized comparison. These are the two canonical trim branches for a singleton coefficient spine. □

Definition 50.166 (Polynomial normalized singleton representative)**.** *Let R be a scalar carrier with classifier $\sim_R$ and zero endpoint 0_R. For a scalar coefficient c, define*

$$\mathsf{NormOne}_R(c) \iff \neg(c \sim_R 0_R).$$

Thus the singleton coefficient spine $\mathsf{cons}(c, \mathsf{nil})$ *is a normalized singleton representative exactly when* $\mathsf{NormOne}_R(c)$ *holds, while* nil *is the empty zero-polynomial representative. This is the one-coefficient boundary of the trailing-zero convention in Definition 50.3 and the canonical trimming rule in Definition 50.22.*

Lean4 (definition) `BEDC.Derived.PolynomialUp.PolynomialSingletonNormalizedRepresentative`

Proposition 50.167 (Raw polynomial addition leaves singleton normal form)**.** *Let R be a scalar ring carrier with classifier $\sim_R$, zero endpoint 0_R, addition $+$, and canonical trim trim_R as in Definition 50.20 and Definition 50.22. Let radd_R and $\mathsf{PolySame}_R$ be the raw addition and normalized raw classifier of Definition 50.30. For scalar sources presented through $\mathsf{CommRing}^{\uparrow}$, Definition 44.8 reads these as the retained $\mathsf{Ring}^{\uparrow}$ addition, zero endpoint, and classifier.*

Suppose a and b are classified nonzero and add to a coefficient classified as zero:

$$\neg(a \sim_R 0_R), \qquad \neg(b \sim_R 0_R), \qquad (a+b) \sim_R 0_R.$$

Set

$$p := \mathsf{cons}(a, \mathsf{nil}), \qquad q := \mathsf{cons}(b, \mathsf{nil}).$$

Then p and q are normalized singleton representatives, but their raw zero-padded sum is not a normalized singleton representative:

$$\mathsf{NormOne}_R(a) \wedge \mathsf{NormOne}_R(b),$$

$$\mathsf{radd}_R(p, q) = \mathsf{cons}(a+b, \mathsf{nil}),$$

$$\neg\mathsf{NormOne}_R(a+b).$$

Moreover its canonical normalized representative is the empty zero representative, and this is exactly what the polynomial classifier records:

$$\mathsf{trim}_R(\mathsf{radd}_R(p, q)) = \mathsf{nil}, \qquad \mathsf{PolySame}_R(\mathsf{radd}_R(p, q), \mathsf{nil}).$$

Proof. By Definition 50.166, the assumptions $\neg(a \sim_R 0_R)$ and $\neg(b \sim_R 0_R)$ are precisely the witnesses $\mathsf{NormOne}_R(a)$ and $\mathsf{NormOne}_R(b)$, so p and q are normalized singleton representatives.

Unfolding p and q, the cons-cons branch of the raw addition recursion in Definition 50.30 gives

$$\mathsf{radd}_R(p, q) = \mathsf{cons}(a+b, \mathsf{radd}_R(\mathsf{nil}, \mathsf{nil})).$$

The nil-nil branch gives $\mathsf{radd}_R(\mathsf{nil}, \mathsf{nil}) = \mathsf{nil}$, hence

$$\mathsf{radd}_R(p, q) = \mathsf{cons}(a+b, \mathsf{nil}).$$

The coefficient hypothesis $(a+b) \sim_R 0_R$ contradicts any witness of $\mathsf{NormOne}_R(a+b)$, since such a witness is a proof of $\neg((a+b) \sim_R 0_R)$. Therefore $\neg\mathsf{NormOne}_R(a+b)$, so the raw singleton spine is not admitted as a normalized singleton representative.

The same coefficient hypothesis activates the trailing-zero clause of the canonical trim from Definition 50.22. Therefore the singleton spine $\mathsf{cons}(a+b, \mathsf{nil})$ trims to nil, and the raw-sum computation above gives

$$\mathsf{trim}_R(\mathsf{radd}_R(p, q)) = \mathsf{nil}.$$

The empty zero-polynomial clause gives $\mathsf{trim}_R(\mathsf{nil}) = \mathsf{nil}$. Unfolding $\mathsf{PolySame}_R$ from Definition 50.30, the classifier goal is

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{nil}, \mathsf{nil}),$$

which is the nil-nil constructor of the finite-spine classifier from Definition 36.12, as isolated by Definition 36.13. Hence $\mathsf{PolySame}_R(\mathsf{radd}_R(p, q), \mathsf{nil})$ holds. □

Lean4 ✓ `BEDC.Derived.PolynomialUp.PolynomialSingletonRawAdd singleton normal form boundary`

Definition 50.168 (Polynomial singleton constant-source schema instance)**.** *The concrete constant-source instance for* $\mathsf{Poly}^{\uparrow}$ *uses the singleton empty-history polynomial carrier. Its coefficient source is the existing singleton scalar carrier, its polynomial constructor is the constant singleton coefficient row* $\mathsf{cons}(c, \mathsf{nil})$*, and its evaluation row is the singleton evaluation readback* PolynomialSingletonEval *at the displayed evaluation endpoint. The classifier is the singleton polynomial classifier on these* BHist *rows, not an abstract coefficient equivalence.*

Theorem 50.169 (Polynomial singleton constant evaluation boundary)**.** *Every constant-source singleton polynomial from Definition 50.168 evaluates to the displayed singleton coefficient endpoint. For a coefficient row* c *and any singleton evaluation endpoint* α*, the readback of the constant spine* $\mathsf{cons}(c, \mathsf{nil})$ *is classified by the singleton polynomial classifier as the same endpoint* c*; at the empty-history endpoint, the zero constant-term readback gives the same classifier boundary. Thus the evaluation classifier exported by this concrete instance is exactly the singleton coefficient classifier.*

Proof. The carrier is the one-coefficient boundary isolated by Definition 50.166 and Definition 50.167: a constant-source row is presented by the singleton spine $\mathsf{cons}(c, \mathsf{nil})$, with no additional coefficient family or abstract scalar quotient.

The singleton evaluation readback applies the checked singleton row PolynomialSingletonEval_singleton, which identifies evaluation of $\mathsf{cons}(c, \mathsf{nil})$ with the coefficient endpoint c under the singleton polynomial classifier. At the empty-history endpoint, PolynomialSingletonEval_zero_constant_term gives the same endpoint boundary for the zero constant-term readback.

Therefore the only classifier visible in the concrete constant-source schema is the singleton polynomial classifier already attached to the coefficient row. Repacking the carrier, constructor, and evaluation readback gives the stated boundary. □

Chapter 51

A Concrete Naming Certificate for $\mathsf{FPS}^{\uparrow}$

The formal power series interface $\mathsf{FPS}^{\uparrow}$ has certificate obligations over a scalar ring from chapter 43 as functions $\mathbb{N} \to R$, interpreted as coefficient sequences without termination. The classifier is pointwise sameness on every index. Formal series addition and Cauchy product are derived operations governed by the ring's certificate fields. Convergence is not asserted: this is the formal carrier, not analytic series.

51.1 Carrier definition

Definition 51.1 (FormalPowerSeries carrier)**.** *Use coefficient functions* $\mathsf{Nat}^{\uparrow} \to R$ *over a certified scalar ring* R*.*

51.2 Concrete singleton zero formal power series instance

Definition 51.2 (Singleton zero formal power series instance)**.** *Let* A_{e} *be the singleton history source of Definition 36.169 at* $a_0 = \mathsf{e}$*. Use the singleton empty-history scalar ring of Definition 43.5. Define the series classifier*

$$\rho_{\mathsf{e}}(h, k) := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h, k).$$

Set the formal-power-series code carrier to A_{e} *on* BHist *endpoints. Represent the zero formal power series by* $Z_{\mathsf{e}} := \mathsf{e}$*, and set the unit formal power series to* $U_{\mathsf{e}} := \mathsf{e}$*. Define the coefficient readout and displayed operations by*

$$\mathsf{coeff}_{\mathsf{e}}(F, n) := \mathsf{e}, \qquad F \oplus_{\mathrm{fps}} G := \mathsf{e}, \qquad F \odot_{\mathrm{fps}} G := \mathsf{e}.$$

Thus every coefficient, zero endpoint, unit endpoint, addition endpoint, and Cauchy-product endpoint is the singleton scalar endpoint e*.*

Lean4 (definition) `BEDC.Derived.FpsUp.FpsSingletonEmptyHistoryCarrier`
Lean4 (definition) `BEDC.Derived.FpsUp.FpsSingletonEmptyHistoryClassifier`

Theorem 51.3 (Singleton zero formal power series laws)**.** *The tuple of Definition 51.2 satisfies the* $\mathsf{FPS}^{\uparrow}$ *law package over the concrete* BHist *carrier:*

1. *Z_{e} and U_{e} are carried by A_{e}.*
2. *Every coefficient query $\mathsf{coeff}_{\mathsf{e}}(F, n)$ is carried by the singleton empty-history scalar ring.*
3. *If $A_{\mathsf{e}}(F)$ and $A_{\mathsf{e}}(G)$, then $A_{\mathsf{e}}(F \oplus_{\mathrm{fps}} G)$ and $A_{\mathsf{e}}(F \odot_{\mathrm{fps}} G)$.*
4. *ρ_{e} is reflexive, symmetric, and transitive on carried series codes.*
5. *Addition is congruent under ρ_{e} and has Z_{e} as left and right zero under ρ_{e}.*
6. *Cauchy product is congruent under ρ_{e} and has U_{e} as left and right unit under ρ_{e}.*
7. *The coefficient ledger of every displayed endpoint is the constant singleton scalar endpoint e, and the scalar clauses are those of Theorem 43.6.*

No convergence field is required.

Proof. The carrier endpoint is supplied by Definition 36.169 at $a_0 = \mathsf{e}$. In particular, Z_{e}, U_{e}, and every displayed operation endpoint reduce to the same carried endpoint e.

For coefficient queries, every value of $\mathsf{coeff}_{\mathsf{e}}(F, n)$ is definitionally e. The scalar side is the singleton empty-history ring of Definition 43.5, and Theorem 43.6 supplies its scalar zero, scalar one, addition, and multiplication clauses.

For addition and Cauchy-product closure, the displayed operations return e for every pair of inputs. The singleton carrier witness therefore discharges both closure obligations without inspecting the input series or the index used in a coefficient view.

Classifier reflexivity, symmetry, and transitivity are inherited from the hsame reflexivity, symmetry, and transitivity laws in the FKernel, together with the two singleton endpoint witnesses required by ρ_{e}. Operation congruence reduces both addition results and both Cauchy-product results to e, so the relation component is again $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$.

The zero laws and unit laws reduce to comparisons of e with e. The same ρ_{e} package gives the left and right zero laws for addition and the left and right unit laws for Cauchy product.

Finally, every coefficient query returns e. Hence the coefficient ledger for the zero series, unit series, sum, and Cauchy product is constant, with no convergence claim involved. □

Lean4 ✓ `BEDC.Derived.FpsUp.fps singleton empty schema laws`

Theorem 51.4 (Singleton coefficient endpoint has empty ledger)**.** *For every displayed singleton formal power series endpoint F and coefficient index n, if F is carried by the singleton source, then*

$$\mathsf{hsame}(\mathsf{coeff}_{\mathsf{e}}(F, n), \mathsf{e})$$

and the coefficient endpoint is classified with the empty scalar endpoint by ρ_{e}.

Proof. The coefficient operation of the singleton formal-power-series instance is definitionally constant at e. The history-sameness part is therefore $\mathsf{hsame}(\mathsf{e}, \mathsf{e})$, and the classifier clause is the triple consisting of the two singleton carrier witnesses for e and the same reflexive history-sameness witness. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCoeff empty ledger`

The $\mathsf{FPS}^{\uparrow}$ schema is instantiated by this concrete BHist carrier and constant coefficient operations, so future Lean targets can be anchored directly in BHist.

Theorem 51.5 (Singleton empty-history FPS semantic name certificate)**.** *The singleton empty-history formal-power-series carrier* $A_{\mathsf{e}}(h) := h\mathsf{hsamee}$ *with classifier*

$$\rho_{\mathsf{e}}(h, k) := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge h\mathsf{hsame}k$$

forms a $\mathsf{SemanticNameCert}(A_{\mathsf{e}}, A_{\mathsf{e}}, A_{\mathsf{e}}, \rho_{\mathsf{e}})$*.*

Proof. The carrier is inhabited by e with hsame reflexivity. Reflexivity, symmetry, and transitivity of the classifier use the corresponding hsame laws, while the two carrier components are part of the classifier witness. Carrier transport across the classifier reads out the right carrier component. Pattern and ledger soundness are identity maps because the source, pattern, and ledger predicates are the same singleton carrier. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonEmptyHistory semanticNameCert`

Theorem 51.6 (Singleton FPS classifier append split empty)**.** *For* $p, q, h : \mathsf{BHist}$*,*

$$\rho_{\mathsf{e}}(\mathsf{append}(p, q), h) \iff p\mathsf{hsamee} \wedge q\mathsf{hsamee} \wedge A_{\mathsf{e}}(h).$$

Proof. In the forward direction, the left carrier component of $\rho_{\mathsf{e}}(\mathsf{append}(p, q), h)$ says $\mathsf{append}(p, q)\mathsf{hsamee}$. The append-empty inversion theorem splits this into $p\mathsf{hsamee}$ and $q\mathsf{hsamee}$, while the right carrier component already gives $A_{\mathsf{e}}(h)$.

Conversely, append-empty introduction turns $p\mathsf{hsamee}$ and $q\mathsf{hsamee}$ into $A_{\mathsf{e}}(\mathsf{append}(p, q))$. Together with $A_{\mathsf{e}}(h)$, transitivity through e supplies the classifier comparison. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonEmptyHistoryClassifier append split empty iff`

Theorem 51.7 (Singleton FPS classifier pair append split empty)**.** *For* $p, q, r, s : \mathsf{BHist}$*,*

$$\rho_{\mathsf{e}}(\mathsf{append}(p, q), \mathsf{append}(r, s)) \iff p\mathsf{hsamee} \wedge q\mathsf{hsamee} \wedge r\mathsf{hsamee} \wedge s\mathsf{hsamee}.$$

Proof. The forward direction applies the one-sided append split theorem to the left endpoint. This gives $p\mathsf{hsamee}$, $q\mathsf{hsamee}$, and the right carrier fact $A_{\mathsf{e}}(\mathsf{append}(r, s))$. The append-empty inversion theorem then splits the right carrier fact into $r\mathsf{hsamee}$ and $s\mathsf{hsamee}$.

Conversely, append-empty introduction turns the two left endpoint witnesses into $A_{\mathsf{e}}(\mathsf{append}(p, q))$ and the two right endpoint witnesses into $A_{\mathsf{e}}(\mathsf{append}(r, s))$. Transitivity of hsame through e supplies the classifier comparison between the two appended histories. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonEmptyHistoryClassifier append pair split empty iff`

Theorem 51.8 (Singleton FPS classifier continuation split empty)**.** *For* $p, q, h : \mathsf{BHist}$*, if* $\mathsf{Cont}(p, q, h)$ *and* $\rho_{\mathsf{e}}(h, \mathsf{e})$*, then*

$$A_{\mathsf{e}}(p) \wedge A_{\mathsf{e}}(q).$$

Proof. Invert the continuation ledger to identify h with $\mathsf{append}(p, q)$. The classifier premise then has the shape handled by Theorem 51.6; projecting its forward direction gives the two empty-history carrier facts for p and q. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonEmptyHistoryClassifier cont split empty`

Theorem 51.9 (Singleton FPS classifier continuation component classifiers)**.** *For* $p, q, h : \mathsf{BHist}$*, if* $\mathsf{Cont}(p, q, h)$ *and* $\rho_{\mathsf{e}}(h, \mathsf{e})$*, then both continuation components are classified with the empty endpoint:*

$$\rho_{\mathsf{e}}(p, \mathsf{e}) \wedge \rho_{\mathsf{e}}(q, \mathsf{e}).$$

Proof. Invert the continuation ledger to put the classifier on $\mathsf{append}(p, q)$. The append split exposes $p\mathsf{hsamee}$ and $q\mathsf{hsamee}$, and each exposed carrier combines with reflexivity of e to rebuild the two component classifiers. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonEmptyHistoryClassifier cont component classifiers`

Theorem 51.10 (Singleton FPS classifier append component classifiers)**.** *For $p, q, h : \mathsf{BHist}$, if the appended endpoint is classified with h,*

$$\rho_{\mathsf{e}}(\mathsf{append}(p, q), h),$$

then both append components are classified with the empty endpoint and the right endpoint is carried:

$$\rho_{\mathsf{e}}(p, \mathsf{e}) \wedge \rho_{\mathsf{e}}(q, \mathsf{e}) \wedge A_{\mathsf{e}}(h).$$

Proof. Apply the append split classifier equivalence of Definition 51.6. This exposes $p\mathsf{hsamee}$, $q\mathsf{hsamee}$, and $A_{\mathsf{e}}(h)$. Each component classifier is then rebuilt from its exposed empty-history carrier, the reflexive carrier of e, and the same exposed history-sameness witness. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonEmptyHistoryClassifier append component classifiers`

Theorem 51.11 (Singleton FPS classifier rejects headed endpoints)**.** *For $h, k : \mathsf{BHist}$, if $\rho_{\mathsf{e}}(h, k)$ holds for the singleton empty-history FPS classifier, then none of h or k is a displayed zero-headed or one-headed endpoint.*

Proof. The classifier exposes singleton carrier witnesses $h\mathsf{hsamee}$ and $k\mathsf{hsamee}$. A displayed headed endpoint for either argument rewrites one of these witnesses into $\mathsf{e}_0(z)\mathsf{hsamee}$ or $\mathsf{e}_1(z)\mathsf{hsamee}$, contradicting the constructor separation lemmas for headed histories and the empty history. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonEmptyHistoryClassifier headed endpoint absurd`

Theorem 51.12 (Singleton FPS classifier continuation commutativity closure)**.** *Let $F, G : \mathsf{BHist}$ be carried by the singleton empty-history FPS carrier A_{e}. If $\mathsf{Cont}(F, G, L)$ and $\mathsf{Cont}(G, F, R)$, then both continuation results are carried by A_{e}, and the singleton FPS classifier relates the two results:*

$$A_{\mathsf{e}}(L) \wedge A_{\mathsf{e}}(R) \wedge \rho_{\mathsf{e}}(L, R).$$

Proof. The carried endpoints F and G are both identified with e. Inverting the two continuation witnesses after those identifications reduces the two results to $\mathsf{append}(\mathsf{e}, \mathsf{e})$, hence to e. The result carriers are the singleton empty-history witnesses, and the classifier follows by pairing those witnesses with reflexivity of hsame at e. □

Theorem 51.21 (FPS Cauchy product classifier congruence)**.** *Let R be a scalar* $\mathsf{CommRing}^{\uparrow}$ *certificate. In the* $\mathsf{FPS}^{\uparrow}(R)$ *interface, let $\sim_{\mathrm{fps}}$ be the pointwise classifier of Definition 51.15. For carried coefficient sequences $F, F', G, G' : \mathsf{Nat}^{\uparrow} \to R$, if*

$$\forall n : \mathsf{Nat}^{\uparrow},\ F_n \sim_R F'_n \qquad \textit{and} \qquad \forall n : \mathsf{Nat}^{\uparrow},\ G_n \sim_R G'_n,$$

then

$$F \odot_{\mathrm{fps}} G \sim_{\mathrm{fps}} F' \odot_{\mathrm{fps}} G'.$$

Equivalently, for every unary coefficient index n,

$$\mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(F,G)) \sim_R \mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(F',G')).$$

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct classifier congruence`

Proof. Read the scalar $\mathsf{CommRing}^{\uparrow}$ certificate through Definition 44.8. The retained $\mathsf{Ring}^{\uparrow}$ certificate has the same scalar carrier, classifier, zero endpoint, addition, and multiplication. Its stability rows include zero self-classification, additive congruence, and multiplication congruence by Definition 43.26.

Fix a unary index n. By Definition 51.20, both product coefficients use the same finite split spine $\mathsf{Split}(n)$. For each displayed split (i,j) with $i+j=n$, the two pointwise FPS hypotheses give $F_i \sim_R F'_i$ and $G_j \sim_R G'_j$. Multiplication congruence transports these two scalar classifier witnesses to

$$F_i \cdot_R G_j \sim_R F'_i \cdot_R G'_j.$$

Structural induction on the finite split spine packages these comparisons as

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{CauchySp}_n(F,G), \mathsf{CauchySp}_n(F',G')).$$

Applying Definition 50.26 to this finite-spine classifier witness gives

$$\mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(F,G)) \sim_R \mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(F',G')).$$

This is exactly the scalar classification of the n-th coefficient of the two Cauchy products by Definition 51.20.

Since n was arbitrary, Definition 51.15 converts the coefficientwise scalar comparison into the FPS classifier judgment

$$F \odot_{\mathrm{fps}} G \sim_{\mathrm{fps}} F' \odot_{\mathrm{fps}} G'.$$

The argument is finite at each coefficient index and uses no convergence field, matching the stability obligations listed in Definition 51.16. □

Definition 51.22 (FPS pointwise addition coefficient)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$ and addition $+_R$. For coefficient sequences $F, G : \mathsf{Nat}^{\uparrow} \to R$ as in Definition 51.1, the formal sum $F \oplus_{\mathrm{fps}} G$ is the coefficient sequence determined by*

$$(F \oplus_{\mathrm{fps}} G)_n := F_n +_R G_n$$

for every unary index $n : \mathsf{Nat}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.FpsUp.FpsSingletonPointwiseAdditionCoeff`

Theorem 51.23 (FPS addition commutativity from scalar additive commutativity)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$ and addition $+_R$. Assume the scalar additive commutativity row retained in Definition 43.26: for all scalar endpoints a, b,*

$$a +_R b \sim_R b +_R a.$$

For a commutative-ring scalar source, Definition 44.8 keeps these additive data unchanged. In the $\mathsf{FPS}^{\uparrow}(R)$ *interface, let* $\sim_{\mathrm{fps}}$ *be the pointwise classifier of Definition 51.15. For carried coefficient sequences* $F, G : \mathsf{Nat}^{\uparrow} \to R$*,*

$$F \oplus_{\mathrm{fps}} G \sim_{\mathrm{fps}} G \oplus_{\mathrm{fps}} F.$$

Equivalently, for every unary coefficient index $n : \mathsf{Nat}^{\uparrow}$*,*

$$(F \oplus_{\mathrm{fps}} G)_n \sim_R (G \oplus_{\mathrm{fps}} F)_n.$$

Proof. Fix a unary index n. By Definition 51.22, the two coefficient endpoints unfold as

$$(F \oplus_{\mathrm{fps}} G)_n = F_n +_R G_n$$

and

$$(G \oplus_{\mathrm{fps}} F)_n = G_n +_R F_n.$$

The scalar additive commutativity row gives

$$F_n +_R G_n \sim_R G_n +_R F_n.$$

Substituting the two coefficient rules gives the displayed scalar comparison at index n:

$$(F \oplus_{\mathrm{fps}} G)_n \sim_R (G \oplus_{\mathrm{fps}} F)_n.$$

Since n was arbitrary, the pointwise classifier specification in Definition 51.15 converts these coefficientwise scalar comparisons into

$$F \oplus_{\mathrm{fps}} G \sim_{\mathrm{fps}} G \oplus_{\mathrm{fps}} F.$$

No convergence or finite-support premise is used; the argument is exactly the pointwise addition closure situation recorded in Definition 51.16. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonPointwiseAdditionCoeff comm classifier`

Lemma 51.24 (Finite additive fold reversal under additive commutativity)**.** *Let* R *be a scalar* $\mathsf{Ring}^{\uparrow}(R)$ *carrier with classifier* $\sim_R$*, zero endpoint* 0_R*, addition* $+_R$*, and finite coefficient fold* $\mathsf{fold}_{+,R}$ *as in Definition 50.26. Assume the scalar classifier equivalence fields and the additive abelian-group, additive congruence, and zero rows retained in Definition 43.26. For every finite carried scalar spine* $xs : \mathsf{ListCarrier}(R)$*,*

$$\mathsf{fold}_{+,R}(xs) \sim_R \mathsf{fold}_{+,R}(\mathsf{reverse}(xs)).$$

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonAddFold reverse empty append hsame`

Proof. First prove by induction on xs that for every carried scalar a,

$$\mathsf{fold}_{+,R}(xs{+}{+}[a]) \sim_R \mathsf{fold}_{+,R}(xs) +_R a.$$

For $xs = \mathsf{nil}$, the two endpoints are $a +_R 0_R$ and $0_R +_R a$. The additive zero laws classify both endpoints with a, and classifier symmetry and transitivity compose the required comparison.

For the cons step write $xs = \mathsf{cons}(x, xs')$. The induction hypothesis gives

$$\mathsf{fold}_{+,R}(xs'{+}{+}[a]) \sim_R \mathsf{fold}_{+,R}(xs') +_R a.$$

Additive congruence transports this under the common left summand x, giving

$$x +_R \mathsf{fold}_{+,R}(xs' {+}{+} [a]) \sim_R x +_R (\mathsf{fold}_{+,R}(xs') +_R a).$$

Additive associativity classifies the right endpoint with $(x +_R \mathsf{fold}_{+,R}(xs')) +_R a$, which is $\mathsf{fold}_{+,R}(\mathsf{cons}(x, xs')) +_R a$ by the cons fold clause. This proves the append-last calculation.

Now induct on xs for the reversal claim. The nil case reduces both folds to 0_R, classified with itself by the zero row. In the cons case write $xs = \mathsf{cons}(a, t)$. The cons fold clause gives $a +_R \mathsf{fold}_{+,R}(t)$. The induction hypothesis and additive congruence classify this endpoint with $a +_R \mathsf{fold}_{+,R}(\mathsf{reverse}(t))$. Additive commutativity then classifies it with $\mathsf{fold}_{+,R}(\mathsf{reverse}(t)) +_R a$. The append-last calculation applied to $\mathsf{reverse}(t)$ gives

$$\mathsf{fold}_{+,R}(\mathsf{reverse}(t) {+}{+} [a]) \sim_R \mathsf{fold}_{+,R}(\mathsf{reverse}(t)) +_R a.$$

Classifier symmetry and transitivity identify the preceding endpoint with $\mathsf{fold}_{+,R}(\mathsf{reverse}(t) {+}{+} [a])$, which is $\mathsf{fold}_{+,R}(\mathsf{reverse}(\mathsf{cons}(a, t)))$ by the finite-list reverse recursion. □

Lemma 51.25 (FPS Cauchy coefficient spine swapped reverse)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read through Definition 44.8 as a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$ and multiplication $\cdot_R$. For carried coefficient sequences $F, G : \mathsf{Nat}^{\uparrow} \to R$ and unary index n, the Cauchy coefficient spines satisfy*

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{CauchySp}_n(F, G), \mathsf{reverse}(\mathsf{CauchySp}_n(G, F))).$$

Proof. Use the finite split spine $\mathsf{Split}(n)$ of Definition 51.20. Its unary recursion lists each decomposition $i + j = n$ exactly once, and the same recursion gives the swapped-reverse spine: after applying $(i, j) \mapsto (j, i)$, the resulting finite spine is $\mathsf{reverse}(\mathsf{Split}(n))$.

Induct on this split recursion. At the base index the only decomposition is $(0, 0)$, and multiplicative commutativity from Definition 44.33 gives

$$F_0 \cdot_R G_0 \sim_R G_0 \cdot_R F_0.$$

For the successor step, the exposed left split $(0, \mathsf{succ}(n))$ is paired with the exposed right split $(\mathsf{succ}(n), 0)$ after swapping and reversing; the middle splits are the successor transports of the predecessor split and are handled by the induction hypothesis. For every matched split (i, j), the coefficient carrier supplies carried endpoints F_i and G_j, and scalar multiplicative commutativity gives

$$F_i \cdot_R G_j \sim_R G_j \cdot_R F_i.$$

The nil and cons clauses of Definition 36.12 assemble these scalar comparisons into the displayed finite-spine classifier witness. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct swapped reverse fold hsame`

Theorem 51.26 (FPS Cauchy product commutativity from CommRing scalars)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate. In the $\mathsf{FPS}^{\uparrow}(R)$ interface, let $\sim_{\mathrm{fps}}$ be the pointwise classifier of Definition 51.15. For carried coefficient sequences $F, G : \mathsf{Nat}^{\uparrow} \to R$,*

$$\forall n : \mathsf{Nat}^{\uparrow}, \quad (F \odot_{\mathrm{fps}} G)_n \sim_R (G \odot_{\mathrm{fps}} F)_n.$$

Consequently,

$$F \odot_{\mathrm{fps}} G \sim_{\mathrm{fps}} G \odot_{\mathrm{fps}} F.$$

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct comm classifier`

Proof. Read the scalar certificate as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. This keeps the scalar classifier, zero endpoint, addition, multiplication, additive abelian-group rows, addition congruence, multiplication congruence, and the finite additive fold used in Definition 51.20. The $\mathsf{CommRing}^{\uparrow}$ layer supplies multiplicative commutativity by Definition 44.33.

Fix $n : \mathsf{Nat}^{\uparrow}$. By Definition 51.25,

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{CauchySp}_n(F, G), \mathsf{reverse}(\mathsf{CauchySp}_n(G, F)))$$

holds. Applying Definition 50.26 gives

$$\mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(F, G)) \sim_R \mathsf{fold}_{+,R}(\mathsf{reverse}(\mathsf{CauchySp}_n(G, F))).$$

By Definition 51.24, applied to $\mathsf{CauchySp}_n(G, F)$, and classifier symmetry,

$$\mathsf{fold}_{+,R}(\mathsf{reverse}(\mathsf{CauchySp}_n(G, F))) \sim_R \mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(G, F)).$$

Classifier transitivity composes the two comparisons. Unfolding Definition 51.20 identifies the composed comparison with

$$(F \odot_{\mathrm{fps}} G)_n \sim_R (G \odot_{\mathrm{fps}} F)_n.$$

Since n was arbitrary, the pointwise classifier specification in Definition 51.15 gives

$$F \odot_{\mathrm{fps}} G \sim_{\mathrm{fps}} G \odot_{\mathrm{fps}} F.$$

□

Theorem 51.27 (FPS Cauchy product distributes over FPS addition)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, multiplication $\cdot_R$, and finite additive fold $\mathsf{fold}_{+,R}$. Let the $\mathsf{FPS}^{\uparrow}(R)$ interface use the pointwise classifier $\sim_{\mathrm{fps}}$ of Definition 51.15, pointwise addition from Definition 51.22, and the Cauchy coefficient spine of Definition 51.20 read over these $\mathsf{Ring}^{\uparrow}$ operations. For carried coefficient sequences $F, G, H : \mathsf{Nat}^{\uparrow} \to R$, the displayed products and sums are carried and*

$$F \odot_{\mathrm{fps}} (G \oplus_{\mathrm{fps}} H) \sim_{\mathrm{fps}} (F \odot_{\mathrm{fps}} G) \oplus_{\mathrm{fps}} (F \odot_{\mathrm{fps}} H)$$

and

$$(F \oplus_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H \sim_{\mathrm{fps}} (F \odot_{\mathrm{fps}} H) \oplus_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H).$$

Equivalently, for every unary coefficient index $n : \mathsf{Nat}^{\uparrow}$,

$$(F \odot_{\mathrm{fps}} (G \oplus_{\mathrm{fps}} H))_n \sim_R ((F \odot_{\mathrm{fps}} G) \oplus_{\mathrm{fps}} (F \odot_{\mathrm{fps}} H))_n$$

and

$$((F \oplus_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H)_n \sim_R ((F \odot_{\mathrm{fps}} H) \oplus_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H))_n.$$

Proof. The carrying clauses follow from the addition and Cauchy-product closure rows in Definition 51.16. By the pointwise classifier of Definition 51.15, it remains to compare the scalar coefficient endpoints at an arbitrary index.

Fix $n : \mathsf{Nat}^{\uparrow}$. For the first comparison, set

$$x_n := \mathsf{CauchySp}_n(F, G), \qquad y_n := \mathsf{CauchySp}_n(F, H).$$

Both finite spines are indexed by the same split spine $\mathsf{Split}(n)$ from Definition 51.20. For each split (i, j) in that spine, pointwise addition gives $(G \oplus_{\mathrm{fps}} H)_j = G_j +_R H_j$. Multiplication congruence and scalar left distributivity from Definition 43.26 give

$$F_i \cdot_R (G \oplus_{\mathrm{fps}} H)_j \sim_R (F_i \cdot_R G_j) +_R (F_i \cdot_R H_j).$$

The matching split order assembles these scalar witnesses, using Definition 36.12, into

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{CauchySp}_n(F, G \oplus_{\mathrm{fps}} H), x_n +_R y_n).$$

Applying Definition 50.26 yields

$$\mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(F, G \oplus_{\mathrm{fps}} H)) \sim_R \mathsf{fold}_{+,R}(x_n +_R y_n).$$

By Definition 49.98,

$$\mathsf{fold}_{+,R}(x_n +_R y_n) \sim_R \mathsf{fold}_{+,R}(x_n) +_R \mathsf{fold}_{+,R}(y_n).$$

Classifier transitivity composes these two comparisons. Unfolding the Cauchy coefficient rule in Definition 51.20 and the pointwise addition rule in Definition 51.22 identifies the composed endpoint comparison with

$$(F \odot_{\mathrm{fps}} (G \oplus_{\mathrm{fps}} H))_n \sim_R ((F \odot_{\mathrm{fps}} G) \oplus_{\mathrm{fps}} (F \odot_{\mathrm{fps}} H))_n.$$

For the second comparison, set

$$u_n := \mathsf{CauchySp}_n(F, H), \qquad v_n := \mathsf{CauchySp}_n(G, H).$$

Again both spines use the same split spine $\mathsf{Split}(n)$. For each split (i, j), pointwise addition gives $(F \oplus_{\mathrm{fps}} G)_i = F_i +_R G_i$. Multiplication congruence and scalar right distributivity from Definition 43.26 give

$$(F \oplus_{\mathrm{fps}} G)_i \cdot_R H_j \sim_R (F_i \cdot_R H_j) +_R (G_i \cdot_R H_j).$$

Thus

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{CauchySp}_n(F \oplus_{\mathrm{fps}} G, H), u_n +_R v_n)$$

holds. The fold congruence theorem Definition 50.26 and the fold-splitting lemma Definition 49.98 classify

$$\mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(F \oplus_{\mathrm{fps}} G, H)) \sim_R \mathsf{fold}_{+,R}(u_n) +_R \mathsf{fold}_{+,R}(v_n).$$

Unfolding Definition 51.20 and Definition 51.22 identifies this scalar comparison with

$$((F \oplus_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H)_n \sim_R ((F \odot_{\mathrm{fps}} H) \oplus_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H))_n.$$

Since n was arbitrary in both calculations, Definition 51.15 packages the coefficientwise scalar comparisons as the two displayed $\mathsf{FPS}^{\uparrow}$ classifier judgments. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct distributes over addition classifier`
Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct left distrib classifier`

Definition 51.28 (FPS threefold Cauchy split spines)**.** *Let R be read as a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, addition $+_R$, multiplication $\cdot_R$, zero endpoint 0_R, and finite additive fold $\mathsf{fold}_{+,R}$. For coefficient sequences $F, G, H : \mathsf{Nat}^{\uparrow} \to R$ and unary index n, define the left and right threefold split spines by*

$$\mathsf{TripSp}^{\ell}_n(F, G, H) := \mathsf{concat}_{(a,k) \in \mathsf{Split}(n)} \mathsf{map}_{(i,j) \in \mathsf{Split}(a)} ((F_i \cdot_R G_j) \cdot_R H_k)$$

and

$$\mathsf{TripSp}^r_n(F,G,H) := \mathsf{concat}_{(i,c)\in\mathsf{Split}(n)}\mathsf{map}_{(j,k)\in\mathsf{Split}(c)}\big(F_i \cdot_R (G_j \cdot_R H_k)\big).$$

The left spine enumerates witnesses (i,j,k) through $(i+j)+k=n$; the right spine enumerates the same triples through $i+(j+k)=n$.

Lean4 (definition) `BEDC.Derived.FpsUp.FpsSingletonThreefoldCauchySplitSpines`

Lemma 51.29 (FPS threefold Cauchy split reassociation)**.** *Let R carry a $\mathsf{CommRing}^\uparrow(R)$ certificate, read through Definition 44.8 as a $\mathsf{Ring}^\uparrow(R)$ certificate. For carried coefficient sequences $F,G,H:\mathsf{Nat}^\uparrow\to R$ and unary index n, the two threefold split folds of Definition 51.72 are scalar-classified:*

$$\mathsf{fold}_{+,R}(\mathsf{TripSp}^\ell_n(F,G,H)) \sim_R \mathsf{fold}_{+,R}(\mathsf{TripSp}^r_n(F,G,H)).$$

Proof. The split spine $\mathsf{Split}(n)$ of Definition 51.20 is finite. Hence each displayed spine in Definition 51.72 is a finite concatenation of finite split spines. Its entries are carried scalars because the coefficient sequences are carried and the multiplication closure row is retained by Definition 43.26.

The left indexing data are quadruples $((a,k),(i,j))$ with $a+k=n$ and $i+j=a$. Sending this data to (i,j,k) gives a triple with $(i+j)+k=n$. The right indexing data are quadruples $((i,c),(j,k))$ with $i+c=n$ and $j+k=c$. Sending this data to (i,j,k) gives a triple with $i+(j+k)=n$. Unary additive associativity for the $\mathsf{Nat}^\uparrow$ split recursion identifies these two triple predicates, and the two reconstructions

$$(i,j,k)\mapsto((i+j,k),(i,j)),\qquad (i,j,k)\mapsto((i,j+k),(j,k))$$

are inverse on the displayed split witnesses.

Apply the split-spine instance of the two-index finite fold swap certificate of Definition 49.94 to this finite reindexing. It reduces the comparison of the two iterated folds to the pointwise scalar comparison attached to a fixed triple (i,j,k). For that triple, the retained multiplicative associativity row in Definition 43.26 gives

$$(F_i \cdot_R G_j)\cdot_R H_k \sim_R F_i \cdot_R (G_j \cdot_R H_k).$$

The fold-swap certificate and Definition 50.26 lift these pointwise comparisons through the finite spines. This is the displayed scalar classification. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonThreefoldCauchySplitSpines classifier`
Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonThreefoldCauchySplitSpines reassociation`

Theorem 51.30 (FPS Cauchy product associativity from CommRing scalars)**.** *Let R carry a $\mathsf{CommRing}^\uparrow(R)$ certificate. In the $\mathsf{FPS}^\uparrow(R)$ interface, let $\sim_{\mathrm{fps}}$ be the pointwise classifier of Definition 51.15. For carried coefficient sequences $F,G,H:\mathsf{Nat}^\uparrow\to R$,*

$$\forall n:\mathsf{Nat}^\uparrow,\quad \big((F\odot_{\mathrm{fps}}G)\odot_{\mathrm{fps}}H\big)_n \sim_R \big(F\odot_{\mathrm{fps}}(G\odot_{\mathrm{fps}}H)\big)_n.$$

Consequently,

$$(F\odot_{\mathrm{fps}}G)\odot_{\mathrm{fps}}H \sim_{\mathrm{fps}} F\odot_{\mathrm{fps}}(G\odot_{\mathrm{fps}}H).$$

Proof. Read the scalar certificate as a $\mathsf{Ring}^\uparrow(R)$ certificate by Definition 44.8. This keeps the scalar classifier, zero endpoint, addition, multiplication, additive abelian-group rows, multiplication congruence, the distributive rows, and multiplicative associativity from Definition 43.26. The finite additive fold is the fold used in Definition 51.20.

Fix $n : \mathsf{Nat}^{\uparrow}$. By Definition 51.20, the left-associated coefficient is

$$\mathsf{fold}_{+,R}\big(\mathsf{CauchySp}_n(F \odot_{\mathrm{fps}} G, H)\big).$$

For a split $(a, k) \in \mathsf{Split}(n)$, the corresponding summand is

$$(F \odot_{\mathrm{fps}} G)_a \cdot_R H_k.$$

Unfolding the inner product at a gives

$$\mathsf{fold}_{+,R}\big(\mathsf{CauchySp}_a(F, G)\big) \cdot_R H_k.$$

The right-multiplication half of Definition 49.95 classifies this endpoint with the inner finite fold over

$$\mathsf{map}_{(i,j)\in\mathsf{Split}(a)}\big((F_i \cdot_R G_j) \cdot_R H_k\big).$$

Applying Definition 50.26 over the outer split spine lifts these inner comparisons and gives

$$\big((F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H\big)_n \sim_R \mathsf{fold}_{+,R}\big(\mathsf{TripSp}^{\ell}_n(F, G, H)\big).$$

The right-associated coefficient expands similarly:

$$\big(F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H)\big)_n = \mathsf{fold}_{+,R}\big(\mathsf{CauchySp}_n(F, G \odot_{\mathrm{fps}} H)\big).$$

For a split $(i, c) \in \mathsf{Split}(n)$, the summand is

$$F_i \cdot_R (G \odot_{\mathrm{fps}} H)_c.$$

Unfolding the inner product at c and applying the left-multiplication half of Definition 49.95 classifies this summand with the inner fold over

$$\mathsf{map}_{(j,k)\in\mathsf{Split}(c)}\big(F_i \cdot_R (G_j \cdot_R H_k)\big).$$

Finite-fold congruence over the outer split spine gives

$$\big(F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H)\big)_n \sim_R \mathsf{fold}_{+,R}\big(\mathsf{TripSp}^{r}_n(F, G, H)\big).$$

By Definition 51.73,

$$\mathsf{fold}_{+,R}\big(\mathsf{TripSp}^{\ell}_n(F, G, H)\big) \sim_R \mathsf{fold}_{+,R}\big(\mathsf{TripSp}^{r}_n(F, G, H)\big).$$

Classifier transitivity composes the left expansion, this threefold split comparison, and the symmetry of the right expansion, giving

$$\big((F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H\big)_n \sim_R \big(F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H)\big)_n.$$

Since n was arbitrary, the pointwise classifier specification of Definition 51.15 yields the displayed $\mathsf{FPS}^{\uparrow}$ classifier judgment. The closure of the two products is the Cauchy-product closure field listed in Definition 51.16, and all folds are finite at the fixed coefficient index. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct carried assoc continuation classifier`

Lemma 51.31 (FPS threefold Cauchy split reassociation over RingUp scalars)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, multiplication $\cdot_R$, and finite additive fold $\mathsf{fold}_{+,R}$. Assume the scalar classifier equivalence fields, multiplication closure, multiplication congruence, and multiplicative associativity rows retained in Definition 43.26. Assume also the split-spine fold-swap field for the triangular finite reindexing of Definition 51.72: the left enumeration by $((a,k),(i,j))$ with $a+k=n$ and $i+j=a$ and the right enumeration by $((i,c),(j,k))$ with $i+c=n$ and $j+k=c$ are fold-swappable after transport to the common triple spine (i,j,k). For carried coefficient sequences $F,G,H : \mathsf{Nat}^{\uparrow} \to R$ and unary index n, the two threefold split folds are scalar-classified: $\mathsf{fold}_{+,R}(\mathsf{TripSp}^{\ell}_n(F,G,H)) \sim_R \mathsf{fold}_{+,R}(\mathsf{TripSp}^{r}_n(F,G,H))$.*

Proof. The split spine $\mathsf{Split}(n)$ from Definition 51.20 is finite. Therefore both threefold spines of Definition 51.72 are finite concatenations of finite coefficient spines. Each displayed summand is carried by the coefficient-carriedness of F, G, and H, followed twice by the multiplication closure row of Definition 43.26. The left spine indexes a summand by data $((a,k),(i,j))$ with $a+k=n$ and $i+j=a$. Sending this data to (i,j,k) gives the triple equation $(i+j)+k=n$. The right spine indexes a summand by data $((i,c),(j,k))$ with $i+c=n$ and $j+k=c$. Sending this data to (i,j,k) gives $i+(j+k)=n$. Unary additive associativity in the split recursion identifies these two triple predicates, and the displayed reconstructions $(i,j,k) \mapsto ((i+j,k),(i,j))$ and $(i,j,k) \mapsto ((i,j+k),(j,k))$ are inverse on the corresponding split witnesses. Apply the assumed split-spine instance of the fold-swap certificate from Definition 49.94 to this finite reindexing. The remaining pointwise scalar comparison at a fixed triple (i,j,k) is exactly the multiplicative associativity row from Definition 43.26: $(F_i \cdot_R G_j) \cdot_R H_k \sim_R F_i \cdot_R (G_j \cdot_R H_k)$. The fold-swap field and the finite additive fold congruence theorem Definition 50.26 lift these pointwise comparisons through the finite spines, yielding the displayed scalar classification. □

Theorem 51.32 (FPS Cauchy product associativity over RingUp scalars)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, multiplication $\cdot_R$, and finite additive fold $\mathsf{fold}_{+,R}$. Assume the scalar classifier equivalence fields, additive fold congruence, multiplication congruence, multiplicative associativity, left and right distributivity, and zero multiplication rows retained in Definition 43.26. Assume the scalar product fold-distribution lemma Definition 49.95 and the split-spine fold-swap field used in Definition 51.52. Let the $\mathsf{FPS}^{\uparrow}(R)$ interface use the pointwise classifier $\sim_{\mathrm{fps}}$ of Definition 51.15. Assume its Cauchy product coefficient at each unary index is the finite-spine rule of Definition 51.20, read over these $\mathsf{Ring}^{\uparrow}$ operations: $(F \odot_{\mathrm{fps}} G)_n := \mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(F,G))$. For carried coefficient sequences $F,G,H : \mathsf{Nat}^{\uparrow} \to R$, the displayed products are carried and $\forall n : \mathsf{Nat}^{\uparrow}, \quad ((F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H)_n \sim_R (F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H))_n$. Consequently, $(F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H \sim_{\mathrm{fps}} F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H)$.*

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct assoc classifier`

Proof. The Cauchy-product closure row in Definition 51.16 carries $F \odot_{\mathrm{fps}} G$ and $G \odot_{\mathrm{fps}} H$, and then carries the two outer products. By the pointwise classifier of Definition 51.15, it remains to compare the scalar coefficients at an arbitrary unary index. Fix $n : \mathsf{Nat}^{\uparrow}$. The left-associated coefficient unfolds to $\mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(F \odot_{\mathrm{fps}} G, H))$. For a split $(a,k) \in \mathsf{Split}(n)$, the corresponding summand is $(F \odot_{\mathrm{fps}} G)_a \cdot_R H_k$. The inner product coefficient at a is $\mathsf{fold}_{+,R}(\mathsf{CauchySp}_a(F,G))$. Applying the right-multiplication half of Definition 49.95 classifies the summand with the inner finite fold over $\mathsf{map}_{(i,j)\in\mathsf{Split}(a)}((F_i \cdot_R G_j) \cdot_R H_k)$. The finite additive fold congruence theorem Definition 50.26 lifts these inner comparisons through the outer split spine, giving $((F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H)_n \sim_R \mathsf{fold}_{+,R}(\mathsf{TripSp}^{\ell}_n(F,G,H))$. The right-associated coefficient unfolds to $\mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(F, G \odot_{\mathrm{fps}} H))$. For a split $(i,c) \in \mathsf{Split}(n)$, the summand is $F_i \cdot_R (G \odot_{\mathrm{fps}} H)_c$. The inner product coefficient at c

is $\mathsf{fold}_{+,R}(\mathsf{CauchySp}_c(G,H))$. Applying the left-multiplication half of Definition 49.95 classifies this summand with the inner finite fold over $\mathsf{map}_{(j,k)\in\mathsf{Split}(c)}(F_i \cdot_R (G_j \cdot_R H_k))$. Again Definition 50.26 lifts through the outer split spine and gives $(F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H))_n \sim_R \mathsf{fold}_{+,R}(\mathsf{TripSp}^r_n(F,G,H))$. By Definition 51.52, $\mathsf{fold}_{+,R}(\mathsf{TripSp}^\ell_n(F,G,H)) \sim_R \mathsf{fold}_{+,R}(\mathsf{TripSp}^r_n(F,G,H))$. Classifier transitivity composes the left expansion, this threefold split comparison, and the symmetry of the right expansion, giving $((F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H)_n \sim_R (F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H))_n$. Since n was arbitrary, Definition 51.15 packages these coefficientwise scalar comparisons as the displayed $\mathsf{FPS}^\uparrow$ classifier judgment. □

Theorem 51.33 (FPS Cauchy product multiplicative semigroup laws)**.** *Let R carry a $\mathsf{Ring}^\uparrow(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, multiplication $\cdot_R$, and finite additive fold $\mathsf{fold}_{+,R}$. Let the $\mathsf{FPS}^\uparrow(R)$ carrier be the coefficientwise carrier of Definition 51.1, let its classifier be the pointwise classifier $\sim_{\mathrm{fps}}$ of Definition 51.15, and let its Cauchy product use the coefficient rule of Definition 51.20. For carried coefficient sequences, these data form the concrete multiplicative semigroup interface consumed by the algebraic formal-power-series layer:*

1. *If F and G are carried, then $F \odot_{\mathrm{fps}} G$ is carried.*
2. *If $F \sim_{\mathrm{fps}} F'$ and $G \sim_{\mathrm{fps}} G'$, then $F \odot_{\mathrm{fps}} G \sim_{\mathrm{fps}} F' \odot_{\mathrm{fps}} G'$.*
3. *$(F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H \sim_{\mathrm{fps}} F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H)$.*

Proof. The carrier part is exactly the Cauchy-product closure row retained by Definition 51.16. With F and G carried, that row returns a carried product $F \odot_{\mathrm{fps}} G$ in the carrier of Definition 51.1.

For compatibility with the classifier, apply Definition 51.21. Its hypotheses are precisely the carried coefficient sequences together with the two pointwise classifier comparisons supplied by Definition 51.15, and its conclusion is the displayed congruence of Cauchy products.

The associativity law is Definition 51.53, read over the same scalar certificate, pointwise classifier, and coefficient rule. The theorem first carries the two intermediate products by Definition 51.16, then identifies the two associated products under $\sim_{\mathrm{fps}}$. These three clauses are exactly the multiplicative semigroup interface required downstream. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct multiplicative semigroup laws`

Definition 51.34 (FPS Cauchy product unit series)**.** *Let R carry a $\mathsf{Ring}^\uparrow(R)$ certificate with multiplicative unit endpoint 1_R and additive zero endpoint 0_R. The Cauchy-product unit series $1_{\mathrm{fps}} : \mathsf{Nat}^\uparrow \to R$ is the coefficient sequence determined by*

$$(1_{\mathrm{fps}})_0 := 1_R$$

and

$$(1_{\mathrm{fps}})_{\mathsf{succ}(n)} := 0_R$$

for every unary index $n : \mathsf{Nat}^\uparrow$.

Lean4 (definition) `BEDC.Derived.FpsUp.FpsSingletonCauchyProductUnitSeries`
Lean4 (definition) `BEDC.Derived.FpsUp.FpsSingletonUnitSeriesCoeff`

Theorem 51.35 (FPS Cauchy product unit laws)**.** *Let R carry a $\mathsf{Ring}^\uparrow(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, multiplicative unit endpoint 1_R, addition $+_R$, multiplication $\cdot_R$, and finite additive fold $\mathsf{fold}_{+,R}$. Assume the scalar classifier equivalence fields, zero self-classification, additive congruence, additive zero rows, multiplication closure, multiplication congruence, left*

and right multiplicative unit rows, and left and right zero multiplication rows retained in Definition 43.26. Let the $\mathsf{FPS}^{\uparrow}(R)$ *interface use the pointwise classifier* $\sim_{\mathrm{fps}}$ *of Definition 51.15 and the Cauchy coefficient rule of Definition 51.20, read over these* $\mathsf{Ring}^{\uparrow}$ *operations. If* $F : \mathsf{Nat}^{\uparrow} \to R$ *is carried, then* 1_{fps} *is carried, the products* $1_{\mathrm{fps}} \odot_{\mathrm{fps}} F$ *and* $F \odot_{\mathrm{fps}} 1_{\mathrm{fps}}$ *are carried, and*

$$1_{\mathrm{fps}} \odot_{\mathrm{fps}} F \sim_{\mathrm{fps}} F \qquad \textit{and} \qquad F \odot_{\mathrm{fps}} 1_{\mathrm{fps}} \sim_{\mathrm{fps}} F.$$

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct unit laws`

Proof. The unit series is carried coefficientwise. At index 0, the coefficient is 1_R, carried by the multiplicative monoid source inside the $\mathsf{Ring}^{\uparrow}$ certificate. At every successor index, the coefficient is 0_R, carried by the zero endpoint row retained in Definition 43.26. The Cauchy-product closure row in Definition 51.16 then carries both products.

For the left unit law, fix a unary index n. If $n = 0$, Definition 51.58 reduces the product coefficient to the singleton fold on $(1_{\mathrm{fps}})_0 \cdot_R F_0$. The coefficient rule of Definition 51.55 reads this as $1_R \cdot_R F_0$, and the scalar multiplicative left-unit row from Definition 43.26 classifies it with F_0. The singleton finite-fold endpoint is transported by the scalar additive zero row and classifier transitivity.

Now let $n = \mathsf{succ}(m)$. The finite split recursion for $\mathsf{Split}(n)$ has exactly one summand whose left index is 0 and all remaining summands have successor left index. The head summand is $1_R \cdot_R F_n$ and is classified with F_n by the scalar left-unit row. Every remaining summand has the form $(1_{\mathrm{fps}})_{\mathsf{succ}(i)} \cdot_R F_j$, hence $0_R \cdot_R F_j$, and the left zero multiplication row classifies it with 0_R.

The zero-summand part of the tail is folded to 0_R by Definition 50.27. Additive fold congruence transports the pointwise comparisons through the finite split spine, and the additive right-zero row removes the folded zero tail. Thus $(1_{\mathrm{fps}} \odot_{\mathrm{fps}} F)_n \sim_R F_n$.

For the right unit law, the zero index is analogous: Definition 51.58 gives the singleton fold on $F_0 \cdot_R (1_{\mathrm{fps}})_0$, the unit-series coefficient rule reads the right factor as 1_R, and the scalar right-unit row classifies the coefficient with F_0.

At $n = \mathsf{succ}(m)$, the finite split recursion has exactly one summand whose right index is 0 and all remaining summands have successor right index. The head summand is $F_n \cdot_R 1_R$ and is classified with F_n by the scalar right-unit row. Each remaining summand is $F_i \cdot_R 0_R$, classified with 0_R by the right zero multiplication row. The same zero-summand fold theorem, additive fold congruence, and additive zero row collapse the tail.

Since n was arbitrary in both directions, Definition 51.15 packages the coefficientwise scalar comparisons as the two displayed $\mathsf{FPS}^{\uparrow}$ classifier judgments. □

Theorem 51.36 (FPS Cauchy product multiplicative monoid laws)**.** *Let* R *carry a* $\mathsf{Ring}^{\uparrow}(R)$ *certificate with scalar classifier* $\sim_R$*, zero endpoint* 0_R*, multiplicative unit endpoint* 1_R*, addition* $+_R$*, multiplication* $\cdot_R$*, and finite additive fold* $\mathsf{fold}_{+,R}$*. Let the* $\mathsf{FPS}^{\uparrow}(R)$ *carrier be the coefficientwise carrier of Definition 51.1, let its classifier be the pointwise classifier* $\sim_{\mathrm{fps}}$ *of Definition 51.15, let its multiplication be the Cauchy product of Definition 51.20, and let its unit be* 1_{fps} *from Definition 51.55. For carried coefficient sequences, these data form the concrete multiplicative monoid interface consumed by the algebraic formal-power-series layer:*

1. *If* F *and* G *are carried, then* $F \odot_{\mathrm{fps}} G$ *is carried.*
2. *If* $F \sim_{\mathrm{fps}} F'$ *and* $G \sim_{\mathrm{fps}} G'$*, then* $F \odot_{\mathrm{fps}} G \sim_{\mathrm{fps}} F' \odot_{\mathrm{fps}} G'$*.*
3. $(F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H \sim_{\mathrm{fps}} F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H)$*.*
4. 1_{fps} *is carried, and* $1_{\mathrm{fps}} \odot_{\mathrm{fps}} F \sim_{\mathrm{fps}} F$ *and* $F \odot_{\mathrm{fps}} 1_{\mathrm{fps}} \sim_{\mathrm{fps}} F$*.*

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct multiplicative monoid laws`

Proof. The first three clauses are exactly Definition 51.54, read over the displayed carrier, classifier, and Cauchy-product coefficient rule.

The unit carrier and the two unit comparisons are Definition 51.56. That theorem supplies the coefficientwise split at zero and successor indices, reduces the off-axis Cauchy summands by scalar zero multiplication, collapses the folded zero tails, and repackages the remaining coefficient comparisons by the pointwise classifier of Definition 51.15. Together with the semigroup clauses, these fields are the required multiplicative monoid surface. □

Lemma 51.37 (FPS zero-index Cauchy spine)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with multiplication $\cdot_R$. For coefficient sequences $F, G : \mathsf{Nat}^{\uparrow} \to R$, the split spine used by Definition 51.20 at the zero index is the singleton split $\mathsf{Split}(0) = \mathsf{cons}((0,0), \mathsf{nil})$. Consequently, $\mathsf{CauchySp}_0(F, G) = \mathsf{cons}(F_0 \cdot_R G_0, \mathsf{nil})$.*

Proof. The split spine is generated by the $\mathsf{Nat}^{\uparrow}$ recursion in Definition 51.20. The zero branch has no predecessor index and contains only the decomposition of 0 as $0 + 0$. Applying the displayed map defining $\mathsf{CauchySp}_n(F, G)$ to this singleton split replaces the split entry by its scalar product $F_0 \cdot_R G_0$. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct zero index spine`

Theorem 51.38 (FPS Cauchy product constant coefficient)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, multiplication $\cdot_R$, and finite additive fold $\mathsf{fold}_{+,R}$. Let the $\mathsf{FPS}^{\uparrow}(R)$ interface use the Cauchy product coefficient rule of Definition 51.20, read over these $\mathsf{Ring}^{\uparrow}$ operations. For carried coefficient sequences $F, G : \mathsf{Nat}^{\uparrow} \to R$, $(F \odot_{\mathrm{fps}} G)_0 \sim_R F_0 \cdot_R G_0$.*

Proof. Put $x := F_0 \cdot_R G_0$. Since F and G are carried coefficient sequences, the multiplication closure row retained in Definition 43.26 carries x. By Definition 51.58 and the product coefficient rule in Definition 51.20, $(F \odot_{\mathrm{fps}} G)_0 = \mathsf{fold}_{+,R}(\mathsf{cons}(x, \mathsf{nil}))$. The finite fold clauses displayed in Definition 50.26 identify this endpoint with $x +_R 0_R$. The additive right-zero theorem Definition 43.31, applied in the scalar ring to x, gives $x +_R 0_R \sim_R x$. Substituting $x = F_0 \cdot_R G_0$ gives the scalar classifier comparison. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct constant coefficient`

Definition 51.39 (FPS pointwise additive monoid instance)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, and the scalar stability rows retained in Definition 43.26. Using the coefficientwise carrier of Definition 51.1, the additive carrier for the formal-power-series layer is*

$$\mathsf{FPSCarrier}_R := \{F : \mathsf{Nat}^{\uparrow} \to R \mid F \textit{ is carried coefficientwise}\}.$$

Its classifier is the pointwise classifier $\sim_{\mathrm{fps}}$ of Definition 51.15. Its binary operation is the pointwise operation $\oplus_{\mathrm{fps}}$ of Definition 51.22:

$$(F \oplus_{\mathrm{fps}} G)_n := F_n +_R G_n.$$

Its zero endpoint is the zero series 0_{fps} with coefficient rule $(0_{\mathrm{fps}})_n := 0_R$ for every unary index $n : \mathsf{Nat}^{\uparrow}$.

Theorem 51.40 (FPS pointwise additive monoid laws)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, and the scalar classifier equivalence, zero self-classification, addition closure, addition congruence, additive associativity, and additive zero rows retained in Definition 43.26. For the concrete data of Definition 51.60, the following laws hold for carried coefficient sequences:*

1. *0_{fps} is carried, and $F \oplus_{\mathrm{fps}} G$ is carried whenever F and G are carried.*
2. *If $F \sim_{\mathrm{fps}} F'$ and $G \sim_{\mathrm{fps}} G'$, then $F \oplus_{\mathrm{fps}} G \sim_{\mathrm{fps}} F' \oplus_{\mathrm{fps}} G'$.*
3. *$(F \oplus_{\mathrm{fps}} G) \oplus_{\mathrm{fps}} H \sim_{\mathrm{fps}} F \oplus_{\mathrm{fps}} (G \oplus_{\mathrm{fps}} H)$.*
4. *$0_{\mathrm{fps}} \oplus_{\mathrm{fps}} F \sim_{\mathrm{fps}} F$ and $F \oplus_{\mathrm{fps}} 0_{\mathrm{fps}} \sim_{\mathrm{fps}} F$.*

Thus $\mathsf{FPSCarrier}_R$ with $\sim_{\mathrm{fps}}$, $\oplus_{\mathrm{fps}}$, and 0_{fps} is the concrete additive monoid interface consumed by the formal-power-series algebra layer.

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonPointwiseAdditionCoeff zero laws`

Proof. The carrier clause follows coefficientwise from Definition 51.1. The zero series is carried because each coefficient is 0_R, and the scalar zero self-classification row in Definition 43.26 supplies the carried scalar endpoint. If F and G are carried, then each coefficient $F_n +_R G_n$ is carried by scalar addition closure. By Definition 51.22, these coefficients are exactly the coefficients of $F \oplus_{\mathrm{fps}} G$.

For congruence, fix $n : \mathsf{Nat}^{\uparrow}$. The hypotheses $F \sim_{\mathrm{fps}} F'$ and $G \sim_{\mathrm{fps}} G'$ become scalar comparisons $F_n \sim_R F'_n$ and $G_n \sim_R G'_n$ by Definition 51.15. Scalar addition congruence from Definition 43.26 gives

$$F_n +_R G_n \sim_R F'_n +_R G'_n.$$

Using Definition 51.22 on both sides and then Definition 51.15 packages the coefficientwise comparisons as $F \oplus_{\mathrm{fps}} G \sim_{\mathrm{fps}} F' \oplus_{\mathrm{fps}} G'$.

Associativity is the existing pointwise associativity theorem Definition 51.51, read with the same carrier, classifier, operation, and scalar associativity row.

It remains to check the zero laws. For the left zero law, fix $n : \mathsf{Nat}^{\uparrow}$. The definitions give

$$(0_{\mathrm{fps}} \oplus_{\mathrm{fps}} F)_n = 0_R +_R F_n.$$

The scalar additive left-zero row retained in Definition 43.26 classifies this endpoint with F_n. Since n was arbitrary, Definition 51.15 yields $0_{\mathrm{fps}} \oplus_{\mathrm{fps}} F \sim_{\mathrm{fps}} F$.

For the right zero law, fix $n : \mathsf{Nat}^{\uparrow}$. The definitions give

$$(F \oplus_{\mathrm{fps}} 0_{\mathrm{fps}})_n = F_n +_R 0_R.$$

The scalar right-zero theorem Definition 43.31, applied in the scalar ring to F_n, classifies this endpoint with F_n. Again Definition 51.15 packages the coefficientwise comparisons as $F \oplus_{\mathrm{fps}} 0_{\mathrm{fps}} \sim_{\mathrm{fps}} F$. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonPointwiseAdditiveMonoid laws`

Definition 51.41 (FPS coefficientwise additive inverse)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, and scalar additive inverse operation $-_R$. For a carried coefficient sequence $F : \mathsf{Nat}^{\uparrow} \to R$, the coefficientwise FPS inverse $-_{\mathrm{fps}}F$ is the coefficient sequence determined by*

$$(-_{\mathrm{fps}}F)_n := -_R(F_n)$$

for every unary index $n : \mathsf{Nat}^{\uparrow}$*. More generally, a sequence* $N : \mathsf{Nat}^{\uparrow} \to R$ *is coefficientwise inverse data for* F *when* N *is carried and, for every* $n : \mathsf{Nat}^{\uparrow}$*,*

$$N_n \sim_R -_R(F_n).$$

Lean4 (definition) `BEDC.Derived.FpsUp.FpsSingletonCoeffwiseInverse`

Theorem 51.42 (FPS coefficientwise additive inverse zero laws)**.** *Let* R *carry a* $\mathsf{Ring}^{\uparrow}(R)$ *certificate with scalar classifier* $\sim_R$*, zero endpoint* 0_R*, addition* $+_R$*, and scalar additive inverse operation* $-_R$*. Assume the scalar classifier equivalence, zero self-classification, addition closure, addition congruence, additive inverse closure, and additive left inverse rows retained in Definition 43.26; assume also the scalar right inverse law of Definition 43.27 for this addition and inverse. Let the* $\mathsf{FPS}^{\uparrow}(R)$ *interface use the pointwise classifier* $\sim_{\mathrm{fps}}$ *of Definition 51.15, pointwise addition from Definition 51.22, and zero series* 0_{fps} *from Definition 51.60. If* $F : \mathsf{Nat}^{\uparrow} \to R$ *is carried and* $N : \mathsf{Nat}^{\uparrow} \to R$ *is coefficientwise inverse data for* F *in the sense of Definition 51.62, then* $F \oplus_{\mathrm{fps}} N$ *and* $N \oplus_{\mathrm{fps}} F$ *are carried and*

$$F \oplus_{\mathrm{fps}} N \sim_{\mathrm{fps}} 0_{\mathrm{fps}} \qquad \textit{and} \qquad N \oplus_{\mathrm{fps}} F \sim_{\mathrm{fps}} 0_{\mathrm{fps}}.$$

Equivalently, for every unary coefficient index $n : \mathsf{Nat}^{\uparrow}$*,*

$$(F \oplus_{\mathrm{fps}} N)_n \sim_R (0_{\mathrm{fps}})_n \qquad \textit{and} \qquad (N \oplus_{\mathrm{fps}} F)_n \sim_R (0_{\mathrm{fps}})_n.$$

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCoeffwiseInverse zero laws`

Proof. The definition of coefficientwise inverse data carries N. The pointwise addition closure row in Definition 51.16 carries $F \oplus_{\mathrm{fps}} N$ and $N \oplus_{\mathrm{fps}} F$, and Definition 51.61 carries the zero series.

Fix $n : \mathsf{Nat}^{\uparrow}$. The inverse-data hypothesis gives

$$N_n \sim_R -_R(F_n).$$

By Definition 51.22,

$$(F \oplus_{\mathrm{fps}} N)_n = F_n +_R N_n.$$

Scalar classifier reflexivity at F_n and scalar addition congruence transport the inverse-data comparison under the common left summand:

$$F_n +_R N_n \sim_R F_n +_R (-_R(F_n)).$$

The scalar right inverse law Definition 43.27 classifies the right endpoint with 0_R. Since Definition 51.60 gives $(0_{\mathrm{fps}})_n := 0_R$, transitivity gives

$$(F \oplus_{\mathrm{fps}} N)_n \sim_R (0_{\mathrm{fps}})_n.$$

For the other order, Definition 51.22 gives

$$(N \oplus_{\mathrm{fps}} F)_n = N_n +_R F_n.$$

Scalar addition congruence transports the same inverse-data comparison under the common right summand:

$$N_n +_R F_n \sim_R (-_R(F_n)) +_R F_n.$$

The scalar additive left inverse row retained in Definition 43.26 classifies this endpoint with 0_R, and the zero-series coefficient rule again gives $(0_{\mathrm{fps}})_n := 0_R$. Thus

$$(N \oplus_{\mathrm{fps}} F)_n \sim_R (0_{\mathrm{fps}})_n.$$

Since n was arbitrary, Definition 51.15 packages the two coefficientwise scalar comparisons as the two displayed $\mathsf{FPS}^{\uparrow}$ classifier judgments. □

Theorem 51.43 (FPS pointwise additive group laws)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, and scalar additive inverse operation $-_R$. Assume the scalar classifier equivalence, zero self-classification, addition closure, addition congruence, additive associativity, additive zero rows, additive inverse closure, and both scalar additive inverse laws retained in Definition 43.26 and Definition 43.27. Then the data of Definition 51.60, together with the coefficientwise inverse operation $-_{\mathrm{fps}}$ of Definition 51.62, form the concrete additive group interface on $\mathsf{FPSCarrier}_R$: 0_{fps} is carried, $F \oplus_{\mathrm{fps}} G$ is carried whenever F and G are carried, $\oplus_{\mathrm{fps}}$ is pointwise congruent, $\oplus_{\mathrm{fps}}$ is associative under $\sim_{\mathrm{fps}}$, both zero laws hold under $\sim_{\mathrm{fps}}$, $-_{\mathrm{fps}}F$ is carried whenever F is carried, $-_{\mathrm{fps}}F$ is coefficientwise inverse data for F, and both inverse-zero laws*

$$F \oplus_{\mathrm{fps}} (-_{\mathrm{fps}}F) \sim_{\mathrm{fps}} 0_{\mathrm{fps}} \qquad \textit{and} \qquad (-_{\mathrm{fps}}F) \oplus_{\mathrm{fps}} F \sim_{\mathrm{fps}} 0_{\mathrm{fps}}$$

hold for every carried coefficient sequence $F : \mathsf{Nat}^{\uparrow} \to R$.

Proof. The carrier, congruence, associativity, and zero-law fields are exactly the fields supplied by Definition 51.61, read over the carrier, classifier, pointwise addition, and zero series fixed in Definition 51.60.

It remains to fit the inverse operation into the same public algebra package. Let $F : \mathsf{Nat}^{\uparrow} \to R$ be carried. For each coefficient index $n : \mathsf{Nat}^{\uparrow}$, scalar additive inverse closure carries $-_R(F_n)$, so the coefficient rule $(-_{\mathrm{fps}}F)_n := -_R(F_n)$ carries the whole sequence $-_{\mathrm{fps}}F$. The same coefficient rule, together with scalar classifier reflexivity at $-_R(F_n)$, makes $-_{\mathrm{fps}}F$ coefficientwise inverse data for F in the sense of Definition 51.62.

Apply Definition 51.63 with $N = -_{\mathrm{fps}}F$. Its hypotheses are precisely the retained scalar inverse, congruence, closure, and zero rows, plus the right inverse law Definition 43.27. The conclusion gives the two displayed inverse-zero laws under $\sim_{\mathrm{fps}}$.

Thus the ten fields just listed form a single concrete additive group interface for the downstream formal-power-series algebra layer: zero carrier, sum carrier, pointwise congruence, associativity, left zero, right zero, inverse carrier, inverse-data fit, right inverse-zero, and left inverse-zero. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonPointwiseAdditiveGroup laws`

Theorem 51.44 (FPS zero series absorbs Cauchy product over RingUp scalars)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, multiplication $\cdot_R$, and finite additive fold $\mathsf{fold}_{+,R}$. Assume the scalar classifier equivalence fields, zero self-classification, additive congruence, additive left-zero, multiplication closure, and left and right zero multiplication rows retained in Definition 43.26. Let the $\mathsf{FPS}^{\uparrow}(R)$ interface use the pointwise classifier $\sim_{\mathrm{fps}}$ of Definition 51.15, the zero series $Z := 0_{\mathrm{fps}}$ of Definition 51.60, and the Cauchy coefficient rule of Definition 51.20, read over these $\mathsf{Ring}^{\uparrow}$ operations. For every carried coefficient sequence $F : \mathsf{Nat}^{\uparrow} \to R$, the two Cauchy products $Z \odot_{\mathrm{fps}} F$ and $F \odot_{\mathrm{fps}} Z$ are carried and*

$$Z \odot_{\mathrm{fps}} F \sim_{\mathrm{fps}} Z \qquad \textit{and} \qquad F \odot_{\mathrm{fps}} Z \sim_{\mathrm{fps}} Z.$$

Equivalently, for every unary coefficient index $n : \mathsf{Nat}^{\uparrow}$,

$$(Z \odot_{\mathrm{fps}} F)_n \sim_R Z_n \qquad \textit{and} \qquad (F \odot_{\mathrm{fps}} Z)_n \sim_R Z_n.$$

Proof. The zero series is carried coefficientwise because Definition 51.60 gives $Z_n = 0_R$ for every n, and the scalar zero self-classification row supplies the carried scalar endpoint. The Cauchy-product closure row in Definition 51.16 therefore carries $Z \odot_{\mathrm{fps}} F$ and $F \odot_{\mathrm{fps}} Z$ from the carriedness of Z and F.

Fix $n : \mathsf{Nat}^{\uparrow}$, and write ZeroSp_n for the finite spine indexed by $\mathsf{Split}(n)$ whose every displayed entry is 0_R. For the left product, each split $(i, j) \in \mathsf{Split}(n)$ contributes the scalar summand

$$Z_i \cdot_R F_j.$$

The zero-series coefficient rule gives the scalar comparison $Z_i \sim_R 0_R$. Together with scalar classifier reflexivity at F_j, the multiplication-congruence row retained in Definition 43.26 compares $Z_i \cdot_R F_j$ with $0_R \cdot_R F_j$; the left zero multiplication row retained in Definition 43.26 then classifies $0_R \cdot_R F_j$ with 0_R. If the coefficient comparison, multiplication-congruence step, or zero multiplication row is read in the opposite orientation, classifier symmetry supplies the displayed orientation. Structural induction on the finite split spine, using the nil and cons clauses of Definition 36.12, assembles these pointwise scalar comparisons into

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{CauchySp}_n(Z, F), \mathsf{ZeroSp}_n).$$

Applying Definition 50.27 to this all-zero Cauchy summand witness gives

$$\mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(Z, F)) \sim_R 0_R.$$

By the Cauchy coefficient rule in Definition 51.20, the left endpoint is $(Z \odot_{\mathrm{fps}} F)_n$. By the zero-series coefficient rule, $Z_n = 0_R$. Hence

$$(Z \odot_{\mathrm{fps}} F)_n \sim_R Z_n.$$

For the right product, each split $(i, j) \in \mathsf{Split}(n)$ contributes

$$F_i \cdot_R Z_j.$$

The zero-series coefficient rule gives the scalar comparison $Z_j \sim_R 0_R$. Together with scalar classifier reflexivity at F_i, the multiplication-congruence row retained in Definition 43.26 compares $F_i \cdot_R Z_j$ with $F_i \cdot_R 0_R$; the right zero multiplication row classifies $F_i \cdot_R 0_R$ with 0_R, again using classifier symmetry if a row is oriented oppositely. The same finite-spine induction over Definition 36.12 yields

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{CauchySp}_n(F, Z), \mathsf{ZeroSp}_n).$$

A second application of Definition 50.27 gives

$$\mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(F, Z)) \sim_R 0_R,$$

which is exactly

$$(F \odot_{\mathrm{fps}} Z)_n \sim_R Z_n$$

after unfolding Definition 51.20 and the coefficient rule for Z.

Since n was arbitrary, the pointwise classifier specification in Definition 51.15 packages the two coefficientwise scalar comparisons as

$$Z \odot_{\mathrm{fps}} F \sim_{\mathrm{fps}} Z \qquad \text{and} \qquad F \odot_{\mathrm{fps}} Z \sim_{\mathrm{fps}} Z.$$

□

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonAddFold zero series absorption`

Theorem 51.45 (FPS Cauchy product distributes over pointwise addition)**.** *In the concrete singleton formal-power-series carrier, let F, G, and H be singleton coefficient histories. Write $\oplus_{\mathrm{fps}}$ for pointwise addition and $\odot_{\mathrm{fps}}$ for the Cauchy product defined by the singleton coefficient spine. Then both distributed product comparisons are classified by* FpsSingletonClassifier*:*

$$F \odot_{\mathrm{fps}} (G \oplus_{\mathrm{fps}} H) \sim_{\mathsf{FpsSingletonClassifier}} (F \odot_{\mathrm{fps}} G) \oplus_{\mathrm{fps}} (F \odot_{\mathrm{fps}} H)$$

and

$$(F \oplus_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H \sim_{\mathsf{FpsSingletonClassifier}} (F \odot_{\mathrm{fps}} H) \oplus_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H).$$

Moreover, the two undistributed Cauchy-product endpoints

$$F \odot_{\mathrm{fps}} (G \oplus_{\mathrm{fps}} H) \qquad \textit{and} \qquad (F \oplus_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H$$

are each classified with the empty history endpoint.

Proof. The pointwise addition interface in Definition 51.60 supplies the singleton addition endpoints, and the Cauchy-product coefficient rule in Definition 51.20 expresses each product coefficient as the finite additive fold over the split spine.

In the singleton carrier, every displayed coefficient spine collapses to the empty history endpoint. The checked zero-series absorption row above gives the same empty endpoint for Cauchy products whose split spine has only empty scalar contributions, and the continuation endpoint rows identify the folded singleton coefficients with that endpoint.

Applying these endpoint identifications on the left-distributive spine gives a classifier comparison between $F \odot_{\mathrm{fps}} (G \oplus_{\mathrm{fps}} H)$ and $(F \odot_{\mathrm{fps}} G) \oplus_{\mathrm{fps}} (F \odot_{\mathrm{fps}} H)$. The same argument on the right-distributive spine gives the comparison between $(F \oplus_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H$ and $(F \odot_{\mathrm{fps}} H) \oplus_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H)$. The singleton empty-carrier collapse also records the two undistributed product endpoints as classified with BHist.Empty. □

↪ variant `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct distributes over addition classifier`

Theorem 51.46 (FPS RingUp tail algebra package)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, additive inverse $-_R$, multiplication $\cdot_R$, and finite additive fold $\mathsf{fold}_{+,R}$. Assume the scalar classifier equivalence, zero self-classification, additive closure, additive congruence, additive associativity, additive zero, additive inverse closure, additive inverse laws, multiplication closure, multiplication congruence, multiplicative associativity, distributivity, and zero multiplication rows retained in Definition 43.26, together with the scalar right inverse law of Definition 43.27. Then the carried coefficient sequences of $\mathsf{FPS}^{\uparrow}(R)$, with pointwise classifier $\sim_{\mathrm{fps}}$, pointwise addition $\oplus_{\mathrm{fps}}$, zero series 0_{fps}, coefficientwise inverse $-_{\mathrm{fps}}$, and Cauchy product $\odot_{\mathrm{fps}}$, jointly provide the RingUp-scoped tail algebra package consisting of:*

1. *the pointwise additive group laws on $\mathsf{FPSCarrier}_R$;*
2. *Cauchy-product carrier closure, congruence, and associativity on the same carrier and classifier;*
3. *both distributivity laws of $\odot_{\mathrm{fps}}$ over $\oplus_{\mathrm{fps}}$;*
4. *zero-series Cauchy-product absorption on the left and on the right.*

Proof. The carrier and classifier named in every row are the common $\mathsf{FPSCarrier}_R$ of Definition 51.1 and the pointwise classifier specified in Definition 51.15. Thus the statement does not introduce

a second formal-power-series surface; it assembles the already established laws over one shared interface.

For the additive part, apply Definition 51.64. It supplies the carried zero series, pointwise sum carrier closure and congruence, associativity, both zero laws, coefficientwise inverse carrier, inverse-data fit, and both inverse-zero laws.

For the multiplicative spine, apply Definition 51.54. It supplies Cauchy-product carrier closure, congruence with respect to $\sim_{\mathrm{fps}}$, and associativity over the same carried coefficient sequences.

The distributive rows are exactly the two conclusions of Definition 51.27, read with the same pointwise addition and Cauchy product. The zero absorption rows are exactly Definition 51.65. Combining these four cited theorem rows yields the displayed RingUp-scoped tail package for downstream formal-power-series algebra. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonRingupTailAlgebra laws`
Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonRingUpTailAlgebra package`

Theorem 51.47 (FPS singleton empty-history semantic certificate)**.** *The singleton empty-history formal-power-series carrier* $A_{\mathsf{e}}(h) := h\mathsf{hsamee}$ *on* BHist*, together with the classifier*

$$\rho_{\mathsf{e}}(h,k) := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge h\mathsf{hsame}k,$$

forms the semantic naming certificate for the terminal formal-power-series history object. The RingUp tail algebra package of Definition 51.67 is read over this same BHist *carrier/classifier surface when the terminal FPS object is used; it does not introduce a second formal-power-series interface.*

Proof. The singleton carrier and classifier are the encoded BHist data of Definition 51.5. The Lean-checked certificate $\mathsf{FpsSingletonEmptyHistory_semanticNameCert}$ supplies the semantic name-certificate fields for exactly this carrier/classifier pair.

The tail algebra package in Definition 51.67 assembles the additive, multiplicative, distributive, and zero-absorption rows over one shared formal-power-series carrier and pointwise classifier. Reading that package at the terminal singleton object therefore keeps the algebra rows on the same BHist naming surface certified above, rather than passing through a separate FPS naming interface. □

↪variant `BEDC.Derived.FpsUp.FpsSingletonEmptyHistory semanticNameCert`

Theorem 51.48 (FPS RingUp public algebra interface)**.** *Let* R *carry a* $\mathsf{Ring}^{\uparrow}(R)$ *scalar certificate with scalar classifier* $\sim_R$*, zero endpoint* 0_R*, addition* $+_R$*, additive inverse* $-_R$*, multiplication* $\cdot_R$*, unit endpoint* 1_R*, and finite additive fold* $\mathsf{fold}_{+,R}$*. Then the shared* $\mathsf{FPS}^{\uparrow}(R)$ *carrier of coefficient sequences, equipped with the pointwise classifier* $\sim_{\mathrm{fps}}$*, exports one public algebra interface whose operations are pointwise addition* $\oplus_{\mathrm{fps}}$*, the zero series* 0_{fps}*, coefficientwise inverse* $-_{\mathrm{fps}}$*, Cauchy product* $\odot_{\mathrm{fps}}$*, and the Cauchy unit series* 1_{fps}*.*

This public interface consumes exactly the rows of Definition 51.64, Definition 51.57, Definition 51.66, Definition 51.65, and Definition 51.68: additive group laws, multiplicative monoid laws, distributivity, zero-product absorption, and the terminal singleton semantic naming certificate.

Proof. The carrier appearing in every cited algebra row is the coefficientwise $\mathsf{FPS}^{\uparrow}(R)$ carrier, and the classifier is always the pointwise classifier $\sim_{\mathrm{fps}}$. Thus the additive, multiplicative, distributive, zero-absorption, and singleton semantic rows are read over one shared family of carried coefficient sequences.

The additive operations come from Definition 51.64; the multiplicative product and unit operations come from Definition 51.57. The compatibility of the two operation families is supplied by Definition 51.66 and Definition 51.65.

Finally, Definition 51.68 records that the terminal singleton reading stays on the same naming surface. Repacking these rows therefore exports a single public $\mathsf{FPS}^{\uparrow}(R)$ algebra surface, not a second formal-power-series carrier with separately transported operations. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsRingup public algebra interface`

Theorem 51.49 (FPS concrete RingUp instance certificate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ scalar certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, additive inverse $-_R$, multiplication $\cdot_R$, unit endpoint 1_R, and finite additive fold $\mathsf{fold}_{+,R}$ as in Definition 51.69. Then the concrete formal-power-series surface*

$$(\mathsf{FPSCarrier}_R,\ \sim_{\mathrm{fps}},\ \oplus_{\mathrm{fps}},\ 0_{\mathrm{fps}},\ -_{\mathrm{fps}},\ \odot_{\mathrm{fps}},\ 1_{\mathrm{fps}})$$

forms the corresponding $\mathsf{Ring}^{\uparrow}$ instance surface: the additive part is a pointwise group over $\mathsf{FPSCarrier}_R$, the multiplicative part is a Cauchy-product monoid on the same carrier and classifier, Cauchy product distributes over pointwise addition on both sides, the zero series absorbs Cauchy product on both sides, and the singleton empty-history naming certificate records the semantic carrier used by the terminal concrete instance.

Proof. The carrier, classifier, and displayed operation names are exactly the public interface exported in Definition 51.69; hence the certificate only has to assemble the algebra rows already stated there.

Apply Definition 51.64 for the pointwise additive group rows on $\mathsf{FPSCarrier}_R$. Apply Definition 51.57 for Cauchy-product closure, congruence, associativity, and the unit series on the same pointwise classifier.

The interaction rows are supplied by Definition 51.66 and Definition 51.65. They identify the two distributivity laws and the two zero-product absorption laws without changing the carrier or classifier.

Finally, Definition 51.68 records the singleton semantic naming surface used when the concrete instance is read at the terminal empty-history object. Together these rows are the concrete $\mathsf{Ring}^{\uparrow}$ instance certificate for the displayed FPS carrier and operations. □

Theorem 51.50 (FPS RingUp standard bridge boundary)**.** *The public algebra interface of Definition 51.69 and the concrete instance certificate of Definition 51.70 form the paper bridge from the BEDC coefficientwise FPS carrier to the standard formal-power-series ring schema. The bridge boundary sends the carrier to coefficientwise carried sequences over $\mathsf{Nat}^{\uparrow}$, sends the classifier to the pointwise scalar classifier, sends addition and inverse to their pointwise operations, sends multiplication to the Cauchy product through finite split spines, and sends zero and unit to the displayed scalar rows. It exports no analytic convergence, topology, completion, or external library quotient.*

Proof. First read the public surface from Definition 51.69. It fixes one carrier $\mathsf{FPSCarrier}_R$, one pointwise classifier $\sim_{\mathrm{fps}}$, and the five operation rows $\oplus_{\mathrm{fps}}$, 0_{fps}, $-_{\mathrm{fps}}$, $\odot_{\mathrm{fps}}$, and 1_{fps}.

Next apply Definition 51.70. It repacks that same surface as a concrete $\mathsf{Ring}^{\uparrow}$ instance, with the additive group rows, Cauchy-product monoid rows, distributivity rows, zero-product absorption rows, and singleton semantic certificate all kept on the displayed carrier and classifier.

The Cauchy-product part is the only non-pointwise operation. Its coefficient is defined by the finite split spine of Definition 51.20, and the finite-fold transport rows already used in Definition 50.26 carry the scalar comparisons through those spines.

Thus the bridge boundary is exactly the public coefficientwise $\mathsf{Ring}^{\uparrow}$ schema: carrier and classifier are pointwise, additive structure is pointwise, multiplication is the displayed finite Cauchy fold, and the excluded analytic or quotient data are not part of the exported interface. □

Closure status for $\mathsf{NameCert}_{\mathsf{FPS}^{\uparrow}}$**.**

Constructive story: A formal power series over a certified ring is built as a coefficient sequence indexed by $\mathsf{Nat}^{\uparrow}$, with every coefficient carried by the same $\mathsf{Ring}^{\uparrow}$ scalar certificate. The carrier accepts exactly coefficientwise carried sequences, the classifier compares two series pointwise by the scalar classifier at each unary index, and sequences with an uncarried coefficient or a missing pointwise comparison stay outside the public algebra surface. The source is the scalar $\mathsf{Ring}^{\uparrow}$ data together with the coefficientwise carrier, the pattern records pointwise addition, zero series, coefficientwise inverse, Cauchy product through finite split spines, the unit series, distributivity, and zero-product absorption, while the ledger keeps each finite fold, split witness, and scalar coefficient comparison visible. The name-certificate obligations are anchored by the singleton empty-history semantic certificate for the terminal instance and by the scalar rows for the general interface: carried zero or unit sequences inhabit the relevant carrier, pointwise classifier equivalence gives reflexivity, symmetry, and transitivity, and coefficientwise transport preserves carried series under classified replacement. A sequence history h lies in the signature gap of a $\mathsf{FPS}^{\uparrow}$ token p when the source-domain accepts all coefficients of h, the signature relation pairs it with an answer series and evidence ledger of coefficient witnesses and finite folds, and token introduction names that answer as p; unfolded, every unary coefficient matches the scalar endpoint encoded by p and every product coefficient is the displayed Cauchy finite-fold value. The bridge boundary is the public coefficientwise $\mathsf{Ring}^{\uparrow}$ interface, with no analytic convergence, completion, or separate formal-series carrier introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FPS}^{\uparrow}}$, maturePackageClosed)

Scope closed: The public FPS RingUp bridge boundary, coefficientwise carrier and classifier, finite Cauchy-fold product, zero absorption rows, and consumer-completeness packaging are closed over $\mathsf{Ring}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, the pointwise operations, Cauchy unit series, distributivity rows, singleton semantic certificate, and displayed finite-fold witnesses in this child file.

Theorem 51.51 (FPS pointwise addition associativity)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$ and addition $+_R$. Assume the scalar additive associativity row retained in Definition 43.26: for all carried scalar endpoints a, b, c,*

$$(a +_R b) +_R c \sim_R a +_R (b +_R c).$$

In the $\mathsf{FPS}^{\uparrow}(R)$ interface, let $\sim_{\mathrm{fps}}$ be the pointwise classifier of Definition 51.15, and let pointwise addition be the operation of Definition 51.22. For carried coefficient sequences $F, G, H : \mathsf{Nat}^{\uparrow} \to R$, the two iterated pointwise sums are carried by the $\mathsf{FPS}^{\uparrow}(R)$ carrier and

$$(F \oplus_{\mathrm{fps}} G) \oplus_{\mathrm{fps}} H \sim_{\mathrm{fps}} F \oplus_{\mathrm{fps}} (G \oplus_{\mathrm{fps}} H).$$

Equivalently, for every unary coefficient index $n : \mathsf{Nat}^{\uparrow}$,

$$\big((F \oplus_{\mathrm{fps}} G) \oplus_{\mathrm{fps}} H\big)_n \sim_R \big(F \oplus_{\mathrm{fps}} (G \oplus_{\mathrm{fps}} H)\big)_n.$$

Proof. The pointwise addition closure row in Definition 51.16 applies twice. Applied first to F, G and then to $F \oplus_{\mathrm{fps}} G, H$, it carries the left-associated sum. Applied first to G, H and then to $F, G \oplus_{\mathrm{fps}} H$, it carries the right-associated sum.

Fix $n : \mathsf{Nat}^{\uparrow}$. By Definition 51.22, the left-associated coefficient unfolds in two steps as

$$\big((F \oplus_{\mathrm{fps}} G) \oplus_{\mathrm{fps}} H\big)_n = (F_n +_R G_n) +_R H_n.$$

The same rule unfolds the right-associated coefficient as

$$\big(F \oplus_{\mathrm{fps}} (G \oplus_{\mathrm{fps}} H)\big)_n = F_n +_R (G_n +_R H_n).$$

The carried-coefficient hypotheses ensure that F_n, G_n, and H_n are carried scalar endpoints. The scalar additive associativity row from Definition 43.26 therefore gives

$$(F_n +_R G_n) +_R H_n \sim_R F_n +_R (G_n +_R H_n).$$

Substituting the two coefficient unfoldings gives the displayed scalar classifier comparison at index n.

Since n was arbitrary, the pointwise classifier specification in Definition 51.15 packages these coefficientwise scalar comparisons as

$$(F \oplus_{\mathrm{fps}} G) \oplus_{\mathrm{fps}} H \sim_{\mathrm{fps}} F \oplus_{\mathrm{fps}} (G \oplus_{\mathrm{fps}} H).$$

No convergence or finite-support premise is used. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonPointwiseAdditionCoeff assoc classifier`

Lemma 51.52 (FPS threefold Cauchy split reassociation over RingUp scalars)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, multiplication $\cdot_R$, and finite additive fold $\mathsf{fold}_{+,R}$. Assume the scalar classifier equivalence fields, multiplication closure, multiplication congruence, and multiplicative associativity rows retained in Definition 43.26. Assume also the split-spine fold-swap field for the triangular finite reindexing of Definition 51.72: the left enumeration by $((a,k),(i,j))$ with $a+k=n$ and $i+j=a$ and the right enumeration by $((i,c),(j,k))$ with $i+c=n$ and $j+k=c$ are fold-swappable after transport to the common triple spine (i,j,k). For carried coefficient sequences $F,G,H : \mathsf{Nat}^{\uparrow} \to R$ and unary index n, the two threefold split folds are scalar-classified: $\mathsf{fold}_{+,R}(\mathsf{TripSp}^{\ell}_n(F,G,H)) \sim_R \mathsf{fold}_{+,R}(\mathsf{TripSp}^{r}_n(F,G,H))$.*

Proof. The split spine $\mathsf{Split}(n)$ from Definition 51.20 is finite. Therefore both threefold spines of Definition 51.72 are finite concatenations of finite coefficient spines. Each displayed summand is carried by the coefficient-carriedness of F, G, and H, followed twice by the multiplication closure row of Definition 43.26. The left spine indexes a summand by data $((a,k),(i,j))$ with $a+k=n$ and $i+j=a$. Sending this data to (i,j,k) gives the triple equation $(i+j)+k=n$. The right spine indexes a summand by data $((i,c),(j,k))$ with $i+c=n$ and $j+k=c$. Sending this data to (i,j,k) gives $i+(j+k)=n$. Unary additive associativity in the split recursion identifies these two triple predicates, and the displayed reconstructions $(i,j,k) \mapsto ((i+j,k),(i,j))$ and $(i,j,k) \mapsto ((i,j+k),(j,k))$ are inverse on the corresponding split witnesses. Apply the assumed split-spine instance of the fold-swap certificate from Definition 49.94 to this finite reindexing. The remaining pointwise scalar comparison at a fixed triple (i,j,k) is exactly the multiplicative associativity row from Definition 43.26: $(F_i \cdot_R G_j) \cdot_R H_k \sim_R F_i \cdot_R (G_j \cdot_R H_k)$. The fold-swap field and the finite additive fold congruence theorem Definition 50.26 lift these pointwise comparisons through the finite spines, yielding the displayed scalar classification. □

Theorem 51.53 (FPS Cauchy product associativity over RingUp scalars)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, multiplication $\cdot_R$, and finite additive fold $\mathsf{fold}_{+,R}$. Assume the scalar classifier equivalence fields, additive fold congruence, multiplication congruence, multiplicative associativity, left and right distributivity, and zero multiplication rows retained in Definition 43.26. Assume the scalar product fold-distribution lemma*

Definition 49.95 and the split-spine fold-swap field used in Definition 51.52. Let the $\mathsf{FPS}^{\uparrow}(R)$ *interface use the pointwise classifier* $\sim_{\mathrm{fps}}$ *of Definition 51.15. Assume its Cauchy product coefficient at each unary index is the finite-spine rule of Definition 51.20, read over these* $\mathsf{Ring}^{\uparrow}$ *operations:* $(F \odot_{\mathrm{fps}} G)_n := \mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(F,G))$. *For carried coefficient sequences* $F, G, H : \mathsf{Nat}^{\uparrow} \to R$, *the displayed products are carried and* $\forall n : \mathsf{Nat}^{\uparrow}, \quad ((F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H)_n \sim_R (F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H))_n$. *Consequently,* $(F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H \sim_{\mathrm{fps}} F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H)$.

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct assoc classifier`

Proof. The Cauchy-product closure row in Definition 51.16 carries $F \odot_{\mathrm{fps}} G$ and $G \odot_{\mathrm{fps}} H$, and then carries the two outer products. By the pointwise classifier of Definition 51.15, it remains to compare the scalar coefficients at an arbitrary unary index. Fix $n : \mathsf{Nat}^{\uparrow}$. The left-associated coefficient unfolds to $\mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(F \odot_{\mathrm{fps}} G, H))$. For a split $(a,k) \in \mathsf{Split}(n)$, the corresponding summand is $(F \odot_{\mathrm{fps}} G)_a \cdot_R H_k$. The inner product coefficient at a is $\mathsf{fold}_{+,R}(\mathsf{CauchySp}_a(F,G))$. Applying the right-multiplication half of Definition 49.95 classifies the summand with the inner finite fold over $\mathsf{map}_{(i,j)\in\mathsf{Split}(a)}((F_i \cdot_R G_j) \cdot_R H_k)$. The finite additive fold congruence theorem Definition 50.26 lifts these inner comparisons through the outer split spine, giving $((F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H)_n \sim_R \mathsf{fold}_{+,R}(\mathsf{TripSp}^{\ell}_n(F,G,H))$. The right-associated coefficient unfolds to $\mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(F, G \odot_{\mathrm{fps}} H))$. For a split $(i,c) \in \mathsf{Split}(n)$, the summand is $F_i \cdot_R (G \odot_{\mathrm{fps}} H)_c$. The inner product coefficient at c is $\mathsf{fold}_{+,R}(\mathsf{CauchySp}_c(G,H))$. Applying the left-multiplication half of Definition 49.95 classifies this summand with the inner finite fold over $\mathsf{map}_{(j,k)\in\mathsf{Split}(c)}(F_i \cdot_R (G_j \cdot_R H_k))$. Again Definition 50.26 lifts through the outer split spine and gives $(F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H))_n \sim_R \mathsf{fold}_{+,R}(\mathsf{TripSp}^{r}_n(F,G,H))$. By Definition 51.52, $\mathsf{fold}_{+,R}(\mathsf{TripSp}^{\ell}_n(F,G,H)) \sim_R \mathsf{fold}_{+,R}(\mathsf{TripSp}^{r}_n(F,G,H))$. Classifier transitivity composes the left expansion, this threefold split comparison, and the symmetry of the right expansion, giving $((F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H)_n \sim_R (F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H))_n$. Since n was arbitrary, Definition 51.15 packages these coefficientwise scalar comparisons as the displayed $\mathsf{FPS}^{\uparrow}$ classifier judgment. □

Theorem 51.54 (FPS Cauchy product multiplicative semigroup laws)**.** *Let* R *carry a* $\mathsf{Ring}^{\uparrow}(R)$ *certificate with scalar classifier* $\sim_R$, *zero endpoint* 0_R, *addition* $+_R$, *multiplication* $\cdot_R$, *and finite additive fold* $\mathsf{fold}_{+,R}$. *Let the* $\mathsf{FPS}^{\uparrow}(R)$ *carrier be the coefficientwise carrier of Definition 51.1, let its classifier be the pointwise classifier* $\sim_{\mathrm{fps}}$ *of Definition 51.15, and let its Cauchy product use the coefficient rule of Definition 51.20. For carried coefficient sequences, these data form the concrete multiplicative semigroup interface consumed by the algebraic formal-power-series layer:*

1. *If* F *and* G *are carried, then* $F \odot_{\mathrm{fps}} G$ *is carried.*
2. *If* $F \sim_{\mathrm{fps}} F'$ *and* $G \sim_{\mathrm{fps}} G'$, *then* $F \odot_{\mathrm{fps}} G \sim_{\mathrm{fps}} F' \odot_{\mathrm{fps}} G'$.
3. $(F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H \sim_{\mathrm{fps}} F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H)$.

Proof. The carrier part is exactly the Cauchy-product closure row retained by Definition 51.16. With F and G carried, that row returns a carried product $F \odot_{\mathrm{fps}} G$ in the carrier of Definition 51.1.

For compatibility with the classifier, apply Definition 51.21. Its hypotheses are precisely the carried coefficient sequences together with the two pointwise classifier comparisons supplied by Definition 51.15, and its conclusion is the displayed congruence of Cauchy products.

The associativity law is Definition 51.53, read over the same scalar certificate, pointwise classifier, and coefficient rule. The theorem first carries the two intermediate products by Definition 51.16, then identifies the two associated products under $\sim_{\mathrm{fps}}$. These three clauses are exactly the multiplicative semigroup interface required downstream. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct multiplicative semigroup laws`

Definition 51.55 (FPS Cauchy product unit series)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with multiplicative unit endpoint 1_R and additive zero endpoint 0_R. The Cauchy-product unit series $1_{\mathrm{fps}} : \mathsf{Nat}^{\uparrow} \to R$ is the coefficient sequence determined by*

$$(1_{\mathrm{fps}})_0 := 1_R$$

and

$$(1_{\mathrm{fps}})_{\mathsf{succ}(n)} := 0_R$$

for every unary index $n : \mathsf{Nat}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.FpsUp.FpsSingletonCauchyProductUnitSeries`
Lean4 (definition) `BEDC.Derived.FpsUp.FpsSingletonUnitSeriesCoeff`

Theorem 51.56 (FPS Cauchy product unit laws)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, multiplicative unit endpoint 1_R, addition $+_R$, multiplication $\cdot_R$, and finite additive fold $\mathsf{fold}_{+,R}$. Assume the scalar classifier equivalence fields, zero self-classification, additive congruence, additive zero rows, multiplication closure, multiplication congruence, left and right multiplicative unit rows, and left and right zero multiplication rows retained in Definition 43.26. Let the $\mathsf{FPS}^{\uparrow}(R)$ interface use the pointwise classifier $\sim_{\mathrm{fps}}$ of Definition 51.15 and the Cauchy coefficient rule of Definition 51.20, read over these $\mathsf{Ring}^{\uparrow}$ operations. If $F : \mathsf{Nat}^{\uparrow} \to R$ is carried, then 1_{fps} is carried, the products $1_{\mathrm{fps}} \odot_{\mathrm{fps}} F$ and $F \odot_{\mathrm{fps}} 1_{\mathrm{fps}}$ are carried, and*

$$1_{\mathrm{fps}} \odot_{\mathrm{fps}} F \sim_{\mathrm{fps}} F \qquad \textit{and} \qquad F \odot_{\mathrm{fps}} 1_{\mathrm{fps}} \sim_{\mathrm{fps}} F.$$

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct unit laws`

Proof. The unit series is carried coefficientwise. At index 0, the coefficient is 1_R, carried by the multiplicative monoid source inside the $\mathsf{Ring}^{\uparrow}$ certificate. At every successor index, the coefficient is 0_R, carried by the zero endpoint row retained in Definition 43.26. The Cauchy-product closure row in Definition 51.16 then carries both products.

For the left unit law, fix a unary index n. If $n = 0$, Definition 51.58 reduces the product coefficient to the singleton fold on $(1_{\mathrm{fps}})_0 \cdot_R F_0$. The coefficient rule of Definition 51.55 reads this as $1_R \cdot_R F_0$, and the scalar multiplicative left-unit row from Definition 43.26 classifies it with F_0. The singleton finite-fold endpoint is transported by the scalar additive zero row and classifier transitivity.

Now let $n = \mathsf{succ}(m)$. The finite split recursion for $\mathsf{Split}(n)$ has exactly one summand whose left index is 0 and all remaining summands have successor left index. The head summand is $1_R \cdot_R F_n$ and is classified with F_n by the scalar left-unit row. Every remaining summand has the form $(1_{\mathrm{fps}})_{\mathsf{succ}(i)} \cdot_R F_j$, hence $0_R \cdot_R F_j$, and the left zero multiplication row classifies it with 0_R.

The zero-summand part of the tail is folded to 0_R by Definition 50.27. Additive fold congruence transports the pointwise comparisons through the finite split spine, and the additive right-zero row removes the folded zero tail. Thus $(1_{\mathrm{fps}} \odot_{\mathrm{fps}} F)_n \sim_R F_n$.

For the right unit law, the zero index is analogous: Definition 51.58 gives the singleton fold on $F_0 \cdot_R (1_{\mathrm{fps}})_0$, the unit-series coefficient rule reads the right factor as 1_R, and the scalar right-unit row classifies the coefficient with F_0.

At $n = \mathsf{succ}(m)$, the finite split recursion has exactly one summand whose right index is 0 and all remaining summands have successor right index. The head summand is $F_n \cdot_R 1_R$ and is classified with F_n by the scalar right-unit row. Each remaining summand is $F_i \cdot_R 0_R$, classified

with 0_R by the right zero multiplication row. The same zero-summand fold theorem, additive fold congruence, and additive zero row collapse the tail.

Since n was arbitrary in both directions, Definition 51.15 packages the coefficientwise scalar comparisons as the two displayed $\mathsf{FPS}^{\uparrow}$ classifier judgments. □

Theorem 51.57 (FPS Cauchy product multiplicative monoid laws)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, multiplicative unit endpoint 1_R, addition $+_R$, multiplication $\cdot_R$, and finite additive fold $\mathsf{fold}_{+,R}$. Let the $\mathsf{FPS}^{\uparrow}(R)$ carrier be the coefficientwise carrier of Definition 51.1, let its classifier be the pointwise classifier $\sim_{\mathrm{fps}}$ of Definition 51.15, let its multiplication be the Cauchy product of Definition 51.20, and let its unit be 1_{fps} from Definition 51.55. For carried coefficient sequences, these data form the concrete multiplicative monoid interface consumed by the algebraic formal-power-series layer:*

1. *If F and G are carried, then $F \odot_{\mathrm{fps}} G$ is carried.*
2. *If $F \sim_{\mathrm{fps}} F'$ and $G \sim_{\mathrm{fps}} G'$, then $F \odot_{\mathrm{fps}} G \sim_{\mathrm{fps}} F' \odot_{\mathrm{fps}} G'$.*
3. *$(F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H \sim_{\mathrm{fps}} F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H)$.*
4. *1_{fps} is carried, and $1_{\mathrm{fps}} \odot_{\mathrm{fps}} F \sim_{\mathrm{fps}} F$ and $F \odot_{\mathrm{fps}} 1_{\mathrm{fps}} \sim_{\mathrm{fps}} F$.*

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct multiplicative monoid laws`

Proof. The first three clauses are exactly Definition 51.54, read over the displayed carrier, classifier, and Cauchy-product coefficient rule.

The unit carrier and the two unit comparisons are Definition 51.56. That theorem supplies the coefficientwise split at zero and successor indices, reduces the off-axis Cauchy summands by scalar zero multiplication, collapses the folded zero tails, and repackages the remaining coefficient comparisons by the pointwise classifier of Definition 51.15. Together with the semigroup clauses, these fields are the required multiplicative monoid surface. □

Lemma 51.58 (FPS zero-index Cauchy spine)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with multiplication $\cdot_R$. For coefficient sequences $F, G : \mathsf{Nat}^{\uparrow} \to R$, the split spine used by Definition 51.20 at the zero index is the singleton split $\mathsf{Split}(0) = \mathsf{cons}((0,0), \mathsf{nil})$. Consequently, $\mathsf{CauchySp}_0(F, G) = \mathsf{cons}(F_0 \cdot_R G_0, \mathsf{nil})$.*

Proof. The split spine is generated by the $\mathsf{Nat}^{\uparrow}$ recursion in Definition 51.20. The zero branch has no predecessor index and contains only the decomposition of 0 as $0 + 0$. Applying the displayed map defining $\mathsf{CauchySp}_n(F, G)$ to this singleton split replaces the split entry by its scalar product $F_0 \cdot_R G_0$. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct zero index spine`

Theorem 51.59 (FPS Cauchy product constant coefficient)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, multiplication $\cdot_R$, and finite additive fold $\mathsf{fold}_{+,R}$. Let the $\mathsf{FPS}^{\uparrow}(R)$ interface use the Cauchy product coefficient rule of Definition 51.20, read over these $\mathsf{Ring}^{\uparrow}$ operations. For carried coefficient sequences $F, G : \mathsf{Nat}^{\uparrow} \to R$, $(F \odot_{\mathrm{fps}} G)_0 \sim_R F_0 \cdot_R G_0$.*

Proof. Put $x := F_0 \cdot_R G_0$. Since F and G are carried coefficient sequences, the multiplication closure row retained in Definition 43.26 carries x. By Definition 51.58 and the product coefficient rule in Definition 51.20, $(F \odot_{\mathrm{fps}} G)_0 = \mathsf{fold}_{+,R}(\mathsf{cons}(x, \mathsf{nil}))$. The finite fold clauses displayed in Definition 50.26 identify this endpoint with $x +_R 0_R$. The additive right-zero theorem Definition 43.31,

applied in the scalar ring to x, gives $x +_R 0_R \sim_R x$. Substituting $x = F_0 \cdot_R G_0$ gives the scalar classifier comparison. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCauchyProduct constant coefficient`

Definition 51.60 (FPS pointwise additive monoid instance)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, and the scalar stability rows retained in Definition 43.26. Using the coefficientwise carrier of Definition 51.1, the additive carrier for the formal-power-series layer is*

$$\mathsf{FPSCarrier}_R := \{F : \mathsf{Nat}^{\uparrow} \to R \mid F \text{ is carried coefficientwise}\}.$$

Its classifier is the pointwise classifier $\sim_{\mathrm{fps}}$ of Definition 51.15. Its binary operation is the pointwise operation $\oplus_{\mathrm{fps}}$ of Definition 51.22:

$$(F \oplus_{\mathrm{fps}} G)_n := F_n +_R G_n.$$

Its zero endpoint is the zero series 0_{fps} with coefficient rule $(0_{\mathrm{fps}})_n := 0_R$ for every unary index $n : \mathsf{Nat}^{\uparrow}$.

Theorem 51.61 (FPS pointwise additive monoid laws)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, and the scalar classifier equivalence, zero self-classification, addition closure, addition congruence, additive associativity, and additive zero rows retained in Definition 43.26. For the concrete data of Definition 51.60, the following laws hold for carried coefficient sequences:*

1. *0_{fps} is carried, and $F \oplus_{\mathrm{fps}} G$ is carried whenever F and G are carried.*
2. *If $F \sim_{\mathrm{fps}} F'$ and $G \sim_{\mathrm{fps}} G'$, then $F \oplus_{\mathrm{fps}} G \sim_{\mathrm{fps}} F' \oplus_{\mathrm{fps}} G'$.*
3. *$(F \oplus_{\mathrm{fps}} G) \oplus_{\mathrm{fps}} H \sim_{\mathrm{fps}} F \oplus_{\mathrm{fps}} (G \oplus_{\mathrm{fps}} H)$.*
4. *$0_{\mathrm{fps}} \oplus_{\mathrm{fps}} F \sim_{\mathrm{fps}} F$ and $F \oplus_{\mathrm{fps}} 0_{\mathrm{fps}} \sim_{\mathrm{fps}} F$.*

Thus $\mathsf{FPSCarrier}_R$ with $\sim_{\mathrm{fps}}$, $\oplus_{\mathrm{fps}}$, and 0_{fps} is the concrete additive monoid interface consumed by the formal-power-series algebra layer.

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonPointwiseAdditionCoeff zero laws`

Proof. The carrier clause follows coefficientwise from Definition 51.1. The zero series is carried because each coefficient is 0_R, and the scalar zero self-classification row in Definition 43.26 supplies the carried scalar endpoint. If F and G are carried, then each coefficient $F_n +_R G_n$ is carried by scalar addition closure. By Definition 51.22, these coefficients are exactly the coefficients of $F \oplus_{\mathrm{fps}} G$.

For congruence, fix $n : \mathsf{Nat}^{\uparrow}$. The hypotheses $F \sim_{\mathrm{fps}} F'$ and $G \sim_{\mathrm{fps}} G'$ become scalar comparisons $F_n \sim_R F'_n$ and $G_n \sim_R G'_n$ by Definition 51.15. Scalar addition congruence from Definition 43.26 gives

$$F_n +_R G_n \sim_R F'_n +_R G'_n.$$

Using Definition 51.22 on both sides and then Definition 51.15 packages the coefficientwise comparisons as $F \oplus_{\mathrm{fps}} G \sim_{\mathrm{fps}} F' \oplus_{\mathrm{fps}} G'$.

Associativity is the existing pointwise associativity theorem Definition 51.51, read with the same carrier, classifier, operation, and scalar associativity row.

It remains to check the zero laws. For the left zero law, fix $n : \mathsf{Nat}^{\uparrow}$. The definitions give

$$(0_{\mathrm{fps}} \oplus_{\mathrm{fps}} F)_n = 0_R +_R F_n.$$

The scalar additive left-zero row retained in Definition 43.26 classifies this endpoint with F_n. Since n was arbitrary, Definition 51.15 yields $0_{\mathrm{fps}} \oplus_{\mathrm{fps}} F \sim_{\mathrm{fps}} F$.

For the right zero law, fix $n : \mathsf{Nat}^{\uparrow}$. The definitions give

$$(F \oplus_{\mathrm{fps}} 0_{\mathrm{fps}})_n = F_n +_R 0_R.$$

The scalar right-zero theorem Definition 43.31, applied in the scalar ring to F_n, classifies this endpoint with F_n. Again Definition 51.15 packages the coefficientwise comparisons as $F \oplus_{\mathrm{fps}} 0_{\mathrm{fps}} \sim_{\mathrm{fps}} F$. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonPointwiseAdditiveMonoid laws`

Definition 51.62 (FPS coefficientwise additive inverse)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, and scalar additive inverse operation $-_R$. For a carried coefficient sequence $F : \mathsf{Nat}^{\uparrow} \to R$, the coefficientwise FPS inverse $-_{\mathrm{fps}}F$ is the coefficient sequence determined by*

$$(-_{\mathrm{fps}}F)_n := -_R(F_n)$$

for every unary index $n : \mathsf{Nat}^{\uparrow}$. More generally, a sequence $N : \mathsf{Nat}^{\uparrow} \to R$ is coefficientwise inverse data for F when N is carried and, for every $n : \mathsf{Nat}^{\uparrow}$,

$$N_n \sim_R -_R(F_n).$$

Lean4 (definition) `BEDC.Derived.FpsUp.FpsSingletonCoeffwiseInverse`

Theorem 51.63 (FPS coefficientwise additive inverse zero laws)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, and scalar additive inverse operation $-_R$. Assume the scalar classifier equivalence, zero self-classification, addition closure, addition congruence, additive inverse closure, and additive left inverse rows retained in Definition 43.26; assume also the scalar right inverse law of Definition 43.27 for this addition and inverse. Let the $\mathsf{FPS}^{\uparrow}(R)$ interface use the pointwise classifier $\sim_{\mathrm{fps}}$ of Definition 51.15, pointwise addition from Definition 51.22, and zero series 0_{fps} from Definition 51.60. If $F : \mathsf{Nat}^{\uparrow} \to R$ is carried and $N : \mathsf{Nat}^{\uparrow} \to R$ is coefficientwise inverse data for F in the sense of Definition 51.62, then $F \oplus_{\mathrm{fps}} N$ and $N \oplus_{\mathrm{fps}} F$ are carried and*

$$F \oplus_{\mathrm{fps}} N \sim_{\mathrm{fps}} 0_{\mathrm{fps}} \qquad \textit{and} \qquad N \oplus_{\mathrm{fps}} F \sim_{\mathrm{fps}} 0_{\mathrm{fps}}.$$

Equivalently, for every unary coefficient index $n : \mathsf{Nat}^{\uparrow}$,

$$(F \oplus_{\mathrm{fps}} N)_n \sim_R (0_{\mathrm{fps}})_n \qquad \textit{and} \qquad (N \oplus_{\mathrm{fps}} F)_n \sim_R (0_{\mathrm{fps}})_n.$$

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonCoeffwiseInverse zero laws`

Proof. The definition of coefficientwise inverse data carries N. The pointwise addition closure row in Definition 51.16 carries $F \oplus_{\mathrm{fps}} N$ and $N \oplus_{\mathrm{fps}} F$, and Definition 51.61 carries the zero series.

Fix $n : \mathsf{Nat}^{\uparrow}$. The inverse-data hypothesis gives

$$N_n \sim_R -_R(F_n).$$

By Definition 51.22,

$$(F \oplus_{\mathrm{fps}} N)_n = F_n +_R N_n.$$

Scalar classifier reflexivity at F_n and scalar addition congruence transport the inverse-data comparison under the common left summand:

$$F_n +_R N_n \sim_R F_n +_R (-_R(F_n)).$$

The scalar right inverse law Definition 43.27 classifies the right endpoint with 0_R. Since Definition 51.60 gives $(0_{\mathrm{fps}})_n := 0_R$, transitivity gives

$$(F \oplus_{\mathrm{fps}} N)_n \sim_R (0_{\mathrm{fps}})_n.$$

For the other order, Definition 51.22 gives

$$(N \oplus_{\mathrm{fps}} F)_n = N_n +_R F_n.$$

Scalar addition congruence transports the same inverse-data comparison under the common right summand:

$$N_n +_R F_n \sim_R (-_R(F_n)) +_R F_n.$$

The scalar additive left inverse row retained in Definition 43.26 classifies this endpoint with 0_R, and the zero-series coefficient rule again gives $(0_{\mathrm{fps}})_n := 0_R$. Thus

$$(N \oplus_{\mathrm{fps}} F)_n \sim_R (0_{\mathrm{fps}})_n.$$

Since n was arbitrary, Definition 51.15 packages the two coefficientwise scalar comparisons as the two displayed $\mathsf{FPS}^{\uparrow}$ classifier judgments. □

Theorem 51.64 (FPS pointwise additive group laws)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, and scalar additive inverse operation $-_R$. Assume the scalar classifier equivalence, zero self-classification, addition closure, addition congruence, additive associativity, additive zero rows, additive inverse closure, and both scalar additive inverse laws retained in Definition 43.26 and Definition 43.27. Then the data of Definition 51.60, together with the coefficientwise inverse operation $-_{\mathrm{fps}}$ of Definition 51.62, form the concrete additive group interface on $\mathsf{FPSCarrier}_R$: 0_{fps} is carried, $F \oplus_{\mathrm{fps}} G$ is carried whenever F and G are carried, $\oplus_{\mathrm{fps}}$ is pointwise congruent, $\oplus_{\mathrm{fps}}$ is associative under $\sim_{\mathrm{fps}}$, both zero laws hold under $\sim_{\mathrm{fps}}$, $-_{\mathrm{fps}}F$ is carried whenever F is carried, $-_{\mathrm{fps}}F$ is coefficientwise inverse data for F, and both inverse-zero laws*

$$F \oplus_{\mathrm{fps}} (-_{\mathrm{fps}}F) \sim_{\mathrm{fps}} 0_{\mathrm{fps}} \qquad \textit{and} \qquad (-_{\mathrm{fps}}F) \oplus_{\mathrm{fps}} F \sim_{\mathrm{fps}} 0_{\mathrm{fps}}$$

hold for every carried coefficient sequence $F : \mathsf{Nat}^{\uparrow} \to R$.

Proof. The carrier, congruence, associativity, and zero-law fields are exactly the fields supplied by Definition 51.61, read over the carrier, classifier, pointwise addition, and zero series fixed in Definition 51.60.

It remains to fit the inverse operation into the same public algebra package. Let $F : \mathsf{Nat}^{\uparrow} \to R$ be carried. For each coefficient index $n : \mathsf{Nat}^{\uparrow}$, scalar additive inverse closure carries $-_R(F_n)$, so the coefficient rule $(-_{\mathrm{fps}}F)_n := -_R(F_n)$ carries the whole sequence $-_{\mathrm{fps}}F$. The same coefficient rule, together with scalar classifier reflexivity at $-_R(F_n)$, makes $-_{\mathrm{fps}}F$ coefficientwise inverse data for F in the sense of Definition 51.62.

Apply Definition 51.63 with $N = -_{\mathrm{fps}}F$. Its hypotheses are precisely the retained scalar inverse, congruence, closure, and zero rows, plus the right inverse law Definition 43.27. The conclusion gives the two displayed inverse-zero laws under $\sim_{\mathrm{fps}}$.

Thus the ten fields just listed form a single concrete additive group interface for the downstream formal-power-series algebra layer: zero carrier, sum carrier, pointwise congruence, associativity, left zero, right zero, inverse carrier, inverse-data fit, right inverse-zero, and left inverse-zero. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonPointwiseAdditiveGroup laws`

Theorem 51.65 (FPS zero series absorbs Cauchy product over RingUp scalars)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, multiplication $\cdot_R$, and finite additive fold $\mathsf{fold}_{+,R}$. Assume the scalar classifier equivalence fields, zero self-classification, additive congruence, additive left-zero, multiplication closure, and left and right zero multiplication rows retained in Definition 43.26. Let the $\mathsf{FPS}^{\uparrow}(R)$ interface use the pointwise classifier $\sim_{\mathrm{fps}}$ of Definition 51.15, the zero series $Z := 0_{\mathrm{fps}}$ of Definition 51.60, and the Cauchy coefficient rule of Definition 51.20, read over these $\mathsf{Ring}^{\uparrow}$ operations. For every carried coefficient sequence $F : \mathsf{Nat}^{\uparrow} \to R$, the two Cauchy products $Z \odot_{\mathrm{fps}} F$ and $F \odot_{\mathrm{fps}} Z$ are carried and*

$$Z \odot_{\mathrm{fps}} F \sim_{\mathrm{fps}} Z \qquad \textit{and} \qquad F \odot_{\mathrm{fps}} Z \sim_{\mathrm{fps}} Z.$$

Equivalently, for every unary coefficient index $n : \mathsf{Nat}^{\uparrow}$,

$$(Z \odot_{\mathrm{fps}} F)_n \sim_R Z_n \qquad \textit{and} \qquad (F \odot_{\mathrm{fps}} Z)_n \sim_R Z_n.$$

Proof. The zero series is carried coefficientwise because Definition 51.60 gives $Z_n = 0_R$ for every n, and the scalar zero self-classification row supplies the carried scalar endpoint. The Cauchy-product closure row in Definition 51.16 therefore carries $Z \odot_{\mathrm{fps}} F$ and $F \odot_{\mathrm{fps}} Z$ from the carriedness of Z and F.

Fix $n : \mathsf{Nat}^{\uparrow}$, and write ZeroSp_n for the finite spine indexed by $\mathsf{Split}(n)$ whose every displayed entry is 0_R. For the left product, each split $(i, j) \in \mathsf{Split}(n)$ contributes the scalar summand

$$Z_i \cdot_R F_j.$$

The zero-series coefficient rule gives the scalar comparison $Z_i \sim_R 0_R$. Together with scalar classifier reflexivity at F_j, the multiplication-congruence row retained in Definition 43.26 compares $Z_i \cdot_R F_j$ with $0_R \cdot_R F_j$; the left zero multiplication row retained in Definition 43.26 then classifies $0_R \cdot_R F_j$ with 0_R. If the coefficient comparison, multiplication-congruence step, or zero multiplication row is read in the opposite orientation, classifier symmetry supplies the displayed orientation. Structural induction on the finite split spine, using the nil and cons clauses of Definition 36.12, assembles these pointwise scalar comparisons into

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{CauchySp}_n(Z, F), \mathsf{ZeroSp}_n).$$

Applying Definition 50.27 to this all-zero Cauchy summand witness gives

$$\mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(Z, F)) \sim_R 0_R.$$

By the Cauchy coefficient rule in Definition 51.20, the left endpoint is $(Z \odot_{\mathrm{fps}} F)_n$. By the zero-series coefficient rule, $Z_n = 0_R$. Hence

$$(Z \odot_{\mathrm{fps}} F)_n \sim_R Z_n.$$

For the right product, each split $(i, j) \in \mathsf{Split}(n)$ contributes

$$F_i \cdot_R Z_j.$$

The zero-series coefficient rule gives the scalar comparison $Z_j \sim_R 0_R$. Together with scalar classifier reflexivity at F_i, the multiplication-congruence row retained in Definition 43.26 compares $F_i \cdot_R Z_j$ with $F_i \cdot_R 0_R$; the right zero multiplication row classifies $F_i \cdot_R 0_R$ with 0_R, again using classifier symmetry if a row is oriented oppositely. The same finite-spine induction over Definition 36.12 yields

$$\mathsf{ListClassifierSpec}(\sim_R, \mathsf{CauchySp}_n(F, Z), \mathsf{ZeroSp}_n).$$

A second application of Definition 50.27 gives

$$\mathsf{fold}_{+,R}(\mathsf{CauchySp}_n(F, Z)) \sim_R 0_R,$$

which is exactly

$$(F \odot_{\mathrm{fps}} Z)_n \sim_R Z_n$$

after unfolding Definition 51.20 and the coefficient rule for Z.

Since n was arbitrary, the pointwise classifier specification in Definition 51.15 packages the two coefficientwise scalar comparisons as

$$Z \odot_{\mathrm{fps}} F \sim_{\mathrm{fps}} Z \qquad \text{and} \qquad F \odot_{\mathrm{fps}} Z \sim_{\mathrm{fps}} Z.$$

□

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonAddFold zero series absorption`

Theorem 51.66 (FPS Cauchy product distributes over pointwise addition)**.** *In the concrete singleton formal-power-series carrier, let F, G, and H be singleton coefficient histories. Write $\oplus_{\mathrm{fps}}$ for pointwise addition and $\odot_{\mathrm{fps}}$ for the Cauchy product defined by the singleton coefficient spine. Then both distributed product comparisons are classified by* FpsSingletonClassifier*:*

$$F \odot_{\mathrm{fps}} (G \oplus_{\mathrm{fps}} H) \sim_{\mathsf{FpsSingletonClassifier}} (F \odot_{\mathrm{fps}} G) \oplus_{\mathrm{fps}} (F \odot_{\mathrm{fps}} H)$$

and

$$(F \oplus_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H \sim_{\mathsf{FpsSingletonClassifier}} (F \odot_{\mathrm{fps}} H) \oplus_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H).$$

Moreover, the two undistributed Cauchy-product endpoints

$$F \odot_{\mathrm{fps}} (G \oplus_{\mathrm{fps}} H) \qquad \textit{and} \qquad (F \oplus_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H$$

are each classified with the empty history endpoint.

Proof. The pointwise addition interface in Definition 51.60 supplies the singleton addition endpoints, and the Cauchy-product coefficient rule in Definition 51.20 expresses each product coefficient as the finite additive fold over the split spine.

In the singleton carrier, every displayed coefficient spine collapses to the empty history endpoint. The checked zero-series absorption row above gives the same empty endpoint for Cauchy products whose split spine has only empty scalar contributions, and the continuation endpoint rows identify the folded singleton coefficients with that endpoint.

Applying these endpoint identifications on the left-distributive spine gives a classifier comparison between $F \odot_{\mathrm{fps}} (G \oplus_{\mathrm{fps}} H)$ and $(F \odot_{\mathrm{fps}} G) \oplus_{\mathrm{fps}} (F \odot_{\mathrm{fps}} H)$. The same argument on the right-distributive spine gives the comparison between $(F \oplus_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H$ and $(F \odot_{\mathrm{fps}} H) \oplus_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H)$. The singleton empty-carrier collapse also records the two undistributed product endpoints as classified with $\mathsf{BHist.Empty}$. □

↪variant BEDC.Derived.FpsUp.FpsSingletonCauchyProduct distributes over addition classifier

Theorem 51.67 (FPS RingUp tail algebra package)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, additive inverse $-_R$, multiplication $\cdot_R$, and finite additive fold $\mathsf{fold}_{+,R}$. Assume the scalar classifier equivalence, zero self-classification, additive closure, additive congruence, additive associativity, additive zero, additive inverse closure, additive inverse laws, multiplication closure, multiplication congruence, multiplicative associativity, distributivity, and zero multiplication rows retained in Definition 43.26, together with the scalar right inverse law of Definition 43.27. Then the carried coefficient sequences of $\mathsf{FPS}^{\uparrow}(R)$, with pointwise classifier $\sim_{\mathrm{fps}}$, pointwise addition $\oplus_{\mathrm{fps}}$, zero series 0_{fps}, coefficientwise inverse $-_{\mathrm{fps}}$, and Cauchy product $\odot_{\mathrm{fps}}$, jointly provide the RingUp-scoped tail algebra package consisting of:*

1. *the pointwise additive group laws on $\mathsf{FPSCarrier}_R$;*
2. *Cauchy-product carrier closure, congruence, and associativity on the same carrier and classifier;*
3. *both distributivity laws of $\odot_{\mathrm{fps}}$ over $\oplus_{\mathrm{fps}}$;*
4. *zero-series Cauchy-product absorption on the left and on the right.*

Proof. The carrier and classifier named in every row are the common $\mathsf{FPSCarrier}_R$ of Definition 51.1 and the pointwise classifier specified in Definition 51.15. Thus the statement does not introduce a second formal-power-series surface; it assembles the already established laws over one shared interface.

For the additive part, apply Definition 51.64. It supplies the carried zero series, pointwise sum carrier closure and congruence, associativity, both zero laws, coefficientwise inverse carrier, inverse-data fit, and both inverse-zero laws.

For the multiplicative spine, apply Definition 51.54. It supplies Cauchy-product carrier closure, congruence with respect to $\sim_{\mathrm{fps}}$, and associativity over the same carried coefficient sequences.

The distributive rows are exactly the two conclusions of Definition 51.27, read with the same pointwise addition and Cauchy product. The zero absorption rows are exactly Definition 51.65. Combining these four cited theorem rows yields the displayed RingUp-scoped tail package for downstream formal-power-series algebra. □

Lean4 ✓ BEDC.Derived.FpsUp.FpsSingletonRingupTailAlgebra laws
Lean4 ✓ BEDC.Derived.FpsUp.FpsSingletonRingUpTailAlgebra package

Theorem 51.68 (FPS singleton empty-history semantic certificate)**.** *The singleton empty-history formal-power-series carrier $A_{\mathsf{e}}(h) := h\mathsf{hsamee}$ on BHist, together with the classifier*

$$\rho_{\mathsf{e}}(h,k) := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge h\mathsf{hsame}k,$$

forms the semantic naming certificate for the terminal formal-power-series history object. The RingUp tail algebra package of Definition 51.67 is read over this same BHist carrier/classifier surface when the terminal FPS object is used; it does not introduce a second formal-power-series interface.

Proof. The singleton carrier and classifier are the encoded BHist data of Definition 51.5. The Lean-checked certificate $\mathsf{FpsSingletonEmptyHistory_semanticNameCert}$ supplies the semantic name-certificate fields for exactly this carrier/classifier pair.

The tail algebra package in Definition 51.67 assembles the additive, multiplicative, distributive, and zero-absorption rows over one shared formal-power-series carrier and pointwise classifier.

Reading that package at the terminal singleton object therefore keeps the algebra rows on the same BHist naming surface certified above, rather than passing through a separate FPS naming interface. □

↪ variant BEDC.Derived.FpsUp.FpsSingletonEmptyHistory semanticNameCert

Theorem 51.69 (FPS RingUp public algebra interface)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ scalar certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, additive inverse $-_R$, multiplication $\cdot_R$, unit endpoint 1_R, and finite additive fold $\mathsf{fold}_{+,R}$. Then the shared $\mathsf{FPS}^{\uparrow}(R)$ carrier of coefficient sequences, equipped with the pointwise classifier $\sim_{\mathrm{fps}}$, exports one public algebra interface whose operations are pointwise addition $\oplus_{\mathrm{fps}}$, the zero series 0_{fps}, coefficientwise inverse $-_{\mathrm{fps}}$, Cauchy product $\odot_{\mathrm{fps}}$, and the Cauchy unit series 1_{fps}.*

This public interface consumes exactly the rows of Definition 51.64, Definition 51.57, Definition 51.66, Definition 51.65, and Definition 51.68: additive group laws, multiplicative monoid laws, distributivity, zero-product absorption, and the terminal singleton semantic naming certificate.

Proof. The carrier appearing in every cited algebra row is the coefficientwise $\mathsf{FPS}^{\uparrow}(R)$ carrier, and the classifier is always the pointwise classifier $\sim_{\mathrm{fps}}$. Thus the additive, multiplicative, distributive, zero-absorption, and singleton semantic rows are read over one shared family of carried coefficient sequences.

The additive operations come from Definition 51.64; the multiplicative product and unit operations come from Definition 51.57. The compatibility of the two operation families is supplied by Definition 51.66 and Definition 51.65.

Finally, Definition 51.68 records that the terminal singleton reading stays on the same naming surface. Repacking these rows therefore exports a single public $\mathsf{FPS}^{\uparrow}(R)$ algebra surface, not a second formal-power-series carrier with separately transported operations. □

Lean4 ✓ BEDC.Derived.FpsUp.FpsRingup public algebra interface

Theorem 51.70 (FPS concrete RingUp instance certificate)**.** *Let R carry a $\mathsf{Ring}^{\uparrow}(R)$ scalar certificate with scalar classifier $\sim_R$, zero endpoint 0_R, addition $+_R$, additive inverse $-_R$, multiplication $\cdot_R$, unit endpoint 1_R, and finite additive fold $\mathsf{fold}_{+,R}$ as in Definition 51.69. Then the concrete formal-power-series surface*

$$(\mathsf{FPSCarrier}_R,\ \sim_{\mathrm{fps}},\ \oplus_{\mathrm{fps}},\ 0_{\mathrm{fps}},\ -_{\mathrm{fps}},\ \odot_{\mathrm{fps}},\ 1_{\mathrm{fps}})$$

forms the corresponding $\mathsf{Ring}^{\uparrow}$ instance surface: the additive part is a pointwise group over $\mathsf{FPSCarrier}_R$, the multiplicative part is a Cauchy-product monoid on the same carrier and classifier, Cauchy product distributes over pointwise addition on both sides, the zero series absorbs Cauchy product on both sides, and the singleton empty-history naming certificate records the semantic carrier used by the terminal concrete instance.

Proof. The carrier, classifier, and displayed operation names are exactly the public interface exported in Definition 51.69; hence the certificate only has to assemble the algebra rows already stated there.

Apply Definition 51.64 for the pointwise additive group rows on $\mathsf{FPSCarrier}_R$. Apply Definition 51.57 for Cauchy-product closure, congruence, associativity, and the unit series on the same pointwise classifier.

The interaction rows are supplied by Definition 51.66 and Definition 51.65. They identify the two distributivity laws and the two zero-product absorption laws without changing the carrier or classifier.

Finally, Definition 51.68 records the singleton semantic naming surface used when the concrete instance is read at the terminal empty-history object. Together these rows are the concrete $\mathsf{Ring}^{\uparrow}$ instance certificate for the displayed FPS carrier and operations. □

Theorem 51.71 (FPS RingUp standard bridge boundary)**.** *The public algebra interface of Definition 51.69 and the concrete instance certificate of Definition 51.70 form the paper bridge from the BEDC coefficientwise FPS carrier to the standard formal-power-series ring schema. The bridge boundary sends the carrier to coefficientwise carried sequences over* $\mathsf{Nat}^{\uparrow}$*, sends the classifier to the pointwise scalar classifier, sends addition and inverse to their pointwise operations, sends multiplication to the Cauchy product through finite split spines, and sends zero and unit to the displayed scalar rows. It exports no analytic convergence, topology, completion, or external library quotient.*

Proof. First read the public surface from Definition 51.69. It fixes one carrier $\mathsf{FPSCarrier}_R$, one pointwise classifier $\sim_{\mathrm{fps}}$, and the five operation rows $\oplus_{\mathrm{fps}}$, 0_{fps}, $-_{\mathrm{fps}}$, $\odot_{\mathrm{fps}}$, and 1_{fps}.

Next apply Definition 51.70. It repacks that same surface as a concrete $\mathsf{Ring}^{\uparrow}$ instance, with the additive group rows, Cauchy-product monoid rows, distributivity rows, zero-product absorption rows, and singleton semantic certificate all kept on the displayed carrier and classifier.

The Cauchy-product part is the only non-pointwise operation. Its coefficient is defined by the finite split spine of Definition 51.20, and the finite-fold transport rows already used in Definition 50.26 carry the scalar comparisons through those spines.

Thus the bridge boundary is exactly the public coefficientwise $\mathsf{Ring}^{\uparrow}$ schema: carrier and classifier are pointwise, additive structure is pointwise, multiplication is the displayed finite Cauchy fold, and the excluded analytic or quotient data are not part of the exported interface. □

Closure status for $\mathsf{NameCert}_{\mathsf{FPS}^{\uparrow}}$**.**

Constructive story: A formal power series over a certified ring is built as a coefficient sequence indexed by $\mathsf{Nat}^{\uparrow}$, with every coefficient carried by the same $\mathsf{Ring}^{\uparrow}$ scalar certificate. The carrier accepts exactly coefficientwise carried sequences, the classifier compares two series pointwise by the scalar classifier at each unary index, and sequences with an uncarried coefficient or a missing pointwise comparison stay outside the public algebra surface. The source is the scalar $\mathsf{Ring}^{\uparrow}$ data together with the coefficientwise carrier, the pattern records pointwise addition, zero series, coefficientwise inverse, Cauchy product through finite split spines, the unit series, distributivity, and zero-product absorption, while the ledger keeps each finite fold, split witness, and scalar coefficient comparison visible. The name-certificate obligations are anchored by the singleton empty-history semantic certificate for the terminal instance and by the scalar rows for the general interface: carried zero or unit sequences inhabit the relevant carrier, pointwise classifier equivalence gives reflexivity, symmetry, and transitivity, and coefficientwise transport preserves carried series under classified replacement. A sequence history h lies in the signature gap of a $\mathsf{FPS}^{\uparrow}$ token p when the source-domain accepts all coefficients of h, the signature relation pairs it with an answer series and evidence ledger of coefficient witnesses and finite folds, and token introduction names that answer as p; unfolded, every unary coefficient matches the scalar endpoint encoded by p and every product coefficient is the displayed Cauchy finite-fold value. The bridge boundary is the public coefficientwise $\mathsf{Ring}^{\uparrow}$ interface, with no analytic convergence, completion, or separate formal-series carrier introduced.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FPS}^{\uparrow}}$, maturePackageClosed)

Scope closed: The public FPS RingUp bridge boundary, coefficientwise carrier and classifier, finite Cauchy-fold product, zero absorption rows, and consumer-completeness packaging are closed over $\mathsf{Ring}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, the pointwise operations, Cauchy unit series, distributivity rows, singleton semantic certificate, and displayed finite-fold witnesses in this child file.

Definition 51.72 (FPS threefold Cauchy split spines)**.** *Let R be read as a* $\mathsf{Ring}^{\uparrow}(R)$ *certificate with scalar classifier $\sim_R$, addition $+_R$, multiplication $\cdot_R$, zero endpoint 0_R, and finite additive fold*

$\mathsf{fold}_{+,R}$. *For coefficient sequences $F, G, H : \mathsf{Nat}^{\uparrow} \to R$ and unary index n, define the left and right threefold split spines by*

$$\mathsf{TripSp}^{\ell}_{n}(F, G, H) := \mathsf{concat}_{(a,k)\in\mathsf{Split}(n)}\mathsf{map}_{(i,j)\in\mathsf{Split}(a)}\big((F_i \cdot_R G_j) \cdot_R H_k\big)$$

and

$$\mathsf{TripSp}^{r}_{n}(F, G, H) := \mathsf{concat}_{(i,c)\in\mathsf{Split}(n)}\mathsf{map}_{(j,k)\in\mathsf{Split}(c)}\big(F_i \cdot_R (G_j \cdot_R H_k)\big).$$

The left spine enumerates witnesses (i, j, k) through $(i + j) + k = n$; the right spine enumerates the same triples through $i + (j + k) = n$.

Lean4 (definition) `BEDC.Derived.FpsUp.FpsSingletonThreefoldCauchySplitSpines`

Lemma 51.73 (FPS threefold Cauchy split reassociation)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate, read through Definition 44.8 as a $\mathsf{Ring}^{\uparrow}(R)$ certificate. For carried coefficient sequences $F, G, H : \mathsf{Nat}^{\uparrow} \to R$ and unary index n, the two threefold split folds of Definition 51.72 are scalar-classified:*

$$\mathsf{fold}_{+,R}(\mathsf{TripSp}^{\ell}_{n}(F, G, H)) \sim_R \mathsf{fold}_{+,R}(\mathsf{TripSp}^{r}_{n}(F, G, H)).$$

Proof. The split spine $\mathsf{Split}(n)$ of Definition 51.20 is finite. Hence each displayed spine in Definition 51.72 is a finite concatenation of finite split spines. Its entries are carried scalars because the coefficient sequences are carried and the multiplication closure row is retained by Definition 43.26.

The left indexing data are quadruples $((a, k), (i, j))$ with $a + k = n$ and $i + j = a$. Sending this data to (i, j, k) gives a triple with $(i + j) + k = n$. The right indexing data are quadruples $((i, c), (j, k))$ with $i + c = n$ and $j + k = c$. Sending this data to (i, j, k) gives a triple with $i + (j + k) = n$. Unary additive associativity for the $\mathsf{Nat}^{\uparrow}$ split recursion identifies these two triple predicates, and the two reconstructions

$$(i, j, k) \mapsto ((i + j, k), (i, j)), \qquad (i, j, k) \mapsto ((i, j + k), (j, k))$$

are inverse on the displayed split witnesses.

Apply the split-spine instance of the two-index finite fold swap certificate of Definition 49.94 to this finite reindexing. It reduces the comparison of the two iterated folds to the pointwise scalar comparison attached to a fixed triple (i, j, k). For that triple, the retained multiplicative associativity row in Definition 43.26 gives

$$(F_i \cdot_R G_j) \cdot_R H_k \sim_R F_i \cdot_R (G_j \cdot_R H_k).$$

The fold-swap certificate and Definition 50.26 lift these pointwise comparisons through the finite spines. This is the displayed scalar classification. □

Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonThreefoldCauchySplitSpines classifier`
Lean4 ✓ `BEDC.Derived.FpsUp.FpsSingletonThreefoldCauchySplitSpines reassociation`

Theorem 51.74 (FPS Cauchy product associativity from CommRing scalars)**.** *Let R carry a $\mathsf{CommRing}^{\uparrow}(R)$ certificate. In the $\mathsf{FPS}^{\uparrow}(R)$ interface, let $\sim_{\mathrm{fps}}$ be the pointwise classifier of Definition 51.15. For carried coefficient sequences $F, G, H : \mathsf{Nat}^{\uparrow} \to R$,*

$$\forall n : \mathsf{Nat}^{\uparrow}, \quad \big((F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H\big)_n \sim_R \big(F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H)\big)_n.$$

Consequently,

$$(F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H \sim_{\mathrm{fps}} F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H).$$

Proof. Read the scalar certificate as a $\mathsf{Ring}^{\uparrow}(R)$ certificate by Definition 44.8. This keeps the scalar classifier, zero endpoint, addition, multiplication, additive abelian-group rows, multiplication congruence, the distributive rows, and multiplicative associativity from Definition 43.26. The finite additive fold is the fold used in Definition 51.20.

Fix $n : \mathsf{Nat}^{\uparrow}$. By Definition 51.20, the left-associated coefficient is

$$\mathsf{fold}_{+,R}\big(\mathsf{CauchySp}_n(F \odot_{\mathrm{fps}} G, H)\big).$$

For a split $(a, k) \in \mathsf{Split}(n)$, the corresponding summand is

$$(F \odot_{\mathrm{fps}} G)_a \cdot_R H_k.$$

Unfolding the inner product at a gives

$$\mathsf{fold}_{+,R}\big(\mathsf{CauchySp}_a(F, G)\big) \cdot_R H_k.$$

The right-multiplication half of Definition 49.95 classifies this endpoint with the inner finite fold over

$$\mathsf{map}_{(i,j)\in\mathsf{Split}(a)}\big((F_i \cdot_R G_j) \cdot_R H_k\big).$$

Applying Definition 50.26 over the outer split spine lifts these inner comparisons and gives

$$\big((F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H\big)_n \sim_R \mathsf{fold}_{+,R}\big(\mathsf{TripSp}^{\ell}_n(F, G, H)\big).$$

The right-associated coefficient expands similarly:

$$\big(F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H)\big)_n = \mathsf{fold}_{+,R}\big(\mathsf{CauchySp}_n(F, G \odot_{\mathrm{fps}} H)\big).$$

For a split $(i, c) \in \mathsf{Split}(n)$, the summand is

$$F_i \cdot_R (G \odot_{\mathrm{fps}} H)_c.$$

Unfolding the inner product at c and applying the left-multiplication half of Definition 49.95 classifies this summand with the inner fold over

$$\mathsf{map}_{(j,k)\in\mathsf{Split}(c)}\big(F_i \cdot_R (G_j \cdot_R H_k)\big).$$

Finite-fold congruence over the outer split spine gives

$$\big(F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H)\big)_n \sim_R \mathsf{fold}_{+,R}\big(\mathsf{TripSp}^{r}_n(F, G, H)\big).$$

By Definition 51.73,

$$\mathsf{fold}_{+,R}\big(\mathsf{TripSp}^{\ell}_n(F, G, H)\big) \sim_R \mathsf{fold}_{+,R}\big(\mathsf{TripSp}^{r}_n(F, G, H)\big).$$

Classifier transitivity composes the left expansion, this threefold split comparison, and the symmetry of the right expansion, giving

$$\big((F \odot_{\mathrm{fps}} G) \odot_{\mathrm{fps}} H\big)_n \sim_R \big(F \odot_{\mathrm{fps}} (G \odot_{\mathrm{fps}} H)\big)_n.$$

Since n was arbitrary, the pointwise classifier specification of Definition 51.15 yields the displayed $\mathsf{FPS}^{\uparrow}$ classifier judgment. The closure of the two products is the Cauchy-product closure field listed in Definition 51.16, and all folds are finite at the fixed coefficient index. □

Chapter 52

A Concrete Naming Certificate for $\mathsf{Preorder}^{\uparrow}$

The preorder interface $\mathsf{Preorder}^{\uparrow}$ is licensed by a carrier with a binary relation $\leq : C \times C \to \mathsf{Prop}$ satisfying reflexivity and transitivity under the carrier's classifier. It is the simplest order-theoretic NameCert and self-contained: no other licensed object is required as a dependency.

On the source side, the preorder certificate is kernel-local: the carrier, classifier, and prefix-comparison ledger are all discharged inside this chapter. Its first order-theoretic sibling consumer is $\mathsf{POSet}^{\uparrow}$ in chapter 53, where the partially ordered set certificate adds the antisymmetry row while preserving the inherited preorder carrier, classifier, and prefix-comparison ledger.

Remark 52.1 (Preorder certificate scope)**.** *This chapter records the preorder licensing target through a history carrier, restricted classifier, and reflexive-transitive relation data.*

52.1 Carrier definition

Definition 52.2 (Preorder carrier)**.** *Use an abstract carrier C, classifier $\sim_C$, and relation $\leq_C$ with preorder law fields.*

52.2 Concrete unary prefix preorder instance

Definition 52.3 (Concrete unary prefix preorder instance)**.** *The concrete unary prefix preorder instance is the following specialization of the* $\mathsf{Preorder}^{\uparrow}$ *source data:*

$$\mathsf{Carrier} := \mathsf{PreorderCarrier} = \mathsf{UnaryHistory}.$$

$$\mathsf{classifier} := \mathsf{PreorderCarrierClassifierSpec}(\mathsf{PreorderCarrier}).$$

$$\mathsf{le} := \mathsf{PreorderPrefixLE}.$$

Theorem 52.4 (Concrete unary prefix preorder laws)**.** *For the concrete unary prefix preorder instance, the carrier is inhabited by* e*, carrier membership transports along* hsame*, the relation* $\mathsf{PreorderPrefixLE}$ *is reflexive on carrier histories, transitive, and congruent under the classifier in both arguments.*

Proof. The carrier and transport fields are supplied by the checked semantic naming certificate named BEDC.Derived.PreorderUp. preorder_carrier_semantic_name_certificate. This identifies the concrete carrier with unary histories and gives the hsame transport operation used by the restricted classifier.

The relational fields come from the checked concrete prefix stability certificate named BEDC.Derived.PreorderUp. preorder_prefix_stability_certificate_fields. Its reflexivity component is the carrier-relative preorder reflexivity field, its congruence component is the classifier-respecting transport of the prefix relation in both endpoints, and its transitivity component is the concrete prefix composition law.

At the theorem level, reflexivity is obtained by applying BEDC.Derived.PreorderUp.PreorderPrefixLE_of_hsame to the reflexive hsame witness, while transitivity is BEDC.Derived.PreorderUp.PreorderPrefixLE_trans. Repacking these fields gives the concrete unary prefix preorder laws. □

Thus the $\mathsf{Preorder}^{\uparrow}$ schema is instantiated by this concrete BHist carrier and relation. The corresponding formal target can therefore address the concrete prefix preorder directly, rather than only the relation fields of an arbitrary carrier.

Definition 52.5 (Prefix-history preorder instance)**.** *The prefix-history preorder instance pins the* $\mathsf{Preorder}^{\uparrow}$ *carrier and relation to the concrete kernel rows*

$$\mathsf{Carrier} := \mathsf{UnaryHistory}, \qquad \mathsf{relation} := \mathsf{PreorderPrefixLE}.$$

Its law row consists of reflexivity from hsame *via* PreorderPrefixLE_of_hsame *and transitivity via* PreorderPrefixLE_trans*.*

Theorem 52.6 (Prefix-history preorder laws)**.** *For the instance of Definition 52.5, every carrier history is related to itself, and whenever* $\mathsf{PreorderPrefixLE}(h,k)$ *and* $\mathsf{PreorderPrefixLE}(k,r)$ *hold,* $\mathsf{PreorderPrefixLE}(h,r)$ *holds. Thus the concrete* BHist *prefix relation supplies a preorder instance without adding an abstract carrier parameter or a separate relation schema.*

Proof. For reflexivity, apply PreorderPrefixLE_of_hsame to the reflexive hsame witness on the displayed UnaryHistory carrier.

For transitivity, apply PreorderPrefixLE_trans to the two displayed prefix comparisons. The resulting law row is exactly the concrete instance row named in the definition, so no additional carrier or classifier parameter is introduced. □

52.3 Concrete singleton empty preorder instance

Definition 52.7 (Concrete singleton empty preorder instance)**.** *Let* A_{e} *be the singleton history source of Definition 36.169 at* $a_0 = \mathsf{e}$*. Define the restricted classifier by*

$$\rho_{\mathsf{e}}(h,k) := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h,k).$$

Define the carrier-guarded restricted order by

$$h \leq_{\mathsf{e}}^{\mathrm{sg}} k := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{PreorderPrefixLE}(h,k).$$

The concrete preorder package is the fixed BHist *tuple* $(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \leq_{\mathsf{e}}^{\mathrm{sg}})$*.*

Theorem 52.8 (Singleton empty preorder laws)**.** *For the concrete package of Definition 52.7, the carrier is inhabited by* e*, carrier membership transports along* hsame*,* $\leq_{\mathsf{e}}^{\mathrm{sg}}$ *is reflexive on carried histories and transitive, and* $\leq_{\mathsf{e}}^{\mathrm{sg}}$ *is congruent under* ρ_{e} *in both endpoints. Moreover, Definition 52.9 gives the exact classifier row for all histories.*

Proof. The singleton source supplies the inhabitance witness $A_{\mathsf{e}}(\mathsf{e})$. Unfolding the source shows that any carried endpoint is identified with e by hsame, and transport along hsame is exactly the transport law recorded for the singleton history source.

Reflexivity follows by applying $\mathsf{PreorderPrefixLE_of_hsame}$ to the reflexive witness $\mathsf{hsame}(h, h)$ for each carried history h, then pairing the prefix witness with the two copies of the carrier witness for h. Transitivity projects the two guarded comparisons to their prefix witnesses and applies $\mathsf{PreorderPrefixLE_trans}$; the endpoint carrier witnesses are carried by the first and second guarded comparisons.

For congruence, unfold ρ_{e} at the source and target endpoints. The classifier fields provide the carrier witnesses and the hsame witnesses needed to move each endpoint. The prefix stability certificate for $\mathsf{PreorderPrefixLE}$ then transports the comparison in the left endpoint and in the right endpoint, after which the transported endpoint carriers are repacked into the guarded comparison.

The exact classifier row is Definition 52.9. □

Theorem 52.9 (Singleton guarded prefix preorder exactness)**.** *For all histories $h, k : \mathsf{BHist}$ in the concrete singleton empty preorder instance,*

$$\rho_{\mathsf{e}}(h, k) \Longleftrightarrow (h \leq_{\mathsf{e}}^{\mathrm{sg}} k \wedge k \leq_{\mathsf{e}}^{\mathrm{sg}} h).$$

Proof. For the forward direction, unfold $\rho_{\mathsf{e}}(h, k)$. The classifier witness contains the two carrier witnesses and the history-sameness witness $\mathsf{hsame}(h, k)$. Apply Definition 52.17 to $\mathsf{hsame}(h, k)$ to obtain the prefix comparison from h to k.

Apply the same theorem to the symmetric history-sameness witness to obtain the prefix comparison from k to h. Pair each prefix comparison with the two carrier witnesses in the appropriate order; this gives the two guarded comparisons.

For the reverse direction, project the carrier witnesses from either guarded comparison. Project the prefix witnesses from both guarded comparisons and apply Definition 52.30 to recover $\mathsf{hsame}(h, k)$.

Finally, combine the carrier witnesses with this history-sameness witness. This is exactly the restricted classifier $\rho_{\mathsf{e}}(h, k)$. □

Theorem 52.10 (Singleton empty preorder terminal comparison package)**.** *For histories $h, k :$ BHist carried by A_{e} in the concrete singleton empty preorder instance, the restricted comparison package is pinned to the terminal endpoint:*

$$A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \Longrightarrow h \leq_{\mathsf{e}}^{\mathrm{sg}} k \wedge k \leq_{\mathsf{e}}^{\mathrm{sg}} h \wedge \rho_{\mathsf{e}}(h, k).$$

Its ten-field fit is the following: the traditional target is the one-point preorder; the BEDC source is BHist *with singleton carrier A_{e}; the carrier is A_{e}; the classifier is ρ_{e}; stability is supplied by singleton endpoint transport and Definition 52.17; the ledger records the two endpoint witnesses; the core theorem is the displayed terminal comparison package; exactness is guarded prefix exactness; the standard bridge is the one-point preorder; and the status is* $\mathsf{ProofTarget}$.

Proof. Assume $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$. Unfolding the singleton carrier witnesses identifies both histories with the endpoint e, giving $h\mathsf{hsame}\mathsf{e}$ and $k\mathsf{hsame}\mathsf{e}$.

Compose the first witness with the symmetry of the second to obtain $h\mathsf{hsame}k$, and compose the second witness with the symmetry of the first to obtain $k\mathsf{hsame}h$.

Apply Definition 52.17 to these two hsame witnesses. The first application gives the prefix part of $h \leq_{\mathsf{e}}^{\mathrm{sg}} k$, and the second gives the prefix part of $k \leq_{\mathsf{e}}^{\mathrm{sg}} h$.

Finally, package $\rho_{\mathsf{e}}(h, k)$ from the two carrier witnesses together with the composed witness $h\mathsf{hsame}k$. Repack the two carrier witnesses with the two prefix witnesses to obtain the guarded

comparisons; these comparisons and the classifier witness are exactly the displayed terminal comparison package. □

Definition 52.11 (Singleton empty preorder public comparison readback)**.** *For the concrete singleton empty preorder instance, the public readback of the guarded comparison $h \leq_{\mathsf{e}}^{\mathrm{sg}} k$ is the endpoint-carrier pair*

$$A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

Theorem 52.12 (Singleton empty preorder single-comparison exactness)**.** *For all histories $h, k :$ BHist in the concrete singleton empty preorder instance, one guarded comparison is exactly endpoint carriage:*

$$h \leq_{\mathsf{e}}^{\mathrm{sg}} k \Longleftrightarrow A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

Its ten-field fit is the following: the traditional target is one-point preorder comparison readback; the BEDC source is BHist; the carrier is A_{e}; the classifier is ρ_{e}; the relation is $\leq_{\mathsf{e}}^{\mathrm{sg}}$; stability is supplied by singleton transport and Definition 52.17; the ledger records the two endpoint witnesses and the single comparison witness; the core theorem is this single-comparison exactness block; exactness is the displayed if-and-only-if; the standard bridge is the one-point preorder; and the status is $\mathsf{ProofTarget}$.

Proof. For the forward direction, unfold the guarded relation $h \leq_{\mathsf{e}}^{\mathrm{sg}} k$. Its witness is a package consisting of $A_{\mathsf{e}}(h)$, $A_{\mathsf{e}}(k)$, and $\mathsf{PreorderPrefixLE}(h, k)$. Project the first two fields to obtain the endpoint-carrier pair.

For the reverse direction, assume $A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k)$. Apply Definition 52.10 to these two carrier witnesses. The resulting terminal comparison package contains $h \leq_{\mathsf{e}}^{\mathrm{sg}} k$ as its first component, which is the required single guarded comparison. □

Theorem 52.13 (Singleton empty $\mathsf{Preorder}^{\uparrow}$ naming certificate)**.** *The tuple $(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \leq_{\mathsf{e}}^{\mathrm{sg}})$ of Definition 52.7 supplies the source, pattern, classifier, stability, ledger, and singleton exactness rows for a concrete $\mathsf{Preorder}^{\uparrow}$ certificate over A_{e}, ρ_{e}, and $\leq_{\mathsf{e}}^{\mathrm{sg}}$. The exactness row is*

$$\rho_{\mathsf{e}}(h, k) \Longleftrightarrow (h \leq_{\mathsf{e}}^{\mathrm{sg}} k \wedge k \leq_{\mathsf{e}}^{\mathrm{sg}} h).$$

Proof. The carrier row is the singleton BHist source A_{e}, and Definition 52.8 supplies its inhabitance by e together with transport along hsame. The pattern row is the restricted comparison judgment $h \leq_{\mathsf{e}}^{\mathrm{sg}} k$, and the classifier row is ρ_{e}.

The same law package gives the stability rows: reflexivity of $\leq_{\mathsf{e}}^{\mathrm{sg}}$ on carried histories, transitivity, and endpoint congruence for the classifier. The ledger row is Definition 52.45, which packages the two carried endpoints and the restricted comparison witness.

Definition 52.9 gives the displayed two-sided exactness statement for all histories. That theorem is exactly the singleton exactness row of the concrete $\mathsf{Preorder}^{\uparrow}$ certificate. □

Theorem 52.14 (Preorder finite comparison induction)**.** *For the concrete singleton empty preorder package $(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \leq_{\mathsf{e}}^{\mathrm{sg}})$, every public singleton comparison read is generated by finite package induction from exactly three visible rows: endpoint carrier witnesses $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$, guarded prefix exactness for $\leq_{\mathsf{e}}^{\mathrm{sg}}$, and the terminal comparison package of Definition 52.10. A reader that reaches a comparison*

$$h \leq_{\mathsf{e}}^{\mathrm{sg}} k$$

therefore has already passed through the endpoint carrier row and can recover the public readback

$$A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k)$$

without invoking an ambient order, quotient equality, selected representative, or external preorder carrier.

Proof. Begin with the finite carrier row. A singleton comparison read is addressed to the displayed package $(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \leq_{\mathsf{e}}^{\mathrm{sg}})$, so its endpoints must first be inspected through the endpoint carrier witnesses of A_{e}.

The base package step is the terminal endpoint. When the two endpoint carrier witnesses are present, Definition 52.10 produces both guarded comparisons and the classifier witness $\rho_{\mathsf{e}}(h, k)$ from the same finite data.

The induction step is guarded exactness. If a public reader starts with a single guarded comparison, then Definition 52.12 projects it back to $A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k)$; if the reader starts with the classifier row, Definition 52.9 projects the two guarded comparisons from the same endpoint witnesses.

Thus every route through the singleton comparison surface factors through endpoint carriage, guarded prefix exactness, and terminal comparison packaging. No additional order object or representative choice is available in the finite package. □

This singleton package gives a concrete BHist source for the $\mathsf{Preorder}^{\uparrow}$ relation fields, so order formalization can target this carrier rather than arbitrary relation parameters.

52.4 The certificate

Definition 52.15 (Preorder source specification)**.** *The source is the carrier C with its classifier and relation.*

Definition 52.16 (Preorder pattern specification)**.** *The pattern is relational judgment formation $a \leq_C b$ over carrier witnesses.*

Theorem 52.17 (Prefix from history sameness)**.** *If h and k are internally history-same, then $h \leq k$ in the concrete unary history prefix relation.*

Proof. Eliminate the $\mathsf{hsame}(h, k)$ witness. The prefix relation is then witnessed by the empty unary tail together with the right-unit continuation law for h. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE of hsame`

Theorem 52.18 (Prefix append by unary tail)**.** *For every history h, appending a unary tail to h gives a concrete prefix relation from h to the append result.*

Proof. Use the unary tail itself as the prefix witness. The continuation component is the definitional append equation, introduced by the BEDC continuation constructor. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE append unary tail`

Theorem 52.19 (Prefix from empty is unary carrier)**.** *For the concrete unary history preorder, $\mathsf{e} \leq h$ holds exactly when h is in the preorder carrier.*

Proof. Eliminate the prefix witness from e to expose its unary tail and continuation result. The left-unit result identifies the target with the tail, so unary membership transports to h. Conversely, use h itself as the unary tail and the continuation left unit. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE empty left iff unary`

Theorem 52.20 (Prefix to empty identifies the source)**.** *For the concrete unary history preorder, $h \leq \mathsf{e}$ holds exactly when h*hsamee*.*

Proof. Eliminate the prefix witness into a unary tail and a continuation into e. The empty-result inversion theorem forces the source history to be e. Conversely, after the history-sameness proof identifies the source with e, use the empty unary tail and the continuation right unit. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE empty target iff`

Theorem 52.21 (Prefix relation preserves the carrier)**.** *For the concrete unary history carrier, if h is a carrier history and h is related to k by appending a unary prefix tail, then k is also in the carrier.*

Proof. Unpack the prefix witness into its unary tail and continuation proof. Unary continuation closure sends the carrier witness for h, the unary witness for the tail, and the continuation proof to a carrier witness for k. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE preserves carrier`

Theorem 52.22 (Prefix target carrier reflects source carrier)**.** *For the concrete unary history carrier, if $h \leq k$ is witnessed by a unary prefix tail and k is in the carrier, then h is also in the carrier.*

Proof. Unpack the prefix witness into its unary tail and continuation proof. The target carrier is unary, so unary continuation left-factor closure recovers unary membership of the source history h. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE source carrier of target carrier`

Theorem 52.23 (Prefix carrier excludes zero target)**.** *If h is in the concrete preorder carrier, then a prefix comparison from h to* $\mathsf{e0}(k)$ *is impossible.*

Proof. The prefix relation preserves the concrete carrier from source to target. Thus $\mathsf{e0}(k)$ would be a unary history, contradicting the BEDC unary history zero-extension exclusion. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE carrier no e0 target`

Theorem 52.24 (Prefix carrier excludes zero source)**.** *If k is in the concrete preorder carrier, then a prefix comparison from* $\mathsf{e0}(h)$ *to k is impossible.*

Proof. The target carrier reflects through a concrete unary prefix witness to the source carrier. Thus $\mathsf{e0}(h)$ would be a unary history, contradicting the BEDC unary history zero-extension exclusion. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE carrier no e0 source`

Definition 52.25 (Preorder classifier specification)**.** *The classifier is the supplied carrier sameness, and the relation is stable under classifier replacement.*

Theorem 52.26 (Prefix right extension)**.** *If $h \leq k$ is witnessed by a unary continuation tail, and k continues by a unary tail to r, then $h \leq r$.*

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE right extension`

Proof. Unpack the first prefix witness as a unary tail from h to k. Compose this continuation with the continuation from k to r; associativity of continuation supplies the resulting path from h, and unary closure under append supplies the combined unary tail. □

Theorem 52.27 (Prefix preserves strict right extension)**.** *If $h \leq k$ is witnessed by a unary continuation tail and k is a strict unary prefix of r, then h is a strict unary prefix of r.*

Proof. Unpack the weak prefix tail from h to k and the nonempty strict tail from k to r. Appending the two tails gives a unary tail from h to r by unary append closure and continuation associativity. If the appended tail were e, append-empty inversion would force the strict right tail to be e, contradicting strictness. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE strict right extension`

Theorem 52.28 (Prefix transitivity)**.** *If $h \leq k$ and $k \leq r$ are witnessed by unary continuation tails, then $h \leq r$.*

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE trans`

Proof. Unpack the two prefix witnesses. Append the two unary tails, use unary closure under append for the combined tail, and use continuation associativity to identify the direct continuation from h to r. □

Theorem 52.29 (Strict unary prefix preserves right extension)**.** *If h is a strict unary prefix of k and $k \leq r$ is witnessed by a unary continuation tail, then h is a strict unary prefix of r.*

Proof. Unpack the nonempty strict tail from h to k and the weak prefix tail from k to r. Their append is unary and composes the two continuations from h to r. If the appended tail were e, append-empty inversion would force the original strict tail to be e, contradicting strictness. □

Lean4 ✓ `BEDC.Derived.PreorderUp.NatUnaryStrictPrefix right extension`

Theorem 52.30 (Prefix antisymmetry collapses to history sameness)**.** *If $h \leq k$ and $k \leq h$ are both witnessed by unary continuation tails, then* $\mathsf{hsame}(h, k)$.

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE antisymm hsame`

Proof. Unpack the two prefix witnesses. Substituting the first continuation equation into the second gives a round trip from h through the two tails back to h. Associativity rewrites this as equality between the empty right tail and the combined tail under the same left prefix, and left cancellation forces the forward tail to be empty. The first continuation equation then reduces to $\mathsf{hsame}(h, k)$. □

Theorem 52.31 (Concrete prefix order laws up to history-sameness)**.** *The concrete unary prefix relation* PreorderPrefixLE *is reflexive, transitive, and antisymmetric up to* hsame*: for every history h, $h \leq h$; for all histories h, k, r, $h \leq k$ and $k \leq r$ imply $h \leq r$; and for all histories h, k, $h \leq k$ and $k \leq h$ imply* $\mathsf{hsame}(h, k)$.

Proof. Reflexivity follows from hsame reflexivity together with PreorderPrefixLE_of_hsame. Transitivity is exactly PreorderPrefixLE_trans. Antisymmetry up to history-sameness is exactly PreorderPrefixLE_antisym □

Theorem 52.32 (Prefix left extension)**.** *If x continues by a unary tail to h, and $h \leq k$ is witnessed by a unary continuation tail, then $x \leq k$.*

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE left extension`

Proof. Unpack the prefix witness from h to k. Append the incoming unary tail to the prefix tail, use unary closure under append for the combined tail, and use continuation associativity to identify the resulting continuation from x to k. □

Theorem 52.33 (Prefix append tail)**.** *For every history h, appending a unary history t gives a concrete prefix comparison $h \leq \mathsf{append}(h, t)$.*

Proof. Use t itself as the prefix witness. Its unary membership is the supplied carrier for the tail, and the continuation component is the defining append-result equality. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE append tail`

Theorem 52.34 (Prefix append tail backforces empty)**.** *If t is unary and $\mathsf{append}(h, t) \leq h$, then t is internally the same as e.*

Proof. The unary tail gives the forward prefix comparison $h \leq \mathsf{append}(h, t)$. Together with the assumed backward comparison, prefix antisymmetry gives $\mathsf{hsame}(h, \mathsf{append}(h, t))$. Rewriting the left endpoint as $\mathsf{append}(h, \mathsf{e})$ and cancelling the common left context forces $\mathsf{hsame}(t, \mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE append tail backforces empty`

Theorem 52.35 (Prefix append tail backforces empty equivalence)**.** *If t is unary, then $\mathsf{append}(h, t) \leq h$ holds exactly when $t\mathsf{hsame}\mathsf{e}$.*

Proof. The forward direction is the backforces-empty implication for unary tails. For the reverse direction, $t\mathsf{hsame}\mathsf{e}$ identifies $\mathsf{append}(h, t)$ with the right-unit endpoint h; the prefix relation is then obtained from endpoint sameness. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE append tail backforces empty iff`

Theorem 52.36 (Prefix left context monotonicity)**.** *If $h \leq k$ is witnessed by a unary continuation tail, then appending the same left context to both endpoints preserves the prefix comparison: $\mathsf{append}(x, h) \leq \mathsf{append}(x, k)$.*

Proof. Unpack the prefix witness as a unary tail and a continuation equation from h to k. Reuse the same unary tail after the common left context. Associativity of append identifies the resulting continuation endpoint with $\mathsf{append}(x, k)$. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE append left context`

Theorem 52.37 (Prefix right context monotonicity)**.** *If x is unary and $h \leq k$ is witnessed by a unary continuation tail, then appending x to both endpoints preserves the prefix comparison: $\mathsf{append}(h, x) \leq \mathsf{append}(k, x)$.*

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE append right context`

Proof. Unpack the prefix witness as a unary tail and a continuation equation from h to k. Reuse the same tail. Associativity moves the right context next to the tail, unary commutativity swaps the two unary histories, and associativity moves the tail back to the continuation endpoint. □

Theorem 52.38 (Prefix two-sided context monotonicity)**.** *If r is unary and $h \leq k$ is witnessed by a unary continuation tail, then placing the same left context outside both right-contexted endpoints preserves the prefix comparison:* $\mathsf{append}(\ell, \mathsf{append}(h, r)) \leq \mathsf{append}(\ell, \mathsf{append}(k, r))$.

Proof. First apply right-context monotonicity using the unary carrier of r. Then apply left-context monotonicity to the resulting comparison. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE append both context`

Theorem 52.39 (Prefix right context cancellation)**.** *If x is unary and* $\mathsf{append}(h, x) \leq \mathsf{append}(k, x)$*, then $h \leq k$.*

Proof. Unpack the prefix witness as a unary tail and a continuation equation. Append associativity brings the right context next to that tail, unary commutativity exchanges the two unary histories, and associativity restores a common right context. Right cancellation removes the shared x, leaving the continuation witness from h to k. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE cancel right context`

Theorem 52.40 (Prefix left context cancellation)**.** *If appending the same left context to h and k makes* $\mathsf{append}(x, h) \leq \mathsf{append}(x, k)$*, then $h \leq k$.*

Proof. Unpack the prefix witness as a unary tail and a continuation equation from $\mathsf{append}(x, h)$ to $\mathsf{append}(x, k)$. Continuation associativity rewrites the right side as a common left append by x; left cancellation removes that context and gives the continuation equation from h to k with the same unary tail. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE cancel left context`

Theorem 52.41 (Prefix two-sided context cancellation)**.** *If r is unary and the two endpoints become prefix-comparable after adding a common left context outside a common right context,*

$$\mathsf{append}(\ell, \mathsf{append}(h, r)) \leq \mathsf{append}(\ell, \mathsf{append}(k, r)),$$

then $h \leq k$.

Proof. First cancel the common left context, giving $\mathsf{append}(h, r) \leq \mathsf{append}(k, r)$. Then use right-context cancellation with the unary witness for r, leaving the prefix comparison from h to k. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE cancel both context`

Theorem 52.42 (Prefix two-sided context equivalence)**.** *If r is unary, then placing the same left context outside both right-contexted endpoints preserves and reflects the concrete prefix comparison:*

$$\mathsf{append}(\ell, \mathsf{append}(h, r)) \leq \mathsf{append}(\ell, \mathsf{append}(k, r)) \quad \Longleftrightarrow \quad h \leq k.$$

Proof. The forward direction first cancels the common left context, then cancels the common unary right context. The reverse direction is exactly two-sided context monotonicity. □

Lean4 ✓ `BEDC.Derived.PreorderUp.PreorderPrefixLE append both context iff`

Definition 52.43 (Concrete prefix stability certificate)**.** *The concrete prefix stability certificate for* PreorderPrefixLE *under* PreorderClassifierSpec *consists of:*

1. *classifier reflexivity*

2. *classifier transitivity*
3. *prefix preorder reflexivity*
4. *prefix preorder transitivity*
5. *prefix relation congruence in both arguments*

Lean4 ✓ `BEDC.Derived.PreorderUp.preorder prefix stability certificate fields`

Definition 52.44 (Abstract preorder stability certificate)**.** *The abstract preorder stability certificate for an arbitrary relation leC consists of:*

1. *classifier reflexivity*
2. *classifier transitivity*
3. *preorder reflexivity*
4. *preorder transitivity*
5. *relation congruence in both arguments*

Lean4 ✓ `BEDC.Derived.PreorderUp.preorder stability certificate fields`

Definition 52.45 (Preorder ledger policy)**.** *Record the compared carrier witnesses and the relation derivation.*

Definition 52.46 ($\mathsf{Preorder}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{Preorder}^{\uparrow}$*.*

Theorem 52.47 (Concrete unary prefix $\mathsf{Preorder}^{\uparrow}$ naming certificate)**.** *The tuple of Definition 52.3 supplies the source, pattern, classifier, stability, ledger, and exactness rows for a* NameCert *licensing* $\mathsf{Preorder}^{\uparrow}$ *over* PreorderCarrier = UnaryHistory*, classifier* PreorderCarrierClassifierSpec(PreorderCarrier)*, and relation* PreorderPrefixLE*.*

Proof. The source, pattern, and classifier rows are the concrete unary-prefix rows fixed in Definition 52.3. The carrier is inhabited by e, and carrier membership transports along hsame by the carrier clauses recorded in Definition 52.4.

The stability row is Definition 52.43. Its reflexivity, transitivity, and endpoint-congruence components are exactly the remaining law clauses collected in Definition 52.4.

The concrete relation witnesses are Definition 52.17 for comparisons induced by history-sameness and Definition 52.28 for composing two prefix comparisons. The ledger row is Definition 52.45; together these rows repack the concrete unary-prefix data as the public NameCert for $\mathsf{Preorder}^{\uparrow}$. □

Corollary 52.48 ($\mathsf{Preorder}^{\uparrow}$ is licensed, not primitive)**.** $\mathsf{Preorder}^{\uparrow}$ *is licensed by relational fields, not as a primitive order.*

Lean4 ✓ `BEDC.Derived.PreorderUp.preorder carrier semantic name certificate`

Definition 52.49 (Opposite preorder certificate data)**.** *Let a* $\mathsf{Preorder}^{\uparrow}$ *certificate be presented by a carrier predicate* $\mathcal{C}$*, classifier* $\sim_C$*, and relation* $\leq_C$*. Define the opposite relation by*

$$a \leq_C^{\mathrm{op}} b := b \leq_C a.$$

The opposite preorder data C^{op} *have the same carrier predicate* $\mathcal{C}$*, the same classifier* $\sim_C$*, and relation* $\leq_C^{\mathrm{op}}$*.*

Theorem 52.50 (Opposite preorder certificate)**.** *If $(\mathcal{C}, \sim_C, \leq_C)$ satisfies the* $\mathsf{Preorder}^{\uparrow}$ *certificate obligations of Definition 52.46, then the data of Definition 52.49 also satisfy the* $\mathsf{Preorder}^{\uparrow}$ *certificate obligations. Thus the same carrier and classifier carry a preorder certificate with relation $\leq_C^{\mathrm{op}}$.*

Proof. Unpack the preorder obligations through Definition 52.46. The carrier row of Definition 52.2 is unchanged, and the carrier-and-classifier core is the same $\mathsf{NameCert}$ data. Hence classifier reflexivity, symmetry, transitivity, and carrier transport are copied from Definition 9.7. The source row of Definition 52.15 is the same carrier and classifier equipped with the reversed relation symbol.

The reflexivity field for the opposite relation is immediate. For every carried endpoint a,

$$a \leq_C^{\mathrm{op}} a$$

unfolds to $a \leq_C a$, which is the original preorder reflexivity field.

For transitivity, assume $a \leq_C^{\mathrm{op}} b$ and $b \leq_C^{\mathrm{op}} c$. By definition these are $b \leq_C a$ and $c \leq_C b$. Applying the original transitivity field of Definition 52.44 to the composable pair $c \leq_C b$ and $b \leq_C a$ gives $c \leq_C a$, which is exactly $a \leq_C^{\mathrm{op}} c$.

Relation congruence is inherited with the two endpoints exchanged. Given $a \sim_C a'$, $b \sim_C b'$, and $a \leq_C^{\mathrm{op}} b$, unfold the last witness to $b \leq_C a$. The original relation-congruence field, applied with endpoint comparisons $b \sim_C b'$ and $a \sim_C a'$, gives

$$b' \leq_C a'.$$

This is precisely $a' \leq_C^{\mathrm{op}} b'$.

The pattern row of Definition 52.16 remains binary comparison expression formation over carried endpoints: a node $a \leq_C^{\mathrm{op}} b$ is read as the original comparison node $b \leq_C a$ with endpoint order exchanged. The classifier row of Definition 52.25 is unchanged because endpoint classification is still $\sim_C$. The ledger row of Definition 52.45 records the same two carrier witnesses and the same relation derivation, with source and target slots exchanged for the displayed comparison.

These source, pattern, classifier, stability, and ledger rows are exactly the five fields of the paper naming-certificate template in Definition 9.6, specialized to the preorder obligations of Definition 52.46. Therefore C^{op} carries a $\mathsf{Preorder}^{\uparrow}$ certificate. □

Theorem 52.51 (Singleton empty $\mathsf{Preorder}^{\uparrow}$ public certificate boundary)**.** *For the concrete singleton package $(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \leq_{\mathsf{e}}^{\mathrm{sg}})$ of Definition 52.7, the public comparison readback of Definition 52.11, the single-comparison exactness theorem Definition 52.12, and the certificate rows of Definition 52.13 determine a concrete* BHist*-anchored* $\mathsf{Preorder}^{\uparrow}$ *public surface.*

The public surface has carrier A_{e}, classifier ρ_{e}, and relation $\leq_{\mathsf{e}}^{\mathrm{sg}}$. For every pair of histories h, k, public comparison witnesses read back exactly as

$$h \leq_{\mathsf{e}}^{\mathrm{sg}} k \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

The surface introduces no abstract carrier, abstract classifier, order parameter, quotient, host equality, or standard bridge.

Lean4 ✓ `BEDC.Derived.PreorderUp.preorder singleton empty public certificate boundary`

Proof. Unfold the singleton package of Definition 52.7. Its source is the closed BHist carrier A_{e}, its classifier is ρ_{e}, and its guarded comparison relation is $\leq_{\mathsf{e}}^{\mathrm{sg}}$.

The public readback row is Definition 52.11. Apply Definition 52.12 to obtain the displayed equivalence between one guarded public comparison and the two endpoint-carrier witnesses.

The preorder laws needed for the surface are the singleton empty preorder laws: reflexivity on carried histories, transitivity of guarded comparisons, and endpoint congruence for ρ_{e}. The guarded prefix exactness theorem Definition 52.9 supplies the classifier equivalence relating $\rho_{\mathsf{e}}(h, k)$ to the two guarded comparison directions.

Finally, repack the source, pattern, classifier, stability, and ledger rows through Definition 52.13. These rows are all anchored in BHist and the singleton endpoint carrier, so the resulting boundary is the concrete public surface described in the statement and contains none of the excluded abstract parameters. □

Definition 52.52 (Preorder terminal endpoint-order surface)**.** *For histories $h, k : \mathsf{BHist}$, define the terminal endpoint order over the singleton carrier A_{e} by*

$$h \preceq_{\mathsf{e}} k := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

The public surface is the concrete tuple $(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \preceq_{\mathsf{e}})$, where ρ_{e} is the restricted singleton classifier of Definition 52.7. Thus both the carrier and the comparison relation are pinned to BHist endpoints, and the relation records exactly the two endpoint carrier witnesses.

This concrete endpoint order is the relation row that chapter 53 extends by adding antisymmetry, and that chapter 1378 later reads as the comparison substrate for arithmetic-facing order packets.

Theorem 52.53 (Preorder terminal endpoint-order laws)**.** *For the endpoint order of Definition 52.52, the following laws hold for histories $h, k, \ell : \mathsf{BHist}$.*

1. *If $A_{\mathsf{e}}(h)$, then $h \preceq_{\mathsf{e}} h$.*
2. *If $h \preceq_{\mathsf{e}} k$ and $k \preceq_{\mathsf{e}} \ell$, then $h \preceq_{\mathsf{e}} \ell$.*
3. *If $\rho_{\mathsf{e}}(h, h')$, $\rho_{\mathsf{e}}(k, k')$, and $h \preceq_{\mathsf{e}} k$, then $h' \preceq_{\mathsf{e}} k'$.*
4. *For all endpoints,*
$$h \preceq_{\mathsf{e}} k \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

Proof. Unfold the definition of $\preceq_{\mathsf{e}}$. Reflexivity on a carried endpoint uses the same witness twice, so $A_{\mathsf{e}}(h)$ gives $A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(h)$.

For transitivity, project $A_{\mathsf{e}}(h)$ from the first comparison and $A_{\mathsf{e}}(\ell)$ from the second comparison. Pairing those witnesses gives $h \preceq_{\mathsf{e}} \ell$ after unfolding the terminal relation.

For classifier congruence, unfold ρ_{e} at both endpoint pairs. The classifier witnesses contain $A_{\mathsf{e}}(h')$ and $A_{\mathsf{e}}(k')$ directly, while the given comparison supplies the source endpoint witnesses. Pair the target carrier witnesses to obtain $h' \preceq_{\mathsf{e}} k'$.

The exact readback is definitional: the forward direction projects the two fields of the relation, and the reverse direction repacks the two endpoint carrier witnesses. The singleton endpoint transport already recorded for A_{e} is the only transport needed by the classifier row. □

Theorem 52.54 (Preorder terminal endpoint-order public certificate)**.** *The tuple $(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \preceq_{\mathsf{e}})$ determines a concrete $\mathsf{Preorder}^{\uparrow}$ public surface over BHist. Its source is the singleton endpoint carrier A_{e}, its carrier is exactly the histories accepted by A_{e}, its classifier is ρ_{e}, its relation is $\preceq_{\mathsf{e}}$, its ledger records the two endpoint carrier witnesses, and its exactness row is*

$$h \preceq_{\mathsf{e}} k \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

The resulting status is a concrete terminal endpoint-order surface for $\mathsf{Preorder}^{\uparrow}$ with no abstract order parameter and no quotient layer.

Proof. The source, carrier, and classifier rows are the singleton rows fixed in Definition 52.7. The relation row is Definition 52.52, so every comparison witness is already a pair of endpoint carrier witnesses.

Apply Definition 52.53. Its reflexivity, transitivity, classifier-congruence, and exact-readback clauses supply the order-law and exactness rows required by the preorder public surface.

The ledger is forced by the definition of $\preceq_{\mathsf{e}}$: a public comparison stores no data beyond $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$. Repacking these rows into the roadmap source, carrier, classifier, relation, ledger, exactness, and status fields gives the stated concrete $\mathsf{Preorder}^{\uparrow}$ surface. □

Definition 52.55 (Preorder terminal opposite endpoint order)**.** *For histories $h, k : \mathsf{BHist}$, define the endpoint-swapped relation of Definition 52.52 by*

$$h \preceq_{\mathsf{e}}^{\mathrm{op}} k := k \preceq_{\mathsf{e}} h.$$

This is the opposite relation of Definition 52.49 specialized to the concrete terminal endpoint-order surface $(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \preceq_{\mathsf{e}})$.

Theorem 52.56 (Preorder terminal endpoint-order opposite self-duality)**.** *For histories h, k : BHist on the terminal endpoint-order surface of Definition 52.52, the opposite relation has the same endpoint readback:*

$$h \preceq_{\mathsf{e}}^{\mathrm{op}} k \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

Consequently,

$$h \preceq_{\mathsf{e}}^{\mathrm{op}} k \iff h \preceq_{\mathsf{e}} k.$$

Thus the concrete terminal endpoint-order surface is its own opposite relation on carried endpoints.

Proof. Unfold Definition 52.55. A witness of $h \preceq_{\mathsf{e}}^{\mathrm{op}} k$ is exactly a witness of $k \preceq_{\mathsf{e}} h$.

Apply the exact-readback clause of Definition 52.53 to the ordered pair (k, h). It gives

$$k \preceq_{\mathsf{e}} h \iff A_{\mathsf{e}}(k) \wedge A_{\mathsf{e}}(h).$$

The conjunction on the right is symmetric: from $A_{\mathsf{e}}(k) \wedge A_{\mathsf{e}}(h)$ project the second and first witnesses to obtain $A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k)$, and the reverse implication is obtained by the same projection swap. Therefore

$$h \preceq_{\mathsf{e}}^{\mathrm{op}} k \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

Apply the same exact-readback clause of Definition 52.53 to (h, k):

$$h \preceq_{\mathsf{e}} k \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

Both $h \preceq_{\mathsf{e}}^{\mathrm{op}} k$ and $h \preceq_{\mathsf{e}} k$ are therefore equivalent to the same pair of endpoint carrier witnesses, which yields the claimed equivalence between the opposite relation and the original terminal endpoint order. □

Closure status for $\mathsf{NameCert}_{\mathsf{Preorder}^{\uparrow}}$**.**

Constructive story: A preorder in the concrete BEDC instance starts from the unary history spine: e and its repeated b1-extensions are admitted, while any b0 branch is outside the carrier. The comparison says that one unary history is below another when a unary continuation tail extends the first to the second, and the classifier on carried endpoints is the carrier-aware hsame relation rather than a quotient of comparable histories. Thus the source-domain is the same unary carrier, the pattern is reflexive and transitive prefix comparison with congruence under endpoint replacement, and the ledger records the continuation tail witnessing each displayed comparison together with the raw unary endpoints. The five name-certificate obligations come from the unary spine itself: e inhabits the carrier, history-sameness gives reflexivity, symmetry, and transitivity for the classifier, and unary transport keeps any history-same representative inside the carrier.

A history h lies in the signature gap of a Preorder$^{\uparrow}$ token p when the source-domain accepts h, the signature relation pairs it with an answer history and comparison ledger, and token introduction names that answer as p; unfolded, h is unary and the recorded prefix continuations are exactly the order evidence encoded by p. The paper bridge reads this surface as the finite unary prefix preorder, where a prefix tail is the ordinary witness that one finite unary word extends another, then reads back to the same continuation data. The chapter registers this continuation-order construction under the name Preorder$^{\uparrow}$; the relation is generated by BEDC append and hsame, with no arbitrary preorder carrier, totality field, antisymmetry quotient, or order topology introduced.

Theory closure: TheoryGate(NameCert$_{\text{Preorder}\uparrow}$, maturePackageClosed)

Scope closed: The public unary-prefix preorder surface binds the comparison constructors, public relation readback, endpoint exactness, carrier/classifier rows, and ledger rows for PreorderPrefixLE over UnaryHistory.

Formal verification: FormalStatus(NameCert$_{\text{Preorder}\uparrow}$, axiomClean)

Lean target: `BEDC.Derived.PreorderUp.preorder\_carrier\_semantic\_name\_certificate`

Bridge status: paperBridge

Not claimed: General order theory: arbitrary preorders, quotient completions, totality, antisymmetry, lattices, order topology, or standard-model bridge closure.

Upgrade path: Lean bridge checking for the standard boundary bridge remains the next verification step; the paper mature closure is the recorded theory grade.

Chapter 53

A Concrete Naming Certificate for $\mathsf{POSet}^{\uparrow}$

The partially ordered set interface $\mathsf{POSet}^{\uparrow}$ extends chapter 52 with the antisymmetry field: if $a \leq b$ and $b \leq a$ then a and b are classified the same by the carrier. The integer order from chapter 31 is the canonical concrete instance.

Remark 53.1 ($\mathsf{POSet}^{\uparrow}$ interface scope)**.** *This chapter records the* $\mathsf{POSet}^{\uparrow}$ *licensing target. The concrete prefix antisymmetry theorem is linked to the unary preorder classifier, and the certificate fields are specified below.*

53.1 Carrier definition

Definition 53.2 (POSet carrier)**.** *Use a preorder setup extended with antisymmetry under the carrier classifier.*

Theorem 53.3 (POSetUp BHist carrier transport obligation)**.** *Let h and k be carried* BHist *endpoints in the concrete unary prefix preorder carrier. If $h\mathsf{hsame}k$, the preorder carrier transport row is present, and the* $\mathsf{POSet}^{\uparrow}$ *antisymmetry row is carried with that preorder package, then transporting the endpoint from h to k leaves it in the* $\mathsf{POSet}^{\uparrow}$ *carrier. The transported package keeps the preorder carrier row and repacks the same antisymmetry field; it does not introduce a quotient carrier or a representative class.*

Proof. Apply the carrier transport row of Definition 52.31. It transports the displayed unary BHist carrier along the classifier row $h\mathsf{hsame}k$, so the preorder carrier component remains available at the target endpoint.

The $\mathsf{POSet}^{\uparrow}$ carrier of Definition 53.2 is precisely that preorder carrier together with an antisymmetry row under the same classifier. Repack the transported preorder carrier with the displayed antisymmetry field. The endpoint remains a carried BHist endpoint, and no host quotient object is used. □

Theorem 53.4 (POSetUp classifier exactness obligation)**.** *For carried unary* BHist *histories h and k, the* $\mathsf{POSet}^{\uparrow}$ *classifier row between them is exact for the bidirectional prefix comparison: the classifier holds exactly when the classifier row is present and the two directed preorder comparison rows $h \leq_{\mathsf{pref}} k$ and $k \leq_{\mathsf{pref}} h$ collapse by the antisymmetry field. The reverse comparison rows are obtained from preorder reflexivity and transport along the classifier.*

Proof. For the forward comparison-to-classifier direction, assume the two directed prefix witnesses. The antisymmetry field of Definition 53.33 collapses them to $\mathsf{hsame}(h, k)$, which is the carrier classifier named by Definition 53.2.

For the classifier-to-comparison direction, assume $\mathsf{hsame}(h, k)$. The preorder package of Definition 52.31 supplies reflexivity at each carried endpoint and transports comparison endpoints along the classifier. Transport the reflexive comparison at h to obtain $h \leq_{\mathsf{pref}} k$, and transport the reflexive comparison at k to obtain $k \leq_{\mathsf{pref}} h$.

These two constructions identify the classifier boundary with the bidirectional comparison boundary, with antisymmetry providing the collapse and the preorder rows providing the transported reflexive comparisons. □

Theorem 53.5 (POSetUp antisymmetry ledger obligation)**.** *An antisymmetry use in the concrete* $\mathsf{POSet}^{\uparrow}$ *ledger records exactly the two comparison witnesses* $h \leq_{\mathsf{pref}} k$ *and* $k \leq_{\mathsf{pref}} h$*, their carried* BHist *endpoints, and the resulting* $\mathsf{hsame}(h, k)$ *classifier row. The ledger contains no host quotient, chosen class representative, or external equality witness.*

Proof. Project the two comparison witnesses from the preorder ledger supplied by Definition 52.31. Their endpoints are the same carried unary BHist histories used by the $\mathsf{POSet}^{\uparrow}$ carrier.

Apply the antisymmetry row Definition 53.33 to the projected comparison pair. It produces the classifier row $\mathsf{hsame}(h, k)$ and no additional object.

Repack the ledger entry as the ordered pair of comparison witnesses, the two displayed endpoints, and the resulting classifier row. This is exactly the ledger policy described by the $\mathsf{POSet}^{\uparrow}$ certificate surface. □

Theorem 53.6 (POSet root carrier obligation)**.** *The root* $\mathsf{POSet}^{\uparrow}$ *carrier obligation is a* $\mathsf{Preorder}^{\uparrow}$ *carrier over* BHist*, equipped with the same prefix relation and with an antisymmetry row under the carrier classifier. No quotient carrier is added: the carried endpoints remain displayed* BHist *histories, and the only collapse allowed by the partial-order field is the classifier conclusion* $\mathsf{hsame}(h, k)$*.*

Proof. The carrier clause is exactly Definition 53.2: start with the preorder carrier and add the antisymmetry field as an extra row, not as a new endpoint space.

For the concrete root instance, Definition 52.31 supplies the BHist carrier, the prefix preorder relation, and the hsame classifier boundary. The partial-order coordinate is supplied by Definition 53.33, which turns opposing prefix comparisons into $\mathsf{hsame}(h, k)$.

Thus the carrier remains the inherited preorder carrier, while the antisymmetry data is an obligation row attached to that carrier. □

Theorem 53.7 (POSet root classifier obligation)**.** *The root* $\mathsf{POSet}^{\uparrow}$ *classifier is the inherited* hsame*-based classifier on carried* BHist *endpoints, and it is stable under the preorder relation: classifier-equivalent endpoints may be read through the same prefix comparison rows without changing the carried* $\mathsf{POSet}^{\uparrow}$ *object.*

Proof. By Definition 53.2, a $\mathsf{POSet}^{\uparrow}$ object does not replace the preorder classifier. It extends the preorder package by demanding antisymmetry under that classifier.

Apply Definition 52.31 to obtain the inherited hsame classifier together with the prefix-order stability rows. Those rows are the classifier transport surface for comparison endpoints.

The additional $\mathsf{POSet}^{\uparrow}$ row from Definition 53.33 is compatible with the same classifier, because its conclusion is again $\mathsf{hsame}(h, k)$. Hence classifier transport remains the inherited preorder transport. □

Theorem 53.8 (POSet root exactness obligation)**.** *For carried unary prefix endpoints h and k, the opposing comparison rows $h \leq_{\mathsf{pref}} k$ and $k \leq_{\mathsf{pref}} h$ are exactly the* $\mathsf{POSet}^{\uparrow}$ *classifier row on those endpoints: the forward direction is antisymmetry, and the reverse direction is the inherited reflexive prefix row transported along* hsame*.*

Proof. For the forward direction, assume the two comparison rows. The concrete antisymmetry theorem Definition 53.33 collapses the opposing prefix witnesses to $\mathsf{hsame}(h, k)$, which is the classifier row specified by Definition 53.2.

For the reverse direction, assume the classifier row $\mathsf{hsame}(h, k)$. The preorder law package of Definition 52.31 provides reflexive prefix comparisons on carried endpoints and transports comparison endpoints along hsame.

Transporting the reflexive comparison on h gives $h \leq_{\mathsf{pref}} k$, and transporting the reflexive comparison on k gives $k \leq_{\mathsf{pref}} h$. The two directions identify the exact comparison boundary of the root $\mathsf{POSet}^{\uparrow}$ row. □

53.2 Concrete unary prefix POSet instance

Definition 53.9 (Concrete unary prefix POSet instance)**.** *The concrete unary prefix POSet instance is the following ten-field tuple.*

1. *The traditional target is the finite unary-word prefix partial order.*
2. *The BEDC source is* BHist *restricted to unary histories.*
3. *The carrier is* PreorderCarrier = UnaryHistory*.*
4. *The classifier is the carrier-aware specification* PreorderCarrierClassifierSpec(PreorderCarrier)*, whose equality content is* hsame*.*
5. *The relation is* PreorderPrefixLE*.*
6. *Stability consists of classifier reflexivity, classifier transitivity, relation reflexivity, relation transitivity, relation congruence, and antisymmetry under the classifier.*
7. *The ledger records both comparison-tail witnesses used for $h \leq k$ and $k \leq h$.*
8. *The core theorem list is the concrete prefix stability certificate together with prefix antisymmetry.*
9. *Exactness is the bidirectional prefix collapse: two opposing prefix comparisons collapse exactly to the classifier relation.*
10. *The standard bridge identifies* PreorderPrefixLE *with the initial-segment order on finite unary words, and the status is* ProofTarget*.*

Theorem 53.10 (Concrete unary prefix POSet laws)**.** *The tuple in Definition 53.9 satisfies the* $\mathsf{POSet}^{\uparrow}$ *carrier field, the preorder fields for* PreorderPrefixLE*, classifier congruence for* hsame*, and antisymmetry under the carrier classifier.*

Proof. The carrier and classifier fields are the concrete preorder fields: the carrier is PreorderCarrier = UnaryHistory, and the classifier is PreorderCarrierClassifierSpec(PreorderCarrier).

The preorder and classifier-congruence fields are supplied by the concrete prefix stability certificate in Definition 52.43. Equivalently, Definition 52.31 records the reflexive and transitive prefix laws together with the history-sameness classifier boundary.

It remains to supply the partial-order field. Apply Definition 53.33: opposing PreorderPrefixLE witnesses provide the two comparison tails, and the theorem collapses them to $\mathsf{hsame}(h, k)$, which is exactly antisymmetry under the carrier classifier. □

Definition 53.11 (Concrete singleton empty POSet instance)**.** *Let A_{e} be the singleton history source of Definition 36.169 at $a_0 = \mathsf{e}$. Define the restricted classifier by*

$$\rho_{\mathsf{e}}(h, k) := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h, k).$$

Define the carrier-guarded restricted order by

$$h \leq_{\mathsf{e}} k := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{PreorderPrefixLE}(h, k).$$

The concrete POSet package is the fixed BHist *tuple $(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \leq_{\mathsf{e}})$.*

Theorem 53.12 (Singleton empty POSet laws)**.** *For the concrete package of Definition 53.11, the carrier is inhabited by* e*, carrier membership transports along* hsame*, and $\leq_{\mathsf{e}}$ has preorder reflexivity, transitivity, and endpoint congruence inherited from the singleton empty preorder laws. The package also satisfies antisymmetry under ρ_{e}. For all histories h, k :* BHist*, the classifier is exact:*

$$\rho_{\mathsf{e}}(h, k) \Longleftrightarrow (h \leq_{\mathsf{e}} k \wedge k \leq_{\mathsf{e}} h).$$

Proof. The carrier and preorder fields are those of Definition 52.8. Inhabitance is witnessed by e, carrier transport is transport along hsame, and the reflexive, transitive, and endpoint-congruent behavior of $\leq_{\mathsf{e}}$ is the restricted PreorderPrefixLE package on the singleton source.

For antisymmetry, suppose h and k are carried and that $h \leq_{\mathsf{e}} k$ and $k \leq_{\mathsf{e}} h$. Project the opposing PreorderPrefixLE witnesses from the guarded comparisons, so PreorderPrefixLE_antisymm_hsame gives $\mathsf{hsame}(h, k)$. Pair this with the carrier witnesses for h and k to obtain $\rho_{\mathsf{e}}(h, k)$.

For exactness, first assume $\rho_{\mathsf{e}}(h, k)$. The classifier supplies the two carrier witnesses and the endpoint witness $\mathsf{hsame}(h, k)$. Apply PreorderPrefixLE_of_hsame to this witness and to its symmetric orientation, then repack the two carrier witnesses with the resulting prefix comparisons to obtain $h \leq_{\mathsf{e}} k$ and $k \leq_{\mathsf{e}} h$.

Conversely, assume the two guarded comparisons. Project the carrier witnesses and the opposing prefix witnesses from them. Apply PreorderPrefixLE_antisymm_hsame to the prefix witnesses to recover $\mathsf{hsame}(h, k)$, and recombine this endpoint witness with the carrier witnesses to get $\rho_{\mathsf{e}}(h, k)$. □

Theorem 53.13 (Singleton empty POSet terminal interval collapse)**.** *For the concrete package of Definition 53.11, let h, k, r :* BHist *be carried by A_{e}. If the displayed terminal chain supplies $h \leq_{\mathsf{e}} k$ and $k \leq_{\mathsf{e}} r$, then all three endpoints collapse inside the singleton interval:*

$$\rho_{\mathsf{e}}(h, k) \wedge \rho_{\mathsf{e}}(k, r) \wedge \rho_{\mathsf{e}}(h, r) \wedge h \leq_{\mathsf{e}} r \wedge r \leq_{\mathsf{e}} h.$$

The ten-field fit is: traditional target one-point partial order interval collapse; BEDC source singleton BHist*; carrier A_{e}; classifier ρ_{e}; relation $\leq_{\mathsf{e}}$; stability from singleton transport, preorder transitivity, and POSet antisymmetry; ledger the two chain comparisons plus carried endpoints; core theorem this block; exactness terminal classifier collapse; standard bridge one-point poset; status* ProofTarget*.*

Proof. Unfold the singleton carrier A_{e}. Each carried endpoint transports through the empty history e, so the endpoint classifier witnesses $\rho_{\mathsf{e}}(h,k)$, $\rho_{\mathsf{e}}(k,r)$, and $\rho_{\mathsf{e}}(h,r)$ are obtained by pairing the two relevant carrier witnesses with the corresponding hsame endpoint comparison.

The comparison $h \leq_{\mathsf{e}} r$ is inherited from preorder transitivity for the restricted prefix relation: compose the displayed witnesses $h \leq_{\mathsf{e}} k$ and $k \leq_{\mathsf{e}} r$.

For the reverse comparison, the same singleton endpoint comparison identifies r with h inside A_{e}. Apply the exactness direction of Definition 53.12 to the classifier witness $\rho_{\mathsf{e}}(h,r)$, then read off $r \leq_{\mathsf{e}} h$ from the opposing comparison. The five displayed conjuncts therefore repack the terminal interval collapse. □

Theorem 53.14 (POSet singleton prefix-chain collapse)**.** *For the concrete package of Definition 53.11, let $h_0, \ldots, h_n : \mathsf{BHist}$ be carried by A_{e} and suppose the finite guarded chain supplies $h_j \leq_{\mathsf{e}} h_{j+1}$ for each adjacent pair. Then every adjacent comparison, every endpoint comparison obtained by transitivity, and every reverse endpoint comparison needed by the singleton interval collapses to the restricted classifier ρ_{e}. Equivalently, the finite chain is recorded entirely by* BHist *endpoints,* hsame *transport, and guarded prefix witnesses, with no host order or quotient row.*

Proof. Induct over the displayed finite guarded chain. The base case is the one-point chain: the carried endpoint lies in A_{e}, so Definition 53.12 supplies reflexivity and the classifier exactness row for the endpoint against itself.

For the step, assume the prefix chain has already collapsed through the current endpoint and append one guarded comparison. Transitivity from Definition 53.12 gives the forward endpoint comparison across the longer chain, while its antisymmetry and exactness rows collapse the adjacent comparison to ρ_{e}.

For any three consecutive endpoints, apply Definition 53.13. This supplies the reverse endpoint comparison required by the singleton interval and identifies each endpoint pair by the same restricted classifier.

Repack the induction data as a finite ledger of carried BHist endpoints, hsame transports, and guarded prefix witnesses. Since each collapse row comes from ρ_{e} and the singleton laws, no additional order structure is used. □

This concrete BHist tuple is the $\mathsf{POSet}^{\uparrow}$ schema instance used by machine checking.

Theorem 53.15 (Concrete singleton empty $\mathsf{POSet}^{\uparrow}$ naming certificate)**.** *The tuple $(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \leq_{\mathsf{e}})$ of Definition 53.11 supplies the source, pattern, classifier, stability, ledger, and exactness rows for a concrete* $\mathsf{NameCert}$ *licensing* $\mathsf{POSet}^{\uparrow}$ *over* BHist*. On carried histories, the exactness row is*

$$\rho_{\mathsf{e}}(h,k) \Longleftrightarrow (h \leq_{\mathsf{e}} k \wedge k \leq_{\mathsf{e}} h).$$

Proof. The source row is the singleton history source A_{e} anchored at e, and the classifier row is the restricted carrier classifier ρ_{e} from Definition 53.11. The pattern row is the restricted prefix comparison $h \leq_{\mathsf{e}} k$ on carried histories.

The preorder, antisymmetry, and stability rows are exactly the concrete law package of Definition 53.12. Its preorder fields give reflexivity, transitivity, and endpoint congruence for the restricted prefix relation, while its antisymmetry field collapses opposing comparisons to ρ_{e}.

The ledger records the two comparison witnesses used by antisymmetry, $h \leq_{\mathsf{e}} k$ and $k \leq_{\mathsf{e}} h$, together with the carried endpoints. The displayed equivalence is the exactness row supplied by the same law package, so the concrete tuple repacks as the public $\mathsf{NameCert}$ for $\mathsf{POSet}^{\uparrow}$. □

Theorem 53.16 (Singleton empty $\mathsf{POSet}^{\uparrow}$ schema instantiation)**.** *The tuple* $(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \leq_{\mathsf{e}})$ *of Definition 53.11 instantiates the* $\mathsf{POSet}^{\uparrow}$ *schema over the fixed BEDC history carrier* BHist*. Its carrier row is* A_{e}*, its classifier row is* ρ_{e}*, and its relation row is* $\leq_{\mathsf{e}}$*. Its preorder reflexivity, preorder transitivity, relation congruence, antisymmetry, and exactness rows are exactly the rows certified in Definition 53.12. Its concrete* $\mathsf{NameCert}$ *packaging is the certificate of Definition 53.15.*

Proof. Unfold Definition 53.11. The carrier is the singleton history source A_{e} inside BHist, the classifier is the restricted history classifier ρ_{e}, and the relation is the carrier-guarded restricted prefix comparison $\leq_{\mathsf{e}}$.

The law rows are supplied without changing carrier. Apply Definition 53.12: it gives the singleton inhabitance and carrier transport, the preorder reflexivity and transitivity rows for $\leq_{\mathsf{e}}$, endpoint congruence for the guarded relation, antisymmetry under ρ_{e}, and the displayed exactness between ρ_{e} and the two opposing guarded comparisons.

Finally apply Definition 53.15. That theorem packages the same source, pattern, classifier, stability, ledger, and exactness fields as a concrete $\mathsf{NameCert}$ licensing $\mathsf{POSet}^{\uparrow}$ over BHist. Therefore the schema instance is pinned to the concrete history carrier and not obtained by transporting an abstract parameter schema. □

Theorem 53.17 (POSet singleton carrier-classifier obligation)**.** *The concrete singleton* $\mathsf{POSet}^{\uparrow}$ *package of Definition 53.11 has carrier* A_{e} *and classifier* ρ_{e} *over the fixed BEDC carrier* BHist*. Carrier transport is exactly transport by* hsame *inside the singleton source, and the package exports no quotient carrier, host equality, or abstract replacement carrier.*

Proof. Unfold Definition 53.11. Its displayed carrier coordinate is the singleton history source A_{e}, and its classifier coordinate is the restricted classifier ρ_{e} on histories of BHist.

Apply Definition 53.12. The law package gives carrier inhabitance at e and carrier transport along hsame, with no change of carrier. The certificate theorem Definition 53.15 then repacks those rows as the concrete $\mathsf{POSet}^{\uparrow}$ naming certificate. □

Theorem 53.18 (POSet singleton antisymmetry exactness obligation)**.** *For the concrete singleton* $\mathsf{POSet}^{\uparrow}$ *package of Definition 53.11, opposing guarded comparisons* $h \leq_{\mathsf{e}} k$ *and* $k \leq_{\mathsf{e}} h$ *are exactly the classifier row* $\rho_{\mathsf{e}}(h, k)$*. Thus antisymmetry is exposed as an exactness predicate on the concrete* BHist *rows, not as an external host-order law.*

Proof. Unfold the guarded relation and classifier of Definition 53.11. The relation $\leq_{\mathsf{e}}$ is the carrier-guarded prefix comparison, and ρ_{e} records the two singleton carrier endpoints together with $\mathsf{hsame}(h, k)$.

Apply Definition 53.12. Its antisymmetry row collapses the two guarded comparisons to the classifier, and its exactness row reads the classifier back as the same opposing comparison pair. The certificate theorem Definition 53.15 exposes this row as the singleton $\mathsf{POSet}^{\uparrow}$ exactness obligation. □

Theorem 53.19 (POSet singleton ledger obligation)**.** *The ledger for the concrete singleton* $\mathsf{POSet}^{\uparrow}$ *certificate of Definition 53.15 consists exactly of the two guarded comparison witnesses* $h \leq_{\mathsf{e}} k$ *and* $k \leq_{\mathsf{e}} h$*, together with the carried endpoints in* A_{e}*. It exports no totality, lattice, host-order, quotient, or non-singleton carrier data.*

Proof. Read the source tuple from Definition 53.11: the only visible endpoints are histories carried by A_{e}, and the only relation witnesses are guarded comparisons for $\leq_{\mathsf{e}}$.

Apply Definition 53.12 to identify the two opposing comparison witnesses as precisely the data used by antisymmetry and exactness. Then apply Definition 53.15. Its ledger row is the repackaging of those two witnesses with the carried endpoints, so no additional order-theoretic or quotient field is exported. □

Theorem 53.20 (POSet prefix ledger row exhaustion)**.** *For the concrete singleton* $\mathsf{POSet}^{\uparrow}$ *certificate of Definition 53.15, every public ledger row is exhausted by a tuple* $(h, k, A_{\mathsf{e}}(h), A_{\mathsf{e}}(k), h \leq_{\mathsf{e}} k, k \leq_{\mathsf{e}} h, \rho_{\mathsf{e}}(h, k))$*. Conversely, any tuple of this form repacks as a public ledger row of that certificate. The ten-field fit is: target ledger exhaustion for the one-point* $\mathsf{POSet}^{\uparrow}$ *ledger; BEDC source the singleton* BHist *carrier; carrier* A_{e}*; classifier* ρ_{e}*; relation* $\leq_{\mathsf{e}}$*; stability from singleton transport and exactness; ledger the two guarded comparisons; core theorem this row-exhaustion statement; exactness the bidirectional repacking; standard bridge the one-point poset; status* $\mathsf{ProofTarget}$*.*

Proof. Unfold Definition 53.11. Its public source rows have histories in the singleton BHist carrier A_{e}, the guarded relation $\leq_{\mathsf{e}}$, and the classifier ρ_{e} on those carried endpoints.

For the forward direction, start with an arbitrary public ledger row of the certificate. Apply Definition 53.19: the row contains only the carried endpoints and the two guarded comparisons $h \leq_{\mathsf{e}} k$ and $k \leq_{\mathsf{e}} h$.

Apply Definition 53.12. Its singleton transport keeps the endpoints inside A_{e}, and its exactness row identifies $\rho_{\mathsf{e}}(h, k)$ with the opposing comparison pair. Thus the row has the displayed tuple form.

For the reverse direction, begin with such a tuple. The endpoint entries give the carried singleton histories, the comparison entries give the two ledger witnesses, and the classifier entry is exact for the same pair by Definition 53.12.

Finally apply Definition 53.15. It packages precisely these endpoint, comparison, transport, and exactness rows as the concrete singleton $\mathsf{POSet}^{\uparrow}$ certificate, while Definition 53.19 rules out any totality, lattice, host-order, quotient, or non-singleton carrier row. □

Theorem 53.21 (POSet singleton comparison endpoint determinacy)**.** *For the concrete singleton* $\mathsf{POSet}^{\uparrow}$ *package of Definition 53.11, any two guarded singleton comparisons over* A_{e} *determine the same endpoint classifier* ρ_{e}*. There is no second endpoint row besides the carried singleton endpoint and its* hsame *transport.*

Proof. Read the comparison rows from Definition 53.11. Their endpoints are required to lie in the singleton carrier A_{e}, so both comparisons have the same displayed carrier boundary.

Apply Definition 53.12. The singleton laws collapse carrier membership to the empty-history endpoint and identify every guarded comparison with the classifier row ρ_{e} on that endpoint.

Finally apply Definition 53.15. The certificate exposes exactly this classifier as the $\mathsf{POSet}^{\uparrow}$ endpoint row, so the two guarded comparisons cannot generate a second endpoint classification. □

Theorem 53.22 (POSet singleton antichain terminality)**.** *Every antichain subcarrier of the concrete singleton* $\mathsf{POSet}^{\uparrow}$ *package is terminal: each carried member is classified with* e*, and every comparison between carried members collapses by Definition 53.12. No nontrivial incomparable pair is exported.*

Proof. Fix an antichain subcarrier inside the carrier of Definition 53.11. Any carried member is already a member of A_{e}, hence the singleton carrier law classifies it with e.

For a comparison between two carried members, apply Definition 53.12. The law package identifies both endpoints with the singleton endpoint and collapses the guarded comparison to the displayed classifier row.

Use Definition 53.15 to read this row as the concrete $\mathsf{POSet}^{\uparrow}$ certificate boundary. An antichain subcarrier therefore has only the terminal singleton member and no exported nontrivial comparison data. □

Theorem 53.23 (POSet singleton ledger exhaustion)**.** *The concrete singleton* $\mathsf{POSet}^{\uparrow}$ *ledger is exhausted by the two guarded comparison witnesses* $h \leq_{\mathsf{e}} k$ *and* $k \leq_{\mathsf{e}} h$ *together with the two carried endpoints in* A_{e}*. It contains no total-order row, lattice row, quotient row, host-order row, or additional carrier row.*

Proof. Start from Definition 53.19. Its ledger description names exactly the two guarded comparison witnesses and the carried endpoints as the visible data of the singleton certificate.

Apply Definition 53.12 to the comparison witnesses. They supply antisymmetry and exactness only through the singleton classifier boundary, so no totality, lattice operation, quotient representative, or ambient host order can be read from them.

The certificate theorem Definition 53.15 repackages precisely those rows as the concrete $\mathsf{POSet}^{\uparrow}$ naming certificate. Hence the ledger is fully exhausted by the displayed comparison and endpoint rows. □

Theorem 53.24 (POSet unary prefix standard bridge boundary)**.** *The concrete unary-prefix and singleton-empty* $\mathsf{POSet}^{\uparrow}$ *packages bridge to the finite unary-prefix partial order by reading* A_{e} *and* $\mathsf{UnaryHistory}$ *as the carried finite-word endpoints,* ρ_{e} *and* hsame *as classifier equality, and* $\leq_{\mathsf{e}}$ *together with* $\mathsf{PreorderPrefixLE}$ *as initial-segment comparison. The bridge exports exactly the concrete carrier, classifier, antisymmetry, exactness, and ledger rows named in Definition 53.10, Definition 53.12, Definition 53.15, and Definition 53.23; it exports no total-order, lattice, quotient, or host-order row.*

Proof. First read the unary-prefix carrier and comparison from Definition 53.10. This identifies $\mathsf{UnaryHistory}$ with finite unary-word endpoints and reads $\mathsf{PreorderPrefixLE}$ as initial-segment comparison.

Next read the singleton-empty endpoint package through Definition 53.12. The singleton carrier A_{e}, classifier ρ_{e}, and hsame transport give the classifier-equality boundary for the carried endpoint.

Finally apply Definition 53.15 and Definition 53.23. They package exactly the carrier, classifier, antisymmetry, exactness, and finite ledger rows available to the concrete $\mathsf{POSet}^{\uparrow}$ surface, and they rule out total-order, lattice, quotient, and host-order data. □

Theorem 53.25 (POSet unary prefix bridged closure package)**.** *The unary-prefix and singleton-empty* $\mathsf{POSet}^{\uparrow}$ *packages, together with the finite-chain endpoint classifier coverage and selector boundary, form the bridge package from the concrete* $\mathsf{BHist}\ \mathsf{POSet}^{\uparrow}$ *surface to the finite unary-prefix partial order. The package exports only the carried unary-prefix endpoints, singleton endpoint classifier, guarded prefix comparisons, finite-chain endpoint classifiers, and selector-consumer boundary; it exports no host order, quotient representative, total-order row, or lattice operation.*

Proof. Start with Definition 53.24. It reads the concrete unary-prefix and singleton-empty packages as the finite unary-prefix partial order interface, with carrier, classifier, comparison, antisymmetry, exactness, and ledger rows coming only from the displayed $\mathsf{POSet}^{\uparrow}$ surface.

Next apply Definition 53.23. This removes any extra host-order, quotient, total-order, or lattice field from the singleton ledger, so the bridge package has no additional exported structure beyond the concrete endpoint and comparison rows.

Finally compose Definition 53.26 with Definition 53.28. The first theorem supplies the finite-chain endpoint classifier rows, and the second restricts selectors to those carried chain rows. Hence

the bridge package is consumable by the finite unary-prefix partial order boundary and exports exactly the rows named in the statement. □

Theorem 53.26 (POSet finite-chain endpoint classifier coverage)**.** *For the concrete singleton* $\mathsf{POSet}^{\uparrow}$ *package of Definition 53.11, let* $h_0, \ldots, h_n : \mathsf{BHist}$ *be a finite guarded chain whose entries are carried by* A_{e} *and whose adjacent rows supply* $h_j \leq_{\mathsf{e}} h_{j+1}$*. Then every endpoint pair* h_i, h_j *with* $0 \leq i \leq j \leq n$ *is classified by* ρ_{e}*, and every public chain-ledger row repacks from carried* BHist *endpoints, adjacent guarded comparisons, transitive prefix witnesses, and the classifier rows of Definition 53.12.*

The ten-field fit is: downstream target $\mathsf{Order}^{\uparrow}$ *finite interval coverage for chains read through the singleton* $\mathsf{POSet}^{\uparrow}$ *boundary; BEDC source* BHist*; carrier* A_{e}*; classifier* ρ_{e}*; relation* $\leq_{\mathsf{e}}$*; stability from singleton carrier transport, guarded-prefix transitivity, and antisymmetry exactness; ledger adjacent comparisons plus endpoint classifiers; core theorem this finite-chain endpoint coverage statement; exactness classifier repacking from Definition 53.12; standard bridge the singleton finite interval seen by* $\mathsf{TotalOrder}^{\uparrow}$ *and* $\mathsf{Order}^{\uparrow}$ *consumers; status* $\mathsf{ProofTarget}$*.*

Proof. Induct on the finite guarded chain. In the one-endpoint case, the carried row $A_{\mathsf{e}}(h_0)$ is a singleton carrier row. Apply Definition 53.12 to obtain the reflexive guarded comparison, the endpoint classifier $\rho_{\mathsf{e}}(h_0, h_0)$, and the exactness row that reads this classifier as the public singleton ledger entry.

For the step, suppose the prefix ending at h_m already has endpoint classifier coverage and append the adjacent guarded comparison $h_m \leq_{\mathsf{e}} h_{m+1}$. The singleton laws keep h_{m+1} inside A_{e} and classify the adjacent endpoint pair through ρ_{e}.

Now take any earlier endpoint h_i. The induction hypothesis supplies the endpoint comparison from h_i to h_m and the classifier row for that pair. Compose this comparison with $h_m \leq_{\mathsf{e}} h_{m+1}$ by transitivity in Definition 53.12. Apply Definition 53.13 to the triple h_i, h_m, h_{m+1}, and use Definition 53.14 to read the resulting endpoint comparison as the singleton classifier $\rho_{\mathsf{e}}(h_i, h_{m+1})$.

It remains to identify the public ledger row. The induction data provide the carried BHist endpoints and all adjacent guarded comparisons, while the preceding paragraph supplies the transitive endpoint witnesses and classifier rows for the newly exposed endpoint pairs. Repack the pairwise rows by Definition 53.20, and then apply Definition 53.23 to rule out any additional total-order, lattice, quotient, host-order, or non-singleton carrier field. Thus the whole finite chain is covered by the concrete singleton endpoint classifier package that downstream $\mathsf{TotalOrder}^{\uparrow}$ and $\mathsf{Order}^{\uparrow}$ consumers cite. □

Theorem 53.27 (POSet prefix chain OrderUp interval coverage)**.** *Every finite guarded* $\mathsf{POSet}^{\uparrow}$ *chain over carried* BHist *endpoints supplies the* $\mathsf{Order}^{\uparrow}$ *finite-interval carrier, endpoint classifier, and adjacent comparison ledger rows needed by the unary-prefix order phase. The carrier rows are the carried endpoint rows, the endpoint classifier rows are those of Definition 53.26, and the interval ledger is exhausted by adjacent guarded comparisons together with the collapse rows of Definition 53.14.*

Proof. Start with a finite guarded chain. Apply Definition 53.26 to obtain classifier coverage for every endpoint pair of the chain.

Next apply Definition 53.14. It reads the adjacent guarded comparisons as the transitive finite-chain comparison rows, so the endpoint pairs form the finite interval consumed by $\mathsf{Order}^{\uparrow}$.

Finally use Definition 53.23. The ledger has no entry beyond carried endpoints, adjacent comparisons, transitive endpoint witnesses, and classifier rows. These are exactly the finite-interval carrier, endpoint classifier, and adjacent comparison rows asserted above. □

Theorem 53.28 (POSet prefix chain TotalOrder selector consumer boundary)**.** *A* $\mathsf{TotalOrder}^{\uparrow}$ *selector consuming a finite guarded* $\mathsf{POSet}^{\uparrow}$ *chain may use only the carried endpoints, the branch comparison rows obtained from the chain, the endpoint classifier rows, and the finite-chain ledger supplied by Definition 53.26. It may not consume host order, quotient representatives, lattice operations, or any comparison datum outside the carried* BHist *chain.*

Proof. Read the consumer rows from Definition 53.26. They are carried BHist endpoints, adjacent guarded comparisons, transitive prefix witnesses, and endpoint classifier rows.

Apply Definition 53.14 to turn the adjacent rows into the branch comparison data visible to a selector. The result still lives over the same carried endpoints and does not introduce a host comparison.

Apply Definition 53.23 at the boundary. It rules out total-order data, quotient representatives, lattice operations, and host-order rows. Therefore the selector boundary is exactly the carried chain data listed in the statement. □

Theorem 53.29 (POSet prefix selector classifier determinacy)**.** *For a finite guarded* $\mathsf{POSet}^{\uparrow}$ *chain over carried* BHist *endpoints, any two* $\mathsf{TotalOrder}^{\uparrow}$ *or* $\mathsf{Order}^{\uparrow}$ *selectors that use the same chain ledger, the same adjacent comparison rows, and the same endpoint classifier coverage select endpoints related by the classifier rows supplied by the chain package. The conclusion is a classifier-equivalent endpoint boundary inside the finite chain, not a host order comparison or quotient representative.*

Proof. Project endpoint coverage by Definition 53.26. It gives classifier rows for every endpoint pair named by the shared guarded chain.

Next apply Definition 53.14. The adjacent comparison rows collapse to the same finite-chain boundary rows for both selectors, because the chain ledger and adjacent comparisons are shared.

Finally use Definition 53.23. It excludes any selector data outside the carried endpoints, adjacent comparisons, transitive witnesses, and endpoint classifiers. Hence both selectors read the same finite-chain classifier boundary, so their selected endpoints are related by the chain package classifier rows. □

53.3 The certificate

Definition 53.30 (POSet source specification)**.** *The source is a certified preorder carrier plus an antisymmetry field.*

Definition 53.31 (POSet pattern specification)**.** *The pattern is preorder relation formation with classifier collapse from bidirectional comparison.*

Definition 53.32 (POSet classifier specification)**.** *The classifier is the preorder carrier classifier.*

Theorem 53.33 (Prefix antisymmetry)**.** *For the concrete unary history prefix preorder, if* $h \leq k$ *and* $k \leq h$*, then* h *and* k *are classified the same by the preorder classifier.*

```
↪variant BEDC.Derived.PreorderUp.PreorderPrefixLE antisymm hsame
```

Proof. Unpack the two prefix witnesses. Substituting the first continuation into the second gives a loop from h through the appended forward and backward tails. Right-unit uniqueness and append-empty inversion force the forward tail to be e, so the first continuation reduces to $\mathsf{hsame}(h, k)$, which is the classifier specification. □

Theorem 53.34 (Prefix classifier exactness for concrete POSet)**.** *For carrier histories h, k in* PreorderCarrier*, the carrier-aware classifier relation* PreorderCarrierClassifierSpec(PreorderCarrier)(h, k) *holds exactly when* PreorderPrefixLE(h, k) *and* PreorderPrefixLE(k, h) *both hold.*

Proof. Assume first that the carrier-aware classifier holds. Its equality content is hsame(h, k), and symmetry gives hsame(k, h). Applying Definition 52.17 in the two orientations gives PreorderPrefixLE(h, k) and PreorderPrefixLE(k, h).

Conversely, assume both prefix comparisons and keep the carrier hypotheses for h and k. By Definition 53.33, the opposing comparisons collapse to hsame(h, k). Combining this equality content with the two carrier witnesses reassembles PreorderCarrierClassifierSpec(PreorderCarrier)(h, k). □

Theorem 53.35 (Prefix interval classifier collapse for concrete POSet)**.** *For carrier histories h, k, r in* PreorderCarrier*, if* PreorderPrefixLE(h, k)*,* PreorderPrefixLE(k, r)*, and* PreorderCarrierClassifierSpec(PreorderCarrier *hold, then both* PreorderCarrierClassifierSpec(PreorderCarrier)(h, k) *and* PreorderCarrierClassifierSpec(PreorderCarrier)(*hold.*

The per-object fields are as follows: the traditional target is interval collapse for order-convex consumers; the BEDC source is the unary BHist *prefix order; the carrier is* PreorderCarrier*; the classifier is* PreorderCarrierClassifierSpec*; stability comes from prefix transitivity and antisymmetry; the ledger records the chains $h \leq k \leq r$ and $r \leq h \leq k$; the core theorem is this interval classifier collapse; exactness is inherited from Definition 53.34; the standard bridge is the finite unary prefix order; and the status is* ProofTarget*.*

Proof. Unpack the endpoint classifier PreorderCarrierClassifierSpec(PreorderCarrier)(h, r). It provides carrier data for h and r together with hsame(h, r). The displayed comparison PreorderPrefixLE(h, k) and Definition 52.21 give the carrier witness for k.

Symmetry of hsame(h, r) and Definition 52.17 give PreorderPrefixLE(r, h). Compose this with PreorderPrefixLE(k, r) by Definition 52.28 to obtain PreorderPrefixLE(k, h). Now Definition 53.33 applies to PreorderPrefixLE(h, k) and PreorderPrefixLE(k, h), yielding hsame(h, k).

For the right subinterval, compose PreorderPrefixLE(r, h) with the displayed comparison PreorderPrefixLE(h, k) to get PreorderPrefixLE(r, k). PreorderPrefixLE(k, r) is already available, so Definition 53.33 gives hsame(k, r).

Finally repackage the two classifier witnesses. Combine the carrier witnesses for h and k with hsame(h, k) to obtain PreorderCarrierClassifierSpec(PreorderCarrier)(h, k), and combine the carrier witnesses for k and r with hsame(k, r) to obtain PreorderCarrierClassifierSpec(PreorderCarrier)(k, r). □

Thus Definition 53.34 supplies the exactness predicate named in item 9 of Definition 53.9.

Theorem 53.36 (Concrete POSet$^{\uparrow}$ naming certificate)**.** *The tuple of Definition 53.9 supplies the source, pattern, classifier, stability, and ledger data of a concrete* NameCert *licensing* POSet$^{\uparrow}$ *over* PreorderCarrier = UnaryHistory*, classifier* PreorderCarrierClassifierSpec(PreorderCarrier)*, and relation* PreorderPrefixLE*.*

Proof. The carrier, preorder, relation-congruence, and antisymmetry fields are exactly the fields certified in Definition 53.10. They identify the carrier with unary histories, use the carrier-aware preorder classifier, and close the partial-order law by prefix antisymmetry.

The classifier exactness field is Definition 53.34. It identifies the carrier classifier with the two opposing prefix comparisons required by the concrete partial-order presentation.

The ledger component records the two comparison witnesses, as specified by Definition 53.44. Repacking these source, pattern, classifier, stability, and ledger components gives the displayed concrete NameCert for $\mathsf{POSet}^{\uparrow}$. □

This theorem fits the per-object template as follows: the traditional target is the finite unary-word prefix partial order; the BEDC source is BHist restricted to unary histories; the carrier is PreorderCarrier = UnaryHistory; the classifier is PreorderCarrierClassifierSpec(PreorderCarrier); the stability obligations are the concrete preorder laws, classifier congruence, and prefix antisymmetry; the ledger records the two comparison-tail witnesses; the core theorem is Definition 53.10; the exactness predicate is Definition 53.34; the standard bridge is the finite unary-word initial-segment order; and the status is ProofTarget. This concrete tuple is the schema instance consumed by the POSet certificate, so Lean can target the BHist prefix construction rather than an abstract relation schema.

Theorem 53.37 (POSet public prefix closure boundary)**.** *For the concrete unary-prefix POSet tuple of Definition 53.9, the public surface is exactly the following* BHist*-anchored data:*

1. *carrier* PreorderCarrier = UnaryHistory*;*
2. *classifier* PreorderCarrierClassifierSpec(PreorderCarrier)*;*
3. *relation* PreorderPrefixLE*.*

Its preorder laws, endpoint congruence, antisymmetry, exactness, and ledger rows are supplied by Definition 53.10, Definition 53.34, and Definition 53.36. The package introduces no abstract carrier, abstract classifier, quotient, host equality, or parameterized order relation.

Proof. Unfold the tuple of Definition 53.9. Its carrier coordinate is PreorderCarrier, which is identified there with UnaryHistory inside BHist; its classifier coordinate is PreorderCarrierClassifierSpec(PreorderCarrier); and its relation coordinate is PreorderPrefixLE.

The stability rows come from Definition 53.10. That theorem supplies the preorder fields for PreorderPrefixLE, endpoint congruence for the carrier-aware classifier, and the antisymmetry collapse under that classifier.

The bidirectional-collapse row is Definition 53.34. It states that the carrier-aware classifier is exact for the two opposing prefix comparisons, so the public exactness field uses no quotient or external equality relation.

Finally, Definition 53.36 repacks the source, pattern, classifier, stability, and ledger rows into the concrete NameCert. Since each repacked row names the same carrier, classifier, and prefix relation, the public $\mathsf{POSet}^{\uparrow}$ surface is anchored in BHist rather than in an abstract carrier or parameterized order schema. □

Theorem 53.38 (POSet antichain subcarrier certificate)**.** *For a concrete* $\mathsf{POSet}^{\uparrow}$ *carrier* $(C, \sim_C, \leq_C)$ *over* BHist*, define the antichain subcarrier* A_C *to consist of carried endpoints* a : BHist *such that every carried endpoint* b : BHist *with* $a \leq_C b$ *or* $b \leq_C a$ *collapses to classifier equality* $a \sim_C b$*. Then* A_C *is a displayed BEDC subcarrier: its carrier row is inherited from* C*, its comparison reads are the two stored* $\leq_C$ *ledger rows, and membership in* A_C *is stable under* hsame *transport and the classifier-congruence fields of Definition 53.37.*

Proof. Start from the public prefix closure boundary. It exposes the carrier PreorderCarrier, the carrier classifier, the prefix relation, the preorder laws, relation congruence, antisymmetry, exactness, and the ledger rows for comparison witnesses.

To build A_C, keep only carried endpoints of the same BHist carrier and attach the displayed antichain clause. No subset quotient is formed: the subcarrier membership row is a package field whose inputs are the carried endpoint, the comparison ledger rows, and the classifier conclusion.

For stability, transport the carried endpoint along hsame and use the relation-congruence rows from the $\mathsf{POSet}^{\uparrow}$ certificate to transport any comparison with a carried target. The antichain clause then returns the classifier equality at the source, and classifier transport repacks it at the target endpoint. □

Theorem 53.39 (POSet antichain discrete NameCert)**.** *The relation induced by $\leq_C$ on the antichain subcarrier A_C of Definition 53.38 is the discrete* $\mathsf{POSet}^{\uparrow}$ *relation. More precisely, for $a, b \in A_C$, a displayed comparison $a \leq_C b$ holds in the induced relation exactly when the carrier classifier collapses the two endpoints, and the resulting* NameCert *has reflexivity from the inherited preorder row and antisymmetry from the antichain clause.*

Proof. Unpack the induced relation on A_C. Its comparison ledger is the same $\leq_C$ ledger stored by the ambient $\mathsf{POSet}^{\uparrow}$ package, but both endpoints now carry the antichain membership row.

Reflexivity is inherited directly from the preorder component of Definition 53.10. Thus every endpoint of A_C has the displayed comparison to itself required by the discrete relation.

For antisymmetry, suppose $a, b \in A_C$ and $a \leq_C b$. The antichain clause for a applies to the carried endpoint b and collapses the comparison to $a \sim_C b$. Conversely, classifier equality transports the reflexive comparison on a to a comparison with b by the relation-congruence fields, so the induced order has no non-discrete comparison content. □

Theorem 53.40 (POSet antichain interval heredity)**.** *For a, b, c in the concrete unary-prefix* $\mathsf{POSet}^{\uparrow}$ *carrier, suppose that $a, c \in A_C$, that the comparison ledger records $a \leq_C b$ and $b \leq_C c$, and that all three endpoints carry the concrete* BHist *carrier rows. Then $b \in A_C$, and the two endpoint comparisons collapse to the carrier classifier:*

$$a \sim_C b \quad \textit{and} \quad b \sim_C c.$$

Proof. Compose the displayed comparisons $a \leq_C b$ and $b \leq_C c$ by the transitivity row of the concrete prefix preorder. This gives $a \leq_C c$ inside the same comparison ledger.

Apply the antichain clause for $a \in A_C$ to the carried endpoint c. Since $a \leq_C c$ is available, the clause collapses the endpoints to the carrier classifier $a \sim_C c$.

Use Definition 53.34 to read this classifier collapse as opposing prefix comparisons between a and c. Relation congruence transports the displayed comparisons $a \leq_C b$ and $b \leq_C c$ through the classifier collapse, yielding the reverse comparisons needed to apply Definition 53.33 on the two subintervals.

Antisymmetry collapses a with b and b with c, giving the two displayed classifier conclusions. To repackage $b \in A_C$, take any carried endpoint d comparable with b; relation congruence transports that comparison across $a \sim_C b$ to a comparison with a, the antichain clause for a collapses a with d, and classifier transitivity transports the collapse back to $b \sim_C d$. □

Theorem 53.41 (POSet antichain functor consumer boundary)**.** *Any downstream finite-set or functor consumer of the antichain construction may read only the antichain carrier row of Definition 53.38, the inherited classifier, the comparison ledger rows, and the* NameCert *provenance of Definition 53.39. It may not read a host-level subset quotient, an external equality relation, or a parameterized order schema beyond the displayed* BHist *package rows.*

Proof. The construction of A_C is package-local. Its carrier, classifier, relation, and comparison ledger are inherited rows from the concrete $\mathsf{POSet}^{\uparrow}$ certificate, while the antichain clause is an additional displayed membership field over carried endpoints.

The discrete $\mathsf{NameCert}$ of Definition 53.39 repacks those rows into the consumer-facing order surface. Finite-set consumers therefore see a finite list of carried endpoints and comparison witnesses; functor consumers see the same classifier and relation-congruence provenance.

Since every field is read from BHist, hsame, the comparison ledger, and $\mathsf{NameCert}$ provenance, the consumer boundary has no access to a host subset quotient or an unrecorded ambient relation. □

Theorem 53.42 (POSet antichain interval consumer exactness)**.** *For a concrete unary-prefix* $\mathsf{POSet}^{\uparrow}$ *packet, restrict any finite-order or functor consumer to the antichain subcarrier* A_C *and to an interval boundary* $a \leq_C b \leq_C c$ *with* $a, c \in A_C$*. The consumer reads exactly the prefix-classifier comparison rows of Definition 53.34, transported to the interval subcarrier by Definition 53.40, and no further order row beyond the public boundary of Definition 53.41.*

Proof. Unpack the concrete $\mathsf{POSet}^{\uparrow}$ naming certificate. The visible carrier, classifier, comparison ledger, and $\mathsf{NameCert}$ provenance are precisely the rows exposed by the unary-prefix packet, so every displayed comparison in the interval is a prefix row before any antichain restriction is applied.

Apply Definition 53.34. It identifies the visible comparison rows with the prefix-classifier data carried by the concrete BHist package. Thus the consumer's comparison information is already the prefix-classifier surface.

Next apply Definition 53.40 to the interval $a \leq_C b \leq_C c$ with antichain endpoints. The middle endpoint is transported into the antichain subcarrier, and both endpoint comparisons collapse to the same classifier rows.

Finally use Definition 53.41. It exhausts the public readback for finite-order and functor consumers by the antichain carrier, inherited classifier, comparison ledger, and $\mathsf{NameCert}$ provenance. Hence no additional order row remains outside the transported prefix-classifier rows. □

Definition 53.43 (POSet stability certificate)**.** *The stability certificate consists of:*

1. *all preorder stability fields*
2. *antisymmetry:* $a \leq b$ *and* $b \leq a$ *imply* $a \sim_C b$
3. *compatibility of antisymmetry with relation congruence*

Definition 53.44 (POSet ledger policy)**.** *Record both comparison derivations when antisymmetry is used.*

Definition 53.45 ($\mathsf{POSet}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{POSet}^{\uparrow}$*.*

Primitive boundary. $\mathsf{POSet}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Proposition 53.46 ($\mathsf{POSet}^{\uparrow}$ forgets to $\mathsf{Preorder}^{\uparrow}$ certificate)**.** *Let* C *carry a* $\mathsf{POSet}^{\uparrow}(C)$ *certificate with classifier* $\sim_C$ *and relation* $\leq_C$*. If the antisymmetry field and the compatibility data whose only role is to transport that antisymmetry field across relation congruence are omitted, the retained carrier, source, pattern, classifier, preorder stability fields, and ledger form a* $\mathsf{Preorder}^{\uparrow}(C)$ *certificate. The carrier* C*, classifier* $\sim_C$*, and relation* $\leq_C$ *are unchanged.*

Proof. By Definition 53.45, the given certificate supplies carrier, source, pattern, classifier, stability, and ledger data for $\mathsf{POSet}^{\uparrow}$. The construction keeps exactly the coordinates that do not require the partial-order antisymmetry clause.

By Definition 53.2, a $\mathsf{POSet}^{\uparrow}$ carrier is a preorder setup together with antisymmetry under the carrier classifier. Removing the antisymmetry coordinate leaves the carrier, classifier, and relation data required by Definition 52.2. Hence C, $\sim_C$, and $\leq_C$ are copied without replacement.

By Definition 53.30, the source is a certified preorder carrier plus an antisymmetry field. Omitting only the antisymmetry field leaves the source described in Definition 52.15. By Definition 53.32, the classifier is the preorder carrier classifier, so it is exactly the classifier specified in Definition 52.25.

By Definition 53.31, the pattern is preorder relation formation together with classifier collapse from bidirectional comparison. Retaining the one-direction judgment formation $a \leq_C b$ and suppressing only the bidirectional-collapse rule leaves the relational judgment formation of Definition 52.16.

By Definition 53.43, the first stability component is all preorder stability fields. These are precisely the classifier reflexivity, classifier transitivity, preorder reflexivity, preorder transitivity, and relation-congruence rows listed in Definition 52.44. The remaining $\mathsf{POSet}^{\uparrow}$ rows, namely antisymmetry and compatibility of antisymmetry with relation congruence, are not obligations for $\mathsf{Preorder}^{\uparrow}$. Relation congruence itself is retained because it belongs to the preorder stability component.

Finally, Definition 52.45 asks for the compared carrier witnesses and the relation derivation. The $\mathsf{POSet}^{\uparrow}$ ledger of Definition 53.44 adds the paired comparison record only when antisymmetry is used. With that antisymmetry use omitted, the remaining comparison provenance is the preorder ledger for the same relation $\leq_C$.

The retained carrier, source, pattern, classifier, stability, and ledger fields are therefore exactly the obligations named in Definition 52.46, giving a $\mathsf{Preorder}^{\uparrow}(C)$ certificate with unchanged carrier, classifier, and relation. □

Definition 53.47 (Preorder quotient presentation)**.** *Let $(C, \sim_C, \leq_C)$ be a $\mathsf{Preorder}^{\uparrow}$ package satisfying the carrier and stability fields of Definition 52.2 and Definition 52.44. On carried representatives define*

$$x \approx_C y :\Longleftrightarrow x \leq_C y \wedge y \leq_C x.$$

Let $q : C \to C_{\approx}$ be the class map for $\approx_C$, and write $\overline{x} := q(x)$. The quotient carrier is $C_{\approx}$. Its induced order and quotient classifier are

$$\overline{x} \leq_Q \overline{y} :\Longleftrightarrow x \leq_C y, \qquad \overline{x} \sim_Q \overline{y} :\Longleftrightarrow x \approx_C y.$$

Theorem 53.48 (Preorder quotient yields $\mathsf{Poset}^{\uparrow}$)**.** *Let $(C, \sim_C, \leq_C)$ supply the carrier, classifier, relation, stability, and ledger fields of a $\mathsf{Preorder}^{\uparrow}$ certificate as in Definition 52.46. For the quotient presentation of Definition 53.47, $\approx_C$ is an equivalence relation on carried representatives, the induced order $\leq_Q$ is independent of representatives, and $(C_{\approx}, \sim_Q, \leq_Q)$ supplies the $\mathsf{POSet}^{\uparrow}$ certificate obligations for the quotient partial order. Its classifier is exact on classes:*

$$\overline{x} \sim_Q \overline{y} \Longleftrightarrow x \approx_C y \Longleftrightarrow (x \leq_C y \wedge y \leq_C x).$$

Proof. The preorder stability fields in Definition 52.44 give reflexivity and transitivity of $\leq_C$ on carried representatives. Reflexivity of $\approx_C$ follows by pairing two copies of $x \leq_C x$. Symmetry follows by exchanging the two comparison witnesses. For transitivity, assume $x \approx_C y$ and $y \approx_C z$.

The forward comparison $x \leq_C z$ is obtained by composing $x \leq_C y$ with $y \leq_C z$, and the reverse comparison $z \leq_C x$ is obtained by composing $z \leq_C y$ with $y \leq_C x$. Hence $\approx_C$ is an equivalence relation.

The induced order is representative-independent. Suppose $x \approx_C x'$, $y \approx_C y'$, and $x \leq_C y$. The reverse half of $x \approx_C x'$ gives $x' \leq_C x$, so transitivity gives $x' \leq_C y$. The forward half of $y \approx_C y'$ gives $y \leq_C y'$, so another use of transitivity gives $x' \leq_C y'$. Thus $\overline{x} \leq_Q \overline{y}$ implies $\overline{x'} \leq_Q \overline{y'}$ under replacement of representatives. Taking one representative fixed gives the two one-sided relation-congruence rows.

The quotient classifier is also representative-independent because $\approx_C$ is an equivalence relation: from $x \approx_C x'$ and $y \approx_C y'$, transitivity and symmetry give $x \approx_C y$ exactly when $x' \approx_C y'$. Therefore $\sim_Q$ is a well-defined classifier on $C_\approx$, and unfolding its definition gives the displayed exactness equivalence.

The $\mathsf{POSet}^\uparrow$ laws follow directly. Reflexivity of $\leq_Q$ is the reflexivity of $\leq_C$ on any representative. Transitivity of $\leq_Q$ is the transitivity of $\leq_C$ after unfolding the two induced comparisons. For antisymmetry, if $\overline{x} \leq_Q \overline{y}$ and $\overline{y} \leq_Q \overline{x}$, then $x \leq_C y$ and $y \leq_C x$, hence $x \approx_C y$, and therefore $\overline{x} \sim_Q \overline{y}$ by the quotient classifier.

The source row is the quotient carrier $C_\approx$, the pattern row is $\leq_Q$ as in Definition 53.31, and the classifier row is $\sim_Q$ as in Definition 53.32. The stability rows required by Definition 53.43 are the quotient reflexivity, transitivity, relation congruence, and antisymmetry just proved. The ledger of Definition 53.44 records the two representatives and, when antisymmetry is invoked, the two induced comparisons. These are exactly the fields listed in Definition 53.45, so the quotient presentation supplies the stated $\mathsf{POSet}^\uparrow$ certificate and hence the $\mathsf{Poset}^\uparrow$ quotient presentation. □

Definition 53.49 (Opposite POSet certificate data)**.** *Let a $\mathsf{POSet}^\uparrow$ certificate be presented by a carrier predicate $\mathcal{C}$, classifier $\sim_C$, and relation $\leq_C$. Define the opposite relation by*

$$a \leq_C^{\mathrm{op}} b := b \leq_C a.$$

The opposite POSet data C^{op} have the same carrier predicate $\mathcal{C}$, the same classifier $\sim_C$, and relation $\leq_C^{\mathrm{op}}$. An antisymmetry ledger for $a \leq_C^{\mathrm{op}} b$ and $b \leq_C^{\mathrm{op}} a$ is the same pair of original comparison derivations, read as $b \leq_C a$ and $a \leq_C b$.

Theorem 53.50 (Opposite POSet certificate)**.** *If $(\mathcal{C}, \sim_C, \leq_C)$ satisfies the $\mathsf{POSet}^\uparrow$ certificate obligations of Definition 53.45, then the data of Definition 53.49 also satisfy the $\mathsf{POSet}^\uparrow$ certificate obligations. Thus the same carrier and classifier carry a POSet certificate with relation $\leq_C^{\mathrm{op}}$.*

Proof. Unpack the given package through Definition 53.45. By Definition 53.46, it has a $\mathsf{Preorder}^\uparrow$ reduct with the same carrier predicate $\mathcal{C}$, classifier $\sim_C$, and relation $\leq_C$. Applying Definition 52.50 to that reduct supplies the carrier, source, preorder pattern, classifier, preorder stability rows, and preorder ledger for the relation $\leq_C^{\mathrm{op}}$ of Definition 53.49.

It remains to supply the partial-order rows of Definition 53.43. Let a and b be carried endpoints and suppose

$$a \leq_C^{\mathrm{op}} b \qquad \text{and} \qquad b \leq_C^{\mathrm{op}} a.$$

Unfolding the opposite relation gives $b \leq_C a$ and $a \leq_C b$. Applying the original antisymmetry field to the ordered pair $a \leq_C b$ and $b \leq_C a$ yields $a \sim_C b$, which is exactly the antisymmetry conclusion required for $\leq_C^{\mathrm{op}}$.

The compatibility of antisymmetry with relation congruence is inherited in the same exchange of endpoints. Given classifier replacements $a \sim_C a'$ and $b \sim_C b'$, the opposite preorder relation-congruence row transports the two opposite comparisons to $a' \leq_C^{\mathrm{op}} b'$ and $b' \leq_C^{\mathrm{op}} a'$. Unfolding

gives $b' \leq_C a'$ and $a' \leq_C b'$, and the original antisymmetry compatibility row applies to these transported original comparisons to produce $a' \sim_C b'$.

The source row of Definition 53.30 is therefore a certified preorder carrier plus the antisymmetry field just proved. The pattern row of Definition 53.31 is still preorder relation formation with classifier collapse from bidirectional comparison: a displayed pair of opposite comparisons is read as the same original pair with the two comparison derivations exchanged. The classifier row of Definition 53.32 is unchanged because endpoint classification remains $\sim_C$.

Finally, the ledger row is Definition 53.44. It records both comparison derivations used by antisymmetry; under Definition 53.49, those are exactly the original derivations $b \leq_C a$ and $a \leq_C b$ with the displayed slots exchanged. Hence the carrier, source, pattern, classifier, stability, and ledger rows satisfy Definition 53.45, so C^{op} carries a $\mathsf{POSet}^{\uparrow}$ certificate. □

Theorem 53.51 (Double opposite POSet certificate data identity)**.** *Let D be a $\mathsf{POSet}^{\uparrow}$ certificate satisfying the obligations of Definition 53.45. Present its POSet data by a carrier predicate $\mathcal{C}$, classifier $\sim_C$, order relation $\leq_C$, and antisymmetry ledger row $\mathcal{L}_C$ as in Definition 53.44. Let $D^{\mathrm{opop}} = (D^{\mathrm{op}})^{\mathrm{op}}$ be obtained by applying Definition 53.49 twice. Then D^{opop} is a $\mathsf{POSet}^{\uparrow}$ certificate, and its carrier predicate, classifier, order relation, and antisymmetry ledger row are componentwise identical to those of D: for carried endpoints a, b and comparison witnesses $p : a \leq_C b$ and $q : b \leq_C a$,*

$$\mathcal{C}^{\mathrm{opop}}(a) = \mathcal{C}(a), \qquad a \sim_C^{\mathrm{opop}} b = a \sim_C b,$$
$$a \leq_C^{\mathrm{opop}} b = a \leq_C b, \quad \mathcal{L}_C^{\mathrm{opop}}(a, b; p, q) = \mathcal{L}_C(a, b; p, q).$$

Here $\mathcal{L}_C(a, b; p, q)$ denotes the ledger entry that records the ordered antisymmetry pair p, q.

Proof. Because D satisfies the $\mathsf{POSet}^{\uparrow}$ obligations, Definition 53.50 makes D^{op} a certified $\mathsf{POSet}^{\uparrow}$ instance. Applying the same theorem to that certified opposite data makes D^{opop} a certified $\mathsf{POSet}^{\uparrow}$ instance.

It remains to compare the displayed data. For the carrier predicate and classifier, two unfoldings of Definition 53.49 give

$$\mathcal{C}^{\mathrm{opop}}(a) = \mathcal{C}^{\mathrm{op}}(a) = \mathcal{C}(a)$$

and

$$a \sim_C^{\mathrm{opop}} b = a \sim_C^{\mathrm{op}} b = a \sim_C b.$$

For the order relation, the two reversals cancel:

$$a \leq_C^{\mathrm{opop}} b = b \leq_C^{\mathrm{op}} a = a \leq_C b.$$

Thus the double opposite order field is exactly the original order field.

For the ledger row, Definition 53.49 says one opposite keeps the same two antisymmetry derivations and exchanges their displayed source and target slots. Hence the first opposite reads the ordered ledger entry for $(a, b; p, q)$ in the exchanged slots, and the second opposite performs the same exchange again. The endpoints and the two comparison slots are restored to $(a, b; p, q)$, so $\mathcal{L}_C^{\mathrm{opop}}(a, b; p, q) = \mathcal{L}_C(a, b; p, q)$.

The certified status and the four displayed component identities therefore identify the double opposite POSet data with the original POSet data. □

Definition 53.52 (POSet chain comparison envelope)**.** *A $\mathsf{POSet}^{\uparrow}$ chain comparison envelope over concrete* BHist *endpoints consists of the following finite data.*

1. *Two finite* PreorderPrefixLE *chains, one from h to k and one from k to h, written as carried* BHist *endpoint rows.*

2. *The two composite comparison rows obtained from those chains:* $p : \mathsf{PreorderPrefixLE}(h, k)$ *and* $q : \mathsf{PreorderPrefixLE}(k, h)$.
3. *Carrier witnesses for every endpoint appearing in either chain, including the boundary endpoints* h *and* k.
4. *A finite* Cont *ledger recording the adjacent comparisons, the two composite comparison rows, and the bidirectional pair* p, q *used by the quotient classifier of Definition 53.47.*

The quotient readback of the envelope is the classifier witness generated by the pair p, q*. The opposite readback is the same finite envelope with the two chains and the two displayed comparison rows exchanged.*

Theorem 53.53 (POSet chain envelope opposite stability)**.** *Let* E *be a* $\mathsf{POSet}^{\uparrow}$ *chain comparison envelope as in Definition 53.52. Reversing* E *to the opposite envelope exchanges the two finite chain ledgers, preserves the quotient classifier generated by the bidirectional comparison pair, and records the same endpoint carrier witnesses. After applying the opposite construction twice, the resulting envelope has the original carrier rows, quotient classifier row, order relation, composite comparison rows, and finite* Cont *ledger rows of* E.

Proof. First read the two finite chains as carrier data. By Definition 53.54, every endpoint in either chain is carried, and the composite rows p and q remain carried PreorderPrefixLE comparisons. Applying Definition 53.55 to the two composite rows gives the endpoint classifier row determined by the envelope.

Next compare the quotient readback. In Definition 53.47, the quotient classifier is generated exactly by a bidirectional comparison pair. The opposite envelope only exchanges the two displayed rows, so the generated classifier witness is the same finite pair read in the opposite order; no additional representative or carrier-equivalence row is introduced.

Finally apply Definition 53.51. One opposite exchanges the two chain ledgers and the two composite comparison slots, and a second opposite exchanges them back. The carrier predicate, quotient classifier, order relation, and ledger slots are therefore restored componentwise to the rows of E. □

Theorem 53.54 (POSet finite-chain carrier closure)**.** *Let*

$$h = h_0,\ h_1, \ldots, h_n = k$$

be a finite chain of carried unary-prefix histories in the concrete $\mathsf{POSet}^{\uparrow}$ *source of Definition 53.9. If each adjacent comparison* $h_i \leq h_{i+1}$ *is recorded by* PreorderPrefixLE *in the finite* Cont *ledger, then every endpoint* h_i *in the chain remains inside* PreorderCarrier = UnaryHistory*, and the composite comparison from* h *to* k *is again a carried unary-prefix comparison recorded by that finite ledger.*

Proof. Argue by induction on the finite chain. The base chain has only the carried endpoint h, so carrier closure is immediate from the displayed source row.

For the step, assume the prefix subchain from h to h_i has already stayed inside UnaryHistory and has produced a carried composite comparison. The adjacent row $h_i \leq h_{i+1}$ is a displayed PreorderPrefixLE comparison between carried histories, so the prefix transitivity row cited in Definition 53.36 composes it with the subchain comparison.

The same finite Cont ledger records the old subchain, the new adjacent comparison, and their composite. Thus the next endpoint remains in PreorderCarrier and the chain closes inside the concrete unary prefix carrier. □

Theorem 53.55 (POSet finite-chain antisymmetry collapse)**.** *Let h and k be carried unary-prefix histories. If the finite* Cont *ledger records a finite* PreorderPrefixLE *chain from h to k and another finite* PreorderPrefixLE *chain from k to h, then the two endpoints collapse to the carrier classifier:*

$$\mathsf{PreorderCarrier}(h) \wedge \mathsf{PreorderCarrier}(k) \wedge h \leq k \wedge k \leq h \Longrightarrow \mathsf{hsame}(h, k).$$

Proof. First apply Definition 53.54 to the chain from h to k. It gives a carried composite comparison $h \leq k$ recorded by the finite ledger.

Apply the same closure theorem to the reverse chain from k to h. This gives the carried composite comparison $k \leq h$ over the same unary-prefix carrier.

Now apply Definition 53.33 to the opposing composite prefix comparisons. The result is $\mathsf{hsame}(h, k)$, and Definition 53.34 identifies this history sameness with the carrier classifier on the displayed unary-prefix endpoints. □

The finite-chain carrier is the POSet-side handoff consumed by $\mathsf{TotalOrder}^{\uparrow}$ and $\mathsf{Lattice}^{\uparrow}$ readers, so it depends on the preorder route of chapter 52 and the order hierarchy routes of chapter 54 and chapter 55 rather than standing alone as an isolated carrier float.

Theorem 53.56 (POSet finite-chain NameCert surface)**.** *The finite-chain carrier closure of Definition 53.54 and the finite-chain antisymmetry collapse of Definition 53.55 package as a* $\mathsf{POSet}^{\uparrow}$ NameCert *obligation surface. Its rows are exactly the concrete unary-prefix carrier, the* hsame *classifier, the* PreorderPrefixLE *relation, prefix stability under finite composition, the finite* Cont *ledger for adjacent and composite comparisons, and the exactness row of Definition 53.34. It adds no quotient carrier, opposite presentation, totality field, lattice operation, or standard bridge.*

Proof. Project the concrete unary-prefix certificate of Definition 53.36. It supplies the carrier, classifier, relation, stability, ledger, and exactness rows for the $\mathsf{POSet}^{\uparrow}$ surface.

The finite-chain carrier row is supplied by Definition 53.54. Its induction uses only prefix transitivity and finite Cont composition already present in the certificate ledger.

The finite-chain antisymmetry row is supplied by Definition 53.55. It reduces two finite chains to opposing composite prefix comparisons, applies Definition 53.33, and then reads the result through Definition 53.34.

Repacking these rows with the source certificate gives a single $\mathsf{POSet}^{\uparrow}$ NameCert obligation surface. Since every row is drawn from the concrete unary-prefix packet and its finite ledger, no additional order structure or bridge datum is exported. □

53.4 Poset root obligation surface

Definition 53.57 (Poset root obligation surface)**.** *The concrete root surface for* $\mathsf{Poset}^{\uparrow}$ *is the* BHist *packet read from Definition 53.9. Its endpoints are carried unary histories h, k :* BHist*; its inherited* $\mathsf{Preorder}^{\uparrow}$ *comparison row is* $\mathsf{PreorderPrefixLE}(h, k)$*; its classifier row is the carrier-aware* hsame *classifier* $\mathsf{PreorderCarrierClassifierSpec}(\mathsf{PreorderCarrier})(h, k)$*; its partial-order row is the antisymmetry collapse for the two directed prefix comparisons; and its ledger is the finite* Cont *record consisting of the two comparison-tail witnesses, their carried endpoints, and the resulting classifier readback.*

Theorem 53.58 (Poset root antisymmetry obligation)**.** *For carried unary* BHist *endpoints h and k in the surface of Definition 53.57, the bidirectional inherited prefix comparison*

$$\mathsf{PreorderPrefixLE}(h, k) \wedge \mathsf{PreorderPrefixLE}(k, h)$$

collapses to the carried classifier row $\mathsf{PreorderCarrierClassifierSpec}(\mathsf{PreorderCarrier})(h, k)$.

Proof. Project the two inherited comparison rows from the root surface. They are the same directed prefix rows used by the concrete unary-prefix preorder package, and their endpoints are the carried BHist histories named in Definition 53.57.

Apply Definition 53.33 to the two opposite prefix comparisons. This gives the $\mathsf{hsame}(h, k)$ classifier content without changing the endpoint carrier.

Finally reassemble the carrier-aware classifier with the two carried endpoint witnesses from the root surface. By Definition 53.34, this is exactly the classifier row of the concrete $\mathsf{Poset}^{\uparrow}$ root obligation package. □

Theorem 53.59 (Poset root certificate readback)**.** *The concrete* NameCert *fields for the root surface of Definition 53.57 are read directly from Definition 53.9 and Definition 53.36. The source is* BHist *restricted to unary histories, the carrier is* PreorderCarrier = UnaryHistory*, the classifier is the carrier-aware* hsame *row, the relation is* PreorderPrefixLE*, the antisymmetry and exactness rows are the prefix collapse rows, and the ledger is the two-comparison finite* Cont *record.*

Proof. Unpack Definition 53.9. Its displayed coordinates name the source, carrier, classifier, relation, stability rows, exactness row, and comparison ledger used by the root surface.

Apply Definition 53.36. It repacks those coordinates as the concrete NameCert licensing $\mathsf{POSet}^{\uparrow}$ over the same BHist carrier and prefix relation.

The antisymmetry component is the row isolated in Definition 53.58. Therefore the root certificate contains no additional carrier, quotient representative, or external equality witness beyond the fields already read from the concrete unary-prefix certificate. □

Theorem 53.60 (Poset root downstream unblock package)**.** *The root package of Definition 53.59 supplies the rows a* $\mathsf{TotalOrder}^{\uparrow}$ *or* $\mathsf{Lattice}^{\uparrow}$ *consumer may inherit from* $\mathsf{Poset}^{\uparrow}$*: carrier, classifier, antisymmetry, exactness, and finite* Cont *ledger. A downstream consumer may append its own total-comparison selector or meet-join bound rows, but it cannot replace the inherited* BHist *carrier,* hsame *classifier, prefix exactness, or antisymmetry ledger.*

Proof. Start with the certificate readback of Definition 53.59. It exposes the carrier, classifier, relation, stability, exactness, and finite ledger rows of the concrete root surface.

For a $\mathsf{TotalOrder}^{\uparrow}$ consumer, keep the inherited carrier and classifier and add only the selector row deciding a directed comparison between displayed endpoints. The antisymmetry and exactness rows still come from Definition 53.58 and Definition 53.34.

For a $\mathsf{Lattice}^{\uparrow}$ consumer, keep the same inherited rows and add only the meet and join bound-characterization rows. The lower-bound and upper-bound comparisons are ledger entries over the same prefix relation, so their endpoint collapse still reads through the root $\mathsf{Poset}^{\uparrow}$ certificate. □

Theorem 53.61 (Poset root scoped certificate boundary)**.** *The root* $\mathsf{Poset}^{\uparrow}$ *package closes exactly the scoped boundary consisting of unary* BHist *carrier rows, inherited* $\mathsf{Preorder}^{\uparrow}$ *prefix comparison rows, the carrier-aware* hsame *classifier, antisymmetry collapse, finite* Cont *comparison ledgers, and* Pkg *provenance. These are precisely the rows inherited by* $\mathsf{TotalOrder}^{\uparrow}$ *and* $\mathsf{Lattice}^{\uparrow}$ *consumers.*

Proof. Begin with Definition 53.59. It reads the concrete unary-prefix certificate of Definition 53.36 from Definition 53.9, naming the carrier, classifier, prefix relation, exactness rows, ledger, and provenance fields.

Apply Definition 53.58 to isolate the partial-order row. The only collapse added beyond the inherited $\mathsf{Preorder}^{\uparrow}$ prefix comparisons is the carrier-aware hsame result of the two directed prefix witnesses.

Finally use Definition 53.60. It states that $\mathsf{TotalOrder}^{\uparrow}$ and $\mathsf{Lattice}^{\uparrow}$ consumers inherit exactly those rows and may only append their own selector or bound-characterization data. Thus the scoped boundary is neither weaker nor larger than the listed BEDC primitives. □

53.5 Poset root comparison surface

Definition 53.62 (POSet root comparison surface)**.** *The root comparison surface for* $\mathsf{POSet}^{\uparrow}$ *is the carried* BHist *surface whose carrier row is the unary* BHist *carrier* UnaryHistory *of Definition 53.2, whose classifier row is the carrier* hsame *row on carried unary histories, and whose relation row is the inherited prefix comparison on* BHist*. Its* NameCert *payload consists of the inherited carrier and classifier rows, the two directed comparison rows, the antisymmetry collapse row, and the finite* Cont *ledger governed by Definition 53.44.*

Theorem 53.63 (POSet root hsame transport surface)**.** *For carried unary* BHist *endpoints* h *and* k *in Definition 53.62, an* $\mathsf{hsame}(h, k)$ *classifier row transports the root carrier, classifier, and prefix-comparison rows without changing the* UnaryHistory *carrier or replacing the* NameCert *object by a quotient representative.*

Proof. Read the carrier and classifier rows from Definition 53.2. The root endpoints are already carried BHist histories in UnaryHistory, so the transport target remains inside the same displayed carrier.

Apply the prefix stability rows of Definition 52.31. They transport comparison endpoints along hsame while preserving the inherited prefix relation on the carried histories.

Finally repack the transported carrier, classifier, and comparison rows into the root surface of Definition 53.62. The NameCert object still names the same BHist rows and the same finite Cont ledger. □

Theorem 53.64 (POSet root antisymmetry surface)**.** *For endpoints* $h, k : \mathsf{BHist}$ *carried by* UnaryHistory*, the two root comparison rows* $h \leq_{\mathsf{pref}} k$ *and* $k \leq_{\mathsf{pref}} h$ *determine the root classifier row* $\mathsf{hsame}(h, k)$*, and this classifier is the one recorded by the* $\mathsf{POSet}^{\uparrow}$ NameCert *surface.*

Proof. Project the two directed relation rows from Definition 53.62. They are precisely the inherited prefix-comparison rows on carried unary BHist endpoints.

Apply Definition 53.33. The theorem collapses the opposite prefix witnesses to the classifier conclusion $\mathsf{hsame}(h, k)$.

Use Definition 53.34 to identify this classifier conclusion with the carrier classifier row recorded by the root NameCert surface. Thus antisymmetry produces no host equality or quotient object beyond the displayed hsame row. □

Theorem 53.65 (POSet root ledger exhaustion surface)**.** *Every root* $\mathsf{POSet}^{\uparrow}$ *ledger entry used by the comparison surface is one of the finite* Cont *rows named by Definition 53.44: the carried* BHist *endpoints, the two directed prefix witnesses, and the resulting* hsame *classifier row. No additional comparison, endpoint, or external equality row is part of the root* NameCert *ledger.*

Proof. Start from the ledger policy of Definition 53.44. It names the finite continuation data attached to a $\mathsf{POSet}^{\uparrow}$ comparison use: carried endpoints, directed prefix witnesses, and classifier readback.

The root surface of Definition 53.62 has no other carrier or relation coordinate. Its only relation rows are the inherited prefix comparisons on UnaryHistory endpoints.

Apply Definition 53.64 to any opposing pair in the ledger. The only possible collapse row is hsame, so the displayed Cont ledger exhausts the root NameCert comparison data. □

Theorem 53.66 (POSet root threshold unblock surface)**.** *The root* $\mathsf{POSet}^{\uparrow}$ *surface supplies the dependency-ready rows needed by downstream order constructions: a* BHist *carrier restricted to* UnaryHistory*, an* hsame *classifier, inherited prefix comparison rows, antisymmetry, classifier exactness, and the finite* Cont *ledger. Any downstream* $\mathsf{TotalOrder}^{\uparrow}$ *or* $\mathsf{Order}^{\uparrow}$ *construction may add selector or public-order rows, but it inherits these root rows as fixed* NameCert *inputs.*

Proof. Collect the carrier and classifier rows from Definition 53.62. Collect the inherited prefix comparison and transport behavior from Definition 53.63.

Next add the antisymmetry collapse of Definition 53.64 and the classifier exactness row of Definition 53.34. These rows give the partial-order boundary over the same carried BHist endpoints.

Finally attach the finite ledger exhaustion statement of Definition 53.65. The resulting package is exactly the root NameCert input available to downstream order surfaces; later selector or public export rows extend this package without replacing its carrier, classifier, comparison, antisymmetry, exactness, or ledger rows. □

Theorem 53.67 (POSet root public handoff boundary)**.** *Any downstream* $\mathsf{Order}^{\uparrow}$ *or* $\mathsf{TotalOrder}^{\uparrow}$ *consumer of the* $\mathsf{POSet}^{\uparrow}$ *root may read exactly the* UnaryHistory *carrier row, the* hsame *classifier row, the inherited prefix-comparison row, the antisymmetry collapse row, the classifier exactness row, and the finite* Cont *and* Pkg *ledger rows assembled by Definition 53.66. No host order relation, quotient equality, or representative equality is exported by this root handoff.*

Proof. First collect the transported carrier and classifier surface from Definition 53.63. It keeps every downstream endpoint inside the carried UnaryHistory row and transports comparison data only through displayed hsame rows.

Next add the comparison and collapse rows. The inherited prefix relation is the comparison row of Definition 53.62; Definition 53.64 supplies the antisymmetry collapse, and Definition 53.34 identifies that collapse with the root classifier row.

Finally attach the finite ledger and threshold rows. Use Definition 53.65 for the Cont ledger and Definition 53.66 for the complete root input package. Repacking these rows gives the public handoff to $\mathsf{Order}^{\uparrow}$ and $\mathsf{TotalOrder}^{\uparrow}$, and the absence clauses follow because none of the cited root rows exports a host order relation, quotient equality, or representative equality. □

53.6 Poset prefix schema target surface

Theorem 53.68 (Poset prefix schema target surface)**.** *The concrete unary-prefix* $\mathsf{Poset}^{\uparrow}$ *instance of Definition 53.9 supplies the non-parametric schema target consumed by* $\mathsf{TotalOrder}^{\uparrow}$ *and* $\mathsf{Lattice}^{\uparrow}$*. Its exported surface is the carrier* UnaryHistory*, the relation* PreorderPrefixLE*, the classifier* PreorderCarrierClassifierS*, the antisymmetry collapse, the finite* Cont *comparison ledgers, and* Pkg *provenance.*

Proof. Project the concrete unary-prefix instance. It names the carrier, prefix relation, carrier-aware classifier, finite comparison ledger, and provenance rows over a fixed BHist surface.

Apply Definition 53.10. The prefix laws provide the reflexive and transitive comparison rows and the antisymmetry collapse needed for the partial-order surface.

Finally apply Definition 53.61. It identifies exactly these rows as the scoped certificate boundary inherited by $\mathsf{TotalOrder}^{\uparrow}$ and $\mathsf{Lattice}^{\uparrow}$, so the schema target is concrete and non-parametric. □

53.7 Poset TotalOrder and Lattice handoff

Theorem 53.69 (POSet TotalOrder and Lattice handoff carrier)**.** *Downstream* $\mathsf{Order}^{\uparrow}$, $\mathsf{TotalOrder}^{\uparrow}$, *and* $\mathsf{Lattice}^{\uparrow}$ *consumers inherit exactly the unary* BHist *carrier, the* hsame *classifier, the inherited prefix-comparison row, antisymmetry, classifier exactness, the finite* Cont *ledger, and the* Pkg *provenance rows from the* $\mathsf{POSet}^{\uparrow}$ *root. No host order, quotient equality, or replacement carrier is part of this inherited surface.*

Proof. Read the carrier, classifier, and inherited comparison rows from Definition 53.62. These rows already place every endpoint inside the unary BHist carrier and use hsame as the displayed classifier.

Add antisymmetry and exactness from Definition 53.64 and Definition 53.34. The collapse row remains the same hsame classifier named by the root surface.

Finally attach the finite ledger and provenance rows of Definition 53.65 and Definition 53.67. The cited handoff surface exports precisely these rows, so downstream order chapters inherit this package without replacing the carrier or adding quotient data. □

Theorem 53.70 (POSet TotalOrder selector extension boundary)**.** *A* $\mathsf{TotalOrder}^{\uparrow}$ *selector may extend the inherited* $\mathsf{POSet}^{\uparrow}$ *package only by adding a directed-comparison choice row for each comparable endpoint pair. The selector does not change the inherited carrier,* hsame *classifier, prefix comparison, antisymmetry, exactness,* Cont *ledger, or* Pkg *provenance rows.*

Proof. Begin with the inherited package of Definition 53.69. It fixes the carrier, classifier, comparison, antisymmetry, exactness, ledger, and provenance rows.

The additional $\mathsf{TotalOrder}^{\uparrow}$ information is a directed comparison selection over the same carried endpoints. Because the selection targets the inherited prefix-comparison row, it adds only the choice of direction and not a new carrier or classifier.

Repack the selected direction together with the fixed $\mathsf{POSet}^{\uparrow}$ package. The root obligation and unblock surfaces, namely Definition 53.66 and Definition 53.67, already exhaust the inherited rows, so the selector boundary has no further field to replace. □

Theorem 53.71 (POSet Lattice bound extension boundary)**.** $\mathsf{Lattice}^{\uparrow}$ *meet and join bound rows extend the same inherited* $\mathsf{POSet}^{\uparrow}$ *package by adding lower-bound and upper-bound witnesses over the displayed prefix comparison. They do not replace the unary carrier, the* hsame *classifier, the comparison row, antisymmetry, exactness, ledger, or provenance rows inherited from the root.*

Proof. Use Definition 53.69 as the inherited input package. Its carrier, classifier, comparison, antisymmetry, exactness, ledger, and provenance rows are fixed before any meet or join witness is read.

A meet row supplies lower-bound data and a join row supplies upper-bound data for the same displayed prefix comparison. These rows quantify over the existing carried endpoints, so they extend the root package rather than selecting a new endpoint universe.

The exhaustion clauses of Definition 53.65 and Definition 53.67 keep the inherited ledger and provenance rows fixed. Repacking the bound witnesses with those rows gives the $\mathsf{Lattice}^{\uparrow}$ extension boundary without changing the Poset root surface. □

Theorem 53.72 (POSet quotient classifier exhaustion)**.** *In the quotient presentation of Definition 53.47, every classifier witness for quotient classes is generated by the displayed finite pair of preorder comparisons*

$$x \leq_C y \qquad \text{and} \qquad y \leq_C x.$$

The quotient carrier, quotient classifier, and comparison ledger are read through the original BHist *endpoints, the induced* hsame *class row, and the finite* Cont *comparison ledger; no abstract carrier-equivalence transport supplies an additional classifier witness.*

Proof. Unpack the quotient presentation of Definition 53.47. Its class relation is the bidirectional comparison row on carried representatives, so the displayed pair $x \leq_C y$ and $y \leq_C x$ is the only generator of the quotient classifier.

Apply Definition 53.48. The theorem builds the $\mathsf{POSet}^{\uparrow}$ quotient certificate from that finite comparison pair, the inherited carrier row, and the induced order on classes. Its antisymmetry clause is therefore read from the same pair of comparisons, now recorded as the quotient hsame class row.

The remaining data are ledger data. The finite Cont comparison ledger records exactly the two comparison witnesses and their endpoint support in BHist. Since neither Definition 53.47 nor Definition 53.48 introduces a separate carrier equivalence field, every quotient classifier witness is exhausted by this displayed comparison ledger. □

Theorem 53.73 (POSet opposite and quotient compatibility)**.** *For a* $\mathsf{Preorder}^{\uparrow}$ *certificate with carrier C, classifier $\sim_C$, and relation $\leq_C$, taking the opposite relation before forming the quotient presentation gives the same quotient classifier and restored comparison ledger as forming the quotient first and then reversing the induced order. In both routes, a class witness between representatives x and y is the same finite pair $x \leq_C y$ and $y \leq_C x$ with the displayed comparison slots exchanged twice.*

Proof. Start with the quotient route. By Definition 53.47, the quotient classifier is generated by the pair $x \leq_C y$ and $y \leq_C x$, and Definition 53.48 records that pair as the antisymmetry ledger of the induced $\mathsf{POSet}^{\uparrow}$ certificate.

For the opposite-first route, unfold Definition 53.49. Reversal exchanges the two comparison slots, so the quotient classifier for the opposite relation is generated by $y \leq_C x$ and $x \leq_C y$. This is the same finite comparison family with the ordered slots exchanged.

Now reverse the induced quotient order. The data identity of Definition 53.51 says that a second reversal restores the carrier, classifier, order relation, and ledger slots componentwise. Hence the opposite-first quotient and the quotient-first opposite expose the same quotient classifier and the same restored finite Cont comparison ledger, without invoking any abstract carrier-equivalence transport. □

Theorem 53.74 (POSet quotient opposite involutive readback)**.** *Let a concrete* $\mathsf{Preorder}^{\uparrow}$ *carrier over* BHist *have carrier C, classifier $\sim_C$, and comparison relation $\leq_C$. Quotienting by the bidirectional comparison ledger of Definition 53.47, reversing the induced order, and reversing again returns the same quotient classifier witness and the same finite* Cont *comparison ledger. At every endpoint pair, the visible witness remains the concrete pair $x \leq_C y$ and $y \leq_C x$.*

Proof. Unfold the quotient presentation of Definition 53.47. The quotient class relation is generated by the two displayed comparisons, so the classifier witness between representatives is the finite pair $x \leq_C y$ and $y \leq_C x$ together with their BHist endpoint support.

Apply Definition 53.48. The induced $\mathsf{POSet}^{\uparrow}$ certificate stores that same pair as its antisymmetry and comparison ledger; no extra representative equality or host quotient row is exported.

Now apply Definition 53.51. The first opposite exchanges the two comparison slots, and the second opposite restores them componentwise. Therefore the readback after quotient, opposite, and opposite again is the original quotient classifier witness and the original finite Cont ledger, with each row still naming exactly $x \leq_C y$ and $y \leq_C x$. □

Closure status for $\mathsf{NameCert}_{\mathsf{Poset}^{\uparrow}}$**.**

Constructive story: A partial order here is the unary-prefix preorder with one additional visible row: if two carried unary histories extend to each other, the two continuation tails must both collapse and the endpoints are classified by hsame. The carrier is still the unary history predicate over BHist, excluding b0 branches and accepting only the empty history and repeated b1-stacks, while the classifier remains the carrier-aware history-sameness relation inherited from $\mathsf{Preorder}^{\uparrow}$. The source covers the certified prefix-preorder carrier plus the antisymmetry field, the pattern records bidirectional prefix comparison followed by classifier collapse, and the ledger stores the two directed continuation witnesses, their carried endpoints, and the resulting hsame readback. Since the inherited unary carrier is inhabited by e, its classifier is an equivalence, and carrier transport along hsame is already present, adding the antisymmetry row preserves all five name-certificate obligations while closing the partial-order law. A history h lies in the signature gap of a $\mathsf{Poset}^{\uparrow}$ token p when the source-domain accepts h, the signature relation pairs it with an answer endpoint and evidence ledger, and token introduction names that answer as p; concretely, h is a unary endpoint in the prefix carrier and every opposing-comparison use in the ledger collapses to the classifier evidence encoded by p. Finite-chain rows and downstream handoff rows reuse the same continuation ledger for $\mathsf{TotalOrder}^{\uparrow}$ and $\mathsf{Lattice}^{\uparrow}$ consumers, but they do not change the carrier or add a standard bridge. The chapter registers this antisymmetric unary-prefix package under the name $\mathsf{Poset}^{\uparrow}$; partial order means an extra collapse theorem on the existing prefix relation, not host equality, quotient representatives, or an external poset object.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Poset}^{\uparrow}}$, maturePackageClosed)

Scope closed: The obligation scope binds the UnaryHistory carrier, BHist predicate, hsame relation, Preorder prefix comparison, antisymmetry row, Cont transport, Pkg provenance, NameCert classifier, and ledger rows displayed by the PosetUp packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Poset}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.PreorderUp.preorder\_prefix\_stability\_certificate\_fields`

Bridge status: paperBridge

Not claimed: The chapter does not claim host order relations, quotient equality, external preorder carriers, or lattice structure.

Upgrade path: No further paper-axis grade remains; only future standard bridge verification can raise the bridge status.

Chapter 54

A Concrete Naming Certificate for $\mathsf{TotalOrder}^{\uparrow}$

The total order interface $\mathsf{TotalOrder}^{\uparrow}$ extends chapter 53 with the trichotomy field, expressed constructively: for any a, b in the carrier, the carrier's apartness predicate decides $a < b$, $a = b$ (under the classifier), or $a > b$. The classical formulation (LEM-style "either $a \leq b$ or $b \leq a$") is replaced by decidable comparison so that the total-order certificate remains 0-axiom.

54.1 Carrier definition

Definition 54.1 (TotalOrder carrier)**.** *Use a poset setup extended with constructive comparison data returning less, same, or greater.*

54.2 Concrete singleton history total order instance

Definition 54.2 (Concrete singleton history total order instance)**.** *Let A_{e} be the singleton history source of Definition 36.169 at $a_0 = \mathsf{e}$. Define*

$$\rho_{\mathsf{e}}(h, k) := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h, k),$$

and let the order relation on carried endpoints be

$$h \leq_{\mathsf{e}} k := \mathsf{PreorderPrefixLE}(h, k).$$

The constructive comparison package has three branches:

$$\mathsf{lt}_{\mathsf{e}}(h, k) := \bot, \qquad \mathsf{same}_{\mathsf{e}}(h, k) := \rho_{\mathsf{e}}(h, k), \qquad \mathsf{gt}_{\mathsf{e}}(h, k) := \bot.$$

Thus the less and greater branches are empty, while the same branch stores the singleton classifier witness.

Theorem 54.3 (Singleton history total order laws)**.** *For carried histories $h, k : \mathsf{BHist}$ with $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$, the comparison package of Definition 54.2 always returns the same branch carrying $\rho_{\mathsf{e}}(h, k)$. The resulting tuple satisfies the $\mathsf{TotalOrder}^{\uparrow}$ carrier field, the $\mathsf{POSet}^{\uparrow}$ fields, classifier stability, strict-to-apartness, trichotomy, and comparison stability.*

Proof. The carrier data are inherited from the singleton history source. The hypotheses $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$ unfold to $\mathsf{hsame}(h, \mathsf{e})$ and $\mathsf{hsame}(k, \mathsf{e})$; symmetry and transitivity of hsame compose these endpoint witnesses into $\mathsf{hsame}(h, k)$. Together with the two carrier facts, this is exactly $\rho_{\mathsf{e}}(h, k)$.

The preorder comparisons in both directions are supplied by PreorderPrefixLE_of_hsame from the displayed $\mathsf{hsame}(h, k)$ witness and its symmetric form. These witnesses give the $\mathsf{POSet}^{\uparrow}$ order relation on the restricted singleton carrier.

Antisymmetry is the concrete prefix collapse: PreorderPrefixLE_antisymm_hsame sends opposing prefix comparisons to $\mathsf{hsame}(h, k)$, which repackages with the carrier facts as the classifier $\rho_{\mathsf{e}}(h, k)$. Classifier stability and comparison stability use the same endpoint transport through e.

The strict branches are false by definition, so strict-to-apartness is vacuous. Trichotomy is the same branch just constructed; no classical comparison principle is used. □

Theorem 54.4 (Singleton total-order comparison exactness)**.** *For carried histories $h, k : \mathsf{BHist}$ with $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$ in the concrete instance of Definition 54.2, the comparison branches are exact in the following sense:*

1. $\mathsf{lt}_{\mathsf{e}}(h, k) \to \mathsf{False}$ *and* $\mathsf{gt}_{\mathsf{e}}(h, k) \to \mathsf{False}$.
2. $\mathsf{same}_{\mathsf{e}}(h, k) \iff \rho_{\mathsf{e}}(h, k)$.
3. $\mathsf{same}_{\mathsf{e}}(h, k) \iff (h \leq_{\mathsf{e}} k \wedge k \leq_{\mathsf{e}} h)$.

Proof. Unfold the three comparison branches in Definition 54.2. The strict branches are both $\bot$, so each strict witness eliminates to False.

The same branch is defined to be $\rho_{\mathsf{e}}(h, k)$, giving the second equivalence by reflexive unfolding.

For the opposing-prefix characterization, apply the exactness part of Definition 53.12 to the carried histories h and k. Composing that equivalence with the displayed unfolding $\mathsf{same}_{\mathsf{e}}(h, k) \iff \rho_{\mathsf{e}}(h, k)$ gives the stated equivalence with $h \leq_{\mathsf{e}} k$ and $k \leq_{\mathsf{e}} h$. □

Theorem 54.5 (TotalOrder carrier selector classifier coherence)**.** *For carried singleton histories $h, k : \mathsf{BHist}$ with $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$, the branch selector of Definition 54.2 is coherent with the carrier classifier:*

1. $\mathsf{same}_{\mathsf{e}}(h, k) \iff \rho_{\mathsf{e}}(h, k)$.
2. $\mathsf{lt}_{\mathsf{e}}(h, k) \to \mathsf{False}$ *and* $\mathsf{gt}_{\mathsf{e}}(h, k) \to \mathsf{False}$.
3. *For histories $h', k' : \mathsf{BHist}$ with $\mathsf{hsame}(h, h')$ and $\mathsf{hsame}(k, k')$, endpoint replacement preserves the selected branch:*
$$\mathsf{same}_{\mathsf{e}}(h', k') \iff \mathsf{same}_{\mathsf{e}}(h, k).$$

The per-object fields are: traditional target singleton total order; BEDC source the BHist *singleton carrier; classifier ρ_{e}; stability by* hsame *endpoint replacement; ledger branch selection; core theorem this selector coherence; exactness same-branch equivalence with the carrier classifier; standard bridge deferred; downstream use by* $\mathsf{TotalOrder}^{\uparrow}$ *obligation closure; status* ProofTarget.

Proof. Unfold the concrete singleton total-order instance. The selected same branch is defined to be $\rho_{\mathsf{e}}(h, k)$, while the strict-left and strict-right branches are both $\bot$.

Apply Definition 54.3 to the carried histories h and k. It supplies the singleton comparison package and the carrier classifier row built from the two carrier witnesses and hsame transitivity through e.

Apply Definition 54.4. Its first clause eliminates both strict branches to False, and its second clause is the displayed equivalence between the same branch and $\rho_{\mathsf{e}}(h, k)$.

For endpoint replacement, transport the carrier facts through $\mathsf{hsame}(h, h')$ and $\mathsf{hsame}(k, k')$. Symmetry and transitivity of hsame repackage the transported witnesses as $\rho_{\mathsf{e}}(h', k')$ exactly when the original witnesses repackage as $\rho_{\mathsf{e}}(h, k)$.

Composing this transported classifier equivalence with the same-branch equivalences for (h, k) and (h', k') proves preservation of the selected branch. □

Theorem 54.6 (TotalOrder singleton branch transport determinacy)**.** *For histories h, k, h', k' : BHist, assume $A_{\mathsf{e}}(h)$, $A_{\mathsf{e}}(k)$, $\mathsf{hsame}(h, h')$, and $\mathsf{hsame}(k, k')$. Then endpoint replacement along hsame determines the singleton comparison data:*

1. $A_{\mathsf{e}}(h') \wedge A_{\mathsf{e}}(k')$.
2. $\mathsf{lt}_{\mathsf{e}}(h', k') \to \mathsf{False}$ *and* $\mathsf{gt}_{\mathsf{e}}(h', k') \to \mathsf{False}$.
3. $\mathsf{same}_{\mathsf{e}}(h', k') \iff \rho_{\mathsf{e}}(h', k')$.
4. $\rho_{\mathsf{e}}(h', k') \iff \rho_{\mathsf{e}}(h, k)$.

Proof. Transport the two carrier facts through the endpoint replacements. Since $A_{\mathsf{e}}(h)$ means $\mathsf{hsame}(h, \mathsf{e})$, symmetry of $\mathsf{hsame}(h, h')$ and transitivity with $\mathsf{hsame}(h, \mathsf{e})$ give $\mathsf{hsame}(h', \mathsf{e})$, hence $A_{\mathsf{e}}(h')$. The same argument using $\mathsf{hsame}(k, k')$ gives $A_{\mathsf{e}}(k')$.

Apply Definition 54.4 to the carried histories h' and k'. Its strict-branch clause gives both eliminations to False, and its same-branch clause gives $\mathsf{same}_{\mathsf{e}}(h', k') \iff \rho_{\mathsf{e}}(h', k')$.

It remains to compare the singleton classifiers before and after transport. The carrier coordinates have already been transported. For the history coordinate, compose symmetry of $\mathsf{hsame}(h, h')$, the original singleton collapse $\mathsf{hsame}(h, k)$ obtained from $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$, and $\mathsf{hsame}(k, k')$ to obtain $\mathsf{hsame}(h', k')$; conversely compose $\mathsf{hsame}(h, h')$, $\mathsf{hsame}(h', k')$, and symmetry of $\mathsf{hsame}(k, k')$ to obtain $\mathsf{hsame}(h, k)$. Repackaging these witnesses with the corresponding carrier facts proves $\rho_{\mathsf{e}}(h', k') \iff \rho_{\mathsf{e}}(h, k)$. □

54.3 Concrete unary prefix total order instance

Definition 54.7 (Concrete unary prefix total order instance)**.** *Let the carrier be the concrete unary-history preorder carrier:*

$$\mathsf{Carrier}_{\mathsf{u}} := \mathsf{PreorderCarrier} = \mathsf{UnaryHistory}.$$

Let the carrier classifier be

$$\rho_{\mathsf{u}}(h, k) := \mathsf{PreorderCarrierClassifierSpec}(\mathsf{PreorderCarrier})(h, k),$$

and let the order relation be the concrete prefix relation

$$h \leq_{\mathsf{u}} k := \mathsf{PreorderPrefixLE}(h, k).$$

The constructive comparison package has the three branches

$$\mathsf{lt}_{\mathsf{u}}(h, k) := \mathsf{NatUnaryStrictPrefix}(h, k), \qquad \mathsf{same}_{\mathsf{u}}(h, k) := \rho_{\mathsf{u}}(h, k), \qquad \mathsf{gt}_{\mathsf{u}}(h, k) := \mathsf{NatUnaryStrictPrefix}(k, h).$$

Thus strict-left means that k extends h by a nonempty unary tail, same is the carrier classifier, and strict-right is the opposite strict unary prefix.

Theorem 54.8 (Concrete unary prefix total order laws)**.** *For carried unary histories h, k in* $\mathsf{Carrier_u}$*, the branches of Definition 54.7 supply constructive total comparison. Each strict branch implies carrier-classifier apartness, the same branch satisfies*

$$\mathsf{same_u}(h, k) \iff (\mathsf{PreorderPrefixLE}(h, k) \wedge \mathsf{PreorderPrefixLE}(k, h)),$$

and the inherited preorder and antisymmetry fields assemble these data into a concrete $\mathsf{TotalOrder}^{\uparrow}$ *law package over unary histories. The strict comparison row is the isolated branch transitivity of Definition 54.17.*

Proof. Start from the total unary prefix comparison of Definition 28.5. For carried histories h and k, this returns a unary continuation from h to k or one from k to h.

Split the selected unary tail by the unary-generation cases. A nonempty tail chooses the corresponding strict branch $\mathsf{NatUnaryStrictPrefix}(h, k)$ or $\mathsf{NatUnaryStrictPrefix}(k, h)$. An empty tail collapses the continuation to $\mathsf{hsame}(h, k)$, which repackages with the two carrier witnesses as $\rho_{\mathsf{u}}(h, k)$ and therefore chooses the same branch.

The strict branches are apart from the same branch. If a strict-left witness and the carrier classifier both held, the classifier exactness of Definition 53.34 would give the reverse prefix comparison as well; splitting that reverse continuation into empty or nonempty form either collapses the strict tail to e or gives opposing strict prefixes, both ruled out by Definition 28.14. The strict-right case is symmetric.

The displayed equivalence for the same branch is exactly the prefix classifier exactness theorem Definition 53.34 after unfolding $\mathsf{same_u}$. Relation stability, reflexivity, and transitivity are inherited from Definition 52.4, while antisymmetry is the same exactness field of Definition 53.34.

For strict-comparison transitivity, use Definition 54.17. It applies the concrete strict unary-prefix transitivity field to the strict-left branch and the same argument with reversed endpoints to the strict-right branch. These fields repack into the concrete $\mathsf{TotalOrder}^{\uparrow}$ law package. □

Theorem 54.9 (Concrete unary prefix total-order comparison partition)**.** *For carried unary histories h, k in* $\mathsf{Carrier_u}$*, exactly one of the three concrete branches*

$$\mathsf{NatUnaryStrictPrefix}(h, k), \qquad \rho_{\mathsf{u}}(h, k), \qquad \mathsf{NatUnaryStrictPrefix}(k, h)$$

supplies the comparison branch. The middle branch is exact:

$$\rho_{\mathsf{u}}(h, k) \iff (\mathsf{PreorderPrefixLE}(h, k) \wedge \mathsf{PreorderPrefixLE}(k, h)).$$

The strict-left and strict-right branches cannot both hold, and neither strict branch is compatible with $\rho_{\mathsf{u}}(h, k)$.

The per-object fields are: traditional target constructive total-order branch partition; BEDC source $\mathsf{UnaryHistory}$*,* $\mathsf{PreorderPrefixLE}$*, and* $\mathsf{NatUnaryStrictPrefix}$ *over* BHist*; carrier* $\mathsf{Carrier_u}$*; classifier ρ_{u}; stability obligations branch totality and incompatibility; ledger selected comparison branch; core theorem this partition; exactness the same-branch equivalence; standard bridge deferred; status* $\mathsf{ProofTarget}$*.*

Proof. Use the total unary prefix comparison of Definition 28.5. For carried histories h and k, it gives a unary continuation in one direction, and the unary tail is then split into empty and nonempty cases.

If the selected tail is nonempty from h to k, the selected branch is $\mathsf{NatUnaryStrictPrefix}(h, k)$. If the selected tail is nonempty from k to h, the selected branch is $\mathsf{NatUnaryStrictPrefix}(k, h)$.

If the selected tail is empty, the continuation collapses to the same-history case. The carrier classifier is exactly the same-history branch, and Definition 53.34 identifies it with the pair of prefix comparisons in both directions.

The two strict branches are incompatible by Definition 28.14. A strict branch together with $\rho_{\mathsf{u}}(h, k)$ would, by Definition 53.34, also provide the opposite prefix comparison; splitting that opposite comparison yields either an empty tail contradicting strictness or the opposing strict branch, again ruled out by Definition 28.14. The strict-right case is symmetric.

These cases give total coverage, the exact middle branch, and pairwise incompatibility, so the three branches form the concrete constructive partition. □

Theorem 54.10 (Concrete unary prefix total-order least upper selector)**.** *For carried unary histories h, k in $\mathsf{Carrier_u}$, there exists a carried history u in $\mathsf{Carrier_u}$ such that*

$$h \leq_{\mathsf{u}} u, \qquad k \leq_{\mathsf{u}} u,$$

and, for every carried history r in $\mathsf{Carrier_u}$,

$$(h \leq_{\mathsf{u}} r \wedge k \leq_{\mathsf{u}} r) \Rightarrow u \leq_{\mathsf{u}} r.$$

The per-object fields are: traditional target finite unary-word maximum/least-upper selector; BEDC source $\mathsf{UnaryHistory}$ *over* BHist*; carrier* $\mathsf{Carrier_u}$*; classifier ρ_{u}; relation $\leq_{\mathsf{u}}$; ledger the selected comparison branch; core theorem this block; exactness least-upper property; standard bridge finite unary prefix maximum; status* $\mathsf{ProofTarget}$*.*

Proof. Apply Definition 54.9 to the carried pair h, k. The proof splits according to the selected branch.

In the strict-left branch $\mathsf{NatUnaryStrictPrefix}(h, k)$, choose $u = k$. Forgetting the nonempty tail gives $h \leq_{\mathsf{u}} k$, while reflexivity from Definition 52.4 gives $k \leq_{\mathsf{u}} k$. If r is any common upper bound of h and k, the second premise already supplies $k \leq_{\mathsf{u}} r$, which is the required leastness clause for the selected u.

In the same branch $\rho_{\mathsf{u}}(h, k)$, choose $u = k$. The exactness row in Definition 54.9 gives $h \leq_{\mathsf{u}} k$ and $k \leq_{\mathsf{u}} h$; the displayed upper-bound clauses again use $h \leq_{\mathsf{u}} k$ and reflexivity of k. For every common upper bound r, the premise $k \leq_{\mathsf{u}} r$ is exactly the required comparison from u to r.

In the strict-right branch $\mathsf{NatUnaryStrictPrefix}(k, h)$, choose $u = h$. The branch supplies $k \leq_{\mathsf{u}} h$ after forgetting strictness, and reflexivity gives $h \leq_{\mathsf{u}} h$. For a common upper bound r, the first premise supplies $h \leq_{\mathsf{u}} r$, so the selected u is below every common upper bound.

These three cases construct the carried selector and verify both upper-bound rows and the least-upper property. □

Theorem 54.11 (Unary prefix least-upper selector successor transport)**.** *For carried unary histories h, k in $\mathsf{Carrier_u}$, suppose u is the selected least upper endpoint supplied by Definition 54.10. Then applying the same unary successor context to all three endpoints transports the selector: the endpoints $\mathsf{E1}(h)$ and $\mathsf{E1}(k)$ have selected least upper endpoint $\mathsf{E1}(u)$, up to* hsame*. More precisely, the transported package exposes*

$$\mathsf{E1}(h) \leq_{\mathsf{u}} \mathsf{E1}(u), \qquad \mathsf{E1}(k) \leq_{\mathsf{u}} \mathsf{E1}(u),$$

and, for every carried unary history r,

$$(\mathsf{E1}(h) \leq_{\mathsf{u}} r \wedge \mathsf{E1}(k) \leq_{\mathsf{u}} r) \Rightarrow \mathsf{E1}(u) \leq_{\mathsf{u}} r,$$

where the successor context is the unary Cont *row determined by* E1*. The construction uses only the concrete prefix preorder,* E1 *context transport, and* hsame *transitivity; it introduces no external endpoint identification.*

Proof. Apply Definition 54.10 to h and k, and keep the same three selector cases as in its proof. The strict-left case selects $u = k$, the same case selects an endpoint hsame-equivalent to either input, and the strict-right case selects $u = h$.

For the upper-bound rows after transport, use prefix context monotonicity. The successor row E1 is a unary left context, so Definition 52.36 carries $h \leq_{\mathsf{u}} u$ to $\mathsf{E1}(h) \leq_{\mathsf{u}} \mathsf{E1}(u)$ and carries $k \leq_{\mathsf{u}} u$ to $\mathsf{E1}(k) \leq_{\mathsf{u}} \mathsf{E1}(u)$. Endpoint-shape carriage is transported by the same Cont row.

It remains to show leastness. In the strict-left case, $u = k$; any transported common upper bound already contains the row $\mathsf{E1}(k) \leq_{\mathsf{u}} r$, which is the required comparison from $\mathsf{E1}(u)$ to r. The strict-right case is symmetric with $u = h$.

In the same case, the exactness row of Definition 54.9 gives $h \leq_{\mathsf{u}} k$ and $k \leq_{\mathsf{u}} h$. Transporting those comparisons through the same successor context and composing them with the two upper-bound premises by the transitivity row of Definition 52.4 gives the comparison from $\mathsf{E1}(u)$ to r. Any endpoint-name mismatch is absorbed by symmetry and transitivity of hsame, so the transported selected endpoint is $\mathsf{E1}(u)$ up to hsame. □

Theorem 54.12 (Concrete unary prefix total-order greatest lower selector)**.** *For carried unary histories h, k in* $\mathsf{Carrier_u}$*, there exists a carried history l in* $\mathsf{Carrier_u}$ *such that*

$$l \leq_{\mathsf{u}} h, \qquad l \leq_{\mathsf{u}} k,$$

and, for every carried history r in $\mathsf{Carrier_u}$*,*

$$(r \leq_{\mathsf{u}} h \wedge r \leq_{\mathsf{u}} k) \Rightarrow r \leq_{\mathsf{u}} l.$$

The per-object fields are: traditional target finite unary-word minimum/greatest-lower selector; BEDC source UnaryHistory *over* BHist*; carrier* $\mathsf{Carrier_u}$*; classifier ρ_{u}; relation $\leq_{\mathsf{u}}$; ledger selected comparison branch; core theorem this block; exactness greatest-lower property; downstream consumer* $\mathsf{Lattice}^{\uparrow}$ *meet and unary interval certificates; status* ProofTarget*.*

Proof. Apply Definition 54.9 to the carried pair h, k. The proof splits according to the selected branch.

In the strict-left branch $\mathsf{NatUnaryStrictPrefix}(h, k)$, choose $l = h$. Reflexivity from Definition 52.4 gives $h \leq_{\mathsf{u}} h$, and forgetting the nonempty tail gives $h \leq_{\mathsf{u}} k$. If r is any common lower bound of h and k, the first premise already supplies $r \leq_{\mathsf{u}} h$, which is the required greatestness clause for the selected l.

In the same branch $\rho_{\mathsf{u}}(h, k)$, choose $l = h$. The exactness row in Definition 54.9 gives $h \leq_{\mathsf{u}} k$ and $k \leq_{\mathsf{u}} h$; the displayed lower-bound clauses use reflexivity of h and the comparison $h \leq_{\mathsf{u}} k$. For every common lower bound r, the premise $r \leq_{\mathsf{u}} h$ is exactly the required comparison from r to l.

In the strict-right branch $\mathsf{NatUnaryStrictPrefix}(k, h)$, choose $l = k$. Forgetting strictness gives $k \leq_{\mathsf{u}} h$, and reflexivity gives $k \leq_{\mathsf{u}} k$. For a common lower bound r, the second premise supplies $r \leq_{\mathsf{u}} k$, so every common lower bound lies below the selected l.

These three cases construct the carried selector and verify both lower-bound rows and the greatest-lower property. □

Theorem 54.13 (Concrete unary prefix total-order branch transport)**.** *For carried unary histories h, h', k, k' in $\mathsf{Carrier_u}$, suppose $\rho_\mathsf{u}(h, h')$ and $\rho_\mathsf{u}(k, k')$. Then classifier replacement transports the three concrete comparison branches exactly:*

$$\mathsf{NatUnaryStrictPrefix}(h, k) \iff \mathsf{NatUnaryStrictPrefix}(h', k'),$$
$$\rho_\mathsf{u}(h, k) \iff \rho_\mathsf{u}(h', k'),$$
$$\mathsf{NatUnaryStrictPrefix}(k, h) \iff \mathsf{NatUnaryStrictPrefix}(k', h').$$

The per-object fields are: traditional target constructive total-order branch transport; BEDC source $\mathsf{UnaryHistory}$ *plus* $\mathsf{NatUnaryStrictPrefix}$ *and ρ_u; carrier* $\mathsf{Carrier_u}$*; classifier ρ_u; stability obligation comparison transport; ledger endpoint replacement witnesses; core theorem this block; exactness the three displayed iff rows; standard bridge finite unary word total order; status* $\mathsf{ProofTarget}$.

Proof. Unpack the two classifier witnesses. The witness $\rho_\mathsf{u}(h, h')$ gives the endpoint comparison $\mathsf{hsame}(h, h')$, and $\rho_\mathsf{u}(k, k')$ gives $\mathsf{hsame}(k, k')$.

For the strict-left row, the forward direction applies Definition 28.24 to the strict witness from h to k with endpoint witnesses $\mathsf{hsame}(h, h')$ and $\mathsf{hsame}(k, k')$.

The reverse direction uses the same transport theorem with the symmetric endpoint witnesses $\mathsf{hsame}(h', h)$ and $\mathsf{hsame}(k', k)$.

For the classifier row, compose the endpoint comparison $\mathsf{hsame}(h, h')$, the middle comparison extracted from $\rho_\mathsf{u}(h, k)$, and the symmetric form of $\mathsf{hsame}(k, k')$. This gives $\mathsf{hsame}(h', k')$, which repackages with the transported carrier witnesses as $\rho_\mathsf{u}(h', k')$.

The reverse classifier direction is the same composition with the two endpoint replacement witnesses reversed. Symmetry and transitivity of the carrier classifier recover $\rho_\mathsf{u}(h, k)$.

For the strict-right row, read the strict witness as a strict unary prefix from k to h. Apply the strict-prefix transport theorem with endpoints $\mathsf{hsame}(k, k')$ and $\mathsf{hsame}(h, h')$.

The reverse strict-right direction again uses the symmetric endpoint witnesses. Thus all three comparison branches are preserved and reflected under concrete classifier replacement. □

Definition 54.14 (Concrete unary successor comparison package)**.** *For a carried unary history h in $\mathsf{Carrier_u}$, the concrete successor comparison package is the pair $(h, \mathsf{E1}(h))$ over the carrier $\mathsf{Carrier_u}$, classifier ρ_u, and order $\leq_\mathsf{u}$ from Definition 54.7. Its selected comparison tail is the visible one-step ledger element $\mathsf{E1(e)}$, so the branch data are fixed as*

$$\mathsf{NatUnaryStrictPrefix}(h, \mathsf{E1}(h)), \qquad \rho_\mathsf{u}(h, \mathsf{E1}(h)), \qquad \mathsf{NatUnaryStrictPrefix}(\mathsf{E1}(h), h).$$

The package records the first branch as the selected concrete successor branch and retains the other two branches as explicit exclusion targets.

Theorem 54.15 (Concrete unary successor total-order strict branch)**.** *For every h with $\mathsf{Carrier_u}(h)$, the successor target $\mathsf{E1}(h)$ is carried by $\mathsf{Carrier_u}$ and the concrete successor comparison package of Definition 54.14 satisfies*

$$\mathsf{NatUnaryStrictPrefix}(h, \mathsf{E1}(h)).$$

Moreover,

$$\rho_\mathsf{u}(h, \mathsf{E1}(h)) \to \mathsf{False} \qquad \textit{and} \qquad \mathsf{NatUnaryStrictPrefix}(\mathsf{E1}(h), h) \to \mathsf{False}.$$

The per-object fields are: traditional target one-step successor separation; BEDC source BHist, $\mathsf{UnaryHistory}$, $\mathsf{NatUnaryStrictPrefix}$, *and* $\mathsf{PreorderPrefixLE}$*; carrier* $\mathsf{Carrier_u}$*; classifier ρ_u; ledger tail* $\mathsf{E1(e)}$*; core theorem this successor strict-branch law; exactness the exclusion of same and reverse-strict branches; status* $\mathsf{ProofTarget}$.

Proof. Unary closure of $\mathsf{Carrier_u} = \mathsf{UnaryHistory}$ under the $\mathsf{E1}$ constructor gives the carried target $\mathsf{E1}(h)$.

Apply Definition 28.13 to the unary witness for h. The selected tail is $\mathsf{E1}(\mathsf{e})$, so this produces $\mathsf{NatUnaryStrictPrefix}(h, \mathsf{E1}(h))$ for the concrete successor pair.

Now instantiate Definition 54.9 at h and $\mathsf{E1}(h)$. Its incompatibility clause says that the selected strict-left branch cannot coexist with the same branch $\rho_\mathsf{u}(h, \mathsf{E1}(h))$.

The same partition also excludes coexistence of the selected strict-left branch with the strict-right branch $\mathsf{NatUnaryStrictPrefix}(\mathsf{E1}(h), h)$. Therefore any witness of either excluded branch yields False. □

Theorem 54.16 (Concrete unary successor strict branch under left context)**.** *For carried unary histories p, h in $\mathsf{Carrier_u}$, both contextual endpoints*

$$\mathsf{append}(p, h) \qquad \textit{and} \qquad \mathsf{append}(p, \mathsf{E1}(h))$$

are carried by $\mathsf{Carrier_u}$, and the contextual successor pair satisfies

$$\mathsf{NatUnaryStrictPrefix}(\mathsf{append}(p, h), \mathsf{append}(p, \mathsf{E1}(h))).$$

Moreover,

$$\rho_\mathsf{u}(\mathsf{append}(p, h), \mathsf{append}(p, \mathsf{E1}(h))) \to \mathsf{False} \qquad \textit{and} \qquad \mathsf{NatUnaryStrictPrefix}(\mathsf{append}(p, \mathsf{E1}(h)), \mathsf{append}(p, h)) \to \mathsf{Fal}$$

The per-object fields are: traditional target context-stable one-step successor separation; BEDC source BHist*,* $\mathsf{UnaryHistory}$*,* append*,* $\mathsf{NatUnaryStrictPrefix}$*, and* $\mathsf{PreorderPrefixLE}$*; carrier* $\mathsf{Carrier_u}$*; classifier* ρ_u*; ledger left context p plus tail* $\mathsf{E1}(\mathsf{e})$*; core theorem this contextual successor strict-branch law; exactness the exclusion of same and reverse-strict branches; status* $\mathsf{ProofTarget}$*.*

Proof. Unary closure of $\mathsf{Carrier_u} = \mathsf{UnaryHistory}$ under append gives the carried endpoint $\mathsf{append}(p, h)$. Unary closure of h under $\mathsf{E1}$ first gives $\mathsf{E1}(h)$, and append closure with the same left context p gives the carried endpoint $\mathsf{append}(p, \mathsf{E1}(h))$.

Apply Definition 28.13 to the unary witness for h, obtaining the strict successor tail $\mathsf{E1}(\mathsf{e})$ from h to $\mathsf{E1}(h)$. Continuation associativity transports this same nonempty tail through the left context p, producing the displayed $\mathsf{NatUnaryStrictPrefix}$ witness between the contextual endpoints.

Instantiate Definition 54.9 at $\mathsf{append}(p, h)$ and $\mathsf{append}(p, \mathsf{E1}(h))$. Its incompatibility clauses exclude coexistence of the selected strict-left contextual branch with the same branch $\rho_\mathsf{u}(\mathsf{append}(p, h), \mathsf{append}(p, \mathsf{E1}(h)$ and with the reverse strict branch $\mathsf{NatUnaryStrictPrefix}(\mathsf{append}(p, \mathsf{E1}(h)), \mathsf{append}(p, h))$. Therefore either excluded branch yields False. □

Theorem 54.17 (Concrete unary strict branch transitivity)**.** *For carried unary histories h, k, l in $\mathsf{Carrier_u}$, strict-left comparison is transitive:*

$$\mathsf{NatUnaryStrictPrefix}(h, k) \wedge \mathsf{NatUnaryStrictPrefix}(k, l) \to \mathsf{NatUnaryStrictPrefix}(h, l).$$

The strict-right branch is transitive in the same concrete carrier:

$$\mathsf{NatUnaryStrictPrefix}(k, h) \wedge \mathsf{NatUnaryStrictPrefix}(l, k) \to \mathsf{NatUnaryStrictPrefix}(l, h).$$

Consequently $\mathsf{lt_u}$ *and* $\mathsf{gt_u}$ *are transitive on the concrete unary prefix* $\mathsf{TotalOrder}^{\uparrow}$ *instance.*

Proof. Unfold the strict-left branch of Definition 54.7. The two hypotheses are exactly a strict unary prefix from h to k and a strict unary prefix from k to l. Apply Definition 28.23; its composite tail witness gives $\mathsf{NatUnaryStrictPrefix}(h, l)$.

For strict-right comparison, unfold $\mathsf{gt_u}(x, y) := \mathsf{NatUnaryStrictPrefix}(y, x)$. The hypotheses become strict unary prefixes from l to k and from k to h. Applying the same composite-tail transitivity theorem yields $\mathsf{NatUnaryStrictPrefix}(l, h)$.

The carrier witnesses for h, k, and l are not consumed by the strict-prefix composition itself; they keep the conclusion inside the concrete $\mathsf{Carrier_u}$ total-order package. The two displayed implications are therefore precisely the transitivity fields for $\mathsf{lt_u}$ and $\mathsf{gt_u}$. □

Theorem 54.18 (Concrete unary total-order branch context equivalence)**.** *Let h, k, ℓ, r be unary histories in $\mathsf{Carrier_u} = \mathsf{UnaryHistory}$, and set*

$$H := \mathsf{append}(\ell, \mathsf{append}(h, r)), \qquad K := \mathsf{append}(\ell, \mathsf{append}(k, r)).$$

Then H and K are carried unary histories, and the three comparison branches of Definition 54.7 are invariant under this common two-sided unary context:

1. $\mathsf{lt_u}(H, K) \iff \mathsf{lt_u}(h, k)$.
2. $\mathsf{same_u}(H, K) \iff \mathsf{same_u}(h, k)$.
3. $\mathsf{gt_u}(H, K) \iff \mathsf{gt_u}(h, k)$.

Proof. Unary closure under append first gives $\mathsf{UnaryHistory}(\mathsf{append}(h, r))$ and $\mathsf{UnaryHistory}(\mathsf{append}(k, r))$. Applying the same closure once more with the unary left context ℓ gives the carrier facts for H and K.

For the same branch, unfold $\mathsf{same_u} := \rho_\mathsf{u}$. By Definition 53.34, the classifier on carried unary histories is equivalent to the pair of opposing prefix comparisons. Apply Definition 52.42 to the comparison $H \leq_\mathsf{u} K$ and again to $K \leq_\mathsf{u} H$; the two applications identify the contextual pair of prefix comparisons exactly with $h \leq_\mathsf{u} k$ and $k \leq_\mathsf{u} h$. A second use of Definition 53.34 repacks these comparisons as $\rho_\mathsf{u}(h, k)$.

For the strict-left branch, unfold $\mathsf{lt_u}$ as $\mathsf{NatUnaryStrictPrefix}$. In the forward direction from $\mathsf{NatUnaryStrictPrefix}(h, k)$, unpack the nonempty unary tail from h to k. Right-context preservation composes this tail past r by continuation associativity and unary-tail commutativity; left-context preservation then places ℓ outside both endpoints. The tail remains the same nonempty unary tail, so the result is $\mathsf{NatUnaryStrictPrefix}(H, K)$.

For the reverse strict-left direction, unpack the nonempty unary tail from H to K. Its underlying prefix comparison cancels through Definition 52.41, leaving a prefix comparison from h to k. If the recovered central tail were empty, append-empty exactness would collapse h and k, hence also H and K after the common unary context. Comparing that collapse with the original strict contextual tail would force the original tail empty, contradicting its strictness. Thus the central prefix tail is nonempty and gives $\mathsf{NatUnaryStrictPrefix}(h, k)$.

The strict-right branch is the same argument with endpoints reversed, since $\mathsf{gt_u}(x, y)$ unfolds to $\mathsf{NatUnaryStrictPrefix}(y, x)$. Applying the strict-left preservation and reflection just proved to the ordered pair (k, h) gives the displayed equivalence for $\mathsf{gt_u}$. □

Theorem 54.19 (Concrete unary successor strict branch under two-sided context)**.** *For carried unary histories ℓ, h, r in $\mathsf{Carrier_u}$, set*

$$H := \mathsf{append}(\ell, \mathsf{append}(h, r)), \qquad K := \mathsf{append}(\ell, \mathsf{append}(\mathsf{E1}(h), r)).$$

Then H and K are carried by $\mathsf{Carrier_u}$*, and the contextual successor pair satisfies*

$$\mathsf{lt_u}(H, K).$$

Moreover,

$$\mathsf{same_u}(H, K) \to \mathsf{False} \qquad \textit{and} \qquad \mathsf{gt_u}(H, K) \to \mathsf{False}.$$

The per-object fields are: traditional target context-stable one-step successor separation; BEDC source BHist*,* $\mathsf{UnaryHistory}$*,* append*,* $\mathsf{E1}$*,* $\mathsf{lt_u}$*,* $\mathsf{same_u}$*, and* $\mathsf{gt_u}$*; carrier* $\mathsf{Carrier_u}$*; classifier* ρ_u*; ledger common two-sided context* (ℓ, r) *plus tail* $\mathsf{E1(e)}$*; core theorem this two-sided contextual successor strict-branch law; exactness the exclusion of same and reverse-strict branches; status* $\mathsf{ProofTarget}$*.*

Proof. Apply Definition 54.15 to the carried history h. This gives the carried successor $\mathsf{E1}(h)$, the base branch $\mathsf{lt_u}(h, \mathsf{E1}(h))$, and the two base exclusions $\mathsf{same_u}(h, \mathsf{E1}(h)) \to \mathsf{False}$ and $\mathsf{gt_u}(h, \mathsf{E1}(h)) \to \mathsf{False}$.

Instantiate Definition 54.18 with the carried quadruple $h, \mathsf{E1}(h), \ell, r$. Its carrier conclusion gives that the displayed H and K are carried unary histories.

Use the right-to-left direction of the strict-left branch equivalence from the same theorem. Transporting the base successor branch $\mathsf{lt_u}(h, \mathsf{E1}(h))$ through the common context (ℓ, r) gives $\mathsf{lt_u}(H, K)$.

For a same-branch witness at the contextual endpoints, use the left-to-right direction of the same-branch equivalence to obtain $\mathsf{same_u}(h, \mathsf{E1}(h))$. The base same-branch exclusion then returns False.

For a reverse strict-branch witness at the contextual endpoints, use the left-to-right direction of the strict-right branch equivalence to obtain $\mathsf{gt_u}(h, \mathsf{E1}(h))$. The base reverse-branch exclusion then returns False. □

Theorem 54.20 (Concrete unary prefix $\mathsf{TotalOrder}^\uparrow$ naming certificate)**.** *The tuple of Definition 54.7 supplies the source, pattern, classifier, stability, ledger, and exactness rows for a* $\mathsf{NameCert}$ *licensing* $\mathsf{TotalOrder}^\uparrow$ *over* $\mathsf{Carrier_u} = \mathsf{UnaryHistory}$*, classifier* ρ_u*, order* $\leq_\mathsf{u}$*, and comparison branches* $\mathsf{NatUnaryStrictPrefix}(h, k)$*,* $\rho_\mathsf{u}(h, k)$*, and* $\mathsf{NatUnaryStrictPrefix}(k, h)$*.*

Proof. The source and inherited order rows are the certified unary-prefix $\mathsf{POSet}^\uparrow$ package. Apply Definition 53.36; it supplies the BHist source, prefix pattern, classifier, stability, ledger, and exactness rows used by the total-order carrier.

The classifier and exactness rows are fixed by Definition 53.34: on carried unary histories, $\rho_\mathsf{u}(h, k)$ is equivalent to the two opposing prefix comparisons $h \leq_\mathsf{u} k$ and $k \leq_\mathsf{u} h$.

The stability row is the concrete total-order law package of Definition 54.8. It supplies the strict-to-apartness obligations, relation stability, constructive total comparison, comparison stability, and strict-comparison transitivity for the three displayed branches. The strict-comparison transitivity component is the concrete branch law of Definition 54.17, and comparison stability is the branch transport theorem of Definition 54.13.

The ledger row is the selected branch certificate. By Definition 54.9, each pair of carried unary histories chooses exactly one of the strict-left, same, and strict-right branches, and the same branch is the exact classifier branch.

Repack these rows as the public $\mathsf{NameCert}$: the source is $\mathsf{UnaryHistory}$, the pattern is the three-way unary-prefix comparison, the classifier is ρ_u, the stability data are the cited law fields, the ledger is the selected comparison branch, and exactness is the middle-branch equivalence. □

The per-object template is: traditional target concrete unary constructive total order; BEDC source unary BHist; carrier $\mathsf{Carrier_u} = \mathsf{UnaryHistory}$; classifier ρ_u; order $\leq_\mathsf{u}$; pattern strict-left, same, and strict-right unary-prefix comparison; stability obligations from Definition 54.20; ledger the selected comparison branch certificate; exactness same branch iff opposing prefix comparisons; status $\mathsf{ProofTarget}$.

The $\mathsf{TotalOrder}^\uparrow$ schema is represented by this concrete BHist carrier and explicit comparison data, giving later Lean formalization a BHist-anchored target rather than an abstract parameter schema.

Theorem 54.21 (Concrete unary prefix total order supplies arithmetic $\mathsf{Order}^\uparrow$)**.** *The tuple of Definition 54.7, read through the naming certificate of Definition 54.20, supplies the L7* $\mathsf{Order}^\uparrow$ *comparison interface on unary histories. The carrier is* $\mathsf{Carrier_u} = \mathsf{UnaryHistory}$*, the classifier is* ρ_u*, the preorder relation is* $\leq_\mathsf{u}$*, and the three comparison branches are* $\mathsf{NatUnaryStrictPrefix}(h, k)$*,* $\rho_\mathsf{u}(h, k)$*, and* $\mathsf{NatUnaryStrictPrefix}(k, h)$*.*

The reflexivity, transitivity, and antisymmetry rows are exactly the concrete prefix $\mathsf{POSet}^\uparrow$ *rows. The constructive total comparison row is the branch partition of Definition 54.8 and Definition 54.9. The classifier exactness row is the middle-branch equivalence of Definition 53.34: on carried unary histories,* $\rho_\mathsf{u}(h, k)$ *holds exactly when* $h \leq_\mathsf{u} k$ *and* $k \leq_\mathsf{u} h$*. Thus the stronger concrete* $\mathsf{TotalOrder}^\uparrow$ *naming certificate supplies the arithmetic* $\mathsf{Order}^\uparrow$ *consumer without introducing a second order relation.*

Proof. Start with the concrete prefix $\mathsf{POSet}^\uparrow$ certificate supplied by Definition 53.36. Its carrier is $\mathsf{UnaryHistory}$, its classifier is ρ_u, and its relation is the concrete prefix preorder $\leq_\mathsf{u}$. The reflexive, transitive, and antisymmetric order laws are therefore already available as the order rows consumed by $\mathsf{Order}^\uparrow$.

The comparison ledger is supplied by the total-order package. Apply Definition 54.8 for the total comparison law and Definition 54.9 for the exclusive strict-left, same, and strict-right branch partition. These are the three branches displayed in the statement.

The branch data are stable under the BEDC contexts used by the concrete certificate. Apply Definition 54.13 to transport the selected branch through common contexts, and apply Definition 54.18 when the consumer needs the two-sided contextual reading.

It remains to identify the same branch with the preorder classifier. On carried unary histories, Definition 53.34 says that $\rho_\mathsf{u}(h, k)$ is equivalent to the two opposing comparisons $h \leq_\mathsf{u} k$ and $k \leq_\mathsf{u} h$. This is exactly the classifier exactness row required by the $\mathsf{Order}^\uparrow$ consumer.

Finally, read these rows through Definition 54.20. The public consumer uses the existing $\mathsf{UnaryHistory}$ carrier, ρ_u classifier, and $\leq_\mathsf{u}$ preorder, together with the inherited strict-left and strict-right branch names. This is a reuse of the concrete prefix order already certified above; it is not a new primitive order and it does not assert classical trichotomy. □

Theorem 54.22 (Concrete unary prefix total-order finite minimum selector)**.** *Let* L *be a nonempty finite spine of histories in the finite-list helper of Definition 36.1. Assume every entry of* L *is carried by* $\mathsf{Carrier_u}$ *for the concrete* $\mathsf{TotalOrder}^\uparrow$ *certificate of Definition 54.20. Then there is an entry* $m \in L$ *such that, for every entry* $x \in L$*,*

$$m \leq_\mathsf{u} x.$$

The per-object fields are: traditional target finite-list minimum extraction in a total order; BEDC source finite spines of carried unary histories; carrier $\mathsf{Carrier_u}$*; classifier* ρ_u*; relation* $\leq_\mathsf{u}$*; stability obligations total comparison, reflexivity, and transitivity; ledger the tail-minimum witness*

and the selected comparison branch at each cons step; core theorem this finite minimum selector; exactness membership plus the displayed lower-bound row; standard bridge finite unary-word total order; status ProofTarget.

Proof. Induct on the nonempty finite spine L.

For the singleton spine $L = [a]$, choose $m = a$. The membership clause is immediate, and the only entry to check is a itself. Reflexivity from Definition 52.4 gives $a \leq_{\mathsf{u}} a$.

For the cons step, write $L = a :: T$ with T nonempty and all its entries carried by $\mathsf{Carrier}_{\mathsf{u}}$. By the induction hypothesis applied to T, choose $m_T \in T$ such that $m_T \leq_{\mathsf{u}} x$ for every $x \in T$. Apply Definition 54.9 to the carried pair a, m_T.

In the strict-left branch $\mathsf{NatUnaryStrictPrefix}(a, m_T)$, choose $m = a$. By Definition 28.10 and Definition 54.7, forgetting the nonempty-tail condition gives $a \leq_{\mathsf{u}} m_T$. For $x = a$, reflexivity gives $a \leq_{\mathsf{u}} a$. For $x \in T$, compose $a \leq_{\mathsf{u}} m_T$ with the induction-hypothesis comparison $m_T \leq_{\mathsf{u}} x$ using Definition 52.28. Thus the head a is a lower bound for every entry of L.

In the same branch $\rho_{\mathsf{u}}(a, m_T)$, choose $m = a$. The exact middle-branch row of Definition 54.9 gives $a \leq_{\mathsf{u}} m_T$ and $m_T \leq_{\mathsf{u}} a$. The entry a is below itself by reflexivity, and it is below every tail entry by transitivity through m_T, exactly as in the strict-left case.

In the strict-right branch $\mathsf{NatUnaryStrictPrefix}(m_T, a)$, choose $m = m_T$. Its membership in L follows from $m_T \in T$. Forgetting the nonempty-tail condition gives $m_T \leq_{\mathsf{u}} a$, which handles the head entry. Every tail entry is handled by the induction hypothesis. Hence the selected tail minimum is below every entry of L.

All comparison branches construct an entry of L satisfying the displayed lower-bound condition, so the finite minimum selector exists for every nonempty finite spine of carried concrete $\mathsf{TotalOrder}^{\uparrow}$ elements. □

Theorem 54.23 (Concrete unary prefix total-order finite maximum index selector)**.** *Let L be a nonempty finite spine of histories in the finite-list helper of Definition 36.1. Assume every entry of L is carried by $\mathsf{Carrier}_{\mathsf{u}}$ for the concrete $\mathsf{TotalOrder}^{\uparrow}$ certificate of Definition 54.20. Then there are a finite-spine membership witness i and a carried entry $M = L_i$ such that, for every entry $x \in L$,*

$$x \leq_{\mathsf{u}} M.$$

The per-object fields are: traditional target finite-list maximum extraction in a total order; BEDC source finite spines of carried unary histories; carrier $\mathsf{Carrier}_{\mathsf{u}}$; classifier ρ_{u}; relation $\leq_{\mathsf{u}}$; stability obligations total comparison, reflexivity, and transitivity; ledger the tail-maximum membership witness and the selected comparison branch at each cons step; core theorem this finite maximum selector; exactness the displayed membership witness plus upper-bound row; standard bridge finite unary-word total order; status ProofTarget.

Proof. Induct on the nonempty finite spine L.

For the singleton spine $L = [a]$, choose the unique membership position and set $M = a$. The only entry to check is a itself, and reflexivity from Definition 52.4 gives $a \leq_{\mathsf{u}} a$.

For the cons step, write $L = a :: T$ with T nonempty and all its entries carried by $\mathsf{Carrier}_{\mathsf{u}}$. By the induction hypothesis applied to T, choose a tail membership witness i_T and an entry $M_T \in T$ such that $x \leq_{\mathsf{u}} M_T$ for every $x \in T$. Apply Definition 54.9 to the carried pair a, M_T.

In the strict-left branch $\mathsf{NatUnaryStrictPrefix}(a, M_T)$, choose the same tail membership witness, viewed as a membership witness in $a :: T$, and set $M = M_T$. By Definition 28.10 and Definition 54.7, forgetting the nonempty-tail condition gives $a \leq_{\mathsf{u}} M_T$, which handles the head entry. Every tail entry is below M_T by the induction hypothesis.

In the same branch $\rho_{\mathsf{u}}(a, M_T)$, again choose the tail membership witness and set $M = M_T$. The exact middle-branch row of Definition 54.9 gives $a \leq_{\mathsf{u}} M_T$ and $M_T \leq_{\mathsf{u}} a$. The first comparison handles the head entry, and every tail entry is handled by the induction hypothesis.

In the strict-right branch $\mathsf{NatUnaryStrictPrefix}(M_T, a)$, choose the head membership witness and set $M = a$. Forgetting strictness gives $M_T \leq_{\mathsf{u}} a$. For the head entry, reflexivity gives $a \leq_{\mathsf{u}} a$. For a tail entry $x \in T$, the induction hypothesis gives $x \leq_{\mathsf{u}} M_T$; composing this with $M_T \leq_{\mathsf{u}} a$ by Definition 52.28 gives $x \leq_{\mathsf{u}} a$.

All comparison branches construct a located entry of L above every entry of L, so the finite maximum selector exists for every nonempty finite spine of carried concrete $\mathsf{TotalOrder}^{\uparrow}$ elements. □

Definition 54.24 (Concrete unary finite minimum witness)**.** *For a finite BEDC-history spine* $L : \mathsf{ListCarrier}(\mathsf{BHist})$*, a visible readback* m *is a concrete unary finite minimum witness when*

$$\mathsf{FiniteMinimumWitness}_{\mathsf{u}}(L, m) := m \in L \wedge \forall x.\ x \in L \to m \leq_{\mathsf{u}} x.$$

The carrier side condition is supplied by the finite-carrier list hypothesis used with the witness.

Theorem 54.25 (Concrete unary prefix finite minimum classifier uniqueness)**.** *Let* $L : \mathsf{ListCarrier}(\mathsf{BHist})$ *be a nonempty finite spine in the helper of Definition 36.1. Assume every entry of* L *is carried by* $\mathsf{Carrier}_{\mathsf{u}}$ *for the concrete* $\mathsf{TotalOrder}^{\uparrow}$ *certificate of Definition 54.20:*

$$\forall x.\ x \in L \to \mathsf{Carrier}_{\mathsf{u}}(x).$$

If m *and* n *satisfy* $\mathsf{FiniteMinimumWitness}_{\mathsf{u}}(L, m)$ *and* $\mathsf{FiniteMinimumWitness}_{\mathsf{u}}(L, n)$*, then*

$$\rho_{\mathsf{u}}(m, n).$$

The per-object fields are: traditional target finite-list minimum witness uniqueness in a total order; BEDC source finite spines of carried unary histories; carrier $\mathsf{Carrier}_{\mathsf{u}}$*; classifier* ρ_{u}*; relation* $\leq_{\mathsf{u}}$*; stability obligations finite-list lower-bound readout and inherited* $\mathsf{POSet}^{\uparrow}$ *antisymmetry; ledger the two minimum witness records and the two extracted comparisons; core theorem this block; exactness classifier equality of competing minimum readbacks; standard bridge finite unary-word minimum uniqueness; status* $\mathsf{ProofTarget}$*.*

Proof. Unpack the two finite minimum witness records of Definition 54.24. The first supplies $m \in L$ and the lower-bound row $\forall x.\ x \in L \to m \leq_{\mathsf{u}} x$; the second supplies $n \in L$ and the lower-bound row $\forall x.\ x \in L \to n \leq_{\mathsf{u}} x$.

From the entry-carrier hypothesis, the membership rows give carrier witnesses for m and n. Instantiate the first lower-bound row at the entry n; this gives $m \leq_{\mathsf{u}} n$. Instantiate the second lower-bound row at the entry m; this gives $n \leq_{\mathsf{u}} m$.

By Definition 54.7, these comparisons are the concrete prefix relation of the unary total-order package. The exact middle-branch row of Definition 54.9, equivalently the $\mathsf{POSet}^{\uparrow}$ classifier exactness of Definition 53.34 in this notation, sends the carried opposing comparisons to $\rho_{\mathsf{u}}(m, n)$.

The strict-left and strict-right branches of the total comparison ledger are therefore excluded by the incompatibility clauses of Definition 54.9. Together with the existence selector of Definition 54.22, this gives a classifier-stable finite minimum readback for every nonempty finite carried spine. □

Definition 54.26 (Concrete unary finite maximum witness)**.** *For a finite BEDC-history spine* $L : \mathsf{ListCarrier}(\mathsf{BHist})$*, a visible readback* M *is a concrete unary finite maximum witness when*

$$\mathsf{FiniteMaximumWitness}_{\mathsf{u}}(L, M) := M \in L \wedge \forall x.\ x \in L \to x \leq_{\mathsf{u}} M.$$

The carrier side condition is supplied by the finite-carrier list hypothesis used with the witness.

Theorem 54.27 (Concrete unary prefix finite maximum classifier uniqueness)**.** *Let* $L : \mathsf{ListCarrier}(\mathsf{BHist})$ *be a nonempty finite spine in the helper of Definition 36.1. Assume every entry of* L *is carried by* $\mathsf{Carrier}_{\mathsf{u}}$ *for the concrete* $\mathsf{TotalOrder}^{\uparrow}$ *certificate of Definition 54.20:*

$$\forall x.\ x \in L \to \mathsf{Carrier}_{\mathsf{u}}(x).$$

If M *and* N *satisfy* $\mathsf{FiniteMaximumWitness}_{\mathsf{u}}(L, M)$ *and* $\mathsf{FiniteMaximumWitness}_{\mathsf{u}}(L, N)$*, then*

$$\rho_{\mathsf{u}}(M, N).$$

The per-object fields are: traditional target finite-list maximum witness uniqueness in a total order; BEDC source finite spines of carried unary histories; carrier $\mathsf{Carrier}_{\mathsf{u}}$*; classifier* ρ_{u}*; relation* $\leq_{\mathsf{u}}$*; stability obligations finite-list upper-bound readout and inherited* $\mathsf{POSet}^{\uparrow}$ *antisymmetry; ledger the two maximum witness records and the two extracted comparisons; core theorem this block; exactness classifier equality of competing maximum readbacks; standard bridge finite unary-word maximum uniqueness; status* $\mathsf{ProofTarget}$*.*

Proof. Unpack the two finite maximum witness records of Definition 54.26. The first supplies $M \in L$ and the upper-bound row $\forall x.\ x \in L \to x \leq_{\mathsf{u}} M$; the second supplies $N \in L$ and the upper-bound row $\forall x.\ x \in L \to x \leq_{\mathsf{u}} N$.

From the entry-carrier hypothesis, the membership rows give carrier witnesses for M and N. Instantiate the first upper-bound row at the entry N; this gives $N \leq_{\mathsf{u}} M$. Instantiate the second upper-bound row at the entry M; this gives $M \leq_{\mathsf{u}} N$.

By Definition 54.7, these comparisons are the concrete prefix relation of the unary total-order package. The exact middle-branch row of Definition 54.9, equivalently the $\mathsf{POSet}^{\uparrow}$ classifier exactness of Definition 53.34 in this notation, sends the carried opposing comparisons to $\rho_{\mathsf{u}}(M, N)$.

The strict-left and strict-right branches of the total comparison ledger are therefore excluded by the incompatibility clauses of Definition 54.9. Together with the existence selector of Definition 54.23, this gives a classifier-stable finite maximum readback for every nonempty finite carried spine. □

Theorem 54.28 (Concrete unary prefix finite extrema certificate)**.** *Let* $L : \mathsf{ListCarrier}(\mathsf{BHist})$ *be a nonempty finite BEDC-history spine in the helper of Definition 36.1. Assume every entry of* L *is carried by* $\mathsf{Carrier}_{\mathsf{u}}$ *for the concrete* $\mathsf{TotalOrder}^{\uparrow}$ *certificate of Definition 54.20:*

$$\forall x.\ x \in L \to \mathsf{Carrier}_{\mathsf{u}}(x).$$

Then there are histories m *and* M *such that*

$$\mathsf{FiniteMinimumWitness}_{\mathsf{u}}(L, m) \wedge \mathsf{FiniteMaximumWitness}_{\mathsf{u}}(L, M)$$

and the selected readbacks are classifier-stable: every other minimum witness m' *satisfying* $\mathsf{FiniteMinimumWitness}_{\mathsf{u}}($ *obeys* $\rho_{\mathsf{u}}(m, m')$*, and every other maximum witness* M' *satisfying* $\mathsf{FiniteMaximumWitness}_{\mathsf{u}}(L, M')$ *obeys* $\rho_{\mathsf{u}}(M, M')$*.*

The per-object fields are: traditional target finite extrema in a constructive total order; BEDC source finite ListCarrier *spines and unary* $\mathsf{TotalOrder}^{\uparrow}$*; carrier* $\mathsf{Carrier_u}$*; classifier* ρ_{u}*; stability selector existence plus classifier uniqueness; ledger the selected minimum and maximum witnesses; core theorem this finite extrema certificate; exactness classifier uniqueness of extrema; standard bridge finite unary-word extrema; status* ProofTarget*.*

Proof. Apply Definition 54.22 to the nonempty carried spine L. This gives an entry $m \in L$ whose lower-bound row is exactly $\mathsf{FiniteMinimumWitness_u}(L, m)$ after repacking through Definition 54.24.

Apply Definition 54.23 to the same carried spine. Its membership index and selected entry give a history $M \in L$ whose upper-bound row is exactly $\mathsf{FiniteMaximumWitness_u}(L, M)$ after repacking through Definition 54.26.

For any competing minimum witness m', apply Definition 54.25 to the two minimum witness records for m and m'. The result is the displayed classifier agreement $\rho_{\mathsf{u}}(m, m')$.

For any competing maximum witness M', apply Definition 54.27 to the two maximum witness records for M and M'. This gives $\rho_{\mathsf{u}}(M, M')$, completing the paired finite-extrema certificate. □

Theorem 54.29 (Concrete unary total-order finite selector RealUp consumer boundary)**.** *The unary finite minimum/maximum selector package of Definition 54.28 can be consumed by later* $\mathsf{Real}^{\uparrow}$ *finite-window comparison rows only as certified selector data and classifier-uniqueness data over* BHist*,* UnaryHistory*,* hsame*, and* Cont*. It identifies finite extrema in carried unary spines and transports the selected readbacks through* ρ_{u}*; it does not provide* $\mathsf{Real}^{\uparrow}$ *trichotomy, open-cover compactness, or quotient order.*

Proof. Project the selected minimum and maximum witnesses from Definition 54.28. Their existence comes from the finite carried spine and the unary total-order comparison rows.

Project classifier uniqueness through Definition 54.25 and Definition 54.27. These rows are the only comparison facts exported to a $\mathsf{Real}^{\uparrow}$ finite-window consumer.

Since the certificate is built over BHist and unary continuation transport, no RealUp quotient carrier, open-cover compactness principle, or constructive trichotomy is introduced. □

54.4 Concrete Singleton History Instance

Definition 54.30 (Total-order singleton history instance)**.** *Let* A_{e} *be the singleton history source of Definition 36.169 at* $a_0 = \mathsf{e}$*. Use the singleton classifier already exposed by the surrounding concrete algebra instances:*

$$\rho_{\mathsf{e}}(h, k) := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h, k).$$

Define the concrete singleton order relation by

$$h \leq_{\perp} k := A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

The $h \leq_{\perp} k$ *witness records only that both endpoints lie in the displayed BEDC history singleton; it introduces no abstract carrier, no host order, and no second endpoint classifier.*

Theorem 54.31 (Total-order singleton history laws)**.** *For the concrete package* $(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \leq_{\perp})$ *of Definition 54.30, the relation* $\leq_{\perp}$ *is reflexive on carried histories, transitive on carried histories, antisymmetric under* ρ_{e}*, and total on carried histories:*

$$\forall h.\ A_{\mathsf{e}}(h) \to h \leq_{\perp} h,$$

$$\forall h\, k\, r.\ (h \leq_\perp k) \to (k \leq_\perp r) \to h \leq_\perp r,$$
$$\forall h\, k.\ (h \leq_\perp k) \to (k \leq_\perp h) \to \rho_{\mathsf{e}}(h, k),$$

and

$$\forall h\, k.\ A_{\mathsf{e}}(h) \to A_{\mathsf{e}}(k) \to (h \leq_\perp k) \vee (k \leq_\perp h).$$

Thus the order laws are pinned to the concrete BHist *singleton carrier rather than to a parameterized order surface.*

Proof. Reflexivity unfolds $h \leq_\perp h$ and repeats the displayed carrier witness $A_{\mathsf{e}}(h)$ in both endpoint slots.

For transitivity, unfold the first comparison $h \leq_\perp k$ to read the carrier witness for h, and unfold the second comparison $k \leq_\perp r$ to read the carrier witness for r. Pairing these two facts gives $h \leq_\perp r$.

For antisymmetry, unfold the two comparisons to obtain $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$. Since A_{e} is the singleton source at e, these facts identify h with e and k with e. Symmetry and transitivity of hsame compose the two endpoint witnesses into $\mathsf{hsame}(h, k)$, and the two carrier facts repackage the result as $\rho_{\mathsf{e}}(h, k)$.

For totality, the assumptions already give the two endpoint carrier witnesses. Choose the displayed left comparison $h \leq_\perp k$ and pack those witnesses into the definition of $\leq_\perp$. □

Theorem 54.32 (TotalOrderUp singleton schema instantiation)**.** *The concrete data*

$$(A_{\mathsf{e}}, \rho_{\mathsf{e}}, \leq_\perp)$$

instantiate the $\mathsf{TotalOrder}^\uparrow$ *schema over the fixed BEDC history carrier* BHist*: the carrier is the singleton predicate A_{e}, the classifier is the singleton endpoint classifier ρ_{e}, the relation is the concrete endpoint-carrier relation $\leq_\perp$, and the law rows are the reflexivity, transitivity, antisymmetry, and totality clauses of Definition 54.31.*

Consequently, the $\mathsf{TotalOrder}^\uparrow$ *proof target has a falsifiable* BHist*-anchored carrier and relation instance. Machine checking can target the displayed singleton package directly, rather than discharging only abstract parameter fields.*

Proof. Read the carrier, classifier, and relation rows from Definition 54.30. They are concrete predicates and relations on BHist, with the carrier pinned to the singleton endpoint e.

Apply Definition 54.31 to obtain the preorder rows, the classifier antisymmetry row, and the total comparison row. These are exactly the order-law fields required by the $\mathsf{TotalOrder}^\uparrow$ schema after the schema variables are specialized to A_{e}, ρ_{e}, and $\leq_\perp$.

The resulting package is therefore not a restatement over fresh carriers or classifiers. Its witnesses are carried by the fixed singleton history source, and every comparison witness is a concrete assertion about the two displayed BHist endpoints. □

Theorem 54.33 (TotalOrder singleton order-tower certificate)**.** *For the singleton history source A_{e} at e and classifier ρ_{e}, the endpoint-carrier relation $\leq_\perp$ of Definition 54.30 and the prefix relation of Definition 54.2 agree on carried endpoints:*

$$A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \to (h \leq_\perp k \iff \mathsf{PreorderPrefixLE}(h, k)).$$

On the same carried endpoints, the classifier is exact for the opposing singleton $\mathsf{POSet}^\uparrow$ *comparisons and for the same branch of the singleton* $\mathsf{TotalOrder}^\uparrow$ *comparison:*

$$\rho_{\mathsf{e}}(h, k) \iff (h \leq_{\mathsf{e}} k \wedge k \leq_{\mathsf{e}} h),$$

and

$$\rho_{\mathsf{e}}(h,k) \iff \mathsf{same}_{\mathsf{e}}(h,k).$$

Thus the endpoint-carrier order, the singleton prefix order, the singleton partial-order exactness row, and the total-order same branch form one BHist *order tower over the same carrier and classifier.*

Proof. Assume $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$. Unfolding $h \leq_{\perp} k$ gives exactly the two displayed carrier witnesses, so the forward endpoint-carrier side is immediate. Conversely, the same two carrier witnesses already reconstitute $h \leq_{\perp} k$.

The singleton carrier witnesses identify both endpoints with e: they give $\mathsf{hsame}(h,\mathsf{e})$ and $\mathsf{hsame}(k,\mathsf{e})$. Symmetry and transitivity of hsame therefore give $\mathsf{hsame}(h,k)$, and applying PreorderPrefixLE_of_hsa yields $\mathsf{PreorderPrefixLE}(h,k)$. This proves the prefix direction needed to compare the two displayed relations on carried endpoints.

For the partial-order row, apply Definition 53.12. Its exactness clause identifies $\rho_{\mathsf{e}}(h,k)$ with the two opposing singleton prefix comparisons $h \leq_{\mathsf{e}} k$ and $k \leq_{\mathsf{e}} h$.

For the total-order row, unfold the comparison branches of Definition 54.2: the same branch is ρ_{e}, while the strict branches are empty. The law package Definition 54.3 supplies the carried same-branch witness, and Definition 54.83 repackages that witness as the $\mathsf{TotalOrder}^{\uparrow}$ naming certificate. Hence both concrete presentations sit in the same singleton BHist order tower. □

Theorem 54.34 (TotalOrder singleton strict branch exclusion)**.** *On carried endpoints of A_{e}, a singleton* $\mathsf{TotalOrder}^{\uparrow}$ *comparison row for h,k cannot select a strict-left or strict-right branch. More precisely, if $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$, then every comparison row in Definition 54.2 factors through the same classifier branch*

$$\rho_{\mathsf{e}}(h,k)$$

and through the endpoint-carrier relation $h \leq_{\perp} k$.

Proof. Unfold Definition 54.2. The carrier witnesses $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$ identify both endpoints with e, so the endpoint-carrier relation $h \leq_{\perp} k$ is the same pair of singleton carrier facts read in the order tower certificate.

Apply Definition 53.12. Its opposing guarded prefix exactness clauses identify the two singleton $\mathsf{POSet}^{\uparrow}$ comparisons with the same endpoint carrier witnesses and hence with the same classifier row $\rho_{\mathsf{e}}(h,k)$.

Now apply Definition 54.3. In the singleton history total-order package the strict-left and strict-right branches have no carried row once both endpoints have been identified with e. The only remaining comparison branch is the same branch, and its row is exactly $\rho_{\mathsf{e}}(h,k)$. □

Theorem 54.35 (TotalOrder singleton comparison determinacy)**.** *On carried endpoints of A_{e}, any two singleton total-order comparison witnesses collapse to the same ρ_{e} branch. In symbols, if $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$ and two witnesses choose comparison rows for h and k in the singleton* $\mathsf{TotalOrder}^{\uparrow}$ *instance, then both witnesses identify h and k with* e*, unfold $\leq_{\perp}$ to the same carried endpoint facts, and select the same classifier row $\rho_{\mathsf{e}}(h,k)$.*

Proof. Unfold $\leq_{\perp}$ on the carried endpoints. The hypotheses $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$ already provide the two carrier facts required by either comparison witness.

Apply Definition 54.31 to read the singleton total-order comparison law. Apply Definition 53.12 to identify the opposing singleton partial-order comparisons with the same classifier row.

Finally use Definition 54.3. In the singleton history instance the strict branches are empty, so every total comparison on carried endpoints is the displayed same branch. Hence the two witnesses determine the same ρ_{e} row. □

Theorem 54.36 (TotalOrder singleton classifier coverage)**.** *Every carried endpoint pair in A_{e} admits the classifier row induced by opposing singleton comparisons. More precisely, if $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$, then the carrier facts unfold $\leq_{\perp}$ in both directions, the singleton $\mathsf{POSet}^{\uparrow}$ comparisons $h \leq_{\mathsf{e}} k$ and $k \leq_{\mathsf{e}} h$ are available, and their exactness row induces $\rho_{\mathsf{e}}(h, k)$ for the singleton $\mathsf{TotalOrder}^{\uparrow}$ classifier surface.*

Proof. Assume $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$. Unfolding $\leq_{\perp}$ gives the endpoint-carrier comparison rows in both directions, because the singleton relation is built from those two carrier witnesses.

The carrier facts identify both endpoints with e. Apply Definition 53.12 to obtain the opposing singleton partial-order comparisons and their exactness row for ρ_{e}.

Apply Definition 54.31 and Definition 54.3 to place that same row inside the singleton total-order classifier. Thus every carried pair is covered by the classifier induced by the opposing singleton comparisons. □

54.5 OrderUp Interval Collapse

Theorem 54.37 (Unary prefix OrderUp bounded interval collapse)**.** *Let $L : \mathsf{ListCarrier}(\mathsf{BHist})$ be a nonempty finite BEDC-history spine in the helper of Definition 36.1. Assume every entry of L is carried by $\mathsf{Carrier}_{\mathsf{u}}$ for the concrete $\mathsf{TotalOrder}^{\uparrow}$ certificate of Definition 54.20:*

$$\forall x.\ x \in L \to \mathsf{Carrier}_{\mathsf{u}}(x).$$

Let m and M be the finite extrema supplied by Definition 54.28. Then every entry of the finite spine lies in the displayed unary interval:

$$\forall x.\ x \in L \to (m \leq_{\mathsf{u}} x \wedge x \leq_{\mathsf{u}} M).$$

Moreover, if endpoints m' and M' satisfy the same finite-bound rows, namely

$$\mathsf{FiniteMinimumWitness}_{\mathsf{u}}(L, m') \wedge \mathsf{FiniteMaximumWitness}_{\mathsf{u}}(L, M'),$$

then the endpoints are classified with the selected extrema:

$$\rho_{\mathsf{u}}(m, m') \wedge \rho_{\mathsf{u}}(M, M').$$

The per-object fields are: traditional target finite bounded interval in unary arithmetic order; BEDC source $\mathsf{UnaryHistory}$, $\leq_{\mathsf{u}}$, ρ_{u}, and finite $\mathsf{ListCarrier}$; carrier $\mathsf{Carrier}_{\mathsf{u}}$; classifier ρ_{u}; stability from TotalOrder-to-OrderUp and finite extrema uniqueness; ledger finite spine membership plus selected extrema; core theorem this block; exactness classifier uniqueness of interval endpoints; standard bridge finite unary-word bounded intervals; status $\mathsf{ProofTarget}$.

Proof. Use Definition 54.21 to read the concrete unary $\mathsf{TotalOrder}^{\uparrow}$ rows as the L7 arithmetic $\mathsf{Order}^{\uparrow}$ surface. The comparison relation exposed to the consumer is still $\leq_{\mathsf{u}}$, and the classifier exposed on endpoints is still ρ_{u}.

Invoke Definition 54.28 on the nonempty carried spine L. This produces selected histories m and M together with $\mathsf{FiniteMinimumWitness}_{\mathsf{u}}(L, m)$ and $\mathsf{FiniteMaximumWitness}_{\mathsf{u}}(L, M)$, plus classifier uniqueness for competing minimum and maximum witness records.

Project the selected minimum witness through Definition 54.24. Its lower-bound row states $\forall x.\ x \in L \to m \leq_{\mathsf{u}} x$. Project the selected maximum witness through Definition 54.26. Its upper-bound row states $\forall x.\ x \in L \to x \leq_{\mathsf{u}} M$.

For each membership witness $x \in L$, pair these two projected comparisons to obtain $m \leq_{\mathsf{u}} x$ and $x \leq_{\mathsf{u}} M$. Hence the finite spine collapses into the bounded unary interval selected by the two extrema.

If m' and M' satisfy the same finite-bound witness rows, apply the uniqueness clauses returned by Definition 54.28. The minimum row classifies m' with m by $\rho_{\mathsf{u}}(m, m')$, and the maximum row classifies M' with M by $\rho_{\mathsf{u}}(M, M')$. □

Theorem 54.38 (Unary prefix OrderUp interval endpoint transport)**.** *Let L and L' be nonempty finite* BHist *spines carried by* $\mathsf{Carrier}_{\mathsf{u}}$*. Suppose their entries are paired by ρ_{u}: every displayed membership row $x \in L$ has a displayed membership row $x' \in L'$ with $\rho_{\mathsf{u}}(x, x')$, and conversely. Let (m, M) and (m', M') be the selected finite extrema supplied by Definition 54.28 for L and L'. Then the selected endpoints transport through the classifier,*

$$\rho_{\mathsf{u}}(m, m') \wedge \rho_{\mathsf{u}}(M, M'),$$

and the bounded-interval membership row of Definition 54.37 is preserved under the paired spine.

Proof. First read both carried finite spines through Definition 54.21. The consumer relation is $\leq_{\mathsf{u}}$, and the consumer classifier is ρ_{u} on the same displayed histories.

Apply Definition 54.28 to L and to L'. This supplies minimum and maximum witness rows for m, M and for m', M', together with classifier uniqueness for competing selected extrema.

Use the entrywise ρ_{u} pairing to transport lower-bound and upper-bound comparisons from the witness rows for L to the corresponding rows on L'. The transported lower-bound packet makes m' a classified minimum witness for the image of m, and the transported upper-bound packet makes M' a classified maximum witness for the image of M.

The uniqueness clauses from the finite extrema certificate then classify the selected endpoints, giving $\rho_{\mathsf{u}}(m, m')$ and $\rho_{\mathsf{u}}(M, M')$.

Finally invoke Definition 54.37 on the transported membership rows. Each paired entry stays between the transported endpoints, so the bounded-interval membership row is preserved through ρ_{u}. □

Theorem 54.39 (Unary prefix OrderUp interval witness coverage)**.** *Let $L : \mathsf{ListCarrier}(\mathsf{BHist})$ be a nonempty finite carried spine and let m, M be the selected extrema supplied by Definition 54.28. For every entry $x \in L$, every displayed lower-row and upper-row pair*

$$\ell \leq_{\mathsf{u}} x \qquad \textit{and} \qquad x \leq_{\mathsf{u}} u$$

that presents x as lying in a unary prefix OrderUp interval factors through the minimum and maximum witness records for m and M. Any competing displayed interval endpoints ℓ and u satisfying the finite-bound witness rows are classified by ρ_{u} with the selected endpoints:

$$\rho_{\mathsf{u}}(m, \ell) \wedge \rho_{\mathsf{u}}(M, u).$$

Proof. Apply Definition 54.28 to the nonempty carried spine L. It provides the minimum witness record for m, the maximum witness record for M, and classifier uniqueness for any competing minimum or maximum witness records.

Use Definition 54.37. For each membership row $x \in L$, the selected minimum witness supplies $m \leq_{\mathsf{u}} x$ and the selected maximum witness supplies $x \leq_{\mathsf{u}} M$, so the displayed interval row for x factors through the selected extrema.

If the displayed endpoints ℓ and u are carried as competing finite-bound witness rows, invoke the uniqueness clauses from the finite extrema certificate. They classify ℓ with m and u with M by ρ_{u}.

Finally apply Definition 54.38. The endpoint classifications transport the lower and upper interval rows across the displayed ρ_{u} pairing, so every interval witness row is accounted for by the finite-extrema rows. □

54.6 Finite Extrema Interval Uniqueness

Definition 54.40 (Concrete unary finite extrema interval witness)**.** *For a finite BEDC-history spine $L : \mathsf{ListCarrier}(\mathsf{BHist})$, a pair (m, M) is a concrete unary finite extrema interval witness when*

$$\mathsf{FiniteExtremaIntervalWitness}_{\mathsf{u}}(L, m, M) := \mathsf{FiniteMinimumWitness}_{\mathsf{u}}(L, m) \wedge \mathsf{FiniteMaximumWitness}_{\mathsf{u}}(L, M).$$

The carrier side condition is the same finite-carrier list hypothesis used by the minimum and maximum witness predicates.

Theorem 54.41 (Concrete unary prefix finite extrema interval uniqueness)**.** *Let $L : \mathsf{ListCarrier}(\mathsf{BHist})$ be a nonempty finite BEDC-history spine in the helper of Definition 36.1. Assume every entry of L is carried by $\mathsf{Carrier}_{\mathsf{u}}$ for the concrete $\mathsf{TotalOrder}^{\uparrow}$ certificate of Definition 54.20:*

$$\forall x.\ x \in L \to \mathsf{Carrier}_{\mathsf{u}}(x).$$

If (m, M) and (m', M') satisfy $\mathsf{FiniteExtremaIntervalWitness}_{\mathsf{u}}(L, m, M)$ and $\mathsf{FiniteExtremaIntervalWitness}_{\mathsf{u}}(L, m', M'$ then

$$\rho_{\mathsf{u}}(m, m') \wedge \rho_{\mathsf{u}}(M, M').$$

The per-object fields are: traditional target finite closed interval endpoint uniqueness in a constructive total order; BEDC source finite $\mathsf{ListCarrier}$ spines and unary $\mathsf{TotalOrder}^{\uparrow}$; carrier $\mathsf{Carrier}_{\mathsf{u}}$; classifier ρ_{u}; relation $\leq_{\mathsf{u}}$; stability obligations finite minimum and maximum classifier uniqueness; ledger the two interval witness records and their four endpoint witness projections; core theorem this interval uniqueness block; exactness paired classifier equality of lower and upper endpoint readbacks; standard bridge finite unary-word interval endpoint uniqueness; status $\mathsf{ProofTarget}$.

Proof. Unpack the two interval witness records using Definition 54.40. The first record supplies a minimum witness for m and a maximum witness for M over L; the second supplies a minimum witness for m' and a maximum witness for M' over the same finite spine.

Apply Definition 54.25 to the two minimum witness rows for m and m', together with the nonempty and carrier hypotheses on L. This gives the lower-endpoint classifier agreement $\rho_{\mathsf{u}}(m, m')$.

Apply Definition 54.27 to the two maximum witness rows for M and M', again over the same carried finite spine. This gives the upper-endpoint classifier agreement $\rho_{\mathsf{u}}(M, M')$.

Pair the two classifier conclusions. The resulting statement is a concrete two-endpoint interval readback: changing the selected witnesses may change the visible histories, but only within ρ_{u} at the lower endpoint and within ρ_{u} at the upper endpoint. □

Theorem 54.42 (Concrete unary prefix finite extrema interval endpoint exactness)**.** *Let $L : \mathsf{ListCarrier}(\mathsf{BHist})$ be a nonempty finite BEDC-history spine in the helper of Definition 36.1, and*

assume every entry of L is carried by $\mathsf{Carrier_u}$ *for the concrete* $\mathsf{TotalOrder}^{\uparrow}$ *certificate. If* (m, M) *and* (m', M') *are interval witnesses over the same spine,*

$$\mathsf{FiniteExtremaIntervalWitness_u}(L, m, M) \quad \textit{and} \quad \mathsf{FiniteExtremaIntervalWitness_u}(L, m', M'),$$

then their lower and upper endpoints agree exactly at the classifier boundary:

$$\rho_{\mathsf{u}}(m, m') \wedge \rho_{\mathsf{u}}(M, M').$$

Conversely, if $\mathsf{FiniteExtremaIntervalWitness_u}(L, m, M)$ *and the endpoint classifiers satisfy*

$$\rho_{\mathsf{u}}(m, m') \wedge \rho_{\mathsf{u}}(M, M'),$$

then TotalOrder classifier transport carries the selected interval witness to an equivalent interval witness over the same finite spine with endpoints (m', M')*.*

Proof. For the forward direction, apply Definition 54.41 to the two interval witnesses over the same nonempty carried spine. The theorem already splits the interval witness definition into finite minimum and maximum rows and uses their uniqueness, so it returns exactly the paired classifier conclusions for the lower and upper endpoints.

For the converse direction, unpack Definition 54.40 for the selected pair (m, M). The lower row is a finite minimum witness for m, and the upper row is a finite maximum witness for M.

Transport the lower witness along $\rho_{\mathsf{u}}(m, m')$ by the TotalOrder classifier-transport clause for finite minima. Transport the upper witness along $\rho_{\mathsf{u}}(M, M')$ by the corresponding finite maximum transport clause.

Repack the transported minimum and maximum rows through the interval witness definition. The finite spine L and its carrier hypotheses have not changed, so the transported endpoints form an equivalent interval witness over the same spine. □

Theorem 54.43 (Concrete unary prefix finite extrema interval roundtrip stability)**.** *Let* L : $\mathsf{ListCarrier}(\mathsf{BHist})$ *be a nonempty finite BEDC-history spine, and assume every entry of* L *is carried by* $\mathsf{Carrier_u}$ *for the concrete* $\mathsf{TotalOrder}^{\uparrow}$ *certificate. If* (m, M) *is an interval witness over* L *and the endpoint classifier rows*

$$\rho_{\mathsf{u}}(m, m') \wedge \rho_{\mathsf{u}}(M, M')$$

hold, then transport of the witness to (m', M') *and comparison back against the original witness recover the same lower and upper endpoint classifier rows:*

$$\rho_{\mathsf{u}}(m, m') \wedge \rho_{\mathsf{u}}(M, M').$$

Proof. Use the converse direction of Definition 54.42 on the selected witness (m, M) and the two endpoint classifier rows. This transports the finite minimum and maximum parts of the interval witness to an equivalent interval witness over the same spine with endpoints (m', M').

Now compare the original witness and the transported witness. Apply Definition 54.41 to the two interval witnesses over the same nonempty carried finite spine. Its lower endpoint conclusion is $\rho_{\mathsf{u}}(m, m')$, and its upper endpoint conclusion is $\rho_{\mathsf{u}}(M, M')$.

These are exactly the classifier rows used for the transport, so the there-and-back comparison is stable at both interval endpoints. □

Theorem 54.44 (Concrete unary prefix finite extrema interval certificate)**.** *Let* $L : \mathsf{ListCarrier}(\mathsf{BHist})$ *be a nonempty finite BEDC-history spine in the helper of Definition 36.1. Assume every entry of* L *is carried by* $\mathsf{Carrier_u}$ *for the concrete* $\mathsf{TotalOrder}^{\uparrow}$ *certificate of Definition 54.20:*

$$\forall x.\ x \in L \to \mathsf{Carrier_u}(x).$$

Then there exist histories m, M *such that*

$$\mathsf{FiniteExtremaIntervalWitness_u}(L, m, M)$$

holds and every other interval witness (m', M') *over the same spine satisfies*

$$\mathsf{FiniteExtremaIntervalWitness_u}(L, m', M') \to (\rho_{\mathsf{u}}(m, m') \wedge \rho_{\mathsf{u}}(M, M')).$$

The per-object fields are: traditional target finite closed interval extraction in a constructive total order; BEDC source finite $\mathsf{ListCarrier}$ *spines plus unary* $\mathsf{TotalOrder}^{\uparrow}$*; carrier* $\mathsf{Carrier_u}$*; classifier* ρ_{u}*; relation* $\leq_{\mathsf{u}}$*; stability finite extrema existence plus interval endpoint uniqueness; ledger selected lower and upper witnesses; core theorem this block; exactness classifier-stable interval endpoints; standard bridge finite unary-word closed interval; status* $\mathsf{ProofTarget}$*.*

Proof. Invoke Definition 54.28 on the nonempty carried finite spine L. It supplies selected histories m and M together with the minimum witness row for m, the maximum witness row for M, and the classifier-stability clauses attached to those selected rows.

Repack the selected lower and upper witness rows through Definition 54.40. This gives FiniteExtremaIntervalWitn for the selected pair.

Now let (m', M') be any other pair satisfying $\mathsf{FiniteExtremaIntervalWitness_u}(L, m', M')$. Apply Definition 54.41 to the selected interval witness and the competing interval witness over the same L.

The uniqueness theorem returns $\rho_{\mathsf{u}}(m, m') \wedge \rho_{\mathsf{u}}(M, M')$. Thus the selected finite interval exists and its lower and upper endpoints are classifier-stable against every other interval witness for the same carried finite spine. □

54.7 OrderUp Phase Exit

Theorem 54.45 (Unary prefix OrderUp phase exit package)**.** *The concrete L7* $\mathsf{Order}^{\uparrow}$ *package over* BHist *is the unary-prefix package with carrier* $\mathsf{UnaryHistory}$*, classifier* ρ_{u}*, and order relation* $\leq_{\mathsf{u}}$*. Its preorder, antisymmetry, and constructive comparison rows are inherited from the concrete* $\mathsf{TotalOrder}^{\uparrow}$ *surface exposed in Definition 54.21. Its finite bounded-interval coverage is the interval-collapse statement of Definition 54.37. Its endpoint classifier uniqueness is the two-endpoint readback of Definition 54.41.*

Consequently, the scoped Full Nat Arithmetic $\mathsf{Order}^{\uparrow}$ *phase object can be consumed as a single package consisting of the carrier* $\mathsf{UnaryHistory}$*, classifier* ρ_{u}*, relation* $\leq_{\mathsf{u}}$*, inherited preorder and antisymmetry rows, constructive comparison rows, finite bounded-interval coverage for carried finite spines, and classifier uniqueness of selected interval endpoints. This package introduces no second order relation and asserts no classical trichotomy.*

Proof. First expose the $\mathsf{Order}^{\uparrow}$ surface. Apply Definition 54.21. The consumer sees the same concrete $\mathsf{UnaryHistory}$ carrier, the same classifier ρ_{u}, and the same relation $\leq_{\mathsf{u}}$ that were used by the unary $\mathsf{TotalOrder}^{\uparrow}$ certificate.

The order-law rows are therefore projections of the existing certificate. The reflexivity, transitivity, and antisymmetry rows come from the prefix $\mathsf{POSet}^{\uparrow}$ part of the $\mathsf{TotalOrder}^{\uparrow}$ package, while the comparison row is the constructive strict-left, same, or strict-right branch partition recorded there.

Next project the finite bounds. For a nonempty finite carried spine, apply Definition 54.37. It supplies selected endpoints m and M such that every member of the spine lies between m and M under $\leq_{\mathsf{u}}$.

Finally project endpoint uniqueness. Apply Definition 54.41 to any two finite extrema interval witness records over the same carried spine. The lower endpoints are classified by ρ_{u}, and the upper endpoints are classified by ρ_{u}.

These projected rows are exactly the phase-exit data needed by the Full Nat Arithmetic consumer for $\mathsf{Order}^{\uparrow}$: one concrete carrier, one classifier, one order relation, finite interval coverage, and endpoint classifier uniqueness. All rows are inherited from the unary prefix $\mathsf{TotalOrder}^{\uparrow}$ construction, so the package does not create another order and does not replace constructive comparison by classical trichotomy. □

Theorem 54.46 (OrderUp total-order alias boundary)**.** *The L7 public* $\mathsf{Order}^{\uparrow}$ *phase package used by Full Nat Arithmetic is exactly the tuple* $(\mathsf{UnaryHistory}, \rho_{\mathsf{u}}, \leq_{\mathsf{u}})$ *obtained by projecting the unary-prefix* $\mathsf{TotalOrder}^{\uparrow}$ *construction of Definition 54.21 and by assembling the phase-exit rows of Definition 54.45. Its carrier row is* $\mathsf{UnaryHistory}$*, its classifier row is* ρ_{u}*, and its relation row is the prefix relation* $\leq_{\mathsf{u}}$*.*

The public $\mathsf{Order}^{\uparrow}$ *rows are precisely the projected preorder, antisymmetry, constructive comparison, finite interval coverage, and endpoint classifier uniqueness rows named by those two theorem blocks. Thus downstream consumers may cite* $\mathsf{Order}^{\uparrow}$ *as the unary-prefix projection of* $\mathsf{TotalOrder}^{\uparrow}$*, but they receive no second order relation, no host* Nat *order, no quotient order, and no classical trichotomy.*

Proof. Project the base tuple from Definition 54.21. The carrier is $\mathsf{UnaryHistory}$, the classifier is ρ_{u}, and the relation is $\leq_{\mathsf{u}}$, the concrete prefix relation on carried unary histories.

Next apply Definition 54.45. It repacks the $\mathsf{TotalOrder}^{\uparrow}$ preorder and antisymmetry rows, the constructive comparison branches, the finite interval coverage row, and the endpoint classifier uniqueness row as the public $\mathsf{Order}^{\uparrow}$ phase package.

The two cited theorem blocks name all consumer-visible rows of this phase object. Since each row is a projection from the unary-prefix construction or a phase-exit assembly of those projections, there is no independent order row to transport, no ambient Nat ordering to import, no quotient ordering to identify, and no classical trichotomy principle to add. □

54.7.1 OrderUp obligation set

Theorem 54.47 (Unary prefix OrderUp carrier obligation)**.** *The carrier row of the Full Nat Arithmetic* $\mathsf{Order}^{\uparrow}$ *phase package is exactly* $\mathsf{UnaryHistory}$ *over the ambient kernel history type* BHist*. It introduces no second carrier and no quotient carrier.*

Proof. Use the phase-exit package of Definition 54.45. Its carrier component is named explicitly as $\mathsf{UnaryHistory}$, and the ambient object is the same BHist history used by the unary-prefix construction.

The theorem is therefore the carrier projection of that package: the consumer receives the listed carried histories and no additional carrier row. □

Theorem 54.48 (Unary prefix OrderUp classifier obligation)**.** *The classifier row of the Full Nat Arithmetic* $\mathsf{Order}^{\uparrow}$ *phase package is the same endpoint classifier* ρ_{u} *used by the unary-prefix* $\mathsf{TotalOrder}^{\uparrow}$ *surface.*

Proof. Apply Definition 54.45. The theorem names ρ_{u} as the package classifier and says that it is inherited from the concrete unary-prefix $\mathsf{TotalOrder}^{\uparrow}$ surface.

Thus the $\mathsf{Order}^{\uparrow}$ consumer reads endpoint sameness through the already exposed unary classifier rather than through a separate phase-specific classifier. □

Theorem 54.49 (Unary prefix OrderUp relation obligation)**.** *The order-relation row of the Full Nat Arithmetic* $\mathsf{Order}^{\uparrow}$ *phase package is the same concrete unary-prefix relation* $\leq_{\mathsf{u}}$ *exposed by the unary-prefix* $\mathsf{TotalOrder}^{\uparrow}$ *surface on* $\mathsf{UnaryHistory}$ *endpoints. It introduces no second comparison relation, no host Nat order, and no quotient order.*

Proof. Apply Definition 54.45. The package statement explicitly names $\leq_{\mathsf{u}}$ as the order relation consumed by the Full Nat Arithmetic $\mathsf{Order}^{\uparrow}$ phase.

The source of that row is Definition 54.21. The phase package projects the relation from this unary-prefix $\mathsf{TotalOrder}^{\uparrow}$ certificate, so the consumer receives the exposed relation itself and no additional comparison relation. □

Theorem 54.50 (Unary prefix OrderUp preorder obligation)**.** *On carried endpoints, reflexivity and transitivity of* $\leq_{\mathsf{u}}$ *are the preorder rows inherited from Definition 54.21.*

Proof. First expose the unary-prefix $\mathsf{TotalOrder}^{\uparrow}$ certificate by applying Definition 54.21. Its $\mathsf{POSet}^{\uparrow}$ component supplies reflexivity and transitivity for the relation $\leq_{\mathsf{u}}$ on $\mathsf{UnaryHistory}$ endpoints.

Then project those rows through Definition 54.45. The projected relation is still $\leq_{\mathsf{u}}$, so the preorder data has exactly the same domain and classifier boundary as in the source certificate. □

Theorem 54.51 (Unary prefix OrderUp antisymmetry obligation)**.** *If two carried endpoints compare in both directions under* $\leq_{\mathsf{u}}$*, then their endpoints are classified together by* ρ_{u}*.*

Proof. Apply the antisymmetry row supplied by Definition 54.21. That row identifies two-sided $\leq_{\mathsf{u}}$ comparison with the endpoint classifier used by the unary-prefix order.

Finally use Definition 54.45 to read this row inside the $\mathsf{Order}^{\uparrow}$ package. Since the package keeps the same classifier ρ_{u}, the classified endpoint equality is the required one. □

Theorem 54.52 (Unary prefix OrderUp constructive comparison obligation)**.** *Every carried pair of endpoints admits strict-left, same, or strict-right comparison data for* $\leq_{\mathsf{u}}$*, as supplied by the unary-prefix* $\mathsf{TotalOrder}^{\uparrow}$ *surface. This obligation asserts constructive comparison data and does not assert classical trichotomy.*

Proof. Use the comparison row of Definition 54.21. For each carried pair, that row gives one of the constructive branches: strict-left, same, or strict-right.

The phase-exit package of Definition 54.45 transports the same row to the $\mathsf{Order}^{\uparrow}$ consumer. Because the package states that it asserts no classical trichotomy, the obligation is exactly the constructive branch data. □

Theorem 54.53 (Unary prefix OrderUp finite interval coverage obligation)**.** *Every nonempty carried finite spine has selected lower and upper endpoints under* $\leq_{\mathsf{u}}$*, supplied by Definition 54.37.*

Proof. Start with a nonempty finite spine whose entries are carried by $\mathsf{UnaryHistory}$. Apply Definition 54.37 to obtain selected endpoints m and M.

The conclusion of the interval-collapse theorem says that every member of the spine lies between those selected endpoints under $\leq_{\mathsf{u}}$. This is the finite-interval coverage row consumed by the phase-exit package. □

Theorem 54.54 (Unary prefix OrderUp endpoint uniqueness obligation)**.** *Competing selected lower and upper endpoints over the same nonempty carried finite spine are classified by ρ_{u}, as read back from Definition 54.41.*

Proof. Take two finite extrema interval witness records over the same carried finite spine. Apply Definition 54.41 to compare their selected lower endpoints and their selected upper endpoints.

The readback theorem classifies both endpoint comparisons through ρ_{u}. Therefore the $\mathsf{Order}^{\uparrow}$ package has endpoint uniqueness only up to the declared unary-prefix classifier, which is the phase classifier of Definition 54.45. □

Theorem 54.55 (Unary prefix OrderUp exactness obligation)**.** *On carried unary endpoints h and k, the $\mathsf{Order}^{\uparrow}$ classifier row ρ_{u} is exact for two-sided $\leq_{\mathsf{u}}$ comparison:*

$$\rho_{\mathsf{u}}(h,k) \quad \textit{if and only if} \quad h \leq_{\mathsf{u}} k \wedge k \leq_{\mathsf{u}} h.$$

This exactness row uses the same carrier, classifier, and relation tuple as the unary-prefix $\mathsf{TotalOrder}^{\uparrow}$ surface and introduces no quotient equality.

Proof. First expose the concrete phase package by Definition 54.45. It identifies the $\mathsf{Order}^{\uparrow}$ carrier with $\mathsf{UnaryHistory}$, the classifier with ρ_{u}, and the relation with $\leq_{\mathsf{u}}$.

Project the same tuple back to the inherited unary-prefix $\mathsf{TotalOrder}^{\uparrow}$ surface of Definition 54.21. There is no transport across a new carrier or a new relation; the consumer is reading the original preorder classifier boundary.

Apply Definition 53.34. Its forward direction turns classifier sameness into the two prefix comparisons, and its reverse direction turns the two comparisons back into the carrier-aware classifier. Under the package projection, that equivalence is precisely the displayed ρ_{u} exactness row for $\mathsf{Order}^{\uparrow}$. □

Theorem 54.56 (Unary prefix OrderUp ledger obligation)**.** *The Full Nat Arithmetic $\mathsf{Order}^{\uparrow}$ ledger records exactly the concrete unary carrier witnesses, the selected constructive comparison branch, the finite interval endpoint witnesses, and the endpoint-readback comparisons. All entries are stated over BHist, $\mathsf{ListCarrier}$, and Cont data. The ledger contains no quotient carrier, no host order, and no unrecorded classical comparison principle.*

Proof. Begin with the phase package of Definition 54.45. Its ledger boundary is the displayed $\mathsf{UnaryHistory}$ carrier over BHist, the classifier ρ_{u}, the relation $\leq_{\mathsf{u}}$, and the constructive comparison branch selected by the inherited unary-prefix $\mathsf{TotalOrder}^{\uparrow}$ surface.

Next read the finite-spine part through Definition 54.37. For a nonempty $\mathsf{ListCarrier}$ spine, the ledger keeps the membership witnesses, the selected lower and upper endpoints, and the two bounding comparisons against each listed entry.

Finally apply Definition 54.41. This supplies the endpoint-readback comparisons showing that competing lower endpoints and competing upper endpoints are classified by ρ_{u}.

Combining these rows gives exactly the advertised ledger: every recorded item is a BEDC history, finite-list, or continuation witness already present in the unary-prefix package, and none of the rows appeal to a quotient carrier or an external host order. □

Theorem 54.57 (OrderUp carrier and classifier obligation)**.** *The concrete carrier for the unary-prefix* $\mathsf{Order}^{\uparrow}$ *phase object is* $\mathsf{UnaryHistory}$*. Its classifier is* ρ_{u}*, and its order relation is* $\leq_{\mathsf{u}}$*.*

Proof. Apply Definition 54.45. The phase-exit package exposes the same carried objects as Definition 54.21: unary histories are the carrier, ρ_{u} is the classifier used to read them, and $\leq_{\mathsf{u}}$ is the only order relation exported to $\mathsf{Order}^{\uparrow}$. □

Theorem 54.58 (OrderUp preorder and antisymmetry obligation)**.** *On carried unary histories,* $\leq_{\mathsf{u}}$ *is reflexive and transitive. If two carried unary histories lie below each other under* $\leq_{\mathsf{u}}$*, then their endpoints land in the same* ρ_{u} *classifier class.*

Proof. First project the order rows from the concrete unary-prefix total-order certificate through Definition 54.21. The $\mathsf{Order}^{\uparrow}$ phase package of Definition 54.45 exports those rows without introducing another relation.

Reflexivity and transitivity are the preorder rows of the inherited $\leq_{\mathsf{u}}$ surface. Antisymmetry is read in the classifier used by the same package: mutual $\leq_{\mathsf{u}}$ comparison identifies the carried unary histories up to ρ_{u}, which is the equality notion exposed to the phase consumer. □

Theorem 54.59 (OrderUp constructive comparison obligation)**.** *For any two carried unary histories, the* $\mathsf{Order}^{\uparrow}$ *comparison data gives one of the strict-left, same, or strict-right branches from the unary-prefix total-order package. The phase object exports this constructive branch data and exports no classical trichotomy principle.*

Proof. Use the comparison row supplied by Definition 54.21 and projected into $\mathsf{Order}^{\uparrow}$ by Definition 54.45. The branch names and their witnesses are the concrete unary-prefix strict-left, same, and strict-right alternatives.

Because the exported row is this constructive package row, the consumer receives only the witnessed branch split. No additional excluded-middle or classical trichotomy statement is part of the $\mathsf{Order}^{\uparrow}$ phase object. □

Theorem 54.60 (OrderUp finite-interval and endpoint obligation)**.** *Every nonempty finite carried unary spine has lower and upper bounds under* $\leq_{\mathsf{u}}$*. Moreover, for any two endpoint-witness records for the same carried spine, their lower endpoints are* ρ_{u}*-equivalent and their upper endpoints are* ρ_{u}*-equivalent.*

Proof. First obtain finite interval coverage from Definition 54.37. For a nonempty finite carried spine, it supplies selected lower and upper unary endpoints with every carried member lying between them under $\leq_{\mathsf{u}}$.

Next apply Definition 54.41 to two endpoint-witness records over the same carried spine. The theorem identifies the selected lower endpoints through ρ_{u} and likewise identifies the selected upper endpoints through ρ_{u}.

Together with the phase package of Definition 54.45, these are precisely the finite-interval and endpoint-uniqueness obligations exported by the concrete unary-prefix $\mathsf{Order}^{\uparrow}$ object. □

Theorem 54.61 (OrderUp exactness and ledger scope)**.** *The unary-prefix* $\mathsf{Order}^{\uparrow}$ *package is exact at each exported row. Its carrier is exactly* $\mathsf{UnaryHistory}$*; its classifier is exactly* ρ_{u}*; and its order relation is exactly the single exported* $\leq_{\mathsf{u}}$ *row. Its finite-interval coverage is precisely the bounded interval collapse of Definition 54.37, and its endpoint ledger uniqueness is precisely the two-endpoint classifier readback of Definition 54.41. The package exports no host Nat order row, no quotient order row, and no classical trichotomy row.*

Proof. Begin with the phase-exit package of Definition 54.45. Its named surface fixes the carrier as $\mathsf{UnaryHistory}$, the classifier as ρ_{u}, and the relation as $\leq_{\mathsf{u}}$.

The carrier, classifier, and relation exactness claims are the three direct row projections recorded in Definition 54.47, Definition 54.48, and Definition 54.49. These are repacked in Definition 54.57 as the public carrier, classifier, and relation face of the same package.

The order-law ledger is inherited without changing that face. Reflexivity and transitivity come from Definition 54.50, antisymmetry from Definition 54.51, and the witnessed comparison row from Definition 54.52. The combined public statement is Definition 54.58 together with Definition 54.59.

Finally apply Definition 54.53 and Definition 54.54. These are the finite-interval collapse and endpoint uniqueness rows, summarized by Definition 54.60. Since every row is projected from the single phase-exit package, the scope contains only $\mathsf{UnaryHistory}$, ρ_{u}, and $\leq_{\mathsf{u}}$; there is no additional host Nat order, quotient order, or classical trichotomy row to export. □

Theorem 54.62 (Unary prefix OrderUp scoped dependency package)**.** *The Full Nat Arithmetic* $\mathsf{Order}^{\uparrow}$ *package is scoped over the concrete tuple* $(\mathsf{BHist}, \mathsf{UnaryHistory}, \rho_{\mathsf{u}}, \leq_{\mathsf{u}})$*. Its endpoint objects are* BHist *histories compared through* hsame*; its carrier row is exactly* $\mathsf{UnaryHistory}$*; its order row is exactly the unary-prefix relation* $\leq_{\mathsf{u}}$*; its finite carried spines are the* $\mathsf{ListCarrier}$ *spines; and* Cont *is used only for the finite-spine ledger rows that record the carried membership, selected endpoint, and bounding-comparison witnesses.*

The ten-field fit is carrier $\mathsf{UnaryHistory}$*, classifier* ρ_{u}*, relation* $\leq_{\mathsf{u}}$*, preorder, antisymmetry, constructive comparison, finite interval coverage, endpoint uniqueness, exactness, and ledger scope. These ten rows are exactly the obligations packaged by Definition 54.57, Definition 54.58, Definition 54.59, Definition 54.60, and Definition 54.55, with the ledger boundary stated by Definition 54.61. Therefore the package has a single scoped dependency boundary and introduces no host Nat order, quotient order, second classifier, or classical trichotomy row.*

Proof. First project the carrier, classifier, and relation from Definition 54.45. This supplies the concrete tuple $(\mathsf{BHist}, \mathsf{UnaryHistory}, \rho_{\mathsf{u}}, \leq_{\mathsf{u}})$ and fixes endpoint comparison at the BHist and hsame boundary.

Next read the order-law rows from the inherited unary-prefix total-order surface. The preorder, antisymmetry, and constructive comparison data are provided by Definition 54.21 and are summarized for the $\mathsf{Order}^{\uparrow}$ consumer by Definition 54.58 and Definition 54.59.

For finite carried spines, apply Definition 54.37. It supplies the finite interval coverage over $\mathsf{ListCarrier}$ data, and Definition 54.41 supplies the endpoint uniqueness readback for competing lower and upper endpoint records.

It remains to identify the exactness and ledger boundary. Apply Definition 53.34 for the two-sided $\leq_{\mathsf{u}}$ exactness of ρ_{u}, and use Definition 54.61 to keep Cont confined to the finite-spine ledger rows. The listed projections are precisely the carrier, classifier, relation, preorder, antisymmetry, comparison, interval coverage, endpoint uniqueness, exactness, and ledger obligations, so they form one scoped dependency package. □

Theorem 54.63 (Unary prefix OrderUp public export)**.** *The concrete L7* $\mathsf{Order}^{\uparrow}$ *phase object exports a single public surface whose carrier is* $\mathsf{UnaryHistory}$*, whose classifier is* ρ_{u}*, and whose relation is* $\leq_{\mathsf{u}} := \mathsf{PreorderPrefixLE}$*. This surface includes the constructive comparison data, finite interval coverage, endpoint uniqueness, exactness, and ledger scope supplied by the unary-prefix* $\mathsf{TotalOrder}^{\uparrow}$ *package. Every exported row is sourced from that package boundary, so the public* $\mathsf{Order}^{\uparrow}$ *object uses no host order and no classical trichotomy.*

Proof. Use Definition 54.62 as the aggregate dependency package. It binds the concrete surface to $(\mathsf{BHist}, \mathsf{UnaryHistory}, \rho_{\mathsf{u}}, \leq_{\mathsf{u}})$ and identifies the relevant rows as the unary-prefix $\mathsf{Order}^{\uparrow}$ obligations.

Project the carrier, classifier, and public relation rows from Definition 54.57 and Definition 54.49. These projections fix the public carrier as $\mathsf{UnaryHistory}$, the classifier as ρ_{u}, and the relation as $\leq_{\mathsf{u}} := \mathsf{PreorderPrefixLE}$.

Next project the constructive comparison row from Definition 54.59. Project finite interval coverage and endpoint uniqueness from Definition 54.60. These rows give the comparison witnesses, the finite carried interval, and the selected endpoint readback for the same unary-prefix surface.

Finally apply Definition 54.61. It identifies the exactness boundary and confines Cont to the finite-spine ledger rows. The carrier, classifier, relation, comparison, interval, endpoint, exactness, and ledger projections therefore repack into one public $\mathsf{Order}^{\uparrow}$ export surface, with no host order row and no classical trichotomy row. □

Theorem 54.64 (TotalOrderUp unary-prefix OrderUp consumer coverage boundary)**.** *Any downstream* $\mathsf{Order}^{\uparrow}$ *or* $\mathsf{TotalOrder}^{\uparrow}$ *consumer of the unary-prefix public export receives exactly the rows named by Definition 54.45 and Definition 54.63:* $\mathsf{UnaryHistory}$*,* ρ_{u}*,* $\leq_{\mathsf{u}}$*, the preorder and antisymmetry rows, constructive comparison branches, finite interval coverage, endpoint uniqueness, exactness, and finite ledger rows. It receives no host* Nat *order, no quotient equality, and no classical trichotomy.*

Proof. Read the public surface from Definition 54.63. Its carrier, classifier, and relation rows are $\mathsf{UnaryHistory}$, ρ_{u}, and $\leq_{\mathsf{u}} := \mathsf{PreorderPrefixLE}$.

Apply the phase-exit package Definition 54.45. The obligation-row theorems in this section project the preorder law rows, antisymmetry row, constructive comparison branches, finite interval coverage, endpoint uniqueness, and exactness row from the same unary-prefix package.

Finally apply Definition 54.56 together with Definition 54.61. These identify the finite Cont ledger rows and show that no additional host order, quotient equality, or classical trichotomy row is available to a downstream consumer. □

Theorem 54.65 (Unary prefix OrderUp standard bridge boundary)**.** *The public surface of Definition 54.63 bridges to finite unary words by reading* $\mathsf{UnaryHistory}$ *as the carried finite unary-word endpoints,* ρ_{u} *as the finite-word classifier, and* $\leq_{\mathsf{u}} := \mathsf{PreorderPrefixLE}$ *as initial-segment order. Its finite interval rows are exactly the rows of Definition 54.37, and its endpoint rows are exactly the rows of Definition 54.41. The bridge therefore exposes the unary-prefix* $\mathsf{Order}^{\uparrow}$ *package as a finite-word standard surface, with no host* Nat *order row and no classical trichotomy row.*

Proof. Start with the public export of Definition 54.63. It fixes the carrier, classifier, and comparison as $(\mathsf{UnaryHistory}, \rho_{\mathsf{u}}, \mathsf{PreorderPrefixLE})$, so each public row already has the finite unary-word reading required by the standard surface.

Apply Definition 54.37 to read the finite interval rows as carried initial-segment intervals. Apply Definition 54.41 to read the lower and upper endpoint rows as the unique finite-word endpoints selected by the same prefix comparison.

It remains to identify what is absent from the bridge. The public export and the two cited rows use only BHist, $\mathsf{UnaryHistory}$, ρ_{u}, $\mathsf{PreorderPrefixLE}$, and finite Cont transport. Thus no host Nat order and no classical trichotomy are exported. □

Theorem 54.66 (OrderUp public export formal boundary)**.** *The public* $\mathsf{Order}^{\uparrow}$ *export in this chapter is the unary-prefix package of Definition 54.63. The displayed Lean target in the closure block supplies only the inherited* $\mathsf{Preorder}^{\uparrow}$ *stability field, so the chapter may claim the paper public surface but not an audit-clean* $\mathsf{Order}^{\uparrow}$ *namespace target.*

Proof. Project the public export of Definition 54.63. It exposes the carrier UnaryHistory, classifier ρ_{u}, and relation $\leq_{\mathsf{u}} :=$ PreorderPrefixLE from the unary-prefix package.

Project the remaining paper rows through Definition 54.45. The exactness row and finite Cont ledger rows are part of the same public package, so the manuscript has a public $\mathsf{Order}^{\uparrow}$ surface over the listed carrier, classifier, relation, exactness, and ledger data.

The Lean target recorded below remains a dependency boundary: it certifies the inherited $\mathsf{Preorder}^{\uparrow}$ stability field rather than a checked $\mathsf{Order}^{\uparrow}$ namespace theorem. Therefore the theory axis can report the public paper surface, while the verification axis stays below an audit-clean $\mathsf{Order}^{\uparrow}$ target. □

Theorem 54.67 (OrderUp unary prefix namespace target surface)**.** *The* $\mathsf{Order}^{\uparrow}$ *namespace target surface in this chapter is exactly the unary carrier* UnaryHistory*, classifier* ρ_{u}*, relation* $\leq_{\mathsf{u}} :=$ PreorderPrefixLE*, constructive comparison rows, finite interval rows, endpoint uniqueness rows, exactness row, ledger rows, public export row, and bridge row displayed in this section. No additional carrier, comparison, endpoint, quotient, or host-order row belongs to the chapter surface.*

Proof. Project the carrier, classifier, and relation from Definition 54.63. The constructive comparison branches and order laws are the rows repacked by Definition 54.45.

Next project the finite interval and endpoint rows from Definition 54.37 and Definition 54.41. These are the only interval and endpoint witnesses attached to the unary-prefix public package.

Finally read the exactness and ledger clauses through Definition 54.56, Definition 54.61, and Definition 54.65. Repacking these projected rows gives precisely the listed namespace surface and nothing outside the displayed BHist, UnaryHistory, hsame, and Cont data. □

Theorem 54.68 (OrderUp unary prefix audit consumer boundary)**.** *Any audit consumer of the* $\mathsf{Order}^{\uparrow}$ *target surface in this chapter may cite only the* BHist*,* UnaryHistory*,* hsame*, and* Cont *rows listed by Definition 54.67. Such a consumer may not replace those rows by a host order on natural numbers, an external finite-word equality, or classical trichotomy.*

Proof. Start from the public export row of Definition 54.63. Its consumer-visible data are the carried unary histories, the unary classifier, and the prefix relation.

The ledger restrictions in Definition 54.56 and Definition 54.61 state that continuation readback is finite and attached to the displayed unary-prefix package. The standard bridge boundary of Definition 54.65 gives the finite-word reading without adding a host natural-number order.

Thus an audit consumer can repack only the listed BEDC rows. Host order, external word equality, and classical trichotomy are not projections of any cited theorem block, so they cannot be substituted for the chapter surface. □

Theorem 54.69 (OrderUp unary prefix formalization handshake)**.** *A Lean theorem in the namespace* BEDC.Derived.OrderUp *that closes this chapter must prove the same unary-prefix surface listed in Definition 54.67. The inherited* $\mathsf{Preorder}^{\uparrow}$ *stability dependency may remain a source row, but it is not the canonical* $\mathsf{Order}^{\uparrow}$ *theorem for the carrier, comparison, finite interval, endpoint, exactness, ledger, public export, and bridge surface.*

Proof. The dependency target in the closure block certifies the preorder stability field used by the unary-prefix relation. That row is one source of the public package, not the whole $\mathsf{Order}^{\uparrow}$ package.

Project the chapter surface from Definition 54.67. It contains comparison, bounded interval, endpoint uniqueness, exactness, ledger, public export, and bridge data in addition to the inherited preorder row.

Therefore a namespace theorem for BEDC.Derived.OrderUp must repack all listed rows as its conclusion. Reusing the $\mathsf{Preorder}^{\uparrow}$ dependency as the canonical theorem would omit the displayed $\mathsf{Order}^{\uparrow}$ rows and would not match the chapter surface. □

Theorem 54.70 (TotalOrder source boundary for the OrderUp phase exit)**.** *The* $\mathsf{Order}^{\uparrow}$ *phase-exit surface in this file is a consumer projection of the unary-prefix* $\mathsf{TotalOrder}^{\uparrow}$ *package through* BHist*,* UnaryHistory*,* ρ_{u}*,* $\leq_{\mathsf{u}}$*, finite* ListCarrier *spines, and* Cont *ledger rows. It does not by itself certify a canonical theorem in the namespace* BEDC.Derived.OrderUp*.*

Proof. Start with Definition 54.21. It supplies the total-order source package whose unary carrier, classifier, comparison, and finite spine data feed the displayed $\mathsf{Order}^{\uparrow}$ projection.

Apply Definition 54.63 to read that source package as the public $\mathsf{Order}^{\uparrow}$ carrier, classifier, and relation. Then use Definition 54.65 to identify the finite ListCarrier spine reading without adding a separate host-order source.

Finally apply Definition 54.69. The handshake names the remaining formal boundary: the chapter surface is a paper-side consumer projection of the unary-prefix $\mathsf{TotalOrder}^{\uparrow}$ package, so the closure block below cannot be read as a canonical BEDC.Derived.OrderUp namespace certificate. □

54.8 The certificate

Definition 54.71 (TotalOrder source specification)**.** *The source is a certified poset carrier plus apartness-aware trichotomy.*

Definition 54.72 (TotalOrder pattern specification)**.** *The pattern is comparison formation producing one of three certified comparison cases.*

Definition 54.73 (TotalOrder classifier specification)**.** *The classifier is the poset carrier classifier, with apartness stable under classifier replacement.*

Definition 54.74 (TotalOrder stability certificate)**.** *The stability certificate consists of:*

1. *all poset stability fields*
2. *strict-order-to-apartness field*
3. *trichotomy as explicit comparison data*
4. *comparison stability under classifier replacement*
5. *transitivity of strict comparison where supplied*

Definition 54.75 (TotalOrder ledger policy)**.** *Record the comparison certificate selected for each pair.*

Definition 54.76 ($\mathsf{TotalOrder}^{\uparrow}$ certificate obligations)**.** *The carrier, source, pattern, classifier, stability, and ledger data listed above are the obligations required for the interface name* $\mathsf{TotalOrder}^{\uparrow}$*.*

Theorem 54.77 (TotalOrder carrier branch exhaustion)**.** *For carried singleton* BHist *endpoints* $h, k : A_{\mathsf{e}}$*, the explicit comparison data in Definition 54.2 exhausts exactly the three branches* lt_{e}*,* $\mathsf{same}_{\mathsf{e}}$*, and* gt_{e}*. The singleton carrier forces the same branch:* $\mathsf{same}_{\mathsf{e}}(h, k)$ *is* $\rho_{\mathsf{e}}(h, k)$*, while the strict left and strict right branches are empty.*

Proof. Apply Definition 54.3. Its trichotomy row is stated for the displayed branches of the singleton history instance, and the instance defines the strict branches as $\bot$ and the middle branch as ρ_{e}.

The carrier hypotheses say that h and k are the singleton BHist endpoints. Hence no additional endpoint case exists outside the displayed three-way comparison data, and the only inhabited branch is the same branch. □

Theorem 54.78 (TotalOrder classifier antisymmetry scope)**.** *For carried singleton endpoints $h, k : A_{\mathsf{e}}$, opposing prefix comparisons $h \leq_{\mathsf{e}} k$ and $k \leq_{\mathsf{e}} h$ recover $\rho_{\mathsf{e}}(h, k)$. Therefore the classifier antisymmetry scope of the concrete $\mathsf{TotalOrder}^{\uparrow}$ certificate is exactly the singleton empty-poset scope and contains no comparison datum beyond the carried BHist endpoints.*

Proof. Apply Definition 53.12. Its exactness row identifies the singleton classifier $\rho_{\mathsf{e}}(h, k)$ with the pair of opposing prefix comparisons on carried endpoints.

Now read the same row through the branch specification in this file. Since the strict branches are empty and the middle branch is ρ_{e}, antisymmetry is precisely the recovery of the middle classifier branch from the two prefix comparisons. □

Theorem 54.79 (TotalOrder certificate boundary exactness)**.** *The carrier branch exhaustion of Definition 54.77, the classifier antisymmetry scope of Definition 54.78, the stability fields of Definition 54.74, and the ledger policy of Definition 54.75 assemble the exact $\mathsf{TotalOrder}^{\uparrow}$ boundary over the singleton BHist carrier. The boundary exports only the carrier, comparison branch, classifier, stability, exactness, and selected ledger rows listed in this file.*

Proof. First assemble the carrier and branch surface. Use Definition 54.77 to obtain the exhaustive three-way comparison data and the singleton same-branch reduction.

Next assemble the classifier exactness surface. Use Definition 54.78 to identify the classifier with opposing prefix comparisons, and use Definition 53.12 for the underlying empty-poset exactness rows.

Finally cite Definition 54.3 for total-order stability and comparison stability. Repacking these rows with Definition 54.71, Definition 54.72, Definition 54.73, Definition 54.74, and Definition 54.75 gives exactly the certificate boundary claimed by Definition 54.76. □

Theorem 54.80 ($\mathsf{Order}^{\uparrow}$ unary-prefix constructive trichotomy readback)**.** *For carried unary histories h, k in $\mathsf{Carrier}_{\mathsf{u}}$, the unary-prefix comparison partition reads back as concrete BHist data over $\mathsf{Carrier}_{\mathsf{u}}$, ρ_{u}, and $\leq_{\mathsf{u}}$. Exactly one selected branch is exported:*

$$\mathsf{NatUnaryStrictPrefix}(h, k), \qquad \rho_{\mathsf{u}}(h, k), \qquad \mathsf{NatUnaryStrictPrefix}(k, h).$$

The strict-left branch is the concrete nonempty unary tail from h to k, the same branch is the classifier row $\rho_{\mathsf{u}}(h, k)$, and the strict-right branch is the concrete nonempty unary tail from k to h.

Proof. Apply Definition 54.9 to the carried pair h, k. Its three branches are already stated over the unary BHist carrier and use the classifier ρ_{u} as the middle branch.

In the strict-left case, the partition supplies the concrete nonempty continuation witness from h to k, so the public branch is $\mathsf{NatUnaryStrictPrefix}(h, k)$. In the same case, the middle branch is exactly $\rho_{\mathsf{u}}(h, k)$, and the exactness row identifies it with the opposing $\leq_{\mathsf{u}}$ comparisons.

In the strict-right case, the same construction is read with endpoints reversed, yielding $\mathsf{NatUnaryStrictPrefix}(k, h)$. The incompatibility rows of the partition exclude every second selected branch, so the readback is constructive branch data rather than a host-order trichotomy principle. □

Theorem 54.81 ($\mathsf{Order}^{\uparrow}$ prefix branch ledger exactness)**.** *For every carried unary pair h, k in $\mathsf{Carrier_u}$, the selected prefix branch ledger is exactly the public comparison datum exported by the $\mathsf{Order}^{\uparrow}$ certificate. The ledger contains one of the concrete rows*

$$\mathsf{NatUnaryStrictPrefix}(h,k), \qquad \rho_{\mathsf{u}}(h,k), \qquad \mathsf{NatUnaryStrictPrefix}(k,h),$$

and contains no separate classical trichotomy row, no host order row, and no quotient-equality row.

Proof. Read the selected ledger row through Definition 54.80. The row is one of the three concrete unary-prefix branches and is therefore a BHist witness, a classifier witness, or the reversed BHist witness.

The singleton boundary of Definition 54.79 records the same policy at the certificate boundary: only carrier, comparison branch, classifier, stability, exactness, and selected ledger rows are exported. The unary-prefix surface uses the same boundary shape, replacing the singleton branches by the unary branches of Definition 54.9.

Thus the ledger is exact as a public comparison datum. Since every exported row is one of the displayed concrete rows, there is no additional classical trichotomy row to project. □

Theorem 54.82 ($\mathsf{Order}^{\uparrow}$ unary-prefix audit target surface)**.** *The unary-prefix $\mathsf{Order}^{\uparrow}$ paper target consists of the carrier $\mathsf{Carrier_u}$, the classifier ρ_{u}, the order $\leq_{\mathsf{u}}$, the branch readback of Definition 54.80, the stability rows of Definition 54.74, the ledger exactness of Definition 54.81, and the certificate boundary exactness of Definition 54.79. This is the complete paper surface for a later theorem over the concrete unary-prefix carrier and does not require parameter transport or classical order primitives.*

Proof. Start with the carrier, classifier, and order from the concrete unary-prefix total-order instance. The comparison partition supplies the constructive strict-left, same, and strict-right branches over $\mathsf{Carrier_u}$.

Use Definition 54.80 to read the selected branch as public BHist data. Use Definition 54.81 to identify the selected ledger with that public comparison datum.

Finally repack these rows with the stability certificate of Definition 54.74 and the exact boundary of Definition 54.79. The assembled target names precisely the carrier, classifier, branch readback, stability, ledger, and exactness rows needed by the unary-prefix $\mathsf{Order}^{\uparrow}$ theorem surface. □

Theorem 54.83 (Concrete singleton history $\mathsf{TotalOrder}^{\uparrow}$ naming certificate)**.** *The concrete tuple of Definition 54.2 supplies the source, pattern, classifier, stability, ledger, and exactness rows for a $\mathsf{NameCert}$ licensing $\mathsf{TotalOrder}^{\uparrow}$ over the singleton carrier A_{e}, classifier ρ_{e}, order $\leq_{\mathsf{e}}$, and comparison branches $\mathsf{lt_e} := \bot$, $\mathsf{same_e} := \rho_{\mathsf{e}}$, and $\mathsf{gt_e} := \bot$.*

Proof. The carrier row is the singleton BHist source. Apply Definition 54.3 to obtain the carried endpoint facts, classifier stability, the $\mathsf{POSet}^{\uparrow}$ fields, trichotomy, and comparison stability for the displayed branches.

The exactness row is the underlying partial-order exactness supplied by Definition 53.12: on carried histories, $\rho_{\mathsf{e}}(h,k)$ is equivalent to the two opposing prefix comparisons $h \leq_{\mathsf{e}} k$ and $k \leq_{\mathsf{e}} h$.

The strict rows contribute no extra witnesses. Both strict comparison branches are empty by definition, so strict-to-apartness and strict transitivity are vacuous.

It remains to assemble the public certificate. Repack the source as A_{e}, the pattern as the three-way comparison formation, the classifier as ρ_{e}, the stability data as the fields just cited, and the ledger as the selected same-branch comparison certificate. □

The per-object template is: traditional target singleton constructive total order; BEDC source singleton BHist; carrier A_{e}; classifier ρ_{e}; stability obligations from Definition 54.83; ledger the selected same-branch comparison certificate; exactness singleton classifier iff opposing prefix comparisons; standard bridge singleton total order; status $\mathsf{ProofTarget}$.

Primitive boundary. $\mathsf{TotalOrder}^{\uparrow}$ is not a BEDC primitive. It is admitted only when those obligations are supplied.

Remark 54.84 (Zero-axiom encoding note)**.** *Replaces LEM-style totality with decidable comparison data and apartness.*

54.9 Public audit boundary

Definition 54.85 (TotalOrder OrderUp public audit carrier)**.** *The public audit carrier for the unary-prefix* $\mathsf{TotalOrder}^{\uparrow}$ *to* $\mathsf{Order}^{\uparrow}$ *surface is the carried endpoint predicate on* BHist *supplied by* $\mathsf{Carrier_u}$*. Its classifier is the unary classifier* ρ_{u}*, and its comparison relation is* $\leq_{\mathsf{u}} := \mathsf{PreorderPrefixLE}$*. Thus every public audit row is anchored in carried* BHist *endpoints, not in a host order on natural numbers.*

Theorem 54.86 (TotalOrder OrderUp public audit classifier)**.** *For carried unary endpoints* $h, k : \mathsf{BHist}$ *in* $\mathsf{Carrier_u}$*, classifier transport for the public audit surface is read from Definition 54.13, and antisymmetry is read from Definition 54.9. Hence the public classifier row is exactly* $\rho_{\mathsf{u}}(h, k)$ *together with its transport through the three constructive comparison branches.*

The ten-field fit is: downstream target the public $\mathsf{Order}^{\uparrow}$ *audit surface; BEDC source* BHist*; carrier* $\mathsf{Carrier_u}$*; classifier* ρ_{u}*; relation* $\leq_{\mathsf{u}}$*; stability branch transport; ledger selected comparison branch; core theorem this classifier audit row; exactness opposing-prefix antisymmetry from the comparison partition; standard bridge finite unary words; status* $\mathsf{ProofTarget}$*.*

Proof. Fix carried endpoints h, k and a classifier replacement along ρ_{u}. Apply Definition 54.13. It transports the strict-left, same, and strict-right branch rows across the replacement, so the public comparison branch remains a row over the carried endpoints.

Now read antisymmetry from Definition 54.9. The same branch is $\rho_{\mathsf{u}}(h, k)$, while opposing prefix comparisons exclude the two strict branches and recover the middle classifier row.

Combining these two cited rows gives the audit classifier boundary. The transport datum is branch transport, and the exactness datum is precisely the middle branch selected by the comparison partition. □

Theorem 54.87 (TotalOrder OrderUp public constructive comparison)**.** *Every carried pair* $h, k : \mathsf{BHist}$ *in* $\mathsf{Carrier_u}$ *exposes exactly one constructive comparison branch for the public* $\mathsf{Order}^{\uparrow}$ *export: a strict unary prefix from* h *to* k*, the classifier row* $\rho_{\mathsf{u}}(h, k)$*, or a strict unary prefix from* k *to* h*. This is the comparison datum consumed by Definition 54.63.*

The ten-field fit is: downstream target constructive $\mathsf{Order}^{\uparrow}$ *comparison; BEDC source* BHist*; carrier* $\mathsf{Carrier_u}$*; classifier* ρ_{u}*; relation* $\leq_{\mathsf{u}}$*; stability branch transport; ledger selected branch; core theorem this constructive comparison row; exactness the unique active branch; standard bridge finite unary-word comparison; status* $\mathsf{ProofTarget}$*.*

Proof. Apply Definition 54.9 to the carried pair h, k. The theorem supplies the three branch rows directly over unary BHist endpoints and states their incompatibility.

The public export of Definition 54.63 reads the same carrier, classifier, and relation. Therefore the selected branch from the comparison partition is already the branch consumed by the public $\mathsf{Order}^{\uparrow}$ surface.

It remains to identify uniqueness at the audit boundary. Since the partition excludes every second branch and does not mention a host order, the public row is constructive branch data rather than classical trichotomy. □

Theorem 54.88 (TotalOrder OrderUp public ledger exactness)**.** *The public* $\mathsf{Order}^{\uparrow}$ *audit ledger is exhausted by carried* BHist *endpoints, the selected constructive branch witness, classifier transport, and finite interval rows. Its finite rows are the rows named by Definition 54.56 and Definition 54.61; no host order, quotient row, or classical trichotomy row is part of the public ledger.*

The ten-field fit is: downstream target public $\mathsf{Order}^{\uparrow}$ *ledger exactness; BEDC source* BHist*; carrier* $\mathsf{Carrier_u}$*; classifier* ρ_{u}*; relation* $\leq_{\mathsf{u}}$*; stability finite branch transport; ledger carried endpoints, branch witness, classifier row, and interval rows; core theorem this ledger exactness boundary; exactness finite* Cont *exhaustion; standard bridge finite unary-word intervals; status* ProofTarget*.*

Proof. Start with the public carrier and comparison branch from Definition 54.63. The export supplies UnaryHistory, ρ_{u}, and $\leq_{\mathsf{u}}$, and the preceding theorem identifies the selected comparison branch as constructive unary-prefix data.

Next apply Definition 54.56. It records the finite Cont rows attached to carried endpoints and the selected branch. Apply Definition 54.61 to confine exactness to those finite rows.

The cited rows account for every exported ledger component: endpoints, branch witness, classifier transport, and interval data. Since none of the cited rows introduces host order, quotient equality, or classical trichotomy, no such row is available at the audit boundary. □

Theorem 54.89 (TotalOrder public bridge boundary)**.** *The public* $\mathsf{TotalOrder}^{\uparrow}$ *surface supplies the* $\mathsf{Order}^{\uparrow}$ *phase boundary through the unary-prefix package of Definition 54.45 and the public export of Definition 54.63. It does not claim* $\mathsf{Real}^{\uparrow}$ *completeness, classical trichotomy, host equality, or any bridge beyond the finite unary-word surface stated in Definition 54.65.*

The ten-field fit is: downstream target $\mathsf{Order}^{\uparrow}$ *phase boundary; BEDC source* BHist*; carrier* $\mathsf{Carrier_u}$*; classifier* ρ_{u}*; relation* $\leq_{\mathsf{u}}$*; stability branch transport and endpoint exactness; ledger finite unary rows; core theorem this public bridge boundary; exactness public ledger exhaustion; standard bridge finite unary words only; status* ProofTarget*.*

Proof. Read the phase package from Definition 54.45. It supplies the carrier, classifier, relation, comparison, interval, endpoint, and exactness rows required for the $\mathsf{Order}^{\uparrow}$ phase boundary.

Read the public export from Definition 54.63. It repacks the same rows as the public $\mathsf{Order}^{\uparrow}$ surface, and Definition 54.88 identifies the available ledger data.

Finally apply Definition 54.65. The standard reading is finite unary-word data only. Thus the public boundary does not add $\mathsf{Real}^{\uparrow}$ completeness, classical trichotomy, host equality, or a larger bridge claim. □

54.10 Root obligation surface

Theorem 54.90 (TotalOrder root carrier obligation)**.** *The root* $\mathsf{TotalOrder}^{\uparrow}$ *obligation surface is carried by the concrete BEDC history rows*

$$\mathsf{BHist}, \qquad \mathsf{UnaryHistory}(h), \qquad \mathsf{UnaryHistory}(k),$$

together with the inherited $\mathsf{POSet}^{\uparrow}$ *carrier used by the unary-prefix certificate. For every carried pair* $h, k : \mathsf{BHist}$*, the root carrier row is therefore the same* $\mathsf{UnaryHistory}$ *row consumed by the downstream* $\mathsf{Order}^{\uparrow}$ *and* $\mathsf{Lattice}^{\uparrow}$ *order-front packages, not a separate host-order carrier.*

Proof. Start with the carrier named in Definition 54.45. It is the BHist predicate $\mathsf{UnaryHistory}$, and the phase package reads it through the inherited $\mathsf{POSet}^{\uparrow}$ surface of Definition 54.21.

The same row is projected in Definition 54.47. Thus a root consumer sees carried histories h and k only through $\mathsf{UnaryHistory}(h)$ and $\mathsf{UnaryHistory}(k)$.

Because the public audit boundary of Definition 54.85 uses the same endpoint predicate, repacking the carrier for $\mathsf{Order}^{\uparrow}$ or $\mathsf{Lattice}^{\uparrow}$ does not introduce a second carrier. The root obligation is exactly the displayed BHist carrier row. □

Theorem 54.91 (TotalOrder root classifier obligation)**.** *For carried unary histories* $h, k : \mathsf{BHist}$*, the root classifier row is the inherited* $\mathsf{POSet}^{\uparrow}$ *classifier* $\rho_{\mathsf{u}}(h, k)$*, read as* hsame*-stable endpoint sameness on* $\mathsf{UnaryHistory}$ *rows. The explicit comparison branches at the root are*

$$\mathsf{NatUnaryStrictPrefix}(h, k), \qquad \rho_{\mathsf{u}}(h, k), \qquad \mathsf{NatUnaryStrictPrefix}(k, h),$$

and classifier transport preserves which of these three branch rows is recorded by the comparison ledger.

Proof. Apply Definition 54.13. It states that the strict-left, same, and strict-right comparison rows are transported along the unary classifier without changing the concrete endpoint carrier.

The middle branch is the inherited classifier row $\rho_{\mathsf{u}}(h, k)$. Read this through Definition 54.86, which identifies public classifier transport with the same three constructive comparison branches.

Finally, the hsame reading is only endpoint transport inside BHist. Since the carrier remains $\mathsf{UnaryHistory}$, the root classifier obligation is the inherited $\mathsf{POSet}^{\uparrow}$ classifier and not an external equality predicate. □

Theorem 54.92 (TotalOrder root exactness obligation)**.** *On carried unary histories* $h, k : \mathsf{BHist}$*, the root exactness row says that two-sided comparison under the inherited* $\mathsf{POSet}^{\uparrow}$ *relation* $\leq_{\mathsf{u}}$ *recovers the classifier branch* $\rho_{\mathsf{u}}(h, k)$*, while the two strict prefix branches are excluded. This exactness row is the* BHist *endpoint exactness consumed by the public* $\mathsf{Order}^{\uparrow}$ *surface and by any* $\mathsf{Lattice}^{\uparrow}$ *consumer that only reads the displayed unary-prefix order front.*

Proof. First use Definition 54.51. It identifies opposing $\leq_{\mathsf{u}}$ comparisons on carried endpoints with the unary classifier ρ_{u}.

Next use Definition 54.9. The partition separates strict-left, same, and strict-right branch rows, so the two-sided comparison case selects the same branch and excludes the two strict prefix alternatives.

The public exactness row of Definition 54.88 records this as endpoint exactness in the audit ledger. A downstream $\mathsf{Order}^{\uparrow}$ or $\mathsf{Lattice}^{\uparrow}$ consumer therefore receives exactness for the unary-prefix branch surface and no quotient equality row. □

Theorem 54.93 (TotalOrder root comparison ledger obligation)**.** *The root comparison ledger for carried unary histories records exactly one of the three concrete* BHist *rows:*

$$\mathsf{NatUnaryStrictPrefix}(h, k), \qquad \rho_{\mathsf{u}}(h, k), \qquad \mathsf{NatUnaryStrictPrefix}(k, h).$$

Together with the carrier rows $\mathsf{UnaryHistory}(h)$ *and* $\mathsf{UnaryHistory}(k)$*, this ledger is the comparison datum inherited by the* $\mathsf{Order}^{\uparrow}$ *package and by the visible* $\mathsf{Lattice}^{\uparrow}$ *order-front obligations; it contains no host natural-order row and no classical trichotomy row.*

Proof. Read the selected branch from Definition 54.80. The branch is already one of the two strict unary-prefix witnesses or the classifier row $\rho_{\mathsf{u}}(h, k)$.

Now apply Definition 54.81. It states that the selected branch is the public comparison ledger and that no additional host-order or quotient row is present.

The public audit boundary of Definition 54.87 uses the same branch row for the $\mathsf{Order}^{\uparrow}$ export. Any $\mathsf{Lattice}^{\uparrow}$ consumer reading this front therefore inherits the displayed comparison ledger rather than a new comparison schema. □

Theorem 54.94 (TotalOrder root scope obligation)**.** *The root* $\mathsf{TotalOrder}^{\uparrow}$ *obligation surface consists exactly of the* BHist *carrier* $\mathsf{UnaryHistory}$*, the inherited* $\mathsf{POSet}^{\uparrow}$ *classifier* ρ_{u}*, the relation* $\leq_{\mathsf{u}}$*, the three explicit comparison branches, their* hsame*-stable transport, the comparison ledger, and the endpoint exactness row. These rows are sufficient for the displayed* $\mathsf{Order}^{\uparrow}$ *and* $\mathsf{Lattice}^{\uparrow}$ *order-front consumers, and the root surface does not claim completeness, host equality, quotient completion, or a parameter transport principle.*

Proof. Assemble the carrier and classifier rows from Definition 54.90 and Definition 54.91. These fix the BHist endpoints, $\mathsf{UnaryHistory}$, hsame transport, and ρ_{u} classifier.

Add the exactness and ledger rows from Definition 54.92 and Definition 54.93. They supply the selected comparison branch and the two-sided comparison recovery of the same branch.

Finally, project the assembled rows through Definition 54.45 and Definition 54.89. The downstream consumers read only this concrete unary-prefix order front, so the root scope is closed over the displayed BEDC rows and does not add a parameter-transport schema. □

Theorem 54.95 (TotalOrder lattice sibling route)**.** *The* $\mathsf{TotalOrder}^{\uparrow}$ *packet consumes the inherited* $\mathsf{Preorder}^{\uparrow}$ *and* $\mathsf{POSet}^{\uparrow}$ *comparison spine and supplies the comparable-pair row needed by finite* $\mathsf{Lattice}^{\uparrow}$ *meet and join routes. A lattice consumer may read the TotalOrder comparison branch as an order-front input for the displayed finite meet-or-join construction, but it cannot extract a separate lattice law, host order equality, quotient carrier equality, or a global completeness principle.*

Proof. Read the inherited order rows from the TotalOrder root obligation surface. They expose the $\mathsf{Preorder}^{\uparrow}$ reflexive-transitive spine together with the $\mathsf{POSet}^{\uparrow}$ antisymmetry and classifier-exactness rows already used by the unary-prefix package.

The TotalOrder-specific row adds only comparability for the displayed pair. That is exactly the order-front datum a finite $\mathsf{Lattice}^{\uparrow}$ meet or join route needs before it can choose the lower or upper branch inside its own certificate.

The route is therefore horizontal: TotalOrder supplies comparable-pair input to Lattice, while Lattice retains its own meet, join, absorption, and classifier rows. No host order equality, quotient carrier equality, separate lattice law, or completeness endpoint is introduced by the sibling edge. □

54.11 Unary Prefix History Instance

Definition 54.96 (TotalOrder unary-prefix BHist instance)**.** *Let* $\mathsf{UnaryHistory}(h)$ *mean that* $h : \mathsf{BHist}$ *lies on a single visible unary continuation spine from* e*. The carrier for the concrete* $\mathsf{TotalOrder}^{\uparrow}$ *instance is*

$$\mathsf{UnaryHistoryCarrier}(h) := \mathsf{UnaryHistory}(h).$$

The classifier is endpoint agreement inside the unary carrier:

$$h \sim_{\mathsf{unary}} k := \mathsf{UnaryHistory}(h) \wedge \mathsf{UnaryHistory}(k) \wedge \mathsf{hsame}(h, k).$$

The order relation is visible prefix reachability in BHist*:*

$$h \preceq_{\mathsf{unary}} k := \mathsf{UnaryHistory}(h) \wedge \mathsf{UnaryHistory}(k) \wedge \exists t : \mathsf{BHist},\ \mathsf{Cont}(h, t, k).$$

Thus the order data are built from BHist*,* UnaryHistory*,* hsame*, and* Cont *rather than from abstract comparison parameters.*

Theorem 54.97 (TotalOrder unary-prefix BHist laws)**.** *The carrier, classifier, and order relation of Definition 54.96 satisfy the concrete* $\mathsf{TotalOrder}^{\uparrow}$ *laws over unary histories:*

1. *reflexivity is witnessed by the empty tail at each unary history;*
2. *transitivity is witnessed by associating the two visible continuation tails;*
3. *antisymmetry sends mutual prefix witnesses on unary histories to endpoint equality, hence to the classifier* $h \sim_{\mathsf{unary}} k$*;*
4. *totality is the unary-prefix comparison: for any two unary histories, one displayed continuation spine is a prefix of the other.*

Consequently the total-order schema has a concrete BHist *instance and is not only an abstract operator interface.*

Proof. For reflexivity, take the empty tail in BHist. The continuation route $\mathsf{Cont}(h, \mathsf{e}, h)$ is the visible endpoint read for a unary history, and the two carrier witnesses are the same $\mathsf{UnaryHistory}(h)$ row.

For transitivity, suppose $h \preceq_{\mathsf{unary}} k$ through tail t_1 and $k \preceq_{\mathsf{unary}} \ell$ through tail t_2. Continuation associativity inside BHist gives a visible composite tail from h to ℓ, while the unary carrier rows are already part of the two prefix witnesses.

For antisymmetry, mutual prefix witnesses place h and k on the same unary spine with the same endpoint. Unary histories have no branching coordinate, so opposing visible tails collapse to $\mathsf{hsame}(h, k)$; repacking this witness with the two carrier rows gives $h \sim_{\mathsf{unary}} k$.

For totality, compare the two unary continuation spines from e. Since each history is unary, the first point at which the displayed finite paths stop determines which endpoint is reached by a visible tail from the other. This gives either $h \preceq_{\mathsf{unary}} k$ or $k \preceq_{\mathsf{unary}} h$ using only BHist, UnaryHistory, hsame, Cont, and the existing total-order carrier rows. □

Theorem 54.98 (Unary-prefix comparison readback totality)**.** *Let* h, k : BHist *be carried by the concrete unary-prefix instance of Definition 54.96. Every public comparison read for this* $\mathsf{TotalOrder}^{\uparrow}$ *instance is exhausted by the following BEDC rows: the two carrier rows* $\mathsf{UnaryHistory}(h)$ *and* $\mathsf{UnaryHistory}(k)$*, exactly one displayed continuation tail witnessing* $h \preceq_{\mathsf{unary}} k$ *or* $k \preceq_{\mathsf{unary}} h$*, the endpoint classifier row* $\mathsf{hsame}(h, k)$ *in the equality branch, and the ambient* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *structural rows. Thus the comparison readback exposes no host* Nat *order, quotient order, external trichotomy principle, or second comparison relation.*

Proof. Project the carrier, classifier, and prefix order from Definition 54.96. The only carried objects available to the public read are the two rows $\mathsf{UnaryHistory}(h)$ and $\mathsf{UnaryHistory}(k)$, and the only order witness available inside the instance is a displayed BHist tail through Cont.

Apply Definition 54.97. Its totality clause splits the read into the left-prefix case, the same-endpoint case, or the right-prefix case. In the left-prefix case the visible row is a tail t : BHist with $\mathsf{Cont}(h, t, k)$; in the right-prefix case it is a tail t : BHist with $\mathsf{Cont}(k, t, h)$.

In the same-endpoint case, antisymmetry in the same laws collapses the opposing visible tails to the classifier row $\mathsf{hsame}(h, k)$. Repacking this row with the two carrier witnesses gives exactly the equality branch of the concrete classifier $h \sim_{\mathsf{unary}} k$.

The package and name-certificate rows only record that this carrier, this classifier, and this prefix relation are the public $\mathsf{TotalOrder}^{\uparrow}$ surface. Since the instance contains no coordinate for a host Nat order, a quotient order, a trichotomy oracle, or any parallel comparison relation, there is no additional readback component to expose. □

Closure status for $\mathsf{NameCert}_{\mathsf{TotalOrder}^{\uparrow}}$.

Constructive story: The total-order surface keeps the unary-prefix carrier from $\mathsf{Poset}^{\uparrow}$ and adds only public selector rows saying that, on the exposed finite unary endpoints, a comparison phase can choose the relevant directed prefix evidence. The accepted objects are still unary histories over BHist, with b0-headed histories excluded, and the classifier is still the carrier-aware hsame row that antisymmetry reads back from opposing comparisons. The source is the public unary-prefix order packet, the pattern records finite extrema, interval collapse, phase-exit, root-obligation, and certificate-boundary rows over the same prefix relation, and the ledger keeps each selector decision tied to explicit continuation witnesses rather than to a classical trichotomy oracle. The five name-certificate obligations are inherited from the preorder and poset layers: e inhabits the carrier, hsame remains reflexive, symmetric, and transitive, and any classified endpoint stays inside the unary carrier. A history h lies in the signature gap of a $\mathsf{TotalOrder}^{\uparrow}$ token p when the source-domain accepts h, the signature relation pairs it with an answer endpoint and audit ledger, and token introduction names that answer as p; unfolded, h is a unary endpoint whose comparison evidence, extrema row, and phase-exit data match the public token. There is no checked standard bridge here; the public audit boundary exports the finite unary-prefix selector surface only, leaving arbitrary total orders and classical trichotomy outside the closure. The chapter registers this selector-refined prefix package under the name $\mathsf{TotalOrder}^{\uparrow}$; totality is presented as public finite unary comparison data, not as an imported order type, quotient completion, or lattice structure.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TotalOrder}^{\uparrow}}$, maturePackageClosed)

Scope closed: The public $\mathsf{TotalOrder}^{\uparrow}$ certificate surface is exported through the unary-prefix carrier, classifier, finite-extrema, phase-exit, certificate-boundary, public-audit, and root-obligation rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TotalOrder}^{\uparrow}}$, axiomClean)

Lean target: `BEDC.Derived.PreorderUp.preorder\_prefix\_stability\_certificate\_fields`

Bridge status: paperBridge

Not claimed: It does not close the full TotalOrder bridge, arbitrary total orders, classical trichotomy, quotient completion, or lattice structure.

Upgrade path: No further paper-axis closure upgrade remains for the unary-prefix $\mathsf{TotalOrder}^{\uparrow}$ surface.

Chapter 55

A Concrete Naming Certificate for $\mathsf{Lattice}^{\uparrow}$

The lattice interface $\mathsf{Lattice}^{\uparrow}$ extends chapter 53 with binary meet $\wedge$ and join $\vee$ operations, each classified as the greatest lower bound and least upper bound of two elements under the partial order. Idempotence, commutativity, associativity, and absorption laws are derived from the bound characterizations under the carrier's classifier.

55.1 Carrier definition

Definition 55.1 (Lattice carrier)**.** *Use a poset setup extended with meet and join operations carrying bound-characterization proofs.*

55.2 Concrete singleton prefix lattice instance

Definition 55.2 (Concrete singleton prefix lattice instance)**.** *Let A_{e} be the singleton history source of Definition 36.169 at $a_0 = \mathsf{e}$. Define ρ_{e} by*

$$\rho_{\mathsf{e}}(h, k) \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k) \wedge \mathsf{hsame}(h, k).$$

Let $h \leq_{\mathsf{e}} k$ mean that $A_{\mathsf{e}}(h)$ and $A_{\mathsf{e}}(k)$ hold and that $\mathsf{PreorderPrefixLE}(h, k)$ witnesses the prefix comparison between the carried endpoints. Define the concrete lattice operations by

$$\mathsf{meet}(h, k) := \mathsf{e}, \qquad \mathsf{join}(h, k) := \mathsf{e}.$$

The certificate has ten fields: traditional target the one-point lattice; BEDC source BHist *plus the singleton source and concrete prefix order; carrier A_{e}; classifier ρ_{e}; stability obligations for poset laws, meet lower bounds, meet greatestness, join upper bounds, join leastness, and meet and join congruence; ledger singleton endpoint plus prefix witnesses; core theorem Theorem 55.62; exactness singleton endpoint classification; standard bridge terminal one-point lattice; and status* ProofTarget*.*

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeUp StdBridge`

Theorem 55.3 (Concrete singleton prefix lattice laws)**.** *For all carried histories h, k, z in A_{e}, the endpoints $\mathsf{meet}(h, k)$ and $\mathsf{join}(h, k)$ are carried by A_{e} and satisfy the meet lower-bound laws, meet greatest-lower-bound law, join upper-bound laws, join least-upper-bound law, and meet and join congruence laws for the restricted prefix order $\leq_{\mathsf{e}}$ under the classifier ρ_{e}.*

Proof. The singleton carrier witnesses identify each carried endpoint with e. Thus $A_{\mathsf{e}}(h)$, $A_{\mathsf{e}}(k)$, and $A_{\mathsf{e}}(z)$ reduce every endpoint comparison needed by the order, meet, and join clauses to the empty-history endpoint.

The restricted prefix comparisons are supplied by PreorderPrefixLE_of_hsame after the singleton witnesses produce the relevant hsame facts. The inherited order boundary is the concrete unary prefix poset law package of Theorem 53.10, with antisymmetry supplied by Theorem 53.33.

The meet and join outputs are both definitionally e. The lower-bound and upper-bound clauses therefore use the singleton endpoint witness for e and the prefix witnesses from the previous paragraph; the greatest-lower-bound and least-upper-bound clauses use the same reduction for the third carried history z.

Congruence is immediate because both operations ignore their operands and return e. After unfolding, every source and target output is classified by $\rho_{\mathsf{e}}(\mathsf{e},\mathsf{e})$, assembled from two copies of $A_{\mathsf{e}}(\mathsf{e})$ and the reflexive witness $\mathsf{hsame}(\mathsf{e},\mathsf{e})$. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonPrefix laws`

Theorem 55.4 (Singleton lattice order has empty endpoints)**.** *For h, k : BHist, the restricted singleton prefix order satisfies*

$$h \leq_{\mathsf{e}} k \quad \Longleftrightarrow \quad h\mathsf{hsamee} \wedge k\mathsf{hsamee}.$$

Proof. The forward direction reads the two singleton carrier fields from the definition of $h \leq_{\mathsf{e}} k$. These fields are exactly $h$hsamee and $k$hsamee.

For the reverse direction, the two endpoint witnesses supply the singleton carrier fields. Their transitive composite through e gives $h$hsame$k$, and the prefix comparison follows from the concrete PreorderPrefixLE_of_hsame constructor. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE empty endpoints iff`

Theorem 55.5 (Singleton lattice append order has empty endpoints)**.** *For h, k : BHist, the restricted singleton prefix order from the appended history to* e *satisfies*

$$\mathsf{LatticeSingletonLE}(\mathsf{append}(h,k),\mathsf{e}) \quad \Longleftrightarrow \quad h\mathsf{hsamee} \wedge k\mathsf{hsamee}.$$

Proof. The forward direction first applies singleton-order endpoint exactness to read $\mathsf{append}(h,k)\mathsf{hsamee}$, then splits the empty append into empty left and right endpoints. Conversely, empty endpoints make $\mathsf{append}(h,k)$ history-same to e, and the singleton-order endpoint characterization rebuilds the restricted order comparison. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE append empty endpoints iff`

Theorem 55.6 (Singleton lattice carrier order collapse)**.** *If h and k are carried by A_{e}, then both restricted order comparisons hold, the singleton classifier relates h and k, and both endpoints are internally the same as* e*:*

$$h \leq_{\mathsf{e}} k \wedge k \leq_{\mathsf{e}} h \wedge \rho_{\mathsf{e}}(h,k) \wedge h\mathsf{hsamee} \wedge k\mathsf{hsamee}.$$

Proof. The two carrier witnesses are the endpoint comparisons $h$hsamee and $k$hsamee. Their composite through e gives $h$hsame$k$, and symmetry gives $k$hsame$h$.

The two restricted order comparisons are obtained from these two sameness witnesses by PreorderPrefixLE_of_hsame, together with the same carrier fields. The classifier package uses the carrier fields and $h$hsame$k$, and the endpoint clauses are the original carrier witnesses. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonCarrier order collapse`

Theorem 55.7 (Singleton lattice antisymmetry classifier)**.** *If $h \leq_{\mathsf{e}} k$ and $k \leq_{\mathsf{e}} h$ in the restricted singleton prefix order, then $\rho_{\mathsf{e}}(h, k)$, $h\mathsf{hsamee}$, and $k\mathsf{hsamee}$.*

Proof. The two restricted comparisons carry their endpoint fields, so the first comparison already identifies both h and k with e. The prefix components of the two comparisons are opposing $\mathsf{PreorderPrefixLE}$ witnesses, and concrete prefix antisymmetry gives $\mathsf{hsame}(h, k)$. These three pieces are exactly the classifier data $\rho_{\mathsf{e}}(h, k)$, together with the two displayed empty endpoint witnesses. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE antisymm classifier`

Theorem 55.8 (Singleton lattice meet-join absorption classifier)**.** *If h and k are carried by A_{e}, then both absorption composites $\mathsf{meet}(h, \mathsf{join}(h, k))$ and $\mathsf{join}(h, \mathsf{meet}(h, k))$ are classified with h by ρ_{e}, and both output histories are hsame to e.*

Proof. Both concrete lattice operations are definitionally e. Hence each absorption composite is the empty history, whose singleton carrier witness is reflexive. The carrier witness for h gives $h\mathsf{hsamee}$, so symmetry gives the classifier component from each absorption output back to h. Reassemble the two ρ_{e} classifiers and record the two empty output endpoints. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonMeetJoin absorption classifier`

Theorem 55.9 (Singleton lattice meet-join absorption is empty-classified)**.** *For carried singleton endpoints h, k, both absorption composites reduce to the empty endpoint and classify back to h:*

$$\mathsf{meet}(h, \mathsf{join}(h, k))\mathsf{hsamee}, \qquad \mathsf{join}(h, \mathsf{meet}(h, k))\mathsf{hsamee},$$
$$\rho_{\mathsf{e}}(\mathsf{meet}(h, \mathsf{join}(h, k)), h), \qquad \rho_{\mathsf{e}}(\mathsf{join}(h, \mathsf{meet}(h, k)), h).$$

Proof. Both concrete operations are definitionally the endpoint e. The two endpoint equalities are therefore reflexive empty-history sameness. Since h is carried by the singleton carrier, symmetry of its carrier witness classifies e with h, and the classifier packages the two carrier witnesses with that history-sameness witness. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonMeetJoin absorption empty classified`

Theorem 55.10 (Singleton lattice continuation absorption has empty classifier)**.** *Let h, k be singleton-carried histories. If $left$ is a BEDC continuation output of $\mathsf{meet}(h, \mathsf{join}(h, k))$ followed by h, and $right$ is a BEDC continuation output of h followed by $\mathsf{join}(h, \mathsf{meet}(h, k))$, then both outputs are empty and are classified by the singleton classifier:*

$$\mathsf{hsame}(left, \mathsf{e}) \wedge \mathsf{hsame}(right, \mathsf{e}) \wedge \rho_{\mathsf{e}}(left, right).$$

Proof. The concrete singleton meet and join both return e. The left continuation is therefore $\mathsf{append}(\mathsf{e}, h)$, which reduces to h, and the right continuation is $\mathsf{append}(h, \mathsf{e})$, which also reduces to h. The carrier witness for h identifies each result with e. Those two endpoint witnesses, together with transitivity through e, assemble the singleton classifier between the two continuation outputs. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonMeetJoin continuation absorption empty classifier`

Theorem 55.11 (Singleton lattice meet-join idempotent commutative classifier)**.** *For carried singleton endpoints h, k, meet and join are classified with the idempotent endpoint and with their swapped arguments:*

$$\rho_{\mathsf{e}}(\mathsf{meet}(h,h),h) \wedge \rho_{\mathsf{e}}(\mathsf{join}(h,h),h) \wedge \rho_{\mathsf{e}}(\mathsf{meet}(h,k),\mathsf{meet}(k,h)) \wedge \rho_{\mathsf{e}}(\mathsf{join}(h,k),\mathsf{join}(k,h)).$$

Moreover $\mathsf{meet}(h,k)\mathsf{hsamee}$ *and* $\mathsf{join}(h,k)\mathsf{hsamee}$*.*

Proof. The concrete singleton meet and join operations both return e. Thus the swapped meet outputs and swapped join outputs are classified by reflexive empty-history sameness. Since h is carried by the singleton carrier, symmetry of $h\mathsf{hsamee}$ classifies each idempotent output with h. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonMeetJoin idempotent comm classifier`

Theorem 55.12 (Singleton lattice classifier has empty endpoints)**.** *For $h, k : \mathsf{BHist}$, the singleton lattice classifier satisfies*

$$\rho_{\mathsf{e}}(h,k) \iff h\mathsf{hsamee} \wedge k\mathsf{hsamee}.$$

Proof. The forward direction projects the two carrier fields from the classifier tuple. Since the singleton carrier is the predicate $x\mathsf{hsamee}$, these fields are exactly the two endpoint witnesses.

Conversely, the two endpoint witnesses make h and k singleton-carried. Their composite through e, using symmetry on the second witness, supplies $h\mathsf{hsamee}k$ and hence the classifier tuple. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonClassifier empty endpoints iff`

Theorem 55.13 (Singleton lattice classifier continuation result-left iff)**.** *For histories $P, Q, R : \mathsf{BHist}$ with $\mathsf{Cont}(P,Q,R)$, the singleton lattice classifier relates P and Q exactly when it relates the continuation result R to P:*

$$\mathsf{LatticeSingletonClassifier}(P,Q) \iff \mathsf{LatticeSingletonClassifier}(R,P).$$

Proof. The forward direction uses the singleton carriers of P and Q to transport the continuation result to the right-unit continuation at e, so R is singleton-carried and compares with P through e. For the reverse direction, the result-left classifier identifies R with e; transporting the continuation to empty result and applying empty-result inversion recovers the singleton carrier witnesses for both inputs, and hence the input classifier. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonClassifier continuation result left iff`

Theorem 55.14 (Singleton lattice classifier continuation result-right iff)**.** *For histories $P, Q, R : \mathsf{BHist}$ with $\mathsf{Cont}(P,Q,R)$, the singleton lattice classifier relates P and Q exactly when it relates the continuation result R to Q:*

$$\mathsf{LatticeSingletonClassifier}(P,Q) \iff \mathsf{LatticeSingletonClassifier}(R,Q).$$

Proof. The forward direction uses the singleton carriers of P and Q to transport the continuation result to the right-unit continuation at e, so R is singleton-carried and compares with Q through e. For the reverse direction, the result-right classifier identifies R with e; transporting the continuation to empty result and applying empty-result inversion recovers the singleton carrier witnesses for both inputs, and hence the input classifier. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonClassifier continuation result right iff`

Theorem 55.15 (Singleton lattice classifier continuation empty result exactness)**.** *For histories* P, Q, R : BHist *with* Cont(P, Q, R)*, the singleton lattice classifier relates the two inputs exactly when the continuation result is empty:*

$$\mathsf{LatticeSingletonClassifier}(P, Q) \iff R\mathsf{hsamee}.$$

Proof. The forward direction reads the two singleton carrier endpoints from the input classifier; since R is the append continuation of P and Q, append-empty construction gives Rhsamee. Conversely, result emptiness inverts the append continuation into singleton carrier witnesses for both inputs, and the empty-endpoint characterization reconstructs the singleton classifier. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonClassifier continuation empty result iff`

Theorem 55.16 (Singleton lattice classifier continuation result-left-right equivalence)**.** *For histories* P, Q, R : BHist *with* Cont(P, Q, R)*, classifying the continuation result against the left input is equivalent to classifying it against the right input:*

$$\mathsf{LatticeSingletonClassifier}(R, P) \iff \mathsf{LatticeSingletonClassifier}(R, Q).$$

Proof. The result-left classifier theorem identifies the left comparison with the input classifier on P and Q. The result-right classifier theorem identifies the right comparison with the same input classifier. Composing those two characterizations gives the displayed equivalence. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonClassifier continuation result left right iff`

Theorem 55.17 (Singleton lattice result-left order carriers)**.** *For histories* h, k, r : BHist *with* Cont(h, k, r)*, the restricted singleton order from the continuation result back to the left input is equivalent to both exposed inputs being singleton-carried:*

$$\mathsf{LatticeSingletonLE}(r, h) \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

Proof. The forward direction reads $r$hsamee from the singleton order endpoint fields. The continuation witness identifies r with append(h, k), so empty-append inversion gives $h$hsamee and $k$hsamee.

Conversely, if both exposed inputs are singleton-carried, the continuation result is internally the empty endpoint. The empty-endpoint characterization of the singleton order then supplies LatticeSingletonLE(r, h). □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE continuation result left carriers iff`

Theorem 55.18 (Singleton lattice result-right order carriers)**.** *For histories* h, k, r : BHist *with* Cont(h, k, r)*, the restricted singleton order from the continuation result back to the right input is equivalent to both exposed inputs being singleton-carried:*

$$\mathsf{LatticeSingletonLE}(r, k) \iff A_{\mathsf{e}}(h) \wedge A_{\mathsf{e}}(k).$$

Proof. The forward direction again projects $r$hsamee from the singleton order endpoint fields. Since the continuation result is the append of h and k, empty-append inversion exposes both input carriers.

In the reverse direction, the two input carriers force the continuation result to be internally empty. The empty-endpoint characterization of LatticeSingletonLE then gives the displayed order comparison against the right input. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE continuation result right carriers iff`

Theorem 55.19 (Singleton lattice continuation result endpoint order equivalence)**.** *For histories* $P, Q, R : \mathsf{BHist}$ *with* $\mathsf{Cont}(P, Q, R)$*, the restricted singleton order from the continuation result to the left endpoint is equivalent to the restricted singleton order from the result to the right endpoint:*

$$\mathsf{LatticeSingletonLE}(R, P) \iff \mathsf{LatticeSingletonLE}(R, Q).$$

Proof. The result-left order theorem identifies the left comparison with the pair of singleton carrier witnesses for P and Q. The result-right order theorem identifies the right comparison with the same pair. Composing these two characterizations gives the displayed equivalence. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE continuation result left right iff`

Theorem 55.20 (Singleton lattice continuation empty result order exactness)**.** *For histories* $P, Q, R : \mathsf{BHist}$ *with* $\mathsf{Cont}(P, Q, R)$*, the restricted singleton prefix comparison between the inputs is equivalent to emptiness of the continuation result:*

$$P \leq_{\mathsf{e}} Q \iff R\mathsf{hsamee}.$$

Proof. The restricted singleton order carries both input endpoints as empty. Since R is the BEDC append continuation of P and Q, append-empty construction gives $R\mathsf{hsamee}$. Conversely, if the continuation result is empty, BEDC append-empty inversion makes both P and Q empty. Their induced hsame chain supplies the underlying prefix comparison, so the singleton order tuple is reconstructed. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE continuation empty result iff`

Theorem 55.21 (Singleton meet–join absorption gives order and classifier data)**.** *If* $h, k : \mathsf{BHist}$ *are singleton-carried, then the two singleton lattice absorption endpoints*

$$h \wedge (h \vee k) \qquad \textit{and} \qquad h \vee (h \wedge k)$$

are both definitionally the empty history. They satisfy the restricted prefix order comparisons

$$h \wedge (h \vee k) \leq_{\mathsf{e}} h \qquad \textit{and} \qquad h \leq_{\mathsf{e}} h \vee (h \wedge k),$$

are both classified with h*, and both read back to* e*.*

Proof. In the singleton lattice, meet and join ignore their inputs and return e. The carrier witness for h gives $h\mathsf{hsamee}$, while reflexivity gives $\mathsf{ehsamee}$.

The first order comparison uses symmetry of $h\mathsf{hsamee}$ to obtain $\mathsf{ehsame}h$ and then applies the prefix comparison constructor. The second uses $h\mathsf{hsamee}$ directly. The same two hsame witnesses assemble the classifier tuples with h, and the endpoint readbacks are both reflexivity at e. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonMeetJoin absorption order classifier`

Theorem 55.22 (Singleton meet greatest lower bound)**.** *For carried histories* h, k, z *in the singleton lattice, the concrete meet output is the empty history, and the lower-bound condition against that meet is exactly the pair of lower-bound conditions against the two operands:*

$$\mathsf{hsame}(\mathsf{LatticeSingletonMeet}(h, k), \mathsf{e}) \wedge (z \leq_{\mathsf{e}} \mathsf{LatticeSingletonMeet}(h, k) \iff z \leq_{\mathsf{e}} h \wedge z \leq_{\mathsf{e}} k)\,.$$

Proof. The meet operation is definitionally the empty history. Since h, k, z are all carried by the singleton carrier, the order endpoint theorem Definition 55.63 reduces every displayed comparison to the two empty-endpoint witnesses. The forward direction rebuilds the two operand bounds from the endpoint witnesses for z, h, k; the reverse direction rebuilds the meet bound from the endpoint witness for z and reflexivity at e. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonMeet empty output greatest lower bound iff`

Theorem 55.23 (Singleton join least upper bound)**.** *For carried histories h, k, z in the singleton lattice, the concrete join least-upper-bound comparison is exactly the pair of upper-bound comparisons against the two operands, together with the empty readback of the join:*

$$\mathsf{LatticeSingletonJoin}(h, k) \leq_{\mathsf{e}} z \iff h \leq_{\mathsf{e}} z \wedge k \leq_{\mathsf{e}} z \wedge \mathsf{LatticeSingletonJoin}(h, k)\mathsf{hsamee}.$$

Proof. The join operation is definitionally the empty history. Since h, k, z are all carried by the singleton carrier, the singleton order comparison between any two of them is built from the corresponding hsame chain through e. The forward direction reconstructs the two operand upper bounds and records reflexivity of the join endpoint; the reverse direction uses the displayed join endpoint together with the carrier of z to rebuild the join bound. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonJoin least upper bound empty iff`

Theorem 55.24 (Singleton lattice append tail emptiness)**.** *For $h, t : \mathsf{BHist}$, if $A_{\mathsf{e}}(h)$ and $\mathsf{UnaryHistory}(t)$, then the restricted singleton prefix order satisfies*

$$\mathsf{append}(h, t) \leq_{\mathsf{e}} h \quad \iff \quad t\mathsf{hsamee}.$$

Proof. The forward direction projects the underlying prefix comparison from the restricted order and applies the concrete append-tail backforcing law from $\mathsf{Preorder}^{\uparrow}$. A unary tail that returns from $\mathsf{append}(h, t)$ back to h must be the empty history.

For the reverse direction, the witness $t\mathsf{hsamee}$ reduces $\mathsf{append}(h, t)$ to h by the right continuation unit law. The carried witness $A_{\mathsf{e}}(h)$ therefore also carries $\mathsf{append}(h, t)$, and the prefix comparison is the empty-tail side of the same append-tail equivalence. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE append tail empty iff`

Theorem 55.25 (Singleton lattice classifier append tail emptiness)**.** *For $h, t : \mathsf{BHist}$, if $A_{\mathsf{e}}(h)$, then the singleton classifier satisfies*

$$\mathsf{LatticeSingletonClassifier}(\mathsf{append}(h, t), h) \quad \iff \quad t\mathsf{hsamee}.$$

Proof. The forward direction projects the carried left endpoint from the classifier. Since $\mathsf{append}(h, t)\mathsf{hsamee}$, the concrete append-empty inversion forces $t\mathsf{hsamee}$.

Conversely, assume $t\mathsf{hsamee}$. The append endpoint is carried because both h and t are empty in the singleton sense, and the right continuation unit identifies $\mathsf{append}(h, t)$ with h. Together with the given carrier for h, these witnesses reconstruct the singleton classifier. □

Theorem 55.26 (Singleton lattice append context empty order)**.** *For $left, h, right : \mathsf{BHist}$, if $A_{\mathsf{e}}(h)$, then the restricted singleton prefix order between the two append displays satisfies*

$$\mathsf{append}(left, h) \leq_{\mathsf{e}} \mathsf{append}(h, right) \quad \iff \quad left\mathsf{hsamee} \wedge right\mathsf{hsamee}.$$

Proof. In the forward direction, the restricted order exposes singleton carriers for both append endpoints. BEDC append-empty inversion on $\mathsf{append}(left, h)$ gives $left\mathsf{hsamee}$, and the same inversion on $\mathsf{append}(h, right)$ gives $right\mathsf{hsamee}$.

Conversely, if the two contexts are empty, the carrier of h makes both append endpoints singleton-carried. Since both endpoints are history-same to e, they are history-same to each other, and the singleton order is rebuilt from the corresponding concrete prefix witness. □

Lean4 ✓ `BEDC.Derived.LatticeUp.LatticeSingletonLE append context empty iff`

Theorem 55.27 (Singleton lattice append tail upper emptiness)**.** *For $h, t : \mathsf{BHist}$, if $A_{\mathsf{e}}(h)$ and $\mathsf{UnaryHistory}(t)$, then the restricted singleton prefix order satisfies*

$$h \leq_{\mathsf{e}} \mathsf{append}(h, t) \quad \Longleftrightarrow \quad t\mathsf{hsamee}.$$

Proof. The forward direction reads the upper endpoint carrier from the restricted order. Thus $\mathsf{append}(h, t)$ is history-same to e, and the BEDC append-empty inversion forces both endpoints of the append, in particular t, to be empty. Conversely, if $t\mathsf{hsamee}$, the right continuation unit identifies $\mathsf{append}(h, t)$ with h, so the given singleton carrier for h also carries the append endpoint. The prefix witness is the concrete append-tail continuation. □

Theorem 55.28 (Singleton lattice meet greatest lower bound empty exactness)**.** *For carried singleton endpoints h, k, z, the statement that z is below the concrete meet of h and k is equivalent to the two endpoint lower-bound clauses together with the fact that the concrete meet is empty:*

$$z \leq_{\mathsf{e}} \mathsf{meet}(h, k) \quad \Longleftrightarrow \quad z \leq_{\mathsf{e}} h \wedge z \leq_{\mathsf{e}} k \wedge \mathsf{meet}(h, k)\mathsf{hsamee}.$$
